

THE
PHARMACEUTICAL JOURNAL

ESTABLISHED 1841.

A Weekly Record of Pharmacy and Allied Sciences.

VOLUME LXI.
FOURTH SERIES—VOLUME VII.
JULY TO DECEMBER, 1898.

LONDON :
PHARMACEUTICAL SOCIETY OF GREAT BRITAIN,
17, BLOOMSBURY SQUARE, W.C.

W. I. RICHARDSON, PRINTER,

4 AND 5, GREAT QUEEN STREET, LINCOLN'S INN FIELDS,

LONDON, W.C.

INDEX TO VOLUME VII.

(FOURTH SERIES.)

A

- Abel, Sir Frederick, and the Flashing Point of Petroleum, 136.
- Aberdeen Pharmaceutical Association, 648*c*.
- Absorbent Cotton Wool, To Prepare, 103.
- Accidental Poisoning, Scheduled Poisons and Cases of, 12.
- Acetanilide Powder, Ammoniated, Formula for, 342.
- Acetanilidum, B.P., Note on, 301.
- Acetic Acid as a Solvent (Stedem), 49.
- Aceto-Sulphanilate, Sodium, 4.
- Acetone, Pyro-, Developer, 492*a*.
- Acetracts, Fluid (Remington), 545.
- Acetylene, Action of Light on (Bone and Wilson), 16.
- Acid Fixing Bath, Formula for (Belitski), 71.
- Solution, Standard, Preparation of, by Direct Absorption of Hydrogen Chloride (Moody), 15.
- Acidimetry or Alkalimetry of Deeply Coloured Fluids (Jean), 57.
- Acids, Constituents of Fatty and Other Organic, Determination of (Crossley and Le Sueur), 561.
- Tartaric and Lactic, Determination of Succinic Acid in the Presence of (Bourdas, Joulin, and Rackowski), 122.
- Acidum Aceticum, B.P., Note on, 301.
- Aceticum Glaciale, B.P., Note on, 302.
- Arseniosum, B.P., Note on, 302.
- Benzoicum, B.P., Note on, 302.
- Carbolicum, B.P., Note on, 334.
- Citricum, B.P., Note on, 334.
- Hydrobromicum, B.P., Note on, 334.
- Hydrochloricum, B.P., Note on, 334.
- Hydrocyanicum Dilutum, B.P., Note on, 354.
- Lacticum, B.P., Note on, 354.
- Oleicum, B.P., Note on, 354.
- Phosphoricum Concentratum, B.P., Note on, 334.
- Salicylicum, B.P., Note on, 378.
- Sulphuricum, B.P., Note on, 426.
- Sulphurosum, B.P., Note on, 354.
- Tannicum, B.P., Note on, 378.
- Tartaricum, B.P., Note on, 378.
- Acne, Yeast for (Brocq), 390.
- Adam, P.—Cade Oil, 241, 635.
- Adeps, B.P., Note on, 426.
- Aderhold and Heintze—Reducing Body in Fruit Juices, 458.
- Administration and Amendment of Pharmacy Law, Editorial Remarks on, 677.
- Adrian and Trillat—Alkaloidal Glycerophosphates, 481.
- and Trillat—Organic Glycerophosphates, 241.
- Adulterant of Powdered Rhubarb, A Novel, (Alcock), 416.
- Adulterated Borax at Birmingham, 534*c*.
- Foods, Mr. Strachey and the Imports of, 22.
- Gamboge (Woolsey), 369.
- Adulteration Bill, Mr. Jeffreys and the Government, 45.
- Laws, Grocers and the Food, 429.
- Legislation, Playing with, 103.
- of Agricultural and Horticultural Produce Bill, 103.
- of Food and Drugs, The (Tichborne), 244.
- of Pimento (Hanausek), 369.
- of Saffron (Wauters), 241.
- Advertising, The Art of, 46; (Anderson), 567.
- Æther Aceticus, The Chemistry of, 552.
- Purificatus, B.P., Note on, 426.
- Agner, H.—Treatment of Anæmia with *Urtica Dioica*, 546.
- Agosti, M.—Creosote Pills, 505.
- Air, Free Hydrogen in (Gautier), 545.
- Pump, An Automatic Water-Mercury (Kraft and Weilandt), 270.
- Aitchison, Brigadier-Surgeon James E. T.—Death of, 406.
- Ajacol and Guäthol (Parthiel), 367.
- Albahary, J. M.—Ovalbuminic Acid, 241.
- Albumin, Artificial (Lilienfeld), 188; (Allen), 242.
- Glycerin for Fixing Microscopic Sections on the Slide, 658.
- Albuminoid Food-Staff from Fœnugreek (Schering), 370.
- Albuminoids, Formation of (Jacobi), 557.
- Albumins and Some Types of Proteid Digestion (Gordon Sharp), 197.
- Alcock, F. H.—A Novel Adulterant of Powdered Rhubarb, 416.
- F. H.—Bacteria, 499.
- F. H.—The Varnish for *Pilula Phosphori*, B.P., 1898, 344.
- F. H.—*Vinum Quininae*, B.P., 1898, 479.
- Alcohol, Ammoniated (Wells), 240.
- Determination of, in *Liquor Iodi Fortis*, B.P. (Gunn), 330.
- Increased Duties on, in France, 514*d*.
- Alcoholic Strengths of Tinctures, 606.
- Algæ, Fresh-Water, Fixing and Colouring (Pfeiffer von Wellheim), 402*b*.
- Influence of, on the Purity of Water (Strohmeyer), 25.
- Alginoid Iron, and Some other Alginoids (Stanford), 199.
- Alkalies in Skin Diseases (Unna), 571.
- Alkalimetry or Acidimetry of Deeply Coloured Fluids (Jean), 57.
- Alkaline Cyanides and Copper, Determination of (Catford), 540.
- Secretions of Ants (Janet), 241.
- Alkalinity of Glass Apparatus (Liebermann), 481.
- Alkaloidal Glycerophosphates (Adrian and Trillat), 481.
- Alkaloidal Residues, Drying, in Organic Assays (Cowley), 540.
- Tinctures, Non-alcoholic, 480.
- Alkaloids in Extracts, Determination of (Rustig), 624.
- in Quinine Wine, Coca Wine, and in like Preparations, Determination of the, 216.
- Micro-Chemical Recognition of (Barth), 635.
- Mydriatic, Note on the (Jowett), 195.
- Precipitation of, Note on, 604.
- Alkannin in Plants (Norton), 50, 417.
- Allen, A. H.—On the Synthesis of Albumin, 242.
- A. H.—The Microscope in Chémico Legal Investigations, 625.
- A. H.—The Use of the Micro-Spectroscope, 626.
- Allman, Professor G. J., Death of, 594*d*.
- Aloes, Chemistry of (Dohme), 325.
- Reactions for (Borntraeger), (Tschirch and Pedersen), 77.
- Resin of (Pedersen), 50.
- Alopecia Caused by Thallium Acetate (Huchard), 402*b*.
- Alpestre, 25.
- Alpine Characters in Plants, Artificial Production of (Bonnier), 461.
- Alsol as an Antiseptic, 661.
- Alstonia Plumosa, Rubber from, 117.
- Althæa, Unguentum, Formula for, 582.
- Alum, Effervescence with, Note on the, 501.
- Alumina, The Production of, 534*e*.
- Aluminium, Action of Nitric Acid on (Stillman), 117.
- Discoloration of, 115.
- Electro-Plating for (Lanseigne and Leblanc), 279.
- Ambulance Class for Chemist Volunteers, 426*c*.
- American Hydrocarbons (Young, Francis, Jackson), 512.
- Pharmaceutical Association, Editorial Remarks on the, 355.
- Ammoniated Acetanilide Powder, Formula for, 342.
- Alcohol (Wells), 240.
- Ammonii Chloridum, B.P., Note on, 426.
- Phosphas, B.P., Note on, 426.
- Ammonium, Lithium, and Calcium (Moissan), 583.
- Salts, Test for, 20.
- Selenide (Lenher and Smith), 117.
- Sulphide, Action of, on Chloral Hydrate (Lesinsky and Gundlich), 57.
- Amomum Angustifolium (Mahon), 370.
- Amyl Nitris, B.P., Note on, 426.
- Amytin and Amytols, 18.
- Anæmia, Treatment of, with *Urtica Dioica* (Agner), 546; (Gair), 633; (Stratton), 663; (Holmes), 685.

- Anæsthetics, Pure, The Use of (Ramsay), 296.
- Analgene in Chorea (Moncorvo), 705.
- Analyst's Report, The Hampstead, 305.
- Analysts' Certificates (Glyn-Jones), 68; (Fair-Play), 116; (Standage), 214.
- "Analysts? Pharmacists or"; The *Chemical Trades Journal* on, 273.
- Analytical Chemist, How to Become an, 582.
- "Analytical Chemist," The Title, 274.
- Analytical Notes, 57, 238, 425, 624.
- Qualification, The "Major" Examination as an (Analyst), 260.
- Anatomical Specimens, Preserving, 279.
- Anderson, J. A., and R. Fischer—Assay of Spirit of Nitrous Ether, 370.
- W.—Advertising, 567.
- Anemonin in Anemone Pulsatilla (Noel and Lambert), 217.
- Anhalonium Lewini (Thompson), 417.
- Aniline Patents, Overthrow of the German Monopoly in, 228.
- Animal Tissues, Hardening, 260.
- Anodyne Application for Burns and Blisters, 446.
- for Toothache (Howe), 115.
- Anomalies, Pharmacopœial (Dowzard), 509.
- Antimonii Oxidum, B.P., Note on, 426.
- Antimonium Sulphuratum, B.P., 426.
- Antiscabine, Composition of (Skettles), 402*b*.
- Antiseptic Dressing, Glycerol of Terebene as an, 237.
- Dressings, 103.
- Solutions, Colouring, 620*g*.
- Antietanic Pill, Peile's, Formula for (Croy), 102.
- Antitussin, Composition of, 630.
- Ants, Alkaline Secretions of (Janet), 241.
- Aperient Pills, Kleewein's, Formula for, 256.
- Apothecaries Act, Proceedings under the (Hobbs—Greenwich), 426*a*.
- The Society of, 492*b*.
- Apparatus, Glass, Alkalinity of (Liebermann), 481.
- Application for Protecting Stone, 687.
- Apprenticeship, Studies During, 297.
- Aqua Camphoræ, B.P., Note on, 426.
- Chloroformi, B.P., Note on, 468.
- Destillata, B.P., Note on, 468.
- Spiræe Ulmarie (Woodman), 215; (Mumbray), (Preston), 239; (Mumbray) 280.
- Arbroath Chemists and the Dispensing at the local Infirmary, 231, 305.
- Arnold, J. P.—Detection of Lactic Acid in the Gastric Contents, 624.
- Argentamine in Ophthalmic Practice (Hoor), 342.
- Aristol for Burns, 285.
- Army Medical Service, Edinburgh Royal College of Surgeons and the, 517.
- Aromatic Waters (Army), 369.
- Arrow Poisons: Their History, Sources, and Constituents (Stockman), 548, 562, 565, 585; (Sharp), 633; (Holmes), 663.
- Arsenic, Coloration of (W.C.), 116.
- Determination of, in Antimony and in other Metals (Ducru), 410.
- in Plants (Stoklasa), 509.
- in Wool (Pearse), 49, 109.
- Arsenical Paste, Formula for, 260.
- Paste for Destroying Pulp, Painless (Dubois), 115.
- Arthur, Professor J. C.—Bacterial Diseases of Plants, 117.
- Artichokes, Bacterial Cultures on (Roger), 457.
- Artificial Albumin (Lilienfeld), 188; (Allen), 242.
- Artificial Persons, Natural *versus*, Editorial Remarks on, 563.
- Production of Alpine Characters in Plants (Bonnier), 461.
- Rubber, 118.
- Artificially Decolorised Wines (Bimm), 118.
- Aseptic Hairwash, Tonic, Formula for, 256.
- Ash of Fats, Determination of the (Delecoeuillerie), 217.
- Asparagus, Odour of Urine after Eating (Carles), 73.
- Assay of Extractum Ipecacuanhæ Liquidum (Wilson), 3.
- of Opium (Cowley), 653; (Merson), (Upsher Smith), 707.
- of Spirit of Nitrous Ether (Fischer and Anderson), 370.
- Assays, Organic, Drying Alkaloidal Residues in (Cowley), 540.
- Associations, Local Pharmaceutical, Work for, Editorial Remarks on, 564.
- Pharmaceutical, Remarks on Meetings of, 651.
- Astringent, Tribenzoyl-Gallic Acid, A New, 500.
- Atkin, Mr. Chas. Ager, Death of, 125.
- Atmosphere, Gases Present in the (Ramsay), 510.
- Atomic Weights, 668; (Tables of), 702.
- Aufrecht—Formoform Dusting Powder, 256.
- Australasia, Pharmacy in, 22, 70, 125, 514*a*, 562*a*, 676*b*.
- Australian Poisonous Plants (Maiden), 505.
- Automatic Water-Mercury Air-Pump (Kraft and Weilandt), 270.
- Averill, J.—Inaugural Address to the North Staffordshire Chemists' and Druggists' Association, 452.
- Ayrton, Professor—The Physics of Smell, 338.

B

- Bacillus Subtilis in Liquor Potassii Citratis (Chamberlin), 528.
- Bacteria (Alcock), 499.
- and Dust (Neisser), 345.
- Counter (Mason), 49.
- in Hailstones (Harrison), 437.
- Photographing (Spitta), 693.
- Sterilised Milk and (Schottelius), 402*b*.
- Bacterial Cultures on Artichokes (Roger), 457.
- Diseases of Plants (Arthur), 117; (Cavara), 118.
- Treatment of Sewage, 524.
- Bacteriological Institute for India, 228.
- Bacteriology, An Atlas of (Slater and Spitta), 382.
- Kitchen, The *British Medical Journal* on, 231.
- Practical, A Class in, at Liverpool, 471.
- Sir R. T. Thorne, on, 702.
- The L.C.C. and the Study of, 188, 358.
- Baldon, Dr. H. Bayse, Appointment for, 402*d*.
- Bailey, H. H.—Retail Chemists and the P.A.T.A., 605, 664, 687, 707.
- Bain, J.—Colour of Robins' Syrup, 653.
- Baker, R. T., and H. G. Smith—Oil of Eucalyptus Punctata, 437.
- R. T., and H. G. Smith—Stringybark Trees and their Essential Oils, 635.
- Balkwill, F. P.—Medicago Sativa, 436, 479.
- Ballynahinch, A Visit to the Spa Wells near (L.P.S.I.), 74.
- Bannister, Mr. Richard, Testimonial to, 565.
- Barclay, J.—Some of the New Standards of the 1898 Pharmacopœia, 568, 655.
- Barrass, T. E.—Pharmaceutical Problems of To-day, 544.
- Barth, G., and C. S. Lintner—Quantitative Determination of the Bitter Principle of Hops, 624.
- H.—Micro-Chemical Recognition of Alkaloids, 635.
- Barton, F. C.—Camphor in Pills, 116.
- Basicity of Quinine, The (D. Howard and D. Lloyd Howard), 154.
- Basidiomycetes, Evolution of the (Masse), 26.
- Basis of Knowledge for Pharmaceutical Students, A, 297.
- Baucher's Test for Red Lead, 238.
- Baumann—Iodine in the Thyroid Gland, 425.
- Bayley, R. C.—Properties of Gelatin, 607.
- Bdellium and Myrrh (Holmes), 547, 565.
- Beal, J. H.—Reform of Pharmacy by Law, 375.
- Beckurts and Fierichs—Determination of Oil in Distilled Aromatic Waters, 238.
- Beecham's Pills—An Injunction, 662.
- Beer, Hamburg, Production and Export of, 705.
- Beeswax, Tunisian (Bertainchand and Marcille), 345.
- Belcher, J. A.—Setting of Plaster of Paris, 369.
- Belfast Conference, Presidential Address at the, Editorial Remarks on the, 184.
- Discussion at, on the British Pharmacopœia, 1898, (Editorial), 229; 232; (Bird), 239; (H. W. Gado), 259; (Umney), 279; (Dowzard), 323.
- Epidemic in, The *British Medical Journal* on the, 534*e*, 698*b*.
- Naturalists' Field Club, 492*d*.
- Notes on the Conference at (M.B.P.C.), 254.
- Pharmacy Prosecutions at (S. Hogg), 435.
- Belitski—Acid Fixing Bath, 71.
- Bell, John, and Co.—A Pharmaceutical Centenary, 87.
- Scholars, Success of, at the London University Intermediate Science Examinations, 324*d*.
- Belladonna, Assay of (Puckner), 97.
- Extracts, B.P., Note on, 514.
- Benevolent Fund Election, The (Pondo), 604; (Hampson), 631; 648.
- Benzene, The Storage of, 96.
- Benzoic Acid as a Preventive of Mould (Runge), 630.
- Berger, F.—Salubrol in Dentistry, 491.
- Bernegau, L.—Kola Tablets, 227.
- Bertainchand and Marcille—Tunisian Beeswax, 345.
- Bertrand, G.—Biochemical Production of Sorbose, 261.
- Beta-Naphthol Pills, 634.
- Betaine in Marshmallow Root (Orloff), 514*d*.
- Beuttner, C.—Testing Milk Sugar, 238.
- Bicycle Tyre, Application for Inner Surface of, 504.
- Bimm, A.—Artificially Decolorised Wines, 118.
- Biochemical Production of Sorbose (Bertrand), 261.
- Biology of the Uredineæ (Klebahn), 117.
- of Yeast, The (J. R. Green), 538.
- Birch Leaves as a Diuretic (Huchard), 237.
- Bird, F. C. J.—The Galenic Pharmacy of the 1898 Pharmacopœia, 162.
- F. C. J.—The Pharmacopœia Discussion at Belfast, 239.

- Birmingham Drugs, City Analyst's Report on, 24c; The *Lancet* on, 89.
— University for, Mr. Chamberlain on a, 566.
Bismuth, Smelters of, 480.
— Mixture, Note on a, 501.
Bismuthi Carbonas, B.P., Note on, 468.
— Subnitrates, B.P., Note on, 468.
Bitartrate of Potassium and the B.P., 1898 (Dowzard), 344; (Duncan), 364.
Bitter Principle of Hops, Quantitative Determination of the (Lintner and Barth), 624.
B'zzczaro, Professor—Sterilised Water, 118.
Black Wax, An Examination of (Blitz), 118.
Blackburn Chemist-Dentist Sued for Damages, 468c.
Blaud's Pill (Brown), 68.
Bleaching Brown Hogskin, 688.
Blitz, E. H.—An Examination of Black Wax, 118.
Blood, Iodine in the (Gley), 689.
Bloomsbury School, Our (Henderson), 281.
Blue-Black Ink, Formula for, 480.
Bills, Ointment for (Bulkley), 278.
Bolas, T.—New Lamp for Glass-Blowing, 607.
Bolton Chemists' Association, 48.
Bonbons, Malt, Formula for, 102.
Bond, C. Knox—The Use of Ipecacuanha in Epileptic Cases, 357.
Bone, W. A., and J. Wilson—The Action of Light on Acetylene, 16.
— W. H.—Improved Form of Gas Analysis Apparatus, 15.
Bonnier, M. G.—Artificial Production of Alpine Characters in Plants, 461.
Boric Acid in Food, Birmingham Grocers and, 260c.
Borates, Influence of, upon Nutrition (Chittenden and Gies), 217.
Borax, Adulterated, at Birmingham, 534c.
— Determination of (Heid), 624.
Boric Acid as a Food Preservative (Price), 446d.
— Acid in Wines (Carles), 73.
— Acid, Solubility of (D. F. C. A.), 544.
Borntraeger's Test for Aloes, 77.
Bosisto, Mr. Joseph, Death of, 678.
Botanic Gardens of the World (Cambridge), 372.
Botanical Nomenclature of the British Pharmacopœia (Druce), 202.
— Work Wanting Workers (Holmes), 90.
Botany, Recent Work in, 461, 509, 557.
Bott, Graham—An Interesting Botanical Specimen, 12.
— Graham—Camphor in Pills, 95, 215.
Bougault, J.—Decomposition of Iodoform Solution, 620g.
Bougies, Urethral, Preparation of (de Toledo), 345; (Soulard), 437.
Bouilhac, M., and A. Etard—Chlorophyll Produced in Obscurity, 241.
Bouillie Bordelaise, Formula for, 456.
Bounema—Reaction for Vanillin, 531.
Bourdas, F., Joulin, and Rackowski—Determination of Succinic Acid in the Presence of Tartaric and Lactic Acids, 122.
Bourdouresques, B.—Simple Method for "Killing" Mercury, 630.
Bournemouth Pharmaceutical Association, 571.
Bourquelot, E., and H. Herissey—Pectin in Gentian Root, 26, 217.
Bradford and District Chemists' Association, 368c, 477, 492b, 542, 594d, 648c, 657.
Brazil Wood Stain, 578.
Breteau, P.—Tincture of Guaiacum as a Reagent, 97.
Brice, H. W.—What is Honey Dew? 337.
Brilliantine, Cloudy and Non-Cloudy, 96.
Brissouet, J.—Phosphote, 342.
BRITISH ASSOCIATION:—
Chemical Section, Address to the (Japp), 359, 382.
Cork and the Meeting of 1900, 514c.
Mathematical and Physical Sectional Address, 338.
Presidential Address, The, 287, 304.

THE

PHARMACEUTICAL JOURNAL

VOLUME LXI. (FOURTH SERIES, VOLUME VII.)

LONDON: SATURDAY, JULY 2, 1898.

Recent Progress in Pharmacy.

WORK in this subject proceeds only tardily, as a rule, at the beginning of a new year, and knowledge of the fact that a new Pharmacopœia would soon be published doubtless tended to act as a further check upon the progress of pharmaceutical investigations. But the past six months have, nevertheless, been marked by a notable degree of activity amongst workers in pharmacy and allied subjects, and the briefest summary of the results of their labours, as recorded in these pages, must needs extend to a not inconsiderable length. One of the first communications of note was a paper by Edmund White, on the modification of the specific gravity of THEOBROMA OIL that takes place under certain conditions. The paper was supplementary to one by White and Braithwaite on SUPPOSITORIES, read at an evening meeting of the Pharmaceutical Society in November last, and the result of the investigation which it recorded was to show that some molecular disturbance is caused in theobroma oil by the application of heat in melting it, the effect of the disturbance not passing away entirely for several days. Thus, it was found that a variation is possible of half a grain in the weight of a fifteen-grain suppository, according to the time allowed to elapse between the solidification of the mass and its removal from the mould. An unfortunate explosion, caused by ERYTHROL TETRANITRATE whilst being triturated in a mortar, led Peter Boa to refer, in a paper read at Edinburgh, to the dangers attending the preparation of that and other explosive substances for administration as remedial agents. He pointed out that the efficiency of a remedy, as well as the convenience of the patient and the reputation of the dispenser, are dependent on the judicious selection of the proper method by which to manipulate it; substances liable to explosion should invariably be powdered in a glass or porcelain mortar with a uniformly glazed surface, the pressure being uniform and not too great, and the subsequent mixing should be performed on paper by the aid of a bone or wooden spatula.

In a paper by C. F. Henry, on the preparation of UNGUENTUM ACIDI CARBOLICI, it was suggested that the phenol should be dissolved in glycerin, and wool-fat used as the basis of the ointment. The first suggestion has since been adopted by the compilers of the British Pharmacopœia. A communication by William Duncan, on RESINOUS EMULSIONS or mixtures of resinous tinctures with aqueous fluids, was intended to advocate the plan of filling the bottle three-fourths full with the latter, then adding the tincture by pouring it through a small funnel so as to avoid touching the sides of the bottle, and afterwards shaking thoroughly. The solvent action of proof spirit and acetic acid on COLCHICUM SEEDS has been investigated by R. C. Cowley and T. P. Catford, whose work on this subject was a continuation of that previously done by the first-named in connection with colchicum corm. The result of the work was to confirm the view

that acetic acid does not possess any advantage over weak spirit as a solvent of colchicine. Later, the subject of BACTERIOLOGY FOR PHARMACISTS was ably treated by Leo Atkinson; a paper on DISPENSING DIFFICULTIES was read by F. H. Alcock; the determination of SUGAR IN URINE was brought prominently under the notice of pharmacists by Arthur McKellar; and an anticipation of the new B.P. process for the preparation of FLUID EXTRACT OF LIQUORICE was published by Peter Boa, who had found that water is the best extraction medium.

An account of some experiments performed to ascertain the SOLUBILITY OF GLASS IN WATER has been recorded by J. C. Fell; a note on the DETERMINATION OF PHENOL by H. Hymans, and a discussion on the RECOPYING OF PRESCRIPTIONS was initiated by F. W. Gamble, after attention had been directed in this Journal to certain omissions to carry out the provisions of the Pharmacy Act in that respect. Some commercial samples of LIQUID EXTRACT OF TARAXACUM were found by A. J. Dey to differ much in appearance, and the results of an examination of the preparations indicated considerable want of uniformity. Notes on the presence of sugar crystals in ALCOHOLIC EXTRACT OF BELLADONNA, and on PHENACETIN which emitted a strong odour of benzene when powdered, were contributed by the same author. Attention has been directed to DAVIESIA LATIFOLIA by J. Bosisto, and a crystalline substance extracted therefrom has been examined by Paul and Cownley, whose results indicate that in all probability it is a glucoside. The work of Podwyssotski on PODOPHYLLUM has been supplemented by Dunstan and Henry, who find that podophyllo-toxin extracted from the Indian drug is identical with that previously obtained from *Podophyllum peltatum*; E. J. Millard has since urged, however, that it is obviously improper for manufacturers to describe resin from Indian podophyllum as podophyllum resin, B.P. The wood of GOUPIA TOMENTOSA has yielded formic, isovaleric, lauric and succinic acids in the hands of Dunstan and Henry, who have also found that oxycannabin from INDIAN HEMP is derived from cannabinol. The use of FORMALDEHYDE in pharmacy was the subject of a useful paper by George Roe; the PHARMACY OF THE PANCREAS was dealt with by Dr. J. C. McWalter; the alleged decay in the ART OF PRESCRIBING has been attributed by Edmund White to deficiencies in the hospital training of medical men; and the influence exercised by English pharmacists on RUSSIAN PHARMACY has occupied the attention of P. Spehr and P. H. Marsden.

A number of DISPENSING DIFFICULTIES have been satisfactorily solved by Harold Wyatt, whose notes dealt with preparations containing silver nitrate with vegetable powders, syrup of ferrous iodide with infusion of calumba, bismuth salicylate, hydronaphthol, cocaine with lead acetate, quinine, storax, Stockholm tar, etc. The demands, claims, and responsibilities of the DISPENSER'S ART afforded Dr. H. Macnaughton-Jones an excuse for some special pleading on behalf of public dispensers, and a paper on POOR LAW DISPENSERS was read by A. W. Antcliffe. The inconvenience caused by the presence of crude petroleum or rock oil in METHYLATED SPIRIT, as supplied for sale by retail, has been

referred to by Peter Boa, whose remarks on the subject were ably supplemented by J. Rutherford Hill and other Scottish pharmacists, the general opinion being that the objectionable addition does not operate in any degree as a check upon the use of the spirit as a beverage. The PHARMACY OF CANTHARIDES has been dealt with by Greenish and Wilson, who suggest new formulæ for liquor epispasticus, collodium vesicans, emplastrum calefaciens, and the tincture, vinegar, ointment, and plaster of cantharides. Unfortunately their suggestions were too late to be utilised in the new Pharmacopœia. An interesting lecture on PHARMACY IN IRELAND was delivered in Dublin by Mr. Robinson, a former examiner of the Irish Society, and the practical application of LIQUEFIED GASES in pharmacy was discussed by Professor Tichborne. The alkaloidal constituents of CASCARILLA BARK have been further examined by W. A. H. Naylor, who is of opinion that the existence of a base in the bark other than one allied to choline may now be accepted as a fact; a simple MOULD FOR SUPPOSITORIES has been devised by H. P. Header; a handy SYRINGE FOR FILLING CAPSULES by J. A. Forret; the PHARMACY OF MERCURY has been discussed by J. Fothergill; and a comprehensive paper on the MELTING POINT OF SOFT PARAFFINS was read at Manchester by James Grier. Other useful papers on the chemical side were those on the DETERMINATION OF ASH by D. B. Dott, and on GLUCOSE DETERMINATION by Cowley and Catford. The dispensing of ANTIPYRINE with spirit of nitrous ether having been touched upon by Professor Caspari, his observations were commented upon at Glasgow by Thomas Dunlop, who pointed out that the conclusion arrived at was to some extent fallacious.

The great event of the half-year, from a pharmaceutical point of view, has, of course, been the publication of the new BRITISH PHARMACOPŒIA. Issued to the press the day before Good Friday, an interval of more than three weeks was allowed to elapse before the book could be purchased. Meanwhile, however, through the courtesy of the Pharmacopœia Committee, opportunity was afforded for supplying information as to the contents of the work, and details regarding all important changes were published in the *Pharmaceutical Journal*—more particularly in regard to the processes and formulæ, full working particulars of which were given—and much was thus done in the way of facilitating a speedy acquaintance with the contents of the book. Naturally, criticism of the work was not long delayed, but up to the present little has appeared that can be justified by work actually performed since the Pharmacopœia was issued, and more extended experience will probably show that those responsible for devising the new processes and altering old ones knew more about the matter than most of their critics. The necessity—always apparent—for pharmaceutical co-operation in the work of revision has been more fully recognised, and thus some advance has been made towards co-ordination of the functions of medicine and pharmacy. Nevertheless, the British Pharmacopœia of 1898 is still essentially a work produced for physicians rather than pharmacists, and in the attempt to simplify matters for medical practitioners, the compilers have gone far to throw the practice of pharmacy more than ever into the hands of manufacturers, to the manifest detriment of the art and those who have been specially trained therein. Meanwhile, the properly trained pharmacist need entertain no fear with regard to the ultimate result in the matter of dispensing and supplying medicinal agents for human beings, inasmuch as individual work must ever exceed in value machine work, in all matters that involve exact adaptation to particular needs.

More recent contributions of pharmaceutical interest have

included an illustrated description of an APPARATUS FOR ADMINISTERING OXYGEN, by George Lunan; an attempt to overcome the difficulty involved in connection with an INCOMPATIBLE STRYCHNINE MIXTURE, by J. Rutherford Hill, and short papers by the same pharmacist on STRYCHNINE HYDRIODIDE, on INVISIBLE AND SYMPATHETIC INKS, and on METHYLATED SPIRIT IN PHOTOGRAPHY. The new official test for QUININE SULPHATE has been criticised by A. J. Cownley, who asserts that quinine sulphate containing 5.99 percent. of crystallised cinchonidine sulphate will answer the new B.P. requirements, though it is stipulated that it shall not yield more than 3 per cent. of crystals of impure cinchonidine. Some notes on PEPSIN ASSAYING, by A. H. Allen, were not altogether favourable to the new B.P. process, comparison of that with the U.S.P. method of assay being shown to be greatly in favour of the latter. The difficulties involved in the preparation of the alcoholic menstrua of the new B.P. have been minimised by the publication of useful dilution tables by F. C. J. Bird and W. Martindale, those by the first-named being particularly practical and adapted for the preparation of either small or large quantities of diluted spirit of any required strength. An examination of commercial samples of BENZOIN AND GUAIAECUM RESIN by J. Evans was a report of good work done in the laboratory of the School of Pharmacy; COMPRESSED TABLETS AND TABLET TRITURATES have again been dealt with by Frank Edel; the results of somewhat extended researches on CORYDALINE are recorded by Dr. W. H. Martindale, the purity of COCAINE HYDROCHLORIDE is the subject of a paper by Paul and Cownley; and the strength of LIQUOR STRYCHNINE HYDROCHLORIDI has engaged the attention of George Lunan. In addition, abstracts of a very large number of papers dealing with pharmacy and the allied sciences have been published in the *Journal* week by week, all investigations and results of importance having thus been dealt with, adequately and promptly.

Turning to the subject of pharmaceutical organisation, we find that the concluding half of the winter session has been no less busy a period amongst provincial associations than the previous half. More associations have come into existence since the beginning of the year, and it is satisfactory to note, on surveying the work of the past half year, that in the great majority of instances the members of the various associations have devoted themselves mainly to the consideration of matters of local or general importance to the craft. The numerous discussions on the Pharmacy Acts Amendment Bill, and the measures taken all over the country to facilitate the progress of that Bill, by bringing pressure to bear on Members of Parliament, have served to emphasise the fact that registered chemists as a class, whilst always prepared to do their utmost in the public interest, are also fully determined to protect their privileges as of old. This is all the more satisfactory since the omens are not altogether favourable in connection with the Government Poisonous Substances Bill. The tendency of that Bill, as cannot be too widely known, is in direct opposition to the established principle that, in regard to the sale of poisons, the safety of the public is best cared for by the special education, qualification, and registration of the seller. Possibly, therefore, the measure may require to be strenuously opposed in the House of Commons, and steps may require to be taken for that purpose at a very early date. Registered chemists throughout Great Britain ought, therefore, to be ready at a moment's notice to protest, through their Parliamentary representatives, against a Bill which may prove most inimical to their interests, whilst admitted by the Lord President of the Council when introducing it, to be little likely to confer any benefit on the public.

THE ASSAY OF EXTRACTUM IPECACUANHÆ LIQUIDUM.

BY HAROLD WILSON.

Demonstrator in Pharmacy to the Pharmaceutical Society of Great Britain.

The British Pharmacopœia contains a liquid extract of ipecacuanha, which is standardised to contain not less than 2 and not more than 2.25 grammes of alkaloid in 100 cubic centimetres, and an assay process is made official, of which the following is an outline:—

Twenty C.c. of the strong liquid extract are diluted with an equal volume of water and the alcohol removed by heating on a water bath; excess of solution of subacetate of lead is then added, and the liquid filtered off, the precipitate being washed with water and the washings added to the filtrate. This liquid is then freed from lead by precipitation with dilute sulphuric acid and subsequent filtration, the precipitate being washed with water, and the washings added to the filtrate. It is now transferred to a separator, excess of solution of ammonia is added, and the alkaloids are removed by shaking with three successive quantities of 25 C.c. chloroform. The mixed chloroformic solutions are evaporated in a tared dish, the residue dried below 80° C. and weighed as total alkaloids.

On trying the above process on a sample of the liquid extract I was struck by its complexity and by the length of time required for its completion. Twenty C.c. of liquid extract required about 7 C.c. of the official solution of subacetate of lead for complete precipitation, and a magma-like mass resulted, which filtered very slowly (taking three to five hours), and which, even after having been washed as thoroughly and carefully as possible, still contained a considerable quantity of alkaloid, as experiments proved.

Two separate assays of 20 C.c. of the liquid extract were made by the official process, 50 C.c. of water being used to wash the precipitate obtained on adding the excess of lead subacetate solution.

No. 1 assay yielded .386 alkaloidal residue.
No. 2 " " " .393 " "

The washed lead precipitates were then examined for alkaloid, as follows:—

The precipitate was washed from the filter with water, decomposed with excess of dilute sulphuric acid, and the liquid filtered from the sulphate of lead into a separator. Ten C.c. of ether-chloroform were then added and the mixture agitated; the ether-chloroform was allowed to separate and was then run off and rejected. This treatment was twice repeated. Excess of solution of ammonia was then added, and the precipitated alkaloids removed by agitation with successive quantities of ether-chloroform. The mixed ether-chloroform solutions were evaporated and the residue dried below 80° C. and weighed.

Precipitate from No. 1 assay yielded .031 gramme alkaloidal residue.
, " No. 2 " " " .028 " " " "

Not only, therefore, is the official process from the nature of the lead precipitate tedious to perform, but it is inaccurate, since it involves loss of alkaloid.

A number of experiments were then made with the object of devising a simpler, quicker and more accurate method of assay, as a result of which I suggest the following as possessing these advantages.

“Take 20 C.c. of the strong liquid extract, dilute with 20 C.c. water, place in a porcelain dish and dissipate the alcohol by evaporating the mixture to rather less than half its bulk; allow to cool. Now add 1 C.c. dilute sulphuric acid and transfer to a separator, washing the dish with 20 C.c. water and adding these

washings to the liquid in the separator. Add 10 C.c. ether-chloroform (ether and chloroform equal volumes), agitate, warm to promote separation; run off and reject the ether-chloroform layer and twice repeat the treatment with the same quantity of ether-chloroform. Add now 10 C.c. ether-chloroform and excess of solution of ammonia, agitate, warm, and run off the separated ether-chloroform layer into a tared dish; agitate with two more similar quantities of ether-chloroform, separate as before, adding these solutions to that in the tared dish. Evaporate the mixed solutions and dry the residue below 80° C. until of constant weight. This weight, less that of the dish, will give the weight of total alkaloids present in the quantity of liquid extract operated on.”

It was determined to compare the values of the official and suggested processes by assaying the same sample by both methods, and to ascertain the weight of alkaloid yielded as well as the amount of decinormal acid such weighed residue was capable of neutralising, thus obtaining a check on the relative amounts of alkaloid present.

Two assays of the same quantity of extract were, therefore, made by the process suggested:—

No. 1 assay yielded .417 gramme alkaloidal residue.
No. 2 " " " .426 " " "

The foregoing gravimetric results may be summarised thus:—

	Alkaloid Extracted.	Lost in Lead Precipitate.	Total.
Official Process	{ No. 1. .386	.031	.417
	{ No. 2. .393	.028	.421
	{ Mean. .389	.029	.419
Suggested Process....	{ No. 1. .417	—	.417
	{ No. 2. .426	—	.426
	{ Mean. .421	—	.421

From the above figures it will be seen that when the alkaloid is recovered from the lead precipitate practically the same quantity of alkaloid by weight is obtained by each process.

The relative alkaloidal value of these residues was then determined by titration. Owing to the fact that when chloroformic solutions of the alkaloids of ipecacuanha are evaporated the solution rapidly darkens and a coloured residue is obtained, it was found necessary to carry out this operation in a very dilute solution, and in order to obtain strictly comparative results exactly the same conditions were observed in every case. Each residue was dissolved in 10 grammes of rectified spirit and diluted with 600 grammes distilled water. Excess of $\frac{N}{10}$ H₂SO₄ solution was then added, and the mixture titrated back with $\frac{N}{100}$ NaOH solution, using tincture of cochineal as indicator. The number of cubic centimetres of soda solution required was divided by ten and subtracted from the number of cubic centimetres of acid added, giving the following figures:—

Official Method.....	{ No. 1. .386	=	13.97 C.c. $\frac{N}{10}$ acid.
	{ No. 2. .393	=	14.18 " "
Suggested Method ..	{ No. 1. .417	=	14.88 " "
	{ No. 2. .426	=	15.24 " "

The residues recovered from the lead precipitate were also titrated.

No. 1.	.031	=	1.02 C.c. $\frac{N}{10}$ acid.
No. 2.	.028	=	1 " "

From these figures the following calculations can be made showing that, within the limits of experimental error, the residue yielded by the suggested process is as rich in alkaloid as that of the official one:—

By official method from No. 1. assay 1 gr. alkaloidal residue	=	36.2 C.c. $\frac{N}{10}$ acid.
" " suggested " " No. 2. " " "	=	36 " "
" " " " No. 1. " " "	=	35.7 " "
" " " " No. 2. " " "	=	35.8 " "

As far as can be seen at present, titration appears useless as a

means of estimating the alkaloids of ipecacuanha. If we take the molecular weight of emetine (248) and cephaeline (234) as given by Paul and Cownley, and, assuming these alkaloids to be present in about equal quantity, we take the mean of their molecular weights (viz., 241), then every C.c. of $\frac{N}{10}$ acid used should correspond to .0241 Gm. of the mixed alkaloids. If, however, we calculate the above titration results by this method we see that there is a difference of from 50 to 60 milligrammes between the results of volumetric and gravimetric determinations, e.g. :—

Gravimetric.	Volumetric.	Difference.
.386	.337	.049
.393	.342	.051
.417	.359	.058
.426	.367	.059

This difference may be due to some impurity, but more probably to the third alkaloid which is present, and which Paul and Cownley believe to have a much higher molecular weight than either emetine or cephaeline.

By the process suggested fatty matter, resinous bodies, etc., are removed by agitation with ether-chloroform in acid solution. If this part of the process be carefully conducted it becomes unnecessary to subject the ether-chloroform solution of alkaloids to the usual purification by acid treatment, as when treated by the latter method the ether-chloroform, after shaking with acidulated water, has been proved to yield no residue on evaporation.

The drying of the alkaloidal residue till of constant weight is tedious, but no means can at present be devised for shortening this operation, as cephaeline has been shown by Paul and Cownley to lose weight at 100° C., and hence to guard against this loss the residue must be dried below 80° C.

The advantages claimed for the suggested assay process over that official are the two very important ones of speed and accuracy. The assay can be easily completed, with the exception of drying the residue, well within the time required by the official process for washing the lead precipitate alone. A residue of greater weight is extracted which has been proved by titration to be equally rich in alkaloid. From the mean results given earlier it will be seen that by the official process .389 Gm. is extracted and .029 Gm. lost, that is to say, the loss is between 1/14 and 1/15 of the total alkaloid present. These figures are based on the results obtained on carefully washing the precipitate with 50 C.c. water which, considering the time taken (at least three hours), was judged a fair quantity; but if double that quantity of water be used to wash the precipitate it has been proved to still contain a notable proportion of alkaloid.

The foregoing experiments have been carried out in the Pharmacy Laboratory of the Pharmaceutical Society.

SODIUM ACETO-SULPHANILATE.—This antipyretic is prepared by the acetylation of sodium sulphanilate, which produces, besides sodium aceto-sulphanilate, free sulfanilic acid and sodium acetate. The impure sodium aceto-sulphanilate is freed from these products by treating it with a little hot water, which leaves the free sulfanilic acid undissolved. The sodium salts are removed from the cold aqueous solution by 98 to 99 per cent. alcohol or by ether-alcohol, and purified from sodium acetate by means of boiling alcohol. Pure sodium aceto sulphanilate possesses the advantage over antifebrine that it is soluble in water, and is therefore much quicker in action.—*Pharm. Zeit. f. Russl.*, xxxvi., 653.

A NEW FORM OF PHOTO-MICROGRAPHIC CAMERA AND CONDENSING SYSTEM.*

BY E. B. STRINGER, B.A.

The apparatus which Mr. Watson Baker has kindly undertaken to submit to the Society on my behalf is an attempt to facilitate the work of photo-micrography, especially with high powers, and to afford an illuminating system more perfectly corrected, more powerful, and more under control than has hitherto been available.

The baseboard is confined to that part of the apparatus which carries the illuminating system and microscope, the further end of the camera being supported by a massive wooden block. To this are attached two long brass tubes, on which slide the supports for the bellows, and which themselves slide in slightly larger tubes attached to each side of the baseboard. By drawing out these inner tubes with the block, and sliding the bellows supports the other way, the camera can be extended to 40 inches, or it may be closed up to 11 inches; but at whatever length it may be used there is no baseboard projecting beyond the end of it, and the focussing screen is always in the most convenient and accessible position, namely, at the end of the bench, where the worker can be comfortably seated; also the firm support of the massive wooden block is always immediately beneath it, conferring the greatest possible solidity and freedom from vibration.

A door is provided at the side of the camera for the examination and adjustment of the image *in situ*, when a white card is substituted for the ground glass or other screen.

If it should be necessary—though in practice it very seldom is—to look down the microscope when it is in position, the camera can readily be drawn backwards altogether out of the way of the observer's head; and it will be seen that the whole camera can in a moment be entirely removed, and the microscope used, if so desired, for screen projection.

I have found that the secret of avoiding vibration is to clamp down nothing, but to let everything rest by its own weight on as large a surface as possible. To increase this effect, and to bring the apparatus into firm and intimate contact with the bench (and also to help to absorb vibration), it has underneath it a layer of sheet cork one-eighth of an inch thick, below which is another layer of felt also one-eighth of an inch thick. On these it rests with great firmness, and at the same time slides easily enough when pushed.

At the end of the baseboard next the camera is a triangular plate of brass, having three holes, into which the round feet of the microscope (Watson's H Edinburgh stand) accurately fit, the feet passing completely through the holes and resting on the board beneath, which is here covered with cloth. At the three angles of the plate are three milled screws, passing through holes which (when the screws are unclamped) are large enough to allow about a quarter of an inch of free movement in each direction. When the microscope is first put down these screws are released, and the microscope shifted until it is found to be exactly centred. The screws are then firmly clamped and are never again touched. The microscope can now be instantly put down in an accurately central position into the holes which receive the feet, and as easily taken up again. This enables the microscope used for ordinary observation to be employed for photography with as much ease and accuracy as the permanently fixed instrument found in some arrangements.

The small model instrument is preferred, not only because it is lighter and more convenient to move about, but also because its

* Read before the Royal Microscopical Society, December, 1897.

optic axis when in the horizontal position is lower; thus the optic axis of the whole apparatus, and consequently its centre of gravity, is lower, and its stability and freedom from tremor the greatest possible. The small, light body-tube also confers a greater sensitiveness on the fine adjustment than can be obtained in the full-sized instrument; and it will be shown farther on how the small tube may be used without any danger of flare from internal reflection.

The "turn out" device is dispensed with as being unnecessary where the microscope is not fixed down. All adjustments are easily made, with the powerful illumination provided, by projecting the image on to a screen of white card.

The front of the camera has sliding movements in both directions, by which the connecting flange can be once for all adjusted to exactly meet the eye-piece of the microscope. Behind it is the usual flap shutter for making the exposures, worked by a large milled head outside the camera.

The focussing arrangement adopted is the one in which an endless cord passes over the fine adjustment screw and round two other pulleys below and on each side of it, by which any lateral drag on the microscope is altogether avoided. These pulleys can be changed

sity, and of that slight divergence which is best suited to working of the substage condenser.

The working of the whole system is as follows:—The light from the jet is first parallelised by the doublet condenser, which consists of two plano-convex lenses having their plane sides turned towards the radiant, the one next the radiant being a quarter of an inch less in diameter than the other, and the focal length of the combination being $2\frac{3}{4}$ inches, taking up an angle of 70° .

The parallel beam passes across an interval of about 10 inches, through the screen or trough of coloured solution carried by the intervening support, and enters the plano-convex lens $4\frac{1}{4}$ inches in diameter (having its convexity turned the other way to minimise the aberrations), by which it is converted into a converging cone. This, after passing through the water in the chamber between the lenses, is again parallelised by the much smaller plano-concave lens, and emerges from it as a parallel or, more strictly speaking, a slightly divergent pencil rather less than an inch in diameter, and enters the substage condenser. The plano-concave lens is of highly dispersive glass, and perfectly achromatises the whole system.

The converging arrangement is clamped at such a distance

B Oxyhydrogen jet with zirconium cylinder, covered by the cowl A when working. C Doublet parallelising condenser, with centring screws. D Iris diaphragm. E Holder for trough and light-filtering media. F Plano-convex $4\frac{1}{4}$ in. diameter, with centring screws G. H Plano-concave lens, with iris diaphragm T. K Connecting pulleys between focussing rod of camera and fine adjustment of microscope. L Triangular frame in which microscope feet are placed. M Flap shutter. N Door through which image is observed on card screen, etc. O Solid block of mahogany on which camera body is fixed and supported. P Dark slide.

and used of various sizes, those for high-power work being as small as it is possible to make them, so that a very slow movement is easily obtained. The focussing rod passes through the block at the end of the camera and terminates in a large milled head, which, whatever length of camera may be in use, is always close to the focussing screen and the left hand of the worker.

In extending or closing up the camera there is only one screw to be released, namely, the small one which clamps the focussing pulley on to the focussing rod. The clamping screws on the ends of the lateral tubes, and those on the bellows supports, are adjusted to a convenient tightness and not afterwards touched.

The condensing system, the oxyhydrogen jet, and a small lantern of sheet iron are all carried on the optical bench, which I have found it a great improvement to make square in section instead of prismatic, as has been usual heretofore. With the condensing system many difficulties were at first experienced, until Mr. E. M. Nelson very kindly interested himself in the matter, and computed a new set of condensers, following the same general plan as I had done, but making them larger ($4\frac{1}{4}$ inches in diameter) and employing the new Jena glasses. These, after one or two final alterations, proved entirely successful, and the result (the perfection of which is due to Mr. Nelson's optical knowledge and skill) is an illuminating system perfectly achromatised, and almost perfectly aplanatic, and, moreover, of much greater power than has hitherto been available, affording a beam of great inten-

from the substage condenser as to throw a spot of light rather larger than the opening in the condenser diaphragm. The smaller the radiant point, or the larger the opening in the diaphragm, the greater this distance should be. The best average distance is about $2\frac{1}{2}$ inches from the substage ring, as it stands at present. This also allows ample room for putting down and taking up the microscope and for using the mirror when the microscope is in place, if it should be necessary to do so. For "dark ground" work, or in using the Lieberkühn, the small iris may be removed and the nose of the converging system slid right up into the substage ring, so that there is no loss of light whatever.

The small weighted cone regulator, attached either to the main or to a tube of compressed hydrogen, supplies gas to the "mixed" jet (which has a much smaller nipple than usual) at a pressure of 2 inches of water; so that, with the hydrogen tap full open, the light is always of the same power, and exposures may be timed with certainty. The oxygen is better taken at a higher pressure direct from a tube having only the usual spring regulator, and controlled by the screw tap of the jet; but it is as well that the spring should be a weak one. The zirconia cylinder which is used, with the jet directed on to the end of it, gives an incandescent point almost as small as the electric arc, and is at the same time much more manageable and in every way superior to lime for the present purpose. With it the beam emerging from the first combination is almost perfectly

parallel. If a larger radiant, such as a lamp flame or Welsbach burner be used, it is much better to bring up the back combination as near to the other as the intervening support will allow.

It will be noticed that not only is the emergent beam entirely robbed of its heat by passing through so large a depth of water, but the jet is, in virtue of the whole arrangement, removed to so great a distance from the microscope that there can be no indirect communication of heat such as might affect the focal adjustment in high-power work. The illumination is also of such power that very deep and approximately monochromatic screens may be used, with moderate exposures; and excellent work may thus easily be done with objectives which are not apochromatic.

The device of the parallelising plano-concave lens is, of course, originally due to Kingsley, who first employed it in a microscope for screen projection about the middle of the present century, and it has since been used by Mr. Lewis Wright in his oxyhydrogen lantern microscope, now so well known.

The large iris in front of the combination next the light is an important feature. By it the substage condenser is focussed and centred, and when it is shut down to the right extent it will be found (besides rendering the whole system perfectly aplanatic) to entirely cut off that surplus light, which when reflected from the inside of the microscope tube and objective mount causes so much trouble and so many failures in photo micrography. So that it is no longer necessary to use a specially large tube, and the small tube with the greater sensitiveness it confers upon the fine focal adjustment can be retained. If no light whatever is to strike the sides of the tube (though a little does not of course matter) the diaphragm of the substage condenser must not be opened beyond its full aplanatic aperture.

There is besides a small iris beyond the plano-concave parallelising lens which cuts off any remaining stray light, and is also used for centreing.

The whole system is provided with centreing screws, and it, like the microscope, is centred once for all and never again touched. The only adjustment that has to be made with each fresh exposure is the centreing of the light itself (which is for this purpose provided with very sensitive centreing screws) and the adjustment of its distance from the condensers, which will be found to vary a little when different objectives and substage condensers are used. The small sheet-iron lantern slides in grooves on each side of the optical bench, and when slid backwards gives easy access to these screws.

Finally, it must be said that to employ this illuminating arrangement to the greatest advantage it is necessary that the substage condenser be proportioned in power as well as in aperture to the objective. The more nearly the power of the substage condenser approaches that of the objective, the wider can the large iris be opened, and the greater is the intensity of the illumination; but it is the intensity alone which is affected, the aperture of the substage condenser, whatever it may be, remaining unaltered. The best results appear to be obtained when the condenser is about one half the power of the objective.

If this proportion be pretty closely maintained, and the other conditions are fairly equal, as is often the case in the general run of work, the exposure varies but little with varying magnifications, averaging about two seconds with a light yellow screen and a plate of medium rapidity.

The apparatus was made for me by Messrs. Watson in the summer of 1896, and I must, in concluding, express my thanks to them for the care and thoroughness with which they have carried out my design.

EXAMINATION OF POWDERED VEGETABLE DRUGS.*

BY HENRY KRÆMER.

QUANTITATIVE EXAMINATION.

In a paper presented to the A. Ph. A. in 1894, a preliminary notice of a method for securing approximate quantitative results of the examination of a powder by means of the microscope was given. After a few years of deliberation and some practice the principles of the process are somewhat more satisfactorily developed and the results will be given. Since 1894 the results of several workers—Day ('A. Ph. A. Proc.', 1896) and Kebler ('Amer. Journ. Pharm.', 1897, p. 244), as well as the labours of some students during the past year, indicate that the principle of the process suggested is satisfactory, whatever the modifications recommended. The following are the important points embracing the principles of the process as developed thus far:—

(1) The same reagents and mounting media are employed in doing quantitative work as were considered in the qualitative examination of the powder. In quantitative work, not only some, but all of the important characteristic tissues and contents are to be rendered visible.

(2) The quantity of powder to be examined by means of the microscope must represent the sample in every particular; in other words, the sampling must be done properly and in accordance with the methods used in the assay of ores. While the quantity to be examined may consist of but a few grammes, it must thoroughly represent the lot of powder on which value is to be given.

(3) The standard powders, with which the powder under investigation is to be compared, must thoroughly represent the drug in the various ways in which it may be treated. The degree of fineness must especially be carefully borne in mind. A sample of a drug of No. 40 powder cannot be compared with one of No. 60. If the sample of a drug to be examined is of a No. 40 powder, the standards must also be of the same degree of fineness. If extraction of active principles is suspected in the powder it must be

$\frac{1}{2}$ = 0.500 gramme; $\frac{1}{4}$ = 0.250 gramme; $\frac{1}{8}$ th = 0.125 gramme; $\frac{1}{16}$ th = 0.0625 gramme; $\frac{1}{32}$ th = 0.03125 gramme; $\frac{1}{128}$ th = 0.0078 gramme; $\frac{1}{256}$ th = 0.0039 gramme.

* From the *American Journal of Pharmacy*. For remarks on qualitative examination see last week's Journal, p. 592. Concluded from last vol., p. 592.

compared with a standard that has been extracted. In fact, every treatment that is possible in a sample to be analysed must be given to a standard, if possible, with which the comparison is made.

(4) The amount of powder used in the examination is generally about 1/256th gramme (= 0.0039 gramme = 0.06 grain). In some cases twice this quantity (1/128th gramme), or but one-half this amount (1/512th gramme) may be used to greater advantage. The quantity of powder may be weighed out, or, what is more convenient, with practice a gramme is weighed out and divided with a spatula with the eye, as follows:—

(5) The cover-glasses used, whether round or square, should be uniform in size and thickness for comparison of the mounts of the standard with those of the specimen to be tested.

(6) The amount of reagent employed in making a mount must be just sufficient to float the cover-glass, and as few air-bubbles as possible are permitted to be formed.

(7) A homogeneous mixture of powder with reagent must be formed before the cover-glass is put down. This is best done by taking the edge of the cover-glass in a pair of forceps and distributing the powder in the mounting media or reagent.

(8) After the mount has been made and the powder examined previously qualitatively, the quantitative estimation of the powder is determined. This is based on one or more of the structures or constituents that are characteristic of the drug or drugs that may be present. A few examples may be given:—

In cinchona, the bast fibres are best selected.

In quillaja, the monoclinic calcium oxalate crystals are most characteristic.

In *Belladonna folia*, the pieces of tissues, with some cells containing the characteristic grayish sand-like crystals of calcium oxalate, are selected.

In *Hyoscyami folia*, the pieces of tissues, with some cells containing the characteristic cubical or tetragonal crystals of calcium oxalate, are used.

In *Stramonii folia*, the pieces of tissues, with some cells containing the characteristic "rosette-shaped" crystals of calcium oxalate, are most characteristic.

In zingiber, the estimation is based on the starch grains, or better, the oil-secreting cells.

In scilla, the number of cells with groups of acicular crystals are best selected.

In *Belladonna radix*, the starch grains are most easily used, but it must be borne in mind that there are several kinds of belladonna root in the market.

In nux vomica, the lignified hairs are most characteristic.

In rheum, the large "rosette-shaped" crystals of calcium oxalate are best selected.

In caryophyllus, the oil-secreting reservoirs are used.

In cinnamomum, the groups of stone cells or starch grains are characteristic, taken in connection with the presence or absence of cork cells.

In sarsaparilla, the starch grains are considered after the kind of root has been ascertained.

In glycyrrhiza, the characteristic fibres with calcium oxalate crystals adjoining them, or the starch grains, are employed.

(9) The method consists in counting the number of characteristic elements in several portions of the slide, and may be performed in several ways:—

(a) By the use of an ocular micrometer ruled in 100 square millimetres, as proposed in 1894. Five portions, at least, of the mount are examined, as in the places marked X (Fig. 2).

The number of characteristic elements that appear in each of these places in certain portions of the ocular micrometer are

counted, as, for instance, those that appear in the square millimetres marked X (Fig. 3).

The low power ($\frac{1}{2}$ to $\frac{2}{3}$ -inch objective) is used in some cases, as in the estimation of rheum, scilla, etc.; but in most instances, especially when starch grains are to be counted, a higher power ($\frac{1}{4}$ to $\frac{1}{3}$ -inch objective) is preferred, as in *Belladonna radix* zingiber, etc.

FIG. 2.

(b) While these ocular micrometers ruled in square millimetre are easily made, still the makers of microscopical accessories charge such a very high price for the same that it has been found desirable to devise another way for doing the same kind of work. An ordinary ocular micrometer divided into tenths of millimetres is taken, and the number of elements between the outer portions, ruled to a less number of divisions (as those marked X, Fig. 4), are counted.

It is better, when using this ocular micrometer, to turn the latter around 180° after counting in the one direction, and counting again. In other words, an additional count is made, i.e., ten are made upon each mount.

(c) There are some cases where it is not desirable to use either (a) or (b), as when the elements or tissues are so large that it is more practicable to exclude the ocular micrometers, and to count all of the tissues or constituents as they appear in the whole field of view of X in Fig. 1.

The low power ($\frac{2}{3}$ to $\frac{1}{2}$ inch) may be used sometimes, as in the estimation of cinchona, quillaja, glycyrrhiza, etc., while in other

FIG. 3.

drugs, such as *Hyoscyami folia*, *Belladonna folia*, etc., a higher power ($\frac{1}{4}$ to $\frac{1}{3}$) is used.

(10) The number of mounts to be made of the standard and the powder under examination should generally not be less than twelve each. But as two to three mounts can be made upon the same slide, from four to six slides only are necessary for each powder.

(11) If the powder is found to be a mixture, a similar compound, representing the proportions found, should be made up, and the powder under investigation be compared with it.

(12) It is apparent that the quantitative results are purely comparisons of an unknown with a known powder. The conditions must be nearly the same in both. The sampling must be done similarly; the same amount of powder must be used in both, and no more reagent or mounting media should be used than is neces-

sary to hold the cover-glass without any air being impinged. The same microscope and powers, as well as other conditions, must be employed to secure even approximate results, as this is all that can be expected at present.

It would be useless for the author to record some of his standards and results; but it no doubt will be profitable to give the records

FIG. 4.

of one or two instances where a number have worked upon the same powder.

STANDARD OF NUX VOMICA.

No.	Hairs.
1. Mean of 10 readings	12
2. " 8 "	12½
3. " 10 "	10·9

A sample of cinchona, that contained 75 per cent. of cinchona and 25 per cent. of wheat starch, was assayed by the process given under 9 (b) for starch and 9 (c) for bast fibres, and gave the following results to nine different workers:

No.	Cinchona. Per cent.	Starch. Per cent.
1. Mean of 20 readings	74	23
2. " 10 "	67	—
3. " 20 "	82	25
4. " 12 "	77	28
5. " 16 "	66	35
6. " 12 "	77	27
7. " 11 "	69	23
8. " 20 "	80	30
9. " 28 "	75	22
Total " 149 "	74·11	26·66

Conclusion.—We need more effective work in the qualitative study of powdered drugs, and we have some recent evidences that this will be done in this country.

Approximate quantitative results may be obtained in the examination of unknown powders by the methods given. There are some cases, at least, where the quantitative determinations of admixtures and adulterations, if they are to be determined at all, can be done so only by means of a microscopical method.

It is possible that a microscopical separation of active principles may be effected of both drugs as well as their preparations. This would be the desideratum in quantitative microscopical work. Thus far the work of the author has been unsatisfactory in this direction, because, while at times results come, still the products disappear as quickly, owing no doubt to microscopic conditions of heat and moisture altering the products formed.

DETERMINATION OF SUGAR.—Reigler (*Zeit. Anal. Ch.*) proposes a new volumetric method for estimating sugars that reduce Fehling solution. The strength of the copper solution is determined by adding KI and a little conc. H_2SO_4 , and titrating the iodine liberated by means of hyposulphite. After adding a certain volume of the saccharine solution to a known quantity of the copper solution, the liquid is filtered and the precipitate washed. The CuO in the filtered liquid is estimated as before, and accurate results may be obtained. The author gives the following details of the solutions employed:—Take 10 C.c. copper solution ($CuSO_4$, $5H_2O$ 34·64 grms. in 500 C.c. H_2O); 10 C.c. tartarated soda solution (173 grms. in 500 C.c. H_2O); 2 C.c. conc., H_2SO_4 ; 30 C.c. H_2O ; 10 C.c. of the saccharine solution, which must not contain more than 1 per cent. of sugar; and lastly 1 gramme KI.—*Bull. de la Soc. Chim. de Paris* [3], xix.-xx., No. 11., 493.

MAKING AND FILLING SOFT GELATIN CAPSULES.

BY FRANK EDEL, DES MOINES, IA.

Some months ago I noticed an article on laboratory notes, in which the writer stated that his experience with the soft empty capsules of the market had not been favourable. The experience of this writer was so different from my own that I could but attribute his lack of success to nothing else than faulty manipulation in closing them. I have succeeded very well with this operation, but I always used extreme care not to get any oily substance on the edges of the capsules, closing them with a blunt glass rod containing a drop of the following gelatin mass:—

Mass for Closing Capsules.	
Gelatin	25 parts.
Glycerin	10 "
Sugar	8 "
Water	45 "

Soak the gelatin in the water, add the sugar and glycerin, then dissolve on a water-bath.

When I first tried to do this work I did not succeed as well as later, owing to the fact that I used the gelatin solution too hot. I found from experiment that a temperature of 120° F. was about right, and never after had any more trouble on this score.

Later I took it into my head that it would not be a difficult matter to make the capsules myself, but for a time I could get no satisfactory moulds. The first moulds I used were made of wood, shellaced well to make them smooth. Subsequently I secured moulds made of tin (manufactured in Germany), and with these I had not the slightest difficulty, after a little practice, in making nice capsules in the winter time; in the summer I found, however, that it was necessary to have some means of hastening the hardening of the gelatin. To obviate this latter trouble I rigged up a rotary fan, working with a foot pedal, which worked satisfactorily.

The moulds should be rubbed with a soft cloth holding enough olive oil so as to leave just a trace of oil on them, the rubbing being some distance up the supporting rod. The gelatin mass having been melted and of a temperature of about 110 degrees, the mould is dipped in and slowly withdrawn, and then rotated so as to distribute the gelatin coat evenly, and when it begins to harden set in a frame in a current of air. As soon as they have become sufficiently firm, the capsules are cautiously removed from the moulds, and then the rough ends cut off by clipping with a pair of shears. The capsules may then be set aside in a suitable frame until perfectly cool, when they are ready to fill.

The mass given above works very nicely, but may be modified to suit individual preferences. If it is desired to make hard capsules, the glycerin must be omitted. I have found the following recommended in a foreign exchange, very satisfactory:—

Mass for Hard Capsules.	
Gelatin	6 oz.
Acacia	1 oz.
Sugar	1 oz.
Water	5 oz.

Dissolve the acacia in the water; in this soften the gelatin, then add the sugar and heat on a water-bath until solution is effected; remove any scum that arises and use as directed for soft capsules. Hard capsules are not used as largely as they formerly were, the soft capsule taking preference, but they are made in the same manner.—*Western Druggist*.

EXTRACT OF NASAL GLANDS.—This organic preparation is obtained, according to Jacquet, by macerating the pituitary membrane of the sheep in 0·4 per cent. resorcin water for 24 hours at a temperature of 65° C. The solution is then filtered and the filtrate again heated for 24 hours to a temperature of 65° C.—*Pharm. Centr.*, xxxviii., 678.

PHARMACEUTICAL SOCIETY.

NORTH BRITISH BRANCH.

A meeting of the Executive of the North British Branch was held in the Society's House, 36, York Place, Edinburgh, on Friday, June 24, 1898, at 11 a.m., Mr. J. LAIDLAW EWING in the chair.

Present: Messrs. Ayre, Boa, Bowman, Coull, Currie, Ewing, Fisher, Henry, Johnston, Kermath, Kerr, McLaren, Moir, Storrar, and Strachan.

Apologies for absence were intimated from Messrs. Johnston, Hardie, McAdam, and Mitchell.

The minute of the meeting for election of the executive was read.

Mr. STORRAR moved that Mr. J. Laidlaw Ewing, Edinburgh, be elected Chairman for the ensuing year.

Mr. CURRIE seconded the motion, and it was unanimously agreed to.

Mr. EWING, in accepting, said he had fully made up his mind to retire this year, but he had yielded to the representations made to him and would willingly do service for another year.

Mr. KERMATH moved that Mr. W. L. Currie, Glasgow, be elected Vice-Chairman for the ensuing year.

Mr. FISHER seconded the motion, and it was unanimously agreed to.

Mr. CURRIE, in accepting, said at last meeting he had felt it might be necessary for him to retire from the Executive altogether, but he was glad to say his health was much better than it had been and he would be pleased to serve for another term.

The CHAIRMAN then formally welcomed the new members, Mr. Boa, who had already done good service, and Mr. Ayre, Perth, whom they were glad to welcome for the first time.

Mr. AYRE returned thanks.

Mr. KERR moved:—

That the Chairman, Vice-Chairman, and resident members of the Executive be appointed a General Purposes Committee to attend any business arising between meetings of Executive or remitted to them by the Executive.

The motion was seconded by Mr. STRACHAN and unanimously agreed to.

The Executive went into Committee to consider the nomination of examiners. On resuming, Mr. FISHER moved:—

That the Chairman and Vice-Chairman, and Messrs. Bowman, Kermath, Kerr, Storrar, and Strachan, be appointed a Committee for nomination of Examiners, and to consider any names that may be submitted to them, and to report to a meeting of Executive to be held prior to the meeting of Council in November.

The motion was seconded by Mr. MOIR, and unanimously agreed to.

The evening meeting arrangements were considered in Committee and remitted to the General Purposes Committee.

A detailed plan and estimate, amounting to about £80, for ventilating the hall and laboratories by means of Blackman fans and electric motors, was considered and remitted to the General Purposes Committee with powers; it being understood that only a portion of the scheme would be carried out in the first instance.

The Chairman and Vice-Chairman, and Messrs. Bowman, Coull, Fisher, Kerr, McLaren, and Moir were appointed delegates to the Belfast meeting of the British Pharmaceutical Conference in August.

On the suggestion of Mr. MOIR it was agreed that meetings of Executive in future should be held at 11.30 a.m. instead of 11.

The meeting then closed.

SCHOOL OF PHARMACY PRIZE EXAMINATION QUESTIONS.

A Paper.

PHARMACY (PRACTICAL DISPENSING). PROFESSOR GREENISH.

Monday, June 27.—From 10 to 1.

Dispense the following prescriptions, labelling, wrapping, and addressing each, writing your own name on both label and wrapper:—

1. Potass. Bromid. gr. ij.
- Ext. Bellad. gr. ½.
- Ol. Theobrom. ℥ss.
- Fiat supposit. Mitte vi.
2. Argenti Oxid. gr. iij.
- Ext. Bellad. gr. iij.
- Ft. pil. xij. Varnish.

3. Ol. Menth. Pip. gtt. j.
- Ft. pulv. Mitte vi.
4. Paraff. Liquid. ℥ij.
- Tinct. Opii ℥xxiv.
- Antim. Tart. gr. ½.
- Aq. Ad. ℥iv.
- Ft. mist. Sig. "The Emulsion."

B Paper.

PHARMACY (PRACTICAL DISPENSING).

PROFESSOR GREENISH.

Wednesday, June 29.—From 10 to 1.

Dispense the following prescriptions, labelling, wrapping, and addressing each, and writing your name on both label and wrapper:—

1. Hydrargyri. gr. i.
- Ol. Theobrom. ℥ss.
- Ft. supposit. Mitte vi.
2. Ol. Carui. gtt. ½.
- Ferri Sulph. gr. ¼.
- Strychnin. gr. ⅓.
- Aloin. gr. ½.
- Pulv. Pip. Nig. gr. i.
- Ft. pil. i. Mitte xii. Take one three times a day.
3. Nitro-glycerin. gr. ʒss.
- Ft. pulv. Mitte vi.
4. Ol. Theobrom. ℥ii.
- Resin. Scamm. gr. xxxii.
- Aq. ad ℥iv.
- Ft. mist. Sig. "The Emulsion."

PHARMACY.

PROFESSOR GREENISH.

Monday, June 27.—From 2 to 5.

1. Describe the apparatus required for the operation of dialysis. How is the operation performed? What is its object? Under what circumstances is the operation likely to be successful or the reverse?
2. What means are at the disposal of the pharmacist for aiding solution? Give instances and exceptions.
3. What characters should a good pill mass possess? What excipient would you select for a volatile oil, carbonic acid, powdered digitalis leaves, sulphonal, extract of aloes, phosphorus, potassium iodide, calomel, ammoniacum? For what class of drugs would you employ syrup, mucilage, powdered tragacanth, marshmallow root, liquorice root?
4. Describe and discuss the processes given in the British Pharmacopœia of 1885 for the preparation of Decoctum Sarzæ Compositum, Syrupus Ferri Iodidi, Syrupus Papaveris, Extractum Stramonii, Extractum Ergotæ liquidum.

BOTANY.

PROFESSOR REYNOLDS GREEN.

Tuesday, June 28.—From 2 to 5.

[Not more than Four Questions are to be answered.]

1. Give an account of the gaseous interchanges between a plant and the atmosphere in which carbon is involved. Point out in what particulars they are of importance to the plant.
2. What do we mean by *cohesion* and *adhesion* respectively as applied to floral structures? Explain how they are brought about and illustrate your answer by reference to an inferior ovary.
3. Give an account of the arrangement of the tissues in the petiole of a foliage leaf, and show how they are continuous with those of the stem on the one hand and the lamina of the leaf on the other.
4. Describe the peculiar features of the fruits of the Umbelliferae and the Compositae.
5. What are gametangia? Describe two forms with which you are familiar.

PRACTICAL BOTANY.

PROFESSOR REYNOLDS GREEN.

Tuesday, June 28.—From 10 to 1.

1. Make a microscopic preparation to show the structure of A. Mount it in glycerin. Leave with it a lettered sketch calling attention to its distinctive features.
2. Identify and briefly describe the microscopic preparations B, C, D.
3. Comment on the morphology of E, F, G.

MATERIA MEDICA.

PROFESSOR HENRY G. GREENISH.

Wednesday, June 29.—From 2 to 5.

1. Write a short account of the Thyroid Gland.
2. Describe carefully the quilled bark obtained from *Cinchona succi rubra*, *C. calisaya*, *C. officinalis*, comparing them with regard to their appearance, alkaloidal constituents and medicinal value.
3. What drugs official in the British Pharmacopœia of 1885 were obtained from *Colechicum autumnale* and *Atropa Belladonna*? Describe them. To which should, in each case, preference be given for medicinal use, and why?
4. How is Galbanum obtained? By what characters would you identify it? What are its chief constituents?
5. In framing the official descriptions of various drugs, to what points should, in your opinion, particular attention be directed? How are the necessary data for such statements to be obtained?

The Sale of Poisons in Great Britain.

Precautions Required by the Pharmacy Act, 1868, to be Observed in Selling by Retail and in Dispensing.

POISONS.

All the Articles named or referred to in the following list, both in Part 1 and Part 2, are POISONS within the meaning of the Pharmacy Act, 1868.

SALE BY RETAIL.

I.—Relating to Part 1 and Part 2 of the List.

It is unlawful to sell any "POISON" by retail, unless the vessel, wrapper, or cover in which it is contained, be distinctly labelled with the name of the article, the word "Poison," and the name and address of the seller. This applies to all the articles in both Parts of the List.

II.—Relating to Part 1 only.

It is unlawful to sell, by retail, any poison included in PART 1 of the List, to any person unknown to the seller, unless introduced by some person known to the seller; and on every sale of any such article the seller shall, before delivery, make or cause to be made an entry in a book to be kept for that purpose, of—

1. The date of sale;
2. The name and address of the purchaser;
3. The name and quantity of the article sold; and
4. The purpose for which it is stated to be required;

to which the signature of the purchaser, and of the person, if any, who introduced him, shall be affixed. *The article must*

also be labelled with the name of the article, the word "Poison," and the name and address of the seller.

III.—Relating only to Arsenic and its Preparations.

It is unlawful to sell Arsenic or any of its preparations, unless, in addition to all the foregoing regulations, the following provisions of the Arsenic Act be also observed:—

1. That the poison, if colourless, be mixed with soot or indigo, so as to colour it.
2. That the person to whom the poison is sold or delivered be of mature age.
3. That the occupation, as well as the name and address, of the purchaser be entered in the poison-book.
4. That when the purchaser is not known to the seller, and is introduced by some person known to both, this person shall be present as a witness to the transaction, and shall enter his name and address in the poison-book.

DISPENSING.

None of the foregoing regulations apply to any article when forming part of the ingredients of any medicine dispensed by a Registered Chemist and Druggist; but it is necessary, if a medicine contain a poison included in Part 1 or Part 2 of the List, that the ingredients of the medicine, together with the name of the person to whom it is sold or delivered, be entered in a book kept for that purpose (*Prescription Book*), and that the name and address of the seller be attached to the medicine.

List of Poisons within the Meaning of the Act.

Part 1.

<p>Not to be sold unless the purchaser is known to, or is introduced by some person known to, the seller;</p> <p>ALSO</p> <p>Entry to be made in Poison-Book.</p> <p>OF</p> <ol style="list-style-type: none"> 1. Date of Sale; 2. Name and address of purchaser; 3. Name and quantity of article; 4. Purpose for which it is wanted; <p>attested by signature;</p> <p>AND</p> <p>Must be labelled with</p> <ol style="list-style-type: none"> 1. Name of article. 2. The word "Poison." 3. Name and address of seller. 	<p>Arsenic, and its preparations. (<i>For special regulations see page 39</i>);</p> <p>Aconite, and its preparations;</p> <p>Alkaloids:—All poisonous vegetable alkaloids and their salts;</p> <p>Atropine, and its preparations;</p> <p>Cantharides;</p> <p>Corrosive Sublimate;</p> <p>Cyanide of Potassium, and all metallic cyanides and their preparations;</p> <p>Emetic Tartar;</p> <p>Ergot of Rye, and its preparations;</p> <p>Prussic Acid, and its preparations;</p> <p>Savin, and its oil;</p> <p>Strychnine, and its preparations;</p> <p>Vermin Killers, if preparations of poisons the preparations of which are in Part 1 of this schedule.</p>
---	---

Part 2.

<p>Must be labelled with</p> <ol style="list-style-type: none"> 1. Name of Article. 2. The word "Poison." 3. Name and address of seller. 	<p>Almonds, Essential Oil of (<i>unless deprived of Prussic Acid</i>);</p> <p>Belladonna, and its preparations;</p> <p>Cantharides, Tincture and all vesicating liquid preparations of;</p> <p>Chloroform;</p> <p>Chloral Hydrate, and its preparations;</p> <p>Corrosive Sublimate, preparations of;</p> <p>Morphine, Preparations of;</p> <p>Nux Vomica, and its preparations;</p> <p>Opium, and its preparations; and preparations of Poppies;</p> <p>Oxalic Acid;</p> <p>Precipitate, Red (Red Oxide of Mercury);</p> <p>Precipitate, White (Ammoniated Mercury);</p> <p>Vermin Killers (see Part 1). Compounds containing "Poisons," prepared for the destruction of vermin, if not subject to the provisions of Part 1 are in Part 2.</p>
--	--

Recommendations by the Pharmaceutical Society of Great Britain for the Keeping, Dispensing, and Selling of Poisons.

(Adopted at a General Meeting of the Society, May 17, 1871.)

1. That in the keeping of Poisons each bottle, vessel, box, or package containing a poison be labelled with the name of the article, and also with some distinctive mark indicating that it contains poison.
2. Also that in the keeping of poisons, each poison be kept on one or other of the following systems, viz. :—
 - (a) In a bottle or vessel tied over, capped, locked, or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop, or dispensary; or
 - (b) In a bottle or vessel rendered distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop, or dispensary; or
 - (c) In a bottle, vessel, box, or package kept in a room or cupboard set apart for dangerous articles.
3. That in the dispensing and selling of poisons all liniments, embrocations, and lotions containing poison be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, and that there also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences

LONDON: SATURDAY, JULY 2, 1898.

"VIRTUALLY A TRADE MONOPOLY."

Few that have any practical acquaintance with the working of the Pharmacy Act, 1868, will entertain any doubt that, as a means of regulating the practice of pharmacy, the provisions of that Act are in many respects imperfect and clumsy. But, at the same time, it must be conceded that, notwithstanding its manifold incongruities, the Act has proved to be useful in regard to the object which was paramount with the Legislature at the time it was passed—the protection of the public against the dangers of indiscriminate sale of poisons. Under the torture of judicial construction the Act has, in some respects, acquired a significance that has been considered different from, or even directly opposed to, the original intention of the Legislature and, consequently, more or less unsatisfactory to parties adversely affected by it. But on the whole the experience of more than thirty years has shown that the administration of the Act has been conducive to the public welfare. It has been the means of establishing, on the basis of certified competent knowledge and under control of the Privy Council, a legal qualification for carrying on the business of a chemist and druggist; it has been successful in the endeavour to enforce the safeguard of individual qualification of sellers of poisons, observance of which the Act declares to be imperatively necessary for public safety; it has also been equally successful in repressing the sale of poisons under the dangerous disguise of secret proprietary articles or "patent medicines," a practice which was, some years ago, matter of strong condemnation by all who were aware of the mischievous results of that practice. In securing these results by the administration of the Pharmacy Act, the main consideration that has led to success has been the safety of the public. Charges have been made that the administration of the Act operates unfairly in restraint of trade; but charges to that effect have hitherto proceeded only from persons infringing or endeavouring to evade the provisions of the Act: they have therefore been of little account except as creating some undue prejudice against its administrators, for if persons registered under the Act have also been to some extent benefited by the restriction the Act imposes upon the sale of scheduled articles, that result has been altogether subsidiary to the attainment of the main object of public security against poison. There is, therefore, no ground whatever for regarding the restricted sale of poisons, within the meaning of the Act, as partaking in any sense of the nature of a monopoly. But within the last week countenance has apparently been given to this view of the restricted sale of poison by a remark of the Lord President of the Council, when moving the second reading of the Poisonous Substances Bill in the House of Lords. The remark quoted at the head of this article, coming from the head of the department which controls the administration of the Pharmacy Act in the public interest, will be noted with considerable surprise by members of the pharmaceutical body.

Considering the nature and object of the Bill which is now before the House of Lords, it may be that the DUKE OF DEVONSHIRE'S remark was not retrospective, but intended to apply only to the trade in articles to which that Bill relates. That constitutes one of the difficulties which have arisen in connection with the Pharmacy Act. The attempt to deal with it according to the provisions of the Act has been a marked illustration that even a sound principle requires to be suitably applied in order to be useful. The dangerous nature of oil of vitriol and the other mineral acids is sufficiently patent to make the exercise of care in the handling of those articles indispensably necessary and, in the case of carbolic acid—which has, from a trade point of view, come into existence since the Pharmacy Act was passed—this necessity has been rendered especially conspicuous by the continual records of fatalities caused by that article. Many years ago the attention of the Council of the Pharmaceutical Society was directed to the danger with which the unregulated sale of these articles was attended: in accordance with its function under the Pharmacy Act, their addition to the Schedule of Poisons was therefore recommended. But the excellent principle that the vendor of poisons requires to be a person of education and certified technical skill was not accepted by the Privy Council as the only point for consideration in approving the suggested additions to the Poison Schedule. Regard for the corresponding inconvenience that might result from such restriction of the sale of these articles, has had such preponderating influence that the efforts of the Council of the Pharmaceutical Society to carry out the provisions of the Pharmacy Act in that respect have consequently been ineffectual.

The Bill now introduced—in tardy response to the very urgent representations that have been made on the subject by medical men, coroners' juries, etc.—is an attempt to remedy the assumed inapplicability of the Pharmacy Act to regulate trade in articles that are a source of danger to the public. But the attempt to meet this public demand is made in such a manner as to involve apparent repudiation of the principle that the seller of poisons should be educated and skilful: at least it suggests that this principle is not applicable to trade as it is in dealing with poisons used as medicine. Possibly the DUKE OF DEVONSHIRE'S mention of trade monopoly may have been intended only to refer to what he considers might be the effect of adding the articles in question to the Poison Schedule of the Pharmacy Act. But before that view can be accepted as conclusive there appears to be need of evidence that it is well founded: very sufficient reasons should be given for departing from the recognised principle of the Pharmacy Act in regard to a matter for which it affords ample provision. The calling of a chemist and druggist has hitherto been barred to all who did not conform to the demand made in the interest of the public for proof of qualification. The entire body of registered chemists will therefore be justified in taking exception to a proposal which practically throws discredit upon the principle on which the business of chemists and druggists has been carried on for the past thirty years under the control of the Privy Council. Indications are already given of a tendency in this direction, but as the subject will certainly be considered by the Pharmaceutical Council as well as by provincial associations, discussion in this place is not desirable at present, except for the purpose of drawing attention to the salient points of the question raised.

ANNOTATIONS.

THE INCOMPETENCE OF THE NEWSPAPER PRESS to instruct the public on the subject of poisons and the statutory provisions intended for the prevention of accidents is again demonstrated by the *Bristol Times and Mirror* in an article which states that the duty of proposing additions to the Poison Schedule of the Pharmacy Act entrusted to the Council of the Pharmaceutical Society "has not been performed," so that by reason of this default in regard to carbolic acid and a considerable number of poisons in common use, and obtainable by any person without inquiry or formality of any kind, many deaths have been caused which would doubtless have been averted if the deadly agents had been more difficult to procure. Bristol city is scarcely the place where such stupid rubbish could find currency, and we trust that some local member of the Pharmaceutical Society will not fail to purge it of the reproach due to such an exhibition of ignorance by enabling the *Mirror* to reflect the facts of the case with less grotesque distortion. Another note on the same subject in the *Universe* is too obscure to be intelligible, except in regard to the astonishment expressed that the Privy Council should have refused to add carbolic acid to the list of poisons included under the Pharmacy Act, and that the Duke of Devonshire's Bill proposes to allow any person to sell it and other poisonous substances. "Curious this" is indeed an appropriate comment of our contemporary.

THOUGH SCHEDULED POISONS are responsible for a large proportion of accidental deaths, it would be far from correct to assume that such a fact indicates any appreciable lack of efficiency in the regulations imposed by the Pharmacy Act, 1868. What those regulations are is shown at page 10, where a list of the scheduled poisons is also printed. In addition, the recommendations adopted by the Pharmaceutical Society twenty-seven years ago for the keeping, dispensing and selling of poisons, have been reprinted. The adoption of the procedure recommended is a voluntary matter, but it says very much for the public spirit of registered chemists that the suggested precautions as to storage, labelling, etc., are almost universally adopted by them, in one form or another, according as their business requirements permit. Moreover, similar precautions are already taken by chemists in respect of all the poisonous substances scheduled in the Privy Council's Bill, as well as many others not so scheduled. Despite the fact, therefore, that there is considerable variation in the manner in which the recommendations of the Society are interpreted, the fact remains that chemists as a class impose upon themselves regulations that go far beyond those required by the Statute, frequently beyond those recommended by the Society, and as a consequence scores, if not hundreds, of fatalities are thus prevented. Almost every reader of the Journal could instance one or more cases in which he has been able to prevent mishaps by interposing obstacles in the way of procuring scheduled poisons, whereas an exceedingly small number have ever been concerned in cases where death has been accidentally caused by such poisons. The list published annually by the Registrar-General must be largely discounted by the fact that scheduled poisons are extensively handled in hospitals and private practice by persons who are not registered chemists, and when due allowance is made for the deaths that occur under chloroform anæsthesia and as the result of mistakes made by nurses and other persons incompetent to deal with poisons, it is obviously unfair to charge chemists with laxity in carrying out the requirements of the law in this matter.

A CASE IN POINT has recently occurred at the Manchester Workhouse Hospital, where an inmate died after a dose of poison had been administered by a nurse in mistake. The practice in that Hospital is to keep all poisons in bottles of a particular type, which are stored in a special cupboard quite apart from other medicines, and the arrangements have worked so successfully that no accident of the kind reported had happened for some twelve years. But the best arranged plans are apt to fail, sooner or later, when machinery is depended upon rather than the qualification of individuals, and so the inevitable accident happened at last. According to the evidence of Miss Jackson, the nurse in charge of the case, the patient was in a state of collapse, and the medical officer ordered that she should be given a half-ounce dose of chloral-bromide solution. Witness thought she carried out this instruction, but half a minute after the dose had been taken she discovered that the bottle she had taken the dose from contained Battley's solution of opium. Questioned by the Coroner, the nurse said the medicine was taken out of a cupboard where the ordinary and poisonous medicines were stored together (*sic*). She at once informed the doctor of the mistake, and the stomach-pump was applied, but the patient became insensible, and though everything possible was done for her she died.

THE SUPERINTENDENT NURSE said the poison cupboard was always locked at night, but Battley's solution being frequently required, and Miss Jackson being a senior nurse, it was left in her care. The consulting physician at the workhouse, who also gave evidence, explained that Battley's solution was put apart from the other poisons during the night because much inconvenience would be caused if it were locked up. In that case the nurse would have to go in search of the night superintendent, and as the building was an immense one, she might be away for an hour from her patients in seeking the superintendent. The jury, in returning a verdict, agreed with the medical evidence, censured Nurse Jackson and the head nurse, as having been guilty of gross carelessness, and recommended that bottles containing poison should be kept solely in a particular cupboard, which should be in the charge of one person only. In the Registrar-General's report for 1898, the case will presumably be included under the head of accidental deaths by opium poisoning, but no clue will be afforded as to whether the poison was supplied by a chemist or not, and it is quite possible that the then Lord President of the Council may base an argument for imposing on chemists and druggists further restrictions with regard to the sale of poisons, on statistics drawn up by the Privy Council officials, and including this and other cases of accidental poisoning due to the carelessness of hospital nurses.

AN INTERESTING SPECIMEN has been sent for the Editor's inspection by Mr. Graham Bott, of Lewisham, in the form of a calceolarea grown in open ground by himself. It shows the curious freak of a calceolate corolla. This curious modification—an instance of peloria—was developed on the same peduncle with the usual shaped corollas, but instead of being somewhat slipper-shaped, it has assumed the form of a tube about three centimetres in length, somewhat swollen in the middle and tapering towards each end. The apex is covered by, or terminates in, a small greenish band having a slit-like opening. The flower is apparently destitute of andrœcium and gynœcium, and it appears as if the growth of all the petals was equal throughout; they are united along its whole length, having no limb, thus presenting a regular, instead of an irregular, corolla. Dr. Maxwell Masters, to whom

the specimen has been shown, points out that all the petals are regular instead of two regular and three irregular, as usual, and that similar cases have been figured in the *Gardeners' Chronicle*. He also remarks that, though Darwin maintained that it is always the central or terminal flower which becomes modified, that is not invariably the case, as is proved by the present instance.

THE EXAMINING BOARD IN ENGLAND, appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England, under a regulation dated May 12, 1898, permits one year of the curriculum of professional study subsequent to registration as a medical student to be spent at institutions recognised by the board for instruction in chemistry, physics, practical chemistry, and biology, provided evidence is produced that such period has been spent by the student in receiving instruction in these subjects. Six months may also be spent subsequent to registration as a medical student at an institution which is recognised by the board for instruction in chemistry, physics, and practical chemistry only, provided evidence is produced that the candidate has been receiving instruction in those subjects during this period. The committee of management reserves the right of visiting and reporting upon the efficiency of any institution recognised by the board for instruction in chemistry, physics, practical chemistry, and biology. Information relating to the conditions of registration as a medical student may be obtained on application to the Registrar of the General Medical Council, 299, Oxford Street, London, W.

THE ENFIELD MEDICO-ETHICAL SOCIETY, at its annual general meeting, held on Wednesday, June 22, passed the following resolution: "That the Enfield Medico-Ethical Society has heard that chemists are in the habit of prescribing for patients, and that they beg to call their attention to the fact that such a practice is illegal, and that proceedings will be instituted against them in the event of such a practice being continued." The Secretary of the Society was also instructed to forward copies of this curiously constructed resolution to every chemist in the district, and that instruction appears to have been acted upon. Medical ethics, no doubt, are mysterious and wonderful in their way, but we fail to see how the members of this little medical coterie at Enfield can justify themselves against a charge of discourtesy in presuming to act in such a manner as they appear to have done. They might at least have had the decency to abstain from insulting chemists who were not known to have offended in the manner objected to.

THE PETROLEUM COMMITTEE has decided by eight votes to six to recommend the raising of the flash-point from 73° to 100°. It is pointed out by the *Times* that when the question was proposed last week that the draft report submitted by the chairman (Mr. Collings) be read a second time paragraph by paragraph, and an amendment was moved to substitute the name of Mr. Ure for that of the chairman—the basis of Mr. Ure's report being the raising of the flash-point—the amendment was rejected by eight votes to five. Two members of the committee, however—Mr. Harold Reckitt and Mr. Compton Rickett—who supported Mr. Collings at the outset, have now thrown in their lot with Mr. Ure; and the transference of their votes, together with the presence of Mr. Tully, a high-flash advocate, who was absent when the first division was taken, changed the chairman's majority of three into a minority of two. Considering that Mr. Collings, who, as chairman, did not vote, must also be treated as an opponent of the amendment, the actual position of affairs is that eight members of the Committee are in favour of the 100° flash-point and seven against it. The paragraph upon which issue was joined was that in which Mr. Collings invited the Committee to recommend the

adoption of the present flash-point—namely, 73° (Abel), as the dividing line between petroleum oil and petroleum spirit. Some of the members would have supported a compromise, 90° and 85° being actually proposed in substitution for the chairman's 73°. But Mr. Ure and his friends would make no concession; and the result is that instead of presenting to the House a practically unanimous recommendation in favour of raising the flash-point to 85° or 90° the Committee recommends, by a bare majority, that the 100° test be adopted.

MR. URE'S CONCLUSIONS, which the Committee was invited to endorse, were:—(1) That, practically, complete immunity from lamp accidents would be obtained if only oil with a flash-point above 100° F. were in common use as an illuminant; (2) that this object would be secured without legislation absolutely forbidding the use as an illuminant of oil with a flash-point below 100° F. by a simple enactment substituting 100° F. for 73° F. where it occurs in the Act of 1879; (3) that it would be desirable at the same time to enact some such provisions as are contained in the Inflammable Liquids Bill of 1891 relative to the test and the verification of the test to be applied in ascertaining the flash-point; (4) that the main conditions attached to the licences under the 1871 Act should be uniform and ought not to be left to the discretion of each local authority, and that further powers should be conferred on the central authority to compel local authorities to enforce the law in their respective districts; (5) that, provided the foregoing conclusions be adopted and given statutory force, it is unnecessary to impose further restrictions on the keeping or conveying of mineral oil, except to insist on adequate means being taken to prevent outflow wherever oil is stored in populous places and in considerable quantities; and (6) that it would be advisable to make some provision, such as is found in Clause 34 of the Inflammable Liquids Bill of 1891, for a formal investigation into all explosions or fires in connection with inflammable liquids, whatever be their flash-point.

PROFESSOR FERDINAND COHN, the distinguished botanist, died suddenly at Breslau on Saturday last of heart disease. He was born in 1828, and appointed to the chair of botany at Breslau University in 1859. His best known work is entitled 'Die Pflanze,' but in recent years he had laboured with success in the field of bacteriology, and published a book on 'The Development of Microscopic Algæ and Fungi,' showing the destructive action of parasitic fungi and bacteria.

A NEW FRENCH PHARMACY LAW has been promulgated, which provides that henceforth there will be only one diploma as *pharmacien*, corresponding to the existing first-class diploma. Persons holding foreign qualifications will no longer be able to practise pharmacy in France, unless they have obtained the diploma of *pharmacien*, after examination by a State Pharmacy Board. Even then, permission will be withheld unless Frenchmen, holding pharmaceutical diplomas granted in the country to which the foreigner belongs, are permitted to practise pharmacy in that country. Foreign students desirous of receiving the French diploma will be governed by the same regulations as French students, though a special diploma may be granted to them, which will not entitle them to practise pharmacy in French territory; whilst allowance may be made for previous studies in foreign countries. Until April 19, 1900, students will be allowed to enter for the title of *pharmacien* of the second class as at present, and holders of the diploma of that class will be able to practise pharmacy anywhere in French territory.

REVIEWS AND NOTICES OF BOOKS.

A TEXT-BOOK OF BOTANY. By Dr. E. STRASBURGER, Dr. FRITZ NOLL, Dr. H. SCHENK, and Dr. A. F. W. SCHIMPER. Translated from the German by H. C. PORTER, Ph.D., and the proofs revised by A. C. SEWARD, M.A. Pp. i.-x., 1 to 632, with 594 Illustrations, in part coloured. Price 18s. net. London: Macmillan and Co., Limited. 1898.

The progress of modern botany is in no way more strikingly indicated than by the growing tendency towards a division of labour in the preparation of text-books on the subject. It is true that most students' books bear a single name on their title pages, but unless the authors have been assisted by specialists in branches with which they are not personally familiar, certain sections of the books usually fail to give satisfaction to those who have occasion to resort to them for assistance. In the present work we have the outcome of a collaboration by four authors, whose names alone should suffice as evidence of the excellence of the matter provided, translated into English in an exceptionally satisfactory manner. The result is a harmonious whole, and the book will probably be resorted to by advanced students for some years to come.

The first part of the book treats of general botany, and is divided into sections on morphology—external and internal, and physiology. Part two is devoted to special botany, and also includes two sections—Cryptogams and Phanerogams. A marked feature of the whole work is the evident care that has been taken to bring the whole subject up to date, whilst pharmaceutical students will appreciate the fact that detailed reference is made to nearly two hundred medicinal plants, many of which are illustrated. The illustrations are exceedingly numerous, and an interesting experiment has been made in the direction of colouring some that are arranged amongst the letterpress. These include *Colchicum autumnale*, *Paris quadrifolia*, *Arum maculatum*, *Agrostemma githago*, *Caltha palustris*, *Aconitum napellus*, *Anemone pulsatilla*, and several others. The colouring greatly enhances the appearance of the pages, and affords a suggestion of what botanical text-books may be like in the not far distant future.

In the section on external morphology, the thallus is taken as the starting point, the transition from the thallus to the cornus described, and after some little attention has been devoted to branch systems, we are introduced to the shoot and its development. The cell, [its contents, varieties, and combinations, are next dealt with, the vascular bundle system being clearly explained without too much dependence being placed on the stellar theory of Van Tieghem. As a result, much unnecessary mystification is avoided, and for that students will doubtless be duly thankful. Some of the illustrations in this part of the work are more or less familiar, but many of them are apparently new, and the whole [are of real assistance in helping to supplement the explanations given in the text. It is interesting to note, by the way, that the term "bark," as used in this work, is applied to all dead tissue external to the innermost layers of cork. "If the layers of the secondary periderm constitute only arcs of the stem circumference, [the bark will be thrown off in scales, . . . if, on the contrary, the periderm layers form complete concentric rings, then hollow cylinders of the cortical tissues are transformed into the so-called ringed bark."

The section on physiology is also freely illustrated, and will be found to give a comprehensive survey of modern views regarding the plant as a living being. Without being too diffuse all

matters of primary importance are clearly explained, and no better guide could be adopted by past students who may be desirous of freshening up their knowledge of the subject. Regarding the remaining sections of the book, space will not permit of much being said. But a few words of praise must be spared for the section on Cryptogams, a fair example of which may be found in the well-arranged pages dealing with the Schizomycetes. In the brief space of four pages a most lucid and comprehensive description of that order of plants is given, and the space devoted to the higher forms is used to equal advantage. The Phanerogamia naturally occupy the largest proportion, relatively, of the whole book, and this concluding section contains much useful information on economic botany. Lists of officinal and poisonous plants, together with a full index, complete the work, which can be strongly recommended to the notice of pharmacists and other advanced students.

A REFERENCE BOOK OF PRACTICAL THERAPEUTICS BY VARIOUS AUTHORS. Edited by FRANK P. FOSTER, M.D. In two volumes. Pp. 652 and 618. Price 50s. London: Smith, Elder and Co.

The names of the thirty-three joint authors of this work are among the best known in the medical profession in America, and they are sufficient guarantee of the soundness of the vast amount of well-arranged information contained within the covers of the two large volumes. The object of the writers has been to provide a work of reference for the use of the practising physician rather than a treatise on materia medica. It is well observed in the preface: "The 'therapeutic nihilism' that but a few years ago was justly deplored by Professor Bartholow has been succeeded by a wave of over-activity for which it is not difficult to account. We have now to master the task of judiciously employing remedial agencies, many of which are new. For this purpose we require the frequent appearance of trustworthy records of what has been accomplished with these novel agents, for in no other way can the individual practitioner keep pace with the progress of therapeutics."

To review a work of this kind adequately would entail the writing of a book of criticism almost equal in size with the original. All that can be attempted is to select here and there a few drugs and to examine the manner in which they are dealt with. Among the familiar minerals embodied in the Pharmacopœia is manganese and some of its salts. To this metal from time to time various remedial properties are attributed, some writers going so far as to recommend it as a substitute for iron. Dr. S. M. Brickner, in his article dealing with this subject, refers to the results of Garrod's investigation, which "proved conclusively that manganese was useless in the treatment of anæmia and chlorosis." A good account of piperazine (di-ethylene diamine) is given by Dr. H. A. Griffin, who says, "It must be confessed, however, that the expectations that were formed of piperazine when first the remedy was introduced, have not been realised, and though in some few cases of uric acid accumulation its administration may be attended with success, this is perhaps due rather to its alkaline reaction and possibly to its favouring the conversion of uric acid into urea by oxidation than to any power it has to act as a solvent of uric acid. In this connection the results of some recently conducted experiments are instructive. Bohland (*Therap. Monats.*, May, 1894) administered piperazine in a case of leucæmia, in which the urine deposited a uric acid sediment. The remedy was given in large doses, and its use was continued for a long time, but not the slightest alteration was observed in the amount of uric acid eliminated."

The surgical aspects of therapeutics are dealt with as fully as the

medical, thus Dr. J. L. Corning gives a detailed account of the various modes of producing local anæsthesia by cocaine, and the directions he gives for the avoidance of large veins, for prolonging the duration of anæsthesia by means of the elastic band, and the use of dilute solutions for hypodermic use, are admirable. In regions like the back, when elastic compression cannot be employed, the author recommends injection of alternate quantities of cocaine solution and of oil of theobroma, which is to be solidified by the subsequent application of the ice-bag. It is doubtful whether this somewhat cumbrous proceeding will find favour among surgeons generally. This article, on the whole, forms a most suggestive compend of the known therapeutic uses of cocaine, and may serve as an example of the thoroughness that characterises even the smallest sections of the work. There is added to the volume a special index, where, under the names of different diseases, the chief remedies most commonly used are enumerated. This index will greatly facilitate the use of the book in any emergency. The editor is to be congratulated on the way in which he has arranged a vast amount of information, and he and all concerned with the production of the book may find satisfaction in having produced a most complete and useful lexicon of modern therapeutics, a work the serious and scientific tone of which, and the fulness and accessibility of the matter, must render it an invaluable addition to medical practitioners in every English-speaking country.

THE BOTANISTS' VADE MECUM. By J. WISHART. 1898. Pp. 143. Price 2s. net. Edinburgh: E. and S. Livingstone.

The author of this little book was at one time a Herbarium Medallist of this Society, and having also been assistant lecturer on botany in Robert Gordon's College, Aberdeen, he has had excellent opportunities of learning the needs of both students and teachers. The work before us is evidently the outcome of a felt want. Every one who has attended a botanical excursion, whether of a university class or a field club, knows that many students (who may or may not be already familiar with the characters of the principal natural orders) ask the names of the plants they find, and too often rest content therewith, without learning the character of the genera to which they belong. 'The Botanists' Vade Mecum,' if properly used, as its author intends, will give this information. It is furnished with an index like a memorandum book, one letter to each page, so that it is extremely easy to refer to the page on which the genus is described. The genera are arranged alphabetically under the natural orders, so that here again time is saved and the characters of the genera are reduced to a minimum. The only book that is easy of reference hitherto available for this purpose is the 'Treasury of Botany,' but this being in two volumes, is not fit for the breast-pocket like the 'Vade Mecum.' The 'Vade Mecum' is not intended to take the place of a teacher, but to help the student, whilst saving the teacher's time. There are many details not mentioned, such as the fugacious character of the sepals in *Thalictrum* and *Fumaria*, the absence of which will compel the student to seek the teacher's aid. But as a guide to the characteristic features of the genera of British plants it is an excellent little work, which will unquestionably be appreciated by beginners in systematic botany. A still further help to students might have been given if the author had had the courage to do what teachers can well do, but which systematic botanists are naturally careless about, viz., using a definite and uniform termination for the natural orders and their subdivisions respectively. It is difficult for a student to remember that Irideæ and Dioscoreæ are natural orders and not tribes when they have the tribal termination "ææ" instead of "acææ," and simi-

larly to remember that Araucariaceæ is a tribe of Conifereæ (Pinaceæ). Another feature that would improve the value of the book would be a concise description of the characters of the subdivisions of the larger natural orders, such as Ranunculaceæ, Compositæ (Asteraceæ), Leguminosæ (Fabaceæ), etc. It is a great help in getting a comprehensive view of the genera if these, when numerous in a natural order, can be formed into groups.

The tabular classification at the end of the book enables the student to see at a glance the general arrangement of the vegetable kingdom, and the number of species given under each order helps the student to realise their relative importance.

The very convenient size, about 3 inches by 5½ inches, and only ⅝ inch thick, and the small price, 2s. net, taken in connection with the immense amount of information concisely and clearly put, should render the book a welcome friend to students who really wish to increase their knowledge of systematic botany.

CHEMICAL SOCIETY.

The last meeting of the session was held on Thursday, June 16, Professor DEWAR, F.R.S., in the chair. There was a fairly large attendance of members, and many of the papers were of an extremely interesting character. The first, by G. T. MOODY, D.Sc., dealt with the

Preparation of Standard Acid Solution by Direct Absorption of Hydrogen Chloride.

The author commented on the difficulty he had experienced in supplying third-year students with a standard acid solution that could be relied on. He threw on the screen drawings of an apparatus which he had devised for generating hydrogen chloride gas and passing it into a weighed quantity of water. Figures were given showing the extreme accuracy with which such solutions could be made, and it was demonstrated that much time may be saved by adopting this method, owing to the readiness with which the gas is absorbed by water.—This communication, which evoked no criticism, was followed by two of a series of papers on the terpenes by J. A. GARDNER, M.A., and G. COCKBURN, B.A. In the first paper the authors dealt with the

Halogen Derivatives of Fenchone.

It was shown how, by the action of phosphorus pentachloride, a substance may be obtained having the formula $C_{10}H_{14}Cl_2$. This may be prepared in two isomeric modifications. It was shown how closely the action of phosphorus pentachloride on fenchone resembles that on camphor. The second paper described a research on the

Oxidation of Fenchone.

Nitric acid was the oxidising agent employed, and the products were separated by means of their salts. The many acids obtained were briefly referred to. The next paper was remarkable from the fact that it drew forth eulogistic remarks from Professor ARMSTRONG. It concerned the

Investigation of Nitro-Camphor and its Derivatives,

by T. M. LOWRY, B.Sc. The author was able to prove a case of desmotropic change without the presence of a third substance. It had been found by Kipping and Lapworth that nitro- π -brom-camphor gave three different crystalline forms, according to the solvent employed, having melting points respectively of 108, 126 and 142° C. By examination of their optical activity, etc., the author concludes that the first and last of these forms are desmotropically related, and that the third is a mixture representing the equilibrium point in the reversible change.—Dr. ARMSTRONG then read a paper for T. B. WOOD, M.A., and W. T. W. SPIVEY, M.A., on

Cannabinal.

The authors had obtained the acetate of cannabinal. To this crystalline substance they assigned the formula $C_{15}H_{18}O_2$, which differs from that given by Dunstan and Henry. They find that the so-called cannabinal is not the active constituent of Indian hemp. There was no discussion, and JAMES WALKER and J. K. WOOD engaged the attention of the members with a paper on the

Solubility of Isomeric Substances.

After this, W. H. BONE described an

Improved Form of Gas-Analysis Apparatus.

The author had found the Dittmar apparatus far from satisfactory

in dealing with small quantities of gas. He then employed the McLeod apparatus, but sometimes experienced a difficulty from the fact that the sides of the explosion-tube frequently became coated with carbon when insufficient oxygen was present for complete combustion. Moreover, this apparatus stands so high above the bench that it is difficult to work it satisfactorily and easily. Therefore, the McLeod apparatus was modified, chiefly as regards its height and the explosion-tube. By lessening the height the author claimed greater facility in manipulation, and by making the explosion-tube separate from the measuring-tube the apparatus was rendered capable of being cleaned more quickly, a very considerable saving of time being effected.—Dr. ARMSTRONG considered that the Frankland apparatus was all that could be wished for, and asked the author to state his objections thereto. He further criticised the so-called improvements in the apparatus devised by the author, and questioned the desirability of altering the position of the explosion-tube. He considered that a serious risk of error was run in transferring the gases after explosion from the explosion-tube to the measuring-tube.—Professor McLEOD rose to disclaim the merit of inventing the apparatus which bears his name. This apparatus is in reality Frankland's apparatus, which Professor McLeod has only slightly modified. One part of the apparatus, however, he did claim as his own, that being the vessel which acts as a mercury reservoir. He, like Professor Armstrong, failed to appreciate the improvements in the apparatus described, and spoke in favour of the Frankland apparatus.—The PRESIDENT then called for a paper, by W. A. Bone and John Wilson, on

The Action of Light on Acetylene.

During June and July of last year, glass vessels containing acetylene were exposed for several days to the action of the sun's rays on the roof of a laboratory. The gas was prepared from copper acetylide by the action of dilute hydrochloric acid. In two or three days a brown deposit formed on the inside of the vessels. In a fortnight the inner surface of the vessels was completely covered with a brownish deposit. That the action was due to light was evident from the fact that the glass away from the light remained clear and uncoated. It appears, also, that when once the vessel has become opaque the action ceases, no more deposit being formed. The experiment was repeated in the summer vacation, *i.e.*, during August and September. The vessels were examined at the end of this period, and it was noticed that the same reaction had gone on, only in a less degree. Tubes of acetylene were diluted, some with an equal volume of oxygen, others with the same proportion of nitrogen. The gas in these tubes after long exposure under similar conditions remained undecomposed. The examination of the decomposed gas in the affected tubes showed that no saturated hydrocarbon had been formed. The solid produced was removed from the tubes by means of nitric acid. The authors have not yet determined the precise nature of the changes that acetylene undergoes in these circumstances, but they intend following up the investigation during the present summer. It was mentioned that Professor Vivian Lewes has noticed the formation of this brown deposit in vessels of acetylene that have been standing for a considerable time. By this time the evening was well advanced and few remained to hear the last paper by ARTHUR CROFT HILL, B.A., on the

Reversible Hydrolysis Effected by Certain Enzymes.

The author dealt with the methods by which enzymes may be extracted and the various analytical methods used in the conversion of certain carbohydrates and proteid bodies. It was shown that, while chloroform is injurious to certain enzymes, alcohol has no effect on them. In experiments with maltose the extract of the enzyme maltase was diluted with twenty times its volume of water. Proof was shown that the hydrolysing action of the enzyme is incomplete, and hindered by the presence of glucose; but the effect may be increased by greater concentration. The author found that in the case of maltose the action is reversible, but it is doubtful whether reverse action takes place in the case of other enzymes, as a high concentration would be necessary. It is open to question whether this reverse action goes on to a large extent in living cells; possibly an essential condition would be the removal of the products, as soon as they are formed, by means of other enzymes.—Dr. BROWN and others spoke in high terms of the value of this communication, and the PRESIDENT alluded to the accuracy of the work and expressed satisfaction with the succinct report of

the investigation which the author had drawn up. The work was carried on in the new Davy-Faraday Research Laboratory, and it would be gratifying to the donor, Dr. Ludwig Mond, who happened to be present, to find that in that building sound original work of the greatest practical value and scientific interest was already being carried out.—The PRESIDENT announced that many papers yet remained, among them being one by Arthur Lapworth, D.Sc., and Charles Mills, dealing with

Nitration and Substitution in Nitro-Compounds.

In consideration of the lateness of the hour these, however, were taken as read. A ballot was taken during the evening, and the names of the newly-elected fellows were read out, among them being Harry Lancelot Lee, late lecture-assistant to Professor Norman Collie at the School of Pharmacy. The PRESIDENT commented on the continued vitality of the Society, as evidenced by the abundance of papers brought before each meeting during the present session, and then adjourned the meeting for the summer vacation.

PHARMACEUTICAL TRANSACTIONS.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

A special meeting of the Cambridge Pharmaceutical Association was held on Friday, the 24th inst., at the "Prince of Wales" Hotel, for the purpose of discussing the proposed regulation of

The Sale of Certain Poisonous Substances

and the Companies Amendment Act.—Mr. A. SIDNEY CAMPKIN, J.P., presided, and there was a good attendance of members, including Messrs. E. Saville Peck, B.A. (Vice-President), B. Sidney Campkin (Hon. Secretary), H. F. Cook, C. S. Addison, H. J. Parson, W. L. White, G. McAvoy, A. P. Barker, C. Male Piggott, and others.—The CHAIRMAN, in submitting a proposition with reference to the proposed regulation of the sale of poisonous substances, pointed out the somewhat invidious position in which qualified chemists would probably be placed, and suggested that the Government Bill had been framed without sufficient reference to the Council of the Pharmaceutical Society, as it would recognise the sale of many potent poisons at present not included in either Schedule of the Act 1868 being placed in the hands of persons who had little or no knowledge of their composition or dangerous effects, and who were in no way qualified (as chemists were under the Pharmacy Act). The Council, as representing the body of qualified chemists, had long endeavoured to secure an extension of the Poison Schedule so as to include the mineral acids, acetate of lead, and other poisonous substances which had largely been sold by ironmongers, oilmen, grocers, and others, but if the new proposal was to be adopted they would find themselves in a worse position than under the present law, inasmuch as unqualified persons would be empowered to sell poisons by the use of "Poison" or "Caution" labels. The principle of the Pharmacy Act was that in the interests and for the safety of the public, the sale of poisons should be restricted, and placed exclusively in the hands of qualified men, who by training and experience were best qualified to form an opinion as to whom and under what conditions a sale should be made. The President of the Pharmaceutical Society, in his address in May last, pointed out that the trained and experienced chemist was the proper person to whom the sale of poisons should be entrusted, and that as a fact he turned away a greater number of would-be customers than any other business man, from the fact that he exercised much discretion towards applications for poisons or poisonous substances, and this they all knew to be a fact. It was, too, by observance of the regulations as to registration that a recent poisoning case had been traced, as it would not probably have been had not the sale been in the hands of a chemist who knew and felt his responsibility in the sale. Accidents did, and would, at times occur, and improper use be made of poisons under the most rigid regulations, but the evil was minimised and the safety of the public secured by insistence of the disposal of poisons (even for most legitimate uses) by properly qualified and responsible persons, who were not only fully acquainted with their composition and danger attendant upon their use, but constantly cautioned those to whom they supplied them at the time of sale. He thought it would have been better that the poisonous substances in the new Schedule should have been

added to Part 2 of the Act of 1868. Had this been done the proposed regulations would have been unnecessary, and the sale would have been restricted to qualified persons. He would suggest that a resolution should be adopted calling attention to the danger to the public if the new regulations became law, and submitted a proposition which was discussed in detail.—Mr. WHITE fully concurred, and thought the resolution should be sent in the first instance to the Pharmaceutical Society, expressing their admiration at the manner in which the Pharmaceutical Society had overcome the opposition to the Pharmacy Acts Amendment Bill. He also thought that there was a risk of the new Act for Regulating the Sale of certain Poisonous Substances would be in conflict with the Act of 1868 relating particularly to the "Substances sold for the purpose of poisoning insects or vermin" where arsenic or strychnine and such-like substances entered into their compositions. These views were supported by Mr. PARSON, Mr. ADDISON, and Mr. C. SAVILLE PECK.—Mr. MCAVOY thought that none but registered and qualified persons should be entrusted with the sale of poisons, and the sooner this was fully recognised the better for the safety of the public.—Mr. H. F. COOK also supported this view and called attention to the remarks of Dr. Clark, M.P., recently in the House, which he thought were in no way justified by their own experience; further discussion followed, and eventually it was agreed unanimously—

That the attention of the Pharmaceutical Council be called to the provisions of Clauses 1 and 2 of the Act for regulating the sale of certain poisonous substances, and to suggest that the Act may be amended so as to provide that no person other than those qualified or registered under the Act of 1868 shall sell any poison scheduled under the Act, and that the proposed new Schedule should be added to Schedule 2 of the Act of 1868.

—The CHAIRMAN then introduced the subject of the Companies Bill, now before Parliament, and submitted a proposition upon the lines of a petition forwarded by the Pharmaceutical Society of Ireland. He had spoken upon the subject more than once at the annual meetings of the Pharmaceutical Society, and he felt that the meeting and pharmacists generally were fully in sympathy with him. There was now an opportunity upon the proposed Act for the insertion of a clause in the direction they had long needed, although it appeared improbable that the Bill would now be passed this session; still, it would be as well to make their wants known by the suggested amendment, he moved:

That this Association urges that a clause should be inserted in the Companies Bill, now before Parliament, to provide that no company may be registered to do acts for which a course of educational training and examination is required by Act of Parliament as a qualification, and unless each member of such company is qualified under such Act.

—Mr. PARSON seconded this, which was supported by Mr. Addison and others, and carried unanimously.—It was agreed that both resolutions should be forwarded to the Pharmaceutical Society, with a request that attention would be given at the earliest opportunity.—The subject of early closing on Thursday afternoons during the summer months was discussed, on the motion of Mr. Parson, when it was agreed that two o'clock should be the hour.—The SECRETARY reported as to the proposed summer outing of the Association, when it was agreed by a majority of twenty to eight in favour of a trip to Hunstanton, on Thursday, July 7, and that final arrangements be left to the Hon. Secretary.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.

A circular has been sent out during the past week by this Association to every medical man in the neighbourhood, and chemists throughout Devon and Cornwall, in order to secure uniformity in the dispensing of B.P. preparations. The circular states that all prescriptions written on and after July 1, will be dispensed according to the new B.P., 1898, in the absence of instructions to the contrary. It also points out that the alterations in potency, etc., of the official preparations are numerous, the list of such alterations given in the *P.J.* Synopsis of the B.P., 1898, being reprinted *in extenso*.—The usual monthly Committee Meeting was held on June 28, when Messrs. Goss and Cooper were elected new members. The SECRETARIES (Messrs. A. D. Breeze and C. J. Park) of the Annual Outing Committee reported the very satisfactory balance in hand of £4, which was unanimously voted to the General Fund.

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.

A special and fully representative meeting of this Association was held at Blackburn on June 23, to protest against the Government's Poisonous Substances Bill, now before the House of Lords. Mr. THOMAS CRITCHLEY of Blackburn, presided, and after explaining the object of the meeting, Mr. R. L. GIFFORD, of Blackburn, the Hon. Secretary said:—Mr. Chairman and Gentlemen. It has been more and more impressed upon the mind of our committee that the conditions under which we labour have become almost if not quite intolerable and the introduction of the "Poisonous Substances Bill" by the Duke of Devonshire, brings matters to such a pitch that our committee demands that the whole position of our professional status be reviewed. I will endeavour to state the case. Thirty years ago Parliament concluded that in the interests of the public it was desirable poisonous substances should be distributed and dispensed by men educated and trained in their properties—in other words, a profession of pharmacy was created. In creating a profession the Legislature cannot carry out its wishes. It can only indicate them because of the time which must elapse before an educated body is produced, and it is not disputed that the Legislature of 1868 intended that our education and training should be made more and more vigorous on the one hand and on the other that at an equal pace our duties and professional work should be extended. What has occurred in its history? Scandalous history, I say. The examinations have been made more and more severe. On this hand the Pharmaceutical Council—the body entrusted by Parliament with the carrying out of its intentions—has done its duty, and a body has been produced able to do the work the framers of the Act had in view. But from the other point of view—the point of view of just as continuously safeguarding and increasing our privileges as in imposing more stringent qualification—we must conclude that the work of the Council for the last thirty years is quite completely unworthy of the great trust the Society acquired. Practically we have obtained no privilege since 1868, and have lost what we had. We see the profession of medicine increasing its privileges almost at the same rate as our difficulties and educational requirements are increased. Twenty years ago the profession of dentistry became in fact what is now an organised profession. The same principle applies to the law, and even the stockbroker is jealous of his legal rights. With us the Act has been emasculated beyond recognition. Would the Legislature of 1868 have expected that in thirty years' time a score of drugs would represent the responsibilities of the chemist. Perhaps this is a fair way of putting the case. Let every man of reasonable education and judgment be asked what ought to be done with all powerful drugs, herbs, and chemicals, and every man will tell you that only trained men should handle them. Well, if you can appeal successfully to the ordinary intelligence, why not press your facts until you produce a more sensible state of affairs? It probably is no exaggeration to say that not more than 1000 chemists obtain a livelihood by their profession—the other 5000 obtain a living more or less in spite of their qualification. It is impossible quite to stamp *esprit de corps* out of men brought up and educated to it, whilst the outsider has neither conscience, knowledge, nor responsibility to restrain him. Would the sane legislator dream of making it possible for the reporter here to become a chemist by the simple process of calling his wife and five children together and making his hearth a registered office. Yet that is what he can do. He can blossom forth as "Reporter, Limited, cash chemist," and our wise judges have made this possible. They have, in fact, created this law. Gentlemen, it seems always to be presumed that we shall not be listened to if we ask for advantages. The imposition of duties gives the right to them. This principle applies in all professions, and if the practice of pharmacy has to advance with equal pace as the nation's life, the principle of responsibility involving rights must operate.—Mr. TAYLOR, of Bolton, then submitted the following resolution:—

That this meeting of chemists and druggists, whilst of opinion that it is necessary to provide some regulations as to the sale of the articles named in the Government's Poisonous Substances Bill, regards that Bill as inadequate for the purpose, and ambiguous in its details. This meeting is also of opinion that the Bill constitutes a dangerous departure from the principles of the Pharmacy Act of 1868, and call upon the Pharmaceutical Council to strongly oppose the Bill.

He moved it, he said, with all his heart. Before saying anything strictly pertinent to the resolution he should like to say that they, as pharmacists, while claiming that the law should be strictly enforced with regard to the sale of poisons, should also be careful to observe the law themselves, and no temptation to try to make a

few pence or a few shillings extra, or to gain a little at the expense of some rival, should prompt them to deviate in the slightest degree from the strict letter of the law. That was the course of conduct he marked out for himself when he started business eighteen years ago, and he could honestly say he had not once departed from it. They must always bear in mind that the Pharmacy Act was not passed primarily to protect him and them, or any of those who should follow them in the trade, but solely for the benefit of the public. Apart from that they had no reason for any restrictions or any privileges being granted to themselves. The State, with a desire to hedge round the sale of poisons with restrictions, found ready-made to its hand a body of men who even at that date were fairly well trained in the handling of such things, into whose hands it could commit the sale of poisons, at the present time they were better qualified than at any other time in the history of pharmacy to deal with those substances. That had placed upon them a moral obligation to observe the law, which should be stronger than any legal obligation, and if they betrayed that trust they would not get, nor would they deserve, the sympathy either of the Legislature or the general public. In going more particularly into the matter he was not going to say anything about the Pharmaceutical Society or its enforcement of the Pharmacy Act, except that they would be foolish, and more than that, if they placed themselves in a false position—if, while calling upon the Council to enforce that Act strictly, they grumbled because it sometimes hit themselves. It would not hurt anybody who observed the law, but only those who broke it, whether qualified or unqualified men. As they claimed to be protected from unqualified men, they on their part should undertake to protect the public from such persons. Every qualified man who had a branch shop was bound, doubly bound by honour—a matter which did not weigh at all with the unqualified man—to put into every branch shop a qualified man. They objected to the Government Bill because it tended to break down the fence which had been put round the sale of poisons. If it became law, it would practically create a new set of poisons. They knew perfectly well from their experience as business men that the public would forget the distinction if they recognised it, and would see only upon a certain bottle a label, "poison." The Bill, in effect, said that those poisonous substances did not need trained men to sell them. They are dangerous, it said, and if their sale is not restricted, it must be regulated. One of them—carbolic acid—held the record as the cause of death to-day, and on that ground the State said: "We must regulate the sale of these things. Because they are useful in the arts, necessary in manufacturing, and because some industrial concerns consume large quantities of them, no restrictions must be placed upon their sale, and they can be trusted to the hands of men not qualified to know how they are made, what they are used for, or any of their properties." He felt sure they would all say that was a dangerous departure from the principle of the Pharmacy Act of 1868. If those things were dangerous, if the sale needed regulation, if it were desirable that they should be hedged round with safeguards that would prevent their indiscriminate use or administration, then on the face of it they were not things to put into the hands of any tradesman to sell. They would know that the legislation was not directed against themselves. It was not claimed that they had neglected their duty in the sale of those things, for they had done voluntarily for years what the Government now sought to impose upon outsiders. They had labelled those substances "Poison," and exercised a great deal of discretion as to the vials in which they should be sold, and at the cost of time to themselves had instructed the public in their use and against their dangers. They had laid upon themselves the duty of standing between the public and the indiscriminate and unsafe use of all the substances, without exception, named in the Bill. The proposed legislation, therefore, was not called for by any neglect on their part or by anything that they, as a trade, had ever done. That tended to lend weight to their argument that if those substances required special protection and regulation they required also to be placed in the hands of those who had been trained to their use, who knew what they were and what dangers they possessed. And the great evil of the Bill, if it passed into law, was that it would allow those substances to be sold indiscriminately if labelled "Poison" and bearing the name and address of the seller. That would destroy, in the public mind, the distinction which now exists between the more dangerous—so-called—of those substances, and people would begin to ask why, if one kind of poison could by

law be sold by a greengrocer, draper, or perfumer, another kind of poison could, by law, be sold only by a qualified chemist and druggist. There seemed to be an idea in the minds of some people that there was no need for regulated sale of poisons except they were to be used for medicine. Dr. Clarke, for instance, seemed to think that all the trade had a right to ask for, and all that public safety demanded, was that the poisons should be carefully labelled only when they were for internal use. Surely Dr. Clarke and those who thought with him did not know that the percentage of deaths occurring, either through accident or suicide, from the more dangerous poisons was very small. He (the speaker) did not think there was any trade or profession in the world to-day which could show fewer mistakes, fewer forgetfulnesses of duty, fewer accidents from carelessness or incapacity than their own. He said that without any reservation. They knew oftentimes that in medical practice mistakes and accidents occurred of which the public heard very little. They were, however, far from being uncommon. If, however, a druggist made a mistake, whether in dispensing or in the sale of poisons which are used for some improper purpose, the public heard all about it, and injustice was often done by irresponsible talk by editors who knew little about the Pharmacy Acts. He thought it was something to be proud of that, as a trade, so little could be said against them. They knew perfectly well that Mr. Gladstone, when a deputation from the British Pharmaceutical Conference at Liverpool a few years ago visited Hawarden, bore testimony to the fact that the number of accidents in their trade was wonderfully small, and the number of deaths infinitesimal. He repeated that none of those precautions were aimed at them or were needed by them. They had strong grounds for going before the Government and the public and saying, "We have done our duty, we are able, capable, and well qualified to discharge all the duties placed upon us with regard to the sale of poisons, and you are making a great mistake and doing us and the public an injustice if you try to break down in the least the distinction in the public mind between things which may be sold by qualified men and things which may be sold by anybody." The Bill was inadequate, because a mere label on the thing did not always suffice to prevent accident or improper use. The fact that poisons were in the hands of qualified men would act as a valuable deterrent to those who desired to use them wrongfully. If these poisons were put into any man's shop, then the suicide and the murderer could get what they wanted. The Bill was ambiguous because it had not properly defined several things. It required redrafting by the aid of practical pharmacists, who knew what their duty was and what they had to safeguard people from. They also objected to the Bill because it departed from the principle of the Pharmacy Act, which provided that all substances dangerous to life should be handled only by trained and licensed men. The Government was taking a dangerous step, for if once the door was opened, they could not tell who would walk in. The last thirty years had proved the wisdom of the Pharmacy Act, and if hundreds of lives had been lost by the misuse of carbolic acid or similar substances, the fault did not lie at their door, or at that of the Pharmaceutical Society. They had only to put their case before the country and before Parliament with a bold front, with as clear logic and as reasonably as they could, to make sure that the Bill would not pass into law in the form in which it was drafted. It was not a mere commercial question, it was a question of principle and moral responsibility.—Mr. WELLS, of Blackburn, seconded the resolution, and said that the accidents due to chemists had been very few indeed, and they were the only people fitted to carry out the sale of dangerous poisonous substances. He also remarked that a similar Bill to the present one was introduced in Parliament in 1875, but it did not go further than the second reading, and he hoped that the one they were discussing would meet with the same fate.—Councillor RALPH SHORROCK (Darwen) and MESSRS. GARLAND (Blackburn) and BROWN (Burnley) supported the resolution, which was unanimously carried.

AMYTIN AND AMYTOLS.—Ichthyolsulphonic acid and the aromatic oily substance which form the two chief constituents of ichthyol, dissolve a third body which is contained in ichthyol, and which is itself insoluble. Ichthyolsulphonic acid exerts the same solvent action on other bodies such as camphor, phenols, ethereal oils, etc. Amytine is a 33 per cent. aqueous solution of this acid and the preparations made with it are introduced under the name of amytons.—*Pharm. Zeit. f. Russl.*, xxvi., 641.

LETTERS TO THE EDITOR.

GLYCERINUM ACIDI BORICI, B.P., 1898.

Sir,—Criticism of this preparation would obviously be premature, but may I ask in what respect is it superior, as a means of exhibiting boric acid, to the solution prepared by boiling together $1\frac{1}{2}$ ounces each of boric acid and borax in sufficient water to produce a pint of solution? The increased strength of *syrupus ferri iodidi* deserves a word of notice. It is 26.7 per cent. stronger than it was. For the preparation of the cold infusions a glass dialyser can be made very useful. The bell-shaped form (not too large) is best, and a piece of muslin twice the size required to cover the larger mouth is necessary. Stretch it over the rim, place on it the quantity of *calumba* or *quassia* ordered, fold the muslin over, and tie round firmly. Then if the dialyser be suspended by loops from a stirring rod resting on a wide-mouthed measure or glass jar, and the length of the loops adjusted so that the drug is just below the surface of the water, the infusion can be poured off clear at the end of the time specified.

Dover, June 22, 1898.

J. F. BROWN.

LIQUOR STRYCHNINÆ HYDROCHLORIDI, B.P., 1898, AND STRYCHNINE HYDROCHLORIDE.

Sir,—Mr. George Lunan points out (*Pharmaceutical Journal* last week, p. 587) a discrepancy in the 'Extra Pharmacopœia,' ninth edition, p. 422, where it is stated that the above "solution is one-tenth weaker than" the corresponding preparation of B.P., 1885. I do not admit, however, the accuracy of his figures. I think I took my formula for strychnine hydrochloride as $C_{21}H_{22}N_2O_2 \cdot HCl$, which is the only one given in Watts' 'Dictionary' (first ed., vol. v., 422). This is the anhydrous salt, and it gives the proportion of alkaloid as 90.16 per cent. Regnault gives the salt as crystallising with $1\frac{1}{2}$ aq.; Ernst Schmidt gives it with 1 and 2 aq.; the British Pharmacopœia gives it with 2 aq., and further states that, dried at $100^\circ C.$, it should lose 7.3 to 8.8 per cent. of moisture. To this latter statement I will refer later. Mr. Lunan makes out that the new solution has only 80.6 per cent. the alkaloidal value of the old preparation, that it is in fact one-fifth weaker. Both preparations (that of B.P. 1885, being made in fluid parts) are so-called 1 per cent. solutions, and if the hydrochloride be reckoned with $1\frac{1}{2}$ aq. the percentage of real alkaloid is 84.04; if with 1 aq. it is 85.46. This gives the solution as being only about one-seventh weaker. In 1885 the preparation was increased in strength about one-eleventh without any serious objection or result; now it will be reduced to about the original strength, that of *liquor strychninæ* B.P. 1867, and with a more consistent name. The advantage in slightly reducing the strength is that it prevents the deposition of crystals complained of when exposed to a low temperature. This crystallisation was shown to be increased by the acidity of the solution. By using the hydrochloride an excess of acid is avoided, and from my experience in preparing several lots, the present official solution will not crystallise by any exposure to cold. The slight reduction in strength, moreover, has the further advantage in being on the side of safety, and medical practitioners have no cause to be alarmed—the strength is not doubled like that of tincture of *nux vomica*. In a contemporary, it is complained that the new solution does deposit crystals on keeping. I have two specimens before me, made on January 19, 1897, and checked by myself; one was prepared exactly as B.P., 1898, the other *sine* alcohol—a 1 per cent. solution in sterilised distilled water for hypodermic injection. Both solutions were then exposed all night to a temperature near freezing point, certainly under $40^\circ F.$, and they did not crystallise. In fact, both are perfectly good and free from fungi at the present time. I have referred to the statement in the B.P. that strychnine hydrochloride should lose 7.3 to 8.8 per cent. of moisture when dried at $100^\circ C.$ This is not correct. Gmelin says (vol. xvii., 494), on the authority of Nicholson and Abel, that the crystals lose the whole of their water of crystallisation, amounting to 7.17 per cent., at $120^\circ C.$, but that Gerhardt states, on the contrary, the salt, dried at $100^\circ C.$, loses 4.81 per cent. (or 2 aq.) at $130^\circ C.$ only. My experiments, on an average of three commercial samples which were not effloresced, give a mean of loss at $100^\circ C.$ of 1.695 per cent.; at $120^\circ C.$ of 6.33 per cent.; and at $130^\circ C.$ of 7.183, which corresponds, I must acknowledge, to nearly 2 aq. The salts are

all neutral. Being carefully stored I have not noticed this salt become effloresced as stated in B.P.

WM. MARTINDALE.

A DISCLAIMER.

Sir,—With reference to the recent prosecution of a chemist in Battersea, in which Frederick Davis, a photographer, is mentioned as the informer, owing to communications which have been forwarded to me, I beg to say I am in no way related to or connected with this person. I shall be glad, therefore, if you will be good enough to publish this disclaimer.

51, Imperial Buildings, E.C.,
June 27, 1898.

FREDERICK DAVIS.

SALE OF POISONS BY UNQUALIFIED PERSONS.

Sir,—It gratifies me as a young member of the craft to see so often in the *Pharmaceutical Journal* reports of convictions of unqualified persons for contravening the Pharmacy Act. It is hard for any chemist, and especially a young aspirant to pharmaceutical honours, to find himself, after his time and money have been spent in study, face to face with an unqualified vendor of drugs and patent medicines, *sine cumque veneno*. I only wish that there were more convictions, and I should only be too glad to help to bring to justice some of these transgressors—a task by no means hard to me. But I come now to a point raised in last week's *Journal*, and that is, in regard to chemists failing to carry out the regulations of the law in their own businesses. We cannot expect to receive much sympathy from Government when chemists wantonly break the Pharmacy Act; and such cases as the cyanide case last week deserve to be punished. I find it is not an uncommon practice to break the law when selling poisons, and it is absurd, as you say, for a chemist to try and stop illegal trading in poisons by unqualified persons when he is breaking the same Act only in another way; and many chemists allow unqualified assistants to handle poisons with impunity. I am afraid it is a case of seeing the mote in out brother's eye whilst not perceiving the beam in our own eye. Let us then—I am appealing now more especially to the younger members of the profession, who have still the battle to fight—try and bring to light these cases of illegal selling where we can, not forgetting ourselves to carry out the law fully. It is as easy to carry it out as to break it, and I am sure we shall only be doing our duty to the Society to which we belong. We are surrounded by much competition, the stores, etc.; there are even some medical men who supply their patients with goods which should pass through a chemist's hands. I could quote instances, but it is sufficient to show what we have to put up with, but if times are bad and we find it a struggle for existence, even that should not keep us from doing our duty and fulfilling the law, which is allowed to be broken by unqualified men and companies.

June, 25, 1898.

IN DIE MALO (136/14).

CHEMISTS AS CO-OPERATORS.

Sir,—In last week's *Journal* I noticed, under the heading of "Pharmacy in Australia," an announcement to the effect that several pharmacists in Melbourne had formed a company to buy special lines in large quantities (thereby obtaining the lowest possible rates), which were then distributed to the members according to their individual requirements. These chemists were thereby enabled to successfully compete with their unqualified competitors, and, by selling patents at the same prices as these people, were in a great measure enabled to counteract and nullify that unhappy and mistaken idea that a part of the public has got hold of, that at the "stores" drugs and chemicals are sold at the same cheap rates as patents. Everyone interested knows that the drug stores simply use low-priced patents as a bait wherewith to hoodwink an unsuspecting public, and to entice them into their (the stores) establishments, when their assistants forthwith proceed to sell some proprietary which bears an outrageously large profit, which compensates, to a certain extent, for the loss on the patent. For, alas, even drug stores must make a profit, albeit they try to make out that they sell medicines for the fun of the thing. If, therefore, it were possible for chemists to advertise and sell patents at the same prices as the stores, the attraction of the latter would cease, and that part of the chemists' custom which has, unfortunately, drifted to the stores, would most certainly return. For it is an undisputed fact, that although chemists may sell patents at rather higher prices than the stores, they most un-

doubtedly sell far superior drugs and chemicals at a much more reasonable price. Then again, a chemist's trade, almost without exception, is a purely personal one, a kind of trade which it is exceedingly difficult to conceive a stores man cultivating. So that as soon as it becomes a *fait accompli* that the public can obtain its patents from the chemist at the same price as from the stores, then, considering the enormous difference between the *locus standi* of the two, and recognising the value of a fully qualified, carefully trained chemist and druggist in whom they may place explicit confidence without the slightest fear of that confidence having been misplaced, the public would entirely ignore and cease entirely to frequent the stores. I would suggest, therefore, as a remedy for the present state of affairs, that all the chemists in each town form a company for the purchase of such lines as may have a ready sale in their neighbourhood, and which, being purchased in large quantities, might be more advantageously bought. I know for a fact that this is done in several towns in England, being found to work admirably. So much so, that the participants in the scheme, being able to meet the stores with their own weapons, are already gaining ground. It is high time that chemists combined for their mutual protection against their common enemy the stores, for it is evident that the chemist and the stores cannot exist together, and I am in favour of existing a little longer yet, if possible. Therefore, if someone more experienced and capable than myself will only take the hint from the above rough suggestion, and formulate some scheme which might be adopted by local organisations in every town, I think a very decisive blow could be struck against the stores. If that were so, and chemists would remunerate their assistants a little more liberally, so as to neutralise any desire on the part of young men to engage with the stores on financial grounds, I feel sure that the life of the stores would be exceedingly short. In conclusion, may I express a hope that some one else will kindly express an opinion with a view to a scheme of some kind being advanced.

June 22, 1898.

C. H. H. (116/7)

THE POISONOUS SUBSTANCES BILL.

Sir,—I notice with considerable regret that the above Bill has already been read a second time in the House of Lords. The Bill is entirely retrograde in its scope and intention, and therefore very objectionable. Should it unfortunately reach the House of Commons, I hope monster petitions will be sent from every town and city in opposition to the same. Personally, I would rather leave the sale of carbolic acid where it is at present, as also the mineral acids. My experience has been that the more poisons are scheduled the less business there is done in them. If, however, the Government are not satisfied with the *status quo*, the present Bill should be dropped, and the substances mentioned in it might be added to the Poison Schedule under Part 2. As regards the last clause, I have always been opposed to any compulsory system of poison storage or poison cupboards, and, therefore, object to that part most strongly. I think each chemist should be allowed to store his poisons in his own manner and be responsible for what he does. In my opinion that is better than being fettered by any cut and dried Government arrangement.

Liverpool, June 29, 1898.

WALTER A. GRACE.

ANSWERS TO QUERIES.

BOTANICAL.—Your curious specimen is the flower of *Aristolochia siphon* (Aristolochiaceæ). [Reply to J. A.—13/4.]

BOTANICAL.—The plant is probably new. Please send a complete herbarium specimen if you can. [Reply to G. B.—12/29.]

BOTANICAL CASE.—Write to Butler's Natural History Agency, Brompton Road, London, S.W., or to Watkins and Doncaster, 36, Strand, W.C., for copies of their lists. You can then decide for yourself. [Reply to G. B. G.—13/5.]

FIRST EXAMINATION.—Any good text-book of arithmetic will serve your purpose, and should give everything you require to know about the metric system. You will find a complete list of metric equivalents in the *Pharmaceutical Journal* for June 4 last, at page 534. [Reply to C. B.—13/2.]

SPECIALIST FOR DISEASES OF THE HAIR.—It is against our rule to recommend particular medical men. Ask the advice of your local medical practitioner. [Reply to EPIDERMIS.—12/30.]

GLUCOSE.—Dextrose or grape sugar. You must have omitted to look in any work on organic chemistry. The liquid glucose of commerce is a variable product, prepared by the action of acids on starch. [Reply to SAXIN.—12/32.]

REAGENTS, METHODS, AND FORMULÆ.—They have not been republished in book form, as yet. It is hoped to continue publication of the supplementary list of reagents, etc., at an early date. [Reply to CAERDYDDIAN.—13/6.]

TEST FOR AMMONIUM SALTS.—The precipitate is only produced in highly concentrated solutions of neutral ammonium salts, and after some time has elapsed. Its separation may be promoted by shaking the mixture, or by rubbing the inside of the test-tube with a glass rod. [Reply to C. B.—13/3.]

SALE OF METHYLATED SPIRIT.—You must obtain a retailer's licence at a cost of 10s. per annum, and may then stock not more than 50 gallons. You must not sell the spirit between 10 p.m. on Saturday and 8 a.m. on Monday, nor more than 1 gallon at any one time. [Reply to X. Y. Z.—12/17.]

PREPARATION FOR FIXING THE MCUSTACHE.—This is a solution of 1 part of sandarach in 5 fluid parts of alcohol, perfumed with mirbane and some other aromatics. You would find the hard resin of tolu, left after making the syrup, or balsam of tolu itself, quite as satisfactory when dissolved. [Reply to SALOL.—12/13.]

DARK ROOM.—It is a decided advantage to prevent the light from the lamp falling directly on the dry plates during manipulation, but if you get a good lamp—such as the Phoenix, described in our last Photographic Supplement—it can be fixed so as to diffuse quite sufficient light on the table without the necessity of fixing reflectors. [Reply to A. McK.—12/33.]

ANALYSIS OF MALT.—We know of no book specially devoted to the analysis of malt. You will find full details of all modern analytical processes in the pages of the 'Journal of the Society of Chemical Industry.' You will also find the best technical information on brewing in the same journal, which devotes a special section to this industry. There is an excellent *résumé* of the analysis of malt in 'Allen's Commercial Organic Analysis,' Vol. ii., pp. 330-327. [Reply to E. W.—12/11.]

PASTE FOR LABELS.—An excellent paste, which is very adhesive and will keep for an indefinite period, can be made by thoroughly mixing rye flour, 400, with powdered boric acid, 2, and water, 1600. Strain through a sieve; add strong nitric acid, 12; heat, with constant stirring, until the mixture thickens; then cool, add clove oil, 1, and again strain through muslin. Add 10 per cent. of glycerin when labels are to be pasted on tin. If at any time the paste should have dried up, the addition of a little warm water will restore it to its original consistence when well stirred. [Reply to L. B. and Co.—13/1.]

PERCENTAGE SOLUTION.—A fluid ounce of water at 62° F. weighs 437.5 grains, and contains 437.5 fluid grains or 480 minims. To make a solution containing a definite percentage by weight, you should first weigh the active ingredient, then dissolve in sufficient water, and finally make up the weight of the solution to 100 parts by adding more water. The B.P. centesimal (not "percentage") solutions contain a definite weight of active ingredient in 100 fluid grains or 110 minims. If you adopt the same plan you will not be far wrong. [Reply to UNDECIDED.—136/8.]

OBITUARY.

MAINWARING.—On June 16, Richard Mainwaring, Chemist and Druggist, Southport. Aged 78.

PRATT.—On June 20, Jonathan Burford Pratt, Chemist and Druggist, Newbury, Berks. Aged 82.

PRIESTMAN.—On June 22, Abraham Priestman, Chemist and Druggist, Barrow-in-Furness. Aged 31.

PARLIAMENTARY NOTES.

THE POISONOUS SUBSTANCES BILL came on for second reading in the House of Lords on Friday, June 24, when the Duke of Devonshire (Lord President of the Council) said:—My Lords, the object of this Bill is to give to the public some protection against the indiscriminate sale of poisons beyond that which is already provided for by the Pharmacy Act, 1868. There are certain poisons which are included in the Schedule of that Act: the Act also imposes certain restrictions—as to labelling and in other respects—on the sale of these poisons; but the principal restriction the Pharmacy Act imposes is that the sale of scheduled poisons is limited to persons registered by the Pharmaceutical Society. It was thought that the list of poisons in the Schedule might be extended by the Privy Council on the recommendation of the Pharmaceutical Society, and repeated applications have been made to the Privy Council to include under the Pharmacy Act certain other articles which are enumerated in the Schedule to this Bill. For instance, carbolic acid, which is largely used by many people as a disinfectant, is the principal one. But the Privy Council has always declined to include these articles in the Schedule to the Pharmacy Act upon two grounds: first, the ground of the inconvenience to which the public would be exposed if any additional difficulty were imposed in the way of obtaining these extremely necessary articles, and secondly, on the ground of the dislocation of trade which would be caused if the sale of these articles were placed in the hands of what is virtually a trade monopoly. On the other hand, the Privy Council has received repeated recommendations from coroners' juries to the effect that some additional precautions should be afforded against the indiscriminate sale of these articles. It is not pretended that legislation of this Bill, or any legislation, can very largely diminish the number of deaths which annually take place in consequence of these articles. Out of 579 deaths which took place in the years 1895 and 1896—which are the most recent statistics available—by the use of articles in the Schedule of this Bill, only 111 were due to accidental or general causes, 468 being cases of suicide. Of course, it is not contended that any restrictions which can be imposed will deter persons who are determined to take their own lives; but of those 111 cases of accidental death by these poisons, 29 were cases of children under ten years of age. I think your Lordships will agree with me that whatever protection can be given against such accidental use of these poisons, it ought to be given. The present Bill is the result of the representations to which I have referred, and in regard to these articles it is confined to placing the sale of substances included in the Schedule to this Bill and not included in the Schedule of the Pharmacy Act, under certain restrictions as to labelling; and, in the next place, giving the Privy Council the power of adding to or removing certain articles from the Schedule. The Bill also contains a certain amendment of the Pharmacy Act itself. That Act has not been altogether effectual in preventing accidental deaths from the use of poisons included in the Schedule of the Act, for, out of 786 deaths which took place in the years which I have referred to, caused by the use of poisons included in the Schedule of the Pharmacy Act, exactly one-half were cases of accident, the other half being cases of suicide. There were 393 cases of suicide by these poisons, and there were 393 cases of accidental death. The Pharmaceutical Society has power to make further regulations as to the sale of these poisons, but, for some reason or other, up to this time it has neglected to do so, and the second clause of this Bill provides that the Privy Council may make such regulations independently of the Pharmaceutical Society. These are the objects of this Bill, and, as I have said, while we cannot hope that it will cause any great diminution in the number of deaths which take place owing to the use of these poisons, I think your Lordships will agree that, so far as possible, the number of accidents caused by them ought to be restricted.—The Bill was then read a second time, without discussion.

IN THE HOUSE OF LORDS on Monday, June 27, the Duke of Devonshire moved that the House go into Committee on the Bill for Regulating the Sale of Certain Poisonous Substances. There were no amendments offered, and the Earl of Morley (Chairman of Committees), on the resumption of the House, reported the Bill without amendments. On the motion of the Duke of Devonshire the report was received.

THE HOUSE OF LORDS STANDING COMMITTEE met on Tuesday, when Lord Herschell occupied the chair, and the Poisonous Substances Bill was considered. No amendments were made and the Bill was ordered to be reported. The Third Reading is fixed for Friday of this week.

THE POISONS BILL has passed through the House of Lords with considerable celerity, and may be expected to appear in the Commons early next week. Nothing but the *ex-parte* statement of the Duke of Devonshire in moving the second reading has yet been urged in its favour; but the veriest bungler in prophecy may safely predict that a good deal will be said against it by the registered men of Great Britain. To those who know the facts it seems something like abuse of position for the Lord President of the Council to couple pharmacy with the words "trade monopoly." His Grace is the head of the Department which supervises, by its own officer, the high educational tests and practical training demanded of registered men, and he should know that there is as little justification for describing pharmacists as monopolists as there is for applying a similar term to medical men or to lawyers. The whole tenor of his remarks was misleading, and steps must be taken in the lower House to correct the misunderstanding. Even Democracy, so we are told by Mr. Burns, does not concede the right of free trade in potent substances, and it is a little incomprehensible to find the foremost of our nobility calmly discounting the principle of technical education by talking about "monopoly" when the public safety is in question.

LORD HARDWICKE has given notice to move the second reading of the Pharmacy Acts Amendment Bill in the House of Lords on Thursday, the 7th inst. No doubt his lordship would have put the Bill down for an earlier date if he had not been in charge of the Aliens Bill, which, by the way, occasioned some slight contention in the Standing Committee.

THE PETROLEUM COMMITTEE is waxing somewhat warm over its report, and appears to be approaching rather dangerously near its own flashing point in wrangling over the "flash point" of the oil it is discussing. The newspaper agitation concerning the "deadly 73°," combined with the fact that Scotch oil is of considerably lower inflammability, have decided the Committee, by a majority of one, to recommend the fixing of 100° (Abel) as the minimum indication of safety. It is very significant that of the majority (seven) voting for the increase three were Scotch members, which may be taken as a further exemplification of the national shrewdness. Mr. Alexander Cross was one of the three. The effect of the Committee's decision will be to render nugatory a large number of the suggestions made to the Committee by the late Col. Sir V. Majendie. It is, however, improbable that legislation will follow the lines of the Committee's recommendation.

ICE CREAM may achieve the distinction of a place in the Schedule to the Poisonous Substances Bill if the note of alarm sounded by Sir H. Maxwell in the House of Commons on June 22 has the rousing effect intended. The hon. baronet, who represents Wigton, asked whether the provisions of the Public Health Acts and the Food and Drugs Acts were inefficient to control or prohibit the sale of poisonous compounds, such as these ices, which swarm with assorted colonics of bacilli and are served up to the youth of Britain in unwashed glasses by unwashed foreigners. It seems pretty certain that the questioner was as ignorant of the scope and application of the Food and Drugs Acts as the vendors of ice cream are of the first principles of cleanliness. Is "ice cream" a food or a drug, and by what standard should it be judged? What a neat question it would be for the Bench to determine whether a sucking-glass of "cream" containing a definite percentage of micro-organisms was "of the nature and substance demanded"! Mr. Chaplin told his questioner that the Public Health (London) Act of 1891 could be made to apply to vendors of the doubtful delicacy.

THE PHARMACEUTICAL SOCIETY, as a body engaged in secondary education, has had its merits recognised by the drafters of the Secondary Education Bill which is tabled for second reading in the Commons on the 18th inst. The object of the Bill is to reconstitute the Education Department, with a view to securing recognition for and increasing the efficiency of secondary education. This ideal is sought to be attained by having an Advisory Council attached to the Central Education Authority. The Council is to

be a corporate body and is to include nine representatives of universities and nine representatives of professional bodies. The latter are the Medical Council, Legal Education Council, Incorporated Law Society, Associated Chambers of Commerce, Institute of Civil Engineers, Institute of Mechanical Engineers, the Pharmaceutical Society, Institute of British Architects, and the Society of Actuaries. There may be some heart-burnings on account of the omissions, but the list is pretty representative of the callings in which personal professional qualifications are demanded.

CHEMISTS SHOULD NOTE the changes in Parliamentary representation, and turn them to account if possible. "The means that heaven yields should be embraced and not neglected." The Crewe Division has become re-enfranchised by the return of the Hon. R. A. Ward, whose lengthy absence had occasioned some comment. Constituents who desire to effect an introduction with a view to Poisons Bill eventualities might find no more favourable moment for approaching him than the present. Durham, too, is in the throes of an election, and both candidates could have been advantageously interviewed by chemists. The candidates are the Hon. Arthur Elliott (U.) and Mr. H. F. Boyd (R.), and the result of the poll will be known by the time the Journal is in the hands of our readers. But some good might be done by seizing the successful candidate at the psychological moment, *i.e.*, in the hour of his triumph. Gravesend is another vacant constituency, present member, Col. Dampier Palmer, having signified his wish to retire. Is the pharmaceutical calling too insignificant in a Parliamentary sense to have any hand in choosing a successor? *Verb. sap.*

MR. STRACHEY (S. Somerset) moved the reduction of the Customs vote on Friday, June 24, for the purpose of calling attention to imports of adulterated foods. He complained of the increase of the imports of adulterated butter and of milk containing boracic acid, and thought the stuff should be stopped, instead of which the cases in which adulteration was detected were merely reported to the local authorities, who more often than not declined to prosecute. The Minister in charge of the vote admitted the justice of the complaint, but thought it was hard on the Chairman of the Board of Customs to have his salary cut down because the law as to adulteration was unsatisfactory. Mr. Strachey thereupon wisely withdrew.

TUNBRIDGE WELLS AND DISTRICT CHEMISTS' ASSOCIATION.

A well-attended meeting of the above Association was held on June 23. The proceedings were of exceptional interest, the subjects dealt with causing considerable discussion. The correspondence included letters from the local members of Parliament in reference to the Pharmacy Bill, both of them having given it their active support. The replies of the medical men to the circular letter sent by the Association respecting the new B.P. were submitted to the meeting, and it was decided, in consequence of the general acquiescence of the doctors to the suggestions made, that the new B.P. be adopted on and after June 24. A letter from Mr. Gower, of Tonbridge, was next read, on the sale of the proprietary articles at unprotected retail prices. Mr. Gower proposed that the Association should communicate with the proprietors of such articles, stating the intention of its members to discourage the sale of their goods on the existing terms. A spirited discussion followed, and as a result the following resolution was passed, and sent to the Secretary of the P.A.T.A.

That this Association is prepared to support the P.A.T.A. in bringing influence to bear on the proprietors of those articles of which the retail prices are not protected, and to encourage the sale of protected preparations.

The proposal by Mr. STANLEY SMITH that all chemists should close at 4 p.m. on Wednesday failed to meet with approval, and Mr. ROGER's amendment that 8 p.m. during the winter be the general hour for closing (Saturday excepted) was also rejected. The "early" hour of 9 p.m. was the nearest approach to unanimity which was attained.—Mr. ALDRIDGE submitted some useful notes on a few of the 1898 B.P. preparations, which were duly discussed. A few brief remarks were made by the PRESIDENT on the Government Poisons Bill, but the subject was deferred to the next meeting.

PHARMACY IN AUSTRALASIA.

[From our Melbourne Correspondent.]

The publication since my last of the annual report to the Government by the Pharmacy Board of Victoria supplies a large amount of up-to-date information, some items of which may prove of interest to your readers. Up to the close of 1879 it appears that the total number of pharmaceutical chemists registered under the Pharmacy Act, 1876, was 631. From 1880 to 1897 (inclusive) 578 have been added, making a total of 1209. Of the number registered since 1879, 244 passed the Final and 67 the Modified examination of Victoria; 139 were registered under certificates from the Pharmaceutical Society of Great Britain, and 16 under the certificate of the Pharmaceutical Society of Ireland; 14 qualified by foreign diplomas, and 118 were registered by virtue of having been in business at or before the passing of the Pharmacy Act, 1876. On December 31, 1897, the names remaining on the *Pharmaceutical Register* of Victoria numbered 829. During the past year, out of 87 students entering for the Preliminary examination, which is compulsory before apprenticeship, and embraces Latin, English, and arithmetic, 42 were successful, and 18 out of 30 candidates passed the Final examination. The qualifications necessary before being eligible for this examination are: Having passed the Preliminary examination before apprenticeship, and served for not less than four years as an apprentice in the business of a registered pharmaceutical chemist, or chemist and druggist, or homœopathic chemist, and having attended one course of lectures, and passed examination in each of the following subjects at the College of Pharmacy, Melbourne, or some school or college of pharmacy recognised by the Board, *viz.*, materia medica, botany, chemistry, and practical chemistry. For the Modified examination, provided for candidates who had served a period of not less than three years' apprenticeship, commencing three months at least before the date of the passing of the Pharmacy Act, 1876, entries have never been very numerous, and last year numbered only two, one of the candidates only proving successful. In a separate report the Government Medical Officer (A. Shields, M.D.) bears high testimony to the care and thoroughness which characterise the Board's examinations, both in the written and oral departments, and were it not for their strictness the proportion of passes would no doubt show to greater advantage than it does.

THE BOARD REFERS in high terms of appreciation to the valuable aid to State education rendered by the Melbourne College of Pharmacy, "which is every year extending its usefulness." During the past year the number of students who presented themselves for examination for the certificate of the College was as follows:—Chemistry and practical chemistry, 70, of whom 29 passed; and materia medica and botany, 69, of whom 29 were successful. Of the examination, as a whole, a paragraph in the report states that the numbers attending—258—are in excess of previous years, "and embrace students who, after serving their indentures of apprenticeship in other colonies, came to Victoria to attend the lectures at the College of Pharmacy, and pass the final qualifying examination"—A fact of which, as you can understand, Victorian pharmacists are naturally not a little proud.

VERY SPECIAL ATTENTION is drawn by the Board to the position in which they are placed by the decision in the "Pink Pills" case. "The effect of this decision leaves the Board powerless to restrict the sale of other crude poisons, and allows of the general and indiscriminate distribution of such common means of suicide and murder as 'Rough on Rats,' 'Battle's Vermin Killer,' and like cheap deadly poisonous admixtures. Facilities for homicide and self-destruction have always been lamentably easy of access, and stronger powers than were believed to have been possessed under the Act were long desired. But the legal dictum takes away the only and inadequate restraining power which it was thought the Act reposed in the Board, leaving it practically impotent to give effect to the expressed intention of the Legislature as contained in the preamble of the Act—to restrict the sale of poisons for the safety of the public, and to lessen the frequency of fatal accidents through crime and careless custody. The Board makes no doubt that this matter of vital importance to the community will receive attention from the Government, and

that such an amendment of the Act will be promptly urged upon Parliament as will place the Board in a position to efficiently discharge its responsible duties to the public." I may add that the Board have been carefully considering and consulting with counsel as to the amendments to be suggested, and resolved at their last meeting that the President and Registrar should wait on the Chief Secretary, and ask that an Amending Act should be introduced into Parliament at the earliest possible moment.

THE VICTORIAN CUSTOMS DEPARTMENT has recently made a slight change in the classification of bottles containing spirits or other liquors. The tariff prescribes that bottles containing spirits, etc., being a reputed quart and under, shall be dutiable at the rate of 6*d.* per dozen; and that bottles of an imperial quart and under, and not containing spirits, etc., shall be charged a duty of 3*d.* per dozen. In future bottles containing over an imperial quart will be free, while the duty on those containing an imperial quart will be 3*d.* a dozen, and on those containing less than an imperial quart, 6*d.*

AT THE MELBOURNE COUNTY COURT an action was recently brought against Mr. S. E. D. Carlisle, a St. Kilda chemist, the plaintiff claiming £175 damages. The case for the plaintiff was that defendant had erroneously dispensed a prescription—"Fluid extract of cascara (Parke Davis), 2 ozs.; fl. extr. of liquorice, 2 ozs. (Capt. Zi. modo dictu). One teaspoonful (measured) to be taken as directed"—erroneously marking the label "one table-spoonful." The plaintiff stated that he had been severely purged, and subsequently suffered from hæmorrhago, but on admitting to the jury that he had not been incapacitated from attending to business, they returned a verdict for the defendant.

A NEW ZEALAND CORRESPONDENT, commenting on the small number of candidates presenting themselves for the Pharmacy Board examinations, throws the blame on the unsatisfactory state of the pharmacy laws, which "encourages young men to look for registration by easier and less commendable methods than examination. Each year that the passage of the Pharmacy Bill through Parliament is delayed increases the number of those who expect to be—and who, no doubt, will be—registered under a special clause, and without examination, and already the number of these is by far too many. We have at the present time many instances where young men lately starting in business—or still in the condition of assistants—are, instead of qualifying by study and subsequent examination, quietly awaiting the passage of the Bill into law, when they will register in virtue of 'vested interests.' The picture is scarcely creditable to our, generally speaking, go-ahead friends in New Zealand.

IT IS CLAIMED BY DR. GINDERS, Government Officer at the Hot Springs Sanatorium, Rotorua (N.Z.), that he has found a spring, lately opened to supply the new sulphur baths, which completely eradicates the desire for alcohol. The doctor writes:—"If I had heard this from one or two individuals only I might have disregarded it, but hearing it commented on almost daily, I have taken the trouble to look up the cases. Two of these were very aggravated examples of inebriety, whose acquaintance I first made in the courthouse, where I found myself under the painful necessity of fining each of them the usual 5*s.* and costs. They assure me that they find themselves new men since bathing in these sulphur baths, and have lost all taste and desire for liquor of every kind. Three other patients of mine, to whom I have found it necessary to advise total abstinence, corroborate this testimony, stating that they have felt no craving for stimulants since using the baths. They are very enthusiastic in the matter, and think that an asylum for inebriates should be established here at once. No doubt the craving for alcohol is kept up by a congested state of the mucous membrane of the stomach, so that the *modus operandi* of these waters is not far to seek; the congestion is relieved by the powerful determination of blood to the skin. In like manner, hæmorrhoids are cured by our acid waters, from the relief afforded to a congested liver. This should be good news for the Prohibitionists, and, in the event of their floating an inebriate asylum company, I shall expect to be remembered in the distribution of promoters' shares.

PHARMACY IN IRELAND.

[From our Belfast Correspondent.]

WHAT THE PHARMACIST REQUIRES is a new "Patent" Medicines law, because his livelihood is being filched away imperceptibly by the spread-eagle American "patent" medicine vendor. Even where a profit is allowed him, the stores descend like the harpies on the Trojan feast, and destroy what they cannot enjoy. The Proprietary Articles Trade Association is undoubtedly helping chemists, but it can hardly be considered an unmixed good that pharmacists and druggists should as it were combine to confer a sort of legal status on vendors who are not pharmacists, and who cannot be considered the friend of the lawful chemist. It is said that the latter has his "prescriptions" to fall back upon, but the recent decisions in Irish Courts of Justice have given such a fillip to companies that the aforesaid monopoly is likely enough to disappear before long.

BESIDES, THE MEDICAL MAN in many instances overlooks the interests of the pharmacist and himself by prescribing some proprietary drug. No one is advantaged by this, except the proprietor; the patient is only charged more heavily. The B.P., with its vast reserve of condensed pharmacy, should surely answer all the ends of a diagnosis. It is somewhat interesting to contemplate the efforts of the pharmacist to sell his own article as "equally good" when compared to the required quackery stuff. The customer, strong in the convictions which the advertiser has not failed to reiterate ceaselessly, that "substitutions must not be accepted," for a time smiles courteously, but firmly refuses. Nevertheless, his manner is as of one who just expected such by-play and duplicity, but was on that account more and more confirmed that the "mellow medicines for mournful men" had gained another trumpeting testimonial. His faith even surpasses that of the young lady who, on feeling faint in a theatre, recovered on receiving from a doctor friend a medical tablet to keep in her mouth, the tablet being—a button!

THE WELL-MEANT EXPLANATIONS of the pharmacist, who is able to give a better and a cheaper medicine, though, of course, not coupled with the hog-wash of testimonialising, are so much waste time. His very earnestness is misread (by old ladies who consume the fag-end of their lives in squandering their money in order to prolong their days) as badness of heart. A chemist I know is so much aware of the absolute adamancy of this class of people that he immediately complies with their request. This excites their suspicion, and they invariably ask a number of questions and examine the bottle well before leaving. Their credulity is not less remarkable than the peculiar disposition which makes them shun all medicines but "one." Some prefer "Brown Bolts for Bilious Beefeaters"; others would live and die by the Whangdoodle variety, whilst each in turn eulogises Father Brown's Elixir, or Holt's curc for the mumps, etc. To mention a case in point. A medical gentleman informs me that he is aware of two cases where death was accelerated, if not caused, by the taking of certain anti-febrine powders without the physician's cognisance. Certainly the indiscriminate drug vendor ought to be suppressed, or at least the law should make him prove by test cases that his "cure" can do what he declares, as in the famous case of the Carbolic Smoke Ball Company. Phenacetine relieves pain, eocaine toothache and neuralgia—but neither will create a new nerve or a sound tooth. But the *fin-de-siècle* pill! What will it not do? It is a travesty of pharmacy and an outrage on the memory of Hippocrates.

I HAVE LYING BEFORE ME a sheaf of "patent" advertisements which advocate the use of marvellous and infallible remedies, culled from a bunch of religious weeklies—the *British Weekly*, *Methodist Times*, *Christian Advocate*, *Life of Faith*, *Wesleyan Mission Notices*, etc. One of them in the Scriptural, as distinct from the flamboyant style, gives an interview on the cure of a hopeless consumptive:—"A skeleton, bad cough, and night sweats. The doctor gave no hope of recovery, said he could not get better. Got a dose of C—'s medicine and a rub with liniment. The doctor when he came again expressed surprise at the change, and told us to continue the medicine. He had no idea what medicine we were giving him." It is thus seen that this "Lourdes" miracle-worker does not hesitate to sneak in behind a legal practitioner's back to ply his quackery. If the patient had died no doubt the doctor would have been blamed. He employs a

medical assistant (ungraduated) and gives personal consultations. Is it not a mischievous thing that reverend editors whose editorials teem with sanctified admonitions should countenance such illegal practices? The system is well worked; the journals being religious bring shoals of poor factory-girls, etc., to the mill of the quack, the latter pays the journal part of the profits, and of course the pharmacist, whom the law has appointed, is robbed.

THE "METHODIST TIMES" last month contained a most lurid and overwhelming diatribe against Bryant and May's matches, urging its readers not to use them because the "matches poisoned those who made them." In the very same issue of that journal some dozen advertisements appear of quack drugs which "cure" everything. Now these vile "medicines" poison the thousands who use them as effectually as yellow phosphorus. The exposure of Hernia Specialists and Harness's Electric Belts, etc., is lost on such journals. The above periodical appeals to the opinions of Sir William Thompson and Sir W. Ferguson as to the demoralisation of vivisection. What, then, has it to say to the opinion of Sir Walter Foster, M.P., an eminent London physician, who declared, "in the interest of the public certain blatant advertisements of drugs ought to be stopped"?

THERE OUGHT NOT TO BE two measures of morality even in a religious paper. These quacks are all recognised by several well-marked characteristics:—1. The doctor declares positively that the patient cannot live (this in spite of the fact that medical reticence is a proverb). 2. After one dose of the quack elixir marked improvement sets in. 3. The patient throws away his crutches or his walking-stick, or anything that will introduce a dramatic climax. The fact that he throws away his money is not mentioned. One victim's testimonial declares that he carried his crutches to the druggist, and yet another chopped his to pieces. There is no reason given for these strange actions, except indeed that the performers were mad, which is not an unlikely result of quackery. Some years ago in Belfast a quack's performance drew large crowds of old men with stiff joints. Their muscles were rubbed with liniment. The roads were littered with crutches, sticks, bandages, etc. The authorities tried to put it down; his made it worse. The doctors emigrated. But the craze passed, and it is common to hear a crippled patriarch remark: "These crutches will never be as good as the old ones." Another old man who had for ten years never come down the stairs without assistance, the morning after the "cure" surprised his family by bounding down the steps like a deer. This was blazoned abroad. The second morning he came down the stairs alone—and broke his neck. That was not blazoned abroad. One is astonished that clergymen of all sects, who uphold the inviolability of their own order, should, by means of public testimonials, eulogise the vilest and unhealthiest concoctions, and thus depreciate the inviolability of the second highest order in the State.

Mr. A. J. O'SHEA, L.P.S.I., Donegall Street, has been appointed apothecary to the new Mater Infirmorum Hospital.

A YOUNG LADY partaking of strychnine from a plate (which had been set as rat-poison) in the presence of her lover, a Mr. Maxwell, of Ballymena, is by no means a cheering spectacle. The fact that it occurred suggests that human nature is still a mystery; that the Coroner system needs a stimulus, especially in country districts; and, further, that the attempt to make a rat-poison itself without any "kitchen" is nearly as good as trying to make a dog drown himself without the stone round his neck.

A WELL-KNOWN RAT-POISON used with great success by professional rat-catchers is a mixture of aniseed, meal, and plaster of Paris. This would not be so dangerous in farmyards. The rodent devours it greedily, and the plaster of Paris, being a great absorbent of moisture, hardens into a flinty mass, and—hey presto! In the days when Hercules Street occupied the site of Royal Avenue in Belfast, rats were numerous.

A CHEMIST in that vicinity was pestered with their invasions. He laid poison on herrings, meat, etc., without success. The linseed meal drawer was cleaned out twice. At last a device suggested itself. He carefully ground up a large dose of arsenic amongst the linseed meal, and the next morning a score or so of belated stragglers had bivouacked near the field of battle.

ANNOUNCEMENTS.

CHEMISTS' ASSISTANTS' UNION.—A meeting will be held at the Horseshoe Hotel, Tottenham Court Road, W., on Thursday, July 7, at 8 o'clock, to elect a Council and draft the rules. It is desired that this meeting should be thoroughly representative, and that every assistant who can will attend.

THE POISONOUS SUBSTANCES BILL.—A meeting of the Manchester Pharmaceutical Defence Association will be held on Thursday evening, June 7, in the Chemical Club, Victoria Hotel (Room No. 68) for the purpose of discussing the above Bill, and to which all chemists are invited. It is suggested that the said Bill is both unsatisfactory and incomplete, and that amendment is necessary. Every chemist in the district is therefore requested to attend, and so assist in adding weight to any amendments that may be forwarded at this meeting. The chair will be taken at 8 p.m. by Mr. Walter Gibbons.

THE ROYAL PHOTOGRAPHIC SOCIETY will hold its forty-third annual exhibition from September 26 next to November 12, in the Gallery of the Royal Society of Painters in Water Colours, 5A, Pall Mall East, London, S.W. Entry forms may be obtained on application to the Secretary of the Society, 12, Hanover Square, London, W.

ACCIDENTAL POISONING CASES.

OXALIC ACID has been taken in mistake for Epsom salts by Walter O. Lamburd (39), potman, of Islington Green, who died as the result. The packets containing the Epsom salts and the poison were both kept in the same room, hence the mistake. A jury found that death was due to accidental poisoning.

A BOTTLE MARKED "LAUDANUM" was found close by Samuel Townley (56), painter, of Hurst, who was sitting in a chair unconscious. He was taken to Ashton Workhouse Infirmarium, where death occurred on Wednesday, June 22. He told the nurse that he took the laudanum to relieve pain. "Misadventure," a jury said.

AN OVERDOSE OF CHLOROFORM self-administered to induce sleep, is supposed to have caused the death of Gladys W. Hewitt, nurse-maid, at Pensnett, on Tuesday, June 14.

SULPHURIC ACID, kept for cleaning corks, was taken in mistake for medicine, by W. J. Womack, a newsagent of Bethnal Green, after a heavy drinking bout. A jury returned a verdict of "Death by misadventure."

PERSONAL NOTES.

MR. C. E. CORTIS STANFORD, B.Sc., eldest son of Mr. Edward C. C. Stanford, an old pharmaceutical student, has passed the final professional examination for the Glasgow University M.B. degree.

MR. C. T. THONGER has purchased the business of his father at Harborne, Birmingham, recently sold by the Sheriff under an execution order.

MR. MARTIN MAGOR is resigning his seat on the Aston District Council.

MR. G. W. KENDALL, chemist and druggist, has disposed of his business at 163, Dewsbury Road, Leeds.

LIEUTENANT-COLONEL CLIFFORD PROBYN was last week elected Sheriff of the City of London, at the Guildhall. Colonel Probyn is a member of the London County Council, and this is the first occasion on which a member of that body has been appointed to the office of Sheriff for the City.

MR. ERNEST ALBERT UMNEY, pharmaceutical chemist, has been admitted as a partner in the firm of Wright, Layman, and Umney, Southwark, London. Mr. E. A. Umney was a pupil with Mr. Martindale, of London, and was the Pharmaceutical Society's silver medallist in practical chemistry in 1897.

Pharmacy and the Allied Sciences

REVIEW OF CURRENT WORK.

G. Dickson and T. H. Easterfield point out that well-burnt charcoal reacts readily with fuming nitric acid, the action being accompanied by a considerable rise of temperature, and that when boiled for twenty-four hours with fuming nitric acid, the charcoal goes entirely into solution. On dilution of the solution with water, a black, amorphous substance is precipitated, resembling the "mellogen" of Bartoli and Papasogli, whilst mellitic and non-crystalline acids remain in solution. The black, amorphous substance is easily soluble in alkali, and on oxidation by alkaline permanganate yields oxalic and mellitic acids in about equal proportions. Charcoal was found to yield 25 per cent. of its weight of crystalline ammonium mellitate by boiling it with fuming nitric acid for twenty-four hours and further oxidising it by adding potassium chlorate to the boiling solution; the organic acids, after precipitation as barium salts, are converted into ammonium salts. The yield of mellitic acid varies only slightly, whether the charcoal contains 2 or only 0.2 per cent. of hydrogen. Coal under similar conditions gives only a small yield of mellitic acid. Even nitric acid of sp. gr. 1.1 can oxidise well-burnt charcoal. After boiling continuously for seven days, the charcoal is changed to a black, impalpable mud, soluble in alkali. The nitric acid solution contains mellitic but no oxalic acid.—*Proc. Chem. Soc.*, 197, 163.

Under this name a mixture has been introduced for making a liqueur. It consists of angelica and coriander fruits, 100; anise fruits, 15; fennel herb, 10; peppermint herb, 50. The herbs are cut up very fine while the seeds are left whole. Chlorophyll makes a suitable green colouring matter, extract of curcuma is serviceable for yellow, and kermes for red.—*Pharm. Post*, xxxi., 246.

A. G. Perkins finds that the Indian dyestuff "Waras"—a purplish powder which covers the seed pods of *Flemingia congesta*, an erect, woody shrub of Africa and India—in its general properties and microscopic appearance closely resembles kamala. The principal crystalline constituent found in the powder was "flemingin," $C_{12}H_{12}O_3$, an orange-red powder consisting of small, prismatic needles melting at 171 to 172°. In appearance and numerous properties it resembles the rottlerin of kamala, but is distinguished from that by its solubility in alcohol, and by the browner tint of its alkaline solutions. In an alkaline bath it dyes silk a golden yellow, and is a stronger dyestuff than rottlerin. On fusion with alkali it gave acetic acid, salicylic acid, and an acid of higher melting point which was not identified. Another constituent, "homoflemingin," was present in minute quantity only. It forms glistening, yellow needles which melt at 164° to 166°, and possess properties resembling those of flemingin. Two resins were extracted, the first of high melting point, described as a brick-red powder soluble in alkali, with a deep brown tint. It yields acetic and salicylic acids on fusion with alkali, and dyes silk in shades which are redder than those produced by flemingin. The resin of low melting point is a deep orange-brown, transparent mass which melts below 100°, is soluble in alkali with an orange-brown colour, and closely resembles the resin of low melting point of kamala. On fusion with alkali, acetic and salicylic acids are obtained, and on boiling with nitric acid (sp. gr. 1.5) oxalic acid is formed. It is concluded that the above substances are closely

related to, though not identical with those present in kamala. Waras dyes silk a golden-yellow shade, and is a much stronger dyestuff than kamala.—*Proc. Chem. Soc.*, 197, 162.

In a work on the algal flora of the Hamburg waterworks, Herr O. Strohmeier states that the green algæ—*Cladophora*, *Spirogyra*, *Enteromorpha*, *Stichococcus*, etc.—have a very powerful effect in purifying water by the destruction of bacteria through the agency of the oxygen which they exhale. Those algæ, on the other hand, which are enclosed in a mucilaginous sheath, especially diatoms, have a very prejudicial effect on drinking water, by stopping the filters through which it passes.

T. B. Osborne and G. F. Campbell have continued their useful work on vegetable proteids, those of the horse-bean (*Vicia faba*), vetch, and soy-bean (*Glycine hispida*) being the latest dealt with. They show that the seeds of the pea, lentil, horse-bean and vetch agree in containing legumin, legumelin and proteose, whilst the three first-named also contain vicilin. A careful comparison of the reactions and properties of those proteids has revealed no difference between preparations of the same substance from different seeds. The globulin legumin is the chief proteid constituent of the seeds, as much as 10 per cent. having been found in the meal of vetch seeds, whilst the pea, lentil, and horse-bean contain a mixture of it, with vicilin, to the extent of 10, 13, and 17 per cent. respectively. No method for the quantitative separation of legumin and vicilin has yet been devised, but it is stated that the lentil contains most vicilin—probably about one-third of the mixed globulins—and the horse-bean least. Vicilin is apparently not a derivative of legumin, as it is absent from vetch seeds, and it is remarkable for containing less sulphur than any other known proteid. Legumelin is either an albumin or a globulin, probably the former, and has been found in all the leguminous seeds examined by the authors, except the white bean (*Phaseolus vulgaris*) and the blue and yellow lupin. The proportion of this constituent in seeds ranges from 2 per cent. in the pea to 1.25 per cent. in the lentil and horse-bean. Proteose is present in small amount only, the pea containing about 1 per cent., the horse-bean about 0.5 per cent., and the lentil and vetch still less.—*Journ. Am. Chem. Soc.*, xx., 393, *et seq.*

The yellow soy-bean and a variety known in Japan as *Kiyusuki diadzu*, have been examined by T. B. Osborne and G. F. Campbell, the result of whose investigation is to show that the chief proteid constituent of the beans is "glycinin," a globulin similar in properties to legumin, but containing nearly twice as much sulphur, four-tenths more carbon, and one-half per cent. less nitrogen. Its percentage composition is given as follows:—Carbon, 52.12; hydrogen, 6.93; nitrogen, 17.53; sulphur, 0.79; oxygen, 22.63. The soy-bean also contains a more soluble globulin which resembles phaseolin in composition and reactions; but the amount of this proteid present is small. Besides these globulins about one and five-tenths per cent. of the albumin-like proteid legumelin was obtained; it had previously been found in the pea, vetch, horse-bean, lentil, adyaki bean, and cow-pea. Finally, a small quantity of proteose was found in the soy-bean.—*Journ. Am. Chem. Soc.*, xx., 419.

F. Escombe supports the view of Gorup-Besanez, that during germination amides and amido-acids perform different functions. The former are produced only in small quantitative by direct hydrolysis, being chiefly formed synthetically from the further transformation of amido-acids and of nitrogenous sub-

stances derived from the reserve carbohydrates. This synthesis of amides can take place in the dark, and the further stages, at all events, of proteo-hydrolysis are due to the action of enzymes. It is most probable that proteids cannot be produced from amides in darkness, and nothing can yet be said as to the rationale of their regeneration in the light. According to Sig. N. Passerini (*Bull. Soc. Bot. Ital.*, 1898, p. 71), it is common, under ordinary circumstances, for not more than 20 per cent. of the seeds of the olive to germinate. If immersed for ten minutes in water at 40°-50° C., they germinate more rapidly; a temperature of 60°-70° in the water increases the proportion that germinate; while immersion in water at 90° destroys the power of germinating.—*Science Progress*, 1898, p. 219.

F. Günther has modified his previous statement that Maclagan's test for the purity of cocaine hydrochloride could not be depended on, by now merely claiming that the liquid above the crystalline precipitate should remain clear. In addition he states that, in carrying out Maclagan's test, as described by Böhringer (*P. J.*, lx., 449), two solutions should be made, each with 0.10 gramme of the cocaine hydrochloride in 85 C.c. of water, one of which should remain clear after the mere addition of 0.2 C.c. of .960 liquor ammonia, and the other solution should give a crystalline precipitate within fifteen minutes of vigorous stirring.—*Pharm. Centralh.*, xxxix., 383.

E. Bourquelot and H. Herissey confirm the statement of Poumède and Figuier, published in 1847, that the gelatinous body of gentian root is pectin. They find that a slight hydration of the gelatinous matter takes place with water at ordinary temperatures, and to a greater extent if the resin present in the root be first removed, as well as when a trace of acid is present. The pectin thus obtained with the aid of mineral acids, however, differs in optical activity from that obtained by water alone.—*Journ. de Pharm.* [6], vii., 473.

These are new products obtained, according to A. Claus, by heating o-acetyl-*p*-bromophenol or the corresponding chlorophenol for some time on the water bath with the theoretical proportion of phenylhydrazin in acetic acid solution. The bromo compound separates from alcohol in yellow shining leaves, larger crystals being slowly deposited from dilute solutions; the latter melt at 167° C. It is insoluble in dilute alkali. The chloroxazolide is obtained in yellow crystals melting at 172° C.—*Zeit. d. allg. oest. Apoth. Ver.*, lii., 305.

H. K. Miller is of opinion that the practice of wiping flasks with a dry cloth just previous to weighing them is the cause of serious errors. In some fat determinations he noticed a considerable increase in weight. On making a second weighing of a flask containing an oil extracted from a sample, and careful experiment led to the conclusion that in wiping the flask it became electrified; the static charge, acting on the floor of the balance, appeared to induce in it a charge of opposite character, and the mutual attraction between the two charges seemed to have the effect of increasing the weight of the flask. The potential of the charge, it is pointed out, would vary with the atmospheric conditions, and with the manner of wiping the flask. Thus, by using a linen cloth, in very dry weather, it was found possible to produce such a charge on a 100 C.c. flask as to require 0.08 Gm. additional weight to restore equilibrium. Since, however, a high charge like this would be rapidly dissipated, the flask would appear to lose weight. It was found that a charge

which apparently caused an increase in weight of about 0.01 Gm. would be retained quite a long time, and the error thus introduced might easily be overlooked. Moreover, a small charge was found to be retained for many days on a flask kept in a desiccator. Whilst, therefore, in damp weather a charge would readily pass off and not give rise to an error, on a very dry day the practice of wiping glassware just before weighing seems liable to cause serious errors.—*Journ. Am. Chem. Soc.*, xx., 428.

From observations on material consisting of about 2000 embryos of barley, Herr J. Grüss asserts that, in the germination of seeds, cane-sugar is formed in the cell out of dextrose; cellulose and starch being then produced out of the cane-sugar. In the formation of the starch and cellulose, no substance belonging to the group of aldehydes is set free in the molecules of sugar.—*Ber. Deutsch. Bot. Gesell.*, vol. xvi., p. 17.

In a paper read before the Quekett Microscopical Club (*Journal*, 1898, p. 1) Mr. G. Masee supports the view that the *Basidiomycetes*, and among them the *Agaricineæ*, constitute the most modern group of fungi, and the one most perfectly adapted to existing circumstances, as is shown by their universal distribution and their immense numbers, amounting to about 11,000 existing species of *Basidiomycetes*. The *Clavariaceæ*, with about 300 species, form the lowest type, and exhibit the smallest amount of differentiation. Then come the *Thelephoreæ*, about 1000 species, which exhibit the gradual evolution of a method for the protection of the hymenium from rain and dust. Next the *Hydneæ*, with about 1000 species, in which we see the introduction of a new plan for increasing the area of the hymenium by covering the spore-bearing portion with densely-packed slender teeth. Next the *Polyporeæ*, about 2500 species, in which the same idea is carried out in another way, the hymenium constituting a lining to the cavities of innumerable slender tubes. Finally, the *Agaricineæ* constitute the most modern and the most highly organised group, comprising the enormous number of about 6000 species.

Dr. A. Nestler describes the mucilage-cells in the leaves of various species of *Malvaceæ*, which he regards as organs for the absorption and retention of water. They are epidermal cells in which the cuticle projects into the interior in a conical or funnel-shaped form, presenting the appearance from the outside as if the cuticle were perforated. The nucleus is always situated near the mouth of the funnel. It is the inner and lateral walls of these cells which become converted into mucilage. The author finds Böhmer's hæmatoxylin the best reagent for demonstrating the mucilage-cells, imparting to them a deep blue colour.—*Oesterr. Bot. Zeitschrift*, 1898, p. 94.

In galls produced on *Ulmus campestris* by the attacks of an aphid, *Schizoneura ulmi*, Sig. N. Passerini finds a gum differing in its properties from other gums—arabin, cerasin, etc.—and from mucilage, dextrine, and other carbohydrates found in vegetable tissues. The solid portion of the gum consists chiefly of a gummy substance which is precipitated by alcohol, the precipitate being amorphous, yellowish, tasteless, very soluble in water, with the appearance of gum arabic, but differing from that substance in several properties. It is strongly dextro-rotatory, and has an energetic reducing action on copper salts.—*Bull. Soc. Bot. Ital.*, 1898, p. 70.

PHOTO-MICROGRAPHY.—IV.

BY EDMUND J. SPITTA, L.R.C.P. LOND., M.R.C.S. ENG., F.R.A.S.

Achromatic and Apochromatic Objectives.

We come now to a far more difficult branch of the subject, namely, the selection of objectives. These are of two kinds, the achromatic and the apochromatic. The former have been in existence for years and are being slowly and steadily improved both in quality and definition, whilst the latter are of more recent invention. So far as the superiority which the apochromatics possess over the achromatics, there is no possible room for doubt, but seeing they are so very much more expensive and that achromatics of recent years—since the introduction of the Jena glass—have reached to so far a greater pitch of perfection than formerly, it will be advisable to discuss the use of both kinds.

The achromatic is built on an entirely different principle to the apochromatic, for even in the best makes, the inevitable residual colour of the secondary spectrum is always well marked: Indeed, with this type it is impossible with our existing knowledge to entirely remove it. Opticians have striven for years to improve their general performance, but no achromatics seem to perform so well as those lately introduced by Mr. Conrady. I have only been able to test a few of the lenses, because his series is not yet complete, but those that have been tested show, besides an excellent performance on all the recognised test objects, a very great advance in one particular, and it is this: The ordinary achromatic will not stand eye-piecing beyond five or seven diameters at the most without producing a "rotten" image, but the objectives in question will work easily with ten, and, using suitable objects, even with an eye-piece of eighteen. Here we have, then, a decided improvement, and I understand that it is dependent upon an entirely different line of thought in their construction. Mr. Conrady considers, *ceteris paribus*, that the real improvement in the construction of achromatics of the future will lie in the careful uniting of equal phases of the rays to be joined in one focus, and inasmuch as his results so overpower those hitherto obtained, I believe his theory worthy of most careful consideration. Notwithstanding what has been said, some very fine lenses do already exist, such as No. 2 Leitz, Nos. 6 and 7A Richert, the 1/10th immersion by Leitz, and the semi-apochromatics by Reichert, let alone some excellent objectives recently brought out by the old-established firms of Ross, Beck, Wray, and others.

But in making a selection we must first pause to consider how we are going to photograph at all with a visually constructed objective. Let us suppose, for instance, we put a visually constructed inch on to the microscope, focus, and take a photograph. We should find (supposing we were photographing the proboscis of a blow fly) that all the suetorial tubes which had been focussed so carefully on the ground glass were absolutely out of focus on the plate. The reason of this is not far to seek. Microscopical objectives computed for visual use are all constructed to give their image by the union of the yellow or yellow-green rays of the spectrum, because the eye perceives this colour more powerfully than any other, hence it is obvious, inasmuch as each colour in the achromatic brings its image to a focus in a different plane, that if we focus in yellow the image produced by the violet rays, which are those used in ordinary photography, will be outstanding at another point on the axis. In photographic lenses this trouble is got over by uniting with the yellow some portion of the violet end of the spectrum, so that when we focus in the yellow we unconsciously focus in the violet at the same time. By this means it is very evident, if the optician has done his work well, our visual focussing will produce a sharp picture on the negative, although taken by the violet ray. There is only one

practical way of getting over this difficulty—using visually corrected objectives for photography—and that is to photograph in monochromatic light and to use a correspondingly stained plate. Yellow light is by far the best, and it works well with the Edward's plate; but what I think much better is to do away with the visually corrected achromatic altogether, and to employ objectives corrected for photography. Wray sells an excellent series, and I have often obtained with them the very best results, and with some specimens, when using low powers, almost indistinguishable from that obtained by the use of apochromatics; although this is not usual unless the object photographed be one with coarse detail, and so not require high N.A. to resolve it. Those, therefore, who must content themselves with the cheaper form of lenses, are strongly advised to buy achromatics especially arranged for photography, although they are of limited use for serious visual purposes. The reader may think this not a little curious, for what can be brighter and more crisp than the image produced by a good photographic lens? But the fact is, the corrections that have to be applied to a microscopical objective are of a far higher order than those which are sufficient for even the best of photographic lenses, errors left outstanding as negligible in the latter are of quite sufficient importance to destroy the best performance of the former. I must caution those who are commencing the subject not to be led away by purchasing achromatics said to be made for the two-fold purpose, visual and photographic. There are other optical reasons which must, both theoretically and practically, in the existing state of our knowledge, forbid anything like perfection in these lenses for double use. At their best they are but a compromise, and so do not give the best of results for either purpose.

The apochromatic system, of which I shall now speak, is necessarily a very intricate one, for a very large number of lenses enter into the formation of one combination. They are therefore necessarily very costly, but the resulting effect is a perfectly colourless image of great excellence, brilliancy, and purity. Readers are also further cautioned most strenuously to avoid apochromatics which have been brought out of cheap design, claiming to be as good as the more expensive ones. I have examined most carefully one of this make, and found that it was not perfectly apochromatic, as stated, and that its N. A. was but slightly over 1.26, although sold as 1.40.

Photographically speaking, one great advantage of the real apochromatic system is that photographs can be taken in any colour, for all rays of the spectrum are sensibly brought to a common focus. It will be seen at once how very important this is, especially when dealing with objects of feeble contrast in colour, such as the bacilli of diseases. It may be mentioned that owing to their feeble staining, in some instances the only chance of making a good photograph is to use some coloured screen, whereby a colour contrast can be produced between the bacillus and the background. This done, a good photograph can be obtained provided the lens focusses the same in all colours, but it is equally obvious that if an ordinary achromatic were used the final result must of necessity—there is no discussing the matter—be greatly inferior. We have only to look at the photographs taken of these objects in past years by achromatics of the then highest order, and compare them with those taken at the present day by means of apochromatics. The sum total, then, of the remarks on lenses comes to this:—When photo-micrographs are desired of the very finest order and of high amplification, such as photographs of diatoms or bacilli at 1000 or 2000 diameters, nothing will give the perfection required save the apochromatic used with its compensating eye-piece; if, however, medium power work up to, say,

300 or 400 diameters, is the sole ambition of the photographer, then he may confidently rest assured his results will be worth looking at should he employ achromatics well corrected for photography. It is an open question whether these photographically corrected achromats should be used with an eye-piece or not. Personally I have no hesitation in saying I prefer that they should; but it is equally well known that in some photographers' hands with certain specimens, and certain degrees of magnification, excellent results have been obtained without. But a doubt still remains in one's mind even then whether better results still would not have been produced should an eye-piece have been used. With the apochromatic system, inasmuch as part of the final correction of the objective is obtained by the use of the special compensating eye-piece, so it is absolutely necessary to use one with this type of objective, and I think that of all the compensating eye-pieces made the best results are usually obtained in photography with those specially designed for projection purposes. They are termed "projection eye-pieces." These, with suitable camera length, will nearly always fulfil the requirements of the photomicrographer, but at times when he wishes over 1000 diameters it may be necessary to put them aside and use the ordinary compensating eye-piece, as they extend so much higher in power, even up to 27 diameters. This is another superiority of great service with apochromatics, they bear eye-piecing to almost any amount without producing a "rotten" image.

Dry and Immersion Objectives.

Whether apochromatic or achromatic, objectives are of two kinds—"dry" and "immersion"—by which is meant that one is used dry as it comes from the maker, and that the other—to insure its best optical performance—needs a drop of cedar wood oil or some other suitable fluid interposed between the front lens and the cover-glass of the specimen. Both these varieties must be explained, but to do so intelligibly it will be necessary to premise my remarks by considering for a moment, in as few words as possible and in a popular manner without mathematical detail, the subject of refraction of light.

Light is always supposed to travel in straight lines—"rectilinear propagation" as it is called. Bundles of rays issuing from an illuminant may not be parallel amongst themselves, constituting what is called diverging or converging light; or they may travel side by side with unerring rectitude—such as we meet with in the light coming from the stars or the sun—when they receive the technical name of "parallel light." The path of any ray in a given medium is always straight until it meets with another medium more or less dense than itself, when, with one exception, it is bent aside, undergoing what is called "refraction." After such bending, however, it will again resume its rectilinear propagation along its new path, until it meets with a fresh medium, when on entrance it will be bent again if the density be different. Change of density then of the medium is the cause of refraction, and this must be held in mind. It will be well now to briefly point out the nature of the alteration of direction brought about by the change of medium, and for purposes of description have resort to Fig. 1.

Let A B C D represent the outline of a circular vessel, A C being the water line, and B D drawn at right angles to this level passes from B to D through E—which direction is called the "perpendicular" or "normal," all angles being referred to this line. When the beam is incident along B to E perpendicularly into the new medium, there is no refraction or reflection—the only instance where it undergoes no bending—for it passes on into the water, uninterrupted following the course of the line E D. But

when it is incident at any other position—say at m along m E there is refraction at E, for the beam will be found to strike the point n. Suppose it is incident at m' along m' E, then there is also refraction at E, for the ray will be found at n'.

Snell made a celebrated investigation concerning this bending of the rays, by which their path can be predicted. Were it not for his discovery, about to be explained, we should not have had the grand computations of lenses with which, in the present day, we are all so familiar.

He first drew a line from m to meet B E at o, and another from n meeting E D at p. The lengths o m and n p were measured and divided one by the other; a quotient was obtained.

Now what he discovered

was the fact that wherever the angles were taken, whether from m or m', the quotients, in all cases using water and air, came out the same viz., 1.333. This was called the refractive index of water. Other substances were tried, and each substance had its special refractive index. Flint glass, for instance, is found to be 1.54 to 1.64, according to its manufacture, and so on with other substances, complete lists being found in all books upon the subject. If the reader be mathematically inclined, he will at once see these lines, m o, n p, really represent the sines of the angles B E m and n E p respectively, so that, continuing our precept, the sines bear certain definite ratios one with the other wherever the incident light striking E comes from; that is, the ratio between o m and n p, which is about 4 to 3, holds good, whether the ray starts from m or m'. It is quite evident now that we can calculate where the ray will strike A D, after starting from any given point in B C. For example, let m strike E to make an angle m E o, say, of 45°. It is required to find the angle n E p, so that we can draw n E correctly. We take out of the tables the sine of 45°, and find, roughly speaking, it is 0.7, and multiply that by 3 and divide by 4, which gives us 0.5. Resorting to our book again, we find 0.5 is the sine of 30°, so that 30° must be marked off from D to find the line n E. Although, simply put, this is the maxim which mainly pervades the optician's mind in constructing new lenses. As a matter of fact, the details become operose in real calculations, as different colours are refracted at different angles, and the problem, where many lenses are concerned, becomes intensely intricate. But the law underlying the calculations is the same from beginning to end. The same law reversed of course equally holds good when rays pass from the water into air, and when passing from one glass to another, although then with certain modifications.

One more remark on the subject yet remains to be said. Seeing that n' passing to E becomes refracted to m', what happens to a ray starting about x? It will pass into the air and graze along E. C. If this be true what will take place if one starts still nearer A, say at z? This ray cannot get out of the water at all and is said to suffer "total reflexion" at E, for it appears again at z'. There is one angle then it is very evident, which is the last, that allows a ray to get out; this is called the critical or "limiting angle," and is known for all kinds of glass.

Let us now see how these remarks apply to our subject. Con-

FIG. 1.

sider Fig. 2. Let *c* be the cover-glass, having a refractive index of about 1.5, and *L* the front lens of the objective. Also consider *A B* an incident ray upon the cover-glass at *B*. As it enters a denser medium than air, according to our precept it must be refracted towards the normal *B N* and follow the path shown as *B D*. When it arrives at *D* (as in the case of what happens when using a dry lens) it passes into air again—a rarer medium so is bent away from the normal *D N'* as much as it had been bent towards *B N* the previous normal on entering the glass, thus continuing its course along *D E* to *E*; *D E*, therefore, is of course parallel to *A B*. It will now be readily understood, without much consideration, that any rays lying between *D E* and the edge of the objective (where *D E'* touches it in the diagram) will be lost to the microscope, as they have no chance of entering the front lens of the objective.

FIG. 2.

But let us consider what happens if we place between the lens and the cover-glass a drop of fluid, say, cedar oil, which has the same refractive index as the cover-glass itself, viz., 1.5. Follow the diagram, commencing at the right hand, and consider the ray starting from *A'*. Arriving at *B*, it will be refracted to *D'* just the same and for similar reasons as *A B* was refracted to *D*. But notice now what happens. As the emerging ray at *D'* enters a fluid of the same refractive index as the substance it has left, it continues its path uninterruptedly in a straight line to *F*, which enables the object-glass to gather up the whole of the rays that were lost when the ray entered air, as shown on the other side of the diagram instead of the oil. It is obvious, then, why immersion lenses give so much more light.

The same class of reasoning holds good with the mounting media of specimens. If they are mounted dry, which means in air, many diffractive beams which pass from the object, all of which, theoretically, if it were possible, should be caught up by the objective, are lost; whereas, if mounted in Canada balsam (refractive index, 1.5), many more may be caught. This will be referred to later, and explained properly, when speaking of mounting materials.

It is very obvious, then, that, theoretically, dry objectives cannot pass so much light as immersion ones, and this is practically found to be correct. What is more to the point, the argument also shows that the limit of dry objectives is *N. A.* 1.0, because all the outside rays will be lost without the interposition of some homogeneous substance to optically join up the gap between the objective and the cover-glass. It is for this reason that immersion lenses are often called homogeneous systems.

Another point not to be forgotten is that the cover-glasses vary in thickness and density, so the bending of *B D* may vary in direct accordance; and it is to obviate this that dry lenses of high *N. A.* are provided with a "cover-glass adjustment," which so regulates the performance of the objective as to accommodate it to the differences in question. To practise the user to arrange the adjustment, as well as for other reasons, the firm of Zeiss sell a

slip upon which several cover-glasses of known thickness are placed, and as the firm mark the adjustments for different thickness of cover-glass on the objective itself, it enables the beginner to practise over and over again the art of getting his adjustment correctly by sight, and then proving his result, until he is quite an adept, by comparing the figures on the cover-glass with those on his objective. This object lesson, which requires some patient practice and learning, is of great service, especially to the photo-micrographer, as it will be seen hereafter when speaking of depth of vision in lenses. It will then be shown a great deal of accurate vision is dependent on the accommodation of the eye—hence the greater amount of accuracy in focussing, etc., is required when photographing an object where the accommodation of the eye does not come into play, and every adjustment to improve such focussing must be employed.

Inasmuch as the presence of the cedar oil forms a homogeneous system, so it is obvious that any small variation in thickness of cover-glasses does not make any difference; hence the majority of immersion lenses have no cover-glass adjustment. Messrs. Powell and Lealand, however, still consider that, notwithstanding what has been said, the very finest of definition under certain circumstances may be only secured by a touch of a cover-glass adjuster, so they provide their immersion objectives with them. Dry lenses which are not provided with a cover-glass adjustment have to be corrected by pushing in or pulling out of the draw-tube of the microscope, which optically amounts to almost the same as the use of the cover-glass adjuster, lengthening the tube with thin glasses and shortening it with thick ones.

The careful reader will now very readily understand what is meant by modern objectives having written upon them very plainly—"For 170 Mm. tube" or perhaps "Tubuscul 250 Mm.," and so on—it is the length of tube for which the objective has been originally corrected with a given thickness of cover-glass. Each maker has his standard thickness of cover-glass, and this can be furnished on application. With low powers all these minutiae vanish to a great extent, but when dealing with high power dry objectives they become of the most paramount importance if perfection of result be aimed at.

(To be continued.)

SELECTED FORMULÆ.

WOOL-FAT PREPARATIONS.

Ihle gives the following formula for preparations of wool-fat ointments:—GREY OINTMENT: Hydrargyri, 20; adip. lanæ, 50; adip. benzoat., 10; ol. bergamot, 3. PASTA MOLLIS: Adip. lanæ, 15.0; ol. olivar, 5; zinci oxid., 10.—*Pharm. Centralh.*, xxxix., 92.

ELDER PERFUME.

Terpineol, 80; cananga oil, 60; African geranium oil, 5; tincture of musk, 5; tincture of storax, 100; alcohol, 5000; distilled water, 500.

ESSENCE OF LILY OF THE VALLEY.

Oils of lignaloe, 7.0; cananga, 60; bergamot, 10; geranium, 9; oil of melissa, tincture of storax, 60; alcohol, 5000; distilled water, 500.—*Pharm. Zeit.*, lxxii., 523.

CHRYSAROBIN OINTMENT (UNNA).

Chrysarobin, 5; ichthyol, 5; salicylic acid, 2; lanoline, 30; vaseline, to produce 100.—*Journ. Pharm. d'Anvers*, after *Oester Zeitsch. für Pharm.*

PHARMACEUTICAL SOCIETY.

MEETING OF THE COUNCIL.

WEDNESDAY, JULY 6, 1898.

Present :

MR. WALTER HILLS, PRESIDENT.

Messrs. Allen, Atkins, Bateson, Bottle, Carteighe, Corder, Cross, Hampson, Harrison, Johnston, Martindale, Park, Southall, Storrar, Symes, Warren, and Young.

In the absence of the Vice-President the Treasurer took the vice-chair.

The Minutes of the last Council Meeting were read and confirmed.

The PRESIDENT said, arising out of the Minutes, he had the pleasure to announce that he had received a letter from Sir James Crichton Browne, consenting to give the inaugural address at the opening of the School in October next.

ELECTION OF ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Archer, George Banks W.; Dalkeith. | Buckingham, Harry; Birmingham.
Daubeny, George; Bristol.

ELECTION OF ASSOCIATES.

The following, having passed the Minor examination and tendered, or paid as "Students," their subscriptions for the current year, were elected "Associates" of the Society:—

Bamford, Harry; Stalybridge. | Freer, Arthur Harry; Uppingham.
Couldery, George Etches; Reading. | Hampton, Peter; Arbroath.
Douglas, James Forrest Reid; Dundee. | Hitchon, Peter; Padiham.

ELECTION OF STUDENTS.

The following, having passed the First examination and tendered their subscriptions for the current year, were elected "Students" of the Society:—

Jones, William Brittain; Brynmawr. | Tillott, John Booty; London,
Tildesley, Robert William; Rotherham. | Waddell, Robert Arthur; Sunderland.

RESTORATION TO THE REGISTER.

Robert Joseph Rastrick, of 13, Marco Road, Hammersmith, having made the required declarations, and paid a fine of one guinea, were restored to the Register of Pharmaceutical Chemists.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a nominal restoration fee of one shilling.

REPORT OF THE FINANCE COMMITTEE.

The report of this Committee, which was read by the SECRETARY, contained the usual recommendations for the payment of sundry accounts.

The PRESIDENT, in moving the adoption of the report, said the payments and receipts were much of the usual character, therefore he would not detain the Council by making any remarks with respect to them.

The resolution passed unanimously.

HILLS ORPHAN FUND.

It was resolved that the Treasurer be instructed to pay to the Watford Orphan Asylum the sum of £12 10s., being the last half-yearly payment on account of the maintenance of the Hills orphan.

The PRESIDENT said a letter had been received from the Secretary of the Asylum saying the Manager could not retain the lad after December next. He would then be 15, and if any member

knew of an opening for a well-educated lad of that age, he hoped they would bear him in mind.

Mr. HAMPSON said he had always taken a great interest in this Fund, and was especially glad that the Council, in administering it, did not put candidates to the trouble and expense of an election.

REPORT OF THE BENEVOLENT FUND COMMITTEE.

The report of this Committee included a recommendation of grants to the amount of £33 in the following cases:—

The widow (64) of a chemist and druggist, who had three grants previous to his death in May, 1893. Applicant has supported herself by keeping a lodging-house. (Gravesend.)

The widow (78) of a chemist and druggist who died in 1888. She had a grant last year. (Durham.)

The widow (41) of a chemist and druggist member whose application was adjourned in May last for further information. (Coventry.)

One application was deferred.

Mr. HAMPSON moved the adoption of the report and recommendations of the Committee.

Mr. BOTTLE, in seconding the motion, said he should like to make a remark with reference to the Hills Orphan Fund. They had just heard of one lad who was about to leave the Watford Asylum, and he must say he was surprised that there were not more applicants for the benefits of this Fund, which, he thought, could only arise from the conditions not being generally known. The Fund was available for the orphan children of Members and Associates who had contributed to the Benevolent Fund for not less than three years. He could not help thinking that there must be a considerable number of their friends who would avail themselves of the advantage offered if their attention were called to it.

The PRESIDENT in moving the adoption of the report, said he should also like to say, with reference to the remarks made by Mr. Bottle, that he also felt it was a great pity that there were not more candidates for the Orphan Fund, although it was to be hoped that this arose from the fact that there were not many requiring assistance of this character. He agreed that the conditions and the existence of the Fund were not sufficiently known. Not only had they sufficient money invested to pay for one orphan, but he felt quite sure that there were many persons who did not at present subscribe who would be glad to subscribe annually if the money was required for an orphan. If they had the orphans he believed they would be able to find the money for their maintenance and education.

The resolution passed unanimously.

LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

The report of this Committee stated that the report of the Librarian had been received, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average
May	{ Day.....	318	24	1	13
	{ Evening	113	10	1	5
	Circulation of Books.	Total.	Town.	Country.	Carriage paid.
May.....	170	88	82		16s. 3d.

Several donations had been received (*Ph. J.*, June 18, p. 581), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the undermentioned books be purchased:—

For the Library in London:—

Dixon Mann's Forensic Medicine, 2nd Edition, 1898.

For the Library in Edinburgh:—

Encyclopædia Britannica, in half Morocco.

Caspari's Pharmacy.

Pharmacopœa Japonica, 1891.

The Committee had ordered that the Library and Museum should not be open in the evening from July 18 to September 30, inclusive.

The Curator's report had also been received, and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
May	{ Day	512	28	8	20
	{ Evening	65	6	1	3

Several donations had been received (*Ph. J.*, June 18, p. 581), and the Committee directed that the usual letters of thanks be sent to the respective donors.

The Committee recommended that Mr. T. Tickle be nominated for the Salters Research Fellowship for another year.

The Council Prizes.

The Committee recommended that the date of the competition for the Council Examination Prizes be altered from July to April, and that the applications for the Redwood Scholarship and the Burroughs Scholarship close on April 25 instead of July 25, the election to take place at the Council meeting in May.

Bye-laws.

A Sub-Committee was appointed to draft such alterations in the Bye-laws, Regulations, etc., as may be deemed necessary, in view of the probable enactment of the Pharmacy Acts Amendment Bill during the present session.

The PRESIDENT, in moving the adoption of the report, said there were one or two points to which he might direct attention. It was proposed to close the Library and Museum in the evening a fortnight earlier than usual this year, and the Committee had also resolved to consider at its October meeting whether the hours during which the Library and Museum were opened in the evening could not be curtailed. There was rather a diminishing number of persons attending in the evening in both the Library and Museum, and it was a question which might well be considered whether it was advisable to keep the staff on night after night when so few of their associates and students found it convenient to attend. The Committee also recommended that the time for the holding of the competition for the Council Examination Prizes be altered from July to April, and that the application for the Redwood and Burroughs Scholarships close on April 25, instead of July 25. At the present time the Major course finished about the end of March or the beginning of April, and it was found that those who had gone through that course and had obtained their qualification naturally were looking about to find some occupation, and they did not always find it easy to come up again in July to compete for these Prizes. While they were encouraging men to take the advanced course, that system would be more or less recognised by other schools, and they thought it would be more convenient not only to those in their own School, but generally, that the competition for the prizes should take place in April, and by that means they had every reason to believe that they would get a larger number of candidates. With regard to the Sub-Committee to consider any alteration which might be required in the Bye-laws and regulations, the appointment of this Committee was a necessary step in view of the probable passing of the Pharmacy Bill.

As stated in the report, the letter which had been received from the Spectacle Makers' Company had been replied to by the President, in which he thanked that Honourable Company for their consideration in bringing the matter before them and making the offer which they did, but it was considered that, on the whole, bearing in mind their duty in respect to examination and the granting of diplomas, it would be undesirable for the Society to associate themselves with them in the way suggested.

Mr. CARTEIGHE, in further elucidation of the matter last referred to by the President, said the Committee had simply decided that it was not wise for the Council to be associated officially with the carrying on of the scheme. It did not mean that any pharmacist who desired to have the certificate of the Spectacle Makers' Company would be ineligible; on the contrary, it would be open to them all, and no doubt many chemists and druggists would think it desirable to obtain it. Those who wished to do so would have to become Freemen of the Company, which they could do on payment of a reduced fee, and they would get a good commercial *quid pro quo* for their trouble.

Mr. BATESON asked if an examination would have to be passed.

Mr. CARTEIGHE said Yes, there would be an examination in optics, but it would not be a difficult one.

The resolution was then passed unanimously.

APPOINTMENT OF PROFESSORS.

The following appointments in the School of the Society for the ensuing session were made:—

Botany.—Professor J. Reynolds Green.

Chemistry.—Professor J. Norman Collie.

Materia Medica.—Professor H. G. Greenish.

THE POISONOUS SUBSTANCES BILL.

The SECRETARY read the report of the Law and Parliamentary Committee, which had held two meetings to consider the Bill recently introduced, intitled an Act to Regulate the Sale of Certain Poisonous

Substances. The Committee recommended that all necessary steps be taken to oppose the Bill, and that the President be authorised to issue a circular to every person on the Register, requesting him to endeavour to obtain the assistance of his representative in Parliament in opposing the further progress of the Bill.

The PRESIDENT said he felt it his duty to say a few words with reference to this Bill, which had now passed the House of Lords. In the first place he wished to make it quite clear that the Council had not been idle in the matter. The Bill did not see the light until after the last meeting of the Council, being introduced by the Duke of Devonshire on June 13. The Law and Parliamentary Committee at once began to consider it, and there had also been two meetings of the Watch Committee, so that the most careful attention had been given to the matter. They were beginning to receive communications from their friends in different parts of the country, and he found that they spoke with one voice in opposition to the principle of the Bill. The Cambridge Pharmaceutical Association had met and passed a resolution that the attention of the Pharmaceutical Council be called to Clauses 1 and 2 of the Bill, and suggesting that the Act might be so amended as to provide that no person other than those qualified or registered under the Act of 1868 should sell any poison scheduled to that Act, and that the proposed new Schedule should be added to Part 2 of the Schedule to the Act of 1868. The Association also urged an amendment of the Companies Acts, by inserting a clause protecting personal professional qualification. The North-East Lancashire Association regarded the Bill as inadequate for its purpose and ambiguous in its details, and was of opinion that the Bill constituted a dangerous departure from the principles of the Pharmacy Act of 1868. The same meeting expressed an opinion that an agitation ought to be organised having for its object the extension of Part 2 of the Schedule and the abolition of company pharmacy. The Manchester Pharmaceutical Association disapproved of the Bill, and relied on the Council taking steps to prevent its passing. Some members of the Executive of the North British Branch had also held a private meeting, and were decidedly opposed to the Bill. Several other communications had been received from individuals urging opposition to the Bill, and only that morning letters had been received from the chemists at Bolton, Bristol, and Liverpool, urging opposition on the grounds mentioned in the Cambridge resolution. He felt that it was a serious matter to oppose a Bill of this description, introduced as it was by the Lord President of Council, but the Committee felt that not only was it impracticable in many of its details, but the principle underlying the Bill was one to which they must offer a strenuous opposition. The principle was not that of the Act of 1868, under which a certain body of persons was registered who should have charge of the retail sale of all poisons, and he thought it might be said that since that Act was passed the public had received a corresponding advantage. That principle had been completely disregarded in the present Bill, and, therefore, without going into details they thought it should be opposed, both from the point of view of the public safety and having regard to the interests of those who, by submitting to examinations conducted under the ægis of the Privy Council, had proved themselves to be competent. It might be possible in Committee of the House of Commons to make the Bill a little less unworkable if it were thought advisable so to do, but the Committee had come to the conclusion that the Bill was wrong in principle, and should be opposed *in toto*. They thought that in the framing of such a Bill it was desirable that the Government should in some way take into consultation the body which was most competent to give practical advice on matters connected with the retail sale of poisonous articles. Clause 2 of the Bill was really an amendment of the Pharmacy Act of 1868, though no reference was made to that fact in the title. His views on that matter were expressed at the annual meeting in May, and he had every reason to believe that the majority of the Council were in favour of passing the regulations with regard to the keeping of poisons such as were referred to in the Act of 1868, and he hoped before long the Society would pass such regulations. He would now content himself with moving that the report and recommendations of the Committee be adopted.

Mr. HAMPSON said it seemed a marvellous thing that after the long and intimate relationship between the Society and the Privy Council that the Council had not been consulted in the first place with regard to the introduction of a Bill of such a character as the one then under discussion. It was a distinctly bad Bill, and was not worthy of being knocked into shape; therefore he was delighted

that it had been unanimously decided to oppose it. He was still the sinner that his colleagues thought him to be some years ago with regard to the necessity of making it compulsory to do certain things with regard to the storage of poisons, and he was of opinion that after a period of more stringent and complete education there was already a body of chemists in the country well able, from their intelligence, to look after the public safety. If the Council and the Society were content that the regulations should be carried out let it be done; they were the people who knew more about the matter than anybody else, and personally he felt affronted when he found that in a Bill which was to deal with the sale of mineral acids their Pharmacy Act should be ridden over roughshod.

Mr. MARTINDALE said this was such a serious matter that he could hardly give a silent vote. He quite agreed that they were the people who, in the interests of the public safety, should have the regulation both of the sale and storage of poisons. The Bill before them was solely in the interests of large manufacturers and consumers, and was brought forward with the suggestion that that Society had not done its duty, but he claimed that they were not so much to blame as the Privy Council themselves. The Society had made repeated applications to the Privy Council to have carbolic acid placed in the Schedule. The Act of 1868 had worked well for the public, and not unfairly to their interests, but the failure with regard to it was the omission from the Schedule of the one poison which had caused more deaths than any other. It would be an indignity for them to be placed under the control of the Privy Council in the way suggested in the Bill without their having a voice in the drawing up of the regulations. By their apprenticeship and expert and scientific training they were certainly the persons who were best able to know how the storage and sale of poisons should be carried on. The provisions of the Act, 1868, often acted in the direction of restricting them in the sale of poisons, but the class of sellers brought into competition with them by this Bill would be under no such restriction, as they would be entitled to sell largely and no questions asked. He was present in the House of Lords when the Bill was read a second time, and was then told that they possessed virtually a trade monopoly. It was true that they had this monopoly for about a dozen poisons, and from an estimate he had made he found that the value of this monopoly was very small indeed. He would ask who wanted to sell poisons, and what profit did it bring them? The sale of poisons by this Bill would be very much increased, and probably with much greater danger to the public, by enabling the public to buy retail of unqualified and ignorant sellers. Could it be said that they had a monopoly in the sale of poisons when seven unqualified persons could sell what one unqualified person could not do? In France the sale of poisons was restricted entirely to the pharmacists. Even in Shakespeare's time there were poison regulations, for in one of his plays he said, if any man needed a poison, which it was death to sell, there lived a caitiff wretch who would supply it. But were they such caitiff wretches that this Bill should be forced upon them? They considered themselves respectable people, and it had not been proved that they had been careless in the storage of their drugs. The Privy Council had treated them badly by bringing forward this Bill without consulting them, and if it were withdrawn probably something might be done to aid in restricting the sale of carbolic acid.

Mr. CARTEIGHE said it was not policy or indeed profitable to go into detail on the subject of the poison laws generally. The whole question was in an unprofessional position, and not very dignified for the educated pharmacist. When the Bills were promoted in 1852 and 1868 they went upon the principle that education was the qualification, and that the question of how a poison should be kept and sold was one that should be left to the intelligence of the educated man who sold it. They were met by their own brethren with opposition to those general principles, and had to accept a Poisons Bill instead of a Pharmacy Bill. It was like putting police measures into a small University Bill; therefore, it was very injudicious for them to lay down any strong views on the practice of selling poisons. In the legislation which was agreed to as the result of a Select Committee in the House of Commons many years ago, a kind of a hybrid Bill was passed through the House, and they had done their best to work that Bill. Of course, they would be always in possible danger of there being a cry for greater security in certain directions with regard to the sale of poisons, and they must be prepared as citizens, as well as pharmacists, not to give reasons that would not hold

water. The main point with regard to the Bill was that the Privy Council had again laid down the doctrine that for such a substance as carbolic acid, to say nothing of other things, the safety of the public could be secured by a purely mechanical regulation. In the Act of 1868 they were made first to accept the 17th Clause, and then they were made to promise to make poison regulations in addition; but now it was proposed to dispose of the official part, and in regard to the sale of carbolic acid mere restrictions were suggested. Why was that? If any person sold a poison very largely, no matter for what purpose, and called himself a manufacturer, great alarm was felt at any possible interference with free trade, but that was the only way in which legislation could be carried on. Carbolic acid could be put into their Schedule with perfect safety to the public, and without anything more than nominal damage to the manufacturer, and without inconvenience to public authorities and medical officers of health who wanted to use it for disinfecting purposes. There was in their Act a provision for wholesale dealing in certain poisons, and the Council, in the exercise of its functions as a prosecuting body, always took care not to interfere with the free trade of the manufacturer. The free trade they had to guard against was the free trade of selling small quantities of toxic drugs to the public. If the Lord President of the Council would take the trouble to consult some member of their body who knew the Pharmacy Act of 1868, he would be able to show his Lordship that they only had a monopoly of the sale of poisons, which was also, to a certain extent, a restriction of their business. The Privy Council is too easily frightened by the manufacturers of carbolic acid, and the cry of free trade is a very influential one, but carbolic acid and the mineral acids could be put into the Schedule to the Act of 1868. It could all be worked if the Privy Council would go into the matter patiently and carefully, and not be frightened of the large manufacturers. In his opinion the proposed Bill was an impossible and impracticable one. He had maintained all his life his own disappointment with the Pharmacy Act. The chemists and druggists of this country wanted no Section 17 to carry on their business. That was imposed upon them by a set of men who were of opinion that mechanical things were required at that time as well as education. The Society had to give way because many of their body had not been examined, but after thirty years' experience it was quite obvious that with examination and training every one of their men was a much better judge of the best way to sell a poison than any Privy Council. The Law and Parliamentary Committee in considering this Bill had had to be politic in its movements, because there was nothing at all to prevent any troublesome Member of the House of Lords moving that the Bill brought in by the Duke of Devonshire on the part of the Government, and the Bill which had come from the Commons, should be referred to a Select Committee of the House. He did not want any Select Committee. They knew how to fight, and did not want any help from outside, or suggestions from trade journals as to the best way of amending or killing a Bill.

Mr. ATKINS believed there had been no lack of promptitude and industry in dealing with this measure, although he knew that correspondence had been received in the office hinting at there being supineness. As a provincial member he had had his share in discussing this matter on the Committees, and he knew that the Watch Committee, which consisted of London members, had been very prompt in their action. He held most strongly the conviction that in anything that was done with regard to poison legislation the Pharmaceutical Society of Great Britain ought to be consulted. He felt intensely indignant at the fact that they who were so much interested in the matter, and who had the special knowledge which had come to them as the result of their training, had not been consulted.

The PRESIDENT, in putting the resolution, said he would only repeat what was said in the introduction to the Calendar of the Pharmaceutical Society: "the education of the vendor is the only safe foundation for a poison Bill." That was, broadly speaking, the ground of their opposition to the Bill now before the House of Lords.

The resolution passed unanimously.

BRITISH PHARMACEUTICAL CONFERENCE.

The following were appointed delegates to the British Pharmaceutical Conference at Belfast:—The President, Vice-President, and Messrs. Atkins, Bateson, Grose, Johnston, Martindale, Park, Symes, Warren, and Young.

Dr. SYMES made a special appeal to his colleagues to attend the

Belfast meeting if they could possibly arrange it. He knew from several sources that their friends in Belfast were exceedingly enthusiastic and desirous of giving the Conference as hearty a welcome as it received in Scotland, and, if possible, of making it a record meeting. Both the pharmaceutical chemists and chemists and druggists were joining heartily in the movement, sinking any differences they might have between themselves for this occasion. He hoped, therefore, there would be a very large attendance.

LEGACY TO THE BENEVOLENT FUND.

The PRESIDENT announced that one of their old members and friends, Mr. John Cripps, of Turnham Green, who recently died, had bequeathed £2000 to the Benevolent Fund on certain conditions, which were easily complied with. It was very satisfactory to find that the good work of the Benevolent Fund was appreciated and encouraged in this way.

CORRESPONDENCE.

The PRESIDENT read a letter from the Assistant-Secretary in Scotland, enclosing a list of the members of the Executive of the North British Branch, which has already been published. He had also received from Mr. Welford a letter with a copy of a petition presented to the Asylums Committee of the London County Council, with reference to the position of dispensers. He suggested that it be referred to the Library Committee, and that was agreed to.

The Decimal System.

The PRESIDENT said a letter had been received from the Secretary of the Decimal Association enclosing a petition in favour of certain facilities being granted by the Post Office, Custom House and other Government Departments for the concurrent use of metric weights and measures, and asking for the Council's approval and signature of the petition. He would suggest that this also be referred to the Library Committee.

Mr. CARTEIGHE suggested that the Council might authorise the Committee to affix the seal of the Society to the petition if it thought fit. He understood the petition was to be presented at an early date, and if it were delayed for another month it might be useless.

Some conversation ensued as to the purport of the petition, and it being stated that it did not ask for the compulsory introduction of the metric system, but merely for its use in certain statistics, side by side with the Imperial weights and measures, with the view of educating the public and making the metric system known, it was resolved that the letter and memorial be referred to the Library Committee, and that the Committee be authorised to request the President to affix the seal of the Society to the petition if they thought fit.

Examination of Colonial Plants and Drugs.

The PRESIDENT said he had received a letter from the Under-Secretary of the Colonial Office, conveying the thanks of Mr. Chamberlain for the report which had been furnished on certain plants forwarded by the Governor of the Windward Islands. He might remind the Council that these things were sent to them a short time ago by the Colonial Office, with a request that they should be examined and reported upon. Dr. Paul kindly undertook the work, and his report having been forwarded to the Colonial Office, had now been acknowledged. Unfortunately, the quantities placed at Dr. Paul's disposal were too small to allow of thoroughly exhaustive reports being made, but so far as they went they would no doubt be interesting and useful. Their thanks were due to Dr. Paul for the trouble he had taken.

The PRESIDENT had also received another letter from the Colonial Office, accompanying a parcel of palm kernels, also sent from the Governor of the Windward Islands, requesting that an analysis might be made of them. It seemed to be rather a large package, and he suggested that the matter be referred to the Library Committee. This was agreed to.

Colonial Pharmacy Reports.

The PRESIDENT further announced the receipt, through the Colonial Office, of the Report of the Pharmacy Board of the Cape of Good Hope for 1897. Also the Report of the Pharmacy Board of Victoria.

REPORT OF THE GENERAL PURPOSES COMMITTEE.

The report of this Committee included reports from the professors as to the Prize Examinations, in accordance with which the Committee recommended the award of the following prizes:—

Botany.

- Bronze Medal Thos. Edward Wallis.
- Certificate of Honour John Evans.

Practical Chemistry.

- Bronze Medal Thos. Wooldridge.
- Certificate of Honour { Alf. Wm. Turner
John Evans.

Chemistry.

- Bronze Medal Thos. Edward Wallis.
- Certificates of Honour { Wm. Jas. Spurway.
Herbert Payne.

Materia Medica.

- Bronze Medal Thos. Edward Wallis.
- Certificates of Honour { Wm. Lockwood Nundy.
Herbert Payne.

Pharmacy.

- Silver Medal Herbert Payne.

The PRESIDENT, in moving the award of the foregoing prizes, alluded to the fact that Mr. Wallis, whose name appeared so often on the list, was the son of one of the Divisional Secretaries for London.

The resolution was carried unanimously.

Herbarium Competition.

The SECRETARY then read the report of Professor Green on the Herbarium Competition, in accordance with which the Committee recommended that the following awards be made:—

- Silver Medal Wm. W. Hellyer Plymouth.
- Bronze Medal John Geo. Hawksworth Sheffield.
- Certificate of Honour Herbert J. Reynolds .. Plymouth.

THE PRESIDENT, in moving the adoption of this portion of the Committee's recommendation, remarked on the fact that two of the successful competitors belonged to Plymouth.

Mr. ALLEN said he thought one of the things on which the Council might congratulate itself was the fatherly interest it took in the young men who distinguished themselves in pharmacy, and if anyone doubted the wisdom of encouraging young men by the bestowal of these prizes they had only to look at the list of prize winners in years gone by, and they would see how many of these young men had distinguished themselves in later life. As a West of England man, he was very pleased to hear Professor Green's report on the Herbarium Competition, a subject which the Council had always had at heart. Any young man who could earn the appreciation of so enthusiastic a botanist as Professor Green must have acquired an amount of knowledge which would be very valuable to him hereafter, and he was very pleased to find that two of the successful competitors came from Plymouth. They were both apprentices in that town, and he thought they might congratulate Mr. Reade, of the Naval Hospital, who had taught these young men, on their success. He was a most enthusiastic teacher, and had no doubt contributed largely to their success. At any rate, he knew that he helped as far as lay in his power all the young men connected with the Plymouth Association. That Association was in some respects unique, as it had a junior section as well as a senior, and it was interesting to know that on some occasions both sections met at the same time and place for friendly intercourse.

Dr. SYMES said it was very gratifying to find that on this occasion there were so many competitors for the Herbarium Prize.

Mr. PARK said the young men of Plymouth were much indebted to the Council for allowing Mr. Holmes, the Curator, to go down there and address them. He was quite sure that what he said to them was a great stimulus to them in their studies.

The resolution was adopted unanimously.

The Council then went into committee to consider the legal portion of the Report of the General Purposes Committee, which included the usual letter from the solicitor.

On resuming the report and recommendations were received and adopted, and special resolutions were passed authorising the Registrar to take proceedings against the person named.

Deaths by Poison in 1895 and 1896.

THE reference made by the Duke of Devonshire to accidental deaths caused by poisons, included in the Schedule to the Pharmacy Act, and the implied suggestion that those deaths were the result of neglecting the precautionary measures prescribed by the Act, gives such especial interest and importance to the reports of the Registrar-General, that it is considered desirable to reproduce, in a classified form, the data given in the reports for the period referred to by the Duke of

Devonshire. From those data it will be seen that the recommendation of the Pharmaceutical Council to add carbolic acid to the Schedule of the Act has been amply supported by subsequent experience, since that article stands out conspicuously as the cause of more deaths than any other kind of poison. It surely cannot be contended in the face of these returns that sanitation requires the terrible sacrifice of human life which is year by year a consequence of the unrestricted sale of carbolic acid.

Statistics of Poisoning according to the Returns of the Registrar-General for the Years 1895 and 1896.

PHARMACY AND POISON.

THERE is much reason for regretting that, in this country, pharmaceutical legislation has been based so much upon the conception of poison as a danger to be guarded against, rather than designed with regard to the wider requisites of a qualification for the practice of pharmacy, such as the Pharmaceutical Society has endeavoured to establish by its educational work during the past fifty years. In the dispensing and compounding of medicine, technical knowledge, skill, and care are necessary for public safety, not only in regard to poisons within the meaning of the Pharmacy Act, but quite as much in regard to other, harmless or comparatively innocuous, articles. Since both have to be handled simultaneously, the exercise of the business requires to be limited to those possessing certified qualification for the performance of the work; not indeed for their particular benefit, but because such a limitation is expedient for the safety of the public. The Society's object in that respect was only partially supported by the State in the Act of 1852, and by further deviation from that object under the influence of temporary acute apprehension of danger from poison, the more comprehensive Act of 1868 was adapted rather for preventing that danger by mechanical contrivances and regulations than for regulating the practice of pharmacy on the more rational basis of educational qualification.

But still it can be stated with confidence that under the operation of those two Statutes the practice of pharmacy properly so-called has for many years been conducted in such a manner that deaths due to accident or negligence in compounding or dispensing of medicine have been almost, if not quite, unknown. Very noticeable, therefore, is the circumstance that when moving the second reading of the Poisonous Substances Bill, the Lord President of the Council should have made a statement apparently in direct opposition to the indisputable fact above mentioned. On that occasion the DUKE OF DEVONSHIRE spoke of the Pharmacy Act, 1868, as not having been "altogether effectual in preventing accidental deaths from the use of poisons included in the Schedule of that Act." This alleged experience was put forward as the reason for proposing Clause 2 of the Bill, involving a sort of oblique amendment of the Pharmacy Act in

regard to the power of making regulations for the keeping and dispensing of poisons. The evidence adduced by his Grace, in support of that position, was statistically correct, so far as information can be obtained from the Reports of the Registrar-General; but it has no kind of reference to the compounding or dispensing of medicine; neither does it furnish any support to the proposition to amend the Pharmacy Act so that the Privy Council may be enabled to make regulations in those respects.

In describing that provision in Clause 2 of the Government Bill, his Grace spoke of it having been proposed because the Pharmaceutical Society has neglected to exercise the power of regulation vested in it. That explanation being coupled with mention of the accidental deaths caused by scheduled poisons, obviously suggested that those deaths had been the result of the alleged neglect. Those imputations are too serious to be ignored, and though it is not intended to enter into consideration of the thorny question whether the permissive power entrusted to the Pharmaceutical Society was accompanied by the acceptance—authorised or not—of an obligation to make compulsory regulations, there is, at least, necessity for pointing out that regulations were drawn up by the Council, and that the members of the Pharmaceutical Society—entrusted with the power of making regulations compulsory, cognisant of the requirements of their business and of their responsibilities in connection with it—deliberately decided that such regulations were not requisite. That is really the most important fact to be considered, and the justice of the decision, then arrived at, has been fully demonstrated by the subsequent experience already mentioned, that the occurrence of deaths from accident or negligence in compounding or dispensing medicine is almost unknown. There is not in the Registrar-General's returns for the period referred to by the DUKE OF DEVONSHIRE, a single instance in which death is stated to have been so caused. In fact, all the evidence available in regard to the practice of pharmacy points in the same direction: it distinctly negatives the assumption that within the ranks of registered chemists there is any need for compulsory regulation of their business. In the absence of any evidence to the contrary, there is no excuse for the proposed Legislative interference. It would only be a means of exciting the intense repugnance with which compulsion in any shape is regarded by most people in this country, and therefore, as recently pointed out by the MARQUIS OF LANSDOWNE in reference to another legislative proposal, a thing eminently undesirable.

In regard to the retail sale of poisons within the meaning of the Pharmacy Act, it must be remembered that specific regulations are prescribed, in the Act itself, observance of which can be enforced by any public authority under the 17th Section. That power might have been more effectually exercised in the public interest than it has been. Instances sometimes occur of those regulations being neglected by registered persons, but they are very infrequent, and are generally to be accounted for by the fact that, though the status and qualification of chemists and druggists have been very considerably improved, there is still some residuum of the conditions prevailing before the Act was passed. Among the large number of persons registered in virtue of having been in business before that time, there may still be a few who are not sufficiently mindful of the obligations imposed upon them in regard to the public and to the craft to which they

belong. Generally, however, the evidence is that the regulations of the Act are carefully observed by chemists and applied even in the sale of articles that are not included in the Schedule. Moreover, the circumstances attending accidental poisoning often show that disaster is caused by negligence in the use of poisonous articles after they have been supplied in full conformity with statutory regulations. Lastly, it is necessary to point out that cases of accidental poisoning form but a small proportion of the total number of deaths by accident. Those caused by poison of all kinds amount to less than 3.5 per cent., and those caused by scheduled poisons amount to 1.25 per cent. of the deaths by accident.

The general conclusion to be drawn from the foregoing considerations is that neither in regard to the dispensing of medicines by registered chemists and druggists, nor in regard to the sale of poisons under the regulations of the Pharmacy Act, is there any reasonable ground for proposing alterations of the kind suggested in the Government Bill, either for the safety of the public or for preventing undue restriction of the trade in poisonous articles.

THE COUNCIL MEETING.

At the opening of the proceedings, the PRESIDENT announced that SIR JAMES CRICHTON BROWNE has consented to deliver the inaugural address at the commencement of the session in October.

The additions to the Society comprised nine Associates and four Students.

The report of the Finance Committee was adopted without comment and the Treasurer was instructed to pay on account of the Hills Orphan Fund the final half yearly sum for the maintenance of an orphan in the Watford Asylum.

On the recommendation of the Benevolent Fund Committee, three grants amounting to thirty-three pounds were ordered to be paid.

The report of the Library, Museum, School, and House Committee recommended an alteration of the competition for prizes from July to April, and that applications for the Redwood and Burroughs Scholarships should close on April 25, the elections to take place in May.

The alteration of the Bye-laws, etc., rendered requisite by the provision of the Pharmacy Act Amendment Bill, has been entrusted to a Sub-Committee, and the consideration of the resolution of the Executive of the North British Branch of the Society has been deferred relating to appointment of Local Secretaries. A reply has been sent to the Spectacle Makers' Company to the effect that the Council, while thanking the Company for its offer, was of opinion that it could not be accepted consistently with the Society's duty in respect to examination and the granting of diplomas.

Mr. CARTEIGHE further explained that the Committee had decided it would not be wise for the Council to be associated officially in the scheme suggested, but that pharmacists who desired to obtain the qualification of the Spectacle Makers' Company would no doubt derive advantage from it.

The Professors of the School of Pharmacy were re-appointed: Botany, Professor GREEN; Chemistry, Professor NORMAN COLLIE; Materia Medica, Professor H. G. GREENISH; and Dr. A. LAPWORTH was appointed Assistant, Lecturer on Chemistry.

The Report of the Law and Parliamentary Committee relating to the Government Bill for Regulating the Sale of

Poisonous Substances, recommended that all necessary steps should be taken to oppose the further progress of the Bill, and that a circular letter should be sent from the PRESIDENT to every person on the Register, requesting that the assistance of all Parliamentary representatives should be obtained for that purpose.

In reference to this report the PRESIDENT said the Council had not been inert in this matter, and that the Bill had been considered at several Committee meetings since its introduction. The communications received from several parts of the country expressed a unanimous decision to oppose the principle of the Bill. He felt that to oppose a Bill of this description, introduced by the Lord President of the Council, was a serious matter, but the Committee also felt that the Bill was impracticable in its details, while the principle underlying it required their most strenuous opposition as being directly contrary to that of the Pharmacy Act, 1868, under the operation of which the public has derived advantage from the establishment of a body of qualified persons charged with the retail sale of poisons. From both points of view the Bill ought to be opposed. In framing a Bill of this nature it is indispensable that the Government should consult the body most competent to give practical advice on matters connected with the retailing of poisonous articles. Clause 2 was mentioned as particularly objectionable, as proposing to effect a change that would really stultify the Act by which the practice of pharmacy and the qualification of chemists and druggists has been regulated for thirty years under control of the Privy Council.

Mr. HAMFSON expressed surprise that the long and intimate relations between the Society and the Privy Council had not led to the Council of the Society being consulted before a Bill of this kind was introduced. In regard to the matter of compulsory regulations he admitted being unconverted and still the sinner some of his colleagues had considered him. In view of the educational improvement effected among chemists and druggists within the past thirty years, he believed that they knew more than anyone else about the conditions under which the storage and sale of poisons should be managed for the safety of the public, and that it was an affront to have such matters dealt with in a Bill of the kind now in question.

Mr. MARINDALE supported the views expressed in regard to the Bill, which he thought was of too much importance to allow of a silent vote against it.

Mr. CARTEIGHE deprecated detailed discussion of the poison laws as neither politic nor profitable for the educated pharmacist. The Bills promoted by the Society in 1852 and 1868 were upon the principle that educational qualification best enabled pharmacists to decide how poison should be kept or sold. The Society, instead of being supported in the application of that general principle, was opposed by members of the craft, and consequently had to accept a Poisons Act instead of a Pharmacy Act. The Society had done its best with that inadequate measure, but it would always be in danger of a cry being raised for greater security, and its members should be prepared both as citizens and as pharmacists to defend their position on reasonable grounds. The main point of the Bill was that the Privy Council again asserted the doctrine that in the sale of such an article as carbolic acid the safety of the public would be sufficiently provided for by purely mechanical regulation. He suggested that the restrictions suggested in the Bill had been made from fear of interference

with free trade. But carbolic acid could be put into the Schedule of the Pharmacy Act without any damage to large manufacturers, with safety to the public and without inconvenience to public authorities or medical officers of health, since there is in the Act a provision for wholesale dealing. Moreover, the Council, in exercising its functions as a prosecuting body, always takes care not to interfere with the free trade of manufacturers. The danger to be guarded against is the free trade in small quantities of toxic articles supplied to the public affording too easy access to poison. If the Lord President of the Council would consult some members of the Society they would be able to show his Grace that the alleged monopoly of the sale of poison was also to a certain extent a restriction of their business. The chemists and druggists of this country want no 17th Section to control their business. That was imposed upon them by men who believed mechanical regulations were required as well as education, and the Society had to give way because many of the body were not then examined, but now, after thirty years, every one of them was a better judge of the way to sell poison than the Privy Council can possibly be.

Mr. ATKINS supported the remark of the PRESIDENT that there has not been any lack of promptitude in dealing with the Bill. He also held that in anything done to regulate the sale of poisons the Pharmaceutical Society should be consulted.

In moving the resolution the PRESIDENT said he would only recall the passage in the introduction to the Society's Calendar that the education of the vendor is the only safe foundation for a Poison Bill. That would be the ground of the Society's opposition to the Government Bill now coming before the House of Commons.

Messrs. ATKINS, BATESON, GROSE, JOHNSTON, MARTINDALE, PARK, SYMES, WARREN, and RYMER YOUNG were appointed delegates to the approaching meeting of the British Pharmaceutical Conference at Belfast, where Dr. SYMES said that the local pharmaceutical chemists and chemists and druggists had heartily joined in preparing a welcome to visitors on that occasion.

The correspondence referred to the Executive of the North British Branch, to a petition in favour of granting facilities for concurrent use of metric weights and measures, to a report on drugs examined for the Colonial Office by request of Mr. CHAMBERLAIN, and to a request for a similar examination of palm kernels sent by the Governor of the Windward Islands.

The report of the General Purposes Committee gave particulars of the award of prizes (see p. 33).

After consideration of the legal portion of the report, resolutions were passed authorising the Registrar to take proceedings for enforcing the provisions of the Pharmacy Act.

PHARMACY ACTS AMENDMENT BILL.

At the moment of going to press we learn that the second reading of this Bill, brought up from the Commons on June 9, was moved on Thursday afternoon in the House of Lords by the EARL OF HARDWICKE and agreed to without discussion. Arrangements which have been made for dealing with the Bill in its subsequent stages will probably secure its further passage through the House within the next few days.

ANNOTATIONS.

THE "BRITISH MEDICAL JOURNAL" has hitherto generally been rational and, at least, well informed in regard to the regulation of the sale of poisons as a matter affecting the safety of the public. But the article on that subject, which appeared in its pages last week, manifests such an extraordinary inversion of the position formerly taken by our contemporary, as to excite profound astonishment. This circumstance is the more to be regretted since the public is greatly indebted to the late Mr. Ernest Hart for the strenuous persistency with which he urged upon the Government authorities that it was their duty to give effect to the salutary provisions of the Pharmacy Act in regard to the sale of poisons. In place of maintaining the position then taken, concerning the sale of carbolic acid, the *British Medical Journal* now regards the Bill introduced by the Duke of Devonshire as a measure calculated to effect the reform, in that respect, which has so long been ineffectually pressed upon the Government as urgently necessary in the interests of public safety. It does not seem to have been perceived by the writer of the article now referred to, that the Government Bill really accepts, as inevitable, all the dangerous conditions hitherto prevailing and merely proposes that they shall be supplemented by the use of a poison label, while admitting that such a provision cannot be expected to have much efficacy in preventing the frightful mortality that has been caused by carbolic acid during the last twenty years.

To SUPPOSE THAT by merely requiring a poison label to be placed upon a ginger-beer bottle, teacup, or any other domestic utensil in which such an article as carbolic acid is supplied, a real provision would be made for preventing accident or misuse, or that by such a legislative measure any adequate response is made to the urgent remonstrations put forward by the *British Medical Journal* on this subject, is scarcely conceivable. But that is the purport of the article which appeared last week in the pages of our contemporary. There is, however, another important matter which is overlooked by our contemporary, viz., the abandonment of the principle—established under the Pharmacy Act, 1868—that the supply of articles dangerous by reason of their poisonous characters requires to be restricted to persons of adequate knowledge and skill. That principle accepted, under the pressure of popular opinion, as the basis of the Pharmacy Act, 1868, is merely a limited expression of the wider principle which the Pharmaceutical Society has so long striven to establish, that the practice of pharmacy necessarily demands thorough scientific and technical qualification of the persons engaged in that occupation. That a journal representing a profession seeking recognition of a similar principle should fail to perceive the imperative necessity of its maintenance in a closely cognate occupation is matter for surprise and regret. The alleged objection to placing carbolic acid on the list of poisons within the meaning of the Pharmacy Act, on the ground that labelling medicines for internal use with the word "poison" would unnecessarily alarm the public mind, is a purely imaginary objection, since there is no occasion for labelling such medicines with the word "poison" if the provisions of the Act in regard to them are observed. Moreover, butter of antimony and chloride of zinc are not used as medicines for internal administration. But the most startling statement made by our medical contemporary in reference to chemists and druggists is that "deplorable laxity in complying with the regulations of the Act has been shown to have occurred in a very large number of instances."

THE POISONOUS SUBSTANCES BILL is also the subject of criticism in the *Medical Press*, which has "clamoured for years for a reform of the laws regulating the sale of poisons, and for the better enforcement of those laws," but is of opinion that the only effect the new Bill is likely to have will be to make matters worse than ever. The Duke of Devonshire is referred to as having introduced the Bill in a light and airy manner, "seemingly oblivious of the fact that the subject is one which affects the life and health of thousands of Her Majesty's lieges." Moreover, he is alleged to have proceeded on the assumption that legislation can do little or nothing to prevent accidental poisonings, and that it is unreasonable to interfere with suicides by poisons. It is urged that the popular view of the absolute necessity of carbolic acid should be "knocked on the head," as, whilst it is an extremely poisonous substance, it is practically useless for general disinfection. The inadequate nature of the protection afforded by labels alone is insisted upon by our contemporary, which is strongly in favour of the exclusive use for violent poisons, such as carbolic and mineral acids, of bottles of a particular and distinctive shape. But much more to the point is the suggestion that the alleged but unproved inaction of the Pharmaceutical Society affords no valid reason for relaxing the safeguards already provided. Not, of course, that any such relaxation has been actually proposed, but there is little reason to doubt that the present proposals of the Privy Council would naturally lead in time to partial abrogation of the much stricter provisions of the Pharmacy Act, 1868.

MISCONCEPTIONS PREVAIL to a greater or less degree in nearly all the newspaper comments on the Bill introduced by the Duke of Devonshire. Even the *Times* has gone astray, though deriving its information from a member of the Legislature, for in its Political Notes last Saturday, it was gravely declared that the friends of sanitation in the poorer parts of London had become alarmed by the measure, and had asked metropolitan members to oppose the Bill when it reached the Commons. The provision to which especial objection was taken was stated to be that compelling the seller of any disinfectant which contains more than 10 per cent. of any of the scheduled poisons to label it as poison and "requiring the vendor and purchaser to comply with the provisions of the Pharmacy Act of 1868." An attempt to remove that misconception was courteously referred by the Editor of the *Times* to the member of Parliament who supplied the information upon which the *Times* paragraph was based, evoking from him a reply which serves to reveal how ignorant members of Parliament can be concerning measures under their consideration. For he contends that the placing of carbolic acid in the Schedule of the Pharmacy Act "would probably necessitate the registration of the name and address of the purchaser of the smallest quantity of carbolic acid." This is nothing less than a gross absurdity, even more stupid in its way than the supposition that regulation of the "sale" of poisons could in any way interfere with gratuitous distribution of disinfectants, as suggested by some would-be smart leader writers.

"AN ACT IN RESTRAINT OF SANITATION" is the title suggested by the *Hackney and Kingsland Gazette* for the Poisonous Substances Bill. In this instance we again find how easy it is to write nonsense about a Bill one has never seen. That is evidently the position of the Hackney and Kingsland scribe, who asserts that the much-abused Bill provides that carbolic acid and other poisonous substances must in future be sold "under the Pharmacy Act" if not labelled "Poison," and with the name and address of the seller. He then proceeds most sapiently to remark that as local authorities

in London and other large towns are constantly using and giving away disinfectants for use among the poor, it will be impossible to proceed with this most necessary and useful work. It is almost bewildering to attempt to understand what can be the frame of mind of an individual who writes in such a fashion, but if once the secret of his peculiar system of logic is mastered, it may not be difficult to agree with him in his assertion that, whilst it has been very hard to make the use of disinfectants general and popular, the Duke of Devonshire's Bill will now make their use well-nigh impossible (*sic*). The *Sun* raves on almost identical lines, beginning by sagely remarking that everyone who has had any experience of sanitary requirements in any part of the Metropolitan area will realise that if all well-known disinfectants are only to be sold under the provisions of the Pharmacy Act it will be impossible to induce the poor to register their names and addresses in the chemist's book !!!

IT MIGHT BE THOUGHT that, after this brilliant logical display, some attempt would be made to render the meaning of the writer's argument clear. But no, he only proceeds to explain that the Schedule to the Poisonous Substances Bill provides that in the case of "preparations of carbolic or cresylic acid or their homologues used as disinfectants, and containing more than ten per cent. of any of them," they cannot be sold unless the box, vessel, or package in which the substance is contained, and also any external wrapper or cover, are distinctly labelled with the word "Poison," and with the name and address of the person selling the substance. What all this has to do with the Pharmacy Act or the registration of the names and addresses of the poor does not appear; doubtless at the early hour in the morning when this was written the writer had got himself inextricably entangled in the network of his own verbiage. If this Bill becomes law, he continues, the smallest trader in a back street must practically print labels of his own, and where local authorities are endeavouring to enforce sanitation by the distribution of Jeyes' Fluid, Sanitas, and other similar compounds, they will find that they are handicapped by the Duke of Devonshire's Bill, which even includes the ordinary (*sic*) carbolic acid. As the Vestries do not sell, but freely distribute these disinfectants, it would hardly appear to a sane person that any difficulty could arise in that connection, but the genius of the *Sun* thinks the effect of the Bill becoming law would be to render it necessary for London and other great centres of population to abandon the use of disinfectants entirely for the want of proper labels. "In the country vermin and insects will have a close time because 'Substances sold for the purpose of poisoning insects or vermin' will have to come under the provisions of the Pharmacy Act." And so the frothy nonsense is poured out in the daily press all over the country, the general effect produced being to cause one to wonder if the Duke of Devonshire really knows what his Poisonous Substances Bill is intended to do.

OPPOSITION TO THE BILL has already been proposed by several local Pharmaceutical Associations, but many others have been waiting for inspiration from headquarters. As will be gathered from our report of the Council meeting this week (see page 31) that is now forthcoming, and no time should be lost in bringing all available pressure to bear upon Members of Parliament, in order that they may oppose the Bill in the House of Commons. A circular letter will shortly be sent to every registered chemist, embodying the objections to the proposed legislation from the point of view of the Pharmaceutical Council, and the arguments therein stated ought to be submitted to every Member of Parliament in Great Britain. Meetings of registered chemists may also be held with advantage in every large centre, and the resolutions

passed at those meetings should emphasise the fact that inasmuch as the chief protection of the public in connection with the sale of poisonous substances is the special qualification of the seller, any attempt to modify the restrictions imposed by the Pharmacy Act, 1868, in regard to the sale of poisons, would be detrimental to the public interest, and a violation of the conditions imposed upon chemists and druggists by the Act. The text of the resolutions in the district, accompanied with an explanatory letter if necessary, and a request to oppose the Bill when it is brought forward. If this be done universally, little doubt need be entertained regarding the fate of the Bill, but it is important that no stone should be left unturned in the endeavour to prevent so mischievous a measure finding a place on the Statute book.

A GREAT MISTAKE is sometimes made by registered chemists, in regard to their position under the Pharmacy Act, by laying claim to any rights or privileges beyond the right to carry on the business of a chemist and druggist. The sale of poisons within the meaning of the Act is by no means a privilege conferred upon them in return for having passed a qualifying examination. The statutory restriction of the sale of poison is, on the contrary, imposed solely out of consideration for the public safety. Any advantage that registered chemists may derive from it, is incidentally consequent upon the restriction which is established for the sake of the public, but not for the benefit of the chemist. It is especially important that this view of the matter should not be overlooked when so many unreasonable remarks are being made about the chemist's monopoly and his interference with the business of other tradesmen. Nothing is more desirable for the maintenance of the chemist's position in regard to the trade in poison, than to avoid giving any pretext for its restriction being regarded as established for the chemist's benefit, or partaking in any degree of the semblance of a monopoly. That view has been so constantly urged in this Journal that repetition of it would be a platitude if it were not that, in some recent letters, a contrary argument has been put forward.

THE VICTORIAN POISONS ACT has been rendered practically inoperative by the decision in the "Pink Pills" case, a report of which recently appeared in the Journal (see last vol., p. 564e). Such, at least, is the opinion of the Pharmacy Board of Victoria, as expressed in its report for the past year. A prosecution was undertaken by the Board against a suburban grocer for having sold pills containing arsenic, but it was argued for the defence that the quantity of the poison was infinitesimal, and that the article named was a proprietary medicine, and as such, came within the exceptions of the section. Moreover, it was contended that the words of the last paragraph of the section—"Provided that all such sales shall be entered in a book and that the bottle or other vessel, wrapper or cover, box or case immediately containing the poison be labelled as required by the Act"—referred to sales by wholesale dealers only. As to the contention that where the poison sold was "an infinitesimal quantity," a prosecution would not be justified, the Court upheld the Board's contention that no matter what might be the quantity of the poison sold, such sale was subject to the Act. The judges ruled, however, that proprietary medicines were expressly exempted from the injunction of the section that sales of the same should be entered in a book and that poison should be labelled as such, the injunction being only applicable to sales by wholesale dealers! The effect of this decision is said to leave the Board powerless to restrict the sale of other than crude poisons,

and to allow of the general and indiscriminate distribution of such common means of suicide and murder as "Rough on Rats," "Battle's Vermin Killer," and similar cheap deadly poisonous admixtures. "Facilities for homicide and self-destruction have always been lamentably easy of access, and stronger powers than were believed to have been possessed under the Act were long desired. But the legal dictum takes away the only and inadequate restraining power which it was thought the Act reposed in the Board, leaving it practically impotent to give effect to the expressed intention of the Legislature as contained in the preamble of the Act—to restrict the sale of poisons for the safety of the public, and to lessen the frequency of fatal accidents through crime and careless custody." The Board makes no doubt that this matter of vital importance to the community will receive attention from the Government, and that such an amendment of the Act will be promptly urged upon Parliament as will place the Board in a position to discharge its responsible duties to the public with efficiency.

THE CONCLUSIVE DEMONSTRATION afforded by the Registrar-General's returns that carbolic acid is the cause of more deaths by accident and suicide than any other poisonous article, and that its unregulated sale is a serious source of danger to human life, acquires additional force when the records of murder by poison are added to those of poisoning by accident and suicide, as in the following summarised statement for the years 1895 and 1896:—

	Scheduled Articles.	Unscheduled Articles (in Schedule of Bill).	Miscellaneous.	Carbolic Acid Alone.
Accident ...	432	108	677	68
Suicide	429	470	153	387
Murder	2	4	1	3
	863	582	831	458
Total Deaths by Poison	2276			

Out of the seven murders in which death is attributed to poison, carbolic acid was the cause in three instances, and a scheduled poison only in two instances. The fact that the deaths caused by carbolic acid exceed those caused by accident with all scheduled poisons ought to be a cogent proof of the utility of restriction.

THE POISONOUS SUBSTANCES BILL was again before the House of Lords on Friday, July 1, when the Duke of Devonshire moved the third reading of the measure. Lord Herschell said he did not know whether the noble Duke was aware that the Bill would prove so stringent as to interfere with the sale of disinfectants. Articles of that kind were very much used at the present time, and their use would be checked by this Bill. He did not know whether that point had been considered. The Duke of Devonshire, in reply, said it was with regard to that matter he was about to move an amendment intended to meet the point. Communications had been made to the Privy Council that the Bill as drawn would interfere with the sale of disinfecting powders extensively used, and he therefore proposed to insert the word "liquid" before "preparations" in the Schedule. The amendment was put and agreed to, and the Bill was then read a third time and passed.

A SCHOOL OF HYGIENE was opened at Liverpool by the Lord Mayor of that city, on Monday last, the new institution being in connection with the University College. Ashton Hall, as the new school is named, is a large building, with well-lighted museum, laboratories, and lecture room, the latter fitted with an electric arc lamp. The museum is well fitted, and stocked with numerous useful exhibits. The building was presented by the late Mr. Holt, whose wish was that it should be devoted to some branch of medicine having for its object the promotion of public health, and the medical faculty of the College thought it would best be giving effect to his wishes by using the building for a museum and school of instruction in public health matters and for research in subjects connected therewith. The school is well equipped for the investigation of advanced sanitary problems, such as purification of water and sewage, the action of disinfectants, and so forth, and meets a pressing need.

A "CURE" FOR YELLOW FEVER mentioned by a correspondent of the *Standard* is an extremely simple one, in fact its very simplicity is said to have often been the cause of its non-adoption, but that, of course, should in no wise prejudice people against its use. According to this writer no fatal result need ever be feared in a case of yellow fever provided the person attacked, as soon as the symptoms make their appearance, takes a tumblerful of olive oil with the juice of a lime squeezed into it, repeating the dose till vomiting and purging ensue. This combination is claimed to be infallible in checking the virulence of the complaint, and a speedy convalescence "invariably follows." The writer of the letter says he has not only proved its efficacy personally, but he has witnessed its complete success in dozens of cases, both in Cuba and South Africa.

THE BRITISH PHARMACEUTICAL CONFERENCE begins its annual proceedings at Belfast on Tuesday, August 9, when the members will be officially welcomed at 10 a.m. by the Right Hon. the Lord Mayor of Belfast, on behalf of the citizens, and the Rev. Thos. Hamilton, D.D., President of the Queen's College, on behalf of the College. The Sessions of Conference will be held in the Library of the Queen's College, and will last from 10 a.m. to 4 p.m., with the usual interval for luncheon, whilst at 4.15 p.m. there will be a drive to Giant's Ring, Purdysburn, Ormeau Park, etc. The Reception and Conversazione will be held in Queen's College at 8 p.m. On Wednesday, August 10, the Sessions of Conference will be followed at 4 p.m. by a garden party in the Botanic Gardens Park, by invitation of the Right Hon. the Lord Mayor and Lady Mayoress, whilst at 8 p.m. the ladies' drawing-room concert and a smoking concert will be held in the Grand Central Hotel. The excursion on Thursday, August 11, will be round the coast of Antrim by coach, *via* Larne, Garron Tower, and Glenariff to Parkmore. The return journey from Parkmore will be by train. The arrangements made for Friday, August 12, include visits to Messrs. Harland and Wolff's ship-building yard, the York Street spinning mills, the Belfast rope works, and Messrs. Gallaher and Co.'s tobacco factory. Those who would like to visit Portrush and the Giant's Causeway will be able to secure tickets at reduced fares. The Conference books of tickets are ten shillings and sixpence each. No. 1 will admit to the meetings, luncheon on Tuesday and Wednesday, the drive, garden party and concerts; No. 2 book will cover the coach and railway fares on Thursday, as well as luncheon and tea. Applications for tickets should be sent at once to the Hon. Local Secretary, Mr. R. W. McKnight, 1, Carlisle Circus, Belfast, who will also secure rooms if asked to do so. The Grand Central Hotel, Royal Avenue, will be the headquarters of

the Conference, and guide books will be distributed to the members free.

THE DIRECTORSHIP OF THE NATURAL HISTORY MUSEUM is at present vacant in consequence of the resignation of Sir William Flower, on the ground of ill-health, and the trustees of the British Museum have been for some time occupied with the arrangements to be made in regard to his successor. The *Times* reports that a committee of the trustees is rumoured to be in favour of the practical abolition of the independent post held by Sir William Flower, and a return to the old plan of the official subordination of the Natural History Museum to the Principal Librarian (or Director as he is now entitled). In connection with this alteration in the character of the post held by the late Director, it is also proposed to treat it now and in future as a part of the ordinary official promotion in the Natural History Museum. A memorial to the trustees has been drawn up and is being circulated for signature, in which it is urged that the post held by Sir William Flower was considered to be a great step gained for the interests of science in the official world, and that it should not now be abolished. It is urged that both Owen and Flower were appointed from the outer world to the headship of the Natural History Museum, and have rendered great public service of a kind which could not necessarily be obtained from the regular museum staff, and that, in any case, the high character of the post should be maintained.

SILVER MEDALS have been issued for centuries in this country with the tables or flat surfaces smooth and mirror-like, while a more or less frosted texture has been given to the portions in relief, but, as is well known, medals with polished surfaces rapidly tarnish and even blacken by exposure to the ordinary atmospheric influences. In France a different system has long been in use, unpolished dies being employed and care taken to impart to the medals struck from them a dead or frosted surface by rubbing them with fine pumice. According to the annual report of the Deputy-Master of the Mint, medals have recently been subjected to "sand blasting" at the French Mint, the effect being to cause the surface of the medal to become minutely granular or frosted. The surface is then darkened by exposure to an aqueous solution of a sulphide, followed by rubbing with very fine pumice, which removes the dark layer of sulphide from the portions in high relief and leaves dark lines in the more deeply-cut recesses. It is, however, preferable to cover the medal with a layer of platinum by immersing it in an alcoholic solution of platinum chloride until a blackened surface is produced. Subsequent rubbing with a brush and very fine pumice changes the blackened surface to a delicate grey, and if this operation is conducted skilfully graduated shadows may be left wherever the artist considers their presence to be desirable. A medal with a frosted platinised surface has a great advantage over one with a polished table, as the platinised medal is merely deepened in tone by exposure to the atmosphere, and, unlike medals which have been struck in the ordinary way, does not become disfigured by blotches of tarnish. The frosted platinised medal may be restored to almost its original freshness by careful rubbing with a soft leather, while a polished silver one cannot be so renovated, as the tarnish attacks the surface and destroys the polish. During the past year, for the first time in the history of the British Mint, silver medals have been issued with frosted and platinised surfaces, more than twenty-seven thousand medals having been platinised by a slight modification of the above method.

NOTICES OF BOOKS.

THE 'TEXT-BOOK OF ZOOLOGY' by H. G. Wells and A. M. Davies (London: W. B. Clive. Pp. 366. Price 6s. 6d.), is one of the most serviceable books of its kind for students preparing for the degree examinations in science of the University of London. It is in reality a new book, for but little is retained of Wells' 'Text-Book of Biology,' published some five years ago, beyond the general plan of the work. The four parts of the book treat respectively of the rabbit, the lower vertebrata, the development of vertebrata, and invertebrata. The advantages and dangers of the "type-system" have both been borne in mind in writing the work, and great pains have been taken throughout to avoid even the semblance of want of clearness. The diagrams have been drawn specially for the book, and they are "labelled" as fully and completely as the most critical and fastidious student could desire.

'BABY FEEDING,' by A Doctor (Bristol: John Wright and Co. Pp. 62. Price 4d.), is a slight production, intended for free distribution, and obtainable in packets at reduced rates for that purpose. The pamphlet is dedicated "in sincere sympathy" to the many children who, through the ignorance or wilfulness of their mothers, have been destined to "a life of ill-health, misery, and poverty."

'FOOD AND DRINK,' by Dr. Thomas Dutton (London: Henry Kimpton. Third edition. Pp. 124. Price 2s.), has previously been noticed in these pages, and the fact that it has been found necessary to reissue it should suffice to prove that the book has been found useful. Both the medical profession and the general public have evinced much interest in the work, and anyone who is in doubt what to eat or drink will find it a safe guide.

'THE EXTRA PHARMACOPŒIA,' by W. Martindale and W. Wynn-Westcott, M.B. (London: H. K. Lewis. Ninth edition. Pp. 626. Price 10s. 6d.), has been in such great demand that it has been necessary to reprint the new edition within less than a month of its original issue. Such errors as crept into the earlier copies have been corrected in the reprint, and the reader who never makes a mistake himself has accordingly been deprived of one more cause for grumbling.

'MATERIA MEDICA, PHARMACY, PHARMACOLOGY, AND THERAPEUTICS,' by Dr. W. Hale White (London: J. and A. Churchill. Third edition. Pp. 621. Price 2s. 6d.), is a work more especially intended for medical students, but it is also very suitable for use by pharmacists who desire to improve their acquaintance with the action of drugs. This edition has been thoroughly revised since the publication of the new British Pharmacopœia, and the preface is devoted to a summary of the more important changes in the national medicine book. In addition several hundreds of alterations and additions have been made in the body of the work, which now embodies the very latest information regarding official medicaments.

THE 'CHEMIST'S COMPENDIUM,' by C. J. S. Thompson (London: Whittaker and Co. Second Edition. Pp. 313. Price 3s. 6d. net), has now virtually become a pocket B.P., for more than half of the daintily-bound volume is devoted to a synopsis of the formulæ and processes of the British Pharmacopœia, 1898, and as the official monographs appear to have been transferred almost bodily, the text is practically identical with that of the less handy and much

more expensive book. The B.P.C. 'Unofficial Formulary' is likewise reprinted *in extenso* by Mr. Thompson, together with selected formulæ from foreign pharmacopœias, and a great variety of miscellaneous information, the importance and accuracy of which is somewhat variable. The same eccentricities are displayed in enumerating the active principles of drugs as in the first edition, and the chemical nomenclature adopted in the photographic section is still sadly in need of revision. These and other minor errors detract considerably from the value of this pretty little book.

'MOUNTS AND FRAMES,' by Rev. F. C. Lambert, M.A. (London: Hazell, Watson and Viney, Ltd. Pp. 146. Price 1s.), is a practical work on the making of those indispensable aids to the picture framer. Amateur photographers in particular should find the book extremely useful. The author explains the use and object of mounts, specifies the most suitable sizes and proportions, and gives advice regarding texture and surface, tone and tint. The mounting of tinted papers, "cut" mounts, and the preparation of prints receive equally careful attention, after which all that is essential is told regarding the making of picture frames.

'BORON FOOD PRESERVATIVES AND THEIR INFLUENCE ON THE HUMAN ORGANISM' (London: Perkins, Bacon, and Co., Ltd., Fleet Street, Pp. 63. Price 6d.) is a collection of medical and scientific data on the subject of which it treats, which may prove useful to those of our readers who are required, at times, to answer questions on the alleged injurious effects of boric acid and borax in articles of food and drink. A number of tables are included.

'THE PEOPLE'S GUIDE TO THE WORKMAN'S COMPENSATION ACT' by R. M. Minton-Senhouse and G. F. Emery, L.L.M. (London: Bemrose and Sons, Ltd. Pp. 32. Price 1d.), is a handy little condensation of the provisions of the Workman's Compensation Act, 1897. Information on this subject is of value to both employers of labour and of employes.

THE 'TOURIST-GUIDE TO THE CONTINENT,' by Percy Lindley (London: 80, Fleet Street. Pp. 158, illustrated, and with maps. Price 6d.), is an annual publication which has proved serviceable to innumerable travellers seeking rest or recreation on the Continent, *viâ* Harwich, during the past eighteen years. The nineteenth annual issue is in no degree behind its predecessors in interest. Among the fresh features are particulars of the new express service to Norway, Denmark and Sweden, *viâ* the Royal Mail Harwich Hook of Holland Route; a series of continental maps, a chapter upon cycling routes in Holland, Belgium and Germany, and a chapter, "Dull Useful Information," giving particulars as to the cost of continental travel.

'PRACTICAL ORGANIC CHEMISTRY,' by Samuel Rideal, D.Sc. (London: H. K. Lewis. Second edition. Pp. 172. Price 2s. 6d.), is a collection of the more important tests and reactions of the common organic compounds, arranged in a very compact form. As in the previous edition, the first half of the book is occupied by descriptions of the organic acids, together with the tests for their purity. The carbohydrates, organic bases, and neutral substances are dealt with in later sections of the book, and the volume has been specially revised to bring it into line with the new B.P. Particulars are also included regarding several organic substances which have recently been included in the schedule for various examinations, and of a few other compounds of general interest. The introduction treats of the detection of organic carbon and nitrogen, halogens and other elements in organic bodies, whilst a brief scheme of analysis is given at the end.

PHARMACEUTICAL SOCIETY.

MAJOR EXAMINATION QUESTIONS.

PHYSICS.

June 30.—Time allowed, Three Hours.

[Not more than six questions to be attempted.]

1. Explain the phenomena of reflection and refraction by the wave theory of light.
2. Describe methods for determining the lengths of waves of light.
3. Describe the processes employed for the liquefaction of gases. What recent advances have been made?
4. Calculate the vapour density referred to hydrogen as 1 of a volatile liquid determined by Victor Meyer's method. The quantity of substance taken was 1.008 gramme, and the vapour was heated to 100° C. The volume of air expelled was 22 C.c. measured at 16.5° C., with the barometer standing at 707.5 Mm. Pressure of aqueous vapour at 16.5° C. = 14.0 Mm. of mercury.
5. What is meant by thermo electricity? Describe some uses that have been made of the phenomenon.
6. What is Ohm's law? Describe some experiments in illustration of the truth of the law.
7. Describe the process of dialysis, and mention cases in which it is used.
8. Mention some freezing mixtures, and describe the principles on which they depend.
9. Show the connection between electricity and magnetism, and describe experiments by which one of these manifestations of energy can produce the other.

CHEMISTRY.

June 30.—Time allowed, Three Hours.

[Not more than six questions to be attempted.]

1. Give the names and formulæ of the hydrides of nitrogen, phosphorus and arsenic; compare and contrast the properties of these compounds.
2. Describe the preparation, properties and uses of potassium dichromate. Starting from this salt, how would you prepare crystallised specimens of (a) chromic acid, (b) potassium chromate, (c) chrome alum, (d) potassium sulphate?
3. 0.7 gramme of pyrolusite is heated with hydrochloric acid, the evolved gas passed into a solution of potassium iodide, and the iodine titrated with $\frac{N}{10}$ sodium thiosulphate. Assuming that the pyrolusite contains 67 per cent. of available manganese dioxide, what volume of the thiosulphate would be required?
4. When the elements are arranged according to the natural system they fall into octaves or periods. Point out any gradual or regular variations in the properties of the members of one of these periods.
5. How would you test a sample of water suspected to be contaminated with sewage? What conclusions would be drawn from the analytical results?
6. How are alcohols classified, and what are the characteristics of the members of each class? What reactions are common to all alcohols?
7. Write an account of the methods you would use for the preparation of ethyl ether or of ethyl acetate (acetic ether) and sketch the apparatus employed.
8. Describe five important general reactions which are employed in dealing with aromatic compounds, and give examples of their application.
9. Give the graphic or constitutional formulæ of the compounds having the molecular formula $C_3H_6O_2$, and describe the properties of the various compounds.

BOTANY AND MATERIA MEDICA (A paper).

July 1.—Time allowed, Three Hours.

BOTANY.

1. Give a careful description of the means by which a plant absorbs food from the ground, gets rid of waste products, stores up reserve food, and prevents excessive transpiration.
2. Briefly describe the following fruits, and mention in each case the method by which the dispersal of the seeds is probably effected: Rose, Cherry, Clematis, Raspberry, Galium aparine (Cleavers), Impatiens noli-me-tangere (Touch-me-not).
3. Describe the difference observable between an ordinary primary root and a primary shoot under the headings (a) external form, (b) internal structure. What explanation can you give of the differences?

MATERIA MEDICA.

1. How would you estimate the value of the following drugs: (a) Jalap, (b) Cloves, (c) Scammony?
2. In what official products do the following bodies occur: (a) Salicine, (b) Eugenol, (c) Menthol? But what tests would you proceed to establish the identity of each?

PRACTICAL BOTANY AND MATERIA MEDICA (A Paper).

July 1.—Time allowed, Three Hours.

BOTANY.

1. Make preparations from the flower A to illustrate the structure of the ovary and ovules. Mount your sections in dilute glycerin and leave not more than two slides for examination, with explanatory diagrams.
2. Give a description of the external morphological features of the specimen B. Refer the plants C and D to their natural orders, giving reasons for your reference.

MATERIA MEDICA.

1. Prepare and leave for inspection not more than two slides showing the histological structure of the leaf provided. Describe and sketch your preparations, calling attention to any important features.
2. Is the "Powdered Digitalis" a genuine sample or not? State the grounds on which your opinion is based.

BOTANY AND MATERIA MEDICA (B Paper).

July 1.—Time allowed, Three Hours.

BOTANY.

1. What is the essential difference between sexual and asexual reproduction? Describe a few examples of asexual reproduction afforded by common plants.
2. Describe the structure of a fern prothallus. Contrast the early stages in the development of a fern embryo with those in the development of a dicotyledonous embryo.
3. Describe the flower and fruit of any six of the following—Beech, Oak, Poppy, Iris, Dandelion, Campanula, Shepherd's Purse, Geum.

MATERIA MEDICA.

1. How would you proceed to ascertain the relative value, for pharmaceutical use, of a number of samples of the following: (a) Balsam of Tolu, (b) Saffron, (c) Aniseed, (d) Ginger?
2. Name the fixed oils official in the B.P. What are their chief points of difference in chemical and physical properties?

PRACTICAL BOTANY AND MATERIA MEDICA (B Paper).

July 1.—Time allowed, Three Hours.

BOTANY.

1. Make preparations from the specimen A to illustrate (1) the structure of the primary root, (2) the origin of secondary roots. Mount your sections in dilute glycerine and leave not more than two slides for examination, with explanatory sketches.
2. Give a description of the external morphological features of the specimen B. Refer the plants C and D to their natural orders, giving reasons for your reference.

MATERIA MEDICA.

1. Prepare and leave for inspection not more than two slides showing the histological characteristics of the leaf provided. Describe and sketch your preparations, calling attention to any important features.
2. Is the sample of powdered Coca leaf genuine, or not? State the grounds on which your opinion is based.

SCHOOL OF PHARMACY PRIZE EXAMINATION QUESTIONS.

PRACTICAL CHEMISTRY.

PROFESSOR J. NORMAN COLLIE.

Thursday, June 30.—From 11 a.m. to 1 p.m.

1. The solution contains two potassium salts. Find the two acids present.
2. The bicarbonate of soda in box A is supposed to be impure. Detect the impurity.

PRACTICAL CHEMISTRY.

PROFESSOR J. NORMAN COLLIE.

Thursday, June 30.—From 2 to 5 p.m.

The solution of permanganate of potassium you are given is decinormal. Determine the percentage amount of iron present in the solution of ferric chloride in the bottle marked A.

CHEMISTRY.

PROFESSOR J. NORMAN COLLIE.

Friday, July 1.—From 10 a.m. to 1 p.m.

1. Compare the chemical and physical properties of the oxides of sulphur, chromium, and iron. Write out your answer in the form of a table.
2. Describe how you would proceed to prepare specimens of strong sulphuric acid, strong nitric acid, and strong hydrochloric acid (aqueous solution), if the only chemicals you possessed were nitre, iron pyrites, and sea water.
3. Give a description of the commercial manufacture, and state what the common impurities are, of any two of the following substances:—Potassium bichromate, hydrobromic acid, bleaching powder, calomel, bismuth subnitrate, chloral, ether.
4. State what is the action of water on prussic acid, peroxide of nitrogen, pentoxide of phosphorus; also the action of strong and dilute sulphuric acid on alcohol, zinc, cane sugar, benzene, calomel.
5. Give two different methods for the determination of the specific gravity of a liquid, using numerical examples to illustrate your answers.
6. Discuss the relative advantages of mercury and alcohol as liquids for use in thermometers.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London, W.C., and not in any case to individuals supposed to be connected with the Editorial Staff; no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ADVERTISEMENTS AND ORDERS for copies of the 'PHARMACEUTICAL JOURNAL' must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C. Cheques and money orders should be made payable to "Street Brothers."

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the Editor will be replied to in the Journal as early as possible after receipt, though not necessarily in the next issue. Replies cannot be sent by post, even though stamped envelopes accompany the queries.

LETTERS TO THE EDITOR.

LIQUOR STRYCHNINÆ HYDROCHLORIDI.

Sir,—I read Mr. Martindale's letter on above subject with great interest. He has begged the point. Throughout he argues on the hypothesis that strychnine hydrochloride crystallises with one and one and a half molecules of water. Why, then, does he not say that the new B.P. is wrong in stating it at two? So far as I can see, simply to throw doubt on the accuracy of my figures. This is unfair, because in the end he admits that commercial samples approximate to two molecules. He must know, as stated, that my figures and conclusions were founded on the B.P. standard, viz., that the formula is $C_{21}H_{22}N_2O_2 \cdot HCl \cdot 2H_2O$. Why should he now attempt to recall the differences of opinion as to water of crystallisation of that salt? The B.P. has, with full information, defined it as $2H_2O$, and why should Mr. Martindale, or I, or anyone take it at anything else, except we are prepared to prove that the B.P. is wrong, which he is not? Can Mr. Martindale prepare solution of strychnine hydrochloride B.P., 1898, with a salt with H_2O or $1\frac{1}{2}H_2O$? The salt from which I prepared my new solution lost 8.4 per cent. on drying at 100 C. This is almost equivalent to $2H_2O$. The residue dissolved in water readily, showing that the salt was not affected. Mr. Martindale entirely ignores the fact which I think is indisputable, that the 1885 B.P. solution contained one grain of alkaloid in nearly 108 m, and that of 1898 one grain of hydrochloride in nearly 110 m, so that 110 m of B.P. 1885 contained $1\frac{1}{4}$ grain of strychnine, consequently the present solution bears a further reduction in alkaloidal value as 110 is to 108. I calculated for clearness, on the basis of finding the exact alkaloidal equivalent of 17.5 grains of the hydrochloride, the molecular weight of alkaloid 331.75, the hydrochloride 403.7; that is, latter contains 82.17 per cent. alkaloid, then $\frac{82.17 \times 17.5}{100} = 14.379$, which gave $\frac{1920}{14.379} = 133.5$, or nearly 134 minims in which each grain is contained. Now twice the B.P., 1885, formula produced from 18 grains of alkaloid 1940 minims (this from careful experiment), and I have $\frac{1940}{18} = 107.7$, or nearly 108 minims, so that by superposing $\frac{108}{134}$ or $\frac{107.7}{133.5}$ you find in minims the comparative strychnine value of 1885 to 1898 solutions, i.e., as 80.59 or 80.5 is to 100, practically one-fifth weaker than 1885. Supposing the formula of the hydrochloride of strychnine to be $(C_{21}H_{22}N_2O_2 \cdot HCl)_2 \cdot 3H_2O$, I find that half the molecular weight is 394.76, so that it would contain 84.03 per cent. of alkaloid, and by making reduction due to $\frac{108}{110}$ I find that the alkaloidal value of solution is 82.5 per cent., that

is, as $\frac{33}{40}$ or 5.5 minims 1885 solution equal 6.66 minims 1898—

practically one-sixth weaker. But I cannot accept this as the formula of strychnine hydrochloride until Mr. Martindale, who should be one of the last to question the B.P. standard, and practically corroborates it in his letter, can prove that one and a half H_2O (or properly, three, doubling the strychnine and HCl) be substituted for two in the formula. Even as 5 is to 6 is neither "slightly weaker" nor "one tenth weaker." Sir, the statement that Mr. Martindale makes that the 1867 B.P. solution was almost similar in strength to 1898 B.P. neither agrees with the molecule of strychnine hydrochloride at $1\frac{1}{2}H_2O$ nor $2H_2O$. With the latter the following are the figures:—

B.P. 1885,	1 gr. strychnine in	108 minims.
" 1867,	1 " " "	120 " "
" 1898,	1 " " "	134 " "

The difference is almost similar between the 1885 and 1867 as between 1867 and 1898, three distinct and not approximate strengths. Tincture of nux vomica is quoted as an example of a double strong preparation, and therefore, according to Mr. Martindale, a most important alteration. If a preparation is made weaker in greater proportion of active ingredient it is to my mind just as important an alteration for physicians to know. Tincture of nux vomica contains 1/83 gr. more strychnine in ten minims. Solution of strychnine hydrochloride contains 1/55 gr. less alkaloid in each ten minims. I repeat that the exact comparative alkaloidal strength of B.P. 1898 and B.P. 1885 solutions of strychnine hydrochloride is as 80.6 is to 100 minims; i.e., 4.47 minims to 5.5, which for all practical purposes is that 4 minims 1885 equal 5, 1898. Permit me to add that I am justifying what I have published, and that alone has urged me, holding Mr. Martindale in the greatest respect, to write this letter.

Edinburgh, July 2, 1898.

GEORGE LUNAN.

SUPPOSITORIA ACIDI CARBOLICI, B.P.

Sir,—Kindly allow me, through the medium of your valuable journal, to call attention to the "Suppositoria acidi carbolic," B.P., 1898. I have made them and find that they are much too soft to leave the mould at the ordinary temperature (65°) of the summer time. They may be stiff enough in winter, but from 6 to 12 grains of wax extra are required, according to the heat of the room, to make them leave the mould easily.

Handsworth, July 5th, 1898.

W. J. FORTNAM.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on separate slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

EXT. ERGOTÆ LIQ.—Presumably cold water should be used, as nothing is stated to the contrary. [Reply to J. W. J. T.—13/11.]

GRAMMA.—The more classical genitive termination is *-atos*, but *-atis* would not be incorrect. [Reply to J. W. J. T.—13/11.]

HERB.—It is the white horehound, *Marrubium vulgare*, a decoction of which is used for chronic asthma and coughs accompanied with abundant thick expectoration. [Reply to W. I. G.—13/12.]

STUDY OF CHEMISTRY.—Write to the Registrar of the Pharmaceutical Society, 16, Bloomsbury Square, London, W.C., for a copy of the pamphlet entitled "Advice to Students." [Reply to STUDENT.—13, 17.]

BOOKS ON BREWING.—The following will probably be useful to you:—Sykes' 'Principles and Practice of Brewing,' published at 21s.; Wright's 'Handy Book for Brewers,' 12s. 6d.; Scammell's 'Brewing and Malting,' 12s. 6d. You can obtain these books as below. [Reply to E. W. S.—12/11.]

PREPARATION FOR WATERING PLANTS.—See reply to H. W. R. in next column. [Reply to OPOPONASE.—13/24.]

SAMPLE OF INSECTICIDE.—This consists of an alcoholic solution of crude nicotine and a little camphor. [Reply to H. H. M.—13/8.]

METALLUM ALBUM.—The name "metallum album" is a synonym for white arsenic. [Reply to H. M. M.—12/24.]

CRUDE NICOTINE FOR INSECTICIDE.—Write to Whiffen and Sons, Howard and Sons, Morson and Sons, or any of the large makers of alkaloids. [Reply to J. S.—13/14.]

RECIPE FOR THICK SAUCE.—See reply to "R. W." at page 604 of last volume. Use the same recipe, but substitute tomatoes, 32 parts, and apples, 32, for apples, 64, as there given. [Reply to E. C.—12/26.]

STERILISATION OF MILK.—Absolute sterilisation can only be secured by heating the milk to boiling point for six hours, but for all practical purposes it suffices to fill a bottle with the milk and heat on a water bath or in a saucepan containing water, to a temperature of 70° C. Keep the milk at that temperature for half-an-hour, then close the bottle securely, and preserve in a cool place. [Reply to J. T. D.—13/22]

GLOSSY NON-INFLAMMABLE PAINT.—Probably increasing the amount of sodium silicate, or the addition of finely-powdered asbestos will do what you require. Borax certainly would not, until the paint was fused. This is a matter in which practical experiment on your part may be usefully conducted. [Reply to ANTISPASMODIC.—12/18.]

PHOSPHORUS PASTE FOR RATS.—Phosphorus, 1 oz.; carbon bisulphide, 5 ozs.; tallow, 24 ozs.; fine oatmeal, 24 ozs.; anise oil, 3 drachms; ultramarine blue, $\frac{1}{2}$ oz. Dissolve the phosphorus in the bisulphide and rub it with the fat until most of the solvent has evaporated. Then add the oatmeal, with which the ultramarine has been previously mixed, and mass intimately, adding a little more tallow if required. [Reply to ALPHA.—12/31.]

TITRATION OF MORPHINE.—The titration with standard sulphuric acid, of the morphine crystals obtained in the new Pharmacopœia method of determining morphine in opium and its preparations, is a refinement of chemical procedure introduced by the compilers of the Pharmacopœia to show that the work is up to date. More important errors are possible in the course of morphine determination by unskilled operators than the error which is likely to arise from the slight impurity in the morphine crystals that titration is intended to guard against. It is assumed in the B.P. process that the weight of pure anhydrous morphine is indicated by titration, which is not always the case. [Reply to W. J. C.—13/10.]

ASSAY OF SULPHUR IN SPENT OXIDE.—Take 1 Gm. of the well-bulked sample, and add to it, in a beaker covered with a watch-glass, 10 C.c. of bromine solution, made by dissolving 7.5 Gm. potassium bromide in 10 C.c. of water, adding 5 C.c. of bromine and water to produce 50 C.c. Mix well and stand for ten minutes in the cold. Add 10 C.c. nitric acid, mix, and allow to stand for another ten minutes. Then heat gently on water-bath and when action ceases remove the watch-glass and evaporate to dryness. Now add 10 C.c. of hydrochloric acid, cover up, and when quiet again evaporate to dryness. Add 1 C.c. hydrochloric acid and 50 C.c. hot water, digest until solution is complete, filter and wash with hot water; add ammonia in slight excess, filter out the precipitated ferric hydrate, and wash it thoroughly. To the filtrate add a slight excess of hydrochloric acid, boil and, while boiling, add excess of barium chloride (10 per cent. solution) at the rate of 1 drop per second. The ferric hydrate precipitate is redissolved in hot dilute hydrochloric acid, and 10 C.c. of barium chloride solution added to it, and allowed to stand over night. The precipitated barium sulphate from both solutions is collected on one filter, ignited, and weighed in the usual manner. The above is Gladding's process, *J. Amer. Chem.*, xvi., 398, through *J. S. C. I.*, xiv., 190. [Reply to LIGNUM.—12/27.]

BOTANICAL.—We hope to identify your specimen shortly. [Reply to W. J. W.—13/7.]

BROWN HAIR DYE.—The amount of silver nitrate is rather large; half the quantity is quite sufficient. The preparation would be improved by adding a drachm of glycerin to each fluid ounce. [Reply to W. F.—12/21.]

FREEDING GOLD CHLORIDE SOLUTION FROM IRON.—The only way to do this is to reduce the gold to the metallic state, wash it thoroughly, and again redissolve it in aqua regia. Mix the solution with an excess of oxalic acid, let it stand in bright sunlight for some hours, when the whole of the gold will be thrown down in a convenient form for washing. [Reply to TAR.—12/10.]

BOOKS ON MILK, BUTTER, ETC.—Probably 'Milk, Butter and Cheese,' by Dr. James Bell, which is Part II. of the series on 'Analysis and Adulteration of Foods,' of the South Kensington Museum Science Handbooks, published by Chapman and Hall, will suit you. For details of current methods you should refer to the volumes of the *Analyst*. [Reply to E. W. H.—12/11.]

DOBELL'S POWDER.—We are informed by Dr. Horace Dobell that he has often been applied to about "this mysterious powder," which appears to have been originated by some American who connected Dr. Dobell's name with it without authority. We have no information regarding the composition of the powder. [Reply to A. McK.—12/33.]

FLASH POINT FOR PETROLEUM.—There is no simple test for the flashing point of petroleum, the results obtained by any but the Abel flash point instrument, or some modification of it, in which the flash is given in a closed, protected vessel, being of little or no use. In this country the "Abel test" is the only legal standard, and you cannot work that without using the special apparatus prescribed for its application. [Reply to HUMUS.—12/20.]

CHEMICAL MANURES FOR PLANTS.—For garden plants or flowers in pots use either of the following: (No. 1), Ammonium sulphate, 10; sodium nitrate, 15; ammonium phosphate, 30; potassium nitrate, 45. (No. 2), Bone black, 4; potassium nitrate, 2; ammonium phosphate, 2; iron sulphate 1. Suspend two teaspoonfuls of either in a gallon of water and apply once a week. No. 1 is best for most plants in bloom; No. 2 for use before flowering. [Reply to H. W. R.—12/25.]

BOOKS ON SHEEP AND CATTLE.—The following books by Armytage are suitable for an intelligent farmer about to emigrate: Armytage's 'Every Man His Own Cattle Doctor,' 21s.; the same author's 'Every Man His Own Sheep Doctor,' 10s. 6d.; and his 'Cattle and Sheep,' 2s. 6d. You can purchase all these books, less 25 per cent. discount, of H. H. Grattan, Tabard Book Store, Borough High Street, S.E. [Reply to J. J. T.—12/28.]

COMPOSITION OF HEADACHE POWDER.—The active ingredient of the headache powder is acetanilide. [Reply to HEADACHE.—13/18.]

LOTION FOR HORSE'S BROKEN KNEES.—This contains lead acetate in quantity, a little zinc oxide, some alcohol, and oil of turpentine. Probably the lead was originally added as soluble basic lead acetate, and the zinc as calamine, but the stuff has evidently been made a very long time. [Reply to FEMINA.—12/23.]

ANONYMOUS QUERIES.

J. L. J. (Ironbridge), and J. L. F. (Birkenhead), are referred to our rule with regard to anonymous queries.

OBITUARY.

CORY.—On May 30, Francis Albert Cory, Chemist and Druggist, Newport, Isle of Wight. Aged 40. Mr. Cory was an Associate of the Pharmaceutical Society.

BLIDBERG.—On June 25, Anders Sven Frederic Blidberg, Chemist and Druggist, late of Forest Gate. Aged 39.

CRANSTON.—On June 28, John Cranston, Chemist and Druggist, Darlington. Aged 69.

PARLIAMENTARY NOTES.

PHARMACY ACTS AMENDMENT BILL.—In the House of Lords on Thursday, The Earl of Hardwicke rose to move the second reading of the Pharmacy Acts Amendment Bill. He said: "My Lords, the objects of this Bill are, I think, so clearly and fully set forth in the memorandum accompanying the Bill, that I need do no more than move that it be read a second time." The Bill was then read a second time, without discussion.

THE HONOURABLE BARONETS associated with measures for the earlier closing of shops—to wit, Sir John Lubbock and Sir Charles Di'ke—have recognised that "What fates oppose, that men must needs abide," and they have consequently dropped the responsibilities involved in watching and hoping for a second reading which never comes. In short, they have thrown over early closing for the Session. It is a curious illustration of the change in Parliamentary procedure, or one might almost say fashion, that the old "this-day-six-months" motion is falling into disuse. The Shops Bills have at no period of their sessional career this year been obstructed by the "block" direct, but the indirect method of stopping nominally unopposed Bills by crying "I object," or "No," whenever they are reached in the House, has proved quite as efficacious, and it allows honourable gentlemen to be obstructive without publicity—a no inconsiderable advantage to the representative of a peppery constituency.

"SENT TO THE COMMONS" is the legend tacked on to the House of Lords Poisons Bill, but that much-discussed measure has not yet appeared in the Lower House. Possibly the angry murmur of approaching opposition may have penetrated the calm of the Privy Council Office, and disturbed that species of divinity that hedges a Government Department. At any rate, the Bill will scarcely be able to rank with non-contentious business, and as the Session has little more than four weeks to run, Ministers may quite reasonably shirk the responsibility of taking up such a prickly piece of legislation. As far as it is at present known, the opposition of the Pharmaceutical Society, with 15,000 chemists at its back, will be supplemented by the political efforts of the Pharmaceutical Society of Ireland, and the possibly more powerful pressure of the manufacturers of the poisonous substances scheduled in the Bill. Moreover, vestries are growing alarmed at a fancied interference with their paternal right to distribute carbolic disinfectants without regulation or restraint; hence it may be assumed that protests may be hurled at the Government by the Parochial and City Fathers throughout Great Britain. Add to these considerations the wrath of Mr. Alexander Cross, whose disinterested desire to protect the seed-selling public has been officially ignored, and the least observant of mortals will see that the elements of a very pretty discord lie handy for mixing.

MR. MONK (Gloucester) on June 30 betrayed a desire to place phosphorus matches on a Home Office "Index Expurgatorius." He asked whether the sale of such poisonous articles should not be made unlawful, on the ground that they are dangerous to the operatives who make them, as well as to those who use them. The Home Secretary did not follow the precedent set in "another place," and talk of monopoly or restriction of trade, but he told his honourable friend to await the result of inquiries which the Department was prosecuting, both at home and abroad, in relation to the use of phosphorus. He added that certain methods have been devised by which it is claimed that the use of phosphorus, both white and yellow, can be rendered harmless. There seems to be a possibility of further scope for the exercise of Departmental ingenuity in the way of regulations.

THE LONDON UNIVERSITY BILL is one of the measures which the Government has set its mind on passing this Session. It is awaiting second reading, but Vaccination claims first consideration. Opposers of the University Scheme saw in this position an opportunity not to be neglected, and they endeavoured to prolong the proceedings in the Committee stage of the Vaccination Bill in the hope of hindering their own pet aversion. Mr. Chaplin, however, met the move by a checkmate by obtaining leave to suspend the ordinary rules as to the adjournment of the Standing Committee, with the result that the business had to proceed to a finish, and one more bar to the consideration of the University Bill has been removed.

MR. JEFFREYS is again worrying the President of the Local Government Board to produce his Adulteration Bill, though what practical purpose the introduction of such a Bill at this late period of the Session would serve is hard to discover. Mr. Chaplin has already told the House that he was not prepared to introduce the measure unless he had a reasonable prospect of making progress with it.

ON THE IRISH SIDE of the St. George's Channel they manage some things better than they do here. Some time ago, at an inquest in a poisoning case, it came out in evidence that a scheduled poison had been sold to the deceased by a limited company in an unlawful manner, that is to say, the statutory requirements as to knowledge of the purchase and entry in the poison-book had not been complied with. The Pharmaceutical Society of Ireland very properly handed the matter over to the police, but the police declined to take it up. Similar instances in England and in Scotland are not uncommon. But the powers in Dublin have not taken the refusal quite so mildly as we are apt to do in Great Britain, for Mr. Field has given notice that he will call attention to the case in the House on Monday, July 11, and will be glad to know why the police did not prosecute, and why the law was not carried out.

MEDICAL JOTTINGS.

THE LATE MR. ERNEST HART'S COLLECTION of Japanese colour prints has been sold during this week by Messrs. Sotheby, Wilkinson and Hodge, at Wellington Street, Strand.

THE REMAINS OF HAHNEMANN, the apostle of homœopathy, have been transferred from the Montparnasse Cemetery, Paris, to Père-Lachaise. Hahnemann died in Paris in 1843.

MR. ARTHUR J. BALFOUR, M.P., and Sir Samuel Wilks, President of the Royal College of Physicians, have been elected to the Corporation of Guy's Hospital.

THE WORKMEN'S COMPENSATION ACT, which came into force on the 1st inst., has caused the disbandment of several firms' accident societies, with the result that in Lancashire a federation of doctors has been formed. The medical men of Pendlebury, Swinton, Pendleton, Walkden, Littlehalton, Farnworth, and Atherton have joined the Association, and decided to make a uniform charge of fifteen shillings for advising upon accident cases brought under the new Act.

COMPRESSED DRUGS.—A doctor, writing to a medical contemporary, states that he had occasion to prescribe for a patient with nervous headache, coupled with vomiting, compressed tablets of phenacetin, gr. iv; caffeine, gr. j. These were made up locally by chemists. Three months ago the tablets from one maker gave relief, though occasionally vomited unchanged three or four hours after administration. They were not noticed in the stools. More recently similar tablets from another maker gave no relief whatever. They were increased up to ten daily without producing any physiological action on the patient. These tablets were sometimes vomited many hours after administration, and were passed in the stools quite unchanged. Antipyrin gr. x. in water was then prescribed, with the most happy results.

PUMICE STONE is recommended for use in the desquamating stage of scarlatina. The soles of the feet and the palms of the hand are rubbed with it frequently in order to remove the hard dead epidermis, the presence of which would otherwise often prevent a case from being released from quarantine till long after the rest of the body had freely desquamated and the orthodox period of six weeks' isolation had expired.

THE FOLLOWING EXTRACTS are taken from 'Collections and Recollections' by "One who has kept a Diary." This volume, which though issued at 16s. a few weeks since, has already run into a third edition and created quite an unusual interest. It is an open secret that the diarist is Mr. G. W. E. Russell, ex-M.P., author of one of the best known biographies of Mr. Gladstone:—"The humour which underlies the roughness of country speech is not only genuine

but subtle. I have heard a story of a young labourer who, on his way to his day's work, called at the Registrar's office to register his father's death. When the official asked the date of the event, the son replied: 'He ain't dead yet, but he'll be dead before night, so I thought it would save me another journey if you could put it down now.' 'Oh, that won't do at all,' said the Registrar, 'Perhaps your father will live till to-morrow.' 'Well, I don't know, sir; the doctor says as he won't, and he knows what he has given him.'"

THE ART OF ADVERTISING is commented on by the Author, who says:—"I cannot quit the subject of advertisements without saying a word about the medical branch of this fine art, and knowing the enormous fortunes which have often been made out of a casual prescription for acne or alopecia, I freely place at the disposal of any aspiring young chemist who reads this paper the following tale of enterprise and success. A few years ago, according to the information before me, a London doctor had a young lady patient who complained of an incessant neuralgia in her face and jaw. The doctor could detect nothing amiss, but exhausted his skill, his patience and his remedies in trying to comfort the complainant, who, however, refused to be comforted. At length, being convinced that the case was one of pure hypochondria, he wrote to the afflicted lady, saying that he did not feel justified in any longer taking her money for a case which was evidently beyond his powers, but recommended her to try a change of air, to live in the country, and to trust for her cure to the *edax rerum* which sooner or later cures all human ills. The lady departed in sorrow, but in faith, obeyed her doctor's instructions to the letter, and established herself not a hundred miles from the good city of Newcastle. Once established there, her first care was to seek the local chemist and to place the doctor's letter in his hands. A smart young assistant was presiding at the counter. He read the doctor's letter, and promptly made up a bottle, which he labelled "Edax Rerum: to be taken twice a day before meals," and for which he demanded 7s. 6d. The lady rejoicingly paid, and requested that a similar bottle might be sent to her every week until further notice. She continued to use and pay for this specific for a year and a half, and then, finding her neuralgia considerably abated, she came to London for a week's amusement. Full of gratitude, she called on her former doctor, and said that though she had felt hurt at the abrupt manner in which he had dismissed so old a patient, still she could not forbear to tell him that his last prescription had done her far more good than any of its predecessors, and that indeed she now regarded herself as practically cured. Explanations followed; inquiries were set on foot; the chemist's assistant sailed for South Africa, and "Edax Rerum" is now largely in demand among the unlettered heroes who bear the banner of the Chartered Company.

EXTRACTS FROM CONSULAR REPORTS.

THE TOTAL NUMBER OF CHEMICAL WORKS registered in all parts of Germany, according to the latest trustworthy statistics, is 6144, the total number of persons employed by them being 125,440. Amongst the industries of the Hamburg Consular district which have attained to the greatest importance are those for manufacturing various chemical products, such as nitrates, sulphuric and nitric acid, sulphates, boracic acid, artificial manures, pharmaceutical products, dyeing and tanning extracts, essences, and more particularly different kinds of explosives. The factories in that district now employ altogether some 4000 workmen as compared with about 1300 ten years ago, thus demonstrating the rapid strides made through Germany by most branches of chemical industry during recent years.

THE MANUFACTURE OF MARGARINE is said to be responsible for the increasing business of Bremen oil manufactories, which make a specialty of sweet oil, one of the ingredients of margarine. The manufacturing of linoleum, in which linseed oil and varnish are used, is another cause for the prosperity of the oil business in Bremen.

THE GREATEST IMPORTER OF RESIN on the Continent, according to recent statistics, is the town of Harburg, a position it has held for many years.

THE ADULTERATION OF SUMACH AND ESSENCE OF LEMON in Sicily was the subject of a decree issued by the authorities during 1897, by which the exporter of these articles of commerce was compelled to mark on the packages, invoices, etc., the quality and quantity, if any, of the adulterant used. This law, however, according to Consul Pigott, has not been put into force, and the general opinion is that it will remain a dead letter.

WITH REGARD TO SUMACH-GROWING, there appears to be a danger of the industry dying out, inasmuch as the grinders of sumach have formed themselves into a syndicate and have fixed the price to be paid to the growers, for first quality leaf, at so low a figure that it barely covers the cost of cultivation, rent and government. Consequently some of the growers are cultivating the crops only twice annually instead of three times, and others have commenced to cultivate wheat and barley where formerly sumach was grown.

OLIVE-TREE NURSERIES in the Vilayet of Tripoli are reported by Consul-General Jago to be practically unknown, the creation of new plantations being impossible on account of a Government tax, which is levied alike on old and young trees, irrespective of their oil-bearing powers. The peasants are unable to pay the tax on young unproductive trees during the years required to attain maturity; consequently few young trees are planted. About eight years ago a Governor of Khoms obtained permission from the Porte to plant some 30,000 young trees to be exempt from taxation for ten years, but since his removal from the post nothing further has been done in that direction.

THE RUSSIAN GOVERNMENT has a monopoly of the sale of spirituous liquors, and heavy penalties are exacted for infringements of the regulations. Special provision is made for the sale of either raw or rectified spirits to chemists and those engaged in scientific work, etc., at a price determined by the Minister of Finance. A very interesting report on this Government spirit monopoly has been prepared by Mr. Carnegie, Second Secretary to Her Majesty's Embassy at St. Petersburg, giving a brief history of the drink question in Russia.

THE CULTIVATION OF VANILLA at Tahiti during 1897 was stimulated by the continued demand and the high prices ruling at the end of the previous year. The growers consequently exercised greater care, and this has led to an increase in the export of the article of 16,606 lbs., valued at £19,351, the total quantity being 75,740 lbs., value £35,408. The price paid for vanilla in January, 1897, was about £1 per kilo, gradually rising in value until £1 16s. per kilo. was reached. Ultimately, however, a reaction commenced, and the price declined to 16s., with little prospect of an immediate improvement.

THE EXPERIMENT OF REFINING NATIVE CHINESE OPIUM at Swatow, so as to give it the smell and taste of the drug imported from India and Persia, is still being persevered in. The enterprising individual who is conducting the refinery estimates that he will be able to produce about 1000 balls of 6 lbs. each per month, and expects to sell it at a profit at less than half the cost of the foreign drug. None of the refined article has so far appeared in the market, and the foreign drug continues to find favour amongst the opium smoking Chinese. The total import of foreign opium into Swatow in 1897 was 4228.29 piculs of 133½ lbs. each (563,772 lbs.), valued at £317,846, being an increase of 486 piculs over the import of 1896, and of 106 piculs over that of 1895.

FLOWER GROWING has made great progress of late years in Germany, and the gardeners are gradually conquering the powerful competition of the flower growers of the Riviera and Upper Italy, notwithstanding the disadvantages of the German winter. It is reported that now imported flowers are only occasionally sold in the streets of the large cities, while in the first-class shops, German cut flowers are almost exclusively used.

A FRESH USE FOR SEAWEED is claimed to have been discovered by a Norwegian engineer, who exhibited an invention at the Stockholm Exhibition for producing paper-glue, dressing-gum, and soap from seaweed. The first establishment for this branch of manufactory was, according to his statement, to be erected in the district of Stavanger, but Vice-Consul Berensten reports that up to the present nothing has been done in this direction.

PHARMACEUTICAL TRANSACTIONS.

WESTERN CHEMISTS' ASSOCIATION (OF LONDON).

A well-attended meeting of this Association was held at the Westbourne Restaurant, Craven Road, W., on Wednesday, July 6, the chief business being to discuss the Poisonous Substances Bill.—The President, Mr. J. H. MATHEWS, occupied the chair.—After the minutes of the previous meeting had been read and confirmed, the PRESIDENT proposed that Mr. Richard Bremridge be elected an honorary member of the Association, also that Mr. J. C. Umney, Divisional Secretary for Southwark, and Mr. William Harvey, Divisional Secretary for one of the Eastern Divisions of London, be elected members.—Mr. G. S. TAYLOR seconded the proposals, which were carried.—The PRESIDENT next intimated that he had received letters apologising for absence from Mr. William Warren and Mr. J. W. Taplin, the ex-President, the latter notifying his decided opposition to the Poisons Bill now occupying the attention of the Legislature. The President then went on to say that he thought the Poisonous Substances Bill lately introduced in the House of Lords by the Duke of Devonshire would injuriously affect the whole country in a greater or less degree, but especially country chemists. In his opinion the Bill had been ill-conceived, introduced at a most inappropriate time, and if passed into law would to a great extent nullify the Pharmacy Act now in existence. There was no formal resolution before the meeting, but he would ask Mr. R. H. Parker to introduce a discussion on the subject.—Mr. PARKER said

THE POISONOUS SUBSTANCES BILL

brought forward by the Privy Council, involves two principles of very great importance. First, as to who is to sell poisons; and second, as to who is to frame regulations for storing, selling, and dispensing them. At the outset he might say that he thought it a great pity the Privy Council has such an objection to consulting with the Pharmaceutical Society with regard to the regulations for the sale of poisons. The members of that body seemed to be of opinion that the main object of the chemist was to sell as much poison as possible. This was a distinct libel on the community. There was no body of men more desirous that the sale of poisons should be conducted in a rational and satisfactory manner than the members of the Pharmaceutical Society. But here they had the Privy Council taking upon itself the entire responsibility of regulating the sale of poisonous substances, about which its members knew very little, and ignoring altogether the men whose training had given them a thorough knowledge of their dangerous properties, and had specially qualified them to handle those substances. In his opinion the only rational *modus operandi* would be for the Privy Council to ask the Pharmaceutical Society to frame practical regulations. Coming to the question as to the sale of poisons, Mr. Parker asked: Did chemists as a body wish to have the sale of poisons monopolised to themselves? He did not think so; as a matter of fact, he knew that a great many chemists would rather be relieved of the sale of poisons, and wash their hands of the whole business. For chemists to monopolise the sale of poisons would be, he believed, to a great extent impracticable. It seemed to him, therefore, that the most satisfactory thing would be for regulations to be made dealing only with those poisonous substances which menace the safety of the public, and those should only be sold by qualified men. There was a certain class of poisons which did not endanger the safety of the public. For instance, there was no need for chromate of lead to be placed in the Schedule; he did not know of any case in which anyone had attempted to commit suicide with that substance. But on the other hand there was carbolic acid which, all would agree, should be placed in the Schedule. Whenever a poison showed itself to be a danger to the public, such as was the case with carbolic acid, so long should its

SALE BE RESTRICTED TO THE TRAINED CHEMIST.

He looked upon the remark of the Duke of Devonshire, with regard to the sale of poisons being a monopoly, as an insult to chemists. Mr. Parker then went on to deal with the difficulty of framing workable regulations. He thought the Pharmacy Act of 1868 would meet all requirements with certain additions to the Schedule. But with regard to the Poisonous Substances Bill, it has many points which render it entirely unworkable. He proceeded to give instances

where, if a literal construction were put upon the Act when passed into law, in dispensing weak solutions of carbolic acid or sulphuric acid, unless prescribed according to the B.P., it would be necessary to label them "poison," or "to be used with caution." Spirit of camphor would also come within the meaning of the Act. Such a state of things as that almost made one laugh at the incapacity of the Privy Council. He was of opinion that as chemists they ought to make it distinctly understood that as they are required to be specially educated and trained for dispensing, they ought to be allowed to use their discretion in the dispensing of prescriptions. It was his experience that very often the physician when prescribing a medicine containing poison did not wish his patients to know the nature of what they were taking, and gave special instructions to the chemist to that effect. But if the Bill passed it would be necessary to label all such medicines. He believed that chemists generally exercised the greatest care in labelling medicines without any special regulations being compulsory. He therefore begged to move—

That this meeting is of opinion that the Privy Council's Poison Bill is altogether opposed to the principle of the Pharmacy Act, 1868, and considers that the sale of all poisonous substances which menace the safety of the public should be in the hands of trained vendors only.

—Mr. H. CRACKNELL, Hon. Secretary, formally seconded the motion.—Mr. J. A. BARNETT said the sale of poisons was a very vexed question, but whatever legislation was brought forward by the Government there was bound to be about the same amount of poisoning cases. He considered it a great anomaly that a person can purchase large quantities of poison from wholesale houses without any restriction, while if a few grains are obtained from a chemist certain objectionable formalities have to be complied with. He thought chemists ought to have better representation in Parliament.—Mr. J. C. HYSLOP thought the Poisons Bill as drafted showed great want of common sense. It was a Bill which ran contrary to the principle embodied in the Pharmacy Act already in existence. The principle underlying it was also contrary to the Duke of Devonshire's own Bill—the University Commission Bill—which aimed at the better education and culture of the citizens of London. There was a danger of that Bill being stamped out simply on the ground of trade interest. Chemists must not oppose the Poisonous Substances Bill on the ground of trade interest, but because there is already an Act of Parliament in existence which can be made to meet the exigencies of the case.—Mr. F. ANDREWS thought that the chemists and druggists of this country, after passing a most stringent examination, are fully qualified to perform the duties of their calling, and that no evidence whatever has been adduced to show any negligence in the performance of those duties. The requirements of their calling vary so much in different localities as to make it impossible to carry out a rigid rule for every occasion and in all places, and therefore any interference in their arrangements, especially by anyone not fully acquainted with the requirements of the business, is not only totally unnecessary and uncalled for, but likely to be productive of much difficulty and even danger to the public.—Mr. JOHN HICK considered that the reason why the Privy Council had brought forward this Bill, and also why it has so persistently refused to place carbolic acid in the Schedule of the Pharmacy Act, 1868, was because certain promises made by the late Mr. Sandford to the Government respecting regulations as to the sale of poison have not been carried out. He thought, however, that by going the right way about the matter the Bill might be so amended as to be of benefit to chemists.—Mr. D. T. DAVIES thought it would relieve chemists of much responsibility if persons requiring poison in any large quantity should first be obliged to obtain an order from the police. He believed that had to be done in Germany.—Mr. G. S. TAYLOR was of opinion that any opposition to the Bill must be made in the House of Commons, therefore he suggested that they as an Association should approach the members of Parliament for the various divisions represented.—Mr. C. A. TILY thought an appeal should be made to the Government by the Pharmaceutical Society, pointing out that chemists generally have invariably carried out all necessary precautions in the sale of poisons, and that the cases of poisoning which have occurred have largely been in cases where the poison has been obtained from other sources than from chemists.

Dr. B. H. PAUL, although not a member of the Association, was by the courtesy of the meeting requested to make a few remarks. He said the Bill which has passed the third reading in the House of Lords is a Bill which deals with two essentially distinct matters,

One is a matter of pure trade. A proposal is made in the Bill to regulate the sale of articles now outside the operations of the Pharmacy Act. They are sold at the present time by anyone, and the intention of the Bill is that the sale should be made so as to ensure the safety of the public. One of those articles is

CARBOLIC ACID,

and the record of poisoning by carbolic acid is such that it stands far above any other substance or class of substances, the number of deaths during 1895 and 1896 from carbolic acid poisoning alone being 455. Therefore, it is very evident that there is great need for something to be done for the protection of the public against the sale of this article. The Bill has been brought in, apparently, in response to the appeal made when the Pharmacy Acts Amendment Bill was before the House of Lords. The appeal was made to the Home Secretary for a Bill to protect the public, and he thought this Bill had been rushed forward in response to that appeal. The mere trade object can easily be fulfilled by placing carbolic acid on the Schedule of the Pharmacy Act, and restricting its sale to chemists. As there is a sufficiency of qualified men throughout the country, that would not interfere with the convenience of the public. In country places chemists have to deal in rough articles as well as the finer preparations of their calling, and many are to all intents and purposes druggists. A man of that class, of superior education, was, he thought, the best man to deal with that class of article for the safety of the public. The other object of the Bill is a perfectly distinct one. It proposes to give the Privy Council power to make regulations for the storing, dispensing, and sale of poisons, which is a matter entirely for the Pharmaceutical Society. The regulations of the sale of poisons contemplated when the Pharmacy Act was passed are embodied in the Act. Those regulations can be enforced by the police or anybody, and were not left to the Pharmaceutical Society. These regulations were intended to apply altogether to the sale of poisons. The statement that the Pharmaceutical Society has failed to carry out a promise alleged to have been made at the time—there is no proof that any such promise was made—is a matter of opinion, and, on the other hand, it has been asserted that

IF ANY PROMISE WAS MADE,

it was made without authority. It is the Society which is to make the regulations and not the Council. The Council did draw up regulations, but the Society refused to adopt them. At that time there were several thousand men who were in the business before the passing of the Act, some thoroughly respectable and competent men, others, however, quite the reverse, and it was upon that fact that the demand was made for the regulations. The Society met, and it was decided that those regulations should not be made compulsory for the conducting of the business of a chemist and druggist. That was thirty years ago, and they did not stand in the same position now. Essentially the requirements of those regulations are observed by all chemists associated with the Pharmaceutical Society. Conditions have altered since then, and although there are still 4,000 men who were registered before the passing of the Pharmacy Act, they are a class of men rapidly passing away. It is reasonable, therefore, for chemists to feel an affront at the proposal, which is an absolute reversal of the principle of the Act of 1868. That Act was not asked for by chemists, but was forced upon them by Parliament for the safety of the public. There was opposition to the Act from a certain class who did not want regulations for the practice of pharmacy, and consequently the Bill degenerated into a mere Poisons Bill. There is another important point. Clause 2 of the Poisonous Substances Bill proposes that the Privy Council shall have powers to make further regulations for the storing and sale of poisons. Now, if the Registrar-General's Report giving the records of deaths from accident and suicide is consulted, it will be seen that not a single accident has been caused in the dispensing of medicine. The reason for regulations that existed thirty years ago is gradually dying out, and in time will entirely cease to exist. With regard to what is to be done in the opposing of this Bill on the ground that the education of the vendor is the best safeguard for the public, the best mode of dealing with this is for the Pharmaceutical Society to act, and throughout the country the members should inspire the Pharmaceutical Council what to do on their behalf.—The PRESIDENT said they were all deeply grateful for the remarks of Dr. Paul, as he had certainly put the

matter in an entirely new light. Continuing, he said that with Mr. Parker's approval he would put this motion in an amended form, viz :—

That this meeting is of opinion that the Privy Council's Poisons Bill is altogether opposed to the principles of the Pharmacy Act of 1868, and such an interference with the arrangements now in force by those not fully acquainted with the requirements of the business is not only totally uncalled for, but is likely to be productive of much difficulty and even danger to the public.

—Mr. W. P. ROBINSON seconded the amended motion, which was carried unanimously, and it was agreed that copies of the resolution should be sent to the Council of the Pharmaceutical Society, to the Privy Council, and to the members of Parliament for the district. It was also agreed that a deputation should wait upon local Parliamentary representatives.—Mr. ANDREWS then moved—

That this meeting of the Western Chemists' Association of London requests the Council of the Pharmaceutical Society to call a meeting of the whole trade with the object of organising opposition to, or amending, the Poisonous Substances Bill now before the Legislature.

—Mr. MATHEWS seconded this, and it was carried, but several members did not vote on the motion.

BOLTON CHEMISTS' ASSOCIATION.

The members of this Association held a special meeting on July 4 to consider the action to take in the matter of the new Poisonous Substances Bill introduced into the House of Lords, and the following resolution was unanimously adopted :—

That this meeting of Bolton chemists and druggists, whilst of opinion that it is necessary to provide some regulations as to the sale of the articles named in the Government Poisonous Substances Bill, regards that Bill as inadequate for the purpose and ambiguous in its details. This meeting is also of opinion that the Bill constitutes a dangerous departure from the principles of the Pharmacy Act of 1868, and calls upon the Council of the Pharmaceutical Society to strongly oppose the Bill, and to endeavour to obtain such an amendment of the law as will be in harmony with the Pharmacy Acts and secure the safety of the public.

SCHOOL OF PHARMACY.

On Friday, July 1, the end of the session at the School of Pharmacy was marked by a presentation to Mr. Wilson, the Pharmacy Demonstrator, on the occasion of his departure from the School. The presentation was made by Mr. T. E. Lescher, who in presenting a handsomely fitted dressing case on behalf of the students, said that they all appreciated Mr. Wilson's efforts to assist them in every possible way, and that they all regretted his departure from their midst, and wished him every success in his new work.—Mr. WILSON, in acknowledging the present, thanked the students for their kind wishes, and said that as a student and demonstrator his reminiscences of the "Square" would always be happy ones. In conclusion he wished them all success at the coming examination.

IMPERIAL COLLEGE OF CHEMISTRY AND PHARMACY.

On Monday, July 4, the last of the visits of the present term to places of interest to pharmaceutical students was made, under the direction of Mr. Frederick Davis, to the Science Galleries, South Kensington. Great interest was shown by the students in the models representing the various natural orders and in the diagrams explanatory of transpiration and the physiological functions of plants. The explanation of the models representing the making of sulphuric acid and sodium bicarbonate occupied more than an hour. A vote of thanks was proposed to Mr. Davis, which was carried unanimously.

MIDLAND PHARMACEUTICAL ASSOCIATION.

At a special meeting of the Council of this Association, held at Mason University College, it was resolved that all prescriptions written on and after July 1, 1898, should be dispensed in accordance with the requirements of the 1898 Pharmacopœia, unless otherwise specified, and it was deemed advisable to notify the medical profession of this important resolution. A circular to that effect has been issued, also drawing the attention of medical men to the alteration in the strength of several important preparations, and asking them to render the Association all possible assistance in the matter by specifying on all prescriptions when 1885 preparations are required.

Pharmacy and the Allied Sciences

A REVIEW OF CURRENT WORK.

Acetic Acid as a Solvent. F. W. E. Stedem, in a paper read before the Pennsylvania Pharmaceutical Association, on "Cheaper Solvents," gave the results of experiments on the exhaustion of drugs with acetic acid. The following table summarises the results obtained with 40 per cent. acetic acid:—

Name of Drug.	Weight Used.	Menstruum Used.	Extract Obtained.
Ergot.....	250 Gm.	500 C.c.	100 Gm.
Gent'an	500 Gm.	1200 C.c.	380 Gm.
Belladonna	500 Gm.	1000 C.c.	210 Gm.
Cascara.....	500 Gm.	1000 C.c.	250 Gm.

—*Am. Journ. Pharm.*, lxx., 365.

Bacteria Counter. W. P. Mason describes the "Miller-McPherson" apparatus for determining the number of colonies of bacteria developing in culture media. A ruled glass plate is fixed horizontally at the top of a wooden stand, being inserted in grooves on two sides, and under this a "Petri" dish rests upon a movable ebonite plate, which can be raised or lowered by a wheel beneath it, actuating a hollow screw. The dish may thus be kept firmly against the ruled plate, with no chance of slipping, and it will always be in focus. If a "Miquel" flask be preferred to a "Petri" dish, the neck of the inverted flask is passed through a hole in the ebonite plate into the hollow screw, and the bottom of the flask can then be raised against the ruled plate by means of the wheel, the same as when a "Petri" dish is employed.—*Journ. Am. Chem. Soc.*, xx., 507.

Chemistry of Cascara. A. R. L. Dohme and H. Engelhardt have investigated the constituents of the bark of cascara sagrada gathered in Oregon, and somewhat less than one year old. It was in thin quills with a light grey cork layer outside a yellowish-brown layer of cortical parenchyma, and was markedly bitter when chewed for a few minutes. The powder was yellowish-brown, and after being air-dried and carefully heated in an air-bath at 110° C. to constant weight, it was found to contain 8.3 per cent. of moisture, whilst the ash determinations varied from 6.9 to 7.05 per cent. Extraction with chloroform yielded 7.5 per cent. of a dark greenish-brown oil of pronounced odour resembling that of the bark. From this was obtained a small quantity of an extremely volatile yellowish-green oil, to which the odour of the bark appears to be due. The fixed oil is probably a mixture of dodecyl palmitate and stearate. Subsequent treatment of the residue from the chloroform extract with 80 per cent. alcohol resulted in the separation of 27 per cent. of a hard, brown, bitter mass which contained a glucoside named "purshianin." Hot water extracted inert starch, sugar, etc., equivalent to 12.3 per cent. of the weight of the original air-dried powder, and 0.5 per cent. caustic potash solution extracted 21.3 per cent. of colouring matter. The result of the analysis is summed up thus:—

Moisture	8.3 per cent.
Soluble in chloroform	7.5 "
" " alcohol (80 per cent.) ..	27.5 "
" " hot water.....	12.3 "
" " dilute alkali	21.3 "
Cellulose	16.1 "
By difference, starch, etc.....	7.0 "

Total 100.0

Buckthorn bark has previously been shown to contain a glucoside, frangulin, which splits up into emodin (trioxymethylantraquinone), and a sugar—rhamnose or isodulcitol, whilst cascara bark has been shown to contain emodin but not frangulin. The glucoside purshianin has now been separated in the form of dark brown-red crystals, melting at 237° C., and found to yield emodin and a dextro-rotatory, non-fermentable sugar. In doses of one-fifth of a grain purshianin produces the same effects upon the bowels as cascara bark. It is tasteless, odourless, and soluble in alcohol, ethyl acetate, acetone, alkalies, and hot water. Whether frangulin and purshianin are identical remains to be proved.—*Journ. Am. Chem. Soc.*, xx., 534.

Arsenic in Wool. J. H. Pearse raises the question of disadvantage or injury likely to arise from the use of woollen apparel and other goods containing traces of arsenic. In Sweden, he points out, there is a law against the sale of material containing appreciable quantities of arsenic, the sale of yarn being prohibited if it contains 0.0009 per cent. of arsenic, whilst a heavy carpet has been condemned because it contained one grain of arsenic, possibly in a completely non-volatile form, in a piece ten feet square. It appears, however, that it is practically impossible to buy any sheep's wool of home or foreign growth which does not contain arsenic in larger quantity than that allowed by the Swedish Government. The reason of this is the fact that sheep growers are obliged at certain seasons to dip their sheep, and in most cases the dip contains arsenic. One firm alone claims that it supplies sufficient arsenical dip each year for one-fourth the sheep in the world, and probably half the woollen fabrics worn in England are made from wools that have been treated with that firm's preparation. The arsenic clings so tenaciously to the wool fibres that it is difficult, if not impossible, to get rid of all traces of the poison. It is now desired to gather information for the use of spinners and manufacturers, as to whether injury is likely to result from the use of woollen materials containing arsenic, and if so what is the maximum amount that may be allowed, without injury to health, in a given weight or size of cloth.—*Lancet*, 3906, 107.

Purity of Milk Sugar. One of the U.S.P. tests for the purity of milk sugar requires that no brownish or blackish colour shall develop within thirty minutes when the sugar is sprinkled over the surface of sulphuric acid. C. H. la Wall and R. C. Pursel point out that occasionally a sample is found which does not respond satisfactorily to this test, though it may polarise as well as a sample that produces no coloration. The cause of this is found to be the presence of thread or string upon which the crystals of sugar are allowed to form; clean crystals from the outer side of the string produced no coloration after being powdered, whilst in the case of a section across the entire string the coloration was directly proportional to the thickness of the crystalline mass, that is, to the quantity of thread which had been powdered with the sugar. Polarisation, therefore, is recommended as the safest test of purity, and it is suggested that manufacturers might well substitute some less carbonisable fibre for that used at present.—*Am. Journ. Pharm.*, lxx., 343.

Java Quinine. J. B. Nagelvoort has examined a sample of Java quinine, and finds it contains 14 per cent. of water of crystallisation when fresh. He describes the process of assay he followed, and concludes by asserting that this new Dutch product is an article of unusual excellence, much purer than United States' pharmacists are accustomed to.—*Am. Journ. Pharm.*, lxx., 345.

Alkannin J. B. S. Norton has had occasion to examine a specimen of a plant collected in Grant County, New Mexico, which he identified as *Plagiobothrys arizonicus*, Greene. He was told that sheep feeding on the plant have their heads coloured red, and the letter containing the specimen was stained violet purple. The colouring matter present appeared to be alkannin, and an examination of specimens of the plant and of kindred species in the Missouri Botanical Garden herbarium revealed the fact that many of them had stained the paper on which they were mounted with the same substance. It exists chiefly in the roots, and was found in *Echium vulgare*, *Eritrichium glomeratum*, *Krynitzkia barbiger* (abundant in the leaves), *K. californica* (slight), *K. maritima*, *K. micrantha*, *K. pterocarya*, *Lithospermum multiflorum*, *L. strictum*, *L. spathulatum*, *L. hirtum*, *L. canescens*, *L. angustifolium* (not abundant), *Plagiobothrys canescens* (in leaves), *P. nothofulvus* (in leaves), *P. tenellus*, *P. arizonicus* (abundant in stem, leaves, and root), *P. torreyi* (very abundant in some specimens, but hardly a trace in others). The characteristic reactions with resin and oils were obtained with the colouring matter from *Plagiobothrys*, in the same manner as that from *Alkanna tinctoria*.—*Am. Journ. Pharm.*, lxx., 346.

Aloes. In addition to the experimental results given in Dr. Tschirch's paper, G. Pedersen has investigated the resin of aloes, and finds that the resin of Barbados aloes is an ester which is split up by acids into cinnamic acid and an alcohol, aloeresinotannol, of the formula $C_{22}H_{24}O_4(OH)_2$. The resin of Cape aloes is a paracumaric acid ester of aloeresinotannol. Barbados aloes contain resin 12.65; barbaloin 12.25; emodin 0.15; amorphous substance, soluble in water, 62.7; ash 17.5, and water 10.5 per cent.—*Archiv der Pharm.*, 236, 200.

Kolanin and Caconin. C. Schweitzer claims to have isolated from the kola nut and the cocoa bean glucosides containing caffeine and theobromine. In order to obtain the glucoside kolanin, the kola nut was extracted with alcohol, and the free caffeine and theobromine, sugar and salts, removed from the spirit residue by treatment with hot water, and the insoluble glucoside obtained as free as possible from ash by repeated solution in alkaline water and re-precipitation by neutralisation. The amorphous glucoside so obtained, when quickly dried, had a reddish-brown colour. It was then hydrolysed with 5 per cent. sulphuric acid, and the amount of glucose, caffeine, and theobromine determined. The results obtained showed in the fresh seed 1.05 per cent. of the glucoside kolanin, which on hydrolysis gave 0.316 per cent. of caffeine and theobromine (79.4 per cent. caffeine, 19.7 per cent. theobromine), so that the relation of the glucose to the alkaloids was in the proportion of 3.1:1. The kola nut contained in the free state 0.613 per cent. of caffeine and theobromine (98.8 per cent. caffeine and 1.2 per cent. theobromine) which was extracted from the seeds by chloroform. The amount of kola red in the glucoside molecule could not be determined, as the kola red, which is uncombined with alkaloids, also dissolves in alcohol and alkaline water. But as, according to Knebel's formula, kola red has the composition $C_{14}H_{13}(OH)_5$ and contains five hydroxyl groups, it is probable that the glucoside, in which the proportion of glucose and caffeine is as 3:1, contains one molecule of kola red. The formula of kolanin would therefore be $C_{40}H_{53}N_4O_{21}$. In a somewhat similar manner a glucoside—caconin—was obtained from the cocoa bean after the

fat had been removed by petroleum ether. Ignoring the small proportion of caffeine, the relation of the theobromine to the glucose obtained on hydrolysis was as 1:6.03, and as, according to Lazarus, cocoa red has the formula $C_{17}H_{11}(OH)_{10}$, containing ten hydroxyl groups, the formula of the glucoside may be expressed as $C_{60}H_{86}O_{15}N_4$. Lazarus' formula, based on the combustion of the cocoa glucoside, was $C_{34}H_{48}O_{18}N_2$ or $C_{63}H_{96}O_{36}N_4$.—*Pharm. Zeit.*, xliii., 380 and 389.

Ripening of Fleshy Fruits. M. C. Gerber speaks of the chemical changes which take place in the ripening of fleshy fruits as consisting mainly in the partial using up of the vegetable acids and the production of carbohydrates. The tannin is completely oxidised without forming carbohydrates, while the starch is transformed into sugars which again partially disappear by oxidation. At certain stages in their development fleshy fruits disengage a volume of carbon dioxide greater than the volume of oxygen absorbed. This respiratory process may be due either to fermentation or to the presence of acids—citric, malic, or tartaric—which oxidise at a high temperature; this temperature is about 30° C. for fruits containing citric or tartaric acid, 15° for those containing malic acid. Fermentation takes place whenever the oxygen of the atmosphere does not reach the cells in sufficient quantity to furnish the energy necessary for vital activity. This deficiency of oxygen is due to the production of pectin.—*Annales des Sci. Nat., Bot.*, vol. iv., pp. 1-280.

Economical Product from Seaweeds. Herr A. Krefting describes the production from certain Fucaceæ of a non-nitrogenous substance, which he calls "tangic acid" (*Tangsäure*). It appears to be related to the carbohydrates, although its empirical formula $C_{13}H_{20}O_{14}$ does not indicate this. It is not dissolved by any medium with which it does not form a chemical combination. Its alkali salts are strongly viscid, forming a substance well adapted for gumming paper and other substances. It has been prepared especially from the broad-leaved Laminariaceæ.—*Chem. Industrie*, 1897; from *Bot. Centralbl.*, 1898, Beihefte, p. 519.

Calcium Malate and Malophosphate in Plants. According to M. Mirande, although malic acid, $C_4H_6O_5$, occurs most commonly in the free state in plants, it is also met with in combination with calcium as neutral calcium malate ($C_4H_5O_5)_2Ca$, or as calcium malophosphate. It may be precipitated by the action of alcohol in the form of spherocrystals of neutral calcium malate of the orthorhombic type, or in one of two forms of calcium malophosphate, the one consisting of spherocrystals of needles, with excess of phosphoric acid, the other in the form of orthorhombic prisms in which malic predominates. The quantity of malophosphate generally exceeds that of malate.—*Morot's Journ. de Bot.* vol. xii., 1898.

Oil of Eucalyptus in Headache. As long ago as 1889, Lewis and de Schweinitz called attention to the value of eucalyptus oil in the treatment of headache. It has since been found to be of great service in the treatment of frontal headache caused by cerebral congestion, and has succeeded where acetanilide, bromides, antipyrine, and other remedies have failed. It is given in doses of 5 minims every four hours. It is not so valuable for the treatment of dyspeptic headache, but is useful for those cases which are found in patients with a gouty tendency.—*Therap. Gaz.* [3], xiv., 237.

NEW DRUGS FROM THE COLONIAL OFFICE.

BY DR. B. H. PAUL AND A. J. COWNLEY.

Specimens of the root-bark of *Chione glabra* and of the leaves of *Neurolæna lobata*, two plants largely used for medicinal purposes in the Windward Islands, have been forwarded to the Pharmaceutical Society by Mr. Chamberlain, the Colonial Secretary, who, in forwarding the drugs, endorsed the request of Sir Alfred Moloney, the Governor of the Windward Islands, that they might be analysed for the information of the Colonial Government. Sir A. Moloney further desired that in order to avoid expense the specimens should be presented to the Pharmaceutical Society, who would no doubt undertake the examination of these new drugs in the interest of pharmacy and without charge.

At the request of the President of the Society we have examined these drugs, and the following results have been obtained in operating on the small quantity of material, some 250 grammes of each drug, placed at our disposal:—

CHIONE GLABRA.—The local name of this bark is "Violette." The root is stated to possess valuable properties as a tonic and also to be used as an aphrodisiac. It is also said to have recently attracted attention in the United States, although inquiries made by us have not elicited any information from America respecting this bark. The specimen received was a pale root bark having a strongly aromatic odour and a slightly astringent taste. From the aromatic odour of the bark it was conjectured that it might contain a volatile oil, and on examination with that object we succeeded in isolating a volatile oily liquid amounting to about 1.5 per cent. by weight. This volatile oil is of a pale yellow colour and has a specific gravity higher than that of water. It gave a mass of acicular crystals on being cooled to about -20°C . The oil gave no crystalline substance with sodic bisulphite, nor could evidence be obtained of méthy salicylate. It gave a semi-solid mass on treatment with a concentrated solution of caustic soda. It is readily soluble in dilute caustic soda and reprecipitated by acids apparently unaltered. It is slightly soluble in water; its aqueous solution gives a purple blue coloration with ferric chloride. The volatile oil is evidently a phenol. There are several volatile oils having somewhat similar properties to those above described, but the quantity of the oil obtained was too small to admit of the further examination which its peculiarity appears to deserve. The oil has a hot pungent taste and aromatic odour resembling that of the bark, and it is to this oil no doubt that the aromatic odour of the bark is to be attributed. Further examination of the bark was made to ascertain the presence of any other active principle. Treatment with various solvents in the presence of an alkali gave negative results for an alkaloid. Extraction with alcohol yielded a quantity of a dark coloured extractive amounting to 25 per cent. of the bark. The extract had a slightly bitter taste and contained an astringent substance resembling, in its chemical characters, tannin, and another substance of the nature of saponin, but it was not possible to obtain a definite crystalline body.

NEUROLÆNA LOBATA.—The leaves of this plant are locally known as "l'herbe à pique." They are used as a substitute for quinine, and are said to be a most valuable remedy for dysentery. The leaves have an intensely bitter taste. They contained no essential oil. On examination for alkaloids a small quantity of an uncrystallisable alkaloid was obtained amounting to 0.10 per cent. The alkaloid is intensely bitter. It readily dissolves in acid, and is reprecipitated by ammoniac hydrate. The alkaloid neutralises acids, but from the small amount of material at our disposal it was not possible to prepare crystallisable salts. The medicinal

value of the leaves is no doubt to be ascribed to the presence of this alkaloid.

Specimens of the volatile oil and bitter extractive of *Chione glabra* and of the alkaloid of *Neurolæna lobata* have been placed in the hands of the President of the Society. These new drugs are certainly worth further attention, in order to obtain a larger supply of the volatile oil of *Chione glabra* and of the alkaloid of *Neurolæna lobata*.

THE FOURTH BRITISH PHARMACOPŒIA.

BY J. C. HYSLOP,
Pharmaceutical Chemist.

"Referred back to his studies for a period of six months" is a phrase that fitly indicates the predicament of a pharmacist—old or young—into whose hands there comes a copy of the fourth British Pharmacopœia. Many, alas! are doomed to feel the chagrin that arises from a conscious ineptitude for reading, with the necessary speed and precision, their "official standard and guide" in business procedure, although it be couched in the tersest of language and is a specimen of the purest diction of their native tongue.

The cause of this evil is not far to trace; the remedy for it is equally simple. Promiscuous trade with its alluring shams and ever-varying vanities has beguiled the pharmacist from attention to his main duties—duties on the due performance of which his whole prosperity depends, and has brought him in many cases to be the easy prey of charlatans who ruin his prospects whilst pretending to further them. The publication of a new Pharmacopœia gives him a fresh start and may prove to many of us the opportunity to

"rise on stepping stones of our dead selves to highest things,"

if only with sober loyalty to pharmacy as an avocation the task be undertaken in a manly spirit and without delay.

Scarcely more than two months old, the 1898 Pharmacopœia has been subjected already to a rush of criticism—chiefly of an unfavourable nature—that seems to call for some kind of a counter-balance from one of a more optimistic frame of mind. The writer dates his pharmacy experience from the closing years of the last "Pharmacopœia Londinensis"; he has lived to behold "the hatches, matches, and dispatches" of the three British Pharmacopœias, and is now rejoicing in the appearance of a fourth, which he has reason to regard as being the best of them.

In the present work we seem to have presented to us at last a completed whole, from which future editions may be generically evolved, without any abruptness of change, as the necessities of the future may demand. The mere outline given us in the first B.P. (1864), an outcome of "the difficult task, which had previously been attempted in vain, of reducing to one standard the processes and descriptions of three different pharmacopœias, and, what was still more difficult, of reconciling the varying usages in pharmacy of the people of three countries hitherto in this respect separate and independent," was followed three years afterwards by the more succinct yet comprehensive edition of 1867.

The short preface to the first edition, composed largely in the imperative mood, speaks of all branches of the medical profession, of prescriber and dispenser, but takes no note of the pharmacist as a fellow-worker, and closes with the solemn warning to "all apothecaries and pharmaceutical chemists, that on the publication of the B.P. it will be necessary, in order to discharge safely their duties to the public, that they should duly alter or destroy all pharmaceutical preparations made according to previous and now altered formulæ." This was followed in the next edition by a preface written in a more sympathetic key. Here it is

admitted that "the object of a pharmacopœia is not so much the selection as the definition of substances which the physician prescribes, and which are required to be kept at one safe and uniform standard of strength and composition." And the closure is one of admiration instead of warning: "The Council think it right to add that the present edition of the Pharmacopœia has been prepared by Professor Redwood, of the Pharmaceutical Society, and Mr. Warrington, of Apothecaries' Hall, under the direction of a committee of the Council."

In the preface to the third edition (1885) the general tone is much the same as in that of the preceding volume. The fact is noted that in "the description of chemical substances now for the first time introduced into the Pharmacopœia . . . it has been deemed sufficient to refer to their production in general terms, while their identity is established by their characters and reactions with chemical tests." The word "pharmacist" occurs once (page x.) and once only, but this is its first appearance above the horizon, and, as events subsequently show, it came to stay. Professors Redwood, Bentley, and Atfield are mentioned as the editors.

The preface to the volume now before us presents a marked contrast for the better in several material points. There is about the diction a fresher and a freer air arising from the greater simplicity and purity of the language used, as indeed is the case all through the volume. Typographical errors must always be expected in the first edition of a work of such magnitude, but as a literary production the book seems to be perfect. For the first time the pharmacist is in the preface (pages xiv., xv., xix.) regulated to his proper duties; notes are struck which may alarm the indolent or he that suffers much from that old complaint

"Auri caecus amore,"

but which must tend to reanimate the man of duty and to greatly brighten the prospect before him, *e.g.*, page xiv: "The appended list of tests is not exhaustive, having been constructed only to meet official requirements. Nor are manipulated details set forth at length, either as regards the selection or application of the tests, the pharmacist being assumed to possess full knowledge of these and all similar points." Again, page xv., "In short, the procedure in these (volumetric estimations) and other chemical operations is now left to the skill and judgment of workers who are assumed to be duly trained." Thus it is evident that the pharmacy alumni can no longer complain of their status and qualifications being unrecognised in the national medicine book. Indeed there is presented here to the old pharmaceutical hand a rare opportunity of renewing his favourite studies by loving and gentle touches to simply bring them up to date, and to the younger members of the craft there is offered guarantee that to a patient and assiduous worker a fairer prospect of recognition and recompense is in store than his predecessors ever enjoyed—except in visionary dreams.

So in the words of the preface to the B.P. thirty-four years ago, let us "trust that no one will complain of being compelled to take up again his Pharmacopœia and study it attentively . . . after all, the inconvenience will be only temporary, and will be compensated by various new facilities. These facilities, in which the public at large will share, as well as the medical profession, are for the most part, too obvious to need mention."

The near future will doubtless show still more clearly than has hitherto been recognised the vast advantage that the individual worker has in such an art as pharmacy over any committee or possible collection of experts that may be chosen to lay down official directions or proclaim official formulæ for general acceptance. The fact that a working pharmacist who is actively engaged in the

practice of dispensing must have at hand a store to fall back upon at a moment's notice of everything that is likely to be wanted by the medical practitioner or prescribed by him, either written or verbally, for the public benefit, and that he has facilities for making the necessary experiments in a leisurely way, almost *ad infinitum*, with respect to what he knows to be the desiderata in any and every case with respect to the preparation or admixture of all the rapidly increasing number of remedies required by the actual needs of an extended civilisation, the results of research or the demands created by commercial enterprise, points him out at once as the man of the future, through whom, when his functions are properly differentiated, the national Pharmacopœia will advance to perfection. The writer himself has the very modest rôle to play of simply pointing out a few defects in the formulæ here and there throughout the book, with suggestions for their amendment; every case being that which he has himself already verified by actual practice, some of them the very faults he was expecting to meet with, and but few of which, so far as he knows, have as yet been alluded to by other workers.

(To be continued.)

OBSERVATIONS UPON MATÉ OR PARAGUAY TEA.

BY JOHN G. MCKENDRICK, M.D., F.R.S.,

Professor of Physiology in the University of Glasgow,

AND

DAVID FRASER HARRIS, M.D., B.SC. (LOND.), F.R.S.E.,

Muirhead Demonstrator of Physiology in the University of Glasgow.

1. Maté, or Paraguay tea, consists of the dried leaves and slender stems of various species of *Ilex*, evergreen shrubs belonging to the same natural order as the common holly. These plants grow abundantly between 22° and 32° of southern latitude, especially in the districts bounded by the Paraná and Uruguay. The leaves are from 4 to 5 inches in length, and are prepared by drying and roasting, not in the manner of Chinese and Indian teas, in which each leaf is gathered separately, but branches are cut off the plants and placed on hurdles over a wood fire until sufficiently roasted or dried. The branches are then placed on a hard floor and beaten with sticks. The dried leaves are thus knocked off and reduced to a powder mixed with fragments of leaves and delicate twigs.

2. At the time of the invasion of South America by the Spaniards, maté was universally used by the Guaraní Indians, who inhabited the districts between the Paraná and Uruguay, and no doubt it had been used by these natives from time immemorial. It was soon adopted as a beverage by their conquerors. Even now maté is food and drink to the Indian who roams over the wide stretches of the Pampas, or over the heights or among the ravines of the Cordilleras. One writer says: "His only food consists at such times of a mouthful of maté taken at long intervals, which has become to him on his long wanderings a veritable hunger-killer." At the present day maté is the national beverage in the border States of La Plata, in Chili, Bolivia, a part of Peru, and in the south of Brazil. In these districts maté may be found in almost every home and at every hour of the day, and, as remarked by Messrs. Park, Davis and Co., "As one cannot conceive a Russian family without their steaming samovar, so it is impossible to think of the South Americans without maté."

3. It is a remarkable testimony to the value of the substance that, although first used by natives, it was soon adopted by European settlers in South America, and the consumption has now reached a large amount. In 1855 the amount of maté annually consumed in South America was estimated by Von Bibra at

15,000,000 lbs., and the consumption is now probably several times greater. In the Argentine Republic alone, the consumption is not less than 27,000,000 lbs., or about 13 lbs. per head, while the proportion of tea is only 2 lbs. per head, and of coffee $\frac{1}{4}$ lb per head, showing to what an extent maté is actually used instead of the beverages better known to the people of Europe. Maté is, however, steadily winning favour in Europe, as shown by the increased exportation. Thus in 1840 Brazil exported to foreign countries over 5,000,000 lbs., in 1850 over 10,000,000 lbs., in 1860 about 14,000,000 lbs., in 1870 about 20,000,000 lbs., while in 1880 the total reached nearly 30,000,000 lbs.

4. It is a remarkable fact that infusions or decoctions of various herbs should have come independently upon their own merits into use in different parts of the world, that they should be derived from plants widely apart in their botanical affinities, and from different structures in the plant, and yet that they all should be found to have similar physiological properties and dietetic value. Still more remarkable is it that they should contain the same active chemical principle. Thus the coffee beans of Arabia yielded caffeine to Runge in 1820, in 1827 Oudry found theine in the tea of China, in 1840 the same principle was found by Martius in Guarana tea, and in 1843 Stenhouse found it in Maté. The identity of caffeine and theine was established by Mulder in 1838, and now it is acknowledged that the same crystalline active principle exists in all four groups of plants. It is also present in kola nut. The amount in each varies. Thus various teas contain from 1.8 to 2.9 per cent., coffees from 0.64 to 2.21, guarana as much as 5 per cent., maté from 1 to 2 per cent., and kola nut about 2.4 per cent. Numerous analyses by various independent observers show that, on the whole, maté contains less caffeine than the other herbs.

5. The most recent chemical research on maté was published in 1893 by Professor Hermann Kuntz-Krause. It shows that an infusion of maté is a very complex fluid, holding many substances in solution. These are:—

- (1) Traces of various ethereal oils;
- (2) Traces of odorous fatty substances, giving it a peculiar smell;
- (3) Small amounts of bodies called glucosides, which in decomposition yield sugar;
- (4) Small quantities of waxy substances.
- (5) Caffeine, say between 1 and 2 per cent.
- (6) A peculiar body known as cholin (so called because first discovered by Stricker in 1868 in ox-bile) and important because we know it is derived from lecithin, a substance that plays an important part in the chemistry of animal and vegetable cells.
- (7) A sugar which reduces copper salts but does not affect polarised light.
- (8) Considerable amounts of potassium and magnesium salts, both chlorides and phosphates; and
- (9) Tannic acid of exactly the same nature as that in tea and coffee, but not to the same amount as in tea; maté has 12.5 per cent., tea between 15 and 17 per cent.

6. While the physiological action of a solution of pure caffeine prepared from tea, coffee, or maté is the same, the action of each beverage is peculiar and differs from that of the others. Thus tea contains more tannic acid than the others, and consequently is more astringent; coffee on the other hand is richer in aromatic bodies, while Maté appears to have what may be termed restorative properties developed to a high degree. None of these substances is nutritive in the strict sense of the word, but all are adjuncts to nutrition. All three appease the sense of hunger, and remove feelings of fatigue. They encourage appetite and in moderation allay nervous excitement. They have all an influence on nutrition, as

shown by the fact that they influence the amount of waste substances thrown out of the body.

7. Experience has shown that maté has several peculiarities entitling it to a trial in Europe on a more extensive scale than it has hitherto enjoyed. These are:—

- (1) It removes feelings of fatigue to a remarkable degree; in our opinion more so than either tea or coffee.
- (2) Although it contains tannic acid, infusion of maté is not so astringent as tea.
- (3) From the same leaves three successive infusions may be made of almost equal strength, so that if the price per pound were the same, maté would be more economical than tea.
- (4) Although its flavour is best developed when taken very hot, its restorative properties appear to be the same whether it be taken hot or cold, and thus it might be used as an agreeable and invigorating beverage in circumstances where it was inconvenient to prepare a warm infusion.

8. We have examined chemically the maté submitted to us by the Maté Tea Company, Limited, according to the general methods described by Kuntz-Krause, and we are able to corroborate most of his statements. For some time past we have also personally used infusion of maté as a beverage in lieu of tea and coffee, and we find it pleasant, wholesome, and restorative. Its general physiological action is similar to that of tea or coffee. When taken hot, with little or no sugar and no cream, its flavour is soon appreciated. We are of opinion that many might, after a time, prefer maté to tea or coffee, while they would find that their experience of its value agreed with that of the millions of persons who already use it in South America.

9. As to the mode of preparation of maté, we would remark that whereas boiling ordinary tea renders it most unpalatable and indigestible, ten minutes' boiling of the maté has no such effect. In other words, there is not so much difference between the infusion and the decoction of maté as there is between the similar preparations of Chinese or Indian tea. The decoction of maté is somewhat more astringent than the infusion, but this is hardly perceptible to the palate, whereas the decoction contains a larger percentage of the various constituents which can pass into solution. We believe the infusion of maté may be taken with impunity along with many articles of diet with which it is inadvisable to drink strong tea, such as fresh meat or eggs. It has been shown by many observers that strong tea interferes with digestion to an extent which may vary in different individuals. The tannic acid of maté is peculiar in that it will not tan hides, and we have found that it does not precipitate gelatin; this is another way of saying its astringency is less than ordinary tannic acid. While both ordinary tea and maté remove fatigue, we find that the latter is unaccompanied by that degree of cerebral excitement which attends the use of the more familiar beverage.

This, in all probability, explains a fact reported to us by persons taking maté for the purposes of this investigation, namely, that although drunk a short time before going to bed, it, so far from keeping one awake, tends rather to induce sleep. This agrees with what we have noticed as to its action in removing fatigue, that while it abolished the disagreeable sensations of weariness, it substituted for them an indescribable feeling of being pleasantly tired which could be easily imagined passing over, under favourable conditions, into sleepiness.

COOLING OINTMENT.—Adeps lanæ, 10.0 grammes; ol. amygdal., 7.5 grammes; sol. boracis (1:25), 75.0 grammes; ol. rosæ, gtt. 1; acid benzoic., vanillin, āā 0.5 gramme.—*Pharm. Centrallh.*, xxxix., 92.

Society of Chemical Industry.

THE annual meeting of this Society was commenced at University College, Nottingham, on Wednesday, when the President, Professor Frank Clowes, D.Sc., F.I.C., took the chair, and after the usual preliminary business, delivered the following address:—

The President's Address.

In the summer of 1890, under the distinguished presidency of Sir Lowthian Bell, and during the local chairmanship of Sir John Turney, the Society of Chemical Industry held its annual meeting in the town of Nottingham; the University College, in which we are now again assembled, being its headquarters. In acknowledging the courtesy which the Mayor and Town Council have again extended to the Society by permitting its use of the College buildings, we desire to congratulate the town of Nottingham upon having been raised since our last visit to the dignity of a city, the present Mayor of Nottingham upon having received academic distinction, and the Town Clerk upon having received the honour of knighthood. We believe that the willingness shown by Nottingham to receive our Society must be connected with the progressive and hospitable spirit which the city has always shown, and with the existence in it of a large and successful University and Technical College, and of a flourishing section of our Society of Chemical Industry.

ORIGIN AND DEVELOPMENT OF THE SOCIETY.

In acknowledging the welcome accorded to our Society, it is natural to compare our present position with our origin and past. We are informed in the report of our Council that the membership of the Society has now reached a total of over 3000, and it must be remembered that this large enrolment has been secured in a period of only seventeen years. We are yet several years removed from attaining our majority. Towards the end of June, 1881, the first General Meeting of the Society was held in London under the presidency of Sir Henry Roscoe. The Society was then only three months old, and numbered about 300 members. It was in every sense a national society, but distinguished continental chemists were willing to help the young association by taking up its membership. The first president stated that "the main object of the Society is to bring together at definite intervals those who are interested in or possess knowledge concerning the utilisation of chemical action on a large scale, and have charge of, or are connected with, those large branches of industry which are dependent upon chemical principles. To the interchange of ideas brought about by such personal contact may well be added the publication of the proceedings of our meetings, as well as of information or intelligence interesting to our members. The Society cannot fail in this way to contribute to the advancement of those important branches of national industry which are dependent on chemical principles. This we hope to do, not only by bringing forward new processes, or discussing the advantages or disadvantages of old ones, but also by acting as a bond of union hitherto non-existent between individuals engaged in cognate pursuits, giving them a personal interest in one another, and thus encouraging that good-fellowship which is not an unimportant factor in the smooth working of our social machinery."

Thus spoke in 1881 the first President of the Society; and those of us who have, with him, noted from those earliest days the development of his scheme, cannot but see how completely his intentions and predictions have been fulfilled. The Journal, referred to by Sir Henry Roscoe, has come into existence, and is one of the most complete and valuable records of technical chemistry in the world. Those interested in the advancement of applied chemistry in this country have become to a large extent united in their efforts, and therefore more successful in obtaining their objects.

The members of the Society value the organisation on account of the information brought together in their Journal. But they have further advantages afforded them by the increased opportunity of meeting together, owing to the establishment of local sections. The existence of these local sections is an important and some-

what special feature of our Society. These sections are now existent and active in London, Manchester, Liverpool, Newcastle, Nottingham, Leeds, Glasgow, and New York; and the existence of a New York section is an indication that the importance of the work of the Society is felt outside our own country; this is further proved by the very large number of foreign general members who have been enrolled.

Those who have watched the gradual rise and development of these local sections of the Society will acknowledge the very important service which has been rendered by our provincial colleges. The great importance and advantage of the movement, which has brought higher university instruction into our large provincial centres, are now universally conceded. But there is cause for congratulation, amongst those who are endeavouring to promote the advancement of applied science in this country, that the foundation of a university college in a provincial centre has not only led to the introduction of higher instruction in pure science, but has also advanced in a most important way the interest and education in applied science. One of the evidences of this gratifying result is the fact that in the centres in which our university colleges are established and successful, we find arising sections of our Association, which has for its object the advancement of applied chemistry. Leading manufacturers associate themselves with those who are promoting science educationally, and with those who have passed through the classes of the College, and together they maintain a useful section of our Society.

My lengthy experience as a chemical teacher in Nottingham leads me to lay stress upon the advantages resulting from the establishment of a local section of our Society in connection with the local college. In 1881 the Town Council of Nottingham, supported by the public spirit of its inhabitants, had responded to a challenge thrown out by an anonymous donor; and, by supplementing his handsome gift by public funds, had built the stately and convenient buildings in which we are assembled; they had also appointed a staff of teachers, amongst whom I represented the branch of chemistry and metallurgy; and they had founded a curriculum of instruction in the principles and applications of science, which was in a great measure a response to the general demand for the provision of technical instruction throughout our country. It was felt desirable that the provision of general higher-class culture should be the main object of this university college, but that instruction should also be provided which would be of value to those equipping themselves for industrial pursuits in an industrial centre. The teachers in the college have therefore always borne in mind that, whilst they teach scientific principles first and foremost as the true foundation of all industrial success, they should also in some considerable measure illustrate their teaching by pointing out the industrial applications of those principles.

What could be more suitable and advantageous than the establishment, in connection with the chemical department of a college possessed of these aims, of a section of the newly founded Society of Chemical Industry? In 1885, a little band of chemists of Nottingham and the neighbourhood started the Nottingham section of this Society. I was honoured by being its first chairman. The early existence of this section naturally depended very largely upon support from those connected with the college, either as members of the management committee or as chemical teachers and senior and past chemical students. Even from the earliest times, however, those engaged in industrial enterprise and pursuits in the town and neighbourhood rallied in rapidly increasing numbers around this original nucleus, and the section soon felt that it was fairly representative of the chemical work and industry of the district. I am glad to say that the section is now as active as at any period of its career, and its activity is shown not only by its frequent contribution of important matter to the Journal, and by its regular and frequent meetings, but by its eagerness to entertain for a second time the general Association of which it is a constituent part. There is no doubt that this section has been of advantage to those concerned in the applications of chemistry in the district. It has certainly had the effect of maintaining an interest in chemistry amongst the past students of our college, and of reminding the teachers of the college that they must con-

sider in their chemical instruction not only the paramount importance of chemical principles and of pure science, but also of chemistry in its connection with industrial applications.

I have been tempted to speak at some length of the experience of the Nottingham section—the Section with which I have had the longest experience and have been for many years personally identified—not because I desire to place it in an unduly prominent position; but rather because the origin and development of the section are, I believe, typical, and represent what has already occurred in most, if not in all, of the other sections of the Society. May I add that we hope that the Society is destined yet to see a similar rise and development of new sections in other important industrial centres of this country? And may we not further hope that the existence of a branch of the Society in New York proves that sections of this Society are destined to arise generally in the industrial English-speaking communities of the world, and to lead thus to a federation of interest in the advancement of industrial chemistry, which may even antedate that more general world-wide federation in general British interests which our politicians are desirous of fostering?

A glance down the names of those who have served the Society since its foundation shows that its interests have been promoted by men who stand prominently before the chemical world, not only as industrial chemists, but also as teachers, as investigators, and as professional chemists; and the stimulus given by such men who, whilst leading a busy life, have found time to help forward the objects of the Society, probably accounts for its continued and increasing progress. During the year which you have allowed me the honour of serving you, I have been gratified to hear of larger accessions to our membership, in the monthly list which is presented at our Council meetings, than have occurred during any recent year.

OBITUARY NOTICES.

The gratification which is naturally felt in seeing the Society thus largely increasing in numbers and in usefulness is, however, somewhat alloyed by the notification of the loss by death of no less than twenty-seven members, and we have to note with regret in the list of recently deceased members the names of such men as Sir Henry Doulton, Horace Koechlin, Dr. F. Hurter, and Charles Cochrane; whilst amongst those who are not members, but whose names are classical, are further to be noted Sir Henry Bessemer, Paul Schützenberger, and August Kekulé. It is only right that we should unitedly avow our indebtedness to men who have exerted so important an influence in furthering the objects which our Society has in view.

It is unnecessary to refer at any length to the distinguished and useful careers of these distinguished chemists who are now numbered with the majority, since our own Journal and the *Journal of the Chemical Society* record in their obituary notices and memorial lectures the principal features of their scientific and industrial work. There is some satisfaction to be derived from the fact that most of these eminent men had attained the usual limit in the span of human life, and had remained long enough amongst their fellow-men for the importance of their work to receive a fair measure of appreciation.

Ferdinand Hurter may, however, be considered to form an unfortunate exception, in that he has been removed from us in the prime of his intellectual vigour, and at a time of life when the matured experience of an active spirit is usually productive of valuable results. It is our Liverpool section which suffers the loss of the stimulating effect of the presence among them of Hurter's personality. But the whole Society will suffer the loss of his original communications, the most important of which have been printed in our Journal. An account of Hurter's career appears in a recent number of our Journal, and will serve as a permanent memorial of the affection and esteem in which he was held by those who knew him best—his fellow-members of the Liverpool section. A friend who had long been associated with him states that: "He had the advantage of a sound and wide education during his student years; but to his credit it may be said that by strenuous and unremitting effort he continued his education during his whole life. He was an intellectual athlete, and he kept himself in splendid mental training by increasing practice. The faculties of his mind were under complete control, and he possessed a most retentive memory, so that whenever occasion required he could set himself to work, bring out of his treasury things new and old, and solve technical problems with amazing rapidity and accuracy. Amongst the most marked elements of his success as a technical chemist were the ability he possessed in a remarkable degree of

devising new apparatus for new problems, and his insight into the nature of the technical and commercial problem before him. He was never lured into any side issue, however interesting from a scientific point of view; he kept but one end in sight—the solution of the problem in hand, and his grasp of the situation, both technically and commercially, was always complete and clear.

Paul Schützenberger, though not enrolled among our members, was one who largely influenced the advancement of industrial chemistry by his researches on the natural dye-stuffs and colouring matters. His original investigations, however, were extended to many other branches of our science. As a teacher his influence was also felt. Commencing as a lecturer in the Realschule and Hochschule of Mülhouse, he became subsequently Ballard's assistant at the Collège de France, then second director of the Chemical Laboratory at the Sorbonne, and Professor in the Collège de France. In 1882 he was finally appointed director of the newly-founded School of Chemical Industry and Physics. His text-book and other contributions to chemical literature are too well known to require any special mention.

It is to Schützenberger that our recently deceased member, Horace Koechlin, owed his early chemical education and inspiration. His many investigations in bleaching, dyeing, printing, and in the production of dye-stuffs indicate, not only the effect of his teacher's influence, but also the effect of his progenitors' occupation, since Horace Koechlin represented the third generation of those who had interested themselves successfully in these pursuits.

August Kekulé represents, amongst those who are no longer with us, the great master in chemistry; the man who promotes the advancement of the science, not only by his own brilliant researches and theoretical conceptions, but also by his systematic teaching and by the publication of students' literature, and more especially by the stimulating and inspiring effect which he exerts upon all those chemists who come into contact with him. I will not attempt to sketch Kekulé's career; this has been done already in the account of his scientific work by Dr. Japp, which has been published in a recent number of the *Journal of the Chemical Society*. It cannot be doubted that members of our Industrial Society will heartily appreciate and honour our great chemical masters, and accord to them the very high position which they should hold in their esteem.

The important work of Doulton and of Bessemer has been before the world so long, that it is known, not only to the chemist and metallurgist, but to the general public. The names of these creators of industry have practically become incorporated into our language, and every educated person knows the meaning of the terms "Doulton ware" and "Bessemer steel."

THE MEDALLIST: WILLIAM HENRY PERKIN.

Men of the stamp of Doulton and Bessemer are peculiarly English; it is the glory of England to have reared many such sons; and amongst them—though fortunately he is still hale and hearty, and actively working in our midst—we must certainly number the man whom your Council has this year selected for the award of its medal: I refer, of course, to William Henry Perkin.

While I am treating of the biographical part of my subject, which unfortunately has been thus far a sketch of those whose labours in this world are ended, I am sure that you will allow me to sketch in a few words the career of our distinguished medallist, to whom I shall, before we separate, have the pleasure of handing, as your representative, a permanent mark of our esteem and appreciation. You are probably all aware that, like Doulton and Bessemer, Perkin has been the founder of a great and important industry. The production of artificial colouring matters from coal-tar products owes its origin, and in large measure its development, to Perkin. As industrial chemists you will all undoubtedly be able to appreciate the great importance of this department of Perkin's work. You will also undoubtedly wish that his devotion to the interests of our Society should be acknowledged. We find him actively supporting this Society in its foundation and in the critical early years of its existence. In 1884 he was elected to serve as its President—his immediate predecessors in that office having been Walter Weldon, Sir Frederick Abel, and Sir Henry Roscoe. Of the very great services which Perkin has rendered on the Council and committees of this Society many here could join me in speaking in the highest terms. But I am sure you will wish me to add to the causes of our appreciation which I have already mentioned the very great additions to our science which have resulted from his chemical researches. On looking through the lists of chemical papers in the

catalogue of scientific papers edited by the Royal Society, Perkin's name stands very high in the honour list of indefatigable and successful investigators, and he ranks in this respect with the leading chemists of our times. It is only right to take every opportunity of emphasising this fact, since, owing to Perkin's personal modesty and retiring disposition, and to the fact that he has held no public scientific appointments, the very great importance and extent of his scientific work is apt to be lost sight of, even by members of our Society. As he has told me himself, he has almost continuously, since his early schooldays, been following scientific research as a recreation; and this was the case even during the years when he was founding and conducting a large chemical manufactory and engaging in manufacturing and mercantile pursuits.

I have referred to Perkin's schooldays. You will, I trust, pardon me if I venture to refer to my own early connection with our medallist, and say that I rank it as an honour, shared amongst others by Edward Rider Cook, John Spiller, William Thorp, F. J. M. Page, and William Garnett, to have been a schoolfellow of Perkin. We all of us owe a great debt of gratitude to the City of London School, then situated in Milk Street, Cheapside, but since removed to the Victoria Embankment. That school was then under the headmastership of the Rev. Canon Mortimer, D.D., and was the pioneer amongst the schools in giving instruction in natural science.

The science-master of those days was to most of us for a time also our form-master. Thomas Hall—still affectionately termed by us "Tommy"—was the man who gave us our early teaching in science, and who by his infectious enthusiasm led us to look upon natural science as an entrancing pursuit. To those of us who were juniors to Perkin at the school, Perkin, who had just made his discovery of "mauve," was freely held up as an illustration of what advantages might be secured by a scientific training. In fact, Thomas Hall, who otherwise does not appear amongst the discoverers of his day, may be said to have made one all-important discovery: he discovered Perkin. It was while Perkin was in Hall's form, and before he had shown special aptitude for any department of study, that his form-master discovered in him an enthusiasm for experimental chemistry, which the master wisely fostered and encouraged to the utmost. In 1851 we find young Perkin assisting in the preparation of the chemistry lectures at the school; and two years later, when he was only fifteen years old, he went by Hall's advice to the newly-instituted Royal College of Chemistry with the intention of continuing his chemical studies under Dr. A. W. Hofmann. Perkin's rapid advance is marked by the fact that two years later he was acting as assistant to Dr. Hofmann in his research laboratory. In the following March he communicated his first research to the Chemical Society; and during the Easter recess (1856), while he was attempting to produce quinine artificially, he discovered "aniline purple" or "mauve"—a discovery which laid the foundation of the extensive coal-tar industry of the present time.

And here it is only right to refer to the enthusiasm which the late Dr. Hofmann aroused, as a teacher and investigator, in the students and assistants who were so fortunate as to be associated with him; and many men who hold prominent positions in our Society owe their early instruction and impetus to this great and genial master.

Experiments made at Messrs. Pullars' dyeworks at Perth encouraged Perkin, at the early age of 18, to devote himself to the development of his discovery, and to extend the laboratory preparation of mauve to an attempt at its manufacture. The manufacture involved the preparation of various substances on the large scale, which had hitherto only been made in small quantities in the laboratory: it was further necessary to devise entirely new plant. But the scientific knowledge and inventive and practical resource of Perkin were equal to surmounting these difficulties. Working in association with his father and brother, the new dye was manufactured and actually sold to the silk dyer in 1857—the year immediately succeeding its discovery. The success achieved by Perkin in making and applying the new dye was rapidly followed by the introduction of additional coal-tar colours, to the discovery and application of which Perkin himself contributed. The credit remains to Perkin of producing Graebe and Liebermann's artificial alizarine, or madder-dye, by an improved and practicable method, which led to the artificial manufacture of the madder-dye taking the place of its preparation from the cultivated madder-root.

In 1873 Perkin retired from strictly technical pursuits, and he has since devoted himself indefatigably to scientific research, with

the most important results. He is still continuing a research on magnetic rotation, and many instalments of his results have already been published. The name of our medallist is thus associated both in the past and at the present time with the progress of chemical knowledge and industry, and we may reasonably indulge in the hope that we have yet many more important researches to receive from his laboratory in the future. We have, further, the satisfaction of knowing that when the time arrives, which we all sincerely trust may be long deferred, for this active researcher to cease to contribute to the advance of science, the family name will still figure largely in the scientific records of the time, since Perkin has sons who are fully imbued with the capacity for, and importance of, scientific research, whose names are already ranged honourably alongside of that of their father, and who will prevent the lustre of the good name from becoming dim.

It has not been possible, within the limits of a paragraph of a presidential address, to do adequate justice, even to an outline, of Perkin's work and activity. Those who wish to pursue the sketch further should refer to the Hofmann memorial lecture delivered in May, 1893, before the Chemical Society, in which much of Perkin's work is followed out in greater detail; whilst a sketch of Perkin's career appears, under "Names of Note," in the *Dyer and Calico Printer* of November 15, 1889. But a full appreciation of his researches can only be secured by studying them in detail in the *Journal of the Chemical Society* and in other scientific and industrial journals in which they have been published.

It is commonly said that the secret of the success of the English soldier in war lies in the fact that he never knows when he is beaten. One is tempted to rise from a study of Perkin's career with the impression that he pursued his work of peace in a similar spirit, and triumphed over the many difficulties which beset him as pioneer and discoverer by never acknowledging an apparent defeat. By conferring our medal on a man of this type—a man also of untiring activity and industry—we feel that we are honouring our Society in the endeavour to honour him.

While we trust that the mark of our appreciation which we to-day bestow upon Perkin will meet with his acceptance, and will be treasured as an heirloom and memorial in later days, it would not be right to overlook the fact that the institution of the award of our medal is very recent, and that the medal is now only awarded for the second time. Accordingly, it naturally occurs that we try to confer honour upon a man already laden with the honours of his fellow chemists. And in attempting to confer one more honour, it is only right to record the recognition which Perkin's work has already received.

In 1859 the "Société Industrielle" of Mülhouse awarded a silver medal, and some time afterwards a gold medal, to Perkin for his discovery of the mauve. Then we note his election to the Chemical Society (1856), the Royal Society (1866) at the early age of twenty-eight, to the Honorary Secretaryship of the Chemical Society (1869), to the Presidency of the Chemical Society (1883), to the Presidency of our own Society (1884), and to the Honorary Membership of the German Chemical Society, in the same year. Our own medal is an addition only to others already in the possession of Perkin: these include the Royal Medal of the Royal Society (1879), the Longstaff Medal of the Chemical Society (1888), the Davy Medal of the Royal Society (1889), the Albert Medal of the Society of Arts (1890), and the Birmingham Medal of the Gas Institute (1892).

Academic distinctions have also been accorded to this truly eminent man, and are evidence of the fact that his honours came from widely different sources. The University of Würzburg, well known to me as my *alma mater*, conferred the title of "Philosophiæ Doctor" (Ph.D.) upon Perkin at its centenary celebration in 1882, and the University of St. Andrews gave him the honorary degree of LL.D. in 1892.

This is a long but, I fear, still an incomplete list of the honours already conferred upon our medallist of this year.

SOME TECHNICAL MATTERS.

In concluding my address, I will now only briefly allude to some matters of applied science which have of late years been prominently under my notice.

Living for upwards of twenty years as a teacher in mining districts, my attention has been constantly directed to the improvement of scientific methods applied to coal-mining, and more especially to methods at once delicate, exact, and trustworthy, for detecting and measuring the fire-damp or methane in the air of the mine. Careful experiments, which were widely extended both in

the laboratory and in the coal-mine, led me to infer that no simple and practicable method equalled in these respects the hydrogen flame when safely and suitably applied. The "flame-cap" over the standard hydrogen flame, as it is seen in the suitably-fitted safety lamp, not only detects, but measures the fire-damp with great precision. This standard test-flame has since been adapted to the detection and measurement of coal-gas in air, and, in conjunction with Mr. Boverton Redwood, our newly-elected London chairman, I have applied it also to the detection and measurement of petroleum vapour in the air. A full summary of our work in these directions, which includes and somewhat extends our papers which have appeared in the Journal of this Society, appears as a monograph published by Messrs. Crosby Lockwood and Son under the title of the "Detection and Measurement of Inflammable Gas and Vapour in the Air."

The new illuminant, acetylene, has claimed in some measure in recent years the attention of most of us. It cannot be maintained that acetylene is a newly-discovered gas, or even that the material from which it is now produced is new to science. But it may certainly be claimed that the cheap production on the large scale of the calcium carbide, from which acetylene is most economically prepared, is a recent discovery. And it is this discovery which has brought acetylene to the front as a possible and powerful illuminant. An inspection of the flame of acetylene, when it is suitably produced from an appropriate burner, is sufficient to satisfy anyone that it is most desirable to secure the service of this brilliantly burning gas. Apparently the general adoption of acetylene for illuminating purposes is being delayed by the feeling that the gas is dangerous, and there certainly are not wanting instances of dire disaster arising from its preparation and storage.

In the liquid condition acetylene can undoubtedly, owing to its endothermic character, undergo most violent explosive decomposition, yet Raoul Pictet strongly urges that the liquid is safe if it is suitably prepared and stored. In the gaseous form we are assured by Vivian Lewes that the gas does not undergo this explosive decomposition when it is stored under a pressure less than two atmospheres. Lewes further states that this gas may be burnt in such a way, if it is properly prepared, as not to rapidly cause obstruction in the burners—a difficulty which has caused trouble in the past; he further states that while it is not of use for enriching coal-gas, it is a valuable enricher of oil-gas.

It is to be hoped that the public may ultimately receive satisfactory assurance that they can employ acetylene as an illuminant with success and safety under suitable conditions. It will be remembered that other endothermic substances, such as nitro-glycerin or dynamite, and nitro-cellulose or guncotton, have now attained this desirable condition, after having in the past worked such disaster as to cause them to be looked upon by the public as hopelessly unsafe. It must be remembered in any case that acetylene when mixed in very small proportion with air furnishes an explosive mixture, but danger arising from this cause must certainly be looked upon as preventable.

The enrichment of coal-gas, which it was hoped might have been effected by acetylene, is now usually secured by the indirect employment of water-gas. The large amount of poisonous carbon monoxide which is thus introduced into the enriched gas has naturally led to apprehension, whilst the use of carburetted water-gas has certainly given rise to serious loss of life. The substitution of a comparatively non-poisonous and highly illuminating gas, such as acetylene, for enriched coal-gas may be one of the solutions of the attempt to furnish the public with gas of high illuminating power.

Those who are interested or concerned in another important problem of applied science—the disposal of our town sewage—will watch with interest the development in recent years of the process of treatment of sewage by artificial filtration through coke or other suitable substances. This filtration is known to secure the oxidation of the putrescible matter of the sewage indirectly through the intervention of bacteria. Perhaps the nearest parallel cases are the change of sugar into alcohol and carbon dioxide under the influence of the yeast cell; followed by the production of vinegar from the alcohol of malt liquor or "must," under the influence of the *mycoderma aceti*, which has long been known to be the organism necessary to transfer the atmospheric oxygen to the alcohol. Indeed, just as it is found necessary that the saccharine liquid shall be sown with the yeast cells, and the alcoholic liquid shall become sown with the *mycoderma*, before alcoholic fermentation and acetification can take place with rapidity; so it is found that the bacterial filter for sewage must become infected with the

bacteria necessary for the liquefaction of the suspended organic matter of the sewage, and with those suited to effect the oxidation of the dissolved organic substances, before it is in a condition to purify the sewage. In experiments conducted on the small scale, a double filtration of raw London sewage through two small coke bacterial filters has in this way effected upon the raw sewage a purification of 95 per cent. It is hoped and anticipated that experimental filters of a similar kind, but on a larger scale, which are now being started, may produce a similarly successful result, and that their action may be continuous and permanent.

CONCLUSION.

And now the time is at hand when I shall delegate my duties as President to my successor. In congratulating him and assuring him of my best wishes, I take the opportunity of thanking the members of this large Association for the entirely unexpected and unsolicited honour which they conferred upon me at their annual meeting last year. I have served the Society for many years in the past, on its Council and committees in London, as well as in the important city in which we are now assembled. By electing me as your President you have conferred upon me the opportunity of higher, if not more arduous, service. No one here is conscious, as I am myself, of the extent to which the performance of these higher duties has fallen below the ideal which I have placed before me; but I trust and believe that after electing me to a position of honour which I have highly valued, you will one and all feel that I have wished and attempted to fulfil the duties which you have entrusted to me.

ANALYTICAL NOTES.

ACTION OF AMMONIUM SULPHIDE ON CHLORAL HYDRATE.—According to Joseph Lesinsky and Charles Gundlich (*Am. Chem. Journ.*), when aqueous solutions of chloral hydrate and yellow ammonium sulphide are mixed, an orange-yellow precipitate forms, which appears to be sulphur.—*Bull. de la Soc. Chim. de Paris* [3], xix.-xx., No. 11, 457.

TEST FOR SAWDUST IN STARCHES.—G. A. Le Roy has turned his attention to the detection of sawdust in the flour of barley, oat, and other grains which normally contain cellulose debris derived from the grain itself. Excellent results were obtained by the use of an alcoholic solution of phloroglucin, strongly acidified with phosphoric acid. On steeping the flour in this solution and warming slightly a deep carmine colour is developed in presence of sawdust, whilst the cellulose matter proper to the grain itself assumes, if at all, a much lighter hue. The starch grains remain colourless. By trying a blank experiment side by side under the same conditions one may colorimetrically determine approximately the proportion of the adulteration present in the starch.—*Bull. de la Soc. Chim. de Paris* [3], xix.-xx., No. 11, 478.

RAPID ASSAY OF LEAD ORES.—Cannon employs the following process for determining the amount of lead in plumbiferous material. A flux is made of sodium bicarbonate, 16; potassium carbonate, 16; anhydrous borax, 8; flour 5. Twenty grammes of this mixture and 5 grammes of the mineral, intimately mixed, are placed in a small crucible covered with another 20 grammes of flux, and heated to bright redness in a muffle for 25 to 30 minutes. As soon as fusion commences the muffle should be closed; a few iron tacks should be added to remove any sulphur; these should be carefully removed when reduction is complete. The metal is collected into a button separated from the flux and scoria, purified and weighed.—*Engineering and Mining Journal*, 1897, 604, through *Mon. Scientif.*, xii., 138.

ACIDIMETRY OR ALKALIMETRY OF DEEPLY COLOURED FLUIDS.—In the titration of fluids of such deep colour that the end-reaction cannot be easily seen with the usual indicators, Jean (*Annales de Chim. Analyt.*) proposes to employ the following methods. *Determination of alkalinity*: A known volume of the liquid is distilled with ammonium sulphate into a standard acid, the equivalent of ammonia liberated indicating the alkalinity of the liquid. *Determination of acidity*: 10 to 20 C.c. of normal alkali are added to a known volume of the liquid, and then ammonium sulphate is introduced. The solution is then distilled into 10 or 20 C.c. of normal acid. The amount of acid used up will indicate the quantity of unneutralised normal alkali present, and, therefore, by difference, the acidity of the original solution.—*Rev. de Chim. Analyt.*, vi., 32.

The Poisonous Substances Bill.

Reasons against the Bill.

The Poisonous Substances Bill was read for the third time in the House of Lords on Friday, July 1, without other than a single verbal amendment. In view, however, of its introduction into the House of Commons, active opposition to the measure was organised, and the following reasons why the Bill should not become law were given in a circular letter signed by the President of the Pharmaceutical Society and sent to every registered chemist last week :—

The law at present requires that for the public safety "poisons" shall be placed under the care of "chemists and druggists" who have been specially educated and trained, and who have demonstrated their capability to undertake the responsibility by having passed the stringent examinations required of them by Statute.

The provisions of the Poisonous Substances Bill involve the substitution of "Regulations" for personal qualification, and the abandonment of the principle which has hitherto obtained.

This is contrary to public policy, and inflicts an injustice upon those who have been ascertained, by examinations approved by the Privy Council, to possess a competent practical knowledge of potent drugs and medicaments.

The Bill, although ostensibly proposing to deal with the regulation of "poisonous substances," would actually effect the repeal of a portion of the Pharmacy Act, 1868, and would make the practice of pharmacy in Great Britain subject to departmental experiments in regulations. There is already in existence a class of persons of high technical training and scientific knowledge (chemists and druggists) specially fitted to dispense, compound, and retail potent and dangerous substances, and if there is any real desire to protect the British public from the indiscriminate distribution of carbolic acid and similar articles by thoughtless or ignorant persons, the means lie ready to hand in Section II. of the Pharmacy Act, 1868. The Privy Council has been many times urged to approve the addition of carbolic acid to the Schedule of statutory poisons, but has for some reason or other always refrained from so doing.

In Ireland, however, that article has been officially declared to be a "poison," and can only be sold by qualified persons. It is not unreasonable to contend that the people of Great Britain have a right to an equal measure of protection. There can be no justification for saying that what is a necessary safeguard in one part of the kingdom would be a "trade monopoly" in another, nor is there any more warrant for free trade in carbolic acid than there is for the untrammelled sale of arsenic.

Labelling alone is practically worthless as a safeguard against accidental poisoning, and, in fact, a too general use of the word "poison" is more likely than not to defeat its own end, and the warning it is intended to convey would probably be weakened in efficacy by too great familiarity. The safety of the public lies chiefly in the competency of the vendor, and not in the wording of a label.

The Poisonous Substances Bill does nothing to ensure real security.

NOTE.—In the House of Commons on Tuesday, the First Lord of the Treasury announced that the Poisonous Substances Bill would not be proceeded with. The opposition has therefore proved effective for the present Session of Parliament, at least.

Medical Opinions on the Bill.

"We fail to see how this Bill, the substance of which, on the occasion of its second reading on the motion of the Duke of Devonshire in the House of Lords on June 24, was given in our Parliamentary columns last week, is likely to afford much more protection to the public against the indiscriminate sale of poisons than at present obtains. It does not at any rate increase the scope of action under the Pharmacy Act which so far as it has related to the poisons placed within the Schedule has worked not with that completeness which might be desired, but still with a fair measure of success. According to the provisions of the Bill carbolic acid (and with it its homologues), which by reason of the ease with which it can be purchased at oil-shops, has been responsible for an enormous increase in the number of self-inflicted and, we need not add, most painful deaths, is still to be procured from any class of shop where the shopkeeper chooses to sell it, with, however, the restriction that the purchase is to be labelled distinctly with the word "poison" and with the name and address of the person selling the substance. Such a clause provides very well against the risks of accidental poisoning, but it does nothing for the deliberate suicide. Indeed, it only advertises the fact, it seems to us, that certain mixtures are poisonous. Surely the principle of scheduling certain substances as legally recognised poisons is a sound one to go upon if any hope at all is to be entertained of ever putting a stop to the indiscriminate sale of poisons.

"The seller should be registered and should be a person who knows exactly the nature of the commodity with which he is dealing and should possess an intelligence which will enable him to an extent to discriminate between purchasers who require the substance for a wrong or a right purpose. But it is urged that if the sale of such things as carbolic acid, disinfectants, and weed-killers, poisonous commodities which are in request every day, was restricted to persons possessing a proper qualification it would cause considerable inconvenience to the public by imposing a difficulty in the way of obtaining these extremely necessary articles, and, again, that it would mean the transfer of a source of business and profit from the ordinary shopkeeper to the druggist. In the interests of the public why should not this be so when instance upon instance is on record of an ordinary tradesman having supplied with disastrous results carbolic acid in cups, ginger-beer bottles, or any receptacle commonly used for containing beverages? The fact is that carbolic acid is a comparatively recent addition to commercial commodities, and its introduction on the market occurred some time after the passing of the Pharmacy Act, as otherwise without doubt it would have been included as a scheduled poison. We do not attach much force to the argument that such restrictions would lead to an abandonment of sanitary measures by the public owing to the *modus operandi* which would be enjoined in order to effect a purchase. There are plenty of excellent disinfectants which are comparatively non-poisonous, indeed, which would be practically free from harm; but carbolic acid is a poison of a powerful kind, and it is monstrous that its sale to the public has hitherto been as unrestricted as that of sugar. If a really protective measure is to become law the Bill introduced by the Duke of Devonshire and now read a second time in the House of Lords must be very seriously altered and amended. Otherwise the undoubted good which the present Pharmacy Act is doing will be to a great extent nullified."—*Lancet*, July 9, 1898

THE POISONOUS SUBSTANCES BILL.

WHEN the long looked-for result of the Privy Council's consideration of the views so repeatedly expressed in regard to the dangers of carbolic acid, made its appearance somewhat suddenly in the House of Lords, the rapidity with which the Bill, dealing with that subject, passed through its several stages in that House and the absence of any comment upon it, beyond those of the Lord President at the second reading, showed that the object and provisions of the Bill were either generally approved or considered of too little importance to require discussion. We will not presume to determine by which of these alternatives the House of Lords was influenced in regard to the Bill, neither do we desire to suggest that the permanent officials of the Privy Council, in drafting a measure relating to a subject which has been for so many years pressed upon their consideration in various ways as being of great public importance, omitted to deal with that subject in the manner which appeared to them most suitable in regard to the several interests involved. Without that necessary limitation any adverse criticism of the Bill might well be regarded as evidence of mere querulous antagonism.

But holding as we do the opinion that the subject to which the Poisonous Substances Bill relates, is one of great public importance in several ways and being cognisant of the circumstances which require to be considered in regard to that subject, we cannot refrain from expressing the opinion that the Government Bill affords emphatic demonstration of the incapacity of the Privy Council, as at present advised, to frame a measure for dealing efficiently with regulation of the trade in poisonous substances. In considering the question how that regulation should be carried out in the general interest, claims of various kinds have to be recognised. Among them, those relating to trade and industrial occupations are entitled to rank according to their importance. But the predominant necessity is that the recognition of any such claims should be controlled and limited by consideration of what is requisite for public safety; for the prevention of injury to health and of undue risk to life. Leaving out of notice for the moment arguments based upon doctrinaire opinions or interested motives, public safety may be regarded as the chief point to be considered in regulating the use or supply of articles liable to cause injury.

That it is the business of the State to impose restrictions in that respect may also be assumed. If danger to life or health be the alternative to restriction, either of trade or productive industry, the lesser evil must be accepted as a necessity. The suggested prohibition of the use of white phosphorus in match-making is a case in point, and the endeavour now being made to impose restriction on the use of lead in pottery glazes will probably lead to similar results.

In various other arts poisons, within the statutory meaning of the term, or poisonous substances, are employed for purposes that are beneficial and desirable. To object to their use merely because they might be prejudicial would be unreasonable; but in any case precautions are desirable to prevent accident or misuse. Naturally the use of such substances is attended with some risk, as in the use of arsenic in operations connected with agriculture and horticulture, or for the destruction of vermin, and that risk needs to be minimised by suitable regulations. Quite on the same footing is the use of carbolic acid for purposes of sanitation, and the apprehension that regulating its sale would be an obstacle to its use in that way has no more foundation than in the case of arsenic. In regard to both these articles the danger of accident or improper use is to a great extent proportionate to the facility with which they can be obtained.

Poisoning by arsenic is now a comparatively rare occurrence; but the victims of carbolic acid are nearly thirty-fold as numerous. That difference is entirely attributable to the relatively more easy means of access to carbolic acid as compared with arsenic. The preponderance of suicides among the deaths caused by carbolic tells the same tale, and still more instructive is the fact that among the cases of accidental death caused by carbolic acid and other unscheduled articles, one-fourth of the number are children under ten years of age. Possibly these facts are not sufficiently well known; but they are conclusive evidence that carbolic acid is too readily obtainable, that it is pre-eminently an article which should be placed under statutory restriction consistently with the whole tenour of the recent discussion in the House of Commons, in order to secure the object admitted by every speaker on that occasion to be urgently required for public safety. A mere poison label would be insufficient for the purpose, and the gratuitous distribution of carbolic acid by sanitary authorities should be restricted to the supply of carbolic in the diluted form ordinarily used for disinfection. For that purpose further legislation is not required, all that is needed is approval by the Privy Council of the recommendation made by the Council of the Pharmaceutical Society that carbolic acid should be added to the Schedule of Poisons within the meaning of the Pharmacy Act. If subsequent experience should prove that the requirements of sanitation were interfered with by that arrangement, there might then be reason for sanctioning the sale or supply of the article in such a manner as to meet special conditions; but such relaxation of the law relating to this dangerous article should be under special licence, and with such control as would prevent abuse.

The fact that the ill-considered Bill will not be further proceeded with during this Session of Parliament would seem to indicate that the Privy Council has not been in earnest about the matter, and the crudeness of expression which distinguished the measure has pointed in the same direction. But, in any case, if it should be re-introduced next Session it must be strenuously opposed.

ANNOTATIONS.

“Let me play the lion too: I will roar, that I will do any man's heart good to hear me; I will roar, that I will make the Duke say—Let him roar again; Let him roar again.”

FOLLOWING THE PRECEDENT OF WORTHY BOTTOM, the amateur pretensions of a trade journal in connection with the Poisonous Substances Bill might appear to suggest the near approach of a time when management of pharmaceutical affairs should be transferred from the chosen Executive of the Pharmaceutical Society to the offices of that journal. Still, the need for apprehending such a contingency is happily even less than our young friend's professed reluctance to usurp the functions of constituted authority. Though a statement has been made that “valuable time has been lost,” the contrary statements made at the last Council Meeting by the President, Mr. Atkins, and Mr. Carteighe may safely be understood as meaning that the Council—authorised to deal with such matters in the public interest and as the representative of registered chemists and druggists, knowing its business better than any would-be advisers, aggressive or parasitic—has taken such steps as were desirable in the exercise of those functions. As an instance of advertising, which has now developed into a fine art, the ingenuity displayed in making the Poisonous Substances Bill an opening for the thin end of a trade circular may excite amused admiration in that respect. But beyond that point and inflated into a pretence of assumed leadership, by apparently spontaneous though conveniently anonymous puffs and back-stair gossip, the latest manifestation of “journalistic enterprise” is more likely to revive recollections of the infatuated frog who endeavoured, by exaggerated distension, to appear unnaturally big.

THE PHARMACY ACTS AMENDMENT BILL has so far proceeded on its way in the House of Lords unchecked. On Monday, July 11, it reached the committee stage, and as there were no amendments, the Earl of Morley (Chairman of Committees) reported the measure to the House without alteration. The report was received accordingly, and on the following day the further ordeal of the Standing Committee of the House of Lords was successfully passed. The third reading of the Bill is fixed for Monday next, and in the ordinary course it would only be necessary to obtain the Royal assent to the measure. But a question of serious importance was raised by the Lord Chancellor when the Bill came before the Standing Committee, for he directed attention to the fact that the Pharmacy Acts do not cover the case of drug stores carried on by joint-stock companies or corporations, and he urged that the common-sense view of the question requires that such bodies should be treated just in the same way as individuals. Lord Herschell supported this contention, and quoted a case which had been brought under his notice, in which a man and his family formed themselves into a company and carried on business outside the operation of the Pharmacy Acts. The Earl of Hardwicke, who was in charge of the Bill, admitted the cogency of the above reasoning, and promised to bring up, on the report stage, an amendment dealing with the point raised by the Lord Chancellor. The proceedings of the House of Lords on Monday next should therefore prove of special interest to chemists and druggists.

THE POISONOUS SUBSTANCES BILL has had a less successful career, its brief and merry life having been brought to a violent close on Tuesday night. Mr. Heywood Johnstone asked, in the House of Commons, whether it was intended to proceed with the Poisonous Substances Bill this session, having regard to the wide-spread

objection to the measure by chemists and druggists throughout the country. Mr. A. J. Balfour postponed his answer for the moment, but later in the evening, in the course of a general statement as to the course of business in the House, he said the Poisonous Substances Bill was one of the measures which there seemed no prospect of being able to pass into law during this session, and it would consequently not be proceeded with. The opposition by registered chemists may or may not have been instrumental in checking the further progress of the Bill, but there is no doubt that such opposition has been considerable and would have produced a definite effect if the measure had been introduced into the lower House. Even though it were a mere *ballon d'essai*, therefore, sent up by the permanent officials of the Privy Council to test the extent to which chemists and druggists were prepared to submit to external authority, the result is eminently satisfactory, and in view of the possibility of a similar Bill being brought before Parliament next session, it will be well for our readers to organise and improve their means of resistance. The unanimous voice of the chemists and druggists of Great Britain is not likely to be ignored by the House of Commons, and unless the lessons of history have been misunderstood, the craft is quite powerful enough to withstand much more powerful assaults than have yet been threatened.

IN THE HOUSE OF COMMONS on Monday, Mr. Field asked whether attention had been drawn to the fact that an inquest was held at Belfast, on May 18, on the body of a man named Robert Patterson, who, it was proved, was supplied with a scheduled poison at an establishment in Mill Street, owned by the Ulster Chemists, Limited. He was given the poison without the statutory requirements or knowledge by or introduction to the seller, or the signing of the book kept for the registration of such sales, contrary to the provisions of the Poisons (Ireland) Act; and it was asked why, although the Pharmaceutical Society of Ireland drew the attention of the Inspector-General of Constabulary to the matter, he had replied that it had been decided they would not undertake prosecutions of this kind? The Chief Secretary said the facts of the case mentioned in the question were fully investigated by the Government, whose advisers thought it was not one in which the Crown should institute a prosecution, and that proceedings in the case should be taken by the Pharmaceutical Society if so advised.

THE QUESTION OF UNWORKED PATENTS came up in the House of Commons a few days ago, when Mr. Cawley asked the President of the Board of Trade whether he had yet considered and come to a decision on the report of the referee appointed to inquire into the application for a licence made by an English firm to work in England a patent granted to a German firm; whether he was aware that a patent for the same discovery was refused by the German patent office; whether, seeing that the English manufacturer had been put to an expense of £1800 in bringing a test case forward at the request of the Board of Trade, they would be prepared to pay the expenses of the applicant; and whether, seeing the advantage the present Patent Law was giving to foreigners, particularly in the manufacture of aniline colours, he was prepared to propose some legislation by which English manufacturers might compete on more equal terms with their foreign competitors in the English markets. Mr. Ritchie said more than one application for an order for the granting of a licence had been before the Board of Trade. If the Hon. Member referred to the case of Levenstein and Meister Lucius and Co., he would find that the reply to the first

part of the question was in the affirmative. He was not in a position to say whether a patent for the same discovery was refused by the German Patent Office, and he declined to admit that the English Patent Law gives an advantage to foreigners. He said the Hon. Member did not state what sort of legislation he contemplated, and he could only say therefore that if it should in any respect be found necessary to amend the existing law on the subject of patents he would bring the matter before Parliament. The Board of Trade was certainly not prepared to pay the expenses of the application, and Mr. Ritchie demurred to the statement that the case was in any respect a test case brought forward at the request of the Board of Trade.

A CASE OF LAUDANUM POISONING IN LEITH affords another example of the device adopted to procure a fatal quantity of poison, which was referred to in the Journal some time ago. John Bain, a labourer, thirty-five years of age, and married, died in Leith Hospital, on Sunday, July 10, from an overdose of laudanum. On the previous night his wife, on awaking, found him lying unconscious at the side of the bed, and in his pockets were six small bottles of laudanum. He was taken to the hospital, but all efforts to restore animation were futile. It is well known to most persons who have occasion to purchase scheduled poisons that no responsible pharmacist would sell a fatal quantity of laudanum to a single purchaser without careful inquiry as to the purpose for which it was to be employed. This man, however, had bought from each of six pharmacists a small and, by itself, comparatively harmless quantity. He then combined the lot into a single draught. It is not necessary to assume that there was carelessness on the part of anyone who supplied this unfortunate man. But it was ascertained that he had been drinking heavily for some time, and he must have borne evidence of his debauch. The case illustrates the fact that pharmacists must be constantly on their guard even when only a small quantity of laudanum is asked for. It is better on the whole to refuse to supply poison than to run the risk of being mixed up in a case of the kind reported.

THE APPROACHING CONFERENCE AT BELFAST has suggested to Mr. W. W. Savage, of Brighton, the desirability of co-operation amongst dwellers in the South of England who propose to visit the North of Ireland on that occasion. The Polytechnic, which successfully organises so many co-operative and educational holiday tours every summer, is willing, we understand, to arrange a special tour in connection with the Belfast meeting if a sufficient number of persons will join the party. Mr. Savage intimates that he is willing to act in the matter, and those of our readers who are desirous of taking advantage of this opportunity should communicate with him at 109, St. James's Street, Brighton, at once. It is proposed that the party should start on the morning of Monday, August 8.

THE SOCIETY OF CHEMICAL INDUSTRY met at Nottingham on Wednesday for its Annual Meeting, and the chair was taken by Professor Frank Clowes, who delivered the address printed at page 54. Mr. George Beilby, the well-known authority on shale oil distillation, was elected President for the ensuing year. The Society's Medal was presented to Dr. W. H. Perkin, F.R.S., and a highly satisfactory report was presented on the Society's affairs. The Society now includes 3200 members, divided among eight local sections, including New York with about 600 members; it is the only British scientific society with an American Branch. By invitation of Alderman Sir John Turney, J.P., the members were entertained at a garden party on Wednesday afternoon, whilst the

Mayor of Nottingham held a reception and conversazione in the Castle during the evening. On Thursday visits were paid to several of the chief steelworks, etc., at Sheffield, and to various places of interest in Nottingham and the vicinity, the Annual Dinner being held in the Exchange Hall the same evening. The programme for Friday included an excursion to Lathkill Dale, and visits to Haddon Hall, Chatsworth, and Edensor.

SIR WILLIAM FLOWER'S RESIGNATION from the Directorship of the Natural History Museum has been followed by an expression of profound regret from the Trustees of the British Museum. They had hoped that the remaining term of years which he might have spent in their service would have enabled him to perfect the arrangements of the collections so admirably planned and so systematically developed by him during his fourteen years of office, and they state that they cannot but regard his retirement at this moment as a real misfortune to the Museum. They also record their high appreciation of his services in the following terms:—"The rare combination of wide scientific knowledge with marked administrative ability and a sympathetic appreciation of the requirements of the uninstructed public has carried you through a most difficult task. Under your hands the natural history collections of the British Museum have fallen into the lines of an orderly and instructive arrangement, which no one, whether man of science or ordinary visitor, can examine without admiration. To you, as a worthy successor of Sir Richard Owen, will attach the honour of having organised a museum of natural history which now occupies a pre-eminent position among all the museums of the civilised world. For these devoted services the Trustees thank you. In your retirement you carry with you their lasting gratitude and their sincere good wishes."

WATER GAS was the subject of a letter received by the Public Control Committee of the London County Council from the Departmental Committee of the Home Office, which is considering the questions of the manufacture and supply of that gas, and has asked the opinion of the Council on the subject. The Public Control Committee reports that, having carefully considered the matter, it has arrived at the following conclusions, which have been communicated to the Departmental Committee:—(1) That considerable danger arises from the introduction of water gas in the process of the enrichment of coal gas; (2) that non-carburetted and non-odorised water gas should not be allowed to be used under any conditions, since it is devoid of smell, which would give warning of any escape of the gas; (3) that 25 per cent. should be the maximum amount of water gas allowed to be introduced in the enrichment of coal gas, the proportion of water gas being ascertained by determining the amount of carbonic oxide in the enriched coal gas (coal gas enriched to this extent would correspond in poisonous character to the Dowson gas which is already in use for heating purposes and for gas engines, and would exclude the use of carburetted water gas); (4) that when it is proposed to supply poisonous enriched gas to houses and the interior of buildings a proper inspection be made of the service pipes by a responsible officer appointed by the local or other suitable authority, who should certify that the pipes are in a sound condition and that there is no escape of gas, and that the cost of such inspection be borne by the gas company.

THE TOTAL VALUE of drugs and medicinal preparations exported during the month ending June 30, 1898, was £97,739, as against £92,015 during the corresponding month last year. For the six months ending June 30, 1898, the value was £531,566 as against £553,437 last year.

DONATIONS TO THE LIBRARY AND MUSEUM.

At a meeting of the Library, Museum, School and House Committee, on Wednesday, July 13, the Librarian and Curator presented the following reports of donations:—

To the Library (London).

Mr. W. Martindale, London:—The Extra Pharmacopœia, 9th ed., two copies.
Kaiserliche Leopoldinisch-Carolinische Deutsche Akademie der Naturforscher:—Nova Acta, Bd. 68-69; Katalog der Bibliothek, Lief 8.
University of London:—Calendar, 1898.
University of Glasgow:—Calendar, 1898.
Missouri Botanical Garden:—Ninth Annual Report.
Mr. C. J. S. Thompson, Liverpool:—The Chemists' Compendium, 2nd ed., 1898.
Students' Association of the School of Pharmacy:—Papers, vol. 23, 1896-97.

To the Museum (London).

Mr. J. G. Prebble:—Specimens of the fruit and stem of the Sarcocoll plant.
Mr. R. T. Baker, F.L.S., Technological Museum, Sydney:—Specimens of the fruits of *Rhus rhodanthema* and *Owenia cepiodora*.
Captain Burrows, Congo:—Specimen of the stems and root of *Strychnos*, *M'Boundon*.

The African Lakes Company, Glasgow:—Specimens of *Strophanthus emini* seeds, leaves and stem. Specimen of the India-rubber and stems of *Landolphia florida*, and *L. Kirkii*, and a red dye wood.

Messrs. L. Lambert and Co., London:—Specimens of a false *Podophyllum*.

To the Herbarium (London).

Professor H. H. Rusby, M.D., New York:—A series of specimens of medicinal and economic plants, including the following species not previously contained in the Herbarium:—*Acer saccharinum*, *Ainus viridis*, *Betula papyracea*, *Celastrus scandens*, *Panax quinquefolium*, *Pieris mariana*.

The Curator of the Biltmore Herbarium, Biltmore, N. Carolina:—Specimens of North American plants, including the following species not previously represented in the Herbarium:—*Amianthium muscetoxicum*, *Apocynum cannabinum*, *Belaincanda chinensis*, *Carya amara*, *Cassia marilandica*, in fruit, *Ipomea pandurata*, *Magnolia acuminata*, *Pinus Feda*, in fruit, *Prunus serotina*, *Quercus palustris*, *Quercus rubra* and *Sabal palmetto*.

FIRST EXAMINATION QUESTIONS.

July 12, 1898.

LATIN.

Time allowed—from 11 a.m. to 12.30 p.m.

I. For all Candidates. Translate into Latin:—

1. He was the seventh and the last of the Roman kings.
2. Neither I nor you have done these things.
3. Philoctetes was wounded in one foot.
4. He asked whether this was true or not.
5. The walls of Babylon were two hundred feet high and fifty feet broad.

II. Translate into English either A (Caesar) or B (Virgil).
(Candidates must not attempt both authors.)

A.—CAESAR.

1. Itaque prius, quam quicquam conaretur, Divitiacum ad se vocari jubet, et, quotidianis interpretibus remotis, per C. Valerium Procellum, principem Galliae provinciae, familiarem suum, cui summam omnium rerum fidem habebat, cum eo colloquitur: simul commonefacit, quae ipso praesente in concilio Gallorum de Dumnorige sint dicta, et ostendit, quae separatim quisque de eo apud se dixerit. Petit atque hortatur, ut sine ejus offensione animi vel ipse de eo, causa cognita, statuatur, vel civitatem statuere jubeat.

2. Postulavit deinde eadem quae legatis in mandatis dederat, ne aut Aeduis aut eorum sociis bellum inferret; obsides redderet; si nullam partem Germanorum domum remittere posset, at ne quos amplius Rhenum transire pateretur. Ariovistus ad postulata Caesaris pauca respondit, de suis virtutibus multa praedicavit.

Grammatical Questions.

(For those only who take Caesar.)

1. Decline in the singular *nullam partem*; and in the plural *suis virtutibus*. (Passage 2.)
2. Give the principal parts of all the verbs in Passage 1.
3. Write in Latin—14, 29, 11th, fifteen times, three books each, every twentieth man.
4. What is meant by an "indirect question"? Write sentences introducing some of the particles used in Latin for questioning indirectly.

B.—VIRGIL.

1. Talibus incusat, gressumque ad moenia tendit.
At Venus obscuro gradientes aere sepsit,
Et multo nebulae circum dea fudit amictu;
Cernere ne quis eos, neu quis contingere posset,
Molirive moram, aut veniendi posseere causas.
Ipsa Paphum sublimis abit, sedesque revisit
Laeta suas; ubi templum illi, centumque Sabaeo
Thure calant arae sertisque recentibus halant.
2. Jamque ibat dicto parens, et dona Cupido
Regia portabat Tyriis, duce laetus Achate.
Cum venit, aulaeis jam se regina superbis
Aurea composuit sponda, mediamque locavit.
Jam pater Aeneas, et jam Troj. na juvenus.
Convenient, stratoque super discumbitur ostro.
Dant manibus famuli lymphas, Cereremque canistris
Expediunt, tonsisque ferunt mantilia villis.

Grammatical Questions

(For those only who take Virgil.)

1. Decline in the singular *pater Aeneas*; and in the singular and plural *mantilia*. (Passage 2.)
2. Give the principal parts of all the verbs in Passage 1.
3. Write in Latin—14, 29, 11th, fifteen times, three books each, every twentieth man.
4. What is meant by an "indirect question"? Write sentences introducing some of the particles used in Latin for questioning indirectly.

ARITHMETIC.

Time allowed—from 12.30 p.m. to 2 p.m.

[The working of these questions, as well as the answers, must be written out in full.]

1. Divide 5 qrs. 6 bus. 3 pks. 2 qts. 1 pt. by 111.
2. If 480 flagstones each 5 feet square will pave a courtyard, how many will be required for a yard 8 times as large, each flagstone being 4 feet by 2 feet?
3. Find the value of $\frac{1}{2} \left(\frac{4}{7} \text{ of } 6\frac{3}{4} \right) \times \frac{3}{5} - 3\frac{1}{2} \text{ of } £182 \text{ } 7\text{s. } 5\text{d.}$
4. Multiply '003625 by 74.2; and divide '03625 by '29.
5. I mix 80 gallons of spirit costing 15s. 6d. per gallon with 96 gallons costing 17s. 1d. per gallon, and sell the mixture at 18s. per gallon. What is my gain per cent.?
6. In a certain company the total amount in shares subscribed is £80,000, of which £10,000 preference shares are to be paid a dividend of 5 per cent. The profits for the year amount to £3475: what percentage will be paid upon the ordinary shares?

The following question must be attempted by every candidate:—

7. Give approximately in yards the equivalent of 2 kilometres.
A cask with two taps holds 240 litres of water. The first tap would empty $\frac{1}{4}$ of the contents in 5 minutes, and the second would empty $\frac{1}{3}$ in 6 minutes. If the cask is filled and the two taps are turned on for 2 minutes, find approximately how many pints of water will then be left in the cask.

ENGLISH.

Time allowed—from 3 p.m. to 4.30 p.m.

1. Parse fully the following sentence:—
"Come in!" the Mayor cried, looking bigger;
And in did come the strangest figure!
2. Explain, with examples, *Noun sentence*, *Adverbial clause*.
3. Correct the following sentences, giving your reasons:—
(a) He cannot distinguish between the old and new boat.

(b) Neither she or her brother are going there to-day.

(c) The story he told you and I is too outrageous to believe.

4. In the following passage supply the necessary capital letters, and put in the stops and the inverted commas where necessary:—next day Charles burst upon me triumphant well he has shown his hand he cried I knew he would he has come to me to day with what do you think a payment of gold in quartz from the long mountain no I exclaimed yes Charles answered he says there a vein there with distinct specks of gold in it

5. Write a short composition on *one* of the following subjects:—

- (a) Recent events in China.
- (b) King Alfred.
- (c) The pernicious influence of idleness.
- (d) "Unity is strength."

JACOB BELL SCHOLARSHIPS EXAMINATION.

Tuesday, July 12, 1898.

Time allowed—three hours (11 a.m. to 2 p.m.).

**FIRST PAPER.
LATIN.**

1. Translate into English:—

Heu, nihil in vitis fas quemquam fidere divis!
Ecce trahebatur passis Priameia virgo,
Crinibus a templo Cassandra adytisque Minervae,
Ad coelum tendens ardentia lumina frustra:
Lumina, nam teneras arcebant vincula palmas.
Non tulit hanc speciem furia mente Choroebus,
Et sese medium iniecit moriturus in agmen.
Consequimur cuncti, et densis incurrimus armis.
Hic primum ex alto delubri culmine telis
Nostrorum obruimur, oriturque miserrima caedes,
Armorum facie, et Gralarum errore jubarum.
Tum Danaï gemitu, atque ereptae virginis ira,
Undique collecti invadunt: acerrimus Ajax,
Et gemini Atridae, Dolopumque exercitus omnis.
Adversis rupto cœu quondam turbine venti
Configunt, Zephyrusque, Notusque, et laetus Eois
Eurus equis: stridunt silvae, saevitque tridenti
Spumeus, atque imo Nereus ciet aequora fundo.

2. Translate in English:—

(a) Omnia medicamenta a nobis praescripta asservari debent. Quae vero locis a reliquis medicamentis seclusis asservanda sunt, venena vulgo vocantur. Talia a reliquis separanda tabula subiecitur sistens.

(b) Misce extracti Aconiti uncias quatuor cum Sacchari Lactis pulverati uncia una, et loco tepido seponere, donec mixta perfecte sicca fuerint.

Massae tritae, si pondus non exacte unciarum quatuor sit, tantum Sacchari Lactis adde, ut unciae quatuor restituantur, quae in vase optime clauso caute serventur.

3. Parse fully:—"Heu nihil in vitis fas quemquam fidere divis." (Question 1.)

4. Translate into Latin.

(a) I expect that whether he comes to Rome or remains at Naples he will not be secure. Nothing but his departure from Italy will satisfy me.

(b) After some hours of anxious suspense the day broke. The Irish, with James at their head, were now four miles from the city. A hurried council of the chiefs was held. Some of them reproached the governor to his face with treason. He had sold them, they cried, to their worst enemy, and had refused admission to the force sent to defend them.

ENGLISH.

1. Parse fully:—

"Life has passed
With me but roughly since I heard thee last."

2. Write a short Essay on *one* of the following subjects:—

- (a) The evils of obstinacy.
- (b) "Bacchus has drowned more than Neptune."
- (c) The causes of Britain's commercial greatness.

ARITHMETIC.

1. A man, having 271½ acres of land, sold ¼ of it to one man and ⅓ of it to another: what was the value of the remainder at £57½ an acre?

2. Simplify $\frac{3\cdot5-1\cdot8\bar{3}}{9\cdot7-6\cdot4} \times \frac{1}{71} \div \frac{3\cdot1 \times 10\bar{1}}{2\cdot1\bar{5}}$

3. If with 53·46 kilogrammes of thread a man can weave 231 mètres of linen 1·4 metre broad, how many kilogrammes of thread will be required to weave 196 metres of linen '95 metre broad?

En revenant, le gondolier nous fit passer par des rues d'eau que nous ne connaissions pas encore. Les villes en décadence sont comme les corps qui meurent; la vie, réfugiée au cœur, abandonne peu à peu les extrémités; des rues se dépeuplent, des quartiers deviennent solitaires, le sang n'a plus la force d'aller jusqu'au bout des veines. L'entrée de Venise, en venant de Fusine, est d'une mélancolie navrante. Quelques rares bateaux, apportant des denrées de terre ferme, glissent silencieusement sur l'eau endormie le long des maisons désertes. Des palais d'une architecture charmante n'ont plus de fenêtres, et les baies en sont fermées par des planches grossièrement placées en travers; le crépi des maisons abandonnées s'écaille, la mousse étend ses tapis verts sur les assises inférieures, les coquillages et les plantes marines s'incrument aux escaliers d'eau, que le crabe monte seul aujourd'hui.

Friedrich sass zu Prag bei der Mittagstafel, als seine Arnee an den Mauern sich für ihn niederschliessen liess. Vermuthlich hatte er an diesem Tage noch keinen Angriff erwartet, weil er eben heute ein Gastmahl bestellte. Ein Eilbote zog ihn endlich vom Tische, und von dem Wall herab zeigte sich ihm die ganze schreckliche Scene. Um einen überlegten Entschluss zu fassen, erbat er sich einen Stillstand von vierundzwanzig Stunden; acht waren alles was der Herzog ihm bewilligte. Friedrich benutzte sie, sich mit seiner Gemahlin und den Vornehmsten der Arnee des Nachts aus der Hauptstadt zu flüchten. Diese Flucht geschah mit solcher Eilfertigkeit, dass der Fürst von Anhalt seine geheimsten Papiere, und Friedrich seine Krone zurückliess. “Ich weiss nun, wer ich bin,” sagte dieser unglückliche Fürst zu denen, welche ihm Trost zusprachen. “Es gibt Tugenden, welche nur das Unglück uns lehren kann, und nur in der Widerwärtigkeit erfahren wir Fürsten, wer wir sind.”

In the time of Cæsar, Paris was a very small town, called Lutetia (which means a habitation in the midst of the waters). It occupied the larger of the islands formed at this place by the Seine. This island was for a long time called the city. The citizens of Paris, when attacked by Labienus, a lieutenant of Cæsar, burnt their two bridges and the town, and defended themselves with great bravery. Paris now possesses a large number of beautiful monuments and public gardens. Most of the streets are planted with trees. Paris is a fortified town, being surrounded by a line of fortifications and a double range of detached forts.

SECOND PAPER.

Time allowed, two hours (3 p.m. to 5 p.m.).

CHEMISTRY.

1. Aqueous solutions of the following substances, acidified with hydrochloric acid, are treated with sulphuretted hydrogen:—Aluminium Chloride, Bismuth Nitrate, Ferric Chloride, Mercuric Chloride, Potassium Chromate, and Sodium Arseniate. Describe whatever reactions may occur, giving equations.

2. A mixture of 5 litres of Oxygen and 20 litres of Hydrogen, measured under normal conditions of temperature and pressure, is exploded by an electric spark. What volume, if any, of gas will remain, and how would you ascertain what it is?

PHARMACY.

1. What is Dialysis? Describe minutely a Dialyser, and define Colloid and Crystalloid.

2. Describe the Pharmacopœial method of 1885 for preparing Extract of Nux Vomica, giving reasons for the various operations.

BOTANY.

1. Contrast the structure of the stem of a dicotyledonous plant and a fern.

2. Define the following botanical terms:—Cystolith, Emergences, Indusium, Meristem, Periblem.

Manchester Pharmaceutical Association Scholarship Examination.

FIRST PAPER.

Time allowed, three hours (11 a.m. to 2 p.m.).

The tests in Latin, English, Arithmetic, French and German, set in this examination, were the same as those for the Jacob Bell Scholarships Examination, except that the following was given as an alternative Latin paper:—

A.—(CAESAR.)

1. Translate into English:—

Quo proelio bellum Venetorum totiusque orae maritimae confectum est. Nam quum omnis juvenus, omnes etiam gravioris ætatis, in quibus aliquid consilii aut dignitatis fuit, eo convenerant, tum navium quod ubique fuerat in unum locum coegerant; quibus amissis, reliqui neque, quo se reciperent, neque quemadmodum oppida defenderent, habebant. Itaque se suaque omnia Caesari dederunt. In quos eo gravior Caesar vindicandum statuit, quo diligentius, in reliquum tempus, a barbaris jus legatorum conservaretur. Itaque, omni senatu necato, reliquos sub corona vendidit.

2. Parse fully:—"Itaque omni senatu necato, reliquos sub corona vendidit." (Question 1.)

SECOND PAPER.

Time allowed, two hours (3 p.m. to 5 p.m.).

CHEMISTRY.

1. Describe several methods of preparing Chlorine, giving full details and equations.

2. What weight of gas can be obtained by heating 32 grammes of Calcium Carbonate (CaCO₃)?

PHARMACY.

1. What is Evaporation? Describe the apparatus employed for evaporating liquids under reduced pressure.

2. Define Calcination, Sublimation, Elutriation, Levigation and Infusion, giving one typical example of each.

BOTANY.

1. Describe and show diagrammatically a Dichasium or False Dichotomy.

2. Define the following botanical terms:—Acropetal, Alburnum, Aleuron, Endosperm, Hairs.

PHARMACEUTICAL TRANSACTIONS.

MEETING OF MANCHESTER CHEMISTS.

A meeting called by the Manchester Pharmaceutical Defence Association was held at the rooms of the Chemical Club, Victoria Hotel, Manchester, on Thursday, July 7, for the purpose of considering

The Poisonous Substances Bill

and taking action thereon. The attendance, although not large, was a fairly representative one, and included Mr. Walter Gibbons (in the chair), Mr. G. S. Woolley, Mr. A. Blackburn, Mr. F. Pilkington Sargeant (Secretary of the Association), Mr. A. J. Pidd, Mr. W. Kirkby, Mr. C. Swinn, Mr. J. Taylor, etc.—The SECRETARY read letters of apology from Mr. Allen Smith (Sale), who regretted his inability to attend, and expressed his agreement with them as to the incompleteness of the Bill, and hoping the amendments might be carried. He also stated that Mr. H. F. Price, Lancashire County Coroner, had written stating that he could not be present, but that he thought the Bill was not sufficient.

The CHAIRMAN said that in calling that meeting it was desired to have an expression of opinion from those interested in the matter in that district as early as possible, because, as they knew, the Bill had already been read three times in the House of Lords, and only required to go before the Commons to become law. He thought they would agree with him that the Bill as it stood constituted a danger not only to themselves, but to the public at large, because it referred to dangerous substances which were to be dealt with by any dealer who chose to sell them—he meant dealt with by retail. It would create a familiarity with the word poison which would of itself be a great danger; but irrespective of that, it proposed to give to the Privy Council, a body which had no practical knowledge of the handling of poisons, power to impose regulations on a body of men who in the past had shown by their record that those regulations were unnecessary, and might become very obnoxious, and even render the business of dispensing next door to impossible. The introduction of this new series of poisons had its disadvantages, and instead of calling it a Poisons Bill they should have called it a Dangerous Substances Bill, and directed that the substances should be labelled as dangerous substances and not as poisons, because they knew well enough that concentrated mineral acids were poisonous in a sense, but only poisonous so long as they were in their concentrated form. It would not have caused people to begin to look upon "poison" as a frivolous term. One substance he wished to refer to, and that was carbolic acid. Carbolic acid had been recommended by the Pharmaceutical Society of Great Britain to the Privy Council for addition to the Schedule of the present Act, and on three occasions the Privy Council had distinctly declined to have anything to do with it. On the fourth occasion the Privy Council's reply was that they were about to bring out a regulation by which a restriction would be put upon the sale of that compound. They had not kept to their word. This was not a restriction, but a regulation, and a regulation was not a restriction, and there was a difference in the terms. On the other hand, it was not only the Pharmaceutical Society, but the whole of the chemists behind them, who considered that carbolic acid should be added to the list of poisons under the present Act, and he might say, without exception, that the whole body of coroners throughout the country were with them in that respect. He therefore asked that they would express their opinions in order that they might go to their Members of Parliament in London and assist the Pharmaceutical Society in blocking the Bill.

Mr. G. S. WOOLLEY maintained that the Bill was crude, inefficient, and unfair, and in his opinion it ought to be opposed *in toto*. He believed that was the ground the Pharmaceutical Society would take, and he believed the Pharmaceutical Council was actively engaged in organising opposition to the measure. He understood they purposed circularising every chemist in the kingdom, stating their objections to the Bill, with a view to inducing them to write to their members to oppose it. As the Chairman had pointed out, a very powerful objection was as regarded the sale of carbolic acid. That of course might be remedied by subsequent regulations, but he looked upon that as a detail. There were two principles outraged

in this Bill. In the first, the opening clause of their Act laid it down for the protection of the public that the only proper safeguard was the qualification of the vendor of poison. That principle was altogether outraged and done away with. Should this Act become law, he failed to see how the 1868 Act would be worth while carrying on. That it should be laid down as law that uneducated persons should be allowed to handle potent substances such as these, and that such a Bill should be introduced by the Chancellor of Victoria University was the most astonishing fact of all. That a noble lord, the head of a great educational Institution such as that, should advocate such a Bill, passed belief. There was another principle that was outraged here. They would remember that shortly after the passing of the 1868 Act they called upon the Pharmaceutical Society to issue regulations for the sale of poisons, and the wording of the Act certainly was that in class one regulations may from time to time be issued for the keeping of poisons, and the Pharmaceutical Council had issued such regulations in the form of recommendations as they would find in that or the previous week's Journal. He thought if anybody would look over the past thirty years to see how the chemists of this country had conducted their business, conducted it with such few accidents, it was ample proof that it was not just, nor proper, nor right that a body of men should have such regulations thrust upon them. The immunity from accidents was really wonderful; but they were an educated body; they had to pass an examination which was now a very stringent one, as shown by the large number of rejections of candidates at examinations. These gentlemen were turned out and registered as qualified to dispense and prepare poisons and to distribute them over the land; they had to do all these delicate operations, and yet they were not capable of storing their poisons on the proper shelves! Moreover than that, that clause would involve inspection. It was a most undignified position to place them in, and it was an outrage on the pharmacists of this country. That particular clause stung him more than even the first one, but it seemed to him that the first one would practically repeal the 1868 Act, and demolished the education qualification entirely by giving to oilmen and uneducated people of all descriptions the power of distributing these potent substances. It seemed to him opposed to all right-minded ideas of every description. He advocated the passing of a simple resolution on the subject, on which one could not help getting a little warm, as it affected them in a good many directions; it affected the principle of the Act, and also one's sentimental nature very considerably.

Mr. F. PILKINGTON SARGEANT agreed with Mr. Woolley and the Chairman that to every chemist on the Register this Bill was totally unfair and unjust. There did not seem any reason why such a Bill should be introduced; but whatever regulations were provided could not in any way that he could see affect the number of accidents that had happened, or, at least, the number of suicides that had taken place under the most potent Schedule poison. There might be some reason for including such things as the minor acids in such a Bill, because mineral acids, as they all knew, were very largely used by tinsmith workers and others; but carbolic acid, so far as he knew, was not used in any of the arts or manufactures to any great extent. It was largely used as a disinfectant; but as such was mostly bought in wholesale quantities, and, when bought, could be conveniently obtained from the chemist and druggist. It had been stated that, should carbolic acid be placed in the second part of the Schedule, it would raise the price very materially, but no one who knew the competition which existed between stores and chemists and druggists would think that for one moment. With regard to what Mr. Woolley had said concerning the 1868 Act it might be advisable if he read the beginning of Clause 1. It started in this way: "Whereas it is expedient for the safety of the public that persons keeping open shop for the retailing, etc., of poison, etc., should possess a competent practical knowledge of their business," and so on. If it were expedient at that time that retailers of poisons should possess a competent practical knowledge of their business, then more so would it be necessary now, because the bulk of the people were inclined to treat poisons as a light matter than they were at that time. There was no doubt that carbolic acid was as potent a poison as many others in Clause 2, and he did not see any reason why oxalic acid should be in Clause 2 and carbolic acid not, as it was the more dangerous of the two articles. He appealed to chemists, especially the younger members of the profession, to take greater interest in legislative matters, because no one would suffer so

much from what he might term obnoxious legislation as the chemist of the future, and if every young chemist after getting through his Minor would only join, if he had not already done so, the Pharmaceutical Society, and support it and take an interest in the work of the Society, it would be better for them in years to come. He hoped that the Bill would be opposed to such an extent that it would not be pressed forward, but they might welcome it from one standpoint. He thought it would bring chemists more together, and destroy the apathy to pharmaceutical politics, which seemed to be the curse of the chemist's trade.—THE CHAIRMAN having explained that the Pharmaceutical Council was sending out circulars to all chemists and druggists, and that it was the best for them to do it, Mr. WOODRUFF proceeded to say that the Privy Council sought by this Bill to annul the power which they had given them in the Act of 1868, and that it placed them in an undignified position, should be one of the chief grounds why they should oppose it. In reference to singling out carbolic acid, he thought it would be better to include all in one Schedule, and he did not think there would be any dislocation of trade by so doing. To speak as the Lord President of the Council did was a great injustice to them. He thought what had been striven for in those Acts had been the public safety, and that would be far from safeguarded by the passing of the proposed Act.—Mr. DUNCALF thought the Bill should be opposed *in toto*. It was an insult to the chemists and druggists of the United Kingdom.—Mr. C. SWINN agreed with the previous speakers that the Bill should be opposed tooth and nail, and that they should obtain its withdrawal. There was one important point that should not be lost sight of, and that was that they should get the co-operation of the coroners throughout the country. Of course, he was fully aware that the coroners of the country had been pretty well sat upon by the Privy Council when they had made reports from time to time, and they would be useful allies in opposing that Bill. He thought that not only the chemists, but the coroners should be circularised and sounded as to it. Their action in asking that the Bill should be withdrawn would be looked upon at headquarters as arising from personal motives, and would be discounted in all probability, whereas the opposition of the coroners would be looked upon as taken in the interests of the people at large.

Mr. KIRKBY said he could not help feeling—and he did not exactly say there was pleasure in the feeling—that they were possibly bound to suffer some inconvenience, notwithstanding what other speakers had said to the contrary, on account of the supineness of the Pharmaceutical Society previous to the years preceding the passing of the Act of 1868. Mr. Pidd had just reminded him that they had heard very little so far on the other side of the question. Government might have something to say, it seemed to him, with regard to the fact that all these substances had already been sold for years by men who have had no qualification whatever, and that all they were doing was simply in some way or other to put a little extra pressure in exercising more care in the distribution of them. Carbolic acid would appear to be one exception from all the other substances in that it could hardly be said to be used in the arts, but they must remember that the Government had no doubt in view the possibilities of actively diffused epidemics, which in country districts would make it inconvenient if carbolic acid could only be obtained from the chemist. This was a difficulty which could be met, and it had already been met in Australia, where it was the custom when a chemist did not reside within a certain area to grant licences to people who were not chemists to sell certain substances which might, under certain restrictions, be allowed to be sold here by persons, if a qualified chemist did not reside within a certain area. He did hope above everything that they as pharmacists while they had the opportunity would come together and make the most of it. It seemed to him that the Government was willing to do something in the way of further regulating the sale of poisons, and if they stood by the principle of the Act of 1868, they might get such an amendment of the Pharmacy Act as would be of some use to them. It had been asked how it came about that in these matters they were so much behind the sister isle. He did not think that was a very difficult question to answer. From what he knew of pharmacists, and from the experience he had had of pharmaceutical meetings, there was unfortunately a lack of that cohesion which was so marked a feature in other business associations. Above all things what they had to aim at was to concentrate their forces, and not go to individual members as though they were working on individual lines. They wished to impress on the public of this country that they were a

united body and that they intended to stand up for their rights as a body of educated men who had not betrayed the trust which had been reposed in them by the public and medical profession during the last quarter of a century. He was perfectly sure from the sentiments which were expressed in Parliament on the occasion of the third reading of the Pharmacy Bill, that members of Parliament were not disposed to sanction what Mr. John Burns, he thought, called "free trade in poisons." He did not think the public required free trade in poisons, but he thought the complaint was that there was not that uniformity among chemists in regard to poisons that there might be. This might be easily remedied if they rallied round the Pharmaceutical Society and give them to understand they were willing to abide by such regulations in reason as they thought fit to formulate. He hoped they would be prepared to go to that body and make such suggestions as would enable them to draw a better Bill. For himself he should be inclined to oppose *in toto* what had been suggested, and he would move the following:—

That this meeting pledges itself to aid the Pharmaceutical Society in every possible way to oppose or amend the Poisonous Substances Bill now before Parliament, and that copies of this resolution be sent to Members of Parliament together with a statement of the objections to the Bill.

—Mr. PIDD seconded the motion.—Mr. J. TAYLOR (Bolton) was glad the proposition had been moved. He was loth to move a resolution or to second one, for the simple reason that a fortnight ago he moved a resolution at Blackburn, and he did not want to create the impression in the minds of the trade or in the minds of anyone outside the trade that this was an agitation in which he had an interest greater than any other pharmaceutical chemist or chemist and druggist, but he supported the resolution very cordially. The two radical objections to that Bill were that it called into being practically a new set of poisons. The fact that it referred to them as poisonous substances did not alter that truth in the least degree. They would have a poison schedule composed of three parts instead of two, and the third part would contain a list of articles which might be dealt in by anyone who liked to handle them. Now Mr. Pidd pointed out that a possible objection to their action might be that Government was not interfering with any privileges that they possessed, and that it is not empowering these men for the first time to handle the articles named in the Poisonous Substances Bill. Therein lay the evil of it. It started the process of dissolution, which, in the public mind, would soon be carried to completion—the distinction between trained, qualified, and registered men and men who went into this thing merely as a matter of business would soon disappear, and the greatest injustice that Bill would do would be that Government which called them as a registered body of men into being started the process by which they would go out of existence. These two things only needed to be brought clearly before the minds of the Members of the Commons for them to get their points home. On the previous Friday he communicated with Mr. George Harwood, the Member for Bolton, giving him his reasons, that it was to himself and others a dangerous departure from the Pharmacy Act of 1868. He received from him this note:—

Dear Mr. Taylor,—I will watch the Bill you name. The grievance seems to be a real one in the public interests.
Yours faithfully,
GEORGE HARWOOD.

They only needed to let their case tell its own tale, and they would find they were well supported. He regretted that the promoters of the meeting had not seen fit to associate themselves with the Manchester Pharmaceutical Association, as that body should have been in its proper place as the head of the movement, but a second Daniel had come to judgment in the form of Mr. Sargeant, and while appealing to young chemists to promote the welfare of the trade, he (Mr. Taylor) would make another appeal, that the example of the promoters of that meeting be not followed.—THE CHAIRMAN called Mr. Taylor to order, and asked him to adhere to the point of the motion.—Mr. TAYLOR said he had travelled outside the motion, but he felt strongly on the point, and he thought it might not be amiss to lay it before them. He, however, disclaimed personal feeling, and urged that at a time like that there should be no appearance of dissension. He pointed out that in regard to inspection they had already this in such things as petroleum oil and benzine, and that the Pharmaceutical Society might go to the Privy Council and say that after thirty years' experience of the Pharmacy Act, which they had not, they might agree that the sale of these substances needed regulation, indeed, that they

needed restriction, and consequently they thought that was a case for negotiation, that they might each appoint representatives and see if between them they could not evolve a Bill which might meet the danger which the public was undoubtedly exposed to, which would do no injustice to a large and honourable body of tradesmen, and which would, above all, for that was the thing to which they must cling with all their might, perpetuate the principle underlying all previous Pharmacy Acts.—Mr. SARGEANT explained in reference to Mr. Taylor's remark that he did not ask any young chemists to join any local association or society, but suggested that after passing the Minor, their best plan was to join the Pharmaceutical Society.—Mr. WOOLLEY supported the motion, and said he would be prepared to listen to reasons which would make the Bill acceptable to the great body of chemists. At present he knew that the Pharmaceutical Council was inclined to oppose the Bill *in toto*. There was no knowing what the House of Lords would do, but he could not think the House of Commons would pass such a Bill.—The CHAIRMAN, in putting the motion, explained, in reference to the remarks of Mr. Taylor, that the first to whom notice of the intended meeting was sent were the officials of the Manchester Pharmaceutical Association. He was glad to find there was such unanimity in regard to the Bill.—The resolution was carried unanimously.—Mr. TAYLOR moved a vote of thanks to the Chairman, which was seconded by Mr. Woolley, and unanimously agreed to.—The CHAIRMAN returned thanks, and expressed his obligations to the Hon. Secretary and the members of the Manchester Pharmaceutical Association for the great assistance they had rendered in enabling the Defence Association to bring forward the resolution which had been passed.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.

At a special meeting held on July 9, 1898, the following resolution was passed:—

That this meeting of the Plymouth, Devonport, Stonehouse and District Chemists' Association, while of opinion that it is necessary to provide some regulations as to the sale of the articles named in the Government's Poisonous Substances Bill, regards that Bill as inadequate for the purpose and impracticable in the working thereof. This meeting is further of opinion that the Bill constitutes a dangerous departure from the principles of the Pharmacy (Poisons) Act of 1868, and earnestly solicits your kind assistance in opposing the passing of the same. The members of this Association consider that the safety of the public will be best secured by the addition of carbolic acid and other poisonous substances to Part 2 of the Schedule of the Pharmacy (Poisons) Act of 1868, according to the repeated recommendation of the Pharmaceutical Society and of coroners throughout the country.

It was also resolved that a copy of the resolution should be forwarded to Members of Parliament throughout the district.

PHARMACEUTICAL SOCIETY OF IRELAND.

On Wednesday, the 6th instant, the monthly meeting of the Council was held at 67, Lower Mount Street, Dublin, at three o'clock, the PRESIDENT, Mr. R. J. Downes, being in the chair, and the other members who attended being the Vice-President (Mr. Beggs), Mr. Grindley (Hon. Treasurer), and Messrs. Wells, Connor, Kelly, Dr. Walsh, Dr. Merrin, Professor Titchborne, Bernard, Simpson, and Conyngham.—The PRESIDENT said that when he saw that the British Pharmacy Acts Amendment Bill had passed the House of Commons he sent a congratulatory telegram to the President of the Pharmaceutical Society of Great Britain, from whom he had received thanks by telegram.—On the motion of the VICE-PRESIDENT, seconded by Mr. WELLS, thanks were voted to the Earl of Mayo and Mr. Lecky, M.P., for having presented in the Houses of Lords and Commons respectively, petitions from the Council, praying an amendment of the Companies Acts.—The REGISTRAR read a letter from the Attorney-General for Ireland stating that a letter addressed to him by the President on the same subject would receive full consideration. That letter of the President, which was dated June 22, directed attention to the difficult position in which the Society was placed in its endeavour to enforce the law. The pharmaceutical chemists of Ireland were qualified both to compound prescriptions and sell poisons; the registered druggists of Ireland were qualified only as sellers of poisons. It had been argued that the public were sufficiently protected if the "hand that sells" was qualified; but the difficulty was to identify the illegal seller on a company's premises. He need not be the manager; and if he were anywhere on the premises, he could be made a cover for the unqualified seller. Last month in Belfast an

unqualified apprentice in one of the establishments of the recently formed Ulster Chemists, Limited, sold cyanide of potassium to a purchaser, who went home, swallowed the cyanide, and died in a few minutes. At the inquest, which was held by two magistrates, the assistant was "cautioned" to be more careful in future. The company could not be made responsible, and the Inspector-General of Constabulary had intimated that the police would not prosecute in the case. What the Council sought was not to curtail the liberty of free trade, but to secure to the public the benefits conferred by the Acts of 1870, 1875, and 1890.—A letter from the Privy Council, Whitehall, acknowledged the receipt of a letter which the President had addressed to the Duke of Devonshire, Lord President of the Council, on the subject of the Bill relating to the sale of poisonous substances. That letter pointed out that there are in Ireland 424 registered druggists, over 300 chemists and druggists, and in addition 550 pharmaceutical chemists. The first two grades had to pass a qualifying examination, and to go through a four years' apprenticeship; and the letter submitted that the sale of poisons should be left with them, and that the proper legislation would be an extension of the second part of the Poisons Schedule, and a continuance of the restrictions imposed on behalf of the public by the Acts of 1870, 1875, and 1890.—The PRESIDENT said this Bill, which had passed through the Lords since the time he wrote to the Lord President of the Council, was really in a public sense a retrograde and unreasonable measure. It allowed what were described as "poisonous substances" to be sold by everybody. On the face of it, it implied that those substances had been sold without label or caution, either because of ignorance or through a deficient sense of morality on the part of the seller, because the only thing the Bill did was to say that they were to be labelled "Poison." The Privy Council was not willing to treat them as poisons, but the public was expected to treat them as poisons. Up to 1870 every sort of poison could be sold in Ireland without registration or anything of the sort; but it should be borne in mind that the chemists and druggists who in 1870 did the poison trade of the country were men who had been trained to sell poisons and who had served five or six years' apprenticeship, because they were then at the tail of the old guild system, which required apprenticeship. At that time there was no idea of crossing trades. The grocer did not try to be a druggist nor the druggist a grocer. Yet though that was the condition of the trade at the time, the Government of the day were so alarmed that in 1868 they passed the British Pharmacy Act, which recognised the licentiates of the Pharmaceutical Society as qualified sellers of poisons. They thought it necessary to place the sale of poisons in their hands. At that time they had no such body in Ireland—they had only the Apothecaries. In 1870 the Irish Poisons Act was passed, which required that poisons should be sold in a particular way. The sale of poisons at that time was exclusively in the hands of men who had been brought up to the business and had served their time to it. This went on until 1875 when this Society was constituted; and from that time the public had the additional advantage of the sale of poisons being placed in the hands of licentiates of the Society. Owing to circumstances there remained in the country a large number of unqualified men who continued selling poisons, and they were recognised as such down to 1890. But they had not been recognised since without having passed an examination. Now, however, the Government actually wanted to revert to the state of affairs that existed prior to 1870—to go back twenty-nine years upon what experience had shown to be a good system. The Government was refusing in this Bill to recognise "poisonous substances" as poisons, whilst requiring the seller to label them as "poisons," thus actually admitting that they were such, and ought to be dealt with as such. If the Bill should pass, the "poisonous substances," such as sugar of lead, etc., would be obtainable throughout the country and in the cities at hucksters' and grocers' shops and at stores; whereas, if they wanted to get corrosive sublimate, they would have to go to another shop. The public would not understand what reason there was for making a distinction between "poisonous substances" and the poisons mentioned in the second part of the Schedule. In his mind the very fact of a person having to go, as at present, to a druggist's shop for these things was in the nature of a safeguard. He therefore thought that the Council should oppose the intended retrograde proceeding. The question was, How were they to reach their object?—Mr. CONYNGHAM: Ask them not to extend the Bill to Ireland.—Mr. BERNARD: Have not

the public every facility at present for obtaining poisons in Ireland?—The PRESIDENT: Will you draft a circular asking your licentiates and the druggists to approach their representatives on the subject.—Mr. WELLS said if the Bill should be passed as it stood now it would be a very serious matter.—Mr. KELLY said they should make a determined stand against this Bill. It was a positive injustice to the pharmaceutical chemists and druggists of Ireland. The pharmaceutical chemists had fifty votes in that division of Dublin, and they could twist the election any way they liked.—Mr. CONYNGHAM: The thing would be to try and prevent this Bill from being applied to Ireland. We do not want it here.—Mr. WELLS said the idea of the Government in promoting this Bill was simply to reward some of their followers. The idea of it had been started by a Member of Parliament who had been prosecuted for selling poisons. He was a large seedsman, and wanted facilities for selling these things in Scotland. It had not been shown that there was any want of poison sellers in England any more than in Ireland. If this Bill should pass they would have people in the country thinking that they had a right to sell scheduled poisons. It would touch the Society's licentiates seriously in the matter of compounding, for even where an eye lotion made upon a medical prescription contained a few grains of sugar of lead it would have to be labelled "Poison," not only on the bottle but on the wrapper, and as the Society were law makers they could not be law breakers. They should, therefore, make a strong stand against the Bill, and ask their licentiates and the registered druggists to speak to their local Members of Parliament about it. Their licentiates had a great deal of power in the local representation. They had two Members in Dublin, and it was the vote of the pharmaceutical chemist that put Mr. Campbell in for that division of the city. They knew that he would do what he could for them, and Mr. Field had also promised to support them. It had been argued in support of the Bill that, notwithstanding the past legislation, a large number of accidental poisonings had taken place in England; but they left out of view in how many hundred cases accidents had been prevented by poisons being properly labelled.—The PRESIDENT: The Privy Council is claiming the right to make regulations about the storage of poisons here. My impression is that the Council should not make regulations for us without our approval of them.—Mr. WELLS: If this Bill is passed as it is there will be no public prosecution. If the measure is left in the hands of the police it will be a dead letter.—Mr. CONYNGHAM suggested that a committee should be instructed to consider the Bill. There were many points in it that the Council would not be able to get altered. Finally, on the motion of the VICE-PRESIDENT, seconded by Mr. WELLS, the following resolution was passed:—

That a circular be sent to all the Irish Members of Parliament drawing their attention to the Sale of Poisonous Substances Bill, and asking them to try to prevent the Bill being passed; also to our licentiates and registered druggists, asking them to write or speak to their local "M.P.'s," and that the Law Committee take the necessary steps.

A letter was received from the Honorary General Secretaries of the approaching British Pharmaceutical Conference to be held in Belfast, asking the Council to name delegates. The President, Vice-President, and Messrs. Kelly, Connor, Dr. Walsh, Conyngnam, and Professor Tichborne were nominated.—On the reading of a letter from the Inspector General, R.I.C., stating that the police would not prosecute the case of an illegal sale of cyanide of potassium in the establishment of the "Ulster Chemists, Limited," the PRESIDENT mentioned that the man who bought it had been drinking, and when he went home his wife clided him for being drunk. He said he had a thing for that and ate the cyanide.—Mr. WELLS: When we waited on the Inspector-General, he said the police would carry out the Poisons Act, and he sent out a circular to that effect. Now you are told that they are not to carry it out.—Mr. BERNARD: Is not the alleged offence that the buyer was unknown to the seller, and did not sign a poisons book?—The PRESIDENT: It was labelled, but a book was not signed. The President added that he had requested Mr. Field, M.P., to ask a question in the House of Commons on the subject.—An election of an Examiner in Chemistry was postponed.—Other business having been disposed of, the Council adjourned.

OBITUARY.

WOODYATT.—On July 2, Richard Woodyatt, Chemist and Druggist, Macclesfield. Aged 68.

LETTERS TO THE EDITOR.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London, W.C., and not in any case to individuals supposed to be connected with the Editorial Staff; no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

LIQUOR STRYCHNINÆ HYDROCHLORIDI.

Sir,—Mr. Lunan strains at a gnat. The B.P., 1885, did not say the above "solution contained one grain of alkaloid in nearly 108 m." It states "the strength is about 1 in 100"—near enough.
London, W., July 9, 1898.

W. MARTINDALE.

THE POISONOUS SUBSTANCES BILL.

Sir,—It is well that the appeal to Cæsar has, at length, been reached in our controversy with the permanent officials of the Medical Department of the Privy Council. And it is also well that our own mobilisation has been effected with a promptitude that may be adequate, in spite of the perfunctory way that so thorny a question as the Poisonous Substances Bill was hurried through the House of Lords. We must not expect the official documents issued by the Council of the Pharmaceutical Society to state our case against the Privy Council officials with the blunt directness which it deserves. But we shall be much more intelligible to our parliamentary representatives, before whom we now go as a court of appeal, if making a plain historical statement on the subject. My association with the matter from a very early stage may justify me in attempting this. Our quarrel with the permanent officials of the Medical Department of the Privy Council dates from 1868, when the Pharmacy Act was passed. Soon afterwards, Sir John Simon asserted that a pledge had been given by the representatives of the Pharmaceutical Society to propose penal regulations for "keeping," etc., poisons, and in 1871 he induced the Vice-President of the Privy Council, the Rt. Hon. W. E. Forster, to bring a Bill before Parliament prescribing the methods of doing this. The scheme was found to be so crude and unworkable that it created dangers greater than those it was intended to remedy. Its inconsistency could not have been worse had it directed that the "up" line of a railway should be guarded by danger signals, and that none should be needed on the "down" line, even when worked by the same staff. The prescribed penalty for an infraction of the regulations by the chemist or by any servant was the removal of the former from the Register. But the whole trade rose in opposition to the Bill, which was withdrawn. In 1871 we alleged that the claim of a bargain was bad, that nothing was known of it by the Council of the Pharmaceutical Society, whose minutes have no such record, and that if the then President (now deceased) had been a party to any agreement it had been secret and unlawful, and was therefore *ultra vires*. The Act itself expressed no compulsion on the subject, but its terms were couched in the permissive sense. Our case must still maintain these justifications of opposition to the new Bill, linked with the very forcible contention of our Council, that the chemists and druggists of to-day are men who have been for the last thirty years drafted into their calling after giving by examinations guarantees of their fitness for its duties. Finally, the constitutional question will not escape the numerous members of our body holding prominent positions in the controlling of municipal institutions as mayors, justices of the peace, members of city and other councils, who are accustomed to negotiate delicate questions involving the civil rights and property of those whom they represent. They will regard it as a scandal that the permanent officials of a Government Department should claim that in assenting to a Bill in 1868 they had loaded it with secret conditions outside its clauses. The thirty years' interval has, on our side, served to convert our ranks almost completely into examined men, but our accusers have for so long a period nursed their wrath, and bring out the same old bogey again. His Grace the Duke of Devonshire has good cause of complaint that he should be so badly informed by those who technically guide him in this matter. That the Medical Department of the Privy Council should have introduced the Bill behind the back of the Pharmaceutical Society was bad enough, but the proposal to make penal regulations for the

"keeping, selling, and dispensing of poisons," whilst excluding every person in the kingdom qualified by experience to offer an opinion on the subject, is carrying despotism too far. The unqualified withdrawal of the Bill will alone be satisfactory.

Leeds, July 11, 1898.

RICHARD REYNOLDS.

CAMPHOR PILLS.

Sir,—One often hears the statement that castor oil is a good excipient for camphor pills, but my experience as a student with it is that it is not satisfactory, and certainly should not be recommended. I have made some camphor pills, each containing 3 grains, with castor oil as the excipient, and find that when they are left exposed to the air on a piece of paper almost all the oil evaporates and leaves the camphor on the paper in the form of an irregular contracted mass, consisting almost entirely of camphor. As far as my experience goes of the subject, glycerin of tragacanth, which has been suggested to me, is not as good as the plan that has been adopted by many experts, which is to make them up with soap, preferably curd soap. Of course it should be understood that this excipient cannot be used where such substances as ferrous sulphate, calomel, and similar compounds are present. When these are used in pills a good general excipient is, I am inclined to think, a "desideratum."

Birmingham, July 12, 1898.

LILIAN MAY HANDS.

BLAUD'S PILL.

Sir,—The pill which passes under this name is remarkable in several ways—most of all for the extent of its consumption. Any effort to gauge it by summing up the available facts conjures up before the mind's eye an endless succession of pills trundling down the public throat, like the blood corpuscles chasing each other through the veins of a frog's foot, seen under the microscope. This extraordinary popularity contrasts strongly with the scantiness of the pharmaceutical literature concerning it. Few newcomers have attained official recognition; fewer still have driven out from before them old and well-established formulæ about which so little pharmaceutical ink has been shed as over Blaud's pill. Like its predecessor, it is of Gallic origin; and Vallet is swept away by Blaud as the successive waves of barbarian invasion lapped over the decaying Roman empire. The reason of this is not easy to find. The strength of the pill now official is about 1 grain of ferrous carbonate in 5 of mass, and the patient is instructed to swallow one to three 5-grain pills three times a day. This is done by people who at other times look upon a single 5-grain compound rhubarb pill as a monstrous bolus, which they flatly refuse to attempt. The pilula ferri carbonatis, which is now expunged from the British Pharmacopœia contained 4 parts in 5 of ferri carbonas saccharata—concerning which it is stated that ferrous carbonate, or what is reckoned as such, forms one-third of the mixture. My note book, under date 1869, gives particulars of volumetric testing, showing the presence of nearly 38 per cent. But taking the lower figure, 4 grains of this preparation will contain one-third more ferrous carbonate than a 5-grain Blaud's pill, and with the substitution of tragacanth and water for the confection would make a smaller pill. Obviously, 3 grains would equal the Blaud's in strength, and be still smaller. Can it be that the presumed advance in therapeutical efficiency is due solely to more liberal dosage; and that Blaud's iron pills do more good than our old accustomed "steel" pills, for the same reason that white sheep eat more than black ones?

Dover, July 12, 1898.

J. F. BROWN.

ANALYSTS' CERTIFICATES.

Sir,—You recently reported a prosecution in regard to lime water, said to be deficient in lime, in which I was defendant. Briefly the facts are as follow:—At the first hearing of the case I took a technical objection to the validity of the analyst's certificate, but without giving a ruling on this objection the magistrate proceeded to hear the case upon its merits. He found that, whilst it was admitted that no fraud had taken place a technical offence had been committed, and he inflicted a nominal fine. So far as the justice of this case is concerned I have no fault to find with the decision. Whilst the lime water in question did not show the deficiency stated by the prosecution, there is no doubt that at the time it was sold it was below strength. Chemists who carry on business in districts where this article is sold in small quantities in customer's own vessels will know the difficulty of keeping lime water at full strength. I considered that the tech-

nical point raised by me was of sufficient importance to justify an appeal to the Courts for a mandamus. In prosecutions under the Foods and Drugs Act the analyst's certificate is of vital importance for several reasons. First, it is upon the information contained in the certificate that the local authorities decide whether to prosecute or not. If in the case of such articles as lime water and spirits of nitre, when the analysis shows a small deficiency and the analyst makes a report upon the certificate that some decomposition had taken place, the local authorities would not be likely to take action, and the chemist would be saved from unpleasant police court proceedings. Secondly, when the case is heard, the analyst's certificate is constituted by the Act complete evidence for the prosecution as to the state in which the analyst found the article. This provision was made in order to avoid the trouble and expense of bringing the analyst into court. By Section 18 of the Act, the analyst's certificate must take a certain form, and in that form the analyst receives an instruction in the following exact terms:—

In the case of a certificate regarding milk, butter, or any article liable to decomposition, the analyst shall specially report whether any change had taken place in the constitution of the article that would interfere with the analysis.

The reason for this provision seems clear. In the case of an article which is liable to decomposition, the prosecution, in fairness to the defendant, are directed to state whether or not any change had taken place in the article, and it was not intended that the onus of proving a change should be thrown upon the defendant; the certificate has to give this information. As I read the Act, it is the duty of the analyst in the case of any article liable to decomposition to state the fact clearly on the certificate, and to show whether there was evidence of decomposition or not. Even supposing that the analyst reported that though the article was liable to decomposition, no change had taken place since its purchase, the mere statement of the fact that the article was liable to change would be of assistance to the defendant in pleading in mitigation that the deficiency was due to decomposition or change; in other words that he was not guilty of a deliberate act of adulteration, but that the article had deteriorated. In the absence of any report on the analyst's certificate such a defence would be seriously prejudiced, as the magistrate would probably discount the defendant's evidence, on the ground, that if what he stated was true, the analyst would have stated so on his certificate. Thirdly, it is a matter of common knowledge that inspectors purchasing such perishable articles as spirits of nitre, etc., do not take the care they ought in seeing that the article is properly dealt with and carefully preserved until the time of analysis. If in future cases the analyst has to report upon this particular point it is only reasonable to suppose that the authorities will insist upon proper precautions being taken in dealing with perishable articles. The magistrate, in dealing with the technical objection raised, seemed to be guided by the statement made by the analyst, namely, that lime water, though it was liable to decomposition, was not liable to such decomposition as butter, and that whilst in the case of butter the decomposition would interfere with the analysis, in the case of lime water it would not. I personally fail to see the reasonableness of such a distinction. The decomposition which takes place in lime water produces an entirely different article and would, as I understand the term, most certainly interfere with the analysis. It was, however upon this magistrate's finding that the Courts decided not to grant a mandamus. My reason for calling attention to this case is that I think, for the reasons stated, the point raised is one of importance to the trade. I cannot think that it was intended to protect the trader who sells butter from being prosecuted, and perhaps convicted, in regard to a sample which had decomposed, without giving to the chemist who sold spirits of nitre or lime water similar protection. In connection with my own case, I have personally done all that was possible to get a High Court decision on this matter, and the refusal of the Courts to order the magistrate to state a case settles the question so far as my case is concerned, though it in no way disposes of the question raised. I think that in the next prosecution of a chemist in reference to either of these articles the point should again be raised and properly contested from the outset. There ought to be no difficulty in raising a small fund for the purpose, and if a sufficient number of your readers think it worth while, and will communicate with me, I shall be pleased to do what lies in my power in the direction of organising a committee for the purpose of contesting a case on the lines indicated.

Purfleet, July 13, 1898.

W. S. GLYN-JONES.

PARLIAMENTARY NOTES.

A GOVERNMENT DEFEAT is to be chronicled this week, and chemists of all shades of political complexion may unfeignedly rejoice thereat. With a display of discretion little short of remarkable, the strongest of modern Administrations has decided to abandon the Poisonous Substances Bill, owing, as a veracious reporter states, to the widespread objection of chemists and druggists throughout the country. Both in the fact and in the exciting cause chemists have reason for satisfaction. Mr. Balfour, in announcing the decision of the Government in respect of the Poisons Bill—an announcement we may add, which was received with cheers in a full house—included it in the category of those Bills which ultimately “it will be found impossible to place on the Statute Book.” These be weighty words from the leader of the House, and they convey a not unmerited snub to the Privy Council and the Lord President.

WHO KILLED THE BILL?—There can be no doubt that one of the chief factors in this justifiable slaying was the remarkable promptitude with which registered men responded to the appeal of the Pharmaceutical Society. The Council representatives can do, and did do, a deal of useful work in the lobbies, but their efforts would have fallen considerably short of success but for the practical backing accorded to them by those for whom they were working. Dangers, like adversities, have their sweet uses. One of the lessons which chemists of Great Britain may learn from the happily averted evil that so recently threatened them is that it is a good thing to have a “buffer-state” like the Society to stand between pharmacy and its enemies. And perhaps the outcome of the death of the second Government Poisons Bill may be the strengthening of the “buffer-state.”

WE MAY NOTE that Mr. Heywood Johnstone (Horsham) was the only Member of the House who publicly called the attention of the First Lord of the Treasury to the attitude of chemists in relation to the Poisons Bill. The letters of his pharmaceutical constituents must have entered his soul.

THE FOOD AND DRUGS FARCE is to be replayed at Westminster this year, for a few nights only; but with the same cast as before. Mr. Balfour has officially said that the Government measure is not to be proceeded with, but it will nevertheless appear on the notice paper, solemnly introduced by Mr. Chaplin; and members will greet its birth with derisive cheers, precisely as in 1897. Why Mr. Chaplin consents to be annually associated with this silly performance is somewhat incomprehensible, but why those who suffer under the present law relating to food and drugs patiently bear the continual exhibition of official indifference is more incomprehensible still.

THE BILLS to be proceeded with include the measures relating to Vaccination and to the London University Commission. Both will need a good deal of engineering to get through, but the latter is in a fairly good position, having only the Committee stage to pass and its third reading. The opposition, which includes Sir J. Gorst, is counting on the irregularity in procedure alleged to exist according to Mr. Healy, and will do its best, or worst (according to which view one takes of the scheme) in Committee, but there is an overwhelming majority in favour of the reconstruction of the University, and there is reasonable hope that before the House rises early in August the first step in the formation of London's Teaching University will be accomplished. After all “*c'est le premier pas qui coute.*”

COMPANIES AND THEIR SINS furnished Mr. Field (Dublin St. Patrick's), with material for a question on Tuesday. Obviously inspired by those most hit by the promotion of corporate entities, he asked the President of the Board of Trade whether any inquiry would be made respecting the promotion of companies, and whether the Public Prosecutor had any duties in this matter. “No,” replied Mr. Ritchie, “no inquiry is contemplated, and as company promoting is not an offence there have been no prosecutions.” The right honourable gentleman exactly hit it. Company promoting is not an offence, but it certainly should be made an offence to promote a corporation for the express purpose of evading a law which applies to individuals. Mr. Field's energies should be directed next session

to rescuing the Companies Bill from its *cul-de-sac* in the House of Lords.

THE PRIVY COUNCIL must beware, for Mr. Caldwell has sworn to effect economies in its administration. The Hon. Member will commence modestly, and has notified his intention of moving the reduction of the Privy Council Office Vote by £1700, being the amount of Sir C. L. Peel's salary. Mr. Caldwell thinks it a sinful waste to have a clerk and an assistant-clerk to administer a department which has less and less to do as years go on, and local Government Acts increase in number as well as in scope. Mr. T. Bayley (Chesterfield) is also anxious to pick holes in the Council Office Vote.

PATENT MEDICINE STAMPS.—Mr. Mildmay (Tiverton) thinks some improvement might be made in these profitable items of public revenue if they were perforated and gummed instead of being issued in their present inartistic form. He asked the representative of the Postmaster-General on Monday to consider the advisability of issuing the three-halfpenny stamp in the perforated and gummed variety. The Postmaster-General, however, has no disposition to undertake any such consideration. Mr. Henniker Heaton gives him quite sufficient to think about in the way of reforms. Moreover, the Post Office is not the Department charged with the administration of the Stamp Duties Acts, and knows little and cares less about the stamps issued to nostrum vendors. Somerset House will doubtless take a lot of moving before it sanctions a change such as Mr. Mildmay is led to think is desirable. It is one of those reforms for which the world may well wait a little.

LEGAL INTELLIGENCE.

PROCEEDINGS UNDER THE PHARMACY ACTS.

PHARMACEUTICAL SOCIETY v. J. G. DESBOROUGH.

At the Manchester County Court on Monday, July 11, before his Honour, Judge Parry, the above case came on for hearing in the absence of the defendant. Mr. T. R. Grey instructed by Messrs. Flux, Thompson and Flux, appeared for the plaintiff Society, who, in the particulars of claim, stated that on the 18th day of April the defendant had sold a poison, to wit, morphine, forming part of the ingredients in a compound called “Kay's Compound Essence of Linseed,” contrary to the provisions of the Pharmacy Act, 1868, 31 and 32 Vic., c. 121, and they claimed the penalty of £5.

Mr. Grey said as the defendant did not appear, he should merely have to formally prove his case. The sale took place on April 18, at a shop, 35, Renshaw Street, Greenheys, Manchester, and at the time the bottle was purchased a notice was wrapped up with it to the following effect:—“Important notice.—Having purchased the business lately carried on by Messrs. Wall and Co., I hope by strict personal attention to business to receive a continuation of your patronage and support. Note the address, Desborough, Pigott Street Drug Stores, corner of Renshaw Street.” The name J. G. Desborough also appeared on the bottle, which was bought at the same time.

His Honour: If you will prove the stuff was purchased, it will be sufficient.

Mr. Grey then called Arthur Foulds, who deposed that on April 18 he went to 35, Renshaw Street and bought the bottle of Kay's essence of linseed produced. He put on a ticket to identify it and handed it to Mr. Moon for analysis.

Mr. Moon, clerk to the Registrar of the Pharmaceutical Society, deposed to receiving the packages alluded to by the last witness, and Mr. Ernest John Eastes, F.I.C., 61, Chancery Lane, London, stated he received from Mr. Moon a bottle of Kay's essence of linseed, which he analysed carefully, and found it contained both morphine and chloroform. There was nearly one sixth of a grain of morphine.

His Honour: There must be judgment for the plaintiff Society for £5 and costs.

PHARMACEUTICAL SOCIETY v. WINN.

In this case there had been three summonses for infringement of the Pharmacy Act, and it was stated by the Registrar of the Court (Mr. A. H. Atkinson) that the defendant, whose name is James Edwin Winn, of 35, Higher Ardwick, Manchester, had

signed an admission and offered to pay the penalties by instalments.

Mr. Flux, informed His Honour that in one case where such an arrangement had been made recently the defendant made an assignment, and the Society was not likely to get anything. It was simply a way of trying to get out of the arrangements.

His Honour: What do you suggest? Is he a chemist?

Mr. Flux: No, he is not, I do not know precisely what he is. It is carried on as a drug stores.

On the application of Mr. Flux, His Honour made an order for £15 with costs.

PHARMACY IN AUSTRALASIA.

[From our Melbourne Correspondent.]

THE TRIAL OF JAMES W. CHRISTOPHER, the chemist who was alleged to have caused the death of Dr. S. I. Williams by supplying him with atropine in mistake for morphia, has been concluded in the Melbourne Criminal Court, and resulted in a verdict of not guilty. Dr. Brett, who made the *post-mortem* examination, stated that death was due to asphyxia, but could not say what caused the asphyxia, and it was contended for the defence that the Crown had not proved that the deceased's death was due to atropine poisoning, or that the deceased had injected the atropine into his body. Mr. Justice Hood summed up the case to the jury very favourably. "Deceased," he said, "for some years had been the victim of a craving for morphia or cocaine, and the case for the Crown was that he injected atropine, which he had received from the accused, in mistake for morphia, and that that was the cause of his death. Was that the right conclusion, or did they think that he died from an overdose of cocaine? The symptoms prior to death helped them very little, for they were as consistent with cocaine as with atropine poisoning. It was for the jury to say which was the right conclusion. It was not proper for them to say that because the medical witnesses were unable to speak positively they (the jury) should not be asked to determine the cause of death. The doctors came there to give a skilled opinion, but if they were asked to give their opinion as men of the world, and not as skilled witnesses, it would be quite a different matter. Even if the jury found that the death was caused by atropine, the accused would not be guilty unless they were of opinion that he was grossly and culpably careless. It was always difficult to decide what degree of carelessness amounted to a crime, but a mere mistake on the part of accused would not justify them in making a criminal of him. The most careful, the most skilful man in the world might make a mistake, and it was not fair to judge a mistake by simply looking at the evil that had followed it and saying, 'Oh! I would not have done that.' What they had to do was too look at the facts as they took place. They should put themselves in accused's place and ask themselves, 'Did he act rashly, did he act recklessly and with gross carelessness?' Was the mistake made by his failing to give that attention to business which a man in his position ought to give. When Dr. Williams called at the shop he was in a great hurry; in such a hurry that he would not give the young man time to change the labels he had wrongly placed on two bottles. The accused saw his mistake in regard to the labels, but the deceased would not give him time to rectify it. The accused was skilled in his business; he was assistant to his father, and he was dealing with poisons, a business requiring special care. On the other hand, he was hustled and hurried by the unfortunate deceased. Those were the facts, and it was for the jury to say whether the mistake was due to the gross carelessness of the young man. The accused from first to last had admitted everything, and his own statement to the detectives completed the evidence against him. If they were not satisfied, first that the doctor died from a dose of atropine, and secondly that accused was to blame for his death, because of great carelessness, it was their duty to return a verdict of not guilty." The verdict, I may add, seems to meet with very general public approval.

IN NEW SOUTH WALES an effort is being made to arrange with the University of Sydney to conduct the necessary pharmaceutical classes, there being apparently little prospect of the Society being in a position to establish a college of its own. Some slight difference of opinion seems to exist in the Council as to applications for membership from a number of persons who have been admitted as pharmacists under the Section D of Pharmacy Act, 1897. It is held by some that the admission of a number of

virtually unqualified men would not add to the dignity and prestige of the Society. On the other hand it is contended that refusing admission would result in the creation of two parties among pharmacists, and that such disunion would be fatal to the interests of all. The subject is still under consideration. The following office-bearers have been appointed for the current year: President, Mr. L. P. Williams; Vice-President, Mr. Jones; Hon. Treasurer, Mr. J. R. Willows.

PHARMACY IN IRELAND.

[From our Belfast Correspondent.]

PROFESSOR WHITLA, Q.C.B., has published a new edition of his *Materia Medica*. It contains all the later additions and modifications of the new B. P.

BELFAST QUEEN'S COLLEGE SPORTS came off on Saturday, June 11, at Ormeau. This is the twenty-seventh annual meeting. Among the many and distinguished patrons are the Lord Lieutenant and the Marquis of Dufferin and Ava. Students from the various colleges of Ireland figured in the events. A tug-of-war took place between the surgery class, pharmacy class, and football teams, Q. C. B. First honours lay with the last, the pharmacy team coming second. The prizes were distributed by Mrs. Redfern, wife of Professor Redfern.

THE BELFAST RIOTS last month arising out of the absurd '98 celebration, offered the opportunity to a number of pharmacists and doctors to act the good Samaritan. One constable, whose leg was broken by a large "paver," was dressed by them; splints and bandages were improvised from broken boxes and torn blankets. There were 103 reported wounded amongst the police, though it is said some were in hospital without a scratch on them. So, what with scalp wounds and cracked and "barked" shins, Mr. Thompson's Medical Hall was the scene of a brisk business for a couple of hours.

THE MEMBERS OF THE INCORPORATED GAS INSTITUTE held their annual meeting in the Exhibition Hall, Belfast. Lord Mayor Henderson gave a few interesting facts in connection with the enormous plant of the Corporation Gasworks. There were six gasholders capable of holding six and a quarter millions of cubic feet, the largest (106 feet high) held 2,600,000 cubic feet of gas, and required 1500 tons of iron to construct it. The consumption per year had almost quadrupled since 1874, being at present fifteen hundred millions of cubic feet. Mr. Stelfox, in order to combat the great demand, started the making of carburetted water gas, not only a sufficient supply being provided, but the consumption of coals being reduced by 50,000 (fifty thousand) tons per year. The apparatus used was the Lowe double superheater, so favoured in U.S.A. The President (Mr. Jas. Stelfox) delivered his inaugural address, in which he referred to the comparative merits of gas and electric illumination, his conclusion being that electric lighting has still a long period of probation before it. He considered the regenerative burners of Frederick Siemens the best of their kind (especially serviceable in shop-lighting) until the invention of the incandescent mantle of Welsbach). The possibilities of the thorium-cerium mantle were not fully realised at first, but the genius of Welsbach has brought about a revolution *in re* incandescence. Professor Lewes, F.I.C., F.C.S., Royal Naval College, Greenwich, gave an experimental lecture on the latest developments of "Acetylene."

THE FOLLOWING, which I have word for word from witnesses, and which I can vouch for as true in every particular, is no doubt one among hundreds of similar cases:—A young girl about twenty, who worked in a Belfast factory, was dying in consumption. The overseer saw in the *Christian Advocate* an advertisement of a person who professed to cure consumption, and spoke to the girl's fellow-workers about it. They agreed to make a collection each Saturday till she was cured. The first bottle (the length of one's middle finger and the circumference of a halfpenny) cost half a sovereign; the second bottle the same. The overseer then wrote that the medicine had been all used, but that no improvement had set in, and asked for instructions. The reply was, "Send forward one guinea for the next bottle, as it contains," etc. The third bottle was to give the disease its quietus. The overseer was wiser, and the girls collected

their pence to procure a few useful necessaries for the consumptive. The girl died shortly after. Now the sheet anchor of this conscienceless Mr. — (though it is with grievous feelings I announce his decease)—his sheet anchor is the religious weekly. If he raked in the shekels from wealthy people it would not matter so much. But that the hard-earned wages of the poorer classes should be filched away and used to pay for fraudulent drugs, and part of the profits handed over to Christian papers, and part employed in building churches—this is an iniquitous conspiracy. The latest quack is Mr. H—— (a full page in both London religious weeklies). One of his testimonials declares that “Mr. C——’s and Mr. A——’s medicines did not do me the good your treatment has done.” When thieves fall out honest men get their due.

A LOCAL JOURNAL, in referring to the Duke of Devonshire’s Poisons Bill, states that carbolic acid is a “very useful disinfectant, and as it bears a resemblance to ordinary water, is very often taken in mistake for this harmless liquid.” This is misleading. The acid used for disinfection, known as crude carbolic, is not like “ordinary water,” but like ordinary porter, and this likeness is, in many instances, strengthened by persons bringing porter bottles to put the crude carbolic into, and this possesses all the requisites necessary to poison a man who has no objection to a glass of stout. The clear carbolic acid (“resembling water”) is only sold by chemists and in small quantities, and whilst the deaths from the crude variety are of frequent occurrence, no fatalities have been attributed to the use of the other; a self-evident proof for including carbolic acid amongst the scheduled poisons.

A WITTY DOCTOR remarked once, “People don’t need wisdom teeth now-a-days; they know everything.” This is like enough; every disease is now explained in rubbishy tracts; its cause and cure. A gentleman the other day asked a chemist for “a cure for te-taneus,” and the high falutin’ hieroglyphic for belladonna plaster is in Hibernian parlance “Ballymena plaster” (pron. vulgarly, Bela-main-a).

POISONOUS SUBSTANCES BILL.

DEWSBURY AND DISTRICT CHEMISTS’ ASSOCIATION.—A special meeting of this Association was held in the Town Hall, Dewsbury, on Monday, July 11, Vice-President Mr. G. Walker in the chair, and he was supported by members from Heckmondwike, Cleckheaton, Morfield, Batley, Ravensthorpe, Ossett, Thornhill, and Dewsbury. A very animated discussion took place on the Poisonous Substances Bill, and the following resolution was passed and copies of it to be sent to the various Members of Parliament in the district:—

That this meeting of the Dewsbury and District Chemists’ Association is of opinion that the Poisonous Substances Bill now before Parliament will be a dangerous and unwarranted interference with the operation of the Pharmacy Act, 1868, being retrograde in principle, ambiguous in detail, and not calculated to achieve its main purpose, namely, the safety of the public, which can be effectively secured by placing all poisonous substances which are considered dangerous to the community under the provisions of the Pharmacy Act of 1868.

It was also resolved that a deputation consisting of the President, Mr. A. Foster; Vice-President, Mr. G. Walker; and the Secretary, Mr. R. Gledhill, should wait upon the Borough Member. It was also decided to hold another special meeting as soon as the Bill came before the House of Commons.

THE NORTH-EAST LANCASHIRE CHEMISTS’ ASSOCIATION sent a deputation consisting of Messrs. W. Wells, Garland, Eatough, R. Lord Gifford, and Howarth, to wait on the senior member for Blackburn on Wednesday, in reference to the Poisons Bill. After the matter had been laid before him, Mr. Hornby promised to give it his careful attention, and expressed astonishment that the present condition of affairs had been allowed to continue so long, remarking that the fact reflected upon the members of the trade, who must have been apathetic in regard to their own interests.

THE CHEMISTS OF GREENOCK have sent to Sir Thomas Sutherland, the Member for the burgh, a letter showing the reasons why the Poisonous Substances Bill should not be passed into law. The letter was accompanied by the sheet of reasons against the Bill, drawn up by the Council of the Pharmaceutical Society.

THE EXETER CHEMISTS, at a meeting held this week, passed a resolution condemning the Poisonous Substances Bill.

PHOTOGRAPHIC NOTES.

DARK ROOM WINDOWS.—According to Stolze, chrome-orange coloured glass can be prepared as follows:—A solution is made by dissolving 10 grammes of gelatin in 150 C.c. of water, and adding 3 grammes of sugar to prevent crystallising out when drying; 50 C.c. of a saturated potassium dichromate solution are added. The glass is coated with this solution, and when completely dry, dipped into a 10 per cent. solution of lead nitrate. After the reaction is complete, the yellow layer is well washed. If not satisfactory the process may be repeated. A good red glass is obtained as follows: dissolve 10 grammes of mercuric chloride in 135 C.c. of boiling water. The solution is allowed to cool to 20° C., and a sheet of glass covered with gelatin is immersed in it for ten minutes. After drying, the sheet of glass is immersed in a solution of 13 grammes of potassium iodide and 150 C.c. of water. The formation of mercurous and mercuric iodide commences immediately, the gelatin sheet being first yellow then more and more scarlet red. After the reaction is complete, the glass is well washed. As this colour permits a little active light to pass, it is best combined with the above described chrome-orange coat. Air may be completely excluded by a coat of paraffin to ensure permanence of the colour.—*Chem. Zeit. Rept.*, xxii., 16, after *Atelier des Phot.*, 5, 4.

DEVELOPER FOR RAPID PLATES AND SNAP SHOTS.—Solution No. 1: Metol, 4, hydroquinone, 6, potassium metabisulphite, 9, potassium bromide, 2, distilled water, 450. Solution No. 2: Soda caustic, 2, sulphite of sodium, 2, water, 10. Equal parts of both solutions make an excellent developer.—*Int. Phot. Monat. f. Medizin.*, 1898, 15, after *Phot. Ctrb.*, 20, 1897.

INTENSIFYING WITH MERCURIC CHLORIDE.—I find that a diluted saccharated solution of lime is better than ammonia to reduce the metallic salts in the bleached negative. The ammonia causes frilling of the film, even to complete stripping sometimes; the lime solution does not. I have not had much experience with either, but what little I have had supports the above view.—“AMATEUR.”

AN ECONOMICAL MOUNTANT.—Soak gelatin, 1, in cold water, 4, till quite soft, then add boiling water, 6, and stand the vessel containing the gelatin in hot water until it is quite melted; finally add methylated spirit, 4. When required to use, stand the mountant in boiling water till melted. This mountant is very easy to use, strong, and beautifully clean. Should any of it dry on the edges of the mount, it may easily be removed by applying a cloth dipped in hot water.—*Photo News*.

ACID FIXING BATH.—Belitski recommends the following formula:—Sodium sulphite, 50 Gm.; water, 800 C.c. When completely dissolved, add sulphuric acid, 6 C.c., and lastly sodium hyposulphite, 200 Gm.—*Deutsche Photo. Zeitung*.

INTENSIFICATION OF PLATINUM PRINTS.—Prepare a cold saturated solution of gallic acid and a 10 per cent. silver nitrate solution, and mix them shortly before use as follows:—Gallic acid solution, 52 C.c.; silver nitrate solution, 2 C.c.; water, 52 C.c.; glacial acetic acid, 10 drops. The well-washed platinum print is immersed in this solution and is left therein, under constant motion, until the desired strength has been obtained. If the intensifier should be discoloured too much, it is replaced by a fresh quantity. The precipitate of silver has a very fine grain, and the process is finished after correct intensification by rinsing and final washing with acid water. In case such intensified picture has become a little brown in consequence of the colour of the silver, it may be turned completely black by using the following platinum bath: Platinum potassio-chloride, 1 Gm.; phosphoric acid, 15 Gm.; water, 750 C.c. After this bath the picture is washed and dried. In place of the gallic acid hydroquinone may be used as follows: (1) Hydroquinone, 2 Gm.; citric acid, 20 Gm.; water, 450 C.c. (2) Silver nitrate, 3 Gm.; water, 30 C.c. To 30 C.c. of solution 1 add 10 drops of solution 2. The solution is left to act until the required intensification has taken place.—*Photographische Chronik*, through *Photography*.

EXTRACTS FROM CONSULAR REPORTS.

THE VALUE OF MEDICINES exported from Hankow (China during) 1897 was £294,594, an increase of £121,254 over the exports of 1896. The export of nutgalls was nearly double that of the former year, the value being £125,697.

COMPETITION IN THE MANUFACTURE OF ALBUMIN at Hankow, according to Consul P. Warren, is likely to become keen. There are three firms engaged in the business, one Austrian and two German, and others are about to take it up. The probable result will be that profits will be small, and this is advanced as a reason why no British firm has seen its way to compete for the trade. Large numbers of eggs are used, one firm alone using between 30,000 and 40,000 eggs each day during the season, but as the eggs employed in the manufacture must be absolutely fresh, the season is restricted to two periods of about two months each year. It is rather a curious fact that notwithstanding the increasing demand the price of eggs remains about the same, no rise apparently being anticipated.

THE ANTI-FRICTION METAL FACTORIES of Papenburg, although otherwise prosperous, are stated to be suffering severely in their export trade with England, owing to the strict interpretation of the Merchandise Marks Acts in England. It is expected that as a consequence the exports to England in this article must, in the near future, cease entirely.

THE PRODUCTION OF COD-LIVER OIL at Bergen during 1897 was larger than in the two previous years. The exportation amounted to 49,000 barrels as against 28,000 barrels in 1896, and 33,000 barrels the previous year. In the beginning of the season the price of steam-refined medicinal oil was £4 9s. per barrel, but fell to £3 per barrel, at which price it remained during the latter part of the season.

THE KELLNER PARTINGTON PAPER PULP COMPANY, LTD., of Manchester, which a few years ago erected its mills at Sarpsborg Falls, Norway, now employ over 1000 workmen, and are about to establish a large electric-power station for the accumulation of motive power to be derived from the waterfall. The "Hafslund Aktieselskab," a new company floated chiefly by German capital, is also erecting an enormous electric-power station on the opposite bank of the falls, and has already contracted, according to Vice-Consul Thiis, for the supply of motive power to two new factories now in course of erection, one for the manufacture of aluminium and other for the production of calcium carbide.

AN IODINE MANUFACTORY, under the name of "Hillevaag Kemiske Fabriker," has been started at Stavanger. Large quantities of seaweed are found along the coast; this is burnt into kelp, from which iodine is prepared.

A RECIPE FOR PREPARING OLIVES for the table is given by Consul Finn in his report on the trade and commerce of Malaga and district. The mode of procedure is as follows:—Soak the olives in a mixture of fresh water and caustic soda. For Manzanilla olives the mixture is 3° (Beaumé's areometer), and for large olives 2½°. The olives are kept for six to nine hours in this mixture, according to the time they are intended to be kept. If they are to be consumed promptly, nine hours; if to be kept some time, six hours. Afterwards they are put in water for twenty-four hours, the water being changed three times during that period. They are then placed in casks floating in a pickle composed of sea salt and water of a consistency of 9° (Beaumé's areometer). A most essential point in this method is that the water used in all the operations must be the softest and freshest possible.

THE OLIVE OIL CROP OF 1897, in the district round about Brindisi, has been considered by those in a position to know as a failure. The failure is attributed to the *Mosca olearia*, which germinates when there has been too much rain during the season, as appears to have been the case in 1897. The crop is estimated at 9200 tons, the medium price for the year being 72 lire 40 c., prices ranging between 70 lire 83 c. and 83 lire 95 c. per quintal.

REPORT OF THE PETROLEUM COMMITTEE.

After an inquiry extending over four Sessions, the Select Committee on Petroleum has now concluded its labours, and Mr. Jesse Collings, Chairman of the Committee, has presented its Report to the House of Commons. The following is a summary of the recommendations agreed to:—

1. That the present law affecting petroleum spirit, not being adequate for public safety, should be amended in the manner specified in the Report.
2. To adopt a flash point of 100° (Abel close test) as the dividing line between petroleum oil and petroleum spirit.
3. Legislation to control the storage, transport, and sale of petroleum generally and admixtures of the same with other substances, certain heavy oils being exempted.
4. To provide for an efficient system of testing.
5. To provide for adequate supervision and administration by local authorities.
6. That official inquiries be made into the causes of accidents arising from the storage, transport, or use of inflammable liquids.
7. Statutory powers to enable the Secretary of State to issue orders affecting the manufacture and sale of lamps.
8. To spread information among the public as to the nature of petroleum and the management of petroleum lamps.

The Committee added to these recommendations the following conclusions:

"That to place such legislative restrictions on petroleum oil below 100° (Abel close test) as are placed on petroleum spirit would have the effect of preventing the use of such oil for domestic or trade purposes; that the effect of such legislation would be to materially raise the cost of petroleum to the consumer; that it is in accordance with the evidence that if immunity from accidents is to be secured it will be necessary to prevent the use of oil below 100°; that the number of lamp accidents has not increased out of proportion to the vast increase in the number of lamps used; and that if freedom from accidents is to be secured ordinary care must be exercised in the use of petroleum, whether of 73° or 100° flash point."

Partnerships Dissolved.

(From the London Gazette)

H. Geary Dyer, M.D., and C. E. Lister, Surgeons, Apothecaries, etc., Ringwood, Southampton.

J. H. Trouncer and Harry Cooper, Physicians, Surgeons, etc., Surbiton, Surrey.

Robert B. Marriott and Vernon F. Allen, Surgeons and Apothecaries, Swaffham, Norfolk.

D. MacKechnie and William Ross, Physicians and Surgeons, West Hartlepool. Debts will be received and paid by William Ross.

T. B. Winter and C. Winter (trading as T. B. Winter and Son), Opticians, 21, Grey Street, Newcastle-on-Tyne. Debts will be received and paid by C. Winter, who will continue the business under the old style.

E. J. George and Frank Fielden (trading as George and Co.), Mineral Water Manufacturers, Gillingham.

E. H. Crisp and T. A. B. Plowman, Physicians, Surgeons, etc., The Lawns, Balham Hill, and Eagle House, South Side, Clapham Common. Debts will be received and paid by E. H. Crisp.

Eliza Foster and George Brown (trading as W. Foster and Son and G. Brown and Sons), Mineral Water Manufacturers, Clare Street and Somerset Street, Northampton. Debts will be received and paid by George Brown.

Receiving Order in Bankruptcy.

(From the London Gazette.)

Hamilton W. Jolly, Surgeon's Assistant, residing at 213, Upper Parliament Street, and practising at 123, Chatsworth Street, both in Liverpool.

Pharmacy and the Allied Sciences

A REVIEW OF CURRENT WORK.

Sterilisation by Heat. There can be no doubt that the most perfect method of sterilisation where it can be applied is heat. Baking, however, is a more or less uncertain process, while boiling is destructive to many substances. Moreover, the boiling temperature is so little above that which is fatal to microbic life that a considerable length of exposure to such a temperature is necessary, if one is to be sure that the process has been effectually carried out. Frying is, however, another matter. Olive oil at a temperature of 160° to 180° C. acts very quickly and with great power. Professor Wright, of Netley, says that to obtain complete sterilisation of an instrument it suffices to dip it for an instant in the hot oil, and that in the case of syringes it is sufficient to fill them twice with oil at the temperature mentioned. The temperature of the heated oil may be determined by a thermometer; but it is often more convenient to adopt the rough and ready methods of the cook by the aid of a bit of bread-crumble. "It will be found that the bread-crumble will become brown and crisp as soon as a temperature of 160° to 180° C. is reached." For the sterilisation of syringes all that is necessary is to heat a little oil in a spoon over a spirit lamp, testing it from time to time by bits of bread-crumble, and when the proper temperature has been attained to fill the syringe twice with hot oil. All microbial infection will then have been destroyed.—*Sci. Amer.*, lxxvii., 291.

Uric Acid in Urine. Triollet and Eury discuss those methods employed for the determination of uric acid in urine which are based upon the formation of insoluble ammonium urate. The methods of Fokker, Hopkins, and Cazé are considered less simple and less accurate than that of Otto Folin, which is as follows:—Take 100 C.c. of urine, add 10 Gm. $(\text{NH}_4)_2\text{SO}_4$, and render it very slightly alkaline; shake and set aside for two hours. Collect the precipitated ammonium urate on a filter and wash with 10 per cent. solution of $(\text{NH}_4)_2\text{SO}_4$. Then dissolve the precipitate on the filter with boiling water made slightly alkaline, allow the solution to cool, and make up the volume to 100 C.c. by the addition of water. On adding 15 C.c. concentrated H_2SO_4 the temperature should rise to 55° to 60° C. This temperature is necessary for the final operation, viz., titration with standardised KMnO_4 solution. Add to the result obtained by calculation 1 Mgm., to allow for loss due to the solubility of ammonium urate.—*Rép. de Pharm.*, June 10, vi., 1898, p. 253.

Boric Acid in Wines. P. Carles points out that boric acid is present in many wines in notable proportions, and that it is found more frequently in white than in red wines. This is partly due to the fact that the clarifying agents generally employed, e.g., gelatin and isinglass, tend to putrefy unless an antiferment is present. For many years H_2SO_3 has been used for this purpose, but among its disadvantages it deprives red wines of their colour, and is readily detected by its odour. Another reason for the use of boric acid is the demand for sweet white wines, hence its addition in order to check fermentation at a certain stage in the process. It is, of course, open to question whether, from a hygienic point of view, the use of boric acid is permissible in articles intended for human consumption, on account of its antiseptic properties.—*Rép. de Pharm.*, vi., June 10, 1898, p. 256.

VOL. LXI. (FOURTH SERIES, VOL. VII.) No. 1465.

The salts of mercury and copper are recommended by P. Carles to be placed in contact with the urine after asparagus has been eaten, in order to prevent the unpleasant smell that frequently prevents patients from partaking of this delicacy. The salts of lead and bismuth do not answer, and the simplest plan is to use a crystal of copper sulphate. Similarly the volatile oil of mustard is not produced in presence of these salts, and any that has already been formed is quickly destroyed.—*Rép. de Pharm.*, vi., June 10, 1898, p. 263.

Preparation of Chloroform Water. According to M. Mansier, a solution of chloroform, containing 0.8 Gm. per litre, placed in a stoppered flask two-thirds full, if maintained at a temperature of 12° to 14° C. without shaking, will be found, after a fortnight has elapsed, to contain only 0.4 Gm. of chloroform. If chloroform water of the same original strength be placed in a flask three times as large as is necessary and examined after it has been violently shaken several times it will be found to contain 0.6 Gm. of chloroform. Hence, the quantity of chloroform necessary to fully saturate air being known for all temperatures, it is easy to prepare a solution of definite strength and better keeping qualities. The proposed formula directs that 4.6 Gm. of chloroform, previously weighed in a small flask, be added to 900 Gm. of distilled water contained in a litre flask, and the whole agitated until globules of chloroform disappear. It is calculated that the air in the flask will be saturated by 0.1 Gm. of chloroform, leaving a solution containing 0.5 Gm. per 100 Gm. The product should be preserved in full vessels.—*Journ. de Pharm. et de Chim.*, xii., June 15, 1898, pp. 585-587.

Pimpinellin. Pimpinellin, the bitter principle from the root of *Pimpinella saxifraga*, has been isolated by G. Hent, in long colourless shining needles. It is insoluble in water, with difficulty dissolved in ether, and readily soluble in alcohol. With concentrated sulphuric acid it dissolves, giving a greenish colour; it melts at 106° C., and has an acrid burning taste.—*Chemik. Ztg.*, xxii., 144, after *Arch. Pharm.*, 236, 163.

Presence of Emulsin in Lichens. Liebig and Wöhler concluded that emulsin was peculiar to bitter almonds, but other investigators, among them Bourquelot and Gérard, have proved the presence of a ferment analogous to emulsin, not only in other members of the natural order Rosaceæ, but in *Aspergillus niger*, *Penicillium glaucum*, and many of the humbler types of plants. Bourquelot's conclusion that most fungi, especially those parasitic on trees, secrete a ferment which, like emulsin, is capable of hydrolysing glucosides, has led Hérissey to look for emulsin in lichens, since they are partly fungal in their nature. Up to the present he has found a ferment, capable of acting on amygdaline, in all fungi which he has examined, viz., *Usnea barbata*, *Physcia ciliaris*, *Parmelia caperata*, *Peltigera canina*, *Pertusaria amara*, *Cladonia pyxidata*, *Evernia furfuracea*, *Ramalina fastigiata*, and *R. fraxinea*. The process adopted in the detection of emulsin consisted in placing from 0.4 to 1.2 Gm. of the bruised lichen in contact with a solution of 0.2 Gm. amygdaline in 20 C.c. of water saturated with thymol. The mixture was placed in a tube, proved free from glucosides, in an oven at a temperature of 35° C. On the next and following days prussic acid was sought for and proved to be present by distilling a portion of the solution, and, on addition of water and the appropriate reagents, obtaining prussic acid. Glucose was detected by the use of Fehling's solution.—*Journ. de Pharm. et Chim.*, xii., June 15, 1898, pp. 577-580.

THE BARK OF *CLEISTANTHUS COLLINUS* AS A FISH POISON.

BY DAVID HOOPER, CALCUTTA.

In the *Indian Forester* for June, 1896, Mr. W. F. Biscoe drew attention to the economic uses of the *Kodarsi* tree in the Nizam's dominions. *Kodarsi* (Telugu and *Oduvan* (Tamil) are the vernacular names of the *Cleistanthus collinus*, Benth., which was formerly known as *Lebidieropsis orbicularis*, Mull-Arg. It was stated that the tree is largely used and has a valuable timber, which, in its pole stage, is considered as good as teak.

On the authority of Dr. Ainslie and Dr. Roxburgh, the fruit of this tree is reported to be exceedingly poisonous; one pagoda weight of the capsule in powder is believed to be sufficient to kill a man. The leaves and roots are also harmful, and the first is avoided by animals. The Chemical Examiner of Madras within the past twelve years has been in a position to confirm these reports, and has discovered the leaves and fruits of the tree being employed for criminal purposes in South Arcot, South Canara, Malabar, and other districts in the Presidency. Mr. Biscoe, in the extract above referred to, specifies the deleterious properties of the bark. He writes: "The bark must contain some poisonous property, for not only do white ants leave it severely alone, but it is used here for poisoning fish. The inner bark placed on the sores of sheep and goats is efficacious in healing them and in destroying maggots."

Wishing to examine the bark of *Cleistanthus*, with the object of detecting the active principle, Mr. Biscoe obligingly sent me a parcel of a few pounds of the freshly-dried bark, together with some of the capsules, for chemical analysis. The bark was in the form of thick, incurved pieces of a reddish-brown colour, with a dark brown exterior. The powder was of a light red colour, having an astringent taste, but destitute of any marked odour.

The amounts of moisture and mineral matter were estimated in a small sample of the powdered bark, and another portion was treated to the successive action of different solvents, which revealed the following approximate composition:—

Moisture	6.70
Fat, etc. (ether extract)78
Spirit Extract	32.42
Water Extract	7.86
Pectin, etc., by difference	2.45
Crude Fibre	42.44
Ash	7.35

Total..... 100.00

The fatty matter removed by ether possessed no peculiar reactions, and, as usual, was associated with chlorophyll. The spirit extract was of a fine red colour, and left a brittle residue when evaporated down to dryness; it consisted almost entirely of tannin. Duplicate estimations of the amount of tannin in the original bark gave an average of 33.3 per cent., a quantity much above that found in ordinary tanning barks. An examination of the various extracts revealed no distinct evidence of such principles as alkaloids or glucosides, and it seems conclusive that the activity of the bark resides in the astringent substance.

Those who have studied the subject of fish poisons will have noticed the wide range of vegetable products used in this connection. *Kakamari*, the berries of *Anamirta cocculus*; bark of *Walsura piscidia*; the fresh bark of various leguminous plants, as *Tephrosia*, *Derris*, *Mundulea*, *Erythrina*; the pungent flower-heads of *Spilanthes*; the fruits of species of *Randia*; and the barks of Euphorbiaceous trees of *Flueggia*, *Macaranga*, and *Securinega*. Some of the last-named are characterised as being rich in tannin.

Fish seem to be particularly sensitive to substances of an acrid, bitter, or astringent nature. Plants containing the soap-like principle, called saponin, are, without exception, fatal to fish life.

The toxicity of tannic acid or tannin does not seem to have been noticed by previous observers, but its occurrence in plants used for destroying fish in which more active principles are absent, leave grounds for supposing that this widely distributed plant constituent is harmful.

A few preliminary experiments have been made by mixing in pure water, containing live fish, a few grains of commercially pure tannic acid. The experiments have shown that the acid has a decidedly toxic action on small fish. From the movements of the fish it was evident that the acid was a most objectionable addition to the water, but whether the tannin itself killed them, or, by abstracting oxygen from the water indirectly produced suffocation, must be left to physiologists to decide.—*Indian Forester*.

A VISIT TO THE SPA WELLS NEAR BALLYNAHINCH,

THE MEDICINAL SPRINGS OF COUNTY DOWN.

BY L.P.S.I.

It might be difficult to find out, and perhaps not complimentary to inquire, how much the Continental watering-places—Baden-Baden, Fredrickshall, etc.—owe in popularity and renown to their intrinsic utility, and how much to custom and the great tendency of the *élite* of the earth to precipitate themselves at a fashionable resort, not so much to escape the "madding crowd," for society life is always awhirl, as to avoid the masses of the cities. Mark Twain, who is a pretty accurate guide as to what is genuine on the Continent and elsewhere, whilst he condemns the Turkish bath as an unmitigated fraud, mentions one spa favourably as removing a touch of rheumatism which troubled him. Let mineral springs possess what value they may, it is evident that in order to be attractive and popular, an expenditure of cash in accommodation and in making the spot easy of access would be needed first. The spa wells of Co. Down were the resort twenty years ago of crowds of Irish gentry, and up to ten years ago, though the visitors had largely decreased, these wells were still fairly popular. *Nous avons changé tout cela*, or at least somebody has done it. Ireland has all the necessary natural attractions for a touring country. The one drawback is the possibility of only reaching the island by a sea voyage of some hours. The proposed tunnel between this country and Scotland, which would cost five or six millions, is rather a high speculation for Mr. Ritchie to assist financially. The Ballynahinch Spa wells might only afford tourists who are accustomed to roam the earth for Alps and Niagaras rather a *bonne mouche* than a feast. It was with the intention of picking up a few particulars that I recently visited them.

The wells are two miles from Ballynahinch. The latter village (population 1500) is somewhat famous, and especially just now as the centenary of 1898 might suggest. It was here that 8000 farmers made a stand against a few thousand Royal troops in 1798. Near by, the tomb of Betsy Grey, who assisted the rebels, is still preserved. With the Spa as centre, and taking a radius of fifteen miles or so, one would enclose a fair collection of historical curiosities and ground. Newcastle with the recently erected Slieve Donard Hotel (cost £80,000), and the fine demesnes of Lord Annesley, and Downpatrick, with its ancient cathedral and the resting-place of the Patron Saint of Ireland. If any members of the British Pharmaceutical Conference visit Ballynahinch they will find the great profession represented by a single pharmacy. I am sorry to say that the architectural construction of the village without exception is humble. Nevertheless the village is a hive of industry, sewed muslin and the flax industry mainly.

There are two ways to the wells, one through Captain Ker's Demesne and the other by the public road which skirts the demesne.

I arrived at my destination in about forty minutes. A neat omnibus runs between the Spa and Ballynahinch to suit railway travellers. The fare is 6d. There is a Presbyterian church at the Spa; it is one of the first things you see.

After looking about this sleepy little village (I must confess the day was Sabbath) we discovered a boy, who informed us the way to the wells, which were about thirty yards from the church. They are situated in a little park, beautifully decorated with trees and flowers, the roses being in enormous quantities. (It should be remembered that a few miles from here is Newtonards, where the gardens of Dickson, the renowned Belfast florist, are.) The wells are two in number, and each is enclosed in a painted, slated, pyramidal shaped wooden house of its own. These were locked. We were informed that an old woman kept the key. So we went in search of her. We entered a neat, tidy garden and hence into a house, and here there appeared a clean, tidy old woman, arrayed in bonnet and white linen.

I said I was sorry for disturbing her on Sunday, but we were anxious to see the wells.

"Oh!" said she, with a great shake of her head, "A' keep the key. A'll go after you."

She opened the door to the iron spring and led the way in. A well-garnished room; in the middle stood a small pump. There were half-a-dozen tumblers in a little receptacle below the pump. There is a brass plate mounted, bearing the following inscription:—

ERECTED
By DAVID KER, Esq.
1810.

The name of the engraver appeared to be J. Brammath and Son, London, but it was somewhat dim. I took a glass of the water and a sample of it.

The old lady shook her head and asked what I wanted the sample for. "To analyse it," I said. "Oh, well," she rejoined, with her usual gesture, "hundreds have tried to analyse that water but they couldn't." I remarked "That that was very queer." "Queer or not queer," she replied, with a more vigorous gesture of the head, "they have tried it over and over again, and they can make nothing out of it. There is iron there and that's all, so you needn't bother trying to analyse it, for (here she shook her head again) it can't be analysed." I do not know what meaning she attached to the word; probably, however, she may have thought that the analysis of it would destroy its virtue. We proceeded to the other well—a similar state of affairs. We took a sample and copied an analysis pinned on the wall:—

BALLYNAHINCH SPA (LOWER WELL).

3.21 grains of residue (obtained by evaporation), contained, according to Sir Robert Kane's analysis—

Muriatic Acid	18
Sulphuric Acid	24
Soda	35
Protoxide of Iron	15
Lime	35
Carbonic Acid	39
Organic Matter	1.55
	3.21

Specific gravity equals 1.000539. The colour: Yellowish-brown, from the organic matter of turf held in solution.

There is a private hotel accommodating about thirty people, and, I was informed, it was kept busy. However, the mentor and guardian of the wells told me with many decisive nods of the head—"that it was going down"—referring generally to the district. There used to be a commodious bathroom attached to the wells. There was also a large ballroom, but it has fallen to ruins and is never used now. It appears that the present owner of the estate does not take the same interest in it as the previous landlord. The water, however, still retains its pristine purity and power.

I asked the old woman did she mind the time when it was in galore.

A series of mournful shakes of her head preceded her reply—

"Mind? A-think, A-mind, indeed, when my father was caretaker. The people used to swarm in here, and the ballroom was crowded. Ah! they were great times."

Ichabod seems to be written over the Spa and its belongings.

The well-houses are circular, having a diameter of eighteen feet.

There is an extract from a Belfast journal which, after describing, in effusive style a visit to the spa, concludes as follows:—

"A prettier place or one better calculated to make the delicate strong, the discontented cheerful, could scarcely be imagined than the neighbourhood of the Ballynahinch Spa." This was written some ten years ago by a young lady when everything was in good repair.

We went to the Puzzle Walks. They are very puzzling, round and round you go, and then you try to get back, and aim for your starting-point—you find yourself out of the road entirely. The "Walks" need repairs, and in some places the hedges meet each other and require clipping.

PHOTO-MICROGRAPHY.—IV.

BY EDMUND J. SPITTA, L.R.C.P. LOND., M.R.C.S. ENG., F.R.A.S.

(Continued from page 29.)

Before quitting the subject of lenses, I should like to mention, as perhaps the most suitable place for so doing, that it is very useful to have placed in the microscope tube, just above the objective, an auxiliary iris diaphragm. It has been called the Davies diaphragm. Its object in this position is to very slightly curtail the marginal rays of low power objectives, by doing which even with apochromatics a better definition—one full of greater contrast—is often obtained. Any reflections too from the side of the tube may be cut off by this means. It should be made truly central with the axis of the microscope and should be in no wise closed when using lenses of high aperture; for if such should be done—seeing that resolution entirely depends upon the numerical aperture of the lens, as already hinted—the wide-angled objective becomes a narrow-angled one and will cease to possess its separating power.

I have frequently used this term "numerical aperture," and hitherto have not had an opportunity of saying anything about it. The N. A. of a microscopical lens bears the same relation to its performance as the aperture of a telescope does to that instrument. Astronomers full well know that the larger the object glass becomes the greater the power the instrument possesses for separating close "double-stars." To put it another way, stars which with a small telescope appear as single are easily separated into "doubles" when sufficient aperture is employed. Increasing the aperture yet more, perhaps one of the "doubles" itself is found to consist of two, and it is no hidden fact that the higher the diameter of the telescopic objective the more "double stars" are found to exist. This is not the place to discourse upon the optical causes of this well-known fact; indeed, it would be foreign to an article on photo-micrography, but it serves to illustrate what N. A. really is to the microscopical objective. The higher it is the more you can see; and the less you have the more objects seem to blend themselves into a state of indivisibility. Opticians, therefore, have striven to obtain the highest degree of N. A. that they can give to each objective. The higher the power, the more easily is this obtained, and we regret that so many opticians understate the magnifying power of their lenses, so as to gain a repute for making wide-angle objectives. For example, it is easy to make a 1/12th of moderate N. A.,

and sell it for a 1/8th of high N. A. It is a fraud, but is often met with. With apochromatics manufactured by Zeiss, and Powell and Lealand, the foci given by the makers may always, without exception, be regarded as truthfully exact. The consequence of this is that the value in magnifying power of any objective is readily known, and this is of no small service in ascertaining how much the photo-micrographer has magnified his object; but to this I shall refer again when a suitable occasion arises. A practical point the photo-micrographer should bear in mind is to always obtain, speaking generally, as high an N. A. objective as he possibly can, for a 1/6th which magnifies 60 diameters with a low N. A. is not comparable in its powers of resolution to a 1/4th of high N. A., although it amplifies 20 diameters less. Magnification, therefore, is not so important—it can be got by camera-length or eye-piecing—as numerical aperture. I hope to illustrate this in due course by two pictures, one taken with a lens of low N. A., and the other with an objective of high angle, the magnification being the same in both cases. But from what has been said it would appear that low-angled objectives are of no use whatever. This is not the case. Seeing that although the depth of focus, which means the power possessed by the objective of viewing simultaneously several planes of focus, varies inversely as the square of the power, still it also varies as the reciprocal of the N. A.; so that the less the N. A. the more depth of focus is obtainable.

Depth of focus used to be thought to be a distinct property peculiar to the best objectives but now that the philosophy of microscopical optics is better understood, it is recognised not to have a separate existence of its own devoid of explanation, for it is known to directly follow as the result of lowering the N. A. As therefore the highest resolving power rests with lenses of the highest N. A., so the converse equally holds true that the less the aperture the less the objective can resolve, but the greater is its depth of focus. It would seem now still more than ever apparent that the day for low-angled objectives is gone, but we again repeat this is not quite the case, for when it is desirable to take in at a glance the entirety of the dimensions of an object, its height, depth, and width, and the place it occupies amidst others that surround it, we may find it far more enlightening to use a low-angled objective with plenty of depth of focus. It is better, we may find, to sacrifice the ideal in definition so as to obtain a more realistic picture—one of greater utility and instruction, seeing it would enable the eye of the observer at a glance to perceive the perspective and realise the general relations of the part to the whole than would be obtained in the case of the mental image only derived by differentially focussing first one plane and then another, as must be done with a high-angled objective.

This is true so far as vision is concerned, but when wishing to photograph what we see, the effect of a low N. A. and depth of focus may be even more apparent, for when visually we inspect an object in the microscope another factor enters into the problem, to which at present I have only referred—the accommodation of the eye itself. According to Professor Abbe, it assists very largely the performance of all objectives so far as relates to their depth of focus, but when taking a photograph there is no eye to assist, hence what appears well in focus to the observer may not be so in the negative, for no amount of dexterity will give to the plate that part of the depth focus which is due to the eye. Consequently objectives of low aperture may be even of more use to the photo-micrographer than to the visual observer.

Each type, then, of lens has its duty to fulfil. But if the reader is limited to the purchase of one kind only, I again state my conviction that the high-angled lens is that to be selected.

Shutting the iris diaphragm below the condenser is known to practically reduce the N. A. of the objective being employed, hence the question has been asked, If this is true, why buy low-angled lenses at all? It is because the image produced by closing the iris is not equal in truth or efficiency, owing to diffraction phenomena, to that given by a low-angled objective made as such.

Owing to apochromatics performing so well with any eye-piecing, anyhow, up to 27, or even more under certain conditions, this type of lens is not made of very low angle, for one which does not possess a great N. A. can be eye-pieced to give the required magnification, and so the depth of focus resulting from the low N. A. can be obtained.

Seeing that numerical aperture is of such importance, it must now be pointed out to the reader how he can learn to ascertain this for himself in any given lens before he purchases it.

There are two methods for dry objectives, but only one for homogeneous ones.

The first, applying to both types of lenses, is by using a special apparatus devised for the purpose by Professor Abbe, called the apertometer (Fig. 3). This consists of a piece of thick glass about 3 inches in diameter, half an inch thick. The part where the glass becomes segmental is bevelled from above downwards to an angle of about 45°. Near the centre (marked a) is a small disc of silvered glass with a tiny hole in its centre, where the silvering is removed. Two plates of metal, which can be shifted around the outer edge of the glass shown at b b are square one side and pointed on the other (see b in the side view). To use this apparatus, the glass is placed with the graduated surface uppermost upon the stage of the

FIG. 3.

microscope (fixed vertically) in such a manner that the circular portion is forwards and the chord or bevelled piece backwards, towards the stem of the instrument. The edges of the little hole are now focussed with the objective to be measured, an eye-piece being used, and the length of the draw tube the same as when the objective is ordinarily in use. The two indices, as b b are called, are then placed on the edge of the glass as shown in the plate, but close to the middle of the semi-circle. Their sharp points should lie along the vertical edge of the disc, and their flat sides upon its upper graduated surface. It is best to direct the points away from each other to the outer side, if the power to be examined is comparatively high (N. A. above 0.6 or 0.7), but towards each other to the inner side if a low objective is employed.

With each instrument an auxiliary objective is supplied which screws, or must be made to screw, into the end of the draw tube, after which both are returned to the microscope, with the auxiliary lens passing down the main tube. The same eye-piece is then placed in the draw tube as before, and the auxiliary microscope then obtained is focussed to the image of the indices by sliding the draw tube in the main tube. Care must be taken both in pulling out and pushing in the draw tube not to alter the adjustment of

the objective under examination by accidentally shifting the main tube.

The indices are now adjusted, taking care they lie close to the glass plate until their sharp points just touch the periphery of the luminous circle seen on looking down the eye-piece. Their position found, the readings of the upper edges, which lie in the same vertical plane as the points, are read from one of the two scales on the plate. The half of the sum of the two readings on the outermost scale—that nearest the edge—will give the measured value of the N. A. of the objective under examination. Likewise the sum of the two readings on the inner scale will give the value of the angular aperture in air.

The illumination must be shifted from right to left or up and down, so that the light falls horizontally upon the edge of the glass.

Special instructions are given with each instrument, but lengthy as the description must necessarily appear, the apparatus is not difficult to use, the only fault is its expense. Still it is the only plan with immersion objectives.

With dry powers, however, a simpler plan of obtaining the approximate N. A. may be employed, and as it is not to be found in any text-book that I am aware of, I will describe it in as few words as possible.

Lay upon the table two pieces of white paper, using a black background, with their straight inner edges parallel to one another, and a definite distance (say 20 centimetres for lenses of N. A. over 0.50, less for low-angled ones) apart, then hold a rule vertically upon the table about midway between the two pieces of paper. Next hold the objective to be tested vertically against the rule and look down at the back lens. Images of the two pieces of paper will be seen there; now slide the objective downwards along the edge of the rule, always watching these images. They will separate farther and farther apart until at last a point is reached where only a slight bluish flicker remains visible on either side in the extreme margin of the lens, which, of course, indicates that the inner edges of the pieces of paper are in the direction of the most oblique rays which the objective is capable of receiving, or that the angle enclosed between these directions, which directions intersect in the principal focus of the objective, is the angle of aperture. To determine this angle, read off the distance from the table to the front of the objective, and subtract the working distance of the lens, so as to get the distance from table to focus. Then this distance divided by half the distance between the two pieces of paper is the cotangent of the semi-angle of aperture; the latter may, therefore, be obtained from a table of trigonometrical ratios, and the sine of the same angle is the N. A. of the objective.

Example:—

Distance between the two pieces of paper, 20 Mm.

Distance of front lens of objective from paper, 33.0 Mm.

Working distance of objective, 0.2 Mm.

$$\therefore \frac{33.0 - 0.2}{20/2} = \frac{32.8}{100} = 0.328$$

0.328 = cotan, of angle 71° 49', as we find from the trigonometrical tables, the sine of which = 0.95 = N. A.

With great care this method will give results accurate to one or two units of the second decimal. In looking at the back of the objective the eye should be at a distance about equal to the tube length for which the objective is designed, but the error caused by even considerable deviations from this theoretically required distance is very small.

THE SIGNIFICANCE OF OXY-METHYL-ANTHRAQUINONE IN SOME ORGANIC CATHARTICS.

Borntraeger's test for aloes, or the aloetin reaction, consists, as is well known, in obtaining a red coloration when the benzene or ether extract is shaken with ammonia. Other substances, however, such as rhubarb, turmeric, catechu, gall nuts are said to give a very similar reaction. Dr. A. Tschirch, in conjunction with G. Pedersen, finds that the substance which gives Borntraeger's reaction in aloes is an emodin, that is to say, tri-oxy-methyl-anthraquinone, of the formula $C_{15}H_{10}O_5$. Emodin can be readily obtained from aloes by extracting Barbados aloes with alcohol, precipitating the resin with water, then neutralising and separating the aloin by crystallisation, and finally extracting emodin from the filtrate with benzol or ether. The emodin is obtained from the benzol or ether residue by crystallisation from boiling alcohol in the form of orange-red needles. "Aloe-emodin" melts at 216° C., and not at 250°, as is usually given for emodin. Emodin can be obtained from Cape aloes in the same manner. Borntraeger's reaction is given by Barbados, Curaçoa, Arabica, and Cape aloes, but less so by *Socotra lucida*, slightly by Zanzibar and Mocha, but not at all by Natal aloes. This last point is interesting, as only the kinds of aloes which contain barbaloin (or socaloin) produce emodin, and those that contain nataloin are without emodin. As emodin is somewhat soluble in water, Borntraeger's test can be better carried out by boiling the substance with water and shaking the filtrate with benzene, and the benzene with a 5 per cent. ammonia solution. By this test it was found that all commercial samples of barbaloin contain emodin, although it is simple enough to remove the latter by treatment with anhydrous ether, which does not dissolve barbaloin. It is found, however, that it is not emodin only that gives Borntraeger's reaction, which is characteristic of a limited group of bodies. It is obtained with chrysophanic acid, morindon, aloexanthin, as well as with emodin, for these bodies are in simple relation to one another, being, in fact, oxy-methyl-anthraquinones. Chrysophanic acid is di-oxy-methyl-anthraquinone; emodin is tri-oxy-methyl-anthraquinone; morindon, its isomer, and aloexanthin is tetra-oxy-anthraquinone. Not only with these bodies, but also with bodies which are convertible into them by oxidation or otherwise, such as frangulin and chrysarobin, hence Borntraeger's reaction can be more correctly described as the oxy-methyl-anthraquinone reaction. It is as much a group reaction as the tannin reaction with iron salts. The examination of several kinds of drugs, such as Barb. Socot. Zanz. aloes, rhiz. rhei, rad. lapathi, cort. frangulæ, cascara sagradæ, rhamni cathartici, fol. sennæ, the wood and bark of *Morinda citrifolia*, by the modified test as above described, showed that the pronounced cathartics gave the reaction, whilst it could not be obtained with the water extract of such drugs as turmeric, catechu, tamarind, jalap, kamala, rhiz. podophylli and many other drugs, which are partly cathartic and partly colouring agents.

In fact, Borntraeger's reaction becomes of typical importance as showing the presence in drugs of the oxy-methyl-anthraquinone group of bodies, of which emodin is the most important. The relation between barbaloin and oxy-methyl-anthraquinone is shown by the conversion of barbaloin into emodin, which is, as stated, a tri-oxy-methyl-anthraquinone, by the action of air in an alkaline solution, thus:—

It is considered, therefore, that in this group of cathartics it is an oxy-methyl-anthraquinone—chrysophanic acid and emodin—which exerts the cathartic action. This view might be regarded as paradoxical, since Barbados aloes contain only 0.2 per cent. emodin

against 12 per cent. of barbaloin, but, as it has been shown that this group contains substances that are convertible into an oxy-methyl-anthraquinone, either by oxidation or by hydrolysis, a similar action no doubt takes place in the intestines. In fact, nataloin, which is not capable of yielding an oxy-methyl-anthraquinone, has no cathartic action. As alkalies assist the oxidation of aloin to emodin, so the aloe group of cathartics should be administered with an alkali.—*Ber. Deut. Pharm. Ges.*, 1898, 174.

PARLIAMENTARY NOTES.

THE SHAPE OF MEDICINE STAMPS was referred to in the House of Commons last week, when Mr. Mildmay asked whether the Postmaster-General would consider the advisability of giving orders that the 1½d. medicine stamp should be issued perforated and gummed instead of as at present.—Mr. Hanbury: The question has more than once been considered by the Board of Inland Revenue, but they find that there is great objection to stamps of a long narrow shape, such as the medicine stamp, being perforated, as they cannot be separated except slowly and with great care without being torn. So far as the Board are aware, those who use these stamps on any large scale prefer to cut and gum them for themselves; and in these circumstances the Board do not see their way to adopt the hon. member's suggestion.

THE LATTER DAYS of the present session will remain on record as the most memorable, from a pharmaceutical point of view, since the passing of the Pharmacy Act thirty years ago. It was something for registered men to learn that they could stop a Government Poisons Bill, and if the session had demonstrated nothing else, this revelation of political potentiality would have raised it to red-letter rank. Since the closing of that incident, however, events of striking importance have followed one another in rapid sequence. In our last issue we reported the words uttered by the Lord Chancellor and the ex-Lord Chancellor in Committee of the House of Lords with reference to one of the defects of the Pharmacy Acts, and one began to fancy that the faint streaks of the dawn of the pharmaceutical millennium were upon the horizon; but after we had gone to press, and the proposals of Lord Halsbury had been moulded into the amendment, which we print on page 89, it was perceived how vast a difference exists between expressed desire and actual performance. The bread which the noble law lords had led the calling to expect turned out to be the hardest of stones. In fact, the proposed salvation from the effects of one mistake in the 1868 Act was nothing more than an extension of another mistake—the Widow's Clause, or, to speak more correctly, Clause XVI. Such an addition to the non-contentious Pharmacy Bill was not likely to meet the approval of the promoters of the Bill, and representations were made which had the effect of postponing the third reading of the measure from Monday till Thursday.

MEANTIME the "companies" have become dreadfully alarmed, and prominent unqualified directors of these fungus concerns have spent a feverish time in flooding noble legislators with telegraphic appeals, and in soliciting public sympathy through the medium of the halfpenny press. "Vested interests" is their battle cry, but it is doubtful if any amount of shrieking will lead the Lord Chancellor to lose sight of the more legitimate vested interests created by the Pharmacy Acts, and which are based upon the technical training and scientific education of individuals. His Lordship may, however, be led to think that under the circumstances it is not quite justifiable to load the present purely domestic Pharmacy Bill with such a heavy tail of contention. The question of the abuse of company incorporation is much too vast and too important to be dealt with in a Lords' amendment. It merits a Bill to itself, and that Bill should be a Government Bill drafted after consultation with the Pharmaceutical Societies of Great Britain and Ireland.

MEDICINE has tried to imitate Law in asking for public aid in carrying out public duties. It may be remembered that last session the Incorporated Law Society was fortunate enough to secure Parliamentary sanction for a grant towards defraying the expense incurred by the Society in keeping the rolls free of black sheep. Dr. Farquharson tried on Tuesday to obtain an appli-

cation of the same principle to the General Medical Council's work of purification. The genial doctor asked that a grant of £5000 (the sum allotted to the Law Society) might be put into the coffers of the Medical Council to enable it to prosecute irregular medical practitioners. But the attempt failed. In the first place the two societies are not on all fours, so the Chancellor of the Exchequer explained, for the Law Society does not receive the penalties and costs resulting from the prosecution of offenders, whereas no such altruism is apparent in medical prosecutions. In the second place the Law Society is not assisted to the tune of £5000, but to only half that extent. Could Pharmacy succeed where Medicine failed? It is tolerably certain that the Pharmaceutical Council would willingly forego the amounts recovered under the Pharmacy Acts—especially in Scotland—for the privilege of having £2500 a year to expend in making the law relating to the sale of poisons more respected.

LEGAL INTELLIGENCE.

PROCEEDINGS UNDER THE FOOD AND DRUGS ACT.

DEFICIENT LIME WATER.

At the Thames Police Court, on Tuesday, Charles Willmer chemist, of 31, Bow Common Lane, appeared to answer a summons, taken out at the instance of Mr. Joseph Anthony, Inspector under the Sale of Food and Drugs Act for the Poplar District Board or Works.—Mr. Young prosecuted, and Mr. Beck, who defended, pleaded guilty. His client sold the lime water as it was received, Lime water was an article extremely likely to undergo chemical changes, and every time the stopper was taken out carbonic acid was admitted; consequently the chemical change went on.—Mr. Mead imposed a penalty of 20s. and £2 2s. costs.

IMPURE PRECIPITATED SULPHUR.

At the Kensington Petty Sessions on Tuesday, the proprietors of Parke's Drug Stores, Ltd., were summoned by the Kensington Vestry, under Section 6, Sale of Food and Drugs Act, 1875, for selling precipitated sulphur containing 44.5 per cent. of non-volatilisable mineral matter consisting of sulphate of lime. Mr. W. J. Stephens appeared on behalf of the Vestry, and the manager at the Kensington branch of Parke's Drug Stores for the defendants.

Mrs. Florence Williams stated that on June 21 last she was instructed by Inspector Ellenden to make a purchase at the local branch of Parke's Drug Stores, 151, High Street, Kensington. She asked for 2 ozs. of precipitated sulphur, and was handed a small packet, for which she paid 2½d. There was no label on the packet, and nothing was said to her by the assistant who served her as to the nature of the article. She afterwards handed the packet to the inspector, who came into the shop.

Inspector Ellenden stated that he received the sample from the last witness, and after explaining that the article had been purchased for analysis by the public analyst, divided it in the usual way. He drew the assistant's attention to the fact that the packet was not labelled, and the assistant asked to be allowed to affix a label. Witness, however, intimated that he could not comply with the request. He now produced the analyst's certificate.

Mr. Stephens intimated to the Bench that the Vestry had never had a conviction against the present defendants, but had found it necessary about two years ago to caution them regarding the sale of mercury ointment.

Defendant's manager admitted that the article, as described, had been supplied, but maintained that it was entirely an accident that the article asked for was not served. In view of the new rules connected with the British Pharmacopœia, which, however, would not come into force for about three months (*sic*), orders had been given at the Stores that all the milk of sulphur—the article in question—which was sold should be put away, and not served to a customer.

Dr. Forman (magistrate) asked whether the milk of sulphur was not an article of commerce.

Witness replied that such was the case, but that it is not scheduled in the Pharmacopœia.

Dr. Forman said that precipitated sulphur, whether in the Pharmacopœia or not, should be sulphur which, when sublimed, would leave no residue.

Witness replied that he was anxious for it to be understood that it was quite an accident that the milk of sulphur was given instead of the precipitate.

Mr. Stephens remarked that the certificate of the public analyst reported the article in question to be not in accordance with the regulations of the British Pharmacopœia.

Dr. Forman: My contention is that, whether the article was in accordance with the Pharmacopœia or not, it was not what the customer asked for.

Mr. Stephens: That is just our contention, sir.

Mr. W. Bird (Magistrate): This, we consider, is a very serious case. It is absolutely necessary that the public, on going to a chemist's shop, or a place where drugs are sold, should get what they ask for, and that they should get pure drugs when they want them. As I said, this is, we consider, a serious case, and the defendants will therefore be fined £3 and costs.

ELEMENTARY EDUCATION IN GERMANY

The Germans attach much importance to compulsory education from the earliest youth, but as regards children of the working classes, in view of the small number of teachers, in proportion to those who have to be taught, the chief advantage gained is giving the latter regular habits and keeping them out of mischief, especially as under military principles a control is exercised by the schoolmasters and mistresses not only in but out of school. Consul Mulvany, of Düsseldorf, says that it is only natural that such a forced system should not be very highly valued by the recipients, and that only a few of the more intelligent children derive much material benefit, but it affords an opportunity to the authorities of testing the quality of brain with a view of development to higher posts in the interests of the pupils and of the State. The education of children is absolutely compulsory from the age of six to fourteen; only in exceptional cases where the child is considered to be sufficiently advanced and is required at home is there a departure from this rule. All elementary schools are free of fees; in small villages there are eight different divisions, though the children may be possibly taught in one room by one and the same master, whereas in towns it is found sometimes necessary to subdivide the division, thereby forming sixteen different classes. There are no examinations. These schools are supported partly by the State, partly by the community, in most cases the State paying about half the cost; as to proportion very much depends upon the tax-paying powers of the community; as a general rule there is no special school tax. In religious education the children are separated according to confession; all must attend Bible history classes; the appointment of schoolmasters is determined in accordance with the preponderance of the Roman Catholic or Protestant religion. There are special seminaries where teachers of both sexes are qualified for higher grades of education; the community appoints the teachers subject to the sanction of the State. Children between six and fourteen years of age can only receive education from duly qualified teachers; no one is allowed to teach at either private or public schools without having passed a specified examination. If parents, no matter what their social rank may be, neglect to have their children taught during the age from six to fourteen by a qualified teacher they are compelled to send them to the public elementary school. All higher schools levy fees. Private schools can only be established under sanction of the State. All schools are subject to the supervision of Government inspectors, whose duty it also is to see that children of men of high rank, even when educated in their parents' house by private tutors or governesses, receive that education from thoroughly qualified persons. Consul Mulvany quotes a case in point, where the inspector insisted upon examining the tutor and the pupil, a boy of some six or seven years of age, as to proficiency. The elementary or preliminary period of education being completed, that is, in the working classes, the boys and girls apprenticed to qualified masters in any trade or business, the same have to attend the evening classes of technical *Fortbildungsschulen*, which now are compulsory; all branches of trade and industry are represented, and even in the higher classes this further education is brought within such easy reach of all that an important groundwork is formed to which in a great measure may be attributed the great strides made in industrial and commercial development. The higher class schools for general

education are *Real Schulen*, where chiefly modern languages and mathematics are taught to lads who are intended for technical and commercial life; and the *Gymnasium* where classics and that class of education is given to prepare for higher professions, such as the Church, the Army, Navy, and the Bar; these are State institutions, being public day schools. Very few boarding schools exist in the country, and they belong to private individuals. The fees of the public schools are extremely moderate, so that they are open to all comers who can pass the necessary school examination. On the school bench no distinction is made between the highest members of the aristocracy and the sons of even the lower middle-classes, so that the man of title later in life buys his shoes and stockings from a school companion who may have passed a better examination than he, and this in a country where the distinction of class is much more marked than in England. There is still a higher class of technical schools or colleges where students take diplomas for professions, for instance, in agriculture, forestry, viticulture, engineering in all its branches, and all of course under State supervision.—*Journal of the Society of Arts.*

BRITISH PHARMACEUTICAL CONFERENCE.

BELFAST MEETING, 1898.

LIST OF PAPERS TO BE READ.

1. "Albumin and Some Types of Proteid Digestion," by Gordon Sharpe, M.D. Edin.
2. "Gluten Flower and Its Analysis," by D. V. Fielden, L.P.S.I.
3. "Materia Medica Animals," by J. C. McWalter, L.R.C.S.I., etc.
4. "Salient Features of the Irish Flora," by G. C. Druce, M.A., F.L.S.
5. "Kiesulguhr," by John Moss, F.I.C., F.C.S.
6. "The Amount of Carbonic Anhydride Available in the Official Granular Effervescent Preparation," by C. S. Dyer, A.P.S.
7. Note on Eucalyptus Oil," by E. J. Parry, B.Sc., F.I.C.
8. "Notes on Concentrated Oil of Lemon," by T. H. W. Idris, F.C.S.
9. "Note on Extract of Ginger," by T. H. W. Idris, F.C.S.
10. "A Quick Polarimetric Method for the Estimation of Strophanthin in the B.P. Tincture and Extract," by Edward Dowzard, F.C.S.
11. "The Characters and Methods of Estimation of the Official Hypophosphites," by H. A. D. Jowett, D.Sc.
12. "Note on the Mydriatic Alkaloids," by H. A. D. Jowett, D.Sc.
13. "Pharmacists and the Pharmacopœia," by P. MacEwan, Ph.C., F.C.S.
14. "Galenic Pharmacy of the 1898 Pharmacopœia," by F. C. J. Bird.
15. "The Nomenclature of Certain Drugs of the Pharmacopœia," by G. C. Druce, M.A., F.L.S.
16. "The Chemistry of the Pharmacopœia," by P. Kelly.
17. "The Galenicals of the Pharmacopœia from a Wholesaler's Point of View," by H. Wippell Gadd.
18. "Notes on Estimation of Ferrum Redactum," by E. Saville Peck, B.A.
19. "The Pharmacopœia Chemically Considered," by A. L. Doran, L.P.S.I.
20. A Paper by J. C. Umney, F.C.S.
21. A Paper by W. A. H. Naylor and John J. Bryant.

Note.—The Hon. Secretary, Mr. W. A. H. Naylor, 38, Southwark Street, London, S.E., requests that all manuscripts of papers may be sent to him without delay, in order that the papers may be formally approved for presentation to the Conference and put in type. Proofs will then be supplied for the authors to correct and read from at Belfast.

THE PHARMACEUTICAL SOCIETY AND ITS PRESIDENTS.

HENRY SUGDEN EVANS.—1869-70.

AT the close of Sandford's six years' occupancy of the presidential chair, the then Vice-President, Henry Sugden Evans, was elected as his successor. As it happened, he was the first President of the Society chosen from the younger generation of examined pharmaceutical chemists. Born in 1830, and educated at Merchant Taylors' School, he was for some time connected with the well-known Liverpool firm, whose interests he afterwards represented in Canada. He was an active member of the Liverpool Chemists' Association from 1849 onward, and to that body, as well as to the British Pharmaceutical Conference, he communicated several scientific papers.

During the year 1869-70 the social and financial advancement of the Pharmaceutical Society was very marked, a large number of those who became registered as chemists and druggists under the Act of 1868 having joined as members. An even more promising feature was the great addition to the lists of registered apprentices and associates, whilst the Society's laboratory and lecture-hall were crowded. Nearly a hundred students entered for each of the courses of lectures, and the provision of increased laboratory accommodation was rendered an imperative necessity.

Already certain imperfections had been detected in the new Act, and a short amending Act had been passed with the object of removing a certain disability of medical men. The Council had also been busily engaged in considering an extension of the schedule of poisons, in drafting proposed regulations for the keeping and storing of poisons, and in preparing a Register of chemists and druggists. Speaking at the annual meeting on May 18, 1870, the President took an extremely, and what many would now consider an unduly, optimistic view of the position of affairs. Thus, he referred to the completeness with which the objects of the founders of the Society had been carried out, and continued: "We are now a united body. The whole of the Chemists and Druggists of Great Britain are united into one band; a system of pharmaceutical education has been perfected; the necessity for education has been legally recognised, and within the custody of this Society is the regulation and test of pharmaceutical education."

A battle royal was fought at this annual meeting over the President's motion that the Society should adopt the regulations as to the keeping, dispensing, and selling of poisons, drawn up by the Council. Mr. Evans urged that the necessity for such regulations had thoroughly imbued the House of Commons at the time the Pharmacy Act of 1868 was passed, and that—since the Council, as the result of a *quasi* compromise, had virtually undertaken to carry out the known intention of the Government and Parliament

in the matter of poisons—it was the duty of the Society to do that which Parliament had determined was necessary. He thought that failure to adopt any regulations would be construed by the Government as a deliberate rejection of the first principles upon which the Act was granted, and that the defect might subsequently be made good by the summary adoption by Parliament of regulations which would prove far more irksome than these which most acknowledged to be practical, while rejecting them because of imagined coercion. But the Society as represented at the meeting, apart from the Council, would have nothing to do with compulsory regulations, and the utmost concession that the Council could obtain in the matter was to secure that the consideration of the question should be referred to the incoming Council, which was to report to the next annual meeting.

Another important matter that cropped up on the same occasion was the question of co-operative trading, and the President was openly called upon by one insistent member to resign from the Society because a report was prevalent that he was very deeply implicated in the supply of drugs to certain stores. This was the first occasion upon which the stores difficulty was publicly referred to, and looking back upon the proceedings after the lapse of twenty-eight years, it is not difficult to imagine that the member who raised the question had a prophetic feeling of the trouble it was destined to bring upon the craft. A third point of interest at the same meeting was the proposition by the late G. F. Schacht that the members should urge upon the new Council the desirability of framing some scheme by which the resources of the Society available for educational purposes might be distributed generally over the country, rather than concentrated upon one

H. SUGDEN EVANS.

particular school. The proposition met with a large measure of support, the President remarking that the strongest argument in its favour was to be found in the fact that more than two-thirds of the young men who had recently passed the qualifying examination had received their education entirely in the provinces. Ultimately the motion was unanimously agreed to in the following modified form: "That this meeting is of opinion the means hitherto adopted by the Society to supply the educational wants of its members are no longer adequate to the necessities of the times; and it respectfully urges upon the new Council the desirability of considering some scheme by which the resources available for such purposes may be more generally distributed."

Throughout his career Mr. Evans was an earnest worker in various departments of science, especially in microscopy, in which he had obtained great proficiency. In his official capacity he attended the Second International Congress, held in Vienna, being the first official representative of the Society to attend a foreign gathering

of pharmacists. On retiring in 1884 from his business engagements at Montreal, he was appointed by the Dominion Government as Chief Public Analyst of Canada. He died February, 1886, in the fifty-fifth year of his age.

ADOLPHUS F. HASELDEN.—1871-73.

Mr. Sandford was again elected President for a brief space in 1870, but resigned from that position in April, 1871, consequent on the decision of the Council to present the proposed poison regulations to the next annual meeting with such alterations as would divest them of a compulsory character. At the Council meeting in May, therefore, the chair was taken by the Vice-President, Mr. Adolphus F. Haselden, who was immediately afterwards elected President. He was a pharmacist who rendered valuable assistance in his time, and was always a consistent supporter of the Society's operations. For many years he served on the Council, having been first chosen in 1859 to fill the vacancy caused by the death of Mr. Jacob Bell. As already mentioned, on the resignation of Mr. Sandford in 1871, he became President, which office he held until his retirement from the Council in 1873. Mr. Haselden was a frequent contributor to the *Pharmaceutical Journal*, now become a weekly publication, his papers bearing on practical subjects and matters of interest to the general community. In these numerous literary efforts he displayed much skill, investing his remarks with a certain play of fancy which rendered them acceptable; amongst them he endeavoured to solve the vexed question, "Are we progressing?" His uncompromising allegiance to the Society must not be unnoticed. Mr. Haselden justly prided himself on being a good Latin scholar, and in consequence of his classical attainments his services were in request in the Preliminary and such Council examinations as required this branch of knowledge.

At the annual meeting held a few days after Mr. Haselden's first election as President, the vexed question of the poison regulations was finally disposed of. After reading a threatening letter from the medical officer to the Privy Council, in which it was stated that the Privy Council thought it right to apprise the Pharmaceutical Council that, should no such regulations be submitted for approval after the annual meeting, the Privy Council would feel it to be its duty to endeavour to protect the public by proposing to Parliament further legislation, the President proposed that the draft regulations should be accepted for voluntary adoption, and that they should not be made compulsory. After a protracted and somewhat heated discussion it was decided to leave the question of poison regulations in the hands of the Council to deal with as it saw fit, and the fate of the regulations was thus decided.

Co-operative trading and proposed grants to provincial associations were the most exciting topics discussed on the second occasion that Mr. Haselden presided over an annual meeting of the Society, whilst the abrogation and alteration of some of the Society's bye-laws lent a passing interest to the proceedings at the close of another year. Otherwise the times were fairly quiet,

and the Society progressed slowly, carrying out its programme in a comparatively uneventful manner

Notice of Mr. Haselden's death was received on the very morning the Council was sitting, Wednesday, February 4, 1880. Several of those present testified most feelingly to his worth. The general opinion expressed was regret for the loss of a faithful Councillor and highly educated man.

THOMAS HYDE HILLS.—1873-76.

The house of John Bell and Co. was again called upon to furnish a head for the Pharmaceutical Society on Mr. Haselden's retirement. Mr. Thomas Hyde Hills was born May 27, 1815, and during the last ten years of his life he was comparatively unknown to the younger generation. For years, however, both in his official and private capacity, he faithfully pursued the course marked out by Jacob Bell, to whom in a double sense he had succeeded. He fulfilled his various public engagements with untiring assiduity, while he cultivated social amenities as part of the duties of his position. His presence at all pharmaceutical functions was invariable. Born at Maidstone, he was apprenticed for seven years at Brighton to Mr. Thorby, who himself came from the house in Oxford Street. Migrating to London to try his fortune in the metropolis he wandered up and down in search of a situation and found none, till finally he obtained a place as temporary assistant with John Bell. We have it from his own recital that it was at the express intervention of Jacob Bell that he was ultimately engaged as a regular assistant, having been beforehand twice refused. The two young men were thrown together as juniors, and thus a friendship was created which was only severed by death. Mr. Hills said, "I did all in my power to make myself useful to the firm, and, as far as might be, indispensable; but for that even my friend could not have carried his point."

So it happened that Mr. Hills became superintendent, and subsequently the head of a great establishment, with his name perpetuated in Hills Place, a

standing topographical memorial. John Bell died in 1849; Frederick John Bell, the younger son, had left; Mr. Hills then was admitted as a partner, and on the death of Mr. Jacob Bell, that gentleman bequeathed his share of the business to the companion of his youth. Mr. Hills was the first associate of the Society, but cannot be included among the Founders. He was elected to the Council in 1860, on which he served more than twenty years. He was Vice-President from 1863 to 1868; then Treasurer in the room of Daniel Bell Hanbury until 1873; and finally President until 1876. Thus a young associate rose to the place of highest honour, an example which may stimulate and encourage others.

We come now to a distinct phase of character; no one, not Jacob Bell himself, so wisely made the hospitalities of private life subservient to the direct advance of pharmacy. Whenever a conference was desired, political, medical, or scientific; whenever difficulties arising from misunderstanding or imperfect knowledge had to be smoothed away, his house was laid at the disposal of the

A. F. HASELDEN.

interested parties. The social element is a great power; no one used it with less ostentation and more beneficial influence than Thomas Hyde Hills. Blessed with a frank and kindly disposition, there was in him an utter absence of jealousy with regard to men who were successful and came to the front in the pharmaceutical or scientific world. With impulsive generosity he befriended young men at the outset of their career.

It will hardly be necessary to mention his liberality to the winners of the Pharmaceutical Society's medals, by a gift of books, the annual presentation of which preserves his memory. The Jacob Bell Memorial Scholarships and the British Pharmaceutical Conference were similarly endowed. He bequeathed a legacy of £1000 for the purpose of assisting or purchasing the election of orphans of members and associates of the Society who had been subscribing members to the Benevolent Fund for three years and upwards, to orphan schools or asylums. The friendship between Mr. Bell and Sir Edwin Landseer was continued by Mr. Hills, who in turn became the great artist's confidential adviser, companion, and financial agent. Time was when Mr. Hills was surrounded by men who were, or who became, famous in their several departments. The personal record of his life is the history of the rise of pharmacy. We can never form a really just estimate of the times by which we are immediately surrounded—men and events are too near for us to judge correctly. The past in an especial way is ours, and we may say with impartiality that the period which has just been sketched may live in the grateful recollection of the pharmacist of the present day. Mr. Hills died November 19, 1891.

During Mr. Hills' three years of office the stream of events flowed placidly on the whole, and nothing of primary importance occurred in connection with the history of the Society. Continued efforts were made, but without avail, to secure the exemption of chemists and druggists from service on juries, and steps were taken by the Council to alter the course and conduct of the educational establishment committed to its care, so as to bring it more strictly into accord with the altered circumstances of the Society. Although one of the objects for which the Society was founded was to promote pharmaceutical education, it was felt to be no part of its duty to defray the cost of educating young men coming into the trade. At the same time, it was considered desirable to give the fullest effect to the appliances for education existing in the Society's house, and to ensure the existence of a school at which students might obtain the necessary instruction under the professors who had hitherto so ably conducted the classes. Whilst, therefore, the outlay of the Society's funds on the School of Pharmacy was reduced to a definite annual charge, arrangements were made by which the Council still retained its controlling authority over the system of education pursued in the School.

Already a tendency had begun to manifest itself for the number of pharmaceutical chemist members to fall off, though associates and apprentices continually increased in numbers. A readjustment

of the subjects for the Minor and Major examinations was effected, and it was hoped that, in consequence of this, a larger proportion of candidates would proceed to the higher examination, but that hope was not realised. As a matter of fact, the recognition of the Minor as the qualifying examination was already beginning to make its influence felt, in the reduction in the number of those who aspired to higher rank in the Society.

A Sale of Food and Drugs Act was passed in which several suggestions by the Council of the Society were embodied; an attempt by the Government to alter the Poisons Schedule was defeated; the "patent" medicine licence was reduced to five shillings, uniformly throughout the country; and the insertion of a "reciprocity" clause in an Irish Pharmacy Bill was successfully opposed, on the ground that it would enable individuals to style themselves "pharmaceutical chemists" in Great Britain after passing a less stringent examination than the British Major examination.

Mr. Hills was the donor of the entire fund provided for the various prizes of books presented to the winners of the medals awarded each year to pharmaceutical chemists who were associates of the Society at the time of passing the Major examination, as well as those given to the holders of the Jacob Bell Memorial Scholarships. Moreover, by his will, he bequeathed to the Benevolent Fund of the Society the sum of one thousand pounds, with the condition that it was to be invested and the income therefrom applied for the purpose of assisting or purchasing the election to orphan schools or asylums of orphans of members and associates of the Society who had been subscribers to the Benevolent Fund. The following is an extract from the proceedings of the Council for November 2, 1892, giving the terms in which the Orphan Fund was formally established:—

That the legacy to the Benevolent Fund, bequeathed by the late Thomas Hyde Hills, be regarded as a nucleus of a fund to be known as the "Orphan Fund of the Pharmaceutical Society

(founded by Thomas Hyde Hills, 1891.)"

That donations and subscriptions be invited, and that donations be invested.

That the income derived from the invested capital and such portion of the subscriptions as the Council may deem desirable, be applied in the discretion of the President and Council of the Pharmaceutical Society of Great Britain for the purpose of assisting or purchasing the election of orphans of Members and Associates of the Society (who have been subscribers to the Benevolent Fund for three years and upwards) to Orphan Schools or Asylums.

That every application for assistance from the Fund be made in the manner directed by clause 7 of the Benevolent Fund Regulations at present in force, and be submitted to the Benevolent Fund Committee, who will, in due course, report to the Council.

That the right of selecting a child for admission into an Orphan School or Asylum be vested solely in the Council.

LONDON: SATURDAY, JULY 23, 1898.

PHARMACY ACTS AMENDMENT BILL.

THE third reading of this Bill, on the motion of the EARL OF HARDWICKE, came on in the House of Lords on Thursday afternoon, and at the moment of going to press we learn that in view of the circumstance that the Bill is intended only to affect the internal organisation of the Pharmaceutical Society, the LORD CHANCELLOR, though strongly impressed with the present unsatisfactory state of the law in regard to companies carrying on the business of chemists and druggists, has decided not to move the amendment standing in his name. The Bill was accordingly read a third time and passed.

A PHARMACEUTICAL CENTENARY.

THE number of pharmacies in this country which can claim to have existed for a hundred years is not great, and special interest, therefore, attaches to the fact that the present year is the centenary of the firm of JOHN BELL and Co., of Oxford Street, London, the present head of which is Mr. WALTER HILLS, President of the Pharmaceutical Society. The founder of the business was JOHN BELL, one of the early promoters of the Society, who, as related in the 'Progress of Pharmacy,' opened his shop in Oxford Street with a small capital and many doubts as to his means of making a business and keeping out of debt. On the first day his receipts amounted to ten shillings, but, in giving change, he was cheated out of half a guinea, "a result which so discouraged him that at night he would not light his lamps until a friendly neighbour came in and consoled him." Success came slowly but surely to the young pharmacist, and in a few years it became unnecessary for the shop-boy to find occupation at the back of the shop "in pounding a dusting-cloth in the bell-metal mortar in order to maintain a semblance of business activity, and at the same time to inform passers-by, through the ringing sound of the mortar, that physic was compounded there." That shop-boy, much advanced in years, is represented with his mortar in the illustration printed at page 84.

Twelve years after the business was started JACOB BELL was born, and in due course that eminent pharmacist became head of the firm, with THOMAS HYDE HILLS as a partner, and destined later to become sole proprietor. In the illustration at page 85, which shows the laboratory at a later stage, Mr. T. H. HILLS is seen standing in the background, to the left, faced by the late SAMUEL GALE, whose name is only one of the extensive list of prominent individuals in the ranks of pharmacy who have, during the past hundred years, been connected with the famous establishment in Oxford Street. That list includes the names of REDWOOD, BENTLEY, BARNARD, FRANCIS, and many others too numerous to men-

tion here. The present proprietor is, as stated above, Mr. WALTER HILLS, President of the Pharmaceutical Society, who is the third representative of the firm of JOHN BELL and Co. to preside over the destinies of that body. JACOB BELL was elected president four times, THOMAS HYDE HILLS three times, whilst their successor now occupies the presidential chair for the third occasion. From this and the foregoing facts it may be gathered, therefore, what a power the Oxford Street house has been in connection with the progress of pharmacy in Great Britain.

PROFESSIONAL MEN AND THE STATE.

IN an address recently delivered at the annual meeting of the Metropolitan Counties Branch of the British Medical Association, Dr. ROBERT FARQUHARSON, M.P., expressed satisfaction that the great medical corporations and the General Medical Council are beginning to press forward in public life, and that they are now being consulted by State departments in matters of hygiene and social legislation. Even the "vague and mysterious body which attracts some awe-stricken attention under the name of the Privy Council" is in occasional communication with the professional leaders, but in Dr. FARQUHARSON'S opinion the Local Government Board ought to be the head centre of everything that concerns public health. That department is, however, undermanned, its officials are underpaid, and its usefulness is seriously hindered by the comparatively subordinate position which it holds. "Why the Home Office, which regulates little more than law and order and factory legislation, should have a full-blown Secretary of State at its head, whilst the bureau to which is confided all our sanitary legislation, all water questions, and the whole of local government should merely rank alongside the Board of Agriculture and Dover House is an anomaly."

Turning next to the question of bringing professional influence to bear, Dr. FARQUHARSON puts in a claim for the British Medical Association as providing the most useful and practical machinery for organisation and educative influence and agitation when necessary. "Our constitution is broad and democratic; we appeal to a wide constituency, and we have planted in every corner of the United Kingdom centres of light and leading, which should illuminate, and instruct, and convince. Out of the 35,000 medical men in these islands nearly 18,000 belong to the Association, and our branches spread and ramify everywhere, from Caithness to India. What an organisation this is for concentrating and co-ordinating the great body of force and influence, which we might and do possess!" Whilst objecting to test questions, Dr. FARQUHARSON suggests that all can operate on the somewhat pliable minds of public men, and persuade them that we are not working for mere power or personal self-interest. This, it may be observed, applies to chemists no less than medical men, for by organised pressure we also can educate the public mind, and force well to the front the questions in which we, "as custodians of public health," are specially interested. In that way—and probably in that way only—can such questions be rendered generally intelligible or sufficiently prominent to attract the required amount of attention, giving them, as Dr. FARQUHARSON puts it, a chance of being picked out from among their competing rivals for early consideration and treatment. Each one can do something in the matter, and as there is much to be done for promoting the common interests of the craft, each one should do all he can individually and by co-operation with others.

ANNOTATIONS.

THE SALE OF POISONS is a subject that has already, for the time being, lost interest for the daily press, but the *Daily Chronicle*, referring to the Poisonous Substances Bill, which is among the massacred innocents for this session, comments on the fact that the *Pharmaceutical Journal* has published an instructive table of the deaths, during 1895 and 1896, by accident and suicide from various kinds of poison. On paper, observes the *Chronicle*, the restrictions placed on the sale of poisons by the Pharmacy Act of 1868 are rigid enough, but "it is a matter of everyday experience that they are evaded with the greatest ease." Presumably this statement refers to the evasions of the Act by joint-stock companies, photographic dealers who are not registered chemists, and other unqualified persons. Continuing, the *Chronicle* points out that in the case of the scheduled poisons alone the deaths amounted to no fewer than 861 in the two years, rather more than half the number being attributable to opium and its cognates and chloroform. "In the former class the suicides were responsible for about two-fifths of the total number of deaths. But it is among the unscheduled articles that the largest proportion of suicides is found, carbolic acid being responsible for no fewer than 224 fatal cases in 1895 and 163 in 1896, the accidental deaths from this cause numbering, curiously enough, 34 in each year. It is obvious, therefore, that the recommendation of the Pharmaceutical Council to add carbolic acid to the Schedule of the Act is one to be taken seriously into consideration. Carbolic acid is no doubt a valuable sanitary agent, but its unrestricted sale will clearly have to be stopped."

THE POISONOUS SUBSTANCES BILL may possibly never be heard of again, but if its untimely birth serves no other purpose, it has at least proved the means of bringing chemists and druggists together for the defence of their class, whilst affording an opportunity to convince legislators that the support or opposition of that class is not a thing to be despised. The letter from Mr. Jas. Cocks, in this week's issue, testifies to the fact that in the House of Commons considerable importance has been attached to the position recently taken up by the Pharmaceutical Society, and also that a marked effect was produced by the circular issued by the Council. Numerous communications have been received by the Editor from registered chemists who have approached their parliamentary representatives on the subject of the sale of poisons, and it is gratifying to find that in most cases extremely favourable replies have been received. Probably the chief difficulty that presents itself to members of Parliament in this connection is the red-herring of so-called "monopoly" that has been drawn across the path by adversely interested parties, and it behoves registered chemists to deal very carefully with this aspect of the matter.

THE IDEA OF MONOPOLY is rightly abhorrent to the average British mind, but when the term is associated with the sale of poisons, it is as much misapplied as it would be if applied to restriction of the practice of law or medicine. For the retailing of certain poisons has not been restricted to registered chemists with the idea of benefiting them, but solely and entirely in the public interest. The man in the street would naturally prefer that he should be able to procure anything and everything he requires, wherever and whenever he chose. But those responsible for the conduct of public affairs have found it desirable in many instances, for the public safety, to place some restrictions upon the freedom of action of individuals. Such was the case when the Pharmacy

Act of 1868 was passed, and chemists had the regulation of the sale of certain poisonous articles thrust upon them. Pharmacists did not desire the position and have never cared for it, but since the development of their business has been influenced to a marked extent by the manner in which the Legislature interpreted public necessities, they feel at the present time that acquiescence in a total change of policy would tend to influence their interests prejudicially. Whilst, therefore, the trade in scheduled poisons is not directly profitable to chemists and druggists, and only to a very limited extent indirectly, they ought to oppose strenuously any attempt to reverse a policy that has been proved to operate successfully in the public interest during the last thirty years.

PROBABLY THE BEST LETTER written to a Member of Parliament on the subject of the Poisonous Substances Bill was that sent by Mr. Archibald MacNaught, of Greenock, to Sir Thomas Sutherland, M.P. Without being unduly long, it contained an admirable summary of the whole case for chemists, and we only regret that space will not permit it to be printed in the Journal. A reply from Sir Thomas Sutherland, in which the "monopoly" difficulty was touched upon, educed a second letter as clear and convincing as the first, and we cordially congratulate Mr. MacNaught, not only upon his complete grasp of the subject, but also because of the felicitous way in which he has been able to explain the numerous points of difficulty.

"DRUG COMPANIES THREATENED" was the heading to a letter which appeared in the *Daily Mail* of Monday, in which the great British public was urged to sympathise with the shareholders in joint-stock companies who have invested their surplus funds in such a manner as to take the bread out of the mouths of chemists and druggists. This would-be alarmist begins by relating that a harmless Bill, styled the Pharmacy Acts Amendment Bill, came before the Grand Committee of the House of Lords last week, and passed through committee without amendment, but that, in response to suggestions, the Earl of Hardwicke, who has charge of the Bill, promised to draft a clause to add to the measure on the report stage, the effect of which would be to prevent companies from trading as pharmacists. This, the writer of the letter observes, is the only preparation for the introduction of a clause that would destroy the vested interests and confiscate the property of shareholders in drug companies. But why such shareholders should be permitted to claim vested interests in the effects of an oversight in drafting an Act of Parliament is not clear, and the writer of the letter is careful not to enlarge upon that point.

A REPLY PROMPTLY APPEARED in the same paper on Tuesday, when "A Qualified Man" insisted that the proposed clause would deal with what constitutes a grave danger to the public. As he observes, with good reason, it amounts to a scandal that seven unqualified persons should be allowed to associate together and do what it is illegal for a single unqualified person to do. The fact that a qualified manager is employed as cover is only an evasion of the law, as the majority of the employes are mostly unqualified. What, he asked, would happen if any seven tinkers were allowed to call themselves "The Metropolitan Doctors, Limited," and, while retaining a qualified medical man as cover, should employ unqualified assistants to attend patients? "Apart from the danger to the public, is it not a gross injustice to men who have been to the trouble and expense of qualifying that these companies, some of which do not pay five per cent. on their ordinary shares, should be allowed to take the bread out of our children's mouths?" In response to this reasonable appeal to the good sense of the public, Mr. Jesse Boot, of Nottingham, rushed in to the

rescue, beginning his insidious attack by complimenting the proprietors of the *Daily Mail* on their struggle with Messrs. Smith in connection with the *Harmsworth Magazine*. He says: "We are particularly interested because we have fought the battle of monopoly in our own trade and won, as you will do." After thus impudently claiming the drug trade as his own, he then proceeds to insinuate that there is something underhand in the fact that the Hon. W. F. D. Smith has acted as sponsor to the Pharmacy Acts Amendment Bill. In this case, as in the one previously referred to, the writer of the letter assumes that Parliament is likely to recognise vested interests in a successful attempt to take advantage of an oversight, but it would have been just as reasonable to acknowledge the existence of such interests in the case of the swarm of bees recently reported to have established themselves in a pillar letter-box. For a time the bees maintained their position, but in the end they were smoked out.

THE CLAUSE OBJECTED TO is equally objectionable to registered chemists, for, as drafted by the Lord Chancellor—not by the Earl of Hardwicke, as has been mistakenly assumed—it only proposes to legalise the existing condition of affairs. Thus, it states that: "A company may carry on the business of a pharmaceutical chemist or chemist and druggist if and so long only as the business is *bonâ fide* conducted by a manager or assistant being a duly registered pharmaceutical chemist or chemist and druggist, but, subject as aforesaid, Sections 1 and 15 of the Pharmacy Act, 1868, shall apply in the case of a company in like manner, as they apply in the case of an individual." The chief effect of this clause if it became law would be formally to recognise the right of companies to carry on business as chemists, whereas at present they are only enabled to do so by virtue of having been accidentally omitted from the operation of the Pharmacy Acts. It would also probably enable companies to be proceeded against in the case of breaches of the Pharmacy Act, 1868, by their employés. But inasmuch also as no machinery is provided for carrying out the intention of the clause it would remain practically inoperative, and there would be no greater protection for the public, so far as companies are concerned, than already exists, which is little enough, as our readers know. So far as the promoters of the present Bill are concerned, they disapprove of the proposed clause as it stands, and prefer that the Bill should continue to be, as originally intended, a non-contentious measure. Unfortunately, the reports of what took place in the House of Lords last week have encouraged baseless hopes in the minds of many registered chemists, but it would be idle to pretend that any satisfactory solution of the problem may be expected at present.

A SOMEWHAT SENSATIONAL NOTE in the *Lancet* of July 9, on the subject of dispensing by chemists, appears to us to have hardly been justified by the facts. In his report on the health of the city of Birmingham for the year 1897, Dr. Alfred Hill stated that fifty-two samples of medicine dispensed from prescriptions were obtained from "persons qualified under the Pharmacy Act," and that eleven of those were condemned. The *Lancet* quite unjustifiably informs its readers that all those samples were obtained from "qualified pharmaceutical chemists." As a matter of fact we have good reason for believing that not one of the eleven defective samples was obtained from a pharmaceutical chemist. But, unfortunately, in pharmacy as in medicine, a number of individuals have been able in time past to secure registration on altogether insufficient grounds, and Birmingham pharmacists are not free from the infliction of a certain proportion of such inefficients in their ranks. Moreover, despite the inevitable existence of a few

black sheep in pharmacy, the cases of professional misconduct amongst medical practitioners are far in excess of such cases proved against registered chemists, and it seems rather unfortunate that a journal which is rightly jealous of the reputation of the class for which it specially caters should give currency to inaccurate statements regarding the innocent members of another and closely allied class.

THE ELEVEN BIRMINGHAM CHEMISTS alleged by Dr. Hill to have supplied defective medicines are, of course, much to blame if the facts be as stated. The report does not distinguish between the samples obtained from chemists and those from unregistered persons, but four individuals appear to have erred by using too little or too much potassium iodide, one used the avoirdupois instead of the apothecaries ounce in weighing magnesium sulphate, one dispensed eighteen per cent. too much quinine sulphate, and another had allowed his sodium bromide to become too damp. None of the errors were at all serious, but their occurrence should nevertheless have been prevented, and it is to be hoped such incidents will not need to be reported in future. It may be suggested to the respectable chemists of Birmingham that they should take steps to secure the publication of full and complete reports of the city analyst in future. When errors are recorded in dispensing medical prescriptions the prescriptions should be published; but it is of even greater importance to the craft to have the offences charged against chemists carefully differentiated from those committed by the employés of joint-stock drug-stores and other unqualified persons. In connection with this matter, a correspondent has directed attention to an absurd paragraph headed "Chemists' Frauds (?)," in a paper which arrogates to itself the title of *Science Siftings*. The paragraph seems to have been instigated by the note in the *Lancet*, but such rubbishy productions as paragraphs from which the facts appear to have been carefully sifted, are not worth troubling about.

THE B.P. CONFERENCE PAPERS so far promised already exceed in number those read at Glasgow last year, and judging from the full programme arranged by our Ulster friends, it will be difficult to find time for any more to be considered at the Belfast meeting. It will be seen, on reference to the list printed at page 79, that several of the papers will deal with the new Pharmacopœia, and we understand that arrangements will probably be made to devote half a day to a general discussion on that subject. It has more than once been suggested that some topic of general interest should be brought up for discussion in this manner, and the new Pharmacopœia seems to suggest itself as a particularly suitable subject. If the experiment succeeds, the idea may subsequently develop in an interesting fashion. Meanwhile, however, it is of importance that the promised papers should be sent in without delay to the Hon. Secretary, Mr. W. A. H. Naylor, in order that they may be submitted to the Conference Executive, and, if approved, put in type prior to the meeting. We are also requested by Mr. R. W. McKnight to state that applications for tickets should be addressed to him at Carlisle Circus, Belfast, before August 1, as that will help the local Committee in completing the arrangements.

THE CHELSEA PHYSIC GARDEN, which has been maintained by the Society of Apothecaries since 1673, is now about to be abandoned by that somewhat decadent body, but it is satisfactory to note that the Garden will be preserved in the public interest. In the House of Commons, on Tuesday, Mr. Whitmore asked the honourable

Member for the Thirsk Division of Yorkshire, as a Charity Commissioner, whether he was aware that the Society of Apothecaries had resolved that it could no longer maintain the Physic Garden at Chelsea; and whether, in view of this decision, and in order to preserve this ancient garden, the Charity Commission would be willing to sanction its acquisition by the governing body of the City Parochial Charities and its subsequent maintenance by them as a botanical garden. In reply, Mr. Grant Lawson said the Society of Apothecaries, as trustees of the Physic Garden at Chelsea, have applied to the Charity Commissioners for the establishment of a scheme for the future administration of the trusts regulating the Garden, which is now maintained at the charge of their corporate funds, and they desire to be relieved from the trusteeship. The Commissioners have received from the trustees of the London Parochial Charities an offer to undertake the trusteeship of the Garden, and to make a provision for its maintenance for the purpose of botanical study, which appears to be sufficient for that purpose. The Commissioners accordingly propose to publish a scheme giving general effect to these proposals. It is worthy of note that the Garden was originally made over to the Society of Apothecaries on condition "that they should at all times be continued as a physic garden for the manifestation of the power and wisdom and goodness of God in creation, and that the apprentices might learn to distinguish good and useful herbs from hurtful ones." A second condition was that each year the Society should present to the Royal Society specimens of sixty new plants until their number reached two thousand.

BOTANICAL WORK WANTING WORKERS is the subject of a suggestive paper read by Mr. E. M. Holmes before the S. E. Union of Scientific Societies, and published in *Natural Science* for July. He points out that the field for investigation in botanical work is so extensive and increases so rapidly every year, as new discoveries open up new vistas of possible knowledge, that the title of his paper refers only to the flora of the county of Kent, as being the one with which he is most familiar, and as best serving his purpose, although the remarks made will probably apply with equal force to other counties. An examination of various county floras that have been published shows that the flowering plants have, as a rule, received much more attention than the cryptogams, and that in very few instances have adequate county lists of mosses, lichens, fungi, or algæ been published. Such as have appeared are usually imperfect in one or other of the groups, especially as regards dates and localities, the mosses and fungi being generally those best represented. It is, therefore, that branch of botanical work which specially needs workers, and to which Mr. Holmes wishes to direct particular attention. But other branches of botanical work to which attention might be directed are:—(1) The relation of the distribution of plants to water-sheds, geological formations, and chemical constituents of the soil, drainage, land carriage, agricultural seeds, and other causes; (2) the special means by which different mosses rarely found in fructification are propagated and distributed; (3) the rate of growth of different species of lichens; (4) the relation of *Hymenomycetes* and *Gasteromycetes* and other plants to the roots of special trees or plants; (5) the spread of parasitic fungi, injurious to plants, from wild plants to cultivated species of the same genus.

TERRESTRIAL CORONIUM has been detected by Professor Nasini, of Padua, amongst the gases emanating from the earth in Italy.

In the spectrum of the gases of Solfatara di Pozzuoli, which contain argon, a bright line was noted with the wave length 531.5, corresponding to that of 1474K, attributed to coronium, an element supposed to be lighter than hydrogen. Other lines observed were of wave-length 653.5, 595.5, 536.2. In the spectrum of gases gathered from the fumarole of Vesuvius, Professor Nasini and his assistants have observed the lines 769.5, 631.8, 572.5, 536.5, 441.5, and again 595.5. These lines do not all belong to the spectrum of argon or helium; they show a coincidence or proximity only with some unimportant lines of various elements, such as iron, potassium, and titanium. Considering the conditions of the experiments, the presence of these elements in the gases studied is not probable. The line 572.5 is near to one of nitrogen, but, being the only visible line of the spectrum of this gas, it cannot be attributed to it. Besides coronium there are thus probably other new elements in these gases. Commenting on the announcement of this discovery, the *Times* points out that this is an announcement of the highest interest from a scientific point of view, as at once confirming the results of spectroscopic examination of the sun and adding another proof of the substantial identity of materials in the sun and earth. Hitherto nothing has been known of the substance which produces the coronial line 1474K. It has not been observed anywhere in nature except in the corona, its supposed identity with the auroral line having long ago been disproved. The unknown substance appears now to have been found just where, if anywhere on earth, it might be expected—*i.e.*, in the gases from volcanoes, or the springs and minerals subject to volcanic action.

THE THIRD INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY will be held in Vienna from July 28 to August 2, and in the Section of Pharmaceutical Chemistry it is intended to discuss (1) a proposal to introduce into all pharmacopœias and supplements to pharmacopœias statements of the physical and chemical properties, and of the qualities requisite to establish the purity of substances; (2) a proposal to introduce for all countries not only uniform methods for the preparation of heroic remedies, but the employment of uniform standards to determine the potency of medicaments; (3) a proposal to introduce uniform methods of determining the amount of active substances contained in surgical dressings; (4) the nature of the analytical researches to be employed for estimating the value of new serum therapeutic preparations, and the precautions to be taken before such preparations are recognised as suitable for use in medical practice; and (5) the general qualities requisite in medicinal wines.

THE REGISTRATION OF TRADE MARKS is simplified by a decision of the House of Lords last week, which reverses the established practice of the Patent Office in regard to "fancy" words. The word "Solio" was objected to as a trade mark in connection with photographic goods, on account of its evident derivation from "Sol," but the House of Lords decided that the objection was too far-fetched. The immediate result of this decision will be to alter the entire practice of the Patent Office, so far as name words are concerned; and doubtless a very large number of invented words which have been refused as descriptive of the goods can now be registered. In recent years Section 64 of the Patents, Designs, and Trade Marks Act has been interpreted by the Comptroller and the Courts in an extremely limited sense, with the result that while applications for patents have greatly increased, those for trade marks have seriously diminished.

PHARMACEUTICAL SOCIETY.

EXAMINATIONS IN LONDON.

July, 1898.

MAJOR EXAMINATION.

Candidates examined	31
" failed	15
" passed	16

Dixon, William.	Hovenden, Sydney Churcher.
Ellis, Hugh Edward.	Jones, George Maurice.
Flemming, Thomas Henry.	Martindale, William Harrison.
Franklin, Arthur Cawte.	Merrickin, Sydney Herbert.
Gale, George Thomas.	Pick, Frank Phillips.
Garnett, John Benbow.	Rhead, Alfred.
Hart, Samuel Henry.	Smallwood, Frederick William.
Hodgson, John Edward.	Teale, John Oliver.

MINOR EXAMINATION.

Candidates examined	340
" failed	238
" passed	104

Barker, Henry John.	Kennard, Lillian Sarah.
Barrett, Thomas Edward.	Kesterton, Walter.
Battle, John Cyril Marfeet.	Kieft, Edward James.
Bennett, Charles Thomas.	Lacey, Richard Samuel.
Bennett, William Chaplin.	Lanc, George.
Benzie, Robert.	Lane, Harry Richard.
Blore, Moulton.	Legg, Harold Beaumont.
Bould, Frederick Ewart.	Lescher, Thomas Edward.
Brian, Ernest.	Lycett, Herbert.
Brookes, Alfred.	McRostie, James.
Bunting, Sydney.	Magnay, William.
Burdon, James Rowland.	Maidment, Harold Harding.
Burridge, Archibald Edger.	Meyler, Thomas.
Calvert, William Eggleston.	Moore, Kate Lillian.
Carr, Charles Frederick.	Morris, Gerald Arthur.
Chambers, Ernest James.	Morrish, Charles Henry.
Chapman, Alexander Sterling Brice.	Mosley, William Francis.
Chatburn, Edwin Jordan.	Nicol, Alexander William Rendall.
Churchill, Arthur Henry.	Nundy, William Lockwood.
Collins, Clifford.	Nunn, Ernest Albert.
Crawford, Ernest.	Parry, Idwal.
Cruse, Thomas Edward Castell.	Paterson, George Frederick.
Dance, James George.	Payne, Herbert.
Darroll, John Walter.	Prescott, Wilfred Egerton Peter.
Dawson, Dan.	Quibell, John William.
Elbourne, Ernest Gilbert.	Rawling, Joshua.
Ellis, Frederick John.	Richardson, James Alfred.
Evans, John.	Roberts, John Lloyd.
Farr, Minnie.	Robertson, Sidney.
Fenn, George.	Rolfe, John Thurlow Twaites.
Frank, John William.	Rouse, William Henry Broom.
Freke, Alice.	Sales, Charles Henry.
Garland, Alfred Harry.	Saltmarsh, Alice Isabella.
George, William Blissett.	Sarjeant, Herbert William.
George, William Foxton.	Sayers, Stephen Percy.
Glaister, Robert.	Selby, Horace Walter.
Gould, Sydney Hartforth.	Sencicle, Fred.
Gray, William.	Sinnett, William.
Green, William Baker.	Smith, Henry Llewellyn.
Harmer, John Daniel.	Smith, James.
Haydon, Arthur Henry.	Spurway, William James.
Hughes, Edward Davies.	Stovin, John.
Inch, Jedediah Paul.	Sykes, Henry Vincent.
James, Ernest Owen.	Tanner, William Edward.
Johns, Aneurin Vaughan.	Thompson, George Pinder.
Jones, Thomas Stephen.	Turner, Alfred William.
Jones, Thomas William.	Vallet, Cyril Edward Franklin.
Keeton, Percy.	Walker, Martin Pybus.

Wallace, William Henry.
Wallis, Thomas Edward.
Wathes, Arthur.
White, Robert Shoebridge.

Whithead, Herbert Joseph.
Whiting, William.
Wild, Thomas Jabez.
Wooldridge, Thomas.

FIRST EXAMINATION.

Certificates by approved examining bodies were received from the undermentioned in lieu of the Society's Examination:—

Alexander, George; Waterloo.	James, Alexander; Hornsea.
Asquith, David Warner; Nuneaton.	Lewis, Llewelyn; Swansea.
Bennett, Reginald Robert; Dover.	Mansbridge, William Alfred; Bristol.
Burgis, William Gaisford; Hampstead.	Marchant, Walter S.; Hereford.
Corke, Herbert Edward; Woolston.	Ness, Alfred; Kennington.
Dale, William A.; Marske.	Oxley, Harry; Edinburgh.
Furness, Sydney Edward; Clerkenwell.	Pearce, Rosa Adeline G.; Cainscross.
Gaubert, Percival S.; Wembley.	Ridyard, Clement W.; Kennington.
Hallam, Isaac; Melton Mowbray.	Scott, Samuel; Barrow in Furness.
Harris, Percy; Erdington.	Seaber, Charles William; Aldershot.
Hirst, Alfred Norman; Manchester.	Sharpley, Major; Market Rasen.
Hughes, Harry; Leicester.	Sillitoe, Harry Archibald; Ipswich.
	Webster, Richard R.; Edinburgh.

COUNCIL PRIZES EXAMINATION QUESTIONS.

CHEMISTRY.

July 19, 1898.—2 till 5 p.m.

1. What is meant by the periodic law? Write an account of it and show the advantages it possesses in the study of chemistry, and also the cases in which it seems to fail as far as our present knowledge extends.
2. Give a general statement of the action of non-metallic elements on the alkaline hydrates, and show how any apparent exception may be reconciled with the general statement.
3. What processes are employed for the manufacture of the alkali metals, and of their hydrates and carbonates?
4. Give a short description of the varieties of carbon. State how far they can be transformed into one another, and describe a chemical test which may be used to identify the principal varieties.

MATERIA MEDICA.

11.30 a.m. to 1 p.m.

1. State the botanical source and the mode of production of Scammony, Asa-fetida, Guaiacum Resin, and Kino.
2. How would you detect the presence of Galbanum in Ammoniacum, Paraffin in White Beeswax, Cotton Seed Oil in Olive oil?
3. By what means would you estimate approximately the quality of Oil of Eucalyptus, Oil of Peppermint, and Copaiba?
4. State what you know about Benzoin; its botanical and geographical sources, its varieties and their constituents. How would you determine the value of a sample for medicinal and for general use respectively?

BOTANY.

10 a.m. to 11.30 a.m.

1. Enumerate and briefly explain the various methods of reproduction known to you amongst Thallophyta and Bryophyta.
2. Describe the anatomical structure of a foliage leaf; and explain clearly how this structure is adapted to the adequate performance of the functions of transpiration and assimilation.
3. Give a complete history of the leafy shoot of any deciduous tree from its origin in the spring from the winter bud up to the time when it loses its leaves in autumn.
4. Sketch briefly the variations in morphological structure in either the Leguminosae or Euphorbiaceae, and show how these variations are adapted to special conditions of climate and environment. Briefly indicate the nature of the floral parts in the Euphorbiaceae.

PHARMACEUTICAL TRANSACTIONS.

EXETER ASSOCIATION OF CHEMISTS AND DRUGGISTS.

A special meeting of the members of the Exeter Association of Chemists and Druggists was held at the Albert Memorial Museum, Queen Street, Exeter, last week, to consider what action should be taken with regard to

The Poisonous Substances Bill.

The President (Mr. D. Reid) occupied the chair, and Mr. J. HINTON LAKE (Vice-President of the Association and local secretary of the Pharmaceutical Society) briefly introduced the subject for discussion. He expressed the opinion that some action should be taken by the Association in the matter.

The PRESIDENT said he had received a letter from Mr. G. Stocker, who had communicated with the Hon. Sir Stafford Northcote, Bart., C.B., M.P. (the member for the city, who recently received a deputation from the Association on the Pharmacy Acts Amendment Bill), on the same subject. Mr. Stocker had received the following reply from Sir Stafford Northcote's private secretary:—

25, St. James's Place, S.W.

July 11, 1898.

Dear Sir,—Sir Stafford Northcote wishes me to acknowledge your letter and say that he notes what you say, but no fresh contentious measures are likely to be proceeded with this session.

Believe me, yours truly,

G. W. MARRIOTT.

Mr. G. Stocker.

Continuing, the President said he took it that the members of the Association were all of one mind as regarded the Poisonous Substances Bill. So far as he could make out, the chemists of Exeter were all dead against it. Of course, the Bill was what was called "slaughtered," so far as the present session was concerned. It, however, would be passed on with others until another session. Therefore, the Association would have to be prepared to take action when it came up then, because there was every reason to believe that a Bill brought forward by such a statesman as the Duke of Devonshire would not be allowed to rest. He thought some very strong opposition should be brought to bear on the matter. He had a conversation with Alderman Gadd, J.P., on the Bill the previous day, and he asked him to say that he had another engagement that day and could not be present at that meeting. If it had been necessary to take immediate action he would certainly have cancelled his other engagement and attended their meeting, but as there was no need for immediate action he asked him to apologise for his absence. His (Mr. Gadd's) idea was that they should simply pass a resolution and send it up to Sir Stafford Northcote, M.P., asking the hon. baronet to give the members an opportunity of allowing a deputation to wait upon him and explain matters to him, in order to ascertain his views before the next session of Parliament.—Mr. J. H. LAKE concurred with the suggestion, and the PRESIDENT said that would be the best course, seeing that there was no chance of the Bill passing into law during the present session. He thought that whether they decided to ask Sir Stafford Northcote to receive a deputation or not, they, as an Association, should pass a resolution stating what their views were on the measure. They ought to condemn the Bill *in toto*.—The PRESIDENT: Decidedly *in toto*.—Mr. LAKE said that was the first thing the Association should do, and he therefore would propose the following motion, if it met the wishes of the members:—

That this meeting of members of the Exeter Association of Chemists and Druggists is of opinion that the introduction of the Poisonous Substances Bill is both unnecessary and dangerous to the public safety, inasmuch as by the Pharmacy Act suitable trained persons are already provided (who possess an intimate knowledge of the nature and use of poisons) for the purpose of distributing those substances. The fact that registered chemists and druggists often refuse to sell poisons at their discretion should be regarded as ample proof of the necessity for some safeguard being adopted for the public safety other than simply attaching a "Poison" label to the poison sold by an unqualified person. In effect the Poisonous Substances Bill stultifies the Pharmacy Act, inasmuch as the discretion of the vendor, which has been hitherto very effective in the case of the pharmacist, is utterly ignored. This Bill should, in the interest of the public, be most strenuously opposed.

Mr. P. F. ROWSELL (Hon. Secretary), for the purpose of discussion, questioned the advisability of inserting the words "is both unnecessary and dangerous to the public safety" into the motion, because whilst he agreed with the principle embodied, looking at it from a general public point of view it would be safer

than things were at present to have the Poisonous Substances Bill, although it was not desirable from a chemist's point of view.—Mr. LAKE said he did not think that the safety of the public would be enhanced by such a Bill. At present the sale of scheduled poisons was in the hands of qualified men, and if the Bill was passed they would be giving the unqualified men greater powers in the sale of the unscheduled poisons.—Mr. ROWSELL pointed out that such poisons as spirits of salts and carbolic acid could be sold by unqualified men in half-pint jugs at present.—The PRESIDENT said he understood that Mr. Rowsell meant that it would be safer for the public to have carbolic acid labelled in an oil-shop, and such places where it could be obtained from unqualified men, than not to have the carbolic acid labelled at all.—Mr. ROWSELL said that such gentlemen as the Duke of Devonshire and Sir Stafford Northcote would look at the question from the point of view of the safety of the general public.—Mr. MILTON said he quite agreed with Mr. Lake's motion. The question was whether it was not dangerous to hand over the sale of these poisons to persons who know nothing about them.—Mr. ROWSELL pointed out that it was not a case of handing over the sale to unqualified persons. It was in the hands of those persons at present. He believed they could get at an oil-shop any of the substances mentioned in the new Bill.—Mr. LAKE, referring to vermin poisons, said he often refused to sell these poisons.—The PRESIDENT: I think we all refuse to sell them.—Mr. W. F. PEARCE said nobody would sell phosphor paste; and in the course of further discussion it was thought that the poison should be added to the list of scheduled poisons.—Mr. LAKE said some gentleman should propose a resolution to the effect that the list of scheduled poisons should be increased by the addition of a number of other articles.—The PRESIDENT: I think myself what we want to do at the present time is not so much to say what we want as to oppose this Bill, and do our part to try and prevent it becoming law. Having regard to the nature of the discussion in the House of Commons when our Bill passed through the other day, we might, at some future time, have a thorough good Poisons Bill. What we want to do at the present time is to clear the ground of all this tinkering business, and not show our hands as regards what we do want, and then when the time comes for concerted action we can get together a thoroughly good Poisons Bill. We ought not to mix matters up at the present time.—Mr. MILTON remarked that he thought Mr. Lake's proposition met the case admirably.—Mr. ROWSELL said Mr. Lake's motion undoubtedly met the case from a chemist's standpoint, and he found that the first part was qualified by the second part. His desire was that it should not be misinterpreted.—There was a general consensus of opinion that the present Bill stultified the Pharmacy Act.—Mr. ROWSELL said that after the discussion that had taken place he would second the motion.—Mr. MILTON and Mr. PEARCE supported the resolution, which was carried unanimously.—The PRESIDENT suggested that a resolution should now be passed to the effect that Sir Stafford Northcote, M.P., be asked to give a deputation from the Association an opportunity of fully explaining their views on the subject at some convenient time when he was in Exeter before the next session of Parliament, with the object of his opposing the measure when it came before the House of Commons.—Mr. LAKE thought that a resolution of that kind would confirm the resolution the meeting had already passed.—Mr. ROWSELL said they might add the suggested resolution to the previous one.—The PRESIDENT said he would move that copies of Mr. Lake's resolution be forwarded to the Pharmaceutical Society, and also to Sir Stafford Northcote, asking him to give a deputation a personal interview before the next session.—Mr. ROWSELL reported that he had received a communication from the Pharmaceutical Society enclosing a copy of the Bill and a circular letter signed by Mr. Walter Hills, as President, who urged that steps should be taken to prevent the Bill becoming law; also a pamphlet setting forth reasons against the Bill, and he (Mr. Rowsell) thought that the Association might use the following paragraph as a strong argument why the Bill should be opposed. "Labelling alone is practically worthless as a safeguard against accidental poisoning, and, in fact, a too general use of the word 'poison' is more likely than not to defeat its own end, and the warning it is intended to convey would probably be weakened in efficacy by too great familiarity. The safety of the public lies chiefly in the competency of the vendor, and not in the wording of a label. The Poisonous Substances Bill does nothing to ensure real security."—He suggested that a copy of the "reasons"

should be forwarded to Sir Stafford Northcote with the resolution.—Several members thought the idea a good one.—Mr. LAKE agreed with previous speakers that it was necessary that they, as an Association, should take some action independent of the Pharmaceutical Society, because they were not entirely led by that Society. If they sent the Society's circular alone it would look as if they were following upon lines which had already been cut and dried for them. It would therefore be advisable to let the resolutions being passed by that meeting go together with the Society's circular.—The PRESIDENT remarked that evidently Mr. Stocker had written to Sir Stafford Northcote after seeing what action the Pharmaceutical Society was taking in the matter. It, however, was necessary that some concerted action should be taken for the moment to carry much weight.—Mr. LAKE said the interview they recently had with Sir Stafford Northcote with reference to the Pharmacy Bill carried very great weight indeed.—Mr. ROWSELL expressed his belief that copies of the report of that interview were sent to many members of Parliament by local chemists in different parts of the country.—Mr. LAKE said he knew for a fact that Sir Stafford Northcote exercised his influence amongst his friends.—The PRESIDENT observed that whatever action they took must be concerted action for it to be of any use.—Mr. ROWSELL thought that by concerted action they would gain very much more than by independent action.—It was eventually resolved that copies of Mr. Lake's resolution and the Pharmaceutical Society's pamphlet be sent to Sir Stafford Northcote, with a request that he would give the interview desired, and also that a copy of the resolution be forwarded to the Pharmaceutical Society.—Mr. ROWSELL then brought forward the question of

Proprietary Articles Containing Poison.

—Mr. MILTON said the subject was an important one, and should not be discussed until notice had been given. Personally he saw no objection. As the subject was in the hands of the chemists he did not see any reason why it should not be protected.—It was decided to consider the question at a future meeting.—Mr. W. F. PEARCE brought forward the question of

Early Closing.

He suggested whether the chemists could not adopt Wednesday as an early closing day.—The PRESIDENT: It is a very mixed question.—Mr. MILTON: I had quite enough of early closing on the last occasion.—Mr. LAKE: My experience has been anything but favourable.—Mr. MILTON: I should never do it again.—Mr. LAKE: Nor I. I would not close on any consideration.—Mr. ROWSELL said he found that early closing was worse than keeping open.—Mr. REID remarked that they were nearly worked to death before 8 o'clock on an early closing day, and it was a considerable strain.—Mr. LAKE said it afforded an excellent opportunity for smaller towns to have a dig at them. When the last early closing movement was being carried out, he had several broad hints from his customers on the subject.—Mr. MILTON said the movement would not be successful unless they had one recognised early closing day. In Exeter there were two early closing days a week.—Mr. ROWSELL suggested whether the chemists could not agree to close earlier of an evening, but several members replied that they were in the habit of closing about eight o'clock of an evening, although there were some who kept open until late. It was pointed out that a chemist desirous of closing at eight o'clock was placed at a disadvantage when in business near another chemist who kept open late because he was obliged to keep open later.—Mr. PEARCE remarked that the chemists of Kingston-on-Thames were in the habit of closing from two to six but the members were of opinion that that would not answer in Exeter.—Mr. MILTON said his assistants had instructions to keep open until eight, and he found that they did not lose much time. The subject was eventually dropped without any action being decided upon. Other matters connected with the trade were discussed, and the meeting closed with a vote of thanks to the Chairman for presiding.

HALIFAX AND DISTRICT CHEMISTS' ASSOCIATION.

A meeting of this Association was held on Thursday evening, July 14, at the Old Cock Hotel, Mr. SWIRE, Vice-President, in the chair.—The President, Mr. G. M. Cobb, sent a letter of apology, regretting his unavoidable absence.—The Hon. Secretary, Mr. H. C. BRIERLEY, said that a letter of

condolence had been sent from the Association to Mr. Farr, one of the oldest members, sympathising with him in his severe illness. A courteous reply had been received from Mr. Farr's daughter.—The Secretary of "Camwal" had written to say that all syphons from their Harrogate factory would in future have the name engraved on the glass.—The HON. SECRETARY then read two letters from the local M.P.'s, with reference to the Poisonous Substances Bill. He had informed them that it was the wish of the Halifax chemists that they should if possible oppose the Bill.—In reply, Mr. ALFRED ARNOLD, M.P., said he had carefully read the circular sent to him, and he should be glad to support the views contained therein.—Mr. ALFRED BILLSON, M.P., said he would look carefully into the matter, and that he was impressed with the statement of the case put before him, it seemed to be reasonable and wise, and he hoped to be able to give his vote on the Bill, if it came up, in accordance with them.—These replies were considered very satisfactory.

NOTTINGHAM AND NOTTS. CHEMISTS' ASSOCIATION.

A meeting of this Association was held on Friday evening, July 15, for the purpose of considering a resolution on the

Poisonous Substances Bill.

In the absence from home of the President, Mr. Richard Fitzhugh, the chair was occupied by the VICE-PRESIDENT, Mr. E. Gascoyne.—Mr. GASCOYNE, in introducing the subject to the meeting, said it required but few words from him, as every member of the Association was undoubtedly well informed on the matter. He believed that all of them were thoroughly opposed to the whole Bill, as being nothing but retrograde in character and a distinct violation of the words of the preamble of the Pharmacy Act, which read: "For the safety of the public," etc. He would, therefore, call upon Mr. Eberlin, the Secretary, to propose the following:—

That this meeting of the Nottingham and Notts. Chemists' Association resolves to oppose the "Poisonous Substances Bill" now before Parliament on the ground that it is subversive of the principles on which the Legislature has decided that the regulation of the sale of and dispensing of poisons should be conducted for the safety of the public, and instructs its Secretary to forward a copy of this resolution to each Member of Parliament for the city and county.

—Mr. LUMBY seconded the motion, which was carried unanimously.—The SECRETARY announced that he had received no less than twenty-six proxy votes in support of the resolution. Mr. Eberlin also read letters which had been received from Mr. J. H. Yoxhall, M.P. for West Nottingham; Lord Henry Bentinck, M.P. for South Nottingham; and Mr. J. Carvell Williams, M.P. for the Mansfield division, promising to give the matter their closest attention should it be necessary.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.

The quarterly meeting of this Association was held on Wednesday, July 13. Mr. JAS. COCKS presided, and a large attendance included Messrs. C. J. Park, C. T. Weary, G. Breeze, H. D. Davey, P. A. Kelly, J. R. Johnson, J. D. Turney, O. A. Reade, F. W. Hunt, Morgan, J. W. B. Swainson, F. Maitland, etc. Messrs. C. J. Park and J. D. Turney were elected delegates to the British Pharmaceutical Conference at Belfast. Mr. J. D. TURNEY (Chairman of the Educational Committee) then distributed the prizes gained by the students at the recent examinations, as follows:—Pharmacy, 1st prize (presented by Mr. Jas. Cocks), H. Vibert; Materia Medica, 1st prize (presented by Mr. J. K. Bond), A. Downing; 2nd in both subjects (presented by Mr. R. F. Roper), W. Hellyer. Mr. Turney said he wished to congratulate the winner of the Herbarium Silver Medal, who was a member of Mr. Reade's class, he considered that the success was to a large extent due to the painstaking efforts which Mr. Reade had always displayed towards members of his class. With regard to the materia medica and pharmacy examinations, the papers sent in showed that the students had a thorough grasp of the respective subjects.—Mr. HELLYER proposed, and Mr. REYNOLDS seconded, a vote of thanks to Messrs. Turney, Reade, and Johnson, which was heartily carried.—Messrs. Reade and Johnson were unanimously elected nominees of the Association as teachers in pharmaceutical subjects at the Technical Schools.—Mr. COCKS referred to the approaching departure of Mr. Cantle for America, and it was unanimously resolved that the Secretary should write to Mr. Cantle expressing the regret of the Association at losing such a worthy member.

MEDICAL JOTTINGS.

MR. ERNEST HART'S SERVICES to the British Medical Association are to be commemorated by the foundation of a scholarship, which is to be endowed for the study of preventive medicine. It will be of the annual value of £200, and tenable for two years.

BARON HENRY DE ROTHSCHILD, a cadet of the Paris branch of the celebrated family of bankers, has recently passed his examination for the degree of Doctor of Medicine. His thesis was on the subject of Infant Feeding, and has been awarded the silver medal by the Academy of Medicine.

THE BRITISH MEDICAL ASSOCIATION has purchased from the Sutton trustees the freehold of the property held on lease by the Association, namely, the corner house, No. 429, Strand, and Nos. 2, 3, 4, and 5, Agar Street, covering 4352 superficial feet. The purchase money was £79,000, of which £41,000 was paid in cash and £38,000 remains on mortgage for ten years at 3 per cent. interest.

SIR WILLIAM BROADBENT, M.D., F.R.S., who since 1893 has been Physician in Ordinary to the Prince of Wales, has just been appointed Physician Extraordinary to the Queen in succession to the late Sir Richard Quain. It will be remembered that Dr. Broadbent, as he then was, attended the late Duke of Clarence in his last illness.

A RECENT NUMBER of the *Lancet* contains an interesting contribution on the sanitary institutions of Madrid. It includes a description of the Provincial Hospital, founded in 1587. This institution contains 1000 beds, and about 14,000 in-patients are received in the course of the year. It is very old, badly situated, and not built according to modern principles of hygiene, though in spite of these defects, epidemics do not spread within the hospital. During the last outbreak of smallpox in Madrid, many patients suffering from this disease were admitted, yet no one in the hospital caught the complaint. The hospital is kept scrupulously clean, but this is scarcely sufficient to atone for the defects of construction. There is one explanation given for this immunity. The hospital was built in days of wealth and luxurious extravagance, therefore to insure solidity the walls were made no less than six feet thick. As a consequence, it is said the wards remain unaffected by the heat of summer or the cold of winter. It is not necessary to light fires. The heat of the summer, stored in the thickness of the walls, reaches the wards by the time the winter comes on, and the walls have barely lost their heat when it is renewed by the returning spring. When sewage is thrown on the land the water, if gathered two yards below the surface, is found to be perfectly pure, and the walls of the Madrid Hospital are six feet thick. Would six feet of masonry have the same action as the soil of a well-organised sewage farm?

THE NEWLY-INSTITUTED Chair of Public Health in the University of Edinburgh has been filled by the appointment of Dr. Charles Hunter Stewart. He is forty-three years of age, and has had a distinguished career as a student in the University of which he has now become a professor. With Sir Douglas MacLagan he undertook in 1884 the organisation of the Public Health Laboratory, and since then has held a number of appointments in Edinburgh University. He has also devoted himself to original research in subjects connected with public health, and has studied in the laboratories of Munich and Amsterdam, and also at the Pasteur Institute in Paris.

SIR WILLIAM MACCORMAC, who was called in to attend the Prince of Wales after his accident, has just been re-elected President of the Royal College of Surgeons. Sir William was surgeon in charge of the Anglo-American Ambulance during the Franco-German war in 1870, and was present at the battle of Sedan. He has been the recipient of several foreign decorations. His contributions to surgical literature comprise several monographs and articles in well-known text-books, but his 'Notes and Recollections of an Ambulance Surgeon' was written for a wider circle of readers, and has been translated into German, French, Dutch, Spanish, Italian, and Japanese.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London, W.C., and not in any case to individuals supposed to be connected with the Editorial Staff; no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ADVERTISEMENTS AND ORDERS for copies of the 'PHARMACEUTICAL JOURNAL' must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C. Cheques and money orders should be made payable to "Street Brothers."

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the Editor will be replied to in the Journal as early as possible after receipt, though not necessarily in the next issue. Replies cannot be sent by post, even though stamped envelopes accompany the queries.

LETTERS TO THE EDITOR.

POISONOUS SUBSTANCES BILL.

Sir,—Having written to Mr. Thos. Burt, M.P. (Member for the borough of Morpeth), drawing his attention to the "Poisonous Substances Bill," at the same time pointing out to him the injustice it would be doing to us qualified chemists and druggists by its becoming law, I asked him to oppose its progress through the House of Commons. I also enclosed the copy of "Reasons Against the Bill," sent to me by the Pharmaceutical Society. I herewith enclose a copy of the reply received from him.

JAMES WHITTLE.

Morpeth, July 19th, 1898.

[COPY]

House of Commons,
July 18, 1898.

POISONOUS SUBSTANCES BILL.

My dear Sir,—I beg to acknowledge yours enclosing printed matter, all of which I have carefully read.

I shall be glad to give every attention to the subject when it comes before the House of Commons.

Very truly yours,
THOS. BURT.

Sir,—In answer to my request to our Member of Parliament (Alfred Baldwin, Esq., M.P. for the Bewdley division of Worcestershire), I received a courteous and favourable reply and opinion against the Bill. I beg to suggest for consideration the advisability of keeping, if possible, a record of opinions received from M.P.'s in answer to the applications of chemists to their respective Members of Parliament. I believe the Society has made several recommendations to the Privy Council to have carbolic acid scheduled. I think these and the refusals of the Privy Council to entertain them have never been sufficiently noticed by the press, and only inadequately brought to the notice of the general public, hence the unfounded charge against the Pharmaceutical Society of apathy and indifference to the matter.

Gt. Witley, July 19, 1898.

JOHN TWINBERROW, Ph.C.

LIQUOR STRYCHNINÆ HYDROCHLORIDI.

Sir,—The 1885 B.P. statement that the strength of the so-called 1 per cent. solutions was "about 1 in 100" has been corrected in the 1898 B.P., under the able published statement on the subject by Mr. C. A. Macpherson, to 1 gramme in 110 minims, i.e., an almost true volume percentage, water at 62° F. being the standard volume. Presuming that Mr. Martindale was well acquainted with that paper, I did not specially direct his attention to it, but I beg respectfully to do so now ([3], vol. xix., page 433, date December 1, 1888, *Pharmaceutical Journal*). "Near enough" is not a term that I should apply to any of the potent preparations of the B.P., because the most exact language attainable should invariably

be used in such a case and for this subject; I submit that it will be found in my note (*Pharmaceutical Journal*, June 25, 1898, page 587) and my letter (*Pharmaceutical Journal*, July 9, page 43). Permit me to add that this controversy has not arisen through straining at a gnat, because my conclusion, which I take it Mr. Martindale now admits, was that the 1898 solution was 20 per cent. weaker than the 1885; his original finding published with all the authority and influence of his 'Extra Pharmacopœia,' that it was 10 per cent. weaker—a difference which in potent preparations is very appreciable.

Edinburgh, July 18, 1898.

GEORGE LUNAN.

THE STRENGTH OF CHEMISTS IN PARLIAMENT.

Sir,—As one of a deputation that waited on Mr. Mendl, M.P. (who I am glad to say has been a strong supporter of the Pharmacy Acts Amendment Bill), *re* the Government Poisonous Substances Bill, I was particularly pleased with his final remark that concluded our interview, that was, "you chemists must be wonderfully well organised, as I found when there was a likelihood of the Bill coming on the majority of members had one of those papers in their hands" (alluding to those sent out by the Society). He also spoke of the great activity shown by our worthy President, Mr. Hills, which I thought was very comforting for the future, and a precedent which I hope will be followed should it at any time become necessary.

Stonehouse, Devon, July 15, 1898.

JAS. COCKS.

IS THE SALE OF POISONS A MONOPOLY?

Sir,—I observe in your "Annotations" a rebuke administered to chemists who think they are entitled to a monopoly. I do not know whether I am one of the recent letter writers to whom you refer, but it is certain that I have upon several occasions pointed out to the best of my ability that the general community never can get the best services of pharmacy so long as unqualified men are allowed the same privileges as qualified men. I never said that we were entitled to a monopoly, because we had been good enough to pass examinations, or that we claimed a monopoly as a reward for passing examinations. Such talk is only childish. The State has enacted certain laws, entirely in its own interests, by which it secures itself against the risks of unqualified men dealing in certain poisonous drugs, the nature and character of which they have an insufficient knowledge of. Can it therefore be said to be in the interest of the State that unqualified men should deal in those poisons, as was stated by an eminent judge some years ago? I do not see why our trade journals should constantly flare this word "monopoly" in our faces. It appears to me that it would be more dignified upon our part if we were to come before the people and say, "We have qualified ourselves in accordance with law to serve you, but so long as we are kept down by noisy advertising tradesmen, and still more noisy charlatans and quacks, the best services of the profession we have the honour to represent cannot be placed at your disposal. We love our profession and are willing to give our whole attention to it, but so long as you force us to divide that attention between the demands of professionalism, roaring advertising tradeism, and quackery you cannot get the best services of which pharmacy is capable." Talk such as this would, I believe, be intelligible to most men. It is quite plain that pharmacy occupies its present position mostly upon account of the fact that the people do not know anything about it. It has often enough been misapprehended, God knows, all over the country almost through every public agency, but it has never to my knowledge been fairly represented to the people. It appears to me, as I read in the public newspapers, that the journalist, the judge, the magistrate, the coroner, and the man in the street have each individually constructed a Pharmacy Act of his own, and the good Lord pity the unfortunate man who tries to bring order or sense out of them when they are all jumbled together. No profession can give its best services to the State so long as it is harassed by unqualified men, and I am quite sure that this will be the lesson taught to the people in the near future. Within the next twenty years I believe the professions will all have shaken themselves free from unqualified competition, and the State will be the benefiter thereby. It is in the highest interests of the State that medicines should be prescribed only by qualified medical men, dispensed only by qualified chemists, and as far as possible administered only by qualified nurses.

Dumfries, July 12, 1898.

JAMES REID.

CAMPHOR IN PILLS.

Sir,—In selecting an excipient for forming camphor into pills, the relative merits of different excipients being so variously advocated, four essential points must be borne in mind:—(a) solubility; (b) prevention of crumbling; (c) retention of shape, and (d) size of the pill. If we regard camphor as a concrete oil it will be perfectly obvious that castor oil alone will form a crumbly mass incapable of being rolled out, and this I have found in practice. Glycerin of tragacanth is an excipient which answers fairly well, but has the disadvantage of making too bulky a pill, besides rendering it rather soft and spongy. Curd soap, alcohol, and water, is another excipient recommended, but one which I have found to result in a mass that crumbles readily under the roller. A fourth suggestion has been the use of olive oil, yellow wax, and resin. This makes a fairly good pill, but the time occupied in making the excipient renders it objectionable on that account, not taking into consideration the insolubility of the mass. The excipient above all others giving an easily manipulated, firm, plastic mass, containing all the physical qualities of a good pill, is the following:

R. Camphor.....	gr. xxiv.
P. Saponis	gr. iii.
Ol Ricini	℥ v. or q.s.
M. ft. pil. xii.	

Turning now to pills containing, besides camphor, other compounds, such as ferrous sulphate, mercurous chloride, etc.; where soap is inadmissible, a good general excipient is that recommended by Mr. Barnard Proctor (slightly modified), viz.:

R. Camphor	gr. xxiv.
Ferrous Sulph.	gr. vi.
P. Amygdal. Co.	gr. xii.
Glycerin	q.s.
M.	

I lay no claim to originality, but have simply passed in review suggestions obtained from various sources.

Lewisham, July 15, 1898.

GRAHAM BOTT.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on separate slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

NON-POISONOUS IRON MOULD EXTRACTOR.—Probably powdered citric acid will answer your purpose. It should be made into a paste with a little water and applied over the spot, keeping it damp for an hour or two, then washed out with water, followed by a little weak ammonia. This will also remove ink stains where these are caused by inks containing iron. [*Reply to A. M. J.*—14/1.]

WATERPROOFING FABRIC.—Unless we know what the "fabric" may be it is impossible to suggest a satisfactory waterproofing. Possibly the following *modus operandi* may be suggestive:—Dissolve soft soap, 4 ozs., strong solution of ammonia, 4 ozs., in rain water, 1 gallon. Soak the material in this for twenty-four hours and wring out nearly dry. Then plunge into a boiling bath of potash alum, 1 lb.; copper sulphate, 2 ozs.; water, 1 gallon. Press out thoroughly while hot, then dry. [*Reply to G. W. M.*—14/11.]

REMEDY FOR WOODLICE IN MUSHROOM BED.—We fear there is no way of driving out the woodlice from the manure after the mushrooms have appeared without making the latter taste. An emulsion of soft soap and paraffin sprayed over the infested places would answer in many cases but not in this instance. Your best way will probably be to trap them with long strips of brown paper bent over like a conduplicate leaf and smeared on one side with a mixture of treacle, foots sugar, and beer. They will crowd to this, when the papers can be lifted up and shaken over boiling water. Small flower-pots coated on the inside with the same mixture are also good traps. [*Reply to W. J.*—14/6.]

REPORT.—It is usually read at the opening of the School of Pharmacy in October. [Reply to L. B. T.—13/32.]

BOTANICAL.—Your specimen seems to have miscarried. Can you send a duplicate? [Reply to A. E. B.—12/31.]

NOTICE TO LEAVE.—A calendar month's notice is usually given. [Reply to E. J. R.—14/2.]

NON-CLOUDY BRILLIANTINE.—Castor oil, 4 fluid ounces; eau de Cologne, $\frac{1}{2}$ fluid ounce; oil of neroli, 10 minims; absolute alcohol to produce 10 fluid ounces. [Reply to COUNTRYMAN.—13/30.]

CLOUDY BRILLIANTINE.—Almond oil, $3\frac{1}{2}$ fluid ounces; glycerin, $1\frac{1}{2}$ fluid ounces; ess. bouquet, 4 fluid drachms; alcohol (90 per cent.) to produce 10 fluid ounces. [Reply to COUNTRYMAN.—13/30.]

BOTANICAL.—It is a leguminous plant, probably *Sutherlandia frutescens*, R. Br., but it is impossible to name with certainty in the absence of flowers and fruit. [Reply to KEENE.—13/17.]

FERRUM REDACTUM.—The only recent communication on the subject has been a note by W. F. Hay, on ferrum redactum in pills, in the Journal for May 11, 1895. [Reply to E. S. P.—13/28.]

BOTANICAL.—It appears to be *Lonicera hispidula*, Pall., a native of N. India and China. [Reply to W. J. W.—13/7, and E. W. H.—13/16.]

BOTANICAL.—The plant belongs to the Gesneraceæ, but a better specimen with leaves as well as flowers must be sent before the species can be determined. [Reply to G. B.—12/29.]

MINOR EXAMINATION.—Write to the Registrar, 17, Bloomsbury Square, London, W.C., for a copy of the pamphlet 'Advice to Students.' [Reply to T. W. R.—13/27.]

DRY SHAMPOO.—Borax, $\frac{1}{2}$ oz.; ammonium carbonate, $\frac{1}{2}$ oz.; tincture of quillaia, 2 fl. drms; rectified spirit, 5 oz.; oil of myrcia acris, 10 minims; oil of lavender, 10 minims; distilled water to produce 20 fl. oz. [Reply to COUNTRYMAN.—13/31.]

PROPRIETARY PILLS.—You may break stamped packets and retail the contents in small quantities, without payment of further duty, if the pills are simply wrapped in paper when handed to the purchaser, and not made into a "packet" by being secured with wax or string, or otherwise. [Reply to BENZENE.—13/31.]

BENZENE.—It must be kept in separate glass, earthenware, or metal vessels, each of which contains not more than one pint and is securely stoppered. The aggregate amount so kept must not exceed three gallons. [Reply to BENZENE.—13/31.]

DISPENSING DIFFICULTIES.—As the salts are evidently not wholly soluble in the quantity of fluid ordered, you should rub them to a fine powder before adding the infusion, and attach a "Shake the Bottle" label. [Reply to ALPHA.—13/25.]

SOCIETY'S ARMS.—Any person using armorial bearings, whether or not their use is claimed as a personal right, is bound to take out a licence at a cost of a guinea a year. But, apart from that, no individual is entitled to use the Pharmaceutical Society's coat of arms. [Reply to AJAX.—13/15.]

CAPSULE FILLING APPARATUS.—Messrs. A. and K. Robertson, Rodney Street, Canonmills, Edinburgh, make one and an illustrated description of a simple apparatus designed by Mr. J. A. Forret, of Edinburgh, will be found at page 283 of the last volume of the Journal. [Reply to GRAVITAS.—14/8.]

BRITISH COLUMBIA.—The local Pharmacy Act provides that persons who hold diplomas from the Pharmaceutical Society of Great Britain may be registered in British Columbia without passing a fresh examination, if approved of by the Board of Examiners for the province. You should submit your case to the Secretary of the Pharmaceutical Association of British Columbia, Victoria, British Columbia. [Reply to VANCOUVER.—13/23.]

THE ORIGINAL MAKER OF OLD BROWN WINDS & SOAP.—The soap was made by John Richardson and Son, soapmakers, of London, in 1781. But it was probably made before that date; in fact, it is likely to be a survival of the time when each housewife made her own soap. [Reply to W. H. B.—13/9.]

SOLUTION OF MERCURIC OXIDE IN NITRIC ACID.—There is more than enough nitric acid ordered to dissolve the prescribed quantity of mercuric oxide, even if the quantity of acid is taken by weight. If you measure it, as you probably do, there will be a still greater excess. The red crystals you note as not dissolving easily are probably nothing but some hard crystals of mercuric oxide. If you gently warm the liquid in a flask those will dissolve. [Reply to SOCIUS.—13/13.]

INFUSION OF SYCAMORE IN FRENCH PHARMACY.—We are not aware that the sycamore is used to any extent for making a tisane. Possibly your customer requires the popular "lime-tree flowers" infusion, which is used to an enormous extent in domestic medicine in France, and produces an infusion which is agreeable to take and acts as a powerful sudorific. This is official in the 'Codex' as Tisane de Tilleul, and is made by infusing dried lime flowers in 100 parts of boiling distilled water for 30 minutes, then straining. You can obtain the dried lime-tree flowers from Messrs. Potter and Clark. [Reply to G. A. T.—13/29.]

EAU DE COLOGNE.—Every practical perfumer has his own recipe for Cologne, and the published formulæ are innumerable. We give you two good working formulæ, which you may modify to suit your taste. No. 1: Oil of neroli, 30 minims; oil of petit grain, 10 minims; oil of bergamot, 2 drachms; terpeneless lemon oil, 10 minims; oil of thyme, 5 minims; oil of rosemary, 15 minims; alcohol (90 per cent.), to produce 1 pint. No. 2: Oil of bitter orange, 3 drachms; oil of neroli, 30 minims; oil of lemon, 60 minims; oil of bergamot, 60 minims; oil of French lavender, 10 minims; alcohol (90 per cent.) to make 20 fluid ounces. [Reply to COUNTRYMAN.—13/30.]

EFFECT OF ADDING ETHER TO EXT. IPECAC. LIQ.—The "slimy-alkaloidal deposit" that you notice when adding ether to ext. ipecac. liq. is not an unusual occurrence when ether is added to an alcoholic extract of drugs containing alkaloids. It merely indicates the precipitation of a substance insoluble in the added liquid, which in your case was ether. The precipitate may or may not contain alkaloid. If a little dilute sulphuric acid and water are first added, ether no longer causes precipitation, and on the addition of ammonia the emetine and cephaeline are extracted by the ether. In this way the determination of the alkaloids could be effected, and the method is worth attention by pharmaceutical students, as being preferable to the B.P. method, which is tedious and has lately been shown by H. Wilson to be also inaccurate (*P.J.*, lxi., p. 3). [Reply to INTER Nos.—14/7.]

INFORMATION WANTED.

ROSOLENE.—"Extension" would be glad to learn the address of the firm which supplies a preparation named "Rosolene" for cleansing purposes (13/26).

CORRECTION.

DR. HALE WHITE'S 'MATERIA MEDICA.'—In the notice of this book, printed at page 41, by a printer's error the price was wrongly given as 2s. 6d. instead of 7s. 6d.

OBITUARY.

IRELAND.—On July 1, William Ireland, Chemist and Druggist, Egremont. Aged 83.

BAYLY.—On July 7, Charles Jasper Bayly, Chemist and Druggist, Waltham Cross, Herts. Aged 77.

CHURCH.—On July 9, Joseph Only Curtis Church, Chemist and Druggist, Acle, Norfolk. Aged 78.

SOWRAY.—On July 10, Robert Duck Sowray, Chemist and Druggist, Liverpool. Aged 59.

MABBETT.—On July 11, George Drew Mabbett, Pharmaceutical Chemist, late of Colnbrook, Bucks. Aged 65.

DRAWBRIDGE.—On July 17, Joseph George Drawbridge, Chemist and Druggist, Liverpool. Aged 59. Mr. Drawbridge had been a member of the Pharmaceutical Society since 1875.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

Tincture of Guaiacum as a Reagent. Pierre Breteau comments on the value of tincture of guaiacum as a reagent. Inasmuch as it strikes a blue colour in contact with blood, copper sulphate, prussic acid, phosphorus, and many other substances, it loses much of its importance as a reagent. Again, experimental conditions should be clearly laid down and strictly adhered to, or wide differences in the behaviour of this reagent will be noted. As an instance of this, Breteau calls attention to Van Deen's method of determining small quantities of blood by the use of tincture of guaiacum. The smallest trace of copper in the distilled water employed appreciably affects the results. One part of copper sulphate in 500,000 of water will strike a blue colour with tincture of guaiacum slowly in the cold, but more rapidly at 40° C.—*Journ. de Pharm. et de Chimie* [6], vii., 569.

Determination of Nitrites in Water. A new process by Lucien Robin, chemist in the Municipal Laboratory of Paris, is based on the fact that when pure potassium iodide is added to a solution of a nitrite in the presence of acetic acid, and set aside for a time, a definite quantity of free iodine is always liberated by a definite quantity of nitrous acid. By this method the water is filtered, if not perfectly limpid. In case it is coloured, aluminium sulphate and sodium carbonate are added in succession, as in the metaphenylenediamine process, or else 100 C.c. of the sample is mixed with 2 C.c. of glacial acetic acid, placed in a distilling flask, and 50 C.c. of distillate collected. Again, if hydrogen sulphide be present, it is necessary to treat 125 C.c. of the sample with a little silver sulphate, and filter; 100 C.c. of the filtrate is then distilled. Whichever way is adopted, 50 C.c. of the sample is mixed with 2 C.c. of a 20 per cent. solution of chemically pure potassium iodide. The solution is shaken, 2 C.c. of glacial acetic acid is added, and after further agitation the vessel is set aside for exactly half-an-hour. The free iodine is then determined by titration with a standardised solution of sodium hyposulphite prepared by diluting 50 C.c. of decinormal solution to a litre. Starch solution is used as an indicator. In this way 0.1 Mgm. of nitrous acid per litre may be detected. If, for some reason or other, the titration cannot be carried out at the end of half an hour, the decomposing action of the acetic acid and consequent liberation of iodine must be prevented by the addition of 10 C.c. of concentrated solution of potassium carbonate.—*Journ. de Pharm. et de Chimie* [6], vii., 575.

Assay of Belladonna. W. A. Puckner proposes the following modification of Keller's method for the assay of such alkaloidal drugs as belladonna and henbane, when comparatively large quantities of the drug are used. To 10 grammes of the drug, dried and powdered, and contained in a flask of 75 to 100 C.c. capacity, add 50 C.c. of the light chloroform ether mixture (as used by Keller, *Am. Journ. Pharm.*, 1894, p. 42) and 5 C.c. of ammonia water (10 per cent.). Cork well and shake at frequent intervals for one hour. Transfer to a small percolator, improvised by drawing out a 50 C.c. test-tube (20 Mm. diameter), and plugging with cotton-wool. Receive the percolate in a separator, rinse the flask twice with 25 C.c. of the chloroform-ether mixture, and transfer to percolator. Take enough of the ethereal

solution to represent 10 grammes of drug, and complete the assay by Keller's method.—*Pharm. Review*, xvi., 180.

Nutation of Helianthus Annuus. J. H. Schaffner has made observations on the nutation of *Helianthus*. There are four distinct periods in the daily process: (1) From shortly after sunrise, when the plant is nutating about 60° east, until sunset there is a gradual movement westward until the terminal bud faces west and the upper part of the stem nutates 90°; (2) from sunset until about 10 p.m., during which time the plant regains its vertical position and the leaves drop downward so that their apices point vertically towards the earth; (3) from 10 p.m. to 1 a.m., the period of repose; (4) from 1 a.m. until sunrise, a gradual turning eastward, accompanied by a rising of the leaves, by which they are again brought with their upper surfaces at right angles to the light. A moderate wind or cloudy weather has little or no effect on nutation, but continued drought has a marked effect; in rainy weather also nutation is scarcely noticeable. The removal of the terminal buds was without result, and cutting slices from the side of the stem, midway between the terminal bud and the central point of curvature, seemed to have no more effect on nutation than would follow from the mechanical interference caused by the wound. On cutting off the leaves, the effect was quite different. Plants thus treated immediately lost their power of nutation. From other experiments connected with delamination the conclusion is arrived at that the irritability which is responsible for the bending of the stem is not inherent in the stem itself, but the stimulus is received by the lamina of the leaf, and the impulse transmitted through the petiole to the stem produces a response from both these parts.—*Bot. Gazette*, xxv., 395.

Volatility of Synthetic Remedies. F. X. Moerk points out that certain of the newer remedies which he has examined, viz., exalgin, acetanilid, methacetin, and phenacetin, are volatile in the order given, which corresponds also to the order of their melting point.

This is of importance in determining their solubilities and estimating them quantitatively. Half a gramme each of exalgin, acetanilid, and phenacetin, exposed separately to a temperature of 85° C. for four hours, weighed respectively 0.1890, 0.4795 and 0.4990 gramme. Hence the possibility arises of detecting the presence of such substances as exalgin and phenacetin by taking advantage of their volatility.—*Am. Journ. Pharm.*, lxx., 335.

Structure of Myristicaceæ. In a very complete and elaborate monograph of this order published in the *Nova Acta Acad. Caes. Leopold-Carol.* (vol. lxxviii., pp. 1-680), illustrated by twenty-five plates, Herr O. Warburg gives full details, in the introduction, of its anatomical characters. The plants belonging to the order are characterised by the presence of sacs containing a reddish astringent kino, which becomes blood-red on exposure to the air. The hairs are very characteristic, being always branched sympodially. Oil-cells containing an essential oil are invariably present. The aril originates before the flower opens and before fertilisation. It is at first nothing but a thickening of the integument in the region of the hilum, the exostome taking a part in its formation. It contains in its cells an essential oil, a resinous substance, crystals of calcium oxalate, and in many species also a substance intermediate between dextrin and starch. The aril is greedily devoured by birds, the ripe seeds passing uninjured through the intestinal canal. All the species of Myristicaceæ appear to be cross-pollinated by the agency of insects.

ON EMETINE AND CEPHAELINE.

BY DR. B. H. PAUL AND A. J. COWNLEY.

Since the extraction of ipecacuanha bases has been undertaken by Messrs. Whiffen on a manufacturing scale and they have introduced the hydrobromide as the most suitable salt of emetine for medicinal and pharmaceutical use, we have, through their courtesy, been enabled to supply Dr. O. Hesse with a sufficient quantity of these substances for chemical examination. Dr. Hesse has very kindly given us the benefit of his valuable assistance in reference to the question as to the molecular weight of emetine and cephaeline, which had not been satisfactorily solved by the results of our earlier experiments. We desire to thank him for that, and, though we hesitate in accepting some of his conclusions, we are pleased to be able to add that his results practically corroborate those originally arrived at by ourselves in the isolation and investigation of these bases.

Before giving the results of Dr. Hesse's investigation, described in the following paper, it is desirable to recall the statement made in our original paper (*Ph. J.*, liv., 111), that the empirical formula $C_{15}H_{22}NO_2$, given to emetine by us, was decided upon as a simple expression of our analytical data, and also as being the formula that had been assigned to emetine by Glénard. The formula $C_{14}H_{20}NO_2$ was also provisionally adopted for cephaeline until it should be possible to obtain further indications as to the molecular weight than the platinum salt analysis afforded.

BY DR. O. HESSE.

Some uncertainty having been expressed as to the formulæ of the interesting bodies, to which Dr. Paul drew the attention of the Society, at the evening meeting of the Pharmaceutical Society, as reported in the *Pharmaceutical Journal*, No. 1430, p. 450, Dr. Paul kindly submitted specimens of emetine and cephaeline to me for comparative examination, for which I tender him my best thanks.

Emetine.

The specimen of emetine was a white powder, and completely agreed in properties with those assigned to it by Paul and Cownley. It dissolved readily in ether, chloroform, benzol, or alcohol, and its alcoholic solution gave no coloration with ferric chloride. It was insoluble in solutions of caustic or carbonated alkalies, but easily dissolved in dilute acetic acid. From the acetic acid solution potassium hydrate precipitated a white flocculent precipitate, insoluble in excess, but readily soluble in ether. Acetic anhydride dissolved emetine, but without effecting substitution.

COMPOSITION.—The substance dried at 100° was employed for elementary analysis, as the desiccator dried substance still contained a small amount of water (0.93 per cent.).

Gramme.	Gramme.	Gramme.
0.2125 dried at 100° gave	0.561 CO_2 and	0.158 H_2O .
0.219 " " " " "	0.578 " " "	0.1605 " "

PLATINUM SALT.—This was obtained as a fine yellow powder by precipitating the hydrochloric acid solution of the base with platinum chloride. It was dried at 120° .

The first preparation,	0.2955 gm.	gave 0.635 platinum.
" second " "	0.2835 " "	" 0.620 " "

DETERMINATION OF METHOXYL.—0.2279 gramme of the anhydrous substance gave, according to Zeisel's method, 0.409 gm. AgI.

MOLECULAR WEIGHT.—The determination by Beckmann's boiling point method was carried out in the apparatus described in the *Zeitschrift für Physikalische Chemie*, 8, 223.

15 grammes of ether employed :

Gramme.

0.177 of the desiccator dried substance gave increased boiling point	0.045°	=	"	552	molecular weight.	"	"	"	Mean =	548.
0.364 " "	0.095°	=	"	545	"	"	"	"		

25 grammes of chloroform used :

Gramme.

0.115 desiccator dried substance gave increased boiling point	0.032°	=	"	523	molecular weight.	"	"	"	Mean =	533.
0.299 " " " " "	0.076°	=	"	540	"	"	"	"		

As the substance employed contained 0.93 per cent. of water, the first mean value had to be reduced to 543, and the second to 528. From these results it would follow that the formula of emetine is $C_{30}H_{42}N_2O_4 = C_{26}H_{30}N_2(OCH_3)_4$.

The following results are those obtained for pure emetine :—

Emetine.	Glénard.		Paul & Cownley.		Hesse.	
C	72.43	72.08	72.23	71.80	72.00	71.98

Molecular Weight ..	494	—	—
Platinum Salt	$C_{30}H_{42}N_2O_4, PtCl_6H_2$	—	—
Platinum	21.56	—	21.63

Cephaeline.

This consisted of small white needles containing 3 to 5.2 per cent. of hygroscopic water, which was entirely lost under the desiccator. It dissolved easily in ether, benzol, chloroform, or alcohol. Ferric chloride added in small quantity to an alcoholic solution of cephaeline gives a dark reddish-brown coloration. Cephaeline contains, therefore, phenolhydroxyl, and is consequently a phenol base; moreover it dissolves easily in caustic potash and is not extracted from the solution by ether. It dissolves also easily in acetic acid and is reprecipitated by cautious addition of caustic potash as a white precipitate that is soluble in excess; hence ether naturally extracts no cephaeline from the solution in caustic alkali. It is therefore on this peculiar behaviour of cephaeline with caustic alkali and ether that the separation of emetine and cephaeline depends.

COMPOSITION OF CEPHAELINE.—0.2000 gramme dried at 80° gave 0.5255 gramme CO_2 and 0.146 gramme H_2O .

PLATINUM SALT.—The base was dissolved in dilute hydrochloric acid and precipitated with platinum chloride, forming a yellow flocculent precipitate.

0.424 gramme dried at 120° gave 0.095 gramme platinum.

DETERMINATION OF METHOXYL.—0.215 gramme of the desiccator-dried substance gave, according to Zeisel's method, 0.279 gramme AgI.

0.208 gramme gave 0.266 gramme AgI.

MOLECULAR WEIGHT.—The determination by Beckmann's boiling point method gave the following results :—

15 grammes of ether taken.

0.082 gramme of substance gave increased boiling point	0.012°	=	"	981	molecular weight.	"	"	"	Mean	956.
0.169 " " " " "	0.025°	=	"	952	"	"	"	"		

Chloroform as solvent.

(1) 402	402
(2) 469	469

Cephaeline. Ethylic alcohol as solvent.

533	593	563
-----	-----	-----

The figures (1), (2), (3) signify that there was a first, second, and third addition of substance to the same solution.

As we have already stated, with the exception of ether the other solvents have a great colour changing action on the alkaloids.

These molecular weight determinations by Beckmann's method fairly agree with Dr. Hesse's results when chloroform and ethylic alcohol were employed as solvents; but the results obtained are open to the objection we have stated. It may be remarked that the combining value of the alkaloids will, of course, be unaffected whether we assume 248 and 234 or 496 and 468 to be correct. The former figures, as we have shown, have a monobasic value, but for a further conception of the constitution of these two interesting alkaloids we are inclined to await further results, such as may be obtained by a splitting up of the molecule.

In conclusion, it is noteworthy to draw attention to the characteristic suggestion of Dr. Hesse as to the probable existence of other alkaloids in ipecacuanha root, and to the fact that we have already noted in our previous papers the existence of a third alkaloid, but have not yet been supplied with it in sufficient quantity for a satisfactory examination.

In addition to the crystalline salts of emetine and cephaeline already obtained and described by us (*P. J.*, liv., 111 and 373) we have been enabled by the courtesy of Mr. W. G. Whiffen to make an examination of the commercial emetine hydrobromide, which is suggested as the most convenient salt of emetine for medicinal use. The following are the results obtained:—

	Commercial Emetine Hydrobromide. Crystalline.	Emetine Hydrobromide. Anhydrous at 100° C.	Calculated for $C_{15}H_{22}NO_2HBr$. Anhydrous Salt.
Water	11.09	—	—
HBr	22.01	24.75	24.62
Emetine ..	66.90	75.25	75.38
	100.	100.	100.

The commercial salt appears to approximate to a salt with two molecules of water, which requires according to theory—

Water	9.86
HBr	22.19
Emetine	67.95
	100.00

Emetine hydrobromide is a permanent salt undergoing no alteration in colour after being kept for some months. It is readily soluble in water, difficultly so in absolute alcohol or in chloroform, and much less soluble in water than emetine hydrochloride. It crystallises from water in beautiful silky tufts of needles, which on being separated and pressed on bibulous paper contained 33.08 per cent. of water, thus approximating to a salt having the composition represented by the formula $C_{15}H_{22}NO_2, HBr \cdot 9H_2O$, which requires by theory 32.99 per cent. of water of crystallisation. Emetine hydrobromide becomes anhydrous at 100° C. and effloresces on exposure to air, until it has the composition approximating to a salt with two molecules of water $C_{15}H_{22}NO_2, HBr \cdot 2H_2O$ when it remains constant.

WHAT IS A MICROSCOPE?*

BY T. E. WALLIS.

A microscope is an optical instrument for viewing small or minute objects. Small objects are seen by making them appear larger to the eye. We will briefly consider how this may be done.

The eye may be compared to a camera with a lens (the crystalline lens) in front and a screen (the retina) at the back; the lens forms an image of an object upon the retina, and a sensation of sight is conveyed to the brain by the optic nerve. It is then evident that the apparent size of an object depends upon the size of the image upon the retina, and also that, to increase the size of this image, the object must be brought nearer to the eye.

We do not always realise that an object is magnified when brought nearer to the eye, because we make allowance for distance. This may be shown by holding a coin before the eye at some distance, when it is seen to cover a certain small portion of the view; but if it is brought nearer to the eye a very large part of the view is hidden, thus showing that the coin appears larger, although we think it is the same size, because we allow for the distance. Again, when the moon is above our heads it appears of a certain size, and if measured by a suitable instrument it is found always to have the same size wherever it may be; but if we look at the moon when near the horizon the density of the atmosphere makes it appear comparatively dim and consequently further off, and as we view it we make allowance for the distance, and so think the moon is larger; hence the nearer we bring an object to the eye the more we magnify it. This method of magnification is not applicable if

FIG. 1.—DIAGRAM OF SIMPLE MICROSCOPE.

the unaided eye is used to view an object, because a person with good sight cannot generally see an object distinctly at a less distance than six inches. This is explained by the fact that rays of light coming from an object must enter the eye almost parallel for distinct vision, and if the object is nearer than six inches the rays of light radiate at too great an angle. The best distance at which to see detail in any object is from six to ten inches. For this reason the tube length selected for English microscopes is ten inches, and for Continental microscopes six and a half inches.

Instruments of whatever kind which can be employed to make an object distinctly visible at a less distance than six inches have a claim to be called microscopes. The simplest device is to take a blackened card with a pin-hole pierced in it, and by looking through this hole objects may be seen at a much shorter distance than that required for normal vision. This may be shown by looking at some small print through the pin-hole, which enables one to read it distinctly at a short distance; but on removing the card, the printing appears blurred and almost invisible. Although an object may be magnified in this way, it is quite evident that the hole only allows a very small amount of light to enter the eye, and hence the image is not particularly clear or bright.

A better means of magnifying an object is to use a simple lens. It acts in the following way:—Diverging rays of light, such as a lamp or candle emits when allowed to pass through a lens, are reconverged to a point beyond the lens, and there form an image of the flame, which may be caught upon a screen, and is hence called a "real image." The magnifying power of a simple microscope (*i.e.*, an ordinary pocket lens) depends upon this property of bending the course of diverging rays to make them so nearly parallel that they can enter the eye for distinct vision. This will be easily understood from the accompanying figure.

* Read before the School of Pharmacy Students' Association.

From the point *a* in the object *O*, diverging rays *ac* and *ad* enter the lens *L*, and are converged by it so as to enter the eye almost parallel, and are brought to a focus at *f* on the retina. Rays from *b* are focussed at *g*, and every other point in the object is similarly focussed. If the rays entering the eye are produced till they meet, they appear to come from points *A* and *B* in *AB*, which is the apparent image of the object as apparently seen at the normal distance for distinct vision.

A more complicated instrument than the simple microscope is the compound microscope, the theory of which may be explained by supposing it is made of two lenses, as in the figure.

FIG. 2.—DIAGRAM OF PATH OF RAYS IN A COMPOUND MICROSCOPE FORMED OF TWO LENSES.

One of these lenses, *A*, is placed near the object *O*, at a distance a little longer than the focal length, and produces in the microscope tube a much enlarged real image, *I*. This image is again magnified by the lens *B*, which, being near the eye, is known as the ocular or eye-piece.

If single lenses perfectly performed their duty, the construction of a microscope would be a simple matter. Unfortunately, ordinary lenses are subject to several defects. There are three ways in which they fail.

1. Lenses are ground to spherical surfaces and consequently refract too much those rays which fall upon the edges of the lens. This causes the image formed by a reading glass to appear more or less blurred.

2. It also accounts for the fact that, when a print or other object on a flat surface is observed through an ordinary lens, the marginal parts appear distorted. These defects in a lens are due to the same cause, which is known as "spherical aberration."

3. When a ray of light is allowed to enter a prism and passes out on the other side, it is not only refracted, but the white light is also split up or analysed into its component colours. This band of colours is known as a spectrum and is formed because blue and violet rays are more easily refracted than red ones. This may be remembered from the fact that "violet" begins with a "v" and is very refracted, while "red" begins with an "r" and is rather refracted. A simple lens may be looked upon as being composed of two prisms placed base to base, and it will be easily understood from the diagram that the blue and violet rays are refracted to a point nearer the lens than that at which the red rays are focussed.

Consequently if the image is caught on a screen placed somewhat beyond the focus of the lens the predominant colour is red, and concentric rings of brown, yellow, green and blue are seen to be formed within the outer circle of light; similarly if the screen be

FIG. 3.—DIAGRAM ILLUSTRATING CHROMATIC ABERRATION OF A SIMPLE LENS.

held somewhat within the focus, the predominant colour is blue, while round the outside of the bright disc are seen concentric rings of green, yellow, brown and red light. This defect in a lens is known as "chromatic aberration."

These faults are not very disadvantageous for rough work with simple lenses, but are quite fatal to precise work with lenses of high magnifying power. To make a really useful microscope, these imperfections must to a great extent be remedied. It is evident that they are worse at the edges of a lens, and the simplest method of improvement that suggests itself is to stop all the lens except a small central portion; but in so doing, a large amount of light is blocked out, and the lens is also affected so that it will not so readily make closely-ruled lines distinctly visible. Aberration differs greatly in amount according to the inclination of the surfaces of lenses to the path of the rays. Thus the spherical aberration of a plano-convex lens in parallel rays is less than one-third, when the flat side is turned towards the focus, of what it is when the spherical surface is towards the focus. A reference to Fig. 4

FIG. 4.—DIAGRAM ILLUSTRATING SPHERICAL ABERRATION OF A PLANO-CONVEX LENS.

will make this clear. The distance $F'F''$ represents the difference in spherical aberration of rays at the edge and centre of the lens; this length is much greater in *A* than in *B*. This fact is applied to the construction of microscope objectives by dividing the entire power among two or more lenses separated by a small space; by this means surfaces of different inclinations are presented to the rays, and the aberration due to one surface is largely corrected by that of another lens. This means of correction is also made use of in forming the ordinary Huyghenian eye-piece, which consists of two plano-convex lenses with a diaphragm between them. Another method for the correction of aberration is to form the separate lenses of different kinds of glass which differ greatly both in refractive and dispersive power. Thus a plano-convex lens may be formed of a flint-glass concave lens and a crown-glass biconvex lens; by this combination both chromatic and spherical aberration may be corrected, and the lens so formed is termed "achromatic."

From these facts it is readily seen that objectives should possess four qualities:—

1. DEFINITION.—Fine objects, such as the hairs on a fly's proboscis, should be clearly imaged, and the edges should be sharply marked and not at all woolly or indistinct.

2. FLATNESS OF THE FIELD.—On looking through a microscope the object viewed appears in a bright disc of light; this bright area is spoken of as the "field" of the microscope. When looking at a flat object, the parts at the edge of the field should be in focus at the same time as the centre of the object, and should not appear in any way blurred. If an objective answers tests of this nature

well, it shows that it has been properly corrected for spherical aberration.

3. RESOLUTION.—However great the magnifying power of a lens, and however good the light and correction of the objective, it is quite unable to separate or "resolve" markings of extreme fineness and very close together, unless it possesses a certain aperture, which is measured comparatively by the width of the angle of the outermost rays grasped by the objective. The numerical aperture N.A. of an objective, as published in opticians' lists, is obtained by

FIG. 5.—DIAGRAM SHOWING ANGLES OF EMERGENCE.

multiplying the sine of half the outside angle by the refractive index of the medium used. The aperture of an objective is tested by seeing whether it will distinctly separate the fine markings on the scales of various insects and on diatoms.

4. PENETRATION.—This is the power of showing the cubical content of a body under examination. This is not a desirable quality, but a good objective should show clearly one plane at a time, and on slightly altering the focus this plane should go out of view and another plane be clearly focussed.

A few words about "immersion objectives" may be suitably included here. If an object is placed on a glass slip without covering it with any medium, the largest angle of light that can enter the face of a dry lens must be less than 180° . Now, suppose the object mounted in Canada balsam, then a cone of rays emerging from the cover-glass into air is so refracted that its angle becomes much wider, and rays forming an angle greater than 80° cannot get out at all, but are totally reflected from the cover-glass. If, however, a drop of water is placed upon the cover-glass between it and the objective, an angle of 112° can emerge from the balsam, and if a drop of cedar oil is used, rays pass out without any refraction at all. The effect of using a drop of water or cedar oil may be understood from Fig. 5, which shows that an angle of 120° in air is reduced to 81° in water, and to 69° in cedar oil.

It is then evident that by this method of oil-immersion an objective is theoretically enabled to grasp any angle less than 180° in balsam, whereas an angle of 82° in balsam is the greatest a "dry" lens can grasp. From these facts it is quite clear that, with oil-immersion objectives, there is a great gain in illuminating power, making the image both brighter and more distinct; and also that correction of the objective for thickness of the cover-glass is entirely obviated.

(To be continued.)

TESTS FOR LEAD.—L. L. de Koninck compares the value of sulphuric acid and potassium chromate in testing for lead. He recommends that the lead be precipitated as sulphate, dissolved in a strongly ammoniacal solution of ammonium tartrate, and confirmed by reprecipitation either by excess of sulphuric acid or by the addition of a chromate (or dichromate). By the latter method small quantities of lead escape detection, unless suitable means are adopted. He recommends the addition of a few drops of acetic acid to the ammoniacal tartrate containing lead either before, or better, after the addition of the chromate. The acid is added to the solution in order first to neutralise the ammonia, and then to convert the chromate to dichromate; in this way an orange colour is developed. Sulphate and chromate of lead dissolve in ammonium tartrate only in the presence of free ammonia. In performing this test the formation of a white crystalline precipitate of ammonium tartrate may be disregarded.—*Bull. de l'Assoc. Belge des Chim.*, xii., 58.

SELECTED FORMULÆ.

EMULSION OF COD-LIVER AND CHOCOLATE.

Decoct. carrageen (2:100), 150; ol. jecor. aselli, 240; glycerin, 60; chocolate powder, 30; tinct. vanill., *q. s.* The chocolate powder is mixed with the mucilage, and heated until a smooth mass has formed. After cooling, the cod-liver oil is added, and the mixture beaten with an egg whisk.—*Zeit. d. Allg. oest. Apoth. Ver.*, lii., 7.

FORMALIN MOUTH WASH.

The following recipe is due to Ganz: 50 grammes of 40 per cent. formaldehyde are dissolved in 1000 grammes of spirit; tincture of benzoin, 200 grammes; tincture of myrrh, 50 grammes; oil of peppermint, 3 grammes; anise oil, 2 grammes; cassia oil, 1 gramme; cinnamon oil, 15 drops; and cochineal powder, 2 grammes, are mixed; the whole well stirred and filtered.—*Deutsch. Amer. Apoth. Zeit.*, xviii., 1430, after *Drog. Ztg.*

MEDICINAL MOUTH SOAP.

Medicinal soap, 30 grammes; glycerin, 30 grammes; alcohol (90 per cent.), 15 grammes; salicylic acid, 1 gramme. Peppermint water and colouring matter as required.—*Zahnzt. Rund.*, vi., 3933.

TAMARIND PASTILLES.

Fol. sennæ, 34 grammes; confect. citri, 6 grammes; confect. aurant., 9 grammes; pulp. tamarind dep., 50 grammes; cardamon, 0.75 gramme; sacch. alb., 116 grammes; ol. rosar., ol. caryoph. aa gtt. 3; divide in pastill., 52. The pastilles are covered with cocoa butter and vanilla sugar and dusted over with pulv. benzoin.—*Zeit. des Allgem. oester. Apoth. Ver.*, li., 893.

MALT BONBONS.

Ten parts of sugar are boiled with 4 parts water, the latter being mixed with the necessary volume of extract of malt. The mixture is boiled on an open fire until a sample dipped into ice water is brittle. It must not be boiled too long or it acquires marked bitter taste. When ready, the mass is poured out on to a marble slab, and cut up into squares.—*Zeit. des allgem. Oest. Apoth. Ver.*, li., 893.

WRITING INK FOR ZINC SHEETING.

Potassium chlorate, 1; copper sulphate, 1, are dissolved in 18 parts of warm water, and a little mucilage is added. Write on a clean zinc sheet with this mixture and wash off the writing in a short time.—*Zeit. des Allg. oest. Apoth. Ver.*, li., 893, after *Pharm. Ztg.*

MIXTURE IN DIFFICULT DENTITION.

Sodium bromide, 50 centigrammes; orange-flower water, syrup of ether, of each 30 grammes; distilled water, 120 grammes. For external use. Rub the child's gums with the mixture several times a day, after nursing.—*Pediatrics*, v., 46.

OINTMENT FOR ECZEMA.

Formalin, 25 centigrammes; zinc oxide and French chalk, of each 25 grammes; vaseline, to make 100 grammes.—*Monatsch. für Dermatolog. through Pediat.*, v., 45.

PEILE'S ANTITETANIC PILL.

As a safeguard in such accidents as are likely to result in tetanus, Dr. H. G. Croly recommends the use of the following antitetanic pill due to Peile:—Calomel, 12 grains; ext. aloes, 12 grains; James's powder (true), 12 grains; extract of opium, 3 grains. Make twelve pills, one to be taken every three hours.—*Med. Press*, cxvi., 26.

CRACKING COAL FOR CUTTING GLASS.

Powdered charcoal, 90; nitre, 2; benzoin, 1; powdered tragacanth, 2. Mix in fine powder, mass with water, roll into pencils and dry. Let one of these, when ignited, pass slowly over the glass, and cause a drop of water to fall in the hot parts, when it cracks. The crack may be led in any desired direction by means of the burning pencil.—*Sci. Amer.*, lxxviii., 55.

LACQUER FOR METAL WARE.

Shellac, 16 parts; dragon's blood, 4; turmeric powder, 1; methylated spirit, 320. Allow the mixture to settle, and filter.—*N. Erf. u. Erf.*, through *Zahntech. Reform.*, xvii., 459.

PARLIAMENTARY NOTES.

THE PHARMACY ACTS AMENDMENT ACT was one of the 110 Acts which received the Royal assent on Monday, the 25th inst., at 3 p.m. The assent was given by Commission in the House of Lords, the "faithful Commons" being in due attendance to a very limited extent. The Bill is now an Act, and every registered chemist of Great Britain is eligible to join the Pharmaceutical Society as a "Member" and offer himself for election to the Council of the Society. The grade of "Associate" is abolished, and no invidious distinction is now drawn between those who have secured a qualification under the Pharmacy Act, 1868.

PLAYING WITH ADULTERATION LEGISLATION.—The President of the Local Government Board cannot be said to have added to his reputation—unless the term be used in its least complimentary sense—by his new Bill; "to make better provision against the adulteration of agricultural and horticultural produce." The Bill deals almost entirely with milk and butter, and the right honourable gentleman, in a long explanation of his views, had the audacity to state that the Sale of Food and Drugs Acts, 1875 and 1879, were adequate to effect the purposes for which they were enacted. This too, in face of the findings of the long-winded Committees which have investigated the state of the law relating to adulteration; and regardless, too, of the fact that Mr. Chaplin himself, in his own peculiar way, acknowledged the inadequacy of the present state of the law so recently as last year by introducing a moribund Food and Drugs Bill during the expiring moments of the last Session. Truly the Chief of the Local Government Board should have a brilliant future before him in the paths of statesmanship. Moreover, his expressed belief that this latest bantling might be included in the category of non-contentious measures is so deliciously cool that it is worthy of a parliamentary Swiveller.

THE BILL proposes to establish the Chief Chemist at Somerset House as the sole authority on butter and milk and injurious additions thereto or fraudulent abstractions therefrom. The Board of Reference which figured in former Bills has disappeared, because Mr. Chaplin deems it cumbrous (and he should be an eminent judge in that respect). In its place are to be set up Regulations of the Board of Agriculture, which body has already endeared itself in the heart of the nation by regulations on another vexed matter. The Board is to determine such nice points as "What is impoverishment?" as well as to define "adulteration"; and the sanguine member for Sleaford thinks that such a plan will do away with those annoying differences between official and non-official analysts. It may do, but those whose business leads them to deal in the substances aimed at by the Bill doubtless consider they know more about the technicalities of the subject than the combined staffs of Somerset House and Whitehall Place.

ONE GOOD FEATURE may be noted. The Bill foreshadows a division in the treatment of food and drug adulteration; for the fact that a separate measure is thought expedient for agricultural produce constitutes a good argument for promoting a separate Bill for drugs. If the logic of such an idea should ever be made to penetrate a ministerial head, it is to be hoped that it will not be associated with Board of Agriculture Regulations. The difficulties surrounding the satisfactory administration of the law as to adulteration can only be dealt with by experts, and the most superlatively excellent Agricultural Department ever fed by competitive examination could not grow an ideal Court of Reference. The Bill has not yet been read a second time.

PROTECTION IN DEGREES.—An interesting attempt to support home-grown academic degrees is embodied in Mr. Sidebotham's (Hyde) Bill to regulate the use of University degrees, which was read a first time on the 22nd, and will appear on the paper again on Bank Holiday. The sponsors are Mr. Carson (M.A., Dublin), Dr. Farquharson (M.D., Edin.), Sir W. Houldsworth (who does not exhibit his degree), Sir J. Lubbock (who is smothered with degrees), Mr. MacNeill (Ch.Ch., Oxon), and Sir William Priestley (M.D., Edin.). The idea seems to be that foreign competition in Ph.D.'s, M.D.'s, and similar distinctions is too much of a good thing when the public becomes so confused as to be unable to distinguish between Dr. Smith who graduated at London, and Dr. Brown who purchased his

diploma at Pumpernickel or Higginopolis. It is, therefore, suggested that any person using affixes indicating the possession of a degree shall, unless he be a graduate of a University of Great Britain or Ireland, clearly state the source of the degree. The maximum penalty for not doing so is "forty shillings or a month." No honest graduate of a continental university is likely to object to the proposal, but there is ground for assuming that the Bill may do for foreign degrees what the Merchandise Marks Act has done for foreign merchandise—namely, give them bold advertisement and bring them into undesired popularity. As the project would do nothing to prohibit the use of bogus titles we are not very much enamoured of it.

ON BEHALF OF THE UNQUALIFIED.—Mr. Logan (Leicester) on Tuesday asked Mr. Balfour to consider the woes of the unqualified medical assistants who had been deprived of a livelihood by the recent action of the General Medical Council in prohibiting the employment of such assistants by medical men. Mr. Balfour, in reply, said that the action of the Council might, in certain cases, have the effect which Mr. Logan deplored; but he was advised that there was no restriction to the employment of unqualified assistants under the immediate supervision of qualified practitioners, nor was there any fear that the resolution of the Medical Council would interfere with the training of medical pupils. Quite gratuitously the right hon. gentleman added that the Privy Council had no jurisdiction in the matter, and that the Medical Council dealt with each case on its merits.

THE LONDON TEACHING UNIVERSITY is practically assured, the Commissioners Bill having passed its third reading in the Commons in the small hours on Monday, after a long and hot fight.

ANTISEPTIC DRESSINGS.*

SERUM SUBLIMATE GAUZE, 5 PER MILLE.—Purified gauze, 100. Moisten with a solution of corrosive sublimate, 0.6; serum of horse blood, 60; distilled water, 90. Rub the sublimate with the serum and dilute the solution thus obtained with the water. Press the wet gauze until the weight is 225, then dry in the air in the dark. Serum sublimate solution may be replaced by mercury albuminate obtained with white of egg.

SAL ALEMBROTH GAUZE.—Purified gauze, 100. Moisten with a solution containing ammonium chloride, 0.1; sublimate, 0.25; distilled water, 150. Press to the weight 225 and dry in the dark. Other medicated gauzes are made in a similar manner.

ABSORBENT COTTON WOOL.—Ordinary cotton wool is boiled for 30 minutes in a 5 per cent. solution of soda or potash, washed freely, and plunged in a 5 per cent. solution of chlorinated lime, again washed, transferred to an acid bath, washed, steeped in an alkali bath for 20 minutes, and finally washed and dried. This cotton alone should be used for the medicated cottons described below.

MERCURIC IODIDE COTTON.—Moisten 100 of absorbent cotton with a solution of mercuric iodide, 0.8; potassium iodide, 0.03 glycerin, 12; in distilled water, 240. Dry.

STERILISATION OF CATGUT BY HOFMEISTER'S METHOD.—The crude catgut rolled on bobbins is first hardened for 24 hours in a 4 per cent. solution of formalin. It is then boiled in water for 10 minutes, and finally preserved in a solution of alcohol, 1000; glycerin, 50; sublimate, 1.

IODISED COTTON.—Moisten absorbent cotton, 100, with a solution of iodine, 10; potassium iodide, 10; glycerin, 120 (?); alcohol, 40, and dry. [This proportion of glycerin must be an error. It is impossible to dry the wool containing more than its own weight of glycerin.—Ed. *Ph. J.*] Or take iodine, 10, wrap in blotting paper, and place in the bottom of a wide-mouthed jar, fill the jar with absorbent cotton, 100, and heat on the water bath, first removing the cork to allow the expanded air to escape, then heat to 100° C., close tightly, and cool quickly.

ASEPTIC SILK THREADS.—To prepare Lister's carbolised silk, colourless threads of silk are plunged in a mixture of white wax 1; crystallised phenol, 10; and left until cold; they are then withdrawn, wiped on a clean cloth, and preserved in a solution of phenol, 1; glycerin, 9; alcohol, 90 p. c., 10.

ODOFORM SILK.—Colourless silk threads rolled on glass are placed in a solution of iodoform, 1; ether, 9; for two days, then dried and kept in yellow glass bottles.

REVIEWS AND NOTICES OF BOOKS.

A COURSE OF PRACTICAL CHEMISTRY OR QUALITATIVE CHEMICAL ANALYSIS. By the late W. G. VALENTIN, F.C.S. Edited and revised by Dr. W. R. Hodgkinson, F.R.S.E., F.I.C., etc. Ninth edition. Pp. 403. Price 9s. London: J. and A. Churchill. 1898.

Valentin's 'Practical Chemistry' is well known as one of the best works of its kind that can be placed in the hands of a student who desires by conscientious work to become acquainted with the operations of analytical chemistry. Originally devised by the late Mr. Valentin for his students in the old Royal College of Chemistry as the basis of work to be carried out by each student, the publication of edition after edition of this book, culminating in the ninth edition now issued, shows how the value of the instruction therein contained is appreciated by teachers and students. Teaching in a laboratory, as enunciated by the author in the preface to the original edition, must be controlled by a daily examination and verification of the progress made by each student, and this ideal of the duty of a chemical teacher originally conceived by Valentin's master, Hofmann, was scrupulously followed by his pupil. It is to be regretted that such principles of laboratory instruction are not now more general, although it is true that "this can obviously only be done in the case of a large practical class by expending much labour and time upon this all-important part of the laboratory work."

In this edition the plan of the work is the same as in previous editions. Some alterations and additions have been made as modern chemistry requires, and it now includes a chapter on quantitative and volumetric analysis. The course of instruction indicated throughout is that of dealing with each metal of a group in such a manner that the student performs the characteristic reactions and then carries out a scheme of qualitative analysis of each group by a systematic method of separation, and the methods chosen are, as a rule, those which are suitable for the quantitative work which will subsequently engage the attention of the student. The tabular form of expressing and arranging chemical reactions is no doubt a most useful way of embodying methods of separation of the various metals and acids, but it is to be remembered that "on no account should a student use any tabular directions without first having made himself practically acquainted with the details of the reactions; and to counteract any pernicious influence which the use of tables might have, the student should exercise and learn to draw up tables for the several processes of separation which are frequently possible." The several methods of writing chemical formulæ introduced in previous editions have been deleted and the student is therefore spared the thick type formulæ which were at one time peculiar to one school of chemistry. The insertion of the Lemniscate diagram of synthesis of elements in a student's text-book, without further explanation than that the diagram is intended to picture the probable condensation, due to cooling and motion in space, of an original molecule, and referring the student to Crookes' presidential address, Chemical Society, 1888, and of the names only of Argon and Helium in a list of the elements, are perhaps rather extreme instances of bringing a work up to date. It is, however, satisfactory to acknowledge the practical and sensible views of the Editor in inserting in the list of elements a column of atomic weights "commonly used." It is refreshing sometimes to be reminded that a super-refinement is possible in practical chemical operations and that more errors may occur in manipulation than can be satisfied by assuming the atomic weight of oxygen as 15.96 or 15.88 than 16, or carbon as 11.97 or 11.91 than 12, and so on through the

entire list of the atomic weights of elements, determinations more or less open to criticism, as Scott has lately pointed out with regard to carbon.

The new chapter on quantitative analysis contains extremely useful details, as usually obtained in analytical operations, although, strange to say, the weighing results in nearly all the examples are placed in reverse order, and weighing to 0.0002 gramme on a balance responding to 0.01 gramme, which is said to suffice for the exercises given, or even on a balance sensitive to 0.001 gramme, is a non-laudable attempt at accuracy, which partakes more or less of guess work. Such pretensions to accuracy in ordinary analytical operations are no doubt to be attributed to the example set by Fresenius, who, in many of his published analyses, carried out the result to the fifth place of decimals, which, while rather impressive to the lay mind, has to most chemists nothing more than a quotential value. It may be noted that the determination of carbon and hydrogen in the manner here described would not yield very accurate results without further modifications, and a more suitable method of determining nitrogen than by a combustion in hydrogen might have been given. The final chapter on the alkaloids would have been better omitted. Alkaloidal work requires special study, and should not be brought in at the tail end of a book treating of inorganic chemical analysis, and then dismissed in a matter of seven pages. Six alkaloids—morphine and narcotine, quinine and cinchonine, strychnine and brucine—only are described, and in so perfunctory a manner that the student can obtain no possible advantage from this portion of the book. Moreover, it is not a good definition to state that "most alkaloids are of vegetable origin and nearly all contain nitrogen," for it would be interesting to know which are the alkaloids that do not contain nitrogen.

The work is concluded with about 350 questions on practical and theoretical chemistry, which when satisfactorily answered by the student, after conscientious laboratory practice, he may consider himself as possessing some knowledge of practical inorganic chemistry. Dr. Hodgkinson is to be congratulated on this new edition of "Valentin."

CHEMICAL ANALYSIS, QUALITATIVE AND QUANTITATIVE. By WILLIAM BRIGGS, M.A., LL.B., F.C.S., and R. W. STEWART, D.Sc., Lond. Pp. 128. Price 3s. 6d. London: W. B. Clive, University Correspondence College Press. 1898.

This book mainly deals with qualitative analysis, the only portion that is quantitative consisting of fourteen pages on volumetric analysis. The information afforded is accurate and covers the ground usual in treatises on this subject, but in a more concise and systematic manner than is generally the case, as might be expected from the joint labours of two University graduates who are evidently acquainted with the examination wants of students. The student is very properly urged to clearly understand the chemical reactions involved in the analytical operations and to make it a rule to express the various reactions by means of equations. As it is intended for students who are able to obtain little or no assistance from a teacher, the book will be useful, although carrying out analytical operations "with no resources but his own" will be found to be uphill work to the most zealous student.

PRACTICAL ORGANIC CHEMISTRY. By GEORGE GEORGE, F.C.S., Assistant Master at Allan Glen's Technical School, Glasgow. Pp. 96. Price 1s. 6d. London: W. B. Clive, University Correspondence College Press. 1898.

This book is intended principally for the use of students preparing for the elementary or advanced stage of the Science and Art Examinations in practical organic chemistry. It describes

methods of determining melting and boiling points, of detecting the more commonly occurring organic acids, grape and cane sugar, glycerin, aniline, morphine, urea, etc., when singly or in mixtures, and the preparation of a few of the test reagents. It also contains the examination papers set by the Science and Art Department in practical organic chemistry for the last ten years. Sound practical illustrations are given of the work necessary to be carried out by students who desire to be successful at the practical organic chemistry examinations held under the South Kensington scheme, such as it is, of scientific education. The book is evidently written by one conversant with his subject, as is shown more particularly by the methods given for taking melting and boiling points, and students can depend on the various tests and methods of analysis as those most suitable for the purpose.

GARDNER'S HOUSEHOLD MEDICINE AND SICK ROOM GUIDE. Edited and revised by W. H. C. STAVELEY, F.R.C.S. Demy 8vo. Pp. 511. Price 8s. 6d. Thirteenth edition. London: Smith, Elder and Co., 1898.

This work is "expressly adapted for the use of families, missionaries, and colonists." The preface informs us that "the first edition of the work, written by the late Dr. John Gardner, was published in the year 1861. He aimed at providing the non-professional reader with a book which, without encroaching on the proper provinces of a physician or surgeon, would enable him to recognise the more common diseases and indicate a line of treatment which could be safely carried out." In the present edition the rudiments of anatomy and physiology are first described, and later the means of preserving health. A book of this character demands great care in the selection of the subject matter in order to avoid arousing morbid fears in the readers. In the present volume the selection of matter is judicious. The section that deals with the hygiene of daily life is very well done, and there is a short but useful section dealing with the special hygiene required in the tropics. Under the heading "Feeding of the sick" useful tables are given. The sections on first aid to the wounded and injured and on poisoning are also good. The limitations of this class of work are most prominent in the part of the work dealing with surgical affections. The attempt to describe the treatment of genu valgum and lateral curvature of the spine is not likely to help any reader whether lay or medical. Within its limitations, however, the book will serve a useful purpose, more especially in districts where medical men are few.

RESPIRATORY EXERCISES IN THE TREATMENT OF DISEASE, NOTABLY OF THE HEART, LUNGS, AND DIGESTIVE SYSTEMS. By HARRY CAMPBELL, M.D., B.S. Lond. Demy 8vo. Pp. 200. Price 8s. 6d. London: Baillière, Tindall and Cox. 1898.

The value of respiratory exercises of late years has been made prominent in the Nauheim treatment of heart disease. Dr. Campbell states in his preface that "This work is the outgrowth of a larger one on the mechanical treatment of heart disease, a subject which has occupied my thoughts from the very outset of my medical career. It was not until the book was well advanced that I became aware that I had been in a measure forestalled by the physicians of Nauheim." The first nineteen chapters are devoted to the consideration of the physiological principles involved. This, the major part of the book, is characterised by great thoroughness, the established facts of physiology being fully and lucidly stated; the author's views being given in the form of commentaries. Special phases of respiration, as in talking, shouting, singing, etc., are fully considered. With regard to singing the author writes: "I am not

as a physician greatly concerned with the method of breathing employed, provided it be not the exaggerated collar-bone type, which I emphatically deprecate. On the whole I am inclined to recommend the costo-abdominal type. It should be observed that when the diaphragm is actively used the effect on the abdomino-pelvic viscera is greater than is otherwise the case. From the medical standpoint singing is a most important exercise, both by virtue of its influence on the emotions, on the respiratory movements, and on the development of the lungs." Chapter XX. is devoted to the description of the various kinds of respiratory exercises. These are classified as "active breathing exercises, active breathing exercises conjoined with other exercises, passive breathing exercises, and exercises for the developing of the abdominal muscles." The remaining chapters deal with the practical application of respiratory exercises in cases of lung, heart, and nervous disease. Dr. Campbell's work constitutes a valuable and most interesting contribution to medical literature.

SURGICAL TECHNICS IN HOSPITAL PRACTICE. By K. W. MONSARRAT, M.B., F.R.C.S.E. Pp. 132. Price 3s. net. Bristol: John Wright and Co. 1898.

This little work, consisting of short essays, is intended for junior men—house-surgeons, students, dressers, and others engaged in hospital work. "In writing them the author has attempted to systematise the routine duties of surgical hospital practice, and the general plan adopted has been to discuss, in order, the duties of the patient from the beginning to the end of his course of treatment." The all-important matter of disinfection of the surgeon's hands is well described. The section dealing with it concludes: "The third stage is the immersion in antiseptic lotion; the one recommended is a 1-500 watery lotion of biniodide of mercury. Put shortly, the advantages of this lotion are efficiency as a disinfectant, slight toxicity, absence of irritating properties, and the fact that it does not tarnish metal nor form albuminates in contact with the blood and other tissue fluids. The hands require immersion in this for about three minutes, and, of course, are not dried when taken out."

This recommendation is a good one, though it is doubtful whether the biniodide is quite as inactive to steel instruments as the author states. Concerning the surgeon's operating outfit, the author writes: "The most suitable dress for the operating theatre is, without a doubt, a linen overall sterilised by heat; and after each occasion on which it is used, it, of course, returns to the laundry and the steriliser. Some hospitals do not, however, possess the necessary steriliser, though, happily, their number is decreasing rapidly. In this case the best dress is one made of 'jaconette,' reaching from above the collar to below the knees, and buttoned behind at the neck and waist; the sleeves should be attached and reach half-way down the upper arm, being finished off with elastic." The charge of the patient before and after operation, the operation theatre and operations, the modifications of details required for special cases, are dealt with clearly and succinctly in separate chapters. Then follow chapters on the dressings, on drainage and instruments. In describing the sterilisation of silk for ligatures, the author states that they should be boiled in soda solution. This is apparently a slip, for such a course would rot the silk. The usual plan is to boil the silk in 5 per cent. carbolic solution. On the whole the book is admirably put together, and will prove of great utility not only to those for whom it has been published, but also to busy practitioners.

PHARMACY ACTS AMENDMENT ACT, 1898.

As briefly announced in last week's Journal, the Pharmacy Acts Amendment Bill was read a third time and passed on Thursday, July 21. In connection therewith we are desired by the President of the Pharmaceutical Society to publish the following letter from Lord Hardwicke's private secretary and an excerpt from the notes of the Official Reporter to the House of Lords:—

(COPY OF LETTER.)

9, CAVENDISH SQUARE, W.

22nd JULY, 1898.

DEAR MR. HILLS,

I am directed by Lord Hardwicke to say that, as the Lord Chancellor's speech was not reported in any of the papers, he got the Official Reporter to send it to him, and also that he has the Lord Chancellor's permission to send it on to you, in case you would like to send it to the press.

Yours faithfully,

W. HILLS, ESQ.

F. R. COCKBURN.

(EXCERPT FROM REPORT.)

THE LORD CHANCELLOR (THE EARL OF HALSBURY): My lords, I have thought it proper to put down an amendment to this Bill in consequence of representations that have been made to me as to the effect produced by recent decisions in the Courts that the provisions of the Pharmacy Acts do not apply to the case of companies. Those Acts expressly deal with persons only, and it has been held that the word "person" in those Acts does not include a corporation. Numerous instances have been brought to my attention of companies formed for the purpose of carrying on the business of chemists by persons who are not themselves qualified within the meaning of the Pharmacy Acts, and it is also stated that there are companies carrying on the general business of stores, and including a drug store amongst their operations, who cannot be brought within the penalties imposed by these Acts upon unqualified persons. It, therefore, became clear to me that some amendment of the law was desired, and it appeared at first sight as if the Bill of the noble Earl offered an opportunity for such legislation. I find, however, that this Bill is confined to England, and that the amendment which I proposed to make would not extend to Ireland, where, as I am informed, the evil is even greater than in this country. I am also told that some undertaking was given in the other House of Parliament that this Bill, as applying to the internal affairs only of the Pharmaceutical Society, should not include any contentious matter. I do not altogether approve of such undertakings being given in one House so as to bind the other, but as I understand that my proposed amendment would wreck the Bill I cannot proceed with it. I wish to add that the evil in question is one which appears in a still more objectionable form in relation to the medical profession, and of course any amendment of the Pharmacy Acts cannot deal with that still more important branch of the subject. I should be glad to see a favourable opportunity of dealing with the question generally, not only as regards the Pharmacy Acts, but also in relation to the Medical Act. Under the circumstances, however, I will not move the amendment of which I had given notice.

The amendment of which the Lord Chancellor had given notice was as follows:—

A company may carry on the business of a pharmaceutical chemist or chemist and druggist if and so long as the business is *bona fide* conducted by a manager or assistant being a duly registered pharmaceutical chemist or chemist and druggist, but, subject as aforesaid, Sections 1 and 15 of the Pharmacy Act, 1868, shall apply in the case of a company in like manner as they apply in the case of an individual.

The amendment having been withdrawn, the Bill was read a third time and passed, on the motion of the Earl of Hardwicke. The Royal Assent to the measure was subsequently received by Commission on Monday last, and the Pharmacy Acts Amendment Act, 1898, is now part of the law of the realm.

NOTE ON THE ANALYSIS OF FIVE SAMPLES OF NATAL TEA.

BY C. EDWARD SAGE, F.C.S., PH.C.

There have been very few analyses of Natal tea published, and the following figures, which have been obtained with five samples of known authenticity, supplied me by C. E. Walkey, Esq., of Durban, should be of interest when compared with the results obtained with China, Indian, and Ceylon teas.

The samples examined were contained in lead foil packages and comprised the following varieties:—(1) Flowery Pekoe, (2) Golden Pekoe, (3) Pekoe Souchong, (4) Pekoe, (5) Broken Pekoe, all of which were grown upon estates in the neighbourhood of Stanger.

The soil on which they were grown was principally a light grey loam, with a substratum of grey sandstone, situated about 700 feet above sea-level. The samples were all of 1897 season's gathering.

The determination of the undermentioned constituents yielded the following results:—

Sample.	1.	2.	3.	4.	5.
	p. c.	p. c.	p. c.	p. c.	p. c.
Caffeine.....	2.95	2.78	3.34	2.94	3.08
Tannin.....	8.1	10.8	10.7	8.9	6.7
Vegetable extractive matter.....	24.61	23.54	19.32	24.91	22.62
Inorganic extractive matter.....	4.24	4.45	4.95	4.46	4.38
Total extracted by water.....	39.90	41.57	38.31	41.21	36.78
Moisture.....	8.19	7.95	9.19	9.36	9.57
Ash.....	5.30	5.25	5.51	5.63	5.26

The figures for caffeine were obtained by exhaustion with boiling water and shaking out with chloroform, after removal of astringent matter; and the tannin was determined by a modification of Löwenthal's process, which gives a much higher figure with Indian teas than those recorded above.

The ash in each case contained a notable proportion of manganese, and the following figures show the results of the determination of other factors.

Sample.	1.	2.	3.	4.	5.
	p. c.	p. c.	p. c.	p. c.	p. c.
Total ash.....	5.30	5.25	5.51	5.63	5.26
Insoluble ash.....	1.91	1.98	1.92	1.98	1.82
Soluble ash.....	3.39	3.27	3.59	3.65	3.44
Alkalinity of ash calculated as K ₂ O.	1.43	1.27	1.53	1.40	1.23

Natal tea has found little favour in the English market in the past, owing to the fact that the shipments which have reached the London market have been only indifferently prepared and imperfectly fired, but I am assured that the largest growers are content with supplying the South African market only, and that none of the best brands have been sent to England. The large growers now possess all the necessary and most modern machinery and cure their crops in the same way as the growers on the Assam estates, and from the above results it seems that their products are likely to find favour in the English market, owing to the low proportion of astringent matter which they contain as compared with Indian teas.

PHARMACEUTICAL JOURNAL.

COMPANIES AND QUALIFICATION.

WITHIN the last few weeks there has been in both Houses of Parliament very decided recognition of the fact that the state of the law relating to the practice of pharmacy is extremely unsatisfactory and requires amendment. That fact has long been painfully apparent to those engaged in the business, though it has not been generally much recognised. The somewhat unexpected reference to this subject by the LORD CHANCELLOR and Lord HERSCHELL, when the Pharmacy Bill was before the Standing Committee of the House of Lords, affords satisfactory evidence, however, that it has not been overlooked and that there is now a prospect of obtaining consideration of the much needed amendment of pharmacy law. The efforts made in that direction may be much facilitated, if advantage be taken of the useful Act which has now received the Royal assent, affording every person on the Register of Chemists and Druggists opportunity of sharing, equally with other members of the craft, in the work of an organisation possessing power of self-government unequalled in any other occupation of a similar nature. If that opportunity be properly used some nearer approach may be made to the original object of the Society, by establishing such a qualification for the practice of pharmacy as would be at once, for the public, a guarantee of competence and for those carrying on the business of chemists and druggists, a corresponding protection. The partial success attained in that direction under the Act of 1852, constituted a mere oasis in the desert of unregulated chemist-and-druggistry, while the mis-application of free trade ideas obscured all other considerations and the idea of protection, on the basis of educational qualification, was scouted as fantastic. When, still later the general state of the practice of pharmacy had been declared "a disgrace to the country and to the Legislature" and the advantages of organised incorporation were irresistibly forced upon the attention of chemists and druggists, the provisions for effecting improvement were so watered down that the qualification conferred under the Act of 1868, instead of realising the Society's object, had reference only to a small portion of the chemist and druggist's business: instead of placing exclusively in his hands the semi-professional work of compounding, dispensing, and supplying drugs and medicinal preparations, it left him in the main open to the purely trading competition of grocers and general store-keepers.

On the first intimation by the LORD CHANCELLOR that he thought amendment of the Pharmacy Acts necessary, special reference was made to the legal decision as to companies being outside the scope of those Acts; but it did not go beyond suggesting the common-sense view that a company should be liable to penalties for infringement as much as an individual. As a company is incapable of the personal qualification held by that decision to be necessary, there was some reason for the inference that the LORD CHANCELLOR desired to extend the application of the word "person" and thus to prevent companies from carrying on the business of a chemist and druggist. That there is need of some means for effecting that object cannot be denied, and that need was further illustrated by Lord HERSCHELL's mention of "one-man companies" as a mode of evading the statutory obligations attaching to the business of a chemist and druggist. Lord HARDWICKE's acquiescence in the suggestion of amendment in that sense was, so far, perfectly natural and, if the object of the Bill before the House had not been confined to the internal affairs of the Pharmaceutical Society, such amendment might have been practicable. But that was not the case; moreover, when the clause, drafted by the LORD CHANCELLOR, appeared some days later, it proved to be of such a nature as would recognise the legality of company trading, even in its worst form of the "bogus" or one-man company, while giving legislative sanction to the vicious practice of lending individual qualification for the purpose of evading and defeating the real intention of the Pharmacy Acts. That such an object was not contemplated by the LORD CHANCELLOR in proposing amendment of the law—or, indeed, by Lord HERSCHELL in supporting that proposition—appears evident from the remarks made by His Lordship, when, in deference to representations made to him, he withdrew the amendment, mainly on the ground that it might impede the passing of the Bill before the House. To suppose that the Pharmaceutical Society—irrespective of the agreed non-contentious nature of the Bill—could have done otherwise than oppose the clause as it stood, would involve the assumption that it is willing to forget its own history, to ignore the spirit of the Pharmacy Acts and to assist in placing persons qualified under them in a position to become the mere servants and tools of antagonistic combinations which are at least outside the law, if they are not actually illegal. Such a decadent compact would invite increased company domination, making the last state of the craft worse than the first.

It will therefore be noted with satisfaction by readers of this Journal that the LORD CHANCELLOR still adheres to his opinion that amendment of the law is needed in regard to the evil of company trading, as it affects the practice of pharmacy and, in a still more objectionable form, the medical profession. Holding that opinion he desires to see a favourable opportunity of dealing with the subject generally, not only as regards the Pharmacy Acts, but also in relation to the Medical Act. In an article on this subject entitled "Companies as Practitioners," the *British Medical Journal*, last week, expressed the opinion that in view of the difficulty of discriminating between a company formed for some legitimate purpose and one formed with the object of evading the restrictions or escaping the penalties enforceable against individuals in regard to occupations requiring personal qualification, there does not appear to be any hope of preventing, at the outset, the incorporation of such improper

companies. In support of that view an account was given of the unsuccessful efforts made to induce the President and the Departmental Committee of the Board of Trade to provide a remedy for the evil. The task must be undertaken from a different point of view, and reference was made to the action of the LORD CHANCELLOR in connection with the Pharmacy Bill as offering a better prospect. One of the chief difficulties to be overcome is the dread of monopoly so artfully fostered by the supporters of companies. But in the case of occupations such as the practice of medicine or surgery, dentistry, the veterinary art, or the practice of pharmacy, requiring special knowledge and technical skill for the proper performance of the functions appertaining to them, deprecation of monopoly on free trade principles has no reasonable applicability. Statutory limitation of the exercise of those functions to persons certified to possess the requisite competence is justifiable, as having for its object the interest of the public. On that account alone it is the duty of the State to prevent evasion and to punish infringement of the law relating to qualifications. But as regards persons acquiescing in the demand for qualification to exercise a particular calling, there is another reason for enforcing the legislative restrictions, for they and the State may be regarded as parties to a contract, securing, on the one hand, efficiency in the public interest and, on the other, freedom from the competition of unqualified persons. It appears to be on such lines that amendment of the Pharmacy Acts and even of the Acts relating to medical, dental, and veterinary practice, should be approached. With due regard for maintenance of the value of qualifications, either by mutual loyalty or the exercise of repressive censorship within the ranks of professional bodies, it should be possible for their representative organisations to join in the demand for legislation, so as to expel from consideration the misleading bogie of monopoly, counteract the mischievous precedent of the decision in the case of the London and Provincial Supply Association and provide a remedy for the systematic evasion by which the trail of the company "limited" is being spread over all those occupations.

A VENEZUELAN PHARMACOPŒIA.

THE latest addition to the list of the world's pharmacopœias is the 'Farmacopea Venezolana,' published at Caracas, this year. The work has been edited by Dr. FRANCISCO A. RISQUEZ, approved by the Medical Council of the Republic and declared authoritative by the National Executive of Venezuela. The book is sent out in paper covers, and it contains 466 pages, of which 26, constituting the index, are printed on coloured paper to distinguish them from the text. In the preface, which is comparatively brief, reasons are given for the existence of the work; the steps taken in connection with its production are also explained in detail. Following the preface is a page of abbreviations of proper names used in the work, next a page of notable errata, another of minor errors, then a list of contents occupying three pages. The language adopted in this pharmacopœia is the vernacular, *i.e.*, Spanish, but synonyms are given in Latin. Unfortunately, however, those synonyms are not indexed, so that their utility is wasted to a considerable extent. The book is divided into four parts, the first consisting of thirty pages and dealing with *nociones preliminares*, including weights and measures, tables of densities, a

comparative table of temperatures indicated by the three thermometers, a table showing the solubilities of the principal substances employed in medicine, together with lists of maximum doses, incompatibilities and reagents. Metric weights and measures alone are used in the body of the work, but in the preface are given the approximate equivalents of what are apparently assumed to be the English weights and measures used in prescriptions, though there would seem to be some confusion between the denominations of avoirdupois and apothecaries weights.

The second part of the work, extending to 141 pages, is devoted to simple medicaments (*drogas simples*), including the acids and other chemical substances as well as vegetable materia medica. In the monographs in this section the Latin synonyms are followed by descriptions of the characters of the substances, after which their properties and uses are briefly summarised. The names of chemicals are followed by their symbols, and, in some cases, the method of preparation is given. Metallic compounds are dealt with under the general headings of the respective metals. Thus, under "Calcio—(Ca)" are described calcium carbonate, chloride, hypophosphite, phosphate, oxide, sulphide, sulphate, and hypochlorite. In like manner the compounds of iron and potassium occupy nearly four large octavo pages for each metal, and those of mercury and sodium some three pages each. Amongst the substances mentioned in this part of the book are: Aniline, antipyrin, apiol, apomorphine, aristol, asaprol, betol, bromoform, chloralamide, curare, diastase, divi-divi, ethyl bromide and chloride, exalgine, guarana, guaiacol, hæmoglobin, hypnal, hypnone, ichthyol, ingluvin, iodol, kairine, kava-kava, lysol, maté, methyl chloride, naphthalin, naphthol, pancreatin, peptone, phenacetin, pyridine, quinoline, resorcin, saccharin, simaruba, sulphonal, thalline, terpin, terpinol, trypsin, and xylo.

Galenical pharmacy is the subject of part three, consisting of 196 pages. This section commences with brief paragraphs on calcination, clarification, dialysis, distillation, filtration, solution, and numerous other operations more or less familiar to the pharmacist, then follows the official formulary in which, as already stated, metric weights and measures are used exclusively. Where the same process is resorted to for the preparation of a number of similar preparations, the same plan is adopted as in the French 'Codex.' Thus, tincture of aconite root is directed to be prepared by macerating the fresh root in an equal weight of alcohol (90°), and at the end of the monograph it is stated that thirteen other tinctures, including those of aconite leaves, arnica flowers, belladonna root, and digitalis leaves, are to be prepared in a similar manner. The last part of the book gives particulars concerning various medicated waters. These are classified as gaseous acidulated waters, alkaline waters, ferruginous, saline and sulphurated waters. In a few instances instructions are given for preparing the waters, but in most cases only the approximate composition of the natural water is stated. At the end of this section of the book information is given respecting the laws of the Republic relating to medicine and pharmacy, with extracts from the Penal Code and a list of substances which may only be supplied when ordered by a medical practitioner. There are also lists of proprietary medicinal preparations (*medicinas patentadas*) approved by the Medical Council and of similar preparations, presumably in common use, which have not as yet been submitted for the approval of that body.

ANNOTATIONS.

THE PHARMACY ACTS AMENDMENT ACT, 1898, is now an accomplished fact, and any registered chemist and druggist is eligible to be elected a "Member" of the Pharmaceutical Society on the same terms as pharmaceutical chemists, and with the same rights and privileges when elected. One of the original intentions of the founders of the Society is thus realised, a standing grievance of chemists and druggists who have passed the qualifying examination is removed, and it may be hoped that the result will tend equally to the benefit of the Society and of the craft. The new Act comes into force on Monday next, and every person who, at the time it passed, was a subscribing "Student" of the Pharmaceutical Society, will, in accordance with the terms of the Act, be duly registered as a "Student-Associate." The existing "Associates" must, if they desire to retain their connection with the Society after the current year, apply to be elected as "Members," whilst "Associates in Business" will probably be elected as "Members" without the necessity of a formal application in each case. But before fully carrying out the new arrangements, an entire revision of the existing Bye-laws will be necessary, and as the requisite Bye-laws must be read on three separate occasions at meetings of the Council, then confirmed at a Special General Meeting of the Society, and finally approved by the Privy Council, it is obvious that some time must elapse before everything is in proper working order. But with the beginning of the year 1899 all these details will doubtless have been successfully arranged, and let us hope that the Pharmaceutical Society will then proceed along the path of progress with brighter prospects than at any former period of its existence.

A SPECIAL ISSUE OF THE JOURNAL will be published the week after next in connection with the Conference at Belfast and, as a means of disseminating amongst the whole craft information regarding the changes in the law affecting pharmacists, a copy of that issue of the Journal will be sent to everyone whose name appears upon the Register of Chemists and Druggists. The total circulation will exceed 17,000, and this will be an exceptional means of addressing as wide a circle of the trade as possible. On professional, business, or political grounds, this opportunity should therefore not be neglected. A full report will be given of the proceedings of the Conference at Belfast, including the whole of the papers read at that meeting, in addition to much other matter of special interest to chemists and druggists.

AN UNFORTUNATE POISONING CASE is reported from Windsor, which appears to reflect blame upon the chemist's assistant involved in the affair, though it is far from clear that he was actually responsible for what took place. According to the evidence, a woman who was a confirmed laudanum drinker went to the pharmacy conducted by Mr. J. G. Everett, and his qualified assistant supplied her, as he thought, with six drachms of laudanum. But shortly after swallowing this, the woman became seriously ill, was removed to the local infirmary, and died within two hours after several attacks of convulsions. The post-mortem examination showed that death was due to strychnine poisoning, and on the assumption that the assistant had accidentally supplied tincture of nux vomica instead of laudanum, the jury returned a verdict of manslaughter by misadventure. The bottle which had contained the poison was quite empty when found, and the case against the accused was mainly based on the fact that, at the inquest, he acknowledged the poss-

bility that he might inadvertently have taken the tincture from the wrong bottle, as both tinctures were kept on the same shelf. The accused was committed for trial on the coroner's warrant, but when brought before the magistrates he was immediately discharged, in accordance with the provision of the law which states that "no punishment or forfeiture shall be incurred by any person who shall kill another by misfortune." Great sympathy has been expressed locally with Mr. Everett and his assistant, and testimony is freely borne to the high character of the latter and to his skill and care as a dispenser. Whether or not he was actually at fault in this matter, it is to be hoped that the unfortunate occurrence may have no lasting effect upon his career, other than that of exceptionally impressing him with the necessity of exercising extreme care in dealing with poisons.

THE MORAL POINTED BY THE CASE appears to be that it is unsafe, under any circumstances, to keep bottles containing potent poisonous liquids on the same shelf in the pharmacy as less poisonous ones. And it is because of this aspect of the matter that so many prominent pharmacists have always protested against the imposition of cast-iron regulations with regard to the keeping of poisons. If all scheduled poisons were to be kept in the same locked cupboard the risk of error would be greatly enhanced, as compared with the prevailing system. At present only the more potent substances are relegated to the poison cupboard, and others take their place, preferably in special bottles with distinctive labels, on the ordinary shelves. The risk of error is thus reduced to a minimum and, with the constant watchfulness which is the first duty of the pharmacist, is practically non-existent. In Mr. Everett's case it is reported that twenty-one bottles containing poisonous liquids stood upon the same shelf, and that only one bottle intervened between those containing the tinctures of laudanum and nux vomica. If that statement be correct, and the bottles are similar in size and shape, the necessity of increased care is obvious, and the arrangement can only be described as an unfortunate one for the pharmacist and his assistants. The bad habit of taking down bottles without looking at their labels is so easily acquired by negligent persons that, in the case of poisonous preparations differing greatly in potency, and resembling each other in appearance, it is safer to have them separated by a considerable distance. But the best safeguard of all is to make a point, whenever dealing with poisonous liquids, of looking carefully at the labels on the bottles, and also paying intelligent attention to the general characters of the contents. Moreover, it should invariably be regarded as extremely unsafe to attempt to converse with customers whilst taking down bottles from the shelves. This is a fruitful cause of error and should be avoided consistently.

THE PRESENCE OF ARSENIC IN WOOL, as a result of using arsenical preparations for dipping sheep, and the consequent possibility that, when spun into fabrics or carpets, etc., sufficient arsenic may remain to be injurious to health, appears to have been much exaggerated by Mr. J. H. Pearse, the Chairman of the Kidderminster Chamber of Commerce, in a recent letter to the *Lancet*. While he states that, it is nearly, if not quite, impossible to buy any sheep's wool—home or foreign grown—which does not contain arsenic, Mr. Robertson, a manufacturer of both arsenical and carbolic preparations for sheep-dipping, writing from Oban, states that, although the great majority of sheep are dipped with an arsenical preparation, a very large number are dipped with other preparations—principally of carbolic acid, next tobacco, and a considerable number with a mixture of lime and sulphur. He also adds that one-fifth of his entire output last year was the car-

bolic preparation, and that 80 per cent. of it was exported to the Colonies and South America.

THE EXCEEDINGLY SHADOWY NATURE of the privileges of duly registered members of the medical profession has been pointed out by Dr. T. R. Henderson in last week's *Lancet* and contrasted with the more adequate protection afforded by law to duly enrolled solicitors against unscrupulous competition on the part of those whose names have never appeared in the 'Law List,' or whose misconduct has entailed their removal from it. Why, he asks, should duly registered members of a profession not a whit less honourable, be obliged to share the right of practice with anyone possessed of sufficient self-assurance to make a show of professional skill and sufficient cunning to keep within the generously defined bounds imposed by the existing law? The same question may be asked by registered chemists and druggists in regard to the invasion of their business by companies.

CARBOLIC ACID has been the cause of yet another death which might have been avoided if the deadly fluid were only scheduled under the Pharmacy Act, 1868. A death from consumption had occurred at Stoke Newington, and the mother of the deceased youth purchased some carbolic acid to expose in the room where the body lay. A "medicine bottle" was sent for the poison, and the seller placed no label upon it. A few days later the woman was taken ill, the medical man in attendance sent her some medicine resembling the carbolic acid in colour, both bottles stood awhile on the same shelf, and the usual result followed. For the husband of the patient administered a dose of what he believed to be the medicine, but it proved to be carbolic acid, and the patient died. At the inquest the Coroner remarked that it is one of the misfortunes of the age that carbolic acid is not on the list of poisons that have been scheduled, and the jury expressed the opinion that its sale ought to be restricted to chemists only. This death may fairly be attributed to the persistent refusal of the permanent officials of the Privy Council to protect the British public in this respect, for so many years past.

PITY THE POOR IMPERIAL INSTITUTE! is the cry now raised by the *Times*. It is pointed out in a pathetic article in that influential organ that for some time the Institute has been struggling with financial difficulties, and that widely divergent opinions exist as to the method, or even as to the possibility, of meeting them. "So-called friends of the people question, indeed, whether they should be met at all. In their opinion the Imperial Institute is a white elephant, and they doubt if the English climate is suited to that class of cattle." This view, it is thought, will hardly commend itself to the country at large, but we may fairly ask, Why not? For what has the Institute done that it was intended to do? Nothing, as those who are running the concern well know, and as the withdrawal of assistance by the Colonies goes to prove! The *Times* writer thinks it is unfortunate that the Institute, while embodying an Imperial idea, has not been recognised as a subject for Imperial support. Presumably the Treasury is opposed to the creation of well-paid sinecures for individuals who are well able to work for a living and pay their own expenses. We are told that after the first flush of enthusiasm (?) accompanying the establishment of the Institute three means presented themselves for justifying its existence, and earning an income, within the scope of its original design. "It might turn itself into a permanent show-house and huge advertising agency for the wares of India and the colonies and lease its superficial area at a handsome figure per square foot, as had been done by the Colonial and Indian Exhibition. Or it might take itself seriously, and

become the central economic museum for the Empire, the great sample-room for the mineral and vegetable products and manufactures of the British race. The third alternative was to develop it on the social side and make it a sort of universal club for colonists and all others whom it could attract by a low subscription and an easy entrance." Whilst acknowledging that there was distinctly money in the first and third plans, the inspired writer for the *Times* audaciously asserts that "to the credit of the managing body it chose the better path." If anyone could believe that statement, it should not be difficult for him to credit all the nonsense about the great benefits that have accrued to India in return for the enormous sum she has sunk in the bottomless pit at South Kensington. It is worthy of note, however, that even the writer of the bombast referred to is compelled to acknowledge that of all the advantages India has reaped "no better example could be given than the exhaustive inquiry by Professor (*sic*) Wyndham Dunstan, F.R.S., into the coal supply of India, appended to the 1898 report," Little as that is, however, so overcome is the enthusiastic writer that he hopes to return to "this admirable piece of research" on a future occasion. Apparently he believes in holding on to the bone he has found in the rubbish heap, lacking anything better to go on with.

WHY NOT WOMEN CHEMISTS? asks a weekly paper of the genus "scrap." And we answer, No reason whatever! There were women engaged in business as chemists and druggists before the Pharmacy Act passed in 1868, and there have been more or less of them ever since. No restriction has ever been placed in the way of women desiring to become registered chemists. The only wonder is the ignorance that enables the lay press to find so much novelty in the idea of women dispensers. Another weekly paper, called the *Ladies' Home*, informs its readers that "the examinations for chemists in England are held by the Society of Apothecaries of London and the Pharmaceutical Society of Great Britain." This, of course, is one of those misleading half-truths that are apt to give rise to much trouble. The Society of Apothecaries has no power, in this respect, but to grant pretty certificates to foolish persons who choose to pay the fee demanded and waste three guineas in that way, and are also able to pass a very second-rate examination. It is greatly to be feared that the notion is spreading among a certain class that the Apothecaries' Assistants' Examination serves as a short cut to a useful qualification, but, as a matter of fact, the successful candidate at that examination has no right to do anything which he was forbidden by the law to do before he spent his three guineas and got so little in return for his money. The examinations conducted by the Pharmaceutical Society under the control of the Privy Council alone entitle those who pass them to call themselves chemists, and such persons alone are entitled to keep open shop for retailing, dispensing, or compounding poisons, or to assume or use the title of chemist. The Apothecaries' Society's fiction about its assistants' qualification has been maintained too long; even if it were an impetuous body increasing its failing revenue by such unworthy means as the sale of ornamental certificates, accompanied by the pretence of a qualification, it should at least have the decency to cease lowering its dignity in so unworthy a fashion.

THE EASTMAN PHOTOGRAPHIC MATERIALS COMPANY, LIMITED, referring to the *Solio* appeal case in the House of Lords, point out that the company was refused registration of the word "*Solio*" in 1895 by the Registrar of Trade Marks, and that decision was upheld successively by the Board of Trade, Justice Kekewich's Court, and the Court of Appeal. The Eastman Company persevered

and paid all costs in every instance, as well as in the final appeal to the House of Lords, which has now reversed the decision of the previous Courts. The word was originally refused on the ground that it was derived from "Sol" (the sun), and that as it was possible to print silver paper in sunlight, the word was descriptive, and so, under the Patents, Designs, and Trade Marks Act, not permissible as a trade mark. This decision was based on a reading of the Act, which held that a trade mark must not only be invented but, even if invented, it must also be in no way descriptive of the goods. The House of Lords has now decided, however, that a registrable word, if it is truly an invented word, may contain skilful allusion to the nature of the goods referred to. But to be held as an invention, a word must not be merely two known words strung together, nor a known word of the language with a slightly modified ending. So long as a new invented word is used and the public are not robbed of the use of a descriptive word which is the property of the community, the object of the Act is attained. It appears that, as a matter of fact, the origin of the word "Solio" had nothing to do with "Sol" (the sun). It arose through an official submitting to one of the principals of the firm the word "Soho"—the business then being conducted in Soho Square. This was misread as "Solio," and so it came to be established. Lord Halsbury, the Lord Chancellor (who is a distinguished amateur photographer), himself happened to be a user of the Eastman Company's "Solio" printing-out paper, and he made a statement to that effect, and added that it never in the world occurred to him that there was anything descriptive in the name. In fact, as Lord Herschell pointed out, there is just as much reason why the word "Solio" should be taken to refer to boots (from the sole), or to agricultural implements (from the Latin "Solum," the ground).

THE PREVENTION OF CONSUMPTION is a most laudable object, and Mr. Malcolm Morris is to be congratulated upon the satisfactory response to his appeal to organise a national boycott against the disease. He has enlisted the sympathy of the leaders of the medical profession, and a circular letter has been issued by the President of the Royal College of Physicians, the President of the Royal College of Surgeons, and Sir William Broadbent, in which they call attention to an association which has been formed with the object of preventing the spread of the most fatal disease to which mankind is subject. They point out that it has gradually become definitely known that tuberculous disease, of which pulmonary consumption, or phthisis, is an example, is not inherent in the constitution, but is communicated indirectly from pre-existing cases, and the principal methods by which it is spread have been identified. Tuberculous disease, which in one or other of its forms is responsible for at least one in ten of the deaths from all causes, and, according to some calculations, for one in six of the deaths among adults, is therefore preventable. For this the education of the public is needed in the methods of prevention and eradication, and the stimulation of individual effort in carrying them out. The objects of the Association are the dissemination of information, the arousing of public feeling as to the necessity for defensive measures, and the provision of sanatoria, which will be both preventative and curative, for the open air treatment of consumption. In order to enlist the co-operation of large numbers, the annual subscription for membership has been fixed at 5s., and the donation for life membership at £5 5s. All members will receive a full description of the measures which are proposed, and information as to the organisation of the Association. The offices of the Association are at 20, Hanover Square, W., where members can now be at once enrolled.

THE POISONOUS SUBSTANCES BILL still continues to interest the lay press, and the London *Echo* appears to have been successful in having a chat with a pharmacist, who had committed to memory the first column of our last week's "Annotations," and retailed them to the newspaper man as his own wisdom, unless indeed there is a very ingenious adapter of paragraphs on the staff of that newspaper. For the only way suggested by the pharmacist, echoing the *P. J.*, in which carbolic acid can be placed beyond the reach of people disposed to misuse it, is that it should be added to the Schedule of the Pharmacy Act of 1868. That, he thinks, would be sufficient, provided the Act could also be amended. Such amendment, he contends, is necessary, because "at the present time the Pharmacy Act of 1868 is evaded with the greatest ease by joint-stock companies, photographic dealers, and others who are not qualified chemists." With regard to the term monopoly, that, he states, in a *P. J.* echo, "would be as much misapplied as if applied to the restriction of the practices of the law or medicine." Another *P. J.* echo is the following paraphrase:—"The man in the street would, of course, like to purchase what he wants whenever and wherever he chose. But in the case of poisons the Legislature has wisely provided that only those competent to deal with poison should sell it." A little more originality was displayed in the pharmacist's concluding remarks, wherein he said that "the administration of medicine forms an important factor in medical treatment; considerable scientific knowledge is required in recognising the chemical and physical relationships of drugs, while the medical profession and the public are entirely at the mercy of the pharmacist. Its practice by irresponsible corporations, large or small, should not be tolerated." But even those words strike us as being strangely familiar.

MOUNTED SPECIMENS FOR THE MICROSCOPE are difficult to prepare for permanent preservation, expensive to purchase, and apt to accumulate and be in the way when their immediate purpose has been served. Much interest, therefore, should attach to the proposal of Mr. C. Baker, High Holborn, London, to start a department for lending such specimens on much the same lines as a lending library. It is thought there can be no doubt such an arrangement would greatly enlarge the range of most amateur microscopists, especially beginners and those who, living in the country, are precluded from joining any of the microscopical clubs or societies, except as corresponding members. As the latter will, it is anticipated, form the bulk of the subscribers, should the undertaking prove a success, Mr. Baker has arranged for the subscription to include postage both ways. The annual subscription will be one guinea, payable in advance. For that sum each subscriber will have the right of borrowing some two hundred and fifty specimens in twelve deliveries, that is to say, twenty-four slides posted monthly for the year, or the same number of slides posted each fortnight for the winter months only. In order to save subscribers as much trouble as possible it is proposed to send the specimens in special boxes with double wrappings, the inner one of which will be stamped and addressed for return, so that the subscriber has only to re-wrap the parcel and post it. Should sufficient subscribers send in their names, steps will at once be taken to compile a catalogue especially for this department, so that subscribers may choose as far as possible the specimens they wish to see. This, however, would not be possible until the undertaking is an assured success. Readers of the Journal desiring to subscribe should communicate with Mr. Baker at once, and they will receive notice in due course when the minimum number, consistent with the idea being a business success, have sent in their names.

British Pharmaceutical Conference

Meeting at Belfast.

Albert Memorial, Belfast.

It is so long since the pharmacists of the three kingdoms held their annual scientific picnic in Erin that it may be news to many that the British Pharmaceutical Conference is about to visit Ireland for the second time in its history. On the former occasion twenty years ago, Dublin was the place of assembly, and the late G. F. Schacht presided over the meeting; on Tuesday week Dr. Symes will take the chair at Belfast, the northern capital of the Green Isle. Situated at the mouth of the river Lagan, the city of Belfast is partly in Antrim and partly in County Down. According to the excellent little guide

to the North of Ireland published by the Belfast and Northern Counties Railway, a copy of which should be procured by everyone visiting Belfast, the name of the city is said to be derived from *Beal-Fearsat*, signifying "the mouth of the ford"; a name anciently applied to the district now occupied by Belfast. The ford is supposed to have been situated near the place where the Albert Memorial now stands. Castle Place marks the site of the castle built by the De Courcey family about the thirteenth century. In the year 1888 Belfast was created a city, and in 1892 the title of Lord Mayor was conferred upon its Chief Magistrate. The boundary of the city was extended by the Belfast Corporation Act of 1896, and the estimated population of Greater Belfast for the present year is 304,610.

The progress of the city has been strikingly rapid, and in addition to the magnificent squares and great works of art, the visitor will see, in the numerous mills, in the busy streets, in the bright, well-dressed shops, in the clang and din of the shipyards, and in the plain but massive linen warehouses, sufficient justification for calling Belfast the commercial capital of Ireland, just as Glasgow is with good reason termed the commercial capital of Scotland. "It is the principal seat of the Irish linen industry. The great Transatlantic steamers for the White Star Line were built at Queen's Island shipyards, on the banks of the Lagan. An extensive foreign and colonial export trade is done in mineral or aerated waters, and in cured hams and bacon sides. Whiskey and tobacco are very largely manufactured, the duty paid on these articles amounting annually to an enormous sum. Belfast returns four members of Parliament, and has 43,550 voters on the Parliamentary Register (1898). The police force, including officers numbers a little over 900 men."

As in the case of Glasgow, Belfast is best seen in its streets, shops, warehouses, and other buildings, and as the city possesses a most complete, efficient, and well-managed tram service, a very convenient, and at the same time economical, way of viewing it is to make a survey from the top of a tramcar. In the handy little "guide" already mentioned the following table is given of

a short tramway tour through Belfast, with such descriptive notes of each route as will enable the visitor to see the characteristic features of the city with a minimum of trouble:—

SHORT TRAMWAY TOUR THROUGH BELFAST.

- (1) Castle Junction to Northern Counties Railway, via Royal Avenue.
- (2) Northern Counties Railway, via Corporation Street (change at Castle Junction), to Shankill Road (as far as Northumberland Street).
Walk along Northumberland Street to Junction of Divis Street and Falls Road (in 5 minutes).
- (3) Falls Road to Station Street (end of Queen's Bridge), via Castle Junction. (Here change.)
- (4) Station Street to Lisburn Road. Change at Castle Junction to tram going via Bedford Street to Balmoral (as far as Methodist College).
Walk from Lisburn Road to Botanic Gardens Park (in 4 minutes), via College Gardens Avenue, in front of Methodist College.
- (5) Botanic Gardens Park to Antrim Road (Terminus, Chichester Park), via Great Victoria Street. (Take Crumlin Road tram and change at Carlisle Circus to one for Antrim Road.)

Approximate time, 1½ hours; Cost, 10d.

Though the tour does not by any means extend over the whole of the tram lines, the routes have been chosen that they give the traveller, in as short a time as possible, a fairly good idea of the various aspects of the city. There is also plenty of variety, for while the routes all have something common to one another, each has, at the same time, something peculiar and characteristic. Route 1 takes the traveller through some of the business avenues of the city; 2, into the mill and artisan district; 3, to the shipping in the harbour; 4, past the offices and warehouses of the linen merchants; and 5, to districts containing the colleges and suburban residences.

The opening meeting of the Conference will be held in the Library of Queen's College on Tuesday, August 9, when welcomes will be offered by the Lord Mayor of Belfast on behalf of the citizens, and by the Rev. Thos. Hamilton, D.D., President of Queen's College, on behalf of his College.

Queen's College was founded in 1845, and lectures are there given in the faculties of arts, medicine, law, and engineering. In the Natural History and Anatomical Museums there are fine collections, and the Examination Hall contains a number of paintings, among which are an ancient portrait of Milton, one of Henry VIII. when a child, and a copy of Titian's "Assassination of St. Peter, Martyr," the value of which has been estimated at five thousand pounds. There is an extensive view from the Tower of the College embracing the city, Belfast Lough, and surrounding country.

After the presidential address has been duly delivered by Dr. Symes, the reading and discussion of papers will commence and continue until 4 p.m., with the usual break for luncheon at 1 p.m. As the luncheon will be served in the Examination Hall of Queen's College, no time will be lost in this connection, a very desirable thing in view of the large number of papers to be read and the extensive programme arranged by the local committee.

Afternoon tea will also be served in Queen's College, after which there will be a drive to Giant's Ring, Purdysburn, Ormeau Park, etc. The Giant's Ring is an immense earthen "rath" or rampart—eighty feet wide at the base—surrounding the remains of what is supposed to have been a huge cromlech; Ormeau Park is very

near to Queen's College, and bordered on one side by the river Lagan. Returning from the drive, at 8 p.m. there will be a reception by the President of the Conference and Mrs. Symes, and a conversazione at Queen's College. Amongst the attractions on this occasion will be a demonstration of radiography, an exhibition of early and rare Irish herbals and other works by Mr. R. M. Young, J.P., and vocal and instrumental music, whilst light refreshments will be served as usual on such occasions.

On Wednesday, August 10, the close of the day's business will be immediately followed at 3.30 p.m. by a garden party in the Botanic Gardens Park, by invitation of the Lord Mayor and Lady Mayoress. The Botanic Gardens Park has an extent of about 17 acres, and is tastefully laid out. Until recently the ground belonged to a company, but the City Corporation having purchased it, the park was formally opened to the public in March, 1895. It contains a fine conservatory and fernery, and a large exhibition hall, which is used occasionally for balls and meetings. The garden party will conclude about 6.30 p.m., and the usual smoking concert and ladies' drawing-room concert will be held subsequently at the headquarters of the Conference—the Grand Central Hotel.

The excursion to Larne, Garron Tower, and Parkmore on Thursday, August 11, will be the great feature of the Conference on the social side. The party will leave Belfast by the train for Larne Harbour departing from the Northern Counties Railway Station, York Road, at 9.5 a.m. Soon after leaving York Road terminus the city is left behind and a fine view obtained of the Cave Hill and of Belfast Lough, the opposite shores of which are in County Down. The first station passed is at Greencastle, a village which is continuous with Upper Whitehouse. The first cotton mill in Ireland was erected at the latter place more than a century ago. The remains of a house, called King William's ruins, which lie, on the right of the railway, in Lower Whitehouse, are said to mark the site of one of the resting-places of King William III. when on his march to the Boyne. In the *Ulster Journal of Archaeology* for 1853 it is stated

that the King's forces disembarked at the Old Whitehouse, or what is better known as Macedon Point, and from Whitehouse the King is said to have driven over the strand to Belfast.

Leaving the sea-shore and passing first through a short tunnel, then between embankments covered with laurel and fir trees, the train reaches Whiteabbey, then crosses a bridge over Glenavana, and arrives at Jordanstown, whence fine views of Belfast

Lough and the hills of Down can be obtained. Next comes Greenisland, formerly called Carrickfergus Junction, after leaving which is seen the Knockagh Hill, which forms part of the margin of the great basaltic plateau of Antrim. The hill used to be the habitat of wild goats, but within quite recent years they have become extinct. Golf links have been laid out on the slopes, and

there is a splendid view from the top of the hill. The next station is Trooper's Lane, from which point a good view is obtained of the mouth of Belfast Lough, whilst in the distance the spire of St. Nicholas' Church, and of the square tower of the ancient castle at Carrickfergus can be seen.

Carrickfergus or Carrick was in olden times one of the most important places in the province. The incorporation of the borough with all the privileges of a county is supposed to date from the reign of King John, and King James I. gave a charter to

the town investing the government of the Corporation in a "Mayor, Sheriff, Aldermen, Burgesses, and Commonality," but Carrickfergus was deprived of its old Corporation, with all its mediæval grandeur, by the Municipal Corporations Act passed early in the present reign. The erection of the Castle, which is the most striking object in the place, has been attributed by some to John de Courcey, by others to Hugh de Lacy, but both probably had a share in its construction. Kilroot is the next station after leaving Carrickfergus, and near it are the remains of a church in which Dean Swift used to preach. Kilroot Point lies a little

beyond the station, and evidence of a raised beach may be observed along the coast where the shelly gravels are to be seen, resting on stiff bluish estuarine clays, of older date, with oyster shells. As the train sweeps round the bay beyond the point, veins of gypsum appear in the slopes of red marls upon the left. These slopes are succeeded by precipitous heights covered with rough grass and gorse bushes. The train next passes through a short tunnel under the promontory of Whitehead, on emerging from which can be seen in a quarry, on the left, a specimen of the columnar structure, so wonderfully developed at the Giant's Causeway, a great mass of basalt overlaying the limestone.

Whitehead Station stands at the head of the peninsula called Island Magee and at the mouth of Belfast Lough, of which it commands a fine view. The ivy-covered ruins of Castle Chichester are near Whitehead Station. Island Magee commences near Whitehead Station, and trends in a north-westerly direction for about seven miles. It is separated from the mainland by Larne Lough, near the head of which stands Ballycarry Station. On the east side of Island

Queen's College, Belfast.

Grand Central Hotel, Belfast.

Magee are situated the Gobbins, a bold precipitous range of cliffs, about three miles from Ballycarry Station. They consist of great masses of basalt, extending along the shore for about a mile and a quarter, and rising sheer from the sea to a height of nearly two hundred and fifty feet. The rocks are penetrated by a number of caves and constitute the home of flocks of sea birds. Taken altogether, they are claimed to present one of the grandest displays of cliff scenery on the north-east coast of Ireland.

Near Magheramore Station will be seen the extensive limeworks belonging to Lord Magheramore, whence are shipped large quantities of lime. Lord Magheramore's residence is seen shortly after leaving the station, and a fine view of Larne Lough is subsequently obtained as the train approaches Glynn, a village at the foot of Glenoe Water. Then comes the town of Larne, which was at one time a seaport of considerable importance. It is situated near the mouth of Larne Lough and on the Inver River, or, as it is sometimes called, Larne Water. The town gradually rose under the protection of Olderfleet Castle, remains of which still exist on the Curran at the Harbour. By the establishment of the Royal Mail and shortest sea route between Great Britain and Ireland, through the port of Larne, the town has been raised to a position of considerable importance. The harbour is sheltered and commodious, and the depth even at low water is sufficient to float the largest Transatlantic vessels. Steamers ply regularly between the port and Stranraer, Glasgow, Ayr, and Liverpool, in addition to which a large number of cargo vessels are annually cleared.

The visitors will alight at Larne Harbour Station, where coaches will be in waiting to convey them to Garron Tower, where there is an imposing headland—Garron Point—formed of limestone and basaltic rocks. Botanists and geologists will find a splendid hunting ground along the road which passes through Glenarm and Carnlough, with fine scenery all the way. After a drive of twenty miles along the Antrim Coast luncheon will be served at Garron Tower, a castellated mansion belonging to Lord Herbert Vane Tempest, whence there is a magnificent prospect. After luncheon, coach will be taken for Glenariff, where woods and waterfalls abound, and an hour is to be devoted to exploring the beauties of the district. Progress being resumed, the party will then proceed to Parkmore, whence the return journey to Belfast will be made by train, after tea has been served.

After crossing a moorland tract between Parkmore and Cargan, a beautiful valley expands itself between the latter station and Cross Roads. Several small roadside stations are then passed, and as the train approaches Ballymena a fine view of Slemish Mountain is obtained. Ballymena is a thriving business town of more than nine thousand inhabitants, built on both sides of the Braid Water. It is largely engaged in the manufacture of linen, in flax-spinning, in ham and bacon curing, and in the production of damasks, cambric handkerchiefs, and embroidered goods. It also carries on an extensive trade with England and Scotland. Buyers from Belfast attend the market on Saturdays, for the purchase of linen, some of which is produced by hand-loom weavers in the rural cottages. The turrets of Ballymena Castle and the square tower of the parish church are easily distinguished from the train. Leaving Ballymena, peat bogs will be observed on both sides of the line between Kellswater and Cookstown Junction stations, and as the train approaches Antrim glimpses may be obtained of Lough Neagh and the famous Round Tower. Shane's Castle, the seat of Lord O'Neill, is near Antrim, and the town itself is on the Six-Mile-Water, close to which stands Antrim Castle, the seat of Lord Massereene.

Beyond Antrim are the railway ballast pits at Moylena, especially interesting to geologists, and the scanty remains of an ancient

abbey will be seen near the picturesquely situated village of Muckamore, as the train passes the railway siding of that name. The train then crosses the Six-Mile-Water, and after passing Dunadry, Templepatrick (adjacent to Castle Upton, the seat of Lord Templetown), Doagh, and Ballyclare Junction stations, Greenisland station is reached once more, and, after a short run of seven miles, Belfast will be reached once more.

The arrangements for Friday, August 12, include visits to Messrs. Harland and Wolff's ship-building yard, the York Street spinning mills, the Belfast rope-works, Messrs. Gallaher and Co.'s tobacco factory, and other works of interest. For those who desire to go further afield, tickets will be issued at reduced rates to Portrush and the Giant's Causeway, whilst inexpensive tours by road and rail can be arranged in various directions. Particulars of the botany and geology of County Antrim, of golf links, cycling tours, etc., will be found in the sixpenny 'Guide to the Belfast and Northern Counties Railway,' which has been freely utilised in the compilation of the foregoing notes.

SPECIAL CONFERENCE ARRANGEMENTS.

Tickets.—No. 1 book of tickets, 10s. 6d. each, will admit to Conference, luncheon, drive, smoking concert, and ladies' drawing-room concert. No. 2 book of tickets, 10s. 6d. each, will include railway and coach fares, luncheon and tea on Thursday. Application for tickets and hotel accommodation must be made to Mr. R. W. M'Knight, Hon. Local Secretary, 1, Carlisle Circus, Belfast, before August 1.

Hotels.—The Grand Central, Royal Avenue, has been selected as headquarters; the Avenue, the Imperial, the Shaftesbury, and the Linen Hall Hotels, are also recommended by the Local Committee at the meeting.

Guide Books to Belfast and the Conference programme will be distributed free, and Mr. Jones, L.P.S.I., of Rostrevor, has kindly offered to present each member visiting the Conference with a copy of his "Guide to Rostrevor and District."

Portrush and the Giant's Causeway.—The Manager of the Northern Counties Railway Company will issue tickets at reduced fares to Portrush for the Giant's Causeway: Return, First Class, 4s.; Return, from Friday or Saturday to Monday, 10s., paid at Station; if fifty are guaranteed, 7s. 6d. each. Combined railway and hotel fares to Portrush, from Friday to Monday, 40s.; from Saturday to Monday 30s.

Cycling.—The coast road from Larne to Parkmore is most suitable for cycling.

Means of Transit.—The ways of getting to Belfast are numerous, and the choice of a route must depend largely upon the position of the original point of departure. It may be mentioned, however, that special terms are being offered by the Belfast and Mersey Steamship Co., Ltd., 14, Water Street, Liverpool. Thus they are offering special terms to convey members of the Conference and their friends by the first-class passenger steamer "Caledonian" from George's Dock, Liverpool, on Tuesday, August 2, at 9.30 p.m.; Thursday, August 4, at 10.30 p.m.; or Saturday, August 6, at 12 p.m., returning from Belfast on any Monday, Wednesday, or Friday evening within two months. The special return saloon fare, including comfortable sleeping accommodation, will be 10s. each passenger, and good berths will be reserved on application. Copies of a dainty little pamphlet, entitled 'Peeps at Irish Scenery,' will be sent gratis by this firm.

DENTAL NOTES.

ANODYNE FOR TOOTHACHE.

Howe recommends the following anodyne:—One part carbolic crystals and 3 parts menthol are melted together; the light amber coloured, aromatic fluid which results has a burning, but not caustic taste, it is readily soluble in alcohol, ether, chloroform, and most oils, and has the property of dissolving iodoform and aristol. The solution is said to possess strongly antiseptic properties, but is specially valuable for its anæsthetic action, especially in the case of painful tooth-pulps.—*Zahnt. Reform.*, xvii., 45.

A GOOD GOLD SOLDER.

It is recommended by Pessa that one part of S. S. White's No. 9 18 carat gold solder and 4 parts of a gold coin of 21.6 carat (American, German, or French currency) should be melted together. The result is stated to be a good solder of 21 carat, of exactly the same colour as gold coins.—*Zahnt. Reform.*, xvii., 449/50, after *Zeit. f. ang. Microscopy.*

THE USE OF CHLORAL CAMPHOR.

In cases of operations of the mouth, where it is, for various reasons, not advisable to use a cocaine or other poisonous solution, Harlan recommends chloral camphor to be applied to the edges of the tooth root. This application continued for some time enables an otherwise painful operation to be performed with hardly any discomfort to the patient.—*Corresp.-blatt f. Zahn.*, xxvii., 93, after *Dental Office Laboratory.*

PAINLESS ARSENICAL PASTE FOR DESTROYING PULP.

Dubois recommends a caustic paste of the following composition:—Arsenious acid, 0.5; eserine, 0.2; cocaine, 0.2; massed into a plastic condition with chloroform. The violent pains which follow from the use of morphine, creosote, and phenol are entirely absent when this compound is used, and the killing of the pulp is obtained more or less quickly.—*Zahn. Reform.*, xviii., 13.

METAL DIES.

Dr. Wm. H. Steele gives a description in the *Ohio Dental Journal* of his method of obtaining a perfect metal die of a badly undercut or rough model. The materials required are: A good smooth plaster model, a jar of paste, fine Spanish whiting, fine powdered chalk, a medium stiff flat brush for soapstone, stereotyper's blacking paper-filling tissue, No. 1, extra white, facing tissue, No. 1, extra cream, and some smooth heavy tea lead. The paste is prepared with 2½ ounces of rye flour, 3½ ounces of starch, ½ teaspoonful of powdered alum, and 2 quarts of soft water. Mix together thoroughly, then add cold water and mix until the mass becomes the consistency of thick cream. Then gradually add the remainder of water, which must be boiling hot, stirring well to prevent lumps; continue stirring until it begins to boil, and set aside to cool; when cold, strain through a fine sieve or cloth, when it should look like jelly. When ready for work add Spanish whiting until thick enough to spread with plaster brush. To make the paper matrix and plaster mould: when the plaster model is fully set go over entire surface with the soft brush and soapstone, rub with finger to remove surplus, and give a gloss to model. Cut a piece of the heavy blacking paper large enough to entirely cover plaster model, also cut from two to five pieces of the No. 1 white tissue, same size for filling (the rougher the model the more sheets will be needed to make a smooth matrix), also a sheet of the cream tissue facing paper, and a piece of sheet lead same size as paper. Soak the piece of heavy paper in water, dry off the surface with blotting paper, coat evenly with paste, and apply sheet of No. 1 tissue, continue with the paste and paper until the requisite number of sheets have been built up, paste on a sheet of cream tissue facing, being careful to avoid wrinkles. Now dust the surface with a bag of fine powdered whiting, oil the plaster model lightly, and quickly apply the prepared paper, smooth surface of model, beginning in the centre, smooth down snugly to the model. Now cut a piece of tea lead large enough to entirely cover the paper, press it down into the centre of arch, slit wherever necessary to avoid folds or wrinkles, being careful to have it hug the paper closely all over, oil the lead, place in casting ring, and pour with plaster. If the plaster mould is to be removed in sections to avoid an undercut, pour it with this object in view, making guides where necessary, so parts will fit together accurately. When the plaster is hard,

place it in the drying oven for a few minutes (model side up), until the paper matrix is hard enough to separate; then remove the plaster model. Now wet the top edge of the paper matrix and plaster mould; mix thin plaster and build all around the edge to prevent the paper drawing away from the investment when pouring. Place the prepared mould back in the oven, and, when the matrix becomes hot, pour the metal. Use good clean metal; do not have it too hot, and the result will be a fine, clean cut, smooth die. To ascertain the right heat for pouring, fold a piece of white paper and dip into the ladle; if it comes a straw colour, it is just right. Be careful the matrix is dry and warm before pouring.

REGULATION OF TEETH.

When the central incisors stand apart, dry the teeth and wrap No. 5 linen thread round them three or four times and tie it. By the next day the shrinkage of the thread will have drawn the teeth together. If necessary retaining band, soldered together, can be afterwards cemented to the teeth.

REMOVING PULPS.

In removing pulps in anterior roots, after cutting off crown for pivoting, lay a little cocaine hydrochloride on the exposed nerve, allowing it to remain for a few minutes, then gently and slowly work it in with a fine point, after which the nerve can be extracted with a brooch without any pain.

PINS FOR CROWNS.

Mr. C. S. Reed, in the *Journ. British Dent. Assn.*, describes his method of making triangular pins for crowns as follows:—These pins are made by soldering together two wedge-shaped pieces of plate of No. 8 gauge. One piece of metal must be slightly wider than the other. The larger piece is placed flat on the soldering block, the other is then placed on its edge, along the mid line of the broader piece; point being to point, the pieces are then soldered together. The result is a piece of T metal tapering to a point at one end. The root is prepared by reducing the canal in the usual way and then enlarging in three directions with a long fine fissure bur, to receive the angular pin. The canal then presents a T-shaped orifice, into which the T-shaped pin just fits. The crown is then fitted by one of many methods known to us. The advantages of this pin are: (1) absence of rotation; (2) great strength—angular metal being considered the strongest possible; (3) disposition of the greatest strength where most needed—that is—where the crown and root approximate; (4) ease and economy of construction—it being possible to make the pins of scraps of plate left in the usual course of work. The pins, if necessary, may be barbed by cutting with a sharp knife towards the point of the wedge, along the three edges of the pins.

ANÆSTHETIC EFFECT OF COCAINE.

The anæsthetic effect of cocaine is materially increased if the liquid be slightly heated—90° F.—before injecting. Anæsthesia sets in sooner, lasts longer, and is more decided. A weaker solution than usual may be employed with less risk of cocaine poisoning.—*Dental Digest.*

DECOLORATION OF ALUMINIUM.

Aluminium may be restored to its white colour by washing with a mixture of 30 Gm. of borax dissolved in 1000 Gm. of water, with a few drops of ammonia added.—*Amer. Druggist.*

AVOIDING PATIENTS' BREATH.

Dentists could save themselves much from the unpleasantness and unhealthfulness of inhaling their patients' breath while performing long operations in gold fillings, when the rubber dam is applied, by placing a sheet of paper from gold-foil book before the patient's nose, securing it under the dam and elastic fasteners. It also prevents the moisture from breath coming in direct contact with the gold while packing. This makes it equally agreeable to the patient.—Dr. G. H. Reynolds, *Dominion Dental Journal.*

MOULDING SAND.

Take ordinary bath-brick, finely powdered, add about 40 per cent. to your moulding sand. It makes a cohesive, compact and sharp impression.—*Ibid.*

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London, W.C., and not in any case to individuals supposed to be connected with the Editorial Staff; no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ADVERTISEMENTS AND ORDERS for copies of the 'PHARMACEUTICAL JOURNAL' must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C. Cheques and money orders should be made payable to "Street Brothers."

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the Editor will be replied to in the Journal as early as possible after receipt, though not necessarily in the next issue. Replies cannot be sent by post, even though stamped envelopes accompany the queries.

LETTERS TO THE EDITOR.

THE HERBARIUM COMPETITION.

Sir,—Would it not be wise to arrange for the exhibition of the contributions sent in for the herbarium competition in the rooms of the North British Branch, Edinburgh? It seems to me it would prove of great interest to students in this part, and might stimulate more of them to compete in future.

Dundee, July 23, 1898.

W. C. (138/32).

COLORATION OF ARSENIC.

Sir,—It is evident from frequent cases of poisoning by liquid weed-killer that an amendment of the regulations relating to the sale of arsenic is necessary. At present soot and indigo are the only colouring substances recommended, and neither of these is any use in a dilute solution. If aniline green or blue were added in such proportion as to give a decided tint to even the weakest solution there would be no chance of accidental poisoning, such as happened at Crieff last week.

Dundee, July 23, 1898.

W. C. (138/31).

CAMPHOR IN PILLS.

Sir,—In your last week's issue you had a letter from Mr. Graham Bott on the subject of camphor in pills. Would he or some other authority give the best excipient for the following?—

R Quin. Sulphur	Gr. xxiv.
Ext. Bellad.	Gr. vi.
Camphoræ	ʒi.
M. ft pil. xxiv.	

St. Ives, Hunts, July 26, 1898.

F. C. BARTON.

MR. GLYN-JONES ON ADULTERATION.

Sir,—Mr. Glyn-Jones writing to the Journal on the recent prosecution of his firm for selling lime water below the standard strength, endeavours to evade in wordy language the main issue of the case, which is simply this: "Was the lime water sold of proper strength?" It was clearly proved that it was deficient in strength. The fact that there may be a certain amount of alteration under certain circumstances is not a sufficient or satisfactory answer, as it is evident that most drugs and chemicals would deteriorate if precautions were not taken to guard against this. If in a preparation so readily made, at so trifling a cost and requiring so little skill, there is no care displayed, how can one expect to have the many other costly and skilled preparations properly manufactured. To form a fund for the purpose of evading the

Food and Drugs Act by technical defence seems to be a very poor scheme for protecting pharmaceutical qualification. The remedy lies in the personal superintendence of the careful pharmacist.

July 20, 1898.

FAIR-PLAY (138/19).

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on separate slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

MACERATION.—It is not intended that the product should be made up to any definite volume. [Reply to J. L. F.—14/3.]

NAME ON LABEL.—The name of the proprietor must appear on the labels if scheduled poisons are sold. [Reply to BETA.—14/14.]

DISPENSERS ON STEAMERS.—We are not aware that there are any such positions as you inquire about. [Reply to MARITIME.—14/15.]

SAMPLE OF ORE.—We are unable to assist you in this matter: Send a specimen, with full particulars, to some dealer in minerals. [Reply to E. J. E.—14/10.]

DEVELOPER.—The formula you send does not appear in either of our photographic supplements—April 2 and May 7 last—though several tried formulæ for developers were given therein. You must add more water if solution is incomplete. [Reply to HYPO.—14/9.]

SAL VOLATICA IN BOILER.—Probably ammon. carb. is what is meant, as it used to be called sal volatile cornu cervi, as of course you know. Probably it would cause a deposit to form on the crack, but we should not recommend such a means of stopping up a defect in a boiler. It would be better to have it properly remedied. [Reply to W. J.—14/5.]

CORRECTION.

LIQUOR STRYCHNINÆ HYDROCHLORIDI.—Mr. George Lunan asks us to correct an obvious error in the fourth line of his letter published last week, where the word gramme appears instead of grain.

OBITUARY.

USHER.—On July 13, Richard Usher, Bodicote. Aged 57. Mr. Usher was widely known as a cultivator of medicinal herbs, his business connections extending to all parts of the Kingdom. He was a member of the Banbury Board of Guardians and of the Rural District Council.

SHAW.—On July 14, William Bourne Shaw, Chemist and Druggist, Handsworth. Aged 46.

MAYHEW.—On July 24, Charles Naunton Mayhew, Chemist and Druggist, Beccles. Aged 67.

VAN VOORST.—On July 24, John Van Voorst, Utrecht House, Clapham. Aged 94. Mr. van Voorst was, it is believed, the *doyen* of London publishers. Born of a Dutch family settled in England for several generations, he passed six years in the house of Messrs. Longmans, and started business on his own account about 1832 in Paternoster Row. He was for many years the publisher of Attfield's 'Chemistry,' and amongst his undertakings of importance were Yarrell's 'British Fishes,' begun in 1835, followed by Bell's 'British Quadrupeds' in 1836, and by Yarrell's 'British Birds' in 1837. These and works on British Crustacea, zoophytes, starfishes, etc., are recognised classics on the natural history of our islands, and the 'British Birds' reached its fourth edition in 1871. Though Mr. van Voorst published many other works, it was in connection with the name of Yarrell that he was best known, and he was one of the executors of that eminent naturalist. He retired from business in 1886.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

The results of an investigation recently carried out by Dr. A. P. Luff as to the value of certain drugs in the treatment of gout throw considerable doubt upon the views held concerning the efficacy of alkalies as remedial agents in that disease, so far as regards the removal of uric acid from the system by their solvent action. From Dr. Luff's experiments it appears that neither potassium or sodium bicarbonates, lithium carbonate, potassium or lithium citrates, or sodium phosphate exercise the slightest influence in delaying the conversion of quadriurate into biurate. A similar conclusion was drawn from experiments with salicylates, piperazine, and lysidine. None of these substances were found to increase the solvent power of the blood for sodium biurate, and hence it is inferred that their administration to gouty subjects with the object of removing uratic deposits in the joints and tissues appears to be useless.

T. E. Stillman records the results of experiments dealing with the action of nitric acid on aluminium. In thick sheets the metal is scarcely at all attacked, and only slowly on raising the temperature. But in thin layers the following results have been obtained, using a hundred times (by weight) as much acid as aluminium:—

Temperature.	Density of Acid.	Duration of Experiment.	Proportion of Aluminium Dissolved.
20° C.	1.15	7 days	94.2
20 "	1.35	7 "	89.0
20 "	1.46	7 "	12.0
100 "	1.15	20 minutes	100.0
100 "	1.35	30 "	100.0
100 "	1.46	2 hours	100.0

—*Journ. de Pharm. et de Chim.* [6], vii., 592.

P. and S. Curie have isolated a substance from pitch-blende which appears to contain a hitherto unknown metal, very similar to bismuth in its analytical properties. The supposed new metal, which is named "polonium," owes its discovery to the new method of investigation by the rays discovered by Becquerel. It was observed that whilst minerals containing uranium and thorium are very active from the point of view of the emission of those rays, the activity in some instances was even greater than that of uranium and thorium. On the supposition, therefore, that some more active substance was present than either of those two metals, an attempt was made to isolate it. On attacking the pitch-blende with acids and treating the resulting solution with sulphuretted hydrogen, the uranium and thorium remained in solution. The precipitated sulphides were then subjected to treatment, and ultimately the supposed new metal remained associated with bismuth. It could only be partially separated from the bismuth, and its activity is claimed to be four hundred times greater than that of uranium.—*Comp. rend.*, cxxvii., 175.

As produced by Bineau, by bringing together ammonia with hydrogen selenide, this compound was a white crystalline solid, which was readily decomposed by water in the presence of air. V. Lenher and E. F. Smith now announce that they have been able to crystallise it from a solution in black, anhydrous, Vol. LXI. (FOURTH SERIES, VOL. VII.) No. 1467.

orthorhombic prisms. An ammoniacal solution of ammonium molybdate was saturated with hydrogen selenide gas and the dark red solution yielded the black crystals when carefully concentrated in a vacuum over sulphuric acid. The residue consisted of ammonium molybdate, metallic selenium, and the crystals of ammonium selenide. When separated as completely as possible from the selenium and extracted for several days with pure carbon disulphide, the purified crystalline mass proved to be stable in air and dissolved readily in water, the freshly-made solution precipitating selenides from neutral or alkaline solutions of metallic salts. On exposure to air the solution decomposed, black selenium separating.—*Journ. Am. Chem. Soc.*, xx., 277.

Fiji Rubber.

In response to a request from Kew for specimens of all plants yielding a milky juice, samples of Fiji rubber have been received and examined. The first samples received proved entirely valueless; but the second, received in March last, were more promising. This rubber is obtained from *Alstonia plumosa*, which is described as abounding in the forests, and likely to prove a useful rubber-producing plant. Judging from the specimen of rubber received, however, the preparation of the article seems to have become almost a lost art, for the specimen was soft and viscid on the outside, with little or no elasticity, and practically without value. A specimen received later was not so viscid, but gradually became hard and inelastic. A sample of rubber from a tree known as "Baka" (*Ficus obliqua*, Forst. f.) has also been received, and, although not sufficiently coagulated, is regarded as suitable for mixing purposes. A substance obtained from the "Ban" tree, possibly a member of the Sapotaceæ, but, in the absence of flowers, otherwise indeterminable, was slightly elastic. Other specimens, obtained from the "Wasalili" (*Carruthersia scandens*, Seem.) and the "Malawaci" (*Trophis anthropophagorum*, Seem.), were entirely deficient of elastic properties, and reported to be of no commercial value.—*Kew Bulletin*, 139, 154.

Biology of the Uredineæ.

In a review of the present position of our knowledge respecting the biology of the Uredineæ, Dr. H. Klebahn gives a summary of the most recent observations. The existence has been established of "biological species," or "species sorores," i.e., of groups in which the æidioforms are scarcely distinguishable from one another, while the uredoforms and teleutoforms present appreciable differences. Of these groups of biological species, the following may be regarded as having been established: *Peridermium Pini f. acicola* comprises at least nine or ten morphologically indistinguishable or scarcely distinguishable species belonging to the genus *Coleosporium*, recognised only by cultivation on their teleutospore hosts. *Cocoma laricis* consists, in like manner, of four or five species, whose teleutospores are species of *Melampsora* parasitic on birches, poplars, and willows. On *Phalaris arundinacea* are a series of puccinioforms of the type of *Puccinia sessilis*, distinguished from one another by their æidioforms, which occur on species of *Convallaria*, *Leucojum*, *Allium*, *Orchis*, and *Arum*. Among the Uredineæ of cereal crops are several series of biologically distinct forms; and this is the case also with the rusts of other grasses and those of species of *Carex*.—*Bot. Zeitung*, 1898, 2te Abtheil, p. 145.

Bacterial Diseases of Plants.

In the reports of the various experimental stations in the United States are papers respecting the diseases of cultivated crops and fruit trees caused by the attacks of various species of *Schizomycetes*, which are summarised by Professor J. C. Arthur (*Bot. Gazette*, 1898, p. 461). A new bacterial disease of sweet corn is described, attacking the plant

chiefly at the time of flowering, clogging the fibrovascular bundles of the stem. The olive-knot, or tuberculosis of the olive, is ascribed to the attacks of *Bacillus oleæ*. Sig. F. Cavara (*Le stazione sperim. agrar. Ital.*, vol. xxx., p. 482) describes the following bacterial diseases of the grape-vine:—Tuberculosis, produced by *Bacillus ampelopsoræ*; necrosis, caused by *Bacillus cubobianus*. Necrosis of the mulberry is due to two different *Schizomyces*: one of them resembling *B. vitivorus* and identical with *B. cubobianus*, the other a new chromogenous species, *Bacillus mori carneus*. Tuberculosis of the peach is caused by the attacks of a hitherto undescribed species, *Clostridium persicæ tuberculosis*.

Two forms of artificial indiarubber, one from France, the other from Germany, are described in the *Engineer*. Textiloid, the French form, consists mainly of resinoline, obtained by treating oil with three or four times its bulk of metallic carbonates, then with nitric acid, afterwards saponifying, precipitating by means of acid, and dissolving in alcohol or ether. A hundred parts of the resinoline are mixed with twenty of zinc oxide, manganese, etc., and sixty parts of methylated spirit; after several hours the mass is kneaded for one hour or more and finally compressed. The German substitute is prepared by the oxidation of linseed oil, to which is subsequently added prepared jute refuse or similar textile refuse. By this means a substance is produced which is claimed to possess many of the qualities of genuine indiarubber and to be capable of being manufactured into various articles hitherto made of indiarubber.

The formation of lenticels is thus described by M. Devaux. The tissue produced on the outside of the generating layer always consists exclusively of true bark. The rounded cells, which enter into the composition of the bark, represent cells of the phelloderm which have increased more or less in size and have become separated from one another. They are developed from a phellogen situated at the internal limit of the layer of bark which lies above them. The generating layer, which is formed below the rounded cells, is a new layer of phellogen intercalated within the phelloderm and producing regeneration. The generating layer of lenticels is not usually a permanent layer; it ceases to be active as soon as a new layer is formed lower down in the phelloderm, or often also in the primary cortex. The only true bark of lenticels, with centripetal development, is represented by the layers known as the intermediate rays or closing layers—that is to say, by suberised cells much more closely united, and having all the essential characters of true bark.—*Procès Verbal Soc. Sci. Phys. et Nat. Bordeaux*, 1898, p. 27.

In advocating the practice of boiling all water (and milk) of uncertain purity, Professor Bizzozero combats the prejudice against boiled water as a beverage. He maintains that the “taste” frequently complained of in boiled water is really caused by the kettle, and can scarcely be due to the absence of CO₂ or dissolved air, of which water from wells of great depth often contains very little.—*Practitioner*, lxi., 63.

A sample of black wax (malam Kjongting) from the Dutch East Indies has been examined by E. H. Blitz. The author finds that the coloration is due to a large number of pollen grains contained in the wax. The colouring matter is dissolved by petroleum ether, ether and alcohol. The wax appears shining black in a reflected light, more or less dark brown in a transmitted light. The odour is similar to honey, the

taste slightly aromatic. The wax is dissolved by chloroform with the exception of the pollen grains; it is almost insoluble in alcohol. The melting point is very low, viz., 54° C. The specific gravity is 0.978; the iodine number, 69.06; the acid number, 34.3; the saponification number, 78.5; the ester number, 43.25.—*Pharm. Ztg.*, xliii., 404, after *Uederl. Tijdschr. voor Pharm.*, 35.

Artificially Decolorised Wines.

The usual diphenylamine sulphate solution, used to detect nitrates, has been found by A. Bimm to afford a means of detecting artificial white wines, which have been produced by decolorising normally red wines by means of animal charcoal; 2 C.c. of the solution are placed in a small porcelain capsule, so as to give a layer of liquid 4 or 5 Mm. deep, 6 drops of wine are then allowed to run down the sides, when, if the wine has been treated with animal charcoal, a marked blue ring will be formed. Natural white wines will not give this reaction. The solution obtained by washing commercial animal charcoal with water was found to give the characteristic reaction for nitrates with all the usual reagents.—*Journ. Pharm. Chim.* [6], viii., 9.

Iodine in Pig's Thyroid.

Tambach finds that in the case of the pig the absolute amount of iodine in the whole gland of a pig is always the same, irrespective of district or locality. The amount of albuminoids capable of extraction vary, however, considerably, both with the season of the year and the origin of the animal. The albuminoids containing iodine can be almost completely extracted from the glands by water. Of the total amount of iodine present, about 96 per cent. exists as a very stable combination, and which is separated by precipitants of albumin, such as alcohol, acids, etc. About 4 per cent. of iodine is contained in the filtrate from the latter; of this 2 per cent. is soluble in water, and freely parts with its iodine; the other is a very stable compound, also soluble in water. Thyro-iodine is not contained free in the gland. The iodine-albumin compounds do not liberate thyro-iodine either on digestion with artificial gastric juice or with pancreatin. On the contrary, they change to digestion products, which retain the iodine in the same combination as the original substances. The separation of thyro-iodine only results after destruction of the albumin molecule, but even then the whole of the iodine is not set free as thyro-iodine. There are several distinct combinations of iodine and albumin present in the glands. This is shown by the circumstance that only a portion yields thyro-iodine, while another portion produces peptone-like bodies which are soluble in water and contain less iodine. These latter do not yield any thyro-iodine after repeated treatment with 10 per cent. sulphuric acid or 5 per cent. soda solution. The therapeutic effect of the fresh gland, or of its extracts, is no doubt due to the absorption of the above-mentioned digestion products containing iodine, and not to the liberation and consequent absorption of thyro-iodine.—*Pharm. Centralh.*, xxxix., 574.

Vapour of Metals.

Dr. W. J. Russell finds that certain metals, at ordinary temperatures, appear to give off vapour which affects a sensitive photographic plate. This vapour can be carried along by a current of air, and even after passing through thin sheets of gelatin, celluloid, etc., is able to produce clear pictures of the surface of the metal from which it came. Nickel is very active in this respect, cobalt only very slightly so, copper and iron are practically inactive.—*Chemical News*, lxxvii., 167.

THE FOURTH BRITISH PHARMACOPŒIA.

BY J. C. HYSLOP, PH.C.

(Continued from page 52.)

With respect to aqua rosæ we have at length a well-merited recognition of the fact that the commercial article, imported from the best manufacturers of the South of Europe, gives us all we can desire as to uniform purity and strength. As with aqua aurantii floris, this is well defined as being "a saturated solution of the essential oil of the fresh flowers." One naturally asks why aqua sambuci is not thus definitely dealt with. The water distilled from fresh elder flowers will keep good for twelve months. Abundance of elder flowers are at hand every springtime, why should the effete salted stuff be allowed as an alternative?

Aquæ anethi, anisi, carui, cinnamomi, fœniculi, menthæ piperitæ, menthæ viridis, et pimentæ, are all unstable products when distilled either from the herbs or from their oils mixed with ordinary water.

When we consider what a complicated mixture (chemically) "good natural potable water" is at its best, no wonder that the result of a stew should eventuate in the production of multifarious impurities that show up more or less in the distillate and render the product unstable and untrustworthy.

The alternative mode of preparation sanctioned for these waters for use in India and other tropical countries is by far the better one, but the best of all seems to be that adopted in the U.S.P. An essential oil is well distributed amongst the filaments of twice its weight of cotton-wool and washed out again with 500 times its weight of distilled water by a process of slow percolation, the result being everything that can be desired—a saturated solution of the essential oil in pure water that retains its brightness and its strength as long as could reasonably be desired. Why this example of our Transatlantic brethren has not been followed, at least for the alternative process, seems a mystery. Powdered phosphate of calcium may be as insoluble in both oil and water as is the cotton wool, but it certainly cannot be relied upon as much for its cleanness. Before leaving the subject of the waters one cannot but express unlimited satisfaction that our national standard and guide is at length freed from the burden of a ten-gallon copper still for the preparation of distilled water. There is now no reason whatever why the pharmacist everywhere should not invest in a small still to be kept solely for use over the smokeless flame of a good gas stove for the preparation of his own aqua destillata. The uncertain character of this indispensable commodity and stinginess in its use lie at the bottom of much bad pharmacy. It should be employed whenever water is necessary for medicaments intended for either internal or for external exhibition. Carbolic acid lotion prepared with pure water has quite a different character from that containing the impurities of the best potable water; these soon display themselves in the form of a dirtiness on the inside of the containing vessel, and, though small, the percentage of impurity is often enough to sully the fair fame of the dispenser in the eyes of discerning people.

The chronic difficulty as to lime water being not up to its proper strength is usually from the same cause. One cannot prepare anything like a saturated solution of lime except pure water is used. Nor, having pure water, can one get the best result with ordinary bricklayers' lime; one must have pure lime obtained from the manufacturing chemist.

And, speaking of lime water, it may be as well to mention in this connection that the addition of tragacanth mucilage to "black mercurial lotion" is practically a mistake. So is trituration. At the School of Pharmacy in olden time we used to learn

that the less calomel was rubbed about the better; however, as to the gum, the black sediment which it is desired to distribute as equally as possible through the liquid by the merest shake is by the agency of the gum tragacanth formed into clots, which segregate in a manner to refine the solution of calcium chloride and produce the very opposite effect. A little acacia mucilage would not be as bad, but after several trials the following formula is offered as being the best that has yet been devised:—

℞ Hyd. subchlor. xxx. gr.
Liq. calcis sacch. v. fl. ʒ.

Shake together and add aq. destill. ad x. ʒ.

Tragacanth has been of late rather too much in vogue as a panacea for a certain class of dispensing difficulties; it should be regarded with the utmost caution. There is one case in which it seems to answer admirably the purpose intended—that of *mistura cretæ*. Here the intractable clottiness of the sediment is just the kind of bad condition that this kind of gum seems created to neutralise by a kind of a "*similia similibus curantur*" action. At last we have a good "chalk mixture" which deserves to become very popular, and which may surely be prescribed as well as dispensed by the intelligent pharmacist for the benefit of suffering infantile humanity without offence to anyone.

Strange it is that commerce will oft run counter to science and persist in its opposition to the bitter end, though no one can doubt as to the result or as to the wisdom of the weaker making it up with the stronger as soon as possible. A great lot of nonsense has been written—and there is a danger of more—as to the "liquores concentrati," because, forsooth, the compilers have not forced Nature into the methods uniform of trade. Why this has been the damaging mark set against the so-called "concentrated infusions" from the first—the bringing them by fair or foul means to the favourite 1 to 7 strength, a concession merely to the indolence of the dispenser, both mentally and physically. One can understand the necessity there is that the skilled physician has at hand an easy scale of dosage, a subject lying quite on the outer fringe of the vast domain of problems he must often have to laboriously solve in the diagnosis of the sufferer's condition and requirements. Dosage is a sort of neutral zone where physician and dispenser meet. But if the chief concerns of the one lie deeper and more intricate, so do those of the other, but in other directions. The chief work of the pharmacist is to detect the kind and determine the quantities of the endless variety of virtues scattered around us from Nature's lap. What solvents are the best to extract these for the convenience alike of prescriber and dispenser, what processes to employ, and what are the ever-varying proportions and conditions in which each will most readily yield its active constituents to the various menstrua that science teaches us to use, with a view to the keeping qualities, the effective action, and the elegance of the resulting preparations. In all this we are ever confronted with the fact that Nature abhors uniformity, that in the exercise of art we must ever revere her mandates if we desire to bring that art to perfection. The objections raised against the liq. concentrati on the score of convenience and uniformity of strength are just on all fours with those about the six different strengths of alcohol that a pharmacist is now supposed to keep at hand. It used to be so convenient to know that all tinctures must be prepared either with S.V.R. or with S.V.T., and no thought used to arise as to the ignorance and the waste that was condoned in the childish procedure.

It is to be hoped, therefore, that the liq. concentrati—10 in number—may be added to in the near future, not as a substitute for the corresponding infusa, but that in course of time prescribers may become so accustomed to their use as to discard the less satisfactory preparations.

One cannot see why the Research Laboratory of the Pharmaceutical Society should not be at times utilised for important investigations connected with the art of pharmacy, as it has been with relation to the science of chemistry, so that some *ex cathedra* pronouncement might be available for the compilers of the Pharmacopœia in the future with respect to preparations where knotty points want clearing up.

A sort of liq. aurantii concentratus has been prepared by the writer for some few years past, which seems very satisfactory, as follows.

From clean "fine cut" dried orange peel, exhaust the oily matter by a three days' maceration in absolute alcohol; filter off the tincture and set aside. Turn the contents of the filter into a covered pot containing boiling distilled water, remove from the source of heat, and macerate for two hours. Strain, express strongly, and mix the two solutions, shake together, set aside for a few hours, and filter the decanted nearly clear portion through a paper filter.

This is made just five times the strength of inf. aurantii P.B. Strength of alcohol in the finished product 1 in 5.

Since the appearance of the Pharmacopœia a liq. gentianæ conc. comp. has been attempted on the same lines, and seems to answer very well. The chief variation being that half the proportion of dried lemon peel takes the place of the fresh ordered for the infusion of gentian, this with the orange peel being macerated in alcohol as above, a little plain alcohol used to wash the mark on filtration, and mixed with the resulting tincture. The contents of the filter, together with fine cut gentian root, is thrown into the pot of boiling distilled water, macerated, strained, and finished off in like manner. The proportion of ingredients are calculated for the same strength, 1 part to 5 of distilled water makes a beautiful imitation of inf. gent. co. It has a high sp. gr., which, together with the alcohol, seems to add to its keeping qualities.

WHAT IS A MICROSCOPE?*

BY T. E. WALLIS.

(Concluded from page 102.)

Now that the lenses used in constructing a modern microscope have been discussed, it will be convenient to consider the combined effect of those lenses in producing an image. This may be easily understood from the accompanying figure, which also shows the action of the Huyghenian eye-piece.

The object O is magnified by the object glass which forms a large image at *a a*; this image is in reality never formed, but the image-forming rays are caught by the field lens *f f* of the eye-piece and are converged to form an image at *b b* in the diaphragm of the eye-piece. This image is magnified by the eye lens *e e* and appears to the observer of the size shown at X Z.

Having briefly considered the optical part of the microscope, we should devote a short time to the stand or fitting in which the lenses are fixed and by means of which they are manipulated. The different parts are best taken separately:—

1. **THE FOOT.**—This is the base on which the whole instrument is supported. The best style of base is a wide tripod, which has the advantage of giving a wide and firm base without undue weight. A similar kind of foot is the claw-foot, which covers a slightly less area than the tripod, but is otherwise very similar. The smaller span of the foot makes the base less steady, but the instrument can be packed into a smaller case, and hence is more convenient for persons who have to carry an instrument about. The third kind of foot is the horse-shoe foot, which is narrower than the claw-foot, and hence much less stable. This foot is frequently made firmer by weighting it with lead; but although the instrument is made steadier, it is at the same time made clumsier, and it is better to make an instrument with a low centre of gravity without addition of material than to insure stability by simply increasing the mass of metal used.

2. **THE STAGE** is the support for holding the object and for enabling one to easily manipulate it beneath the lens. It should be pierced with a hole to admit light from below, and this hole should not be too small, but of about an inch in diameter. A more convenient form is the horse-shoe stage, in which the opening is cut quite out to the front of the stage, and which possesses the advantage of enabling one to manipulate a slide with the forefinger. A plain stage is usually fitted with two spring clips to

hold the slide in position; but these clips are often in the way of the operator, and a much more useful appliance is the sliding bar, which enables one to systematically search a slide, and for ordinary use is to be preferred to a complicated mechanical stage.

3. **THE TUBE OR BODY** is the support for the magnifying lenses, and is made of two lengths, viz., the Continental length of 160 Mm., and the English length of 250 Mm. Modern microscopes are usually fitted with a draw-tube to enable lenses corrected for either length to be used. The screw for receiving the objectives is

FIG. 6.—Diagram of path of rays through the lenses of a modern microscope.

always made of one pattern, so that any objectives the microscopist requires may be easily fitted. The eye-piece slides into the top of the tube.

4. **THE COARSE ADJUSTMENT** is an arrangement for roughly focussing the lenses. It usually consists of a rack and pinion, with

FIG. 7.—Diagram of fine adjustment by a lever.

FIG. 8.—Diagram of Campbell's differential screw.

diagonal rackwork to make it move without undue jerking. It should work so well that a $\frac{1}{4}$ in. or $\frac{1}{8}$ in. objective can be focussed without using the fine adjustment.

* Read before the School of Pharmacy Students' Association.

5. THE FINE ADJUSTMENT is a contrivance for more accurately focussing lenses of high magnifying power. It is sometimes made to move the nose-piece only, but as this interferes with the correction of the objectives, it is usually constructed to move the entire body. Of this adjustment there are three varieties we will briefly consider.

(a) A lever of the first order with a long arm and a short one. By turning the milled head H, the hardened steel point P moves the lever L about the fulcrum F, and raises or lowers the block B, which is attached to the body of the instrument; a spring S keeps the working parts in contact. The disadvantage of this form lies in the fact that the whole frictional wear acts upon the point P; but this is much lessened by the length of the lever L, which also gives a very slow and smooth movement to the fine adjustment.

(b) The fine adjustment in many stands is worked by a direct acting micrometer screw, which, to give a slight movement, must have a very fine thread, upon which friction or rough handling tells greatly.

(c) Campbell's differential screw is a modification of the ordinary micrometer screw, which enables one to obtain a fine movement with a screw of coarser thread. Its construction and method of action will be easily understood from Fig. 8. The upper part A of the screw has twenty threads to the inch and works through a plate in the top of the pillar of the microscope; the lower part B of the screw has twenty-five threads to the inch and works in the opposite direction to A. It also carries the travelling socket T, which is fixed to the microscope tube; S is a spring to keep the working parts in contact. It will be readily seen that by turning the milled head H through one revolution, the socket T is depressed $\frac{1}{20}$ th of an inch, due to the screw A, and is raised $\frac{1}{25}$ th of an inch due to the screw B, the total effect therefore, of one revolution is to move the socket T through $\frac{1}{20}$ th - $\frac{1}{25}$ th = $\frac{1}{100}$ of an inch. This is undoubtedly the smoothest and most delicate device for fine adjustment by a direct acting screw, and if good and carefully used will stand a large amount of wear. Its great advantage lies in the fact that a very fine movement can be obtained with a correspondingly coarse thread.

6. THE MIRROR.—Another essential is a good mirror to reflect light upon the slide; it should be of a good size, and have a plane mirror on one side and a concave one on the other.

7. THE SUBSTAGE.—A really efficient microscope should be provided with some sort of substage, which is an appliance to enable one to add apparatus for improving or modifying the illumination. There are two forms commonly used:—

(a) A plain "underfitting," or tube which is adapted to cheaper microscopes, and is a spring tube of standard gauge, which screws on to the underside of the stage. This is a useful appliance, and enables one to use a substage condenser when a more elaborate substage would be too expensive.

(b) A compound substage is a much better form, and is fitted with focussing and centering adjustments. It consists of a metal ring of standard gauge, which can be racked by a milled head so as to exactly focus the light upon the object, and the light can be precisely centered with the objective by using the two centering screws which are placed at right angles in the frame of the metal ring.

This concludes the description of the stand, and the next subject which calls for attention is the method of illumination. The first essential is a good source of light; either daylight or a lamp may be used. Daylight is the most pleasant source of light, especially when working with low powers. The majority of students, however, have little opportunity for day work, hence an artificial light is necessary. The best form of lamp is an ordinary oil-lamp with a half-inch flat wick, and all light should be carefully screened from the eyes and upper side of the stage (unless wanted there) by using a plain cardboard lamp shade. The reservoir should be shallow, so that, when required, the light may be placed on a low level; if the light is wanted higher up, the lamp may be easily raised by standing it on blocks of wood. Most microscope makers sell special lamps, which are useful for critical work, and which differ from an ordinary lamp in that the chimney is made of sheet iron and has a flat glass slide let into the front of it. By this means the use of a shade is avoided, and the image of the flame is not distorted as it is when the rays of light pass through an ordinary curved lamp chimney. They are also generally mounted on a stand with an arrangement for raising or lowering the lamp at will. These lamps are necessarily rather expensive, and for all ordinary purposes a plain paraffin-oil lamp answers perfectly.

When using a lamp, a bull's-eye condenser is advantageously employed to give a parallel beam of light from the edge of a lamp flame. It must be placed at about its focal distance from the lamp flame with the flat side turned towards it, and should be adjusted to throw the parallel beam of rays upon the plane mirror, which reflects it into the microscope objective. This condenser is a plano-convex lens mounted on a brass stand, and is hence called the "bull's-eye" or "stand condenser" to distinguish it from the substage condenser.

The substage condenser is composed of a combination of two or

FIG. 9.—Diagram of optical part of Abbe illuminator, 1.2 N.A.

three lenses, and fits into the substage already described; its use is to enable the operator to exactly focus an image of the lamp flame upon the object under examination, and the principle upon which it depends may be briefly explained as follows:—

Objects are seen by diverging cones of rays from every point of their surface, and images of the objects are produced by reconverging these cones of rays to corresponding points in the image. When a transparent object is viewed by transmitted light it is evident that some rays will pass straight through the object into the objective, while others are caught by the object and go to form the image. The rays direct from the source of light are focussed behind the objective, while those from the object are imaged in the eye-piece, and thus the image is blurred with confused light. To overcome this, the condenser is made to focus the source of light upon the object when rays from the source of light and image rays from the object both diverge from the same point; crossing of the two kinds of rays is thus prevented; we get the object more brilliantly illuminated, and the image is clearer and more distinct.

The pieces of illuminating apparatus hitherto considered have been devised to increase the illumination, but sometimes it is just as harmful to have too much light as to have too little. Thus many fine markings or striations can scarcely be seen with a full light, while if part of the light is shut off so as to throw the irregularities of the object into stronger light and shade, fine markings are more clearly visible. For this purpose a diaphragm is used; the most convenient form is the iris diaphragm, which enables one to adjust the size of the opening to a nicety. A revolving disc of metal with holes of various diameters pierced in it is also commonly fitted below the microscope stage.

Another means of altering or modifying the light to suit special objects is to use "stops," which may easily be made from pieces of blackened cardboard. By using an oblique pencil or cone of light to illuminate the object fine striations are much more sharply thrown into relief by intensifying the shadows. By this means markings scarcely visible otherwise may be altered into something which can be seen, but which does not give a true idea of the object. Various forms of stops are made to give different oblique pencils of light, and they are put in below the condenser on a little arm provided for the purpose and called a "stop-carrier."

FIG. 10.—Diagram of stops for oblique illumination.

The plain central stop A gives oblique rays all round the axis; B will give a single oblique pencil of light, and C will give two pencils at right angles. The stop D gives a single oblique pencil which is shallower but much wider than that given by B.

Another important use of stops in conjunction with a condenser is to give objects the appearance of being self-luminous upon a dark ground. A plain central stop is put into the stop-carrier and the condenser is racked back till the field appears black and the object stands out brightly. The principle may be thus explained:—

All rays passing through the centre of the condenser are cut off and the remaining peripheral rays are focussed upon the object; but being so very oblique, all direct rays are thrown quite outside the front lens of the objective so that the ground appears dark. The object, however, catches and scatters some of the rays and thus has the appearance of being self-luminous. Many objects, such as minute seeds (poppy and henbane), when illuminated in the ordinary way do not appear strikingly beautiful; but by applying the device just described they assume a really astonishing beauty. Special stops are used for special purposes; thus the eye of a blow-fly can be shown to consist of numerous separate lenses by inserting in the substage a stop with a small star cut out of its centre. Then by careful focussing the image of the eye goes out of sight, and instead a bright star of light is distinctly seen in the place of each lens or facet.

We have now considered most of the details of construction of a microscope suitable for any ordinary botanical or pharmaceutical work, and a few words about general arrangements for work will not be out of place. If the microscopist has not a special table for his microscope it is useful to have a board with a bead round the edge. The board should be about eighteen inches long and fifteen inches wide; the microscope is placed upon the board and the lamp in the left hand corner; the bull's eye is adjusted between the lamp and the plane mirror, which throws a parallel beam of light into the condenser. For high powers the edge of the flame should be used, and for low powers the flat of the flame; with a condenser the plane mirror should always be used, and with low powers the upper lens of the condenser may be screwed off. By using the board, the lamp bull's-eye, and microscope are kept in the same relative position, and they are less likely to be displaced by accident; the bead serves to keep any slides, objectives, or other pieces of apparatus from rolling off onto the floor. If the undersurface of the board is covered with baize, it may be passed from one person to another by sliding the whole apparatus along the polished top of a table, which will not be damaged, neither will the adjustments of the lamp and microscope be displaced. The milled heads should always be turned by holding them between the finger and thumb, and exerting pressure equally on both sides of the head; they should never be turned by pressing the thumb against one side only. A higher power than that required to show detail in the object should never be used, and when working with a high power it is often useful to view the object first with a low power. For this purpose a double nose-piece or objective changer is a useful addition, and to a practical worker almost indispensable. Much care should be taken to see that the object is properly illuminated, as the clearness of the image depends quite as much upon this as upon careful and accurate focussing. When working with low powers and a condenser an uncomfortable glare of light is frequently seen in the field; this may be subdued, and the work rendered much less tiring to the eyes by putting a slip of finely ground glass below the slide under examination.

DETERMINATION OF SUCCINIC ACID IN THE PRESENCE OF TARTARIC AND LACTIC ACIDS.—When a concentrated solution of silver nitrate is added to a neutral solution of the mixed salts of these acids, succinic is entirely precipitated, tartaric acid partially, while lactic acid remains in solution. F. Bourdas, Joulin, and Rackowski avail themselves of the different solubility of these silver salts for the quantitative determination of succinic acid in the presence of lactates and tartrates. The solution of the three acids in the free state is exactly neutralised with 1/10 normal KOH solution, the number of C.c. thus used being noted. An excess of concentrated silver nitrate solution is then added, and the precipitate washed until the washings give no reaction for silver with neutral chromate; the residue thus obtained is pure silver succinate. This is washed into a flask, and one or two drops of neutral potassium chromate are added, which converts the silver succinate into chromate. Sufficient $\frac{\text{NaCl}}{10\text{N}}$ solution is then run in to produce a white precipitate suspended in a yellowish liquid. The excess of $\frac{\text{NaCl}}{10\text{N}}$ solution is titrated back with $\frac{\text{AgNO}_3}{10\text{N}}$ solution, the difference in the two amounts of solution indicating the silver solution used up by the succinic acid. One C.c. of $\frac{\text{AgNO}_3}{10\text{N}}$ solution is equivalent to 0.0059 gramme of succinic acid.—*Journ. de Pharm.* [6], vii., 417.

REVIEWS AND NOTICES OF BOOKS.

ST. THOMAS'S HOSPITAL REPORTS, 1897. Edited by Dr. HECTOR MACKENZIE and Mr. G. H. MAKINS. Pp. 499. London: J. and A. Churchill.

This volume, besides a great amount of well-classified statistical information, contains many interesting original articles, among which are several of general interest. Thus Dr. T. D. Acland writes on "Compulsory Vaccination," in which the arguments for and against are judicially and fairly considered. The article is well worth reading by everyone who is interested in this important subject. The lessons of recent epidemics, as at Dewsbury, Leicester, and Gloucester, are carefully and temperately analysed, the result showing the efficacy of vaccination in diminishing the death-rate from small-pox.

Two cases of abdominal actinomycosis are recorded by Mr. G. H. Makins. One patient was a woman, aged 25, in whom the ray-fungus attacked the vermiform appendix, and caused its perforation and the formation of an abscess in the abdomen and secondary foci in the liver. This patient succumbed to the disease. The second case was that of a farm labourer, aged 33, whose symptoms began with pain in January, 1897; this was followed by the formation of a thickening in the region of the vermiform appendix, for which he was admitted into hospital on March 21. In spite of surgical treatment, the area of induration increased, and though an examination of the tissue lining one of the tracks left by the draining of an abscess gave a negative result, the patient was put on iodide of potassium, which has been found, when perseveringly used, to arrest the progress of this disease. The extent of the induration began to diminish under the influence of the drug, and a little later it became necessary to open some new abscesses, and from the examination of scrapings examined at that time Mr. Shattock was able to report that the ray-fungus was present. The diagnosis was thus confirmed, and the use of iodide was continued in increased doses; the patient taking 5iss. per diem without any interference with his general health. The treatment had the happiest result, seeing that in August, 1897, the patient was practically convalescent. Actinomycosis is not uncommon in calves, causing in them ulceration of the tongue and tumours in the lower jaw. Neither of the patients could, however, be shown to have been exposed to direct infection from calves. Another and perhaps commoner mode of infection by the ray-fungus is by eating fresh grain in the autumn, and both Mr. Makins' patients were shown to have been exposed to this source of infection.

Dr. T. G. Brodie contributes a paper on the "Chemical Nature of the Antitoxins." After sketching the attempts of Brieger and Boer to isolate the antitoxins of diphtheria and tetanus, attempts which failed from the impossibility experienced of separating them from proteids, the author relates his own observations.

The German observers found that dried serum retained its antitoxic properties, but Brodie found that the more complete the drying the more difficult is the re-solution of the serum, and that after complete drying the latter loses some of its power. Touching the nature of the antitoxin, the author observes: "One of the first questions that we would wish to decide is as to whether the antitoxin is a proteid. . . . In the first place we find that just as a proteid is coagulated and loses its distinctive qualities when its solution is heated above a certain point, so, too, we find that a solution of diphtheria antitoxin heated above 75° C. at once loses its antitoxic properties."

"I found that the diphtheritic antitoxin was completely precipitated by adding alcohol or acetone to its solution in quantity sufficient to precipitate all the proteids. If the bulky precipitate thus obtained be at once filtered off from the coagulating fluid, it is readily soluble either in water or dilute saline solutions. In such solution the antitoxin is found in undiminished amount, none has been lost; though if the precipitant be kept for a longer time in contact with the precipitate, I found that more and more of the antitoxin was destroyed, and accompanying this more and more of the proteid is coagulated; so that it will no longer redissolve in water or saline solution. Other experiments also pointed to the antitoxin being itself a proteid. One observation made by Smirnow in 1894 is against it. This observer found that by submitting a solution of diphtheria toxin to the action of the constant current, the toxin was converted into antitoxin, the strength of the latter being in proportion to the initial strength of the toxin.

KING'S COLLEGE HOSPITAL REPORTS, 1897. Edited by Drs. NESTOR TIRARD, JOHN PHILLIPS, W. D. HALLIBURTON, and Mr. WATSON CHEYNE. Pp. 334. London: Adlard and Sons.

The first article in this volume is an obituary notice of the late Sir George Johnson, F.R.S., whose life and labours ceased on June 3, 1896. His work on diseases of the kidneys and on cholera will always hold an honourable place among the classics of medicine. He reached the mature age of 70 years, and in the course of his professional career he occupied some of the highest places of honour that are open to medical men; amongst other distinctions he was appointed Physician Extraordinary to the Queen in 1889, and the honour of knighthood was conferred upon him in 1892.

In a later portion of the volume Mr. Malcolm McHardy gives a description of an unusually well-arranged theatre for ophthalmic operations, which was erected in 1897 as a memorial to the deceased physician and teacher.

Among the original articles that are contained in this volume are: "Hæmaturia and Allied Conditions," by Dr. Nestor Tirard; "An Unusual Variety of Vesico-Vaginal Fistula," by Dr. John Phillips; "Graves' Disease," by S. Raymond Crawford. The report of the surgical department is carefully drawn up by the surgeons and the Surgical Registrar to the hospital, and it forms a readable and practically useful section of the book, being in the form of a short report of interesting cases, and a full list of all fatal surgical cases. The reports of the medical and obstetrical, and those of the special and pathological departments are done in an equally instructive manner, so that the volume is worthy of the series to which it belongs, and forms a valuable contribution to the post-graduate teaching of the medical school, as well as a record of continued good work of the hospital.

THE MIDDLESEX HOSPITAL REPORTS, 1896. Edited by Dr. F. J. WETHERHEAD, Mr. JOHN MURRAY, and Dr. A. F. VOELCKER. Pp. 306. Price 2s. 6d. net. London: H. K. Lewis.

These reports contain, in a well-classified form, a digest of the history of all cases under treatment at the hospital for the year 1895. "The report of the diphtheria cases for 1895 is of special interest, as during this period the diphtheria antitoxin was employed as a routine method of treatment. The remedy was obtained from the British Institute of Preventive Medicine. The results, as shown below, are sufficiently striking in themselves, and no comments are necessary."

This is the introductory paragraph to the report on the diphtheria cases numbering thirty-four admitted in 1895. The death rate was 17.64 per cent. The lowest death rate in the previous five years being 26.66, which was in 1894, when antitoxin was given in nine out of forty-five cases. In the years previous to 1894, when no antitoxin was given, the lowest death rate was 35.71 per cent. As usual the benefit of antitoxin is seen most markedly in cases in which tracheotomy was required on account of urgent dyspnoea. Out of eleven cases so treated seven recovered, a very high percentage. Abstracts of the clinical notes on the cases treated in the wards are given under the headings of the disease. Thus under "enteric fever," "appendicitis," a list of clinical records of great value to workers are put down. Cases of unusual nature rightly receive separate consideration. The editors are to be congratulated upon the way in which they have done their work.

ST. BARTHOLOMEW'S HOSPITAL REPORTS, Vol. xxxiii., 1897. Edited by NORMAN MOORE, M.D., and W. J. WALTHAM, F.R.C.S. Pp. 557. 1898. London: Smith, Elder and Co.

This volume opens with a sympathetic record of the life of the late James Andrew, M.D., by Dr. Church. Andrew was elected assistant-physician to the hospital in 1864, and for thirty-two years he continued to work as physician to the hospital and a teacher to the medical school. He was better known in his profession than among the public, a fact that carries with it the testimony that he worked for love of his work, and not for the profits of the profession. Among the original articles are many of much interest to medical men, e.g., Dr. Horton Smith writes on the bacteriology of acute broncho-pneumonia; Mr. C. A. Morton on the surgical treatment of increased intra-cranial pressure; Dr. W. E. Lee discusses some points in the Maidstone epidemic, and Mr. T. Forbes, cystic disease of the kidneys and liver. Drs. Lauder Brunton and Tunnicliffe contribute an interesting article on the relative digestibility of white and brown bread, in the course of which many practical observations are made. The following passage may be quoted:—

"The mere chemical composition of any food-stuff is a very poor index of its nutritive value. A stick of charcoal, the atmospheric air, a little water, and some sea salt contain all the elements of a typical diet, and in ample quantity, but the nutritive value of this composition is practically *nil*; hence it is not always a matter of what a food-stuff contains, but how it contains it." The tabulated matter and abbreviated registrar's notes and museum catalogue, which occupy about one-half of the volume, are clear and well arranged.

IL MANUALE DEL FARMACISTA. By P. E. ALESSANDRI. Second edition, revised. Pp. xvi., 731, with 145 tables and 82 illustrations. Price, lire 6.50. Milan: Ulrico Hoepli. 1898.

In the present go-ahead days when new remedies are introduced and pass into oblivion with vertiginous rapidity, the pharmacist frequently finds himself at a loss to know where to search for reliable and accurate and at the same time concise information concerning the little used or new compounds he is called upon to dispense. Our continental brethren seem to be better catered for than us in England in this respect, the Germans have numerous hand books of great utility, the French have the admirable works of Crinon and Bocquillon-Limousin, and the Italians, as we see by the manual before us, are just as well posted and up-to-date as their Teutonic and Gallic neighbours. It would be difficult to produce a book better thought out, better arranged, or more comprehensive than the one in question, the amount of matter compressed into the limits of a handy manual being phenomenal. The first part is devoted to a treatise on general pharmacy, pharmaceutical operations, prescribing and prescription reading, with chapters on density, in which are included some useful tables on saccharine solutions, showing the amount of sugar and water by weight in solutions of different densities. There are also glycerin, acetic acid, hydrochloric, nitric, and sulphuric acid tables of like object, together with freezing mixtures and alcohol tables. Chemical problems are explained and worked out in a special short chapter, and a list of abbreviations used in Italian prescriptions is given, which we would commend to the notice of our readers interested in Italian pharmacy.

The second and third parts of the book are devoted to inorganic and organic chemistry respectively, the chemicals mentioned having their reactions described and the methods of detecting falsifications and impurities minutely explained. The grouping of the organic compounds is noteworthy, all the new remedies being referred to their proper class, such as alcohols, aldehydes, ketones, amines, benzols, amido-phenols, aniline, pyrrhol, etc., derivatives. The chapters on alkaloids and glucosides, together with camphor derivatives and albuminoids, contain much valuable information as regards the tests and composition, as well as uses, of these bodies. The fourth part comprises *materia medica*, both vegetable and animal. Under *elemi* we notice that the one variety described is the Brazilian and not the Manila. The estimation of cinchona bark and ipecacuanha, as well as that of opium, is clearly explained, a volumetric process being advised for cinchonal. The reactions of the alkaloids are all given, with special notes on quinine and the metallic compounds of albumin, casein, and peptone, noted with their characters and doses.

The articles and tables dealing with oils, fixed and volatile, and organic medicines of indefinite composition are worthy of the book, whilst the part treating of galenical pharmacy is full of interesting formulæ and methods. The extracts, fluid and solid, have a chapter to themselves, in which it will be noted that the Italians, like the other continental pharmacists, evidently do not favour what we in England term "green extracts," and also that the author has very strong opinions against the use of concentrations in the extemporaneous preparation of medicated wines or syrups. The formulæ given for eau de melisse, eau de Cologne, and acqua senza pari, as well as for certain elixirs or liqueurs such as "Alchermes liquido," much used in Tuscany, ratafia di caffè, Curaçao, calisaya, Chartreuse and pepsine elixir are worth the notice of those desirous of extending their knowledge of elegant pharmacy. Antiseptics are fully described, Lister's method explained, and the making of gauzes, cottons and wools of various medications elucidated. The remainder of the book consists of formulæ for hypodermic solutions, pills, ointments and powders, and a posological table, and another of poisons and antidotes. It is a book for which there should be a demand in England if it were translated and produced in the same compact form as the Italian, of which the usefulness is much increased by the excellent wood-cuts interspersed in the text.

EXTRACTS FROM CONSULAR REPORTS.

THOSE WHO WISH TO PURCHASE English-made eau de Cologne while in Spain should look well to the label on the bottles, some of which though of foreign manufacture, bear the words "Nom plus perfume Especialnes in Cologne Water, London."

ANOTHER INGENIOUS FRAUD practised in Spain is the imitation of well-known articles of British manufacture. The labels of these goods are printed in such a manner as to lead the confiding public to believe they are purchasing the products of the best known British firms, whose name appears on the label in large capitals. A close inspection, however, reveals the words "better than" printed in small type above the firm's name, while the actual manufacturer's name is so written as to deceive many purchasers.

A NEW EDUCATIONAL INSTITUTION was opened on April 25 at Leipzig, viz., the first Commercial High School ("Handelshochschule") in Germany. According to the report of Mr. Gastrell, Commercial Attaché to Her Majesty's Embassy at Berlin, it is a kind of commercial university or college where higher and finishing studies on commercial subjects may be obtained. This new school is an instance of German foresight in grasping future necessities, and in providing betimes the means of supplying them. Professor Hermann Raydt, for years head of the great Commercial School of Leipzig, is the Director of the institution, the whole educational scheme, which is thoroughly practical, having been thought out and planned by himself, and others having practical experience in such questions. The whole scheme is worked very economically, and at present only costs £400 per annum, the income being raised without help from the Imperial Government of Germany. There are about ninety-five students attending the lectures, which embrace a wide range of subjects, the hours of study being from 7 a.m. to 7 p.m.

THE WINE-PRODUCERS of the province of Lecce (Italy) appear to be using sulphate of copper washes more and more extensively, not merely as a curative, but also as a preventative of peronospora. Consul Cocoto reports that during 1897 the sulphate of copper imports amounted to 781 tons, as against 637 tons in 1896 and 222 tons in 1895, thus demonstrating the increasing popularity of the washes. When they are applied during the earlier stages of the plant's growth, before the leaves and grapes are fully developed, up to the time of the complete ripening of the grape, the quality of the wine is not affected so long as there has been no peronospora of a pronounced type. But if the sulphate of copper washes have been used late, or if peronospora has been treated curatively, then the wine suffers, the result being diminished alcoholic strength and great loss of colour.

THE QUANTITY OF OLIVE OIL exported from Gallipoli during 1897 was 4469 tons, value £148,798, as compared with 3426 tons, value £112,298, in the previous year. There were also exported 2752 tons of olive husks, realising £1651, the quantity sent out in 1896 being 1116 tons, value £513.

THE IMPORT OF SULPHUR to Gallipoli in 1897 amounted to 1400 tons, and was valued at £4089. This quantity was a decrease of 100 tons as compared with the import of 1896, which realised £4380.

THE PRICE OF OLIVE OIL is certain to rise, so at least is the opinion of Vice-Consul the Hon. W. G. Thesiger, who, in reporting on the trade of the port and district of Taranto, states that the olive crops of 1897, though deficient in the yield of the finer oil, gave an excellent oil for burning, such as is greatly in demand in Russia. The prices of oil for 1897, according to the quality, were rather below the average, in consequence of the large supply, foreign competition, and the hope of a still better harvest for 1897-98. This hope has, however, been disappointed by the failure of the last crop, hence the reason for a rise in price. Reports from other districts in Italy and also from Turkey, speak of the complete failure of the 1897 olive crops. Prices on the Syrian coast are reported to have advanced at least 30 per cent.

THE IMPORTS INTO GREAT BRITAIN of chemicals, dyestuffs, and tanning substances during the six months ending June 30, 1898, show a decrease in value of £479,437, the totals being £3,750,226

for the corresponding period in 1897, and £3,270,789 this year. The imports for June alone, however, show an increase in value of £77,881; the 1897 import being £401,507, as compared with £479,388.

CHEMICALS AND CHEMICAL, AND MEDICINAL PREPARATIONS exported from the United Kingdom in the half-year ending June 30, amounted in value to £4,391,846, as against £4,631,705 for the same period of 1897, a decrease of £239,859. On the other hand, the exports for the month of June show an increase of £50,030, the total value for the month being £678,061, in 1898, and £623,031 the previous year.

THE OPIUM EXPORT from the province of Ssü-ch'uan during 1897 is estimated at £1,800,000, and other drugs at £400,000.

OPIUM SMOKING is reported to have originated in Yunnan and Kuei-chow, and from thence the practice spread to the coast provinces. The cultivation of the poppy on an extensive scale is stated to have begun at the end of the reign of K'ien-lung (1796), at which time opium was worth its weight in silver. In the opinion of Consul Bourne there is no doubt that the officials tried at the beginning of the century to stop the cultivation of the poppy, but this must have been a very difficult task, because an export, such as opium, light in weight for its value, is just what these provinces, with their antiquated means of communication, want. Without opium Yunnan and Kuei-chow would have no means of paying for imports.

CHINA COULD SUPPORT TWICE HER PRESENT POPULATION, according to Consul Bourne, and each individual might be twice as well off as he is now without any revolutionary change in the present manner of life; all that is necessary being capital and good government. The commercial future of the Empire, he says, is wonderful to think of, there being every requisite for production on a huge scale, except capital, good leadership, and good administration.

THE VEGETABLE KINGDOM OF CHINA, in Dr. Augustine Henry's opinion, affords a good and quite untrodden field for the development of an export trade. Camphor might be largely extracted from leaves, branches, etc., little or no camphor being now produced in China. A host of plants would supply rubber. Paper materials also abound, together with boxwood, soap trees, vegetable oils and tallows.

ARTIFICIAL MANURES (phosphates) imported into Genoa during 1897 amounted to 15,000 tons. Of these, 4307 tons were supplied by Germany, 2826 tons from Austria, and 7735 tons from America. England and Germany are largely responsible for an increase of nearly 8000 tons of other chemical products.

A VALUABLE DEPOSIT OF CINNABAR has been opened at Black Butte Lane County, Oregon, which report says can be worked very economically at a cost of 10 cents per pound. This, Consul Laidlaw thinks, is probably an underestimate, but the deposits are said to be very large. Cinnabar is also found in many districts of Peru, especially in the department of Huancavetica, where the Santa Barbara Mine was at one time world-famous. In the neighbourhood of this mine many cinnabar-bearing veins are found, and it is asserted that within a radius of thirty miles from the Santa Barbara mine the metal is found in abundance in many localities, although the extraction of cinnabar was given up years ago.

THE VALUE OF ALBUMIN exported from Beirut, quoted in the returns for 1896 as £13,200, Consul-General Drummond-Hay states was erroneous, as it exceeded the value of the whole trade, including Lattakia, the principal port for the production of that article. The trade in albumin is now said to be almost extinct.

THE MOST IMPORTANT COCA-GROWING DISTRICT IN PERU, according to Mr. Alfred St. John, is the province of Otuzco. There are at present 2,700,000 plants in the province, which produce about 4700 quintals, or 213 tons of coca leaves a year. The production, it is believed, might be increased considerably, but it has been checked by the fall in price of this product. The plant is grown at a height varying from 2000 to 5000 feet above the sea, but it thrives best at a height of from 3000 to 4000 feet.

PHARMACY IN AUSTRALASIA.

[From our Melbourne Correspondent.]

ALTHOUGH the General Medical Council omitted to supply the organs of Australasian pharmacy with advance copies of the new Pharmacopœia, we are, thanks to the admirable synopsis and trenchant criticisms published in your pages, generally conversant with its principal points of new departure; and if somewhat disappointed at the limited nature of these from a specially colonial point of view, console ourselves with the reflection that we shall in due course have an addendum "all to ourselves." One alteration, however, has been noted as of special interest to Australians engaged in the culture or distillation of medicinal plants, and that is that the former injunctions that the oils used in medicinal preparations must be distilled, and in some instances that the plants from which prescribed oils are obtained must actually have been grown in Great Britain are no longer insisted on. The attention of the Victorian Secretary of Agriculture has been drawn to the fact that the effect of this is to allow essential oils manufactured from plants grown in the Colonies to enter into the production of medicine in Great Britain, thus opening up a possibly lucrative branch of horticulture for us. With our favourable conditions of soil and climate, the incentive thus afforded will, it is considered, lead to very important results, and Australian supplies of essential oils may in the near future become a leading factor in the English market. In the meantime Victorian pharmacists are anxious to have a definite date gazetted on which the new Pharmacopœia shall come into practical operation, and the Pharmacy Board has been requested to approach the Government on the subject, and suggest that the day to be fixed should be January 1 next.

THE DEATH OF MR. CHAS. AGER ATKIN, on June 6, has removed from amongst us one of the oldest and most respected pharmacists in the colony. Mr. Atkin, who was born at Nottingham and served his apprenticeship with his father, arrived in Victoria in 1853, and a few months afterwards commenced business in the suburb of North Melbourne, then called Hotham, in which he permanently settled down and established an extensive business, identifying himself prominently with the manufacture of quinine wine, his brand of which has for many years past enjoyed a high reputation throughout Australia. Mr. Atkin was one of the founders of the Pharmaceutical Society of Australasia, of which he was at one time Vice-President. We have also to regret the loss, on May 15, of George Foord, F.C.S., who for nearly half a century has held a prominent position in our scientific world. Mr. Foord, who, by the way, received his early education at the Blue Coat School, at one time held an important position in the Royal Mint in this city, from which he retired on a pension. He was a Vice-President of the Royal Society, and an honorary member of the Pharmaceutical Society of Australasia, in which he took a very warm interest.

The widow of Dr. S. I. Williams, the particulars of whose death were given in a previous letter, has instituted proceedings against Mr. James Christopher, chemist, Clifton Hill, to recover £3000 damages, the action being founded on the allegation that Dr. Williams died from the effects of an injection of sulphate of atropine supplied to him by a son of the defendant in mistake for sulphate of morphine. Mr. Christopher, jun., was, it will be remembered, charged with the manslaughter of Dr. Williams, and acquitted. The result of the present proceedings is awaited with considerable interest by the craft.

A very satisfactory test was recently given before the Victorian Chief Inspector of Stock and leading pastoralists of a new patent (Kemp's) sheep-branding liquid, the sole agency and rights of manufacture of which have now been secured by Messrs. Felton, Grimwade, and Co. The merits of this liquid are that while it will brand sheep equally well wet or dry, is unaffected by heat and impervious to rain or moisture, the brand will dissolve and leave no trace behind when the wool is subjected to the ordinary process of scouring at the usual temperature.

THE PHARMACEUTICAL SOCIETY OF NEW SOUTH WALES held a special general meeting on June 8, to consider a proposed amendment of Article 4 in their Articles of Association, dealing with the qualifi-

cation required to render applicants eligible for membership. In introducing the subject, Mr. Cox explained that it had been ruled that the word "qualified" in the Article in question meant "qualified by law," and he believed it was the general desire of members that that interpretation should be amended. He accordingly moved that the Article be amended so as to read:—"Any person who (a) has at any time prior to the 1st day of January, 1898, been a member of the Pharmaceutical Society of New South Wales as then existing, or who (b) has passed an examination recognised by the Council in the subjects of chemistry and pharmacy, and such other allied sciences as the Council shall from time to time decide, may, subject to the following provisions, become a member of the Society." The general feeling on the subject was voiced by Mr. Marshall, who urged that although, looked at from the point of view of the general body of members, the Society might be said to represent an organisation of pharmacists who had come together for the benefit of the trade, the influence of the Society and its position in the estimation of kindred societies throughout the world would be greatly weakened were undesirable persons elected to membership. The motion was duly adopted, and is to be submitted for confirmation to another special meeting on 29th inst.

THE PHARMACY BOARD OF SOUTH AUSTRALIA recently decided to add botany to the list of its subjects of examination, and at the May meeting adopted the following regulation:—"Every candidate must have a theoretical knowledge of the structure of plants, and an intimate acquaintance with the parts of the root, stem, leaf, flower, fruit, and seed; the functions and mode of the arrangement of the different organs of plants; a knowledge of the general principles of classification; and he must be able to distinguish practically between each of the following orders: Compositæ, Cruciferae, Leguminosæ, Rosaceæ, Ranunculaceæ, and Umbelliferae, and refer to their respective orders such specimens as may be shown him."

IN PASSING SENTENCE upon two young men recently convicted of conspiring to defraud the public by selling, as Dr. Williams' Pink Pills, pills which they had themselves put up in boxes imitating the genuine article, the Chief Justice of South Australia commented in very strong terms on the representations as to the efficacy of their pills, made by the Dr. Williams' Company in the pamphlets issued by them, which had come before the Court. The medicine might, he said, be a good or a harmless one, but if the former it was a pity that people carrying on business on such an immense scale should have recourse to such unworthy subterfuges and untruthful statements, which were made merely to impose on the gullibility of mankind.

FROM NEW ZEALAND we learn that the Dunedin chemists are endeavouring to form an association composed of chemists and their assistants, and also those connected with the wholesale drug trade, the objects being the establishment of friendly intercourse between the members and the promotion of the interests of the members generally in matters "educational, political, commercial or otherwise."

MESSRS. SHARLAND & Co., LTD., wholesale druggists, held their annual meeting recently at Auckland, when a very satisfactory report and balance sheet were presented, showing that a previous deficit of £2300 had been cleared off. A call of 7s. 6d. per share had been promptly paid on 43,268 shares, leaving only 74, which had been forfeited by non-payment. The volume of trade for the year showed an increase of 25 per cent., and the prospects of the Company appear to be very encouraging.

I CLIP THE FOLLOWING INTERESTING PARAGRAPH from an Auckland paper:—A stalwart young Maori walked into Mr. Gatenby's chemist's shop at Wanganui recently, and said he wanted to learn the business. The suddenness of the offer almost took the chemist's breath away, but he thought he could cool the ardour of the dusky aspirant when he stated that a premium of £100 was required. The Maori, however, followed up his impertunity by "planking" down the £100, and has since signed an agreement for a three years' apprenticeship. The young man in question is an old Wellington College boy, and he came out with credit in a recent medical preliminary examination.

PHARMACEUTICAL SOCIETY.

MEETING OF THE COUNCIL.

WEDNESDAY, AUGUST 3, 1898.

Present :

MR. WALTER HILLS, PRESIDENT.

MR. G. T. W. NEWSHOLME, VICE-PRESIDENT.

Messrs. Allen, Atkins, Bateson, Bottle, Carteghe, Corder, Cross, Grose, Hampson, Harrison, Johnston, Martindale, Park, Savory, Storrar, Warren, and Young.

The minutes of the previous meeting were read and confirmed.

THE LATE DR. J. E. DE VRIJ.

The PRESIDENT said a Reuter's telegram from the Hague appeared in the *Times* of the previous day announcing the death of Dr. de Vrij. This was the only notice that had reached the Society of his death, but he could not let the occasion pass without referring to Dr. de Vrij. It was not necessary to do so in any detail, because it was only recently that he had had occasion to allude to the great services he had rendered to pharmacology. Dr. de Vrij was the ninth recipient of the Hanbury Medal, which was awarded to him last year. At the opening of the School of Pharmacy last October he (the President) referred in some detail to his work, but he would remind the Council that Dr. de Vrij was born as long ago as 1813, that he was trained and educated as a pharmacist, and that from about 1835 he made the subject of quinine and investigations into cinchona bark his special study. Dr. de Vrij was sent out by the Dutch Government to Java in the year 1857, and did great work there with reference to the introduction of the growth of cinchona in the Dutch East Indies. He would also remind the Council that in 1880 Dr. de Vrij received the distinction of being made a Companion of the Order of the Indian Empire for the work he had done in India in the same direction. Dr. de Vrij had been an honorary member of the Society for over forty years; therefore, he felt that under these circumstances special notice should be taken of the death of this eminent worker in science, and that a special resolution should be passed on that occasion. Dr. de Vrij had been taken away at a ripe old age, but they had hoped from the vigorous letter he sent the Society last year that he would keep his health for several years to come. He was sure the Council would wish to express his grief at the death of Dr. de Vrij, and its sincere sympathy with the family in their bereavement. He would, therefore, propose: "That this Council learns with much regret the death, on July 31, of Dr. de Vrij, one of the most eminent investigators of the cinchona alkaloids, and for over forty years a highly esteemed honorary member of the Society. In recognition of his labours in pharmacology he was awarded the Hanbury Medal in 1897, and he will be long remembered as a co-worker with Daniel Hanbury. The Council tenders its sympathy with the family of Dr. de Vrij." The resolution passed unanimously.

APPLICATIONS FOR MEMBERSHIP, ETC.

The PRESIDENT said the next item on the agenda was one which appeared monthly, viz., Election of Members, Associates, etc., and a certain number of applications had been received, but the present circumstances were exceptional, and it had been thought on the whole that it would be better to defer all elections until new Bye-laws had been duly passed for the purpose of carrying out the provisions of the Pharmacy Acts Amendment Bill, which had now become law. Of course, it was a matter for regret that any delay should take place in perfecting the adherence of any of their friends to the Society, but it had been carefully considered by the General Purposes Committee, and it was felt that the proper course would be to have new Bye-laws properly passed by the Council, confirmed by a special general meeting of members, and approved by the Privy Council before any further elections were made.

REPORT OF THE FINANCE COMMITTEE.

The report of this Committee was read by the Secretary, including the recommendation that sundry accounts be paid.

The PRESIDENT, in moving the adoption of the report and recommendations, said there was nothing to which he need call special attention. The payments were rather heavy, but in the case of salaries they represented two months. He should add that a letter had been received from the Hon. Sec. of the Midland Pharmaceutical Association, enclosing a cheque for £5 as a donation to the

Benevolent Fund, the resolution in favour of which was passed last year, but circumstances had prevented its transmission earlier. This was another pleasing illustration of the interest taken in the Fund.

The resolution was carried unanimously.

DIPLOMAS.

The undermentioned, being duly registered as pharmaceutical chemists, were granted diplomas stamped with the seal of the Society:—

Bennison, Ernest Carr.
Dixon, William.
Ellis, Hugh Edward.
Flemming, Thos. Henry.
Franklin, Arthur Cawte.
Gale, George Thomas.
Garnett, John Benbow.
Hart, Samuel Henry.

Hodgson, John Edward.
Hovenden, Sydney Churcher.
Jones, George Maurice.
Martindale, Win. Harrison.
Merrikin, Sydney Herbert.
Pick, Frank Phillips.
Rhead, Alfred.
Smallwood, Fredk. William.

Teale, John Oliver.

REPORT OF THE BENEVOLENT FUND COMMITTEE.

The report of this Committee stated that only one case had been before the Committee, which was deferred for further information.

The VICE-PRESIDENT moved the adoption of the report, which was at once agreed to.

REPORT OF THE LAW AND PARLIAMENTARY COMMITTEE.

The report of this Committee simply stated that the President had explained the steps he had taken in connection with the Pharmacy Acts Amendment Bill, and that the Committee had approved.

The PRESIDENT, in moving the adoption of the report, said it might be well if he gave a brief account of what had taken place. He would take that opportunity of referring to one of the political matters which had occurred since the Council last met. Although it did not arise out of the resolution then before them he would like to refer to the Poisonous Substances Bill. In accordance with the resolution passed by the Council a month ago he sent out a circular to every registered chemist and druggist throughout the country asking them to do all that was possible to oppose the further progress of the Bill, giving them certain reasons to guide them in taking that opposition. It was hardly necessary for him to say much about the Bill now, because on the very day that their own Pharmacy Acts Amendment Bill went through the Committee of the House of Lords an announcement was made by the leader of the House of Commons that the Poisonous Substances Bill would not be proceeded further with that Session. Mr. Balfour then stated that he found there was a very considerable amount of opposition to this Bill throughout the country, and on that ground, and bearing in mind the state of the session, he did not propose to take steps to make further progress with it. It might well be believed that the opposition which was taken by the Society through the various registered chemists and druggists throughout the country had had a very considerable effect in stopping the further progress of that Bill. Of course, it was quite on the cards that the Government might take up that Bill again, but he believed they had given another evidence that they were a distinct power in the country. He had come to the conclusion during the last few months that the Society had considerable influence throughout the country. The system of local secretaries was such that the Society was in close touch with them throughout the length and breadth of the country, and if they could only show anything like union in any steps they took, the effect of their power was very considerable. With regard to the Pharmacy Acts Amendment Bill, it was very satisfactory to note that it had now gone through Parliament and become a Statute. In view of what occurred in the House of Lords since the last meeting of the Council it was as well that he should refer in a little detail to what had happened. The second reading of the Pharmacy Acts Amendment Bill was taken in the House of Commons on Thursday, July 7. At that time it was proposed that the Committee stage, assuming the Bill passed the second reading, should be taken on July 11, and that the Standing Committee stage on July 12, whilst the third reading was proposed for the 14th. The second reading passed without any comment. The Committee stage on July 11 was also passed without any amendment, and the Bill was duly reported to the House; but on the occasion of the Standing Committee on July 12 certain speeches were made by the Lord Chancellor and Lord Herschell which raised hopes among themselves and their friends

throughout the country, and gave rise to a certain amount of concern in the tents of the limited companies. This took place on the Tuesday, and there was nothing further to report before the *Pharmaceutical Journal* and the trade journals appeared. Consequently, all that was to be known at that time was what had been said very sympathetically by the Lord Chancellor and by Lord Herschell; but on the Friday morning, July 15, the amendment, which they all knew so well now, was put into his hands. Lord Hardwicke, who was in charge of the Bill, and knew that the Society was labouring under certain disadvantages, thought that, having regard to the remarks made by the Lord Chancellor and Lord Herschell, he could do no other than say that he would consider the amendment. It was suggested afterwards that, as it was a very intricate matter, it would be advisable if the Lord Chancellor himself would be good enough to draw up the amendment. This amendment appeared on the Friday after the *Pharmaceutical Journal* of that week had been published. When he saw the amendment he felt at once that it was not, standing by itself, an amendment which would be of any great advantage to the Society, and there was of course a possibility that it might in some way jeopardise the Bill. He had a consultation that afternoon with Mr. Carteighe, who was good enough to see Lord Herschell, and later in the day Mr. Carteighe, the Secretary, and himself had an interview with Lord Hardwicke, when it was pointed out that the amendment, as it stood, was one which could not very well be accepted, as there were several objections to it. The Lord Chancellor himself realised this, and that it would be necessary that other amendments should be added in order to make it really workable. Lord Hardwicke was asked to postpone the third reading from the Monday to the Thursday, in order that they might have an opportunity of further considering the matter. In the meantime he thought it was expedient to call the Watch Committee together, and consult them as to the action to be taken with reference to this amendment. That Committee met on July 19, on the morning of which day he had had an interview with Lord Hardwicke, when he explained to him the objections to the amendment. He was authorised by the Committee to take such steps as he thought fit to secure the passing of the Bill without amendment. On the following day he had another interview with Lord Hardwicke, and put before him the views of the Committee, with which his Lordship agreed, and said he would inform the Lord Chancellor that he could not accept the amendment. It was now matter of history that the Lord Chancellor withdrew the amendment, and he hoped all their friends had read or would read with care the speech which his Lordship made on that occasion. The Watch Committee objected to the amendment on various grounds. In the first place it was opposed to the main principle of the Bill, which from the first had been considered as one simply for the consolidation of the Society, and for regulating its internal arrangements, so that everyone who had a statutory qualification should be eligible for membership, and even for a seat on the Council. That was considered to be both necessary and practicable, and when that was done it was hoped they might afterwards be able to tackle some other subjects which required to be dealt with. This view he had always put forward when discussing the Bill with members of the House of Commons, and always spoke of it as a non-contentious Bill which had practically the unanimous support of those interested, and on that ground it passed through the House of Commons. It was therefore felt that to introduce extraneous matter of an important character at a late stage in the House of Lords was a serious thing, which required considerable thought. It was also felt that the amendment proposed that the legalisation by statute of the position of limited companies, which could not be accepted. It seemed to the Committee that if such an amendment became law, limited liability companies would not only be permitted to practise, but would also have a right to assume the titles of "pharmaceutical chemists" and "chemists and druggists," to which there was the gravest objection. Further, no machinery was provided for ascertaining whether the businesses carried on by such companies were really under the management of duly qualified managers, and therefore further amendments would have been necessary to make such a clause workable. Another objection to the amendment was that it did not apply to Ireland, where the same difficulties existed, some said in greater degree, and at any rate they sympathised with their Irish friends in the matter and hoped that in due course some means might be found of diminishing the evil, if not of removing it altogether. The third reading took place on July 21, and he might again refer to the important speech

made by the Lord Chancellor on that occasion. He felt that this was a matter which did require early consideration, and only yesterday the Lord Chancellor was good enough to accord him an interview, when he had a very pleasant conversation with him. Whilst he did not think it either wise or right to report what took place at a personal interview, he thought he might go so far as to say that Lord Halsbury showed considerable sympathy with many of the views which he had the honour to lay before him; he also pointed out that the subject must be dealt with in a practical and careful way, and he believed they might rely on the help of Lord Halsbury later on if they could suggest anything which appeared to him to be both practical and desirable. At the risk of delaying the Council he should like to add a word or two of appeal to those outside the Society. The door was now opened to all who had the statutory qualification to join the Society and work with it on equal terms for the advancement of its interests and those of pharmacy in general. He would, therefore, earnestly ask those who had hitherto kept aloof to seriously consider their position and make up their minds that in future they would work with the Society. Within the last few days he had received a letter from a gentleman who, while acknowledging the good work which had been done in getting the Bill through, said he should still wait to see what they were going to do. Now he did not want that sort of thing any more. He appealed to such men to come in and help to do something practical to improve their position. He had received a large number of communications from registered persons and local organisations respecting the two Bills which he had referred to, and as he could not personally reply to each correspondent he hoped this public acknowledgment would be accepted. Various suggestions had been made, some of which were valuable, and they would all be duly considered. He felt that the Watch Committee and the Law and Parliamentary Committee had done their duty with reference to this Bill.

Mr. ALLEN seconded the motion.

Mr. HAMPSON expressed his great satisfaction at the position the Society held to-day, inasmuch as outsiders had now the opportunity of becoming insiders, and carrying on the work for the benefit of the Society and of the public. He would also congratulate the President on what he had achieved and on his retaining his health, which a month ago, he feared, would be somewhat impaired by his exertions, which had been very great, and in which he had been very ably seconded by the Secretary. He believed that now their house was in order, as far as the immediate progress of pharmacy was concerned, and it depended on those at present outside whether the Society should be strengthened or remain as it was. He should have scarcely believed it possible for the President to have received such a letter as he had mentioned. Everyone who was qualified was now invited to come within the ranks and help to mould the future of pharmacy, which required a great deal of moulding. He believed the Society had a great future as it had a great past, and that the time would arrive when by statute the whole dispensing of the country would be done by persons entitled to do it. Why should Ireland occupy a better position in this matter than England? They could not rest content until that distinction was removed. With regard to the stores question he thought the Watch Committee and Law and Parliamentary Committee and President had acted quite rightly with regard to the proposed amendment in the House of Lords, because it would have legalised the position. He did not know what the necessary steps might be, but he thought before long it would be necessary to call on every member of the trade to support some kind of measure whereby store practice should be either put on a proper basis or entirely abolished. He could not say at all what would be possible. It was a great misfortune in one sense that the matter could not have been dealt with two years ago before it attained such great dimensions. Perhaps it would have been impossible, but at any rate the past was past, and they would have now to consider what could be done in the future.

Mr. MARTINDALE congratulated the President on his success in carrying this measure through Parliament. He had hoped that the amendment to be proposed in the House of Lords would not have been such a disappointment, but he thought that, as the result of the debate which took place, they had got on to a higher place than they had hitherto occupied, and he hoped that when another opportunity occurred they would be able to follow up the success now attained, and to regulate company business in a way which would protect the interests of the trade as well as of the public. They were in a different position to the medical profession and the dentists, with whom they had been in

communication, having their practice to protect as well as their title; but he hoped that in future both would be secured. He thought the carrying of their own Bill and the rejection of the other showed that they occupied a stronger position than they had done hitherto, and hoped that with the help of the present and past Lords Chancellor they might on a future occasion go to Parliament with good hopes of obtaining a much more secure position than they had hitherto held. Great credit was due to the President for the way in which he had carried the Bill through, he had been unflinching in his attention, and never let slip an opportunity of gaining support, as he could testify, having been on duty with him on many occasions when the Bill was expected to come on. Their thanks were also due to several members of Parliament who had given them great assistance.

Mr. BOTTLE said he had not been one of those who had troubled the President with any letters, but he wished to congratulate him very much upon the success that had attended his work in procuring the passing of the Pharmacy Acts Amendment Bill and defeating the Poisonous Substances Bill. He noticed that in one of the trade journals the President and the Watch Committee were taunted with a betrayal of confidence, but in his opinion if the President had accepted the suggested amendment he would have been guilty of betraying the confidence reposed in him by the Watch Committee. For his part he would deprecate any immature legislation on the matter, as there was a large amount of divers interests to be dealt with and thought out before a Bill of that sort was rushed through. He would conclude by thanking the President and the London members for the great energy and ability they had displayed and the success which had attended their efforts.

Mr. CARTEIGHE also wished to congratulate the President on the fact that he passed one Bill through the present session of Parliament and killed another. These two events would probably never occur again during the official lifetime of a President. He (Mr. Carteighe) could take the position of the old hand, and felt bound to issue a word of caution. They talked of their power, but they must remember they had shown their power that session in killing a Bill by the process of opposition, and the power of passing their own Bill had been shown by the skill, care, and tact with which every serious difficulty which might cause contention in the House of Commons had been surmounted by the President. When they came to the thorny question of companies he would also use one word of caution, and that was that no one had ever given the Council authority to consider for one moment the series of regulations under which company trading should be carried on in pharmacy. No resolution to that effect had ever been passed at that Council table. When he was speaking at various places throughout the country, he pointed out that the first thing a lawyer who wanted to take an opposite view to them would say, would be, "put the companies in the same position as the trustees are under your own Act." It would be remembered that the Lord Chancellor's devil drafted for him what was called the "Widow's clause." Lest the observations of Mr. Martindale should make them feel that they had only to make an active effort in the House of Commons in order to put down company trading, let him remind them that they must be prepared to fight very heavily. The question as to whether they could put down a thing, or whether they could regulate were very different. At present he knew of no public opinion in the pharmaceutical world which had given any indication that regulations or modifications of any sort should at present be dealt with. He did not say that they might not come to that, or that it might not be possible so to draft a clause which would conduce to the safety of the public and remove every objection. Before they attempted to assist the Lord Chancellor or give their sanction to any modification of the pharmacy laws as affecting companies they must remember that no measure of that sort could be carried through the House of Commons unless it had the Government at its back, and that a measure of that sort which might pass the House of Lords need not necessarily pass the House of Commons, so easy was it to oppose. In Ireland they had seen a complete revolution. At one time the Council of the Irish Society thought they would accept some recent modification of the law, but a recent petition presented to the House of Lords by the President of that Society showed that they would not accept any modification whatever; that was to say that they would not accept for a moment the regulation of a department of pharmacy in or on a company's premises. There were many of their friends who thought the same. He had over and over again pointed out

that they had a very large number of people among them who wanted to have the privilege of doing what they liked with their business when they died by means of trusteeship or a qualified manager, but who did not at all like the notion of a company doing the same thing. That had been stated to him when their President, and he had replied that there was nothing before the Council to justify them in acting, nor was there anything which would justify the Council in accepting any amendment of the amendment put down by the Lord Chancellor. It would indeed have been a betrayal to have allowed a complete alteration of the law to be introduced into a Bill which was proclaimed from the presidential chair to be a non-contentious measure.

Mr. ATKINS entirely agreed with the arguments advanced by Mr. Carteighe. He was quite sure that whenever they attempted to deal with the subject of company trading they would have a crusade before them such as they had never attempted before, therefore they required to marshal all their forces. It would have been a betrayal of confidence if the Watch Committee had consented to wreck the Bill, as they would most distinctly have done if they accepted the amendment, and engrafted a contentious matter on their Bill. He wished to say personally how much he felt indebted to the President for having killed one Bill and passed another. It was not a question of good luck; it had been the result of sheer hard work on the part of the President, Mr. Carteighe, and the Secretary, and the result which they that day congratulated the President upon had been arrived at by a minute attention to details.

The PRESIDENT, before putting the resolution, wished to say that he was very much obliged for the kind remarks that had been made with reference to himself and any work that he had done with reference to either of the two Bills under discussion. After all, he took very little credit to himself. He happened to be the figurehead at the particular time when things were ripe for dealing with these two matters, and they came off successfully. The report he had received of their representatives throughout the country had been very gratifying to him, and he had to thank particularly the members of the Council for the unanimous and very kindly support they had given to him. He had also to thank the Law and Parliamentary Committee and the Watch Committee, and he wished particularly to record on that occasion his indebtedness to his friend Mr. Richard Bremridge. He had been unwearied in his efforts during the last three or four months, and he was afraid that his nights' rest had been very much interfered with. Whenever he (the President) felt inclined to flag, if it did not happen to be Mr. Martindale calling him out in the snow, it was his friend the Secretary who said "Don't you think we ought to go to the House to-night?" With reference to Mr. Carteighe's note of warning, for which he thanked him, he did not wish in his remarks to be too triumphant. He did wish to call attention to the fact that they did exercise a very considerable influence throughout the country, but, as he had occasion to say before, that influence and power must only be used when it was parallel with public benefit, otherwise the power would not make itself manifest. He quite agreed that the subject of limited companies practising pharmacy was one that required the very greatest care in dealing with, and he hoped that during the coming winter every one who was interested in the matter would give it the very closest consideration, looking at the matter from every point of view and not from a selfish point of view. Possibly in the next or succeeding session something would be done to effect an improvement of the present condition of affairs. Bearing in mind the great interest that was taken in the matter, he should like to suggest that the Law and Parliamentary Committee might find it expedient next session to consider the formation of a proposal for dealing with limited liability companies. He thought he might take it from the Council that they would like the Law and Parliamentary Committee to be summoned as soon as convenient after the holidays to consider the expediency of drafting a Bill, or at least considering the matter. He would move that the best thanks of this Council be tendered to the Hon. W. F. D. Smith, M.P., Mr. Brookfield, M.P., and the Earl of Hardwicke, for their much appreciated services in connection with passing the Pharmacy Acts Amendment Bill through the Houses of Parliament. Letters of thanks had been sent by himself not only to these three gentlemen, but to other M.P.'s who had been kind enough to render assistance, but he thought that a special vote of the Council was due to the two hon. members and the noble Earl, who had taken charge of the Bill.

The VICE-PRESIDENT, in seconding the resolution, said he

knew what a deal of time Lord Hardwicke and the two members of the House of Commons had given to this matter, and they were also much indebted to many other members. He thought those who had been in communication with M.P.'s in their own districts would do well to write to them expressing their thanks, as had been done in his own town, as this would help to produce a suitable frame of mind on the part of their representatives if they had to appeal to them on any future occasion. With regard to the question of the amendment, he thought it would have been a distinct breach of faith if that amendment had been accepted, because in corresponding with members of Parliament it had always been stated to be a non-contentious Bill, and on the strength of that assurance support had been obtained.

Mr. MARTINDALE said there were two other members of the House of Commons who had rendered great assistance—Mr. Boulnois and Dr. Farquharson—and several members of the House of Lords. He thought they might learn from this Bill that when they brought their united forces to bear on the House of Commons they were not without some power, and that they might expect to get equity from the House of Lords. If companies wished to carry on the business of chemists, which involved a personal qualification, it should be conducted by someone whose identity and qualifications were known.

The resolution was carried unanimously.

LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

The Librarian presented his report, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
June	Day	464	32	5	18
	Evening	127	11	3	6
Circulation of Books. Total.		Town.	Country.	Carriage paid.	
June	195	104	91	18s. 4d.	

Several donations had been received (*Ph. J.*, July 16, p. 62), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee recommended that the undermentioned books be purchased for the Library in London:—

- Hewlett's 'Manual of Bacteriology.'
- Lafar's 'Technical Mycology.'

The Curator's report had also been received, and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
June	Day	687	42	18	26
	Evening	54	6	1	2

Several donations had been received (*Ph. J.*, July 16, p. 62), and the Committee directed that the usual letters of thanks be sent to the respective donors.

The Curator had presented a report on the meetings of the Museums Association held at Sheffield in July. The recommendations of the Executive of the North British Branch with regard to local secretaries were again deferred. The communication from the Colonial Office with regard to the examination of medicinal plants from the Windward Islands had been considered, and the Committee recommended that the Colonial Office be advised to apply to the Imperial Institute. The Committee authorised the signing and sealing of the petition put forward by the Decimal Association. Certain repairs were recommended to be carried out during the vacation. A Sub-Committee had prepared a new set of Bye-laws which were considered and accepted subject to final revision by the Solicitor.

At a second meeting on August 2, the Committee considered the application of Mr. Edgar M. Chapman to be appointed Burroughs Scholar for the ensuing session, and recommended his appointment. It also recommended that the applications of Mr. Herbert Payne and Mr. John Evans, Bell Scholars, to be permitted to continue their studies in the Research Laboratory be acceded to. The Draft Bye-laws with verbal alterations were agreed to.

The PRESIDENT, in putting the resolution for the adoption of the report, said all these matters had been dealt with at the meetings of the Library, etc., Committee, and he did not think, unless any member wished any further enlightenment on any special points, that he need detain them that day by referring to any of the details. With regard to the alteration of the Bye-laws, that would come on later for special consideration.

The resolution passed unanimously, and a separate resolution was passed appointing Mr. Edgar M. Chapman Burroughs Scholar for the ensuing session.

THE NEW BYE-LAWS.

Mr. CARTEIGHE handed the President the text of the proposed Bye-laws (see page 137, *et seq.*).

On the motion of the PRESIDENT the proposed Bye-laws were taken as read.

The PRESIDENT, in moving that the proposed Bye-laws be read a first time in accordance with the provisions of the Charter, said he would call attention to one or two points in connection with them. The *raison d'être* of the amendments of the Bye-laws was the fact of the passing of the Pharmacy Acts Amendment Bill. Until they got Bye-laws which would enable them to make use of that Bill they were in an interim condition and could not do their work satisfactorily. The Committee had hoped that these Bye-laws might perhaps have received the approval of the Privy Council before the autumn recess; but owing to certain delays which had taken place in the passage of the Bill through Parliament, the third reading did not come off in the House of Lords till July 21, and the Bill did not become a Statute till the 25th. After that date there would not have been sufficient time to give the necessary notice of a special general meeting of the members to confirm the Bye-laws before the holidays, even if they had been able to arrange the necessary meetings of the Council. Therefore these Bye-laws would not receive the approval of the Privy Council until, possibly, November. It was proposed that there should be another meeting of the Council to read them a second time towards the end of September, and he hoped they would be read a third time on the first Wednesday in October. The alterations include a better definition of terms; a provision for transferring associates in business to the lists of members without special application being made; the abolition of the fee payable on restoration; the disappearance of the grade of "associate"; alterations in the procedure of Council elections; extension of the time within which any person nominated for a seat on the Council could declare his acceptance of the nomination. The restriction on the number of chemists and druggists on the Council had been removed. There was also a suggestion which did not arise out of the passing of the Act, and that was that the appointment of Examiners should in future take place in November instead of December; under the old arrangement the time was too limited before they were called upon to commence their duties.

The VICE-PRESIDENT, in seconding the resolution, hoped that the approval of the Privy Council would be obtained at an early date.

REPORT OF EXAMINATIONS.

July, 1898.

	Candidates.		
	Examined.	Passed.	Failed.
England and Wales:—			
Major	31	16	15
Minor	340	104	236
Scotland:—			
Major	3	1	2
Minor	120	49	71
First Examination	346	163	183

Twenty-five certificates were received in lieu of the Society's examination.

RESIGNATION OF A LOCAL SECRETARY.

The PRESIDENT announced that a letter had been received from Mr. Bolton, their local secretary at Nottingham, resigning his office on the ground of ill-health. Mr. Bolton had done really good work for the Society at Nottingham, and the Council would be particularly sorry at his resignation, and also the cause for the same. With the sanction of the Council he would write to Mr. Bolton thanking him for his past services. Mr. Bolton had been good enough to suggest that Mr. F. Ross Sergeant should be appointed to the office he was vacating, therefore he would propose the election of Mr. F. Ross Sergeant for the remainder of the current year in the place of Mr. Bolton, who was compelled to resign owing to ill-health. Bearing in mind the important matters that would be discussed during the next few months it was well that a centre like Nottingham should not be without a local secretary. Mr. Ross Sergeant was well known at the Council, and they had

every reason to believe that he would make an excellent local secretary.

The resolution passed unanimously.

APPOINTMENTS IN THE SCHOOL.

Mr. C. B. Fry and J. A. Dewhirst were appointed Demonstrators in Chemistry, Mr. C. Horrell Demonstrator in Botany, and Mr. Upsher Smith Demonstrator in Materia Medica and Pharmacy.

THE JACOB BELL AND MANCHESTER SCHOLARSHIPS.

The following reports were presented:—

Jacob Bell Memorial Scholarships.

The Examiners appointed to conduct the examination for the Jacob Bell Scholarships had reported that twenty-five candidates had competed for the Scholarships at the following centres:—

Birmingham	2	Cheltenham	2	Northampton	2
Brighton	1	Glasgow	1	Nottingham	1
Cambridge	1	Liverpool	1	Oxford	1
Canterbury	2	Manchester	1	Southampton	1
Cardiff	2	Newcastle	1	London	6

The envelopes bearing the mottoes of the successful candidates having been opened by the Committee appointed to make the award had been found to contain the following names:—

John Irwin Scott.

Horace Finnemore.

The Committee had awarded the Scholarships to Mr. Scott and Mr. Finnemore, subject to the approval of the Council.

The competitors who adopted the following mottoes had obtained upwards of two-thirds of the maximum number of marks (which is the minimum for the award of a Bell Scholarship). The arrangement is in order of merit:—

- | | |
|-------------------------|-------------------------|
| 3. Orando Laborando. | 7. Spes fortunæ sit. |
| 4. Est juvenis sperare. | 8. Eba. |
| 5. Audax. | 9. Absque labore nihil. |
| 6. One and all. | 10. Zephyrus. |

Manchester Pharmaceutical Association Scholarship.

The Committee reported that two candidates had competed, and that one had reached the standard of marks entitling him to the award of the Scholarship.

The envelope bearing the motto of the successful candidate was opened by the Committee appointed to make the award, and had been found to contain the name of

Arthur William Ryder,

to whom the Scholarship had been awarded, subject to the approval of the Council.

Pereira Medal and Council Prizes.

Professor McLeod, Professor Harvey Gibson, and Mr. E. H. Farr, who had been appointed to conduct this examination, had reported that nine candidates had entered for the competition, and that two had attained the requisite standard of efficiency for the awards. The envelopes bearing the mottoes of the successful competitors having been opened were found to contain the names of Frederick Alfred Upsher Smith, Birmingham; and Pierre Elie Felix Perrédès, Jersey.

The remaining competitors did not reach the standard of efficiency referred to.

The following awards were therefore recommended:—

Pereira Medal (Silver); and Books value £5, presented by the late Thomas Hyde Hills.

Frederick Alfred Upsher Smith.

Pharmaceutical Society's Medal (Silver).

Pierre Elie Felix Perrédès.

The PRESIDENT, in moving the adoption of the reports, said it was very satisfactory. It had been perhaps the keenest competition on record, there being twenty-five candidates, of whom eleven obtained

sufficient marks to qualify them for the prize, viz., 66 per cent. of the maximum number, and six obtained over 75 per cent. He was glad to learn from Mr. Pinches, who conducted the examination in scholastic subjects, that there had been a distinct advance in the last few years in the standard of education of those who competed for these scholarships, and he spoke in the highest terms of the work done by several of the candidates.

The resolution was carried, as was also a further resolution authorising Mr. Ryder to pursue his studies at Owens College, Manchester.

Mr. ALLEN said it was matter for congratulation that there had been such an excellent competition for the Bell Scholarships, and that so many as eleven candidates had obtained a qualifying proportion of marks, but there was one matter in connection with this examination on which he should like to make a suggestion; he had always taken a great interest in this competition, and there was one matter which he had found very embarrassing to candidates. The classical and scholastic portion of the examination was well defined, and they all knew what was expected of them, but the technical portion was simply defined in the Calendar as Elementary Chemistry, Pharmacy and Botany, and though there was a foot-note saying that a scholar was supposed to be commencing his studies, or at least to have made only that progress which might reasonably be expected during apprenticeship, that left the subject matter of the examination very wide. He was not finding fault with the examination papers, which of course were as fair for one candidate as another, but he thought it would be much more satisfactory if there were some better definition of what was meant by elementary chemistry, botany, and pharmacy. Some twenty-three or twenty-four years ago, when he went in for the examination, he felt the difficulty himself, and he had reason to believe that it existed still, the result being that candidates were driven to guide their studies by questions set at former examinations, which was not a satisfactory state of things. If he might venture a suggestion it would be that the elementary knowledge required should be based upon the chemical tests, substances, and processes of the British Pharmacopœia.

Mr. HAMPSON said the suggestion was an important one, and he thought it should be referred to the Committee to consider.

The PRESIDENT and Mr. CARTEIGHE both expressed the view that the matter should be referred to the Library and School Committee, and this was at once agreed to.

A resolution was passed making these awards, and resolutions were also passed thanking the Examiners for their services.

THE DECIMAL ASSOCIATION.

A letter had been received from the Secretary of this Association inviting the Council to be represented on the Committee of the Association. The letter was referred to the Library, Museum, School, and House Committee.

REPORT OF THE GENERAL PURPOSES COMMITTEE.

The Council went into Committee to hear and consider the report of this Committee, which dealt only with legal matters.

On resuming, the report and recommendations were unanimously adopted, and special resolutions were passed authorising the Registrar to take proceedings against the persons named therein.

The PRESIDENT announced that no meeting of the Council would be held in September.

"FIRST" EXAMINATION RESULTS.

A meeting of the Board of Examiners for England and Wales was held on Tuesday, August 2.

The report of the College of Preceptors on the examination held on July 12 was received. 346 candidates had presented themselves for examination, of whom 183 had failed.

The following 163 passed, and the Registrar was authorised to place their names upon the Register of Apprentices and Students:—

Abram, Arthur William; Wawne.	Atkinson, Richard Jowett; Bradford.
Adamson, John; Kinross.	Aves, Owen; Bridlington Quay.
Archer, William Leiper; Govanhill.	Bacon, Joseph William; Consett.
Arnott, Andrew Baxter; Cowdenbeath.	Baker, Albert John Joseph; London.
Arnott, David; Glasgow.	Barbour, Archibald; South Shields.

Barclay, Charles, jun.; Cowdenbeath.
 Barley, Oliver James; Stony Stratford.
 Batley, Joseph Howard; Barnsley.
 Beswick, James Herbert; Blackburn.
 Bickford, Harding; Hampstead.
 Body, Sydney Francis; Plymouth.
 Boyle, James Wood; Forfar.
 Brown, William Alfred D.; Brighton.
 Browne, Lewis Alexander; Uddingston.
 Bruce, George; Thurso.
 Burgess, John H. E.; Newport, I.W.
 Busbridge, Harry L.; Birmingham.
 Butterfield, William; Gt. Driffield.
 Button, Charles; Bodmin.
 Cameron, William R.; Lancaster.
 Cammell, Horace Watson; Hull.
 Chalmers, Robert; Inverness.
 Chard, Ernest Alfred; Bristol.
 Chisholm, John M.; Spennymoor.
 Clancy, Matthew Walter; Sidcup.
 Clark, Ernest Harold; Birmingham.
 Coney, Joyce Muriel; London.
 Cordiner, David G.; South Shields.
 Corlett, Daniel Mybrea; Douglas.
 Cornibeere, Albert Edward; London.
 Cruickshanks, John Bate; Montrose.
 Davies, Alfred Robert; Mold.
 Davies, Edwin Gladstone; Rhyl.
 Davies, Morgan Rhys; Cardiff.
 Deacon, George; Nuneaton.
 Dempster, John; Peebles.
 Donald, Stanley; Banff.
 Douglas, Joseph C.; Cockermonth.
 Downie, James Walker; Glasgow.
 Dryerre, Henry, jun.; Blairgowrie.
 Duggleby, F. C.; Gt. Driffield.
 Duguid, Joseph; Aberdeen.
 Dyer, Frederick Julian; Ramsgate.
 Eastmead, Leonard C. A.; Chatham.
 Edwards, David Miles; St. Dogmells.
 Ellison, Charles Kitchen; Skipton.
 Evans, James; Llandyssul.
 Fail, C. H. B.; Newcastle-on-Tyne.
 Farnworth, Samuel; Bolton.
 Field, William James; Witney.
 Fife, Donald Fullford; Barnstaple.
 Finlayson, Daniel; Glasgow.
 Forbes, John Pringle; Leigh.
 Foster, Francis John; Leeds.
 Francis, Alfred Bernard; Newport.
 Fraser, Alexander; Edinburgh.
 Goodier, Aloysius; Preston.
 Gordon, John Hamilton; Bathgate.
 Gorrie, Peter; Edinburgh.
 Graham, Linley; Kendal.
 Graham, William T.; Birmingham.
 Gregory, Nicholas; Whitehaven.
 Halliday, Robert James; Cupar.
 Hamilton, Frank Tinning; Carlisle.
 Harcus, John Sinclair; Kirkwall.
 Hardie, Charles Fullerton; Aberdeen.
 Hay, Thomas Hamilton; Lockerbie.
 Heely, Frederick W.; Gt. Grimsby.
 Hewson, John; Manningham.
 Hinchco, John Henry; Stoke-on-Trent.
 Hirst, Tom Eastwood; Slaithwaite.
 Hoad, Henry; Lewisham.
 Horner, Arthur Jeff; Bedale.
 Howarth, Sam Crabtree; Norden.
 Hughes, Charles O. E.; Birmingham.
 Hunt, Eric Bernard K.; Wellington.
 Hunter, James Edward; Alnwick.
 Ingrouille, Leonard John; Guernsey.
 James, William; Nottingham.
 Jarvis, William; Wisbech.
 Jones, John Evans; Llanfyrnach.
 Young, Charles Edward; Grantham.

Kemp, William G. F. H.; Gainsborough.
 Kerfoot, Ernest Hodgson; Manchester.
 Latham, David Paterson; Kirkealdy.
 Lewis, Dan; Clynderwen.
 Lewis, Edward Day; London.
 Lloyd, Ernest Frederick; Leicester.
 McArthur, Donald; Glasgow.
 Macgregor, John F. S.; Birmingham.
 Mackenzie, Elizabeth; Birmingham.
 McLeod, William A.; Thornaby-on-Tees.
 McMillan, James G.; Broughty Ferry.
 Madgshon, Flora Curle; Edinburgh.
 Marris, Stanley; Gt. Grimsby.
 Massie, Duncan; Glasgow.
 Mather, John Fleming C. B.; Buckie.
 Matthams, P.; Dunmow.
 Matthews, Joseph; Kelso.
 Maxey, Frank Ream; Wisbech.
 Middlemass, J. S.; Stockton-on-Tees.
 Miller, David; Dundee.
 Miller, Edward; Bloxwich.
 Mitchell, Herbert George; Boscombe.
 Morrison, William Davidson; Keith.
 Munt, Harry William; Scarborough.
 Nicolson, Charles; Glasgow.
 Norkett, Charles F.; Caversham.
 O'Malley, Thomas; Jedburgh.
 Orme, Herbert Gaywood; Brighton.
 Owen, Robert Cecil; Chester.
 Owens, Thomas Owen; Amlwch.
 Paley, Joseph; Pontefract.
 Parker, Benjamin; Mansfield.
 Peake, George Arthur; Birmingham.
 Pearman, Hurry; Blackpool.
 Peden, John; Stranraer.
 Philip, George; Kely.
 Phillips, Evan Albert I.; New Quay.
 Preston, John Priestley; Keighley.
 Purdy, Ernest Gibson; Seacroft.
 Revill, George Edwin; Romford.
 Riley, William Albert; Atherton.
 Roberts, Shergold Lovell; Sherborne.
 Robertson, John Grant; Govan.
 Robertson, Margaret Millar; Alloa.
 Rothwell, William; Bolton.
 Ryder, James Gove; Aberdeen.
 Sanders, Charles; Smethwick.
 Sandwith, Rowland; Bracknell.
 Sant, Harry Thomas; Newport.
 Scollick, Ernest Arthur; Gipsy Hill.
 Scrafton, Ralph; Middlesbrough.
 Shaw, Francis Veale; Leeds.
 Simpson, John W.; Stalybridge.
 Smart, Basil Austin; Cambridge.
 Smith, William; Lugar.
 Spruce, Charles Francis; Birmingham.
 Steel, Darrell; Stratford-on-Avon.
 Stephens, Benjamin Morrell; Paris.
 Storey, Francis Hubert; West Kirby.
 Talbot, John; Halifax.
 Taylor, Emma Bennett; Hungerford.
 Taylor, Walter John; Ruabon.
 Troup, James; Aberdeen.
 Varley, Edwin G.; Weston-super-Mare.
 Walker, James Thomas; Nottingham.
 Walters, Hopkin Thomas; Maesteg.
 Warne, Herbert Llewellyn; Shanklin.
 Warton, Wilfred; Streatham.
 West, Tom Edgar; Keighley.
 Weston, A. J. C.; Walsall.
 White, William; Gainsboro'.
 Whitehouse, Colston Henry; Bristol.
 Williams, Richard Maldwyn; Penrhyn.
 Willoughby, George E.; Carn Brea.
 Wood, George Laban; Uttoxeter.
 Yates, Matthew; South Shields.

The questions set at this examination were published in the *Pharmaceutical Journal* for July 16, p. 62.

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre, and the result:—

	Candidates.				Candidates.		
	Examined.	Passed.	Failed.		Examined.	Passed.	Failed.
Aberdeen	10	7	3	Inverness	2	2	0
Birmingham	24	13	11	Kirkwall	3	2	1
Brighton	2	2	0	Lancaster	4	2	2
Bristol	8	4	4	Leeds	22	10	12
Cambridge	2	1	1	Lincoln	4	3	1
Canterbury	3	1	2	Liverpool	18	6	12
Cardiff	11	1	10	London	37	16	21
Carlisle	7	3	4	Manchester	26	10	16
Carmarthen	9	5	4	Newcastle-on-Tyne	11	7	4
Carnarvon	7	3	4	Northampton	2	1	1
Cheltenham	2	0	2	Nottingham	13	5	8
Darlington	8	5	3	Oxford	3	1	2
Douglas	2	1	1	Penzance	2	1	1
Dundee	9	6	3	Peterborough	2	2	0
Edinburgh	29	13	16	Plymouth	8	3	5
Exeter	6	2	4	Sheffield	3	1	2
Glasgow	20	10	10	Shrewsbury	4	3	1
Guernsey	2	1	1	Southampton	5	2	3
Hull	13	7	6	York	3	1	2

SELECTED FORMULÆ.

PERU COGNAC.

This is a solution of Peru balsam in cognac. It contains 25 grammes of active principle in one litre. Schmey recommends it as suitable for tuberculosis and other tuberculous diseases.—*Pharm. Ztg.*, xlii., 41, after *D. Med. Ztg.*, 1898, 2.

CAMPHORATED TOOTH POWDER.

Camphor, 50 centigrammes; soap, 1 gramme; saccharin, 25 milligrammes; thymol, 5 centigrammes; precipitated chalk, 50 grammes; sassafras oil, 1 or 2 drops.—*Pharm. Zeitch. f. Russl.*, xxxvi., 696, after *Pharm. Era*.

TOBACCO FLAVOURINGS OR ESSENCES.

(1) Fluid extract of valerian, 1 fl. oz.; tincture of tonka bean (1-8), 8 fl. ozs.; alcohol (60 per cent.), to 32 fl. ozs. (2) Valerianic acid, 1 fl. dr.; butyric ether, 10 Mm.; acetic ether, 40 Mm.; alcohol (60 per cent.), 64 fl. ozs. (3) Tincture of valerian, 4 fl. drs.; butyric ether, 4 fl. drs.; tincture of vanilla, 2 fl. drs.; sp. ath. nitr., 1 fl. dr.; alcohol, 5 fl. ozs.; water to make 16 fl. ozs. *Cape Agricult. Journ.*, xi., 522.

KOLA PREPARATIONS.

Kola Tablets.—Dry extract of kola, 50; soluble chocolate, 20; vanillin sugar (1-500), 30 grammes; starch, *q. s.* Make 50 to 100 tablets. *Kola Emulsion*.—Fluid extract of kola, 10; yolk of egg (to emulsify), 20; glucose, 10; syrup, 20; tincture of vanilla, 5; cognac, 35.—*Apoth. Zeit.*, 1897, 404.

CAPTOL HAIR DYE.

Eichhoff recommends the following formula for the exhibition of captol: Captol, 2; chloral hydrate, 2; tartaric acid, 2; castor oil, 1; alcohol, 65 per cent., 200; perfume, *q. s.*—*Apoth. Zeit.*, 1897, 682.

PEPSINE ELIXIR.

Pure pepsin, 8 grammes; distilled water, 50 grammes; extract of coca, 2 grammes; extract of cinchona, 2 grammes; sugar 50 grammes; dry sherry, 100 grammes; hydrochloric acid, 10 drops; dissolve in the cold and filter bright through paper.—*Bol. Farm.*, through *Bullet. Com.*, xxvi., 37.

LEATHER VARNISH.

Caoutchouc, 1; petroleum, 1; carbon bisulphide, 1; shellac, 4; bone black, 2; methylated spirit, 20. Add the caoutchouc to the carbon bisulphide in a well-closed bottle, and set aside for a few days. When softened, add the petroleum and the spirit, then the shellac in fine powder, and heat to 125° C.; when nearly clear add the bone black, shake well and fill into well-corked bottles. This varnish dries quickly and produces a deep black coating which has a certain elasticity.—*Sci. Amer.*, lxxviii., 55.

PARLIAMENTARY NOTES.

THE POLITICAL ARENA is still the scene of active strife, but for chemists and druggists it possesses little interest now that their particular gladiators have retired with the laurels of victory. A feverish desire to get rid of the remaining business and pack up for the vacation characterised last week's work. A Saturday's wrangle over "conscientious objection" in relation to vaccination and a Bank Holiday debate on the superannuation of elementary school teachers were among the "extras" provided at St. Stephen's. In Committee of Supply on the Home Office Vote, Mr. Tennant (Berkshire) revived the question of lead poisoning and phosphorus necrosis, and called the Department hard names for not protecting sufficiently the workers in dangerous trades. He maintained that the use of lead was not essential in the process of glazing, and dramatically emphasised his point by producing for the critical inspection of the House a plate which was innocent of lead, but which shone with a glaze that had earned the approval of experts, and had undergone the severe test of being associated with the baking of seven separate loaves. Mr. Tennant stated that a firm was manufacturing these plates by way of experiment, and the House generally seemed to feel that chemical science was on the eve of settling for ever a problem which has long afflicted the country, and has a very important bearing on the health of a large number of Her Majesty's subjects.

PATENT LAWS AND ANILINE DYES formed a pretext to Mr. Cawley (Prestwich, Lancs.) on Friday last for a little tilt at the Board of Trade. He pointed out that a foreigner who could not get a patent in his own country, say for a dye process, could get one here, though he need not work it here. This had the effect of shutting out English manufacturers who desired to use the process and wished to obtain a licence from the patentee for that purpose. The present law provided that in cases where the patentee refused a licence and refused to work the patent himself, application might be made to the Board of Trade, but as this procedure involved the expenditure of about £1800, it was practically useless. Mr. Ritchie did not deny it, nor did he attempt to defend it. "This is the result of free trade in patents," said the right hon. gentleman. Captain Phillpotts (Torquay) also thought that the patent laws were unsatisfactory and ought to be inquired into, as also did Mr. Bryce (S. Aberdeen), but the representative of the Board of Trade gave them no comfort, and seemed to think that the present law provides remedies for all grievances, and that, if the cure happens to be expensive, it is better than having nothing.

ONE OF THE SCANDALS OF THE SESSION, and, indeed, of the last two sessions, is the supineness of the Lords on the companies question. The Select Committee to which the amending Bill was referred has not been sitting for a long time past, and shows no signs of meeting to even report that it cannot finish its work. In short, the policy of the last three years has been little else than barefaced shirking the question. The recent Hooley revelations may give rise to a good deal of unholy suspicion that Parliament is too much interested in companies to wish to disturb the *statu quo*. Evidence is daily accumulating of the most shocking abuses of the privilege of incorporation, and questions on the subject are continually coming before the House. Only last Tuesday Mr. Field directed attention to the scandals in connection with the promotion of limited companies, and asked the Government to introduce a Companies Act early next session. But what was the result? The Government could not pledge itself for next session, and the departments regulating home affairs and trade had no power to instruct the Public Prosecutor. One is inclined to think that public opinion will force the Government to do something next session, and recent events seem to signify that the time is getting ripe for serious legislation on the subject. The Pharmaceutical Society will no doubt take advantage of these facts, to impress upon the proper authorities that the public are quite as much swindled in having their pharmaceutical needs catered for by an impersonal combination of unqualified individuals as they are in having their expected dividends swallowed up by fraudulent directors or unscrupulous promoters.

PETROLEUM.—Mr. Ure (Linlithgow), who was successful in forcing the 100° flash test on the Petroleum Committee as the dividing line between oil and spirit, followed up his action on Tuesday by introducing a Bill to amend the Petroleum Act, 1879.

IRISH PHARMACISTS AND THE COMPANIES ACTS.

The following letter, with enclosures, has been received by the Editor from the Registrar of the Pharmaceutical Society of Ireland:—

The Pharmaceutical Society of Ireland,
67, Lower Mount Street,
Dublin, July 30, 1898.

Sir,—By direction of the President, I beg to hand you herewith copy of a letter forwarded on the 23rd inst. to the Lord Chancellor; also copy of his Lordship's acknowledgment.

ARTHUR T. FERRALL, Registrar,
Pharmaceutical Society of Ireland.

The Editor, *Pharmaceutical Journal*.

[COPY OF LETTER.]

The Pharmaceutical Society of Ireland,
67, Lower Mount Street,
Dublin, July 23, 1898.

To the Right Hon. The Lord Chancellor,
House of Lords.

My Lord,—I write to voice the astonishment and indignation of the Pharmaceutical Chemists of Ireland at the treatment their Petition to the Parliament of the Country has received.

We have asked for bread and you have tried to put a millstone round our necks. We claim to have the same treatment as the Medical Profession; to be dealt with in the same manner, and in the same clause. We are the necessary auxiliaries of that profession and have qualified for our position by education and examination as required by law.

If a number of persons seek to obtain the legal rights of any other body they have to go through the process of obtaining a Special Act of Parliament for the purpose, and the words "lawful purpose" in the Companies Acts clearly indicate that the purposes for which persons may incorporate themselves at pleasure, without going to Parliament, were such as the individual may do without appealing to Parliament, and which do not over-ride Acts of Parliament.

In Ireland, since 1791, it has been illegal for any person to "keep open shop" for the compounding of medicines, unless such person was registered and legally qualified by education and examination, and in 1875 this Society was incorporated by Special Act of Parliament to over-ride this right of the apothecaries of Ireland.

And we respectfully urge that the Companies Acts give no authority or right to over-ride either the Apothecaries Act or the Pharmacy Act (Ireland), 1875.

I have, etc.,

R. J. DOWNES, President.

[COPY OF REPLY.]

House of Lords, S.W.

July 26, 1898.

Sir,—I am directed by the Lord Chancellor to acknowledge the receipt of your letter of the 23rd instant.

I am, etc.,

KENNETH MUIR MACKENZIE.

The Registrar of the Pharmaceutical
Society of Ireland.

LEGAL INTELLIGENCE.

PROCEEDINGS UNDER THE PHARMACY ACTS.

PHARMACEUTICAL SOCIETY *v.* AUSTIN.

At the Grimsby County Court on Tuesday, before Judge Shortt, a case of considerable interest to chemists was heard. The Pharmaceutical Society of Great Britain claimed from Mr. J. Austin, 133, Cleethorpe Road, Grimsby, £5, being the penalty to which the defendant was liable under the Pharmacy Act, 1868, for having assumed the title of "chemist," not being a registered person under that Act. Mr. T. R. Grey, barrister (instructed by Messrs. Flux, Thompson, and Flux) represented the Society, whilst Mr. White (Grimsby) appeared on behalf of the defendant.

Evidence was given by Jonathan Mitchinson (Hull), inquiry agent, to the effect that, acting on instructions from the Society, he visited the shop of the defendant, and saw painted on the shop the words "Manufacturing Chemist." He went inside and purchased some neuralgia mixture, which contained chloroform, etc. For the defence it was urged that Austin, who was a herbalist, had decided to commence the business of manufacturing chemicals to sell wholesale, and, in consequence, had had the words "Manufacturing Chemist" painted above the door, and just below the word "Laboratory," together with a hand indicating the place where the chemicals were intended to be manufactured. The title did not mean to imply that the defendant was a chemist.

His Honour held that the defendant was not entitled to use the word "chemist," even in conjunction with the word "manufacturing," and pointed out that the power given to wholesale dealers by Section XVI. of the Pharmacy Act in no way entitled them to use the title chemist, or any other title which might imply that they were registered persons under the Act, and judgment was entered for the plaintiffs, with costs.

THE COUNCIL MEETING.

LAST Wednesday the winding-up of official work for the session was marked by reference to several unusually important events which have occurred since the previous meeting. After the minutes of the last meeting had been read and confirmed, the PRESIDENT drew attention to a telegraphic report in the *Times* of Tuesday announcing the death of Dr. DE VRIJ, an old honorary member of the Society and the last recipient of the Hanbury Medal in October last. On that occasion the PRESIDENT spoke at length of the work done by Dr. DE VRIJ in connection with the cultivation of cinchona in Java and India, and of his intimate association with the late DANIEL HANBURY in pharmacological research. A resolution expressing sympathy with Dr. DE VRIJ'S family was passed on the motion of the PRESIDENT.

In reference to a number of applications for membership of the Society, the PRESIDENT explained that they must be deferred for the present, and until the new Bye-laws required by the Act of 1898 shall have been passed and approved.

The report of the Finance Committee did not call for any special comment, and as is usual at this period, the larger amount of the payments recommended was a result of their being for two months in place of one. Mention was made of a donation of five pounds to the Benevolent Fund as having been received through the Honorary Secretary of the Midland Pharmaceutical Association and as a pleasing illustration of the interest taken in the Fund.

The report of the Benevolent Fund Committee was unique, inasmuch as it did not recommend a single grant, and there had been only one application to consider.

The report of the Law and Parliamentary Committee simply expressed approval of the steps taken by the PRESIDENT in connection with the Bill which has now become the Pharmacy Act, 1898. In moving its adoption, the PRESIDENT spoke of the action taken in stimulating opposition to the Poisonous Substances Bill, by addressing registered chemists and druggists on the subject and pointing out the lines of procedure to be adopted. The PRESIDENT did not think any further remarks were necessary on that subject, since Mr.

BALFOUR had stated that, in view of the opposition offered, the Bill would not be proceeded with. If the subject should again be taken up, evidence had been given that they were a power, and that the Society has considerable influence. Passing on to what has occurred in the House of Lords, the PRESIDENT said that the action taken in reference to the LORD CHANCELLOR'S proposed amendment was necessary for several reasons, which he stated at length (see p. 127), emphatically reiterating the view expressed in last week's Journal, that the course taken was the only one possible for the Society. Finally the PRESIDENT reminded those unconnected with the Society that all who have the statutory qualification are now able to come in and work on equal terms for the advancement of the common interests of the craft. He appealed to them to assist in doing something practical for the improvement of their position.

Mr. HAMPSON supported the remarks of the PRESIDENT, and congratulated him on the success he had achieved, expressing also a hope that it would meet with such a response from those outside the Society as would permit of energetic action in the future.

Mr. MARTINDALE expressed his opinion that, as the result of what had been said in the House of Lords, a somewhat improved position had been gained and he hoped the advantage would be followed up whenever opportunity arose.

Mr. BOTTLE, in congratulating the PRESIDENT on the passing of the Pharmacy Act and the defeat of the Poisonous Substances Bill, expressed his opinion that if he had accepted the suggested amendment he would have been open to the charge of betraying their confidence that has been unjustly brought against him for the opposite reason. He deprecated any attempt at hasty legislation in regard to a matter involving several interests.

Mr. CARTEIGHE also congratulated the PRESIDENT on the passing of one Bill and the killing of another—events that would probably never again fall to the lot of a President. In reference to what had been said of the power that could be exercised by registered persons, caution was necessary in the exercise of that power, especially in dealing with such a thorny subject as company trading. Lest Mr. MARTINDALE should induce the belief that to put down company trading they have only to make an effort, he would remind them that the effort would involve a very hard fight. In the pharmaceutical world he knew of no public expression of opinion as to the propriety of regulating or controlling company trading. Before attempting to assist the LORD CHANCELLOR in that direction or giving their sanction to such a proceeding, they must also remember that no measure to that end could be carried unless it had the support of the Government. In the present instance it would have been really a betrayal to have allowed a complete alteration of the law to be introduced in a Bill which had been declared from the presidential chair to be a non-contentious domestic measure.

Mr. ATKINS also concurred in these views, believing that whenever the attempt was made to deal with the subject of company trading all their power would be required for the contest.

The PRESIDENT, in putting the motion, thanked the members of the Council for their unanimous and kindly support, also their representatives throughout the country and Mr. RICHARD BREMRIDGE for his efforts during the past six months. As to future proceedings, he thought that it would

be expedient that the Law and Parliamentary Committee should consider the formulation of a proposal for dealing with companies and possibly drafting a Bill with that object.

On the motion of the PRESIDENT, a resolution was passed that the best thanks of the Council be addressed to the HON. W. F. SMITH, Mr. BROOKFIELD, and the EARL OF HARDWICKE, for their services in connection with the passing of the Pharmacy Act, 1898.

The report of the Library Committee dealt with various matters of detail, one of the principal being the new Bye-laws, a draft of which was agreed to. On the recommendation of the Committee, Mr. EDGAR M. CHAPMAN was appointed Burroughs Scholar; Mr. HERBERT PAYNE and Mr. JOHN EVANS were permitted to continue their studies as Bell Scholars in the Research Laboratory.

Mr. CARTEIGHE handed to the PRESIDENT a draft of the proposed new Bye-laws, which were taken as read, and in moving that they be read the PRESIDENT called attention to the several points on which they differ from the old Bye-laws.

The PRESIDENT announced that he had received from Mr. BOLTON, of Nottingham, a resignation [of his office as Local Secretary, and expressed his regret that ill-health was the cause of his discontinuing the good work he has done at Nottingham. In accordance with Mr. BOLTON's suggestion, Mr. F. R. SERGEANT was appointed Local Secretary.

In connection with the Society's School, Mr. C. B. FRY was appointed Demonstrator in Chemistry, Mr. C. HORRELL Demonstrator in Botany, and Mr. UPSHER SMITH Demonstrator in Materia Medica and Pharmacy.

On the recommendation of the Committee, Mr. JOHN IRWIN SCOTT, of Bootle, and Mr. HORACE FINNEMORE, of Seaford, Staffs, were elected Bell Scholars; Mr. ARTHUR W. M. RYDER, of Elworth, was awarded the Manchester Scholarship and permission was given him to pursue his studies at Owens College, Manchester. The competition for these scholarships was unusually keen, and the general results exceedingly satisfactory.

Mr. ALLEN drew attention to the need for some better definition of what is meant by elementary chemistry, botany, and pharmacy in connection with the competition for the Bell Scholarships. He had reason to believe that candidates experienced some difficulty in this respect, for though it is stated that they are supposed to be commencing their studies, or at least to have made only such progress as may reasonably be expected during apprenticeship, that statement left the matter so indefinite that candidates have recourse to questions set at former examinations as a guide to their studies. He therefore suggested that the elementary knowledge required should be based upon the chemical tests, substances, and processes of the British Pharmacopœia. Recognising the importance of the matter, the Council referred it to the Library Committee for consideration.

On the recommendation of Professors HARVEY GIBSON and McLEOD and Mr. FARR, the Pereira Medal was awarded to Mr. FRED A. UPSHER SMITH and the Silver Medal to Mr. P. E. F. PERREDES.

On the reading of the report of the General Purposes Committee, special resolutions were passed authorising the Registrar to take proceedings against various persons for infringement of the Pharmacy Acts, and the Council adjourned until October next.

A FERTILE SOURCE OF ERRORS.

IN referring to the 'Farmacopea Venezolana' last week, it was stated that, whilst denominations of metric weights and measures are used exclusively in the body of the work, the approximate equivalents of certain English weights and measures are given in the preface, apparently with the idea that those equivalents may prove useful if at any time Venezuelan pharmacists should require to dispense English prescriptions. But, as will be seen, some confusion is manifested with regard to the two older systems of weights used by English pharmacists, and a considerable degree of laxity is also permitted in connection with the suggested equivalents. The pound (*libra*), for example, is said to correspond to 16 ounces, and its equivalent is given as 460.0 Gm., or in round numbers (*en número redondo*) 500.0 Gm., whilst the ounce (*onza*) is said to correspond to 8 drachms, and its equivalent given as 28.80 Gm., or in round numbers 30.0 Gm. Similarly, the drachm (*dracma*), containing 3 scruples, is to be regarded at will as equivalent to 3.60 Gm., or 4.0 Gm., whilst the scruple (*escrúpulo*) of 20 grains may be represented by either 1.20 Gm. or 1.0 Gm. The grain (*grano*) is considered equivalent to 50 Mgm. The fluid measures, of which metric equivalents are given, correspond more closely to those in use here. Thus, it is stated that the gallon (*galón*) may be regarded as equivalent to 4548 C.c. or 4.5 Lit.; the pint (*pinta*) to 578 C.c. or 500 Gm.; the fluid ounce (*onza fluida*) to 29 C.c. or 30 Gm.; the fluid drachm (*dracma fluida*) to 3.5 C.c. or 4 Gm.; and the minim (*mínima*) or drop (*gota*) to 0.06 C.c. or 5 Cgm.

Apart from the confusion manifested between avoirdupois and apothecaries' weights, the free and easy manner in which the metric equivalents of English weights is given is remarkable. It would seem that a difference of 40 Gm. on the pound or of 2.2 Gm. on the ounce is regarded in Venezuela as of little consequence, to say nothing of the fact that the equivalents of the pound and ounce, as stated in round numbers, do not agree between themselves. The explanation of the matter is, of course, apparent, the idea prevailing in fixing the equivalents having been to give the nearest convenient weights in whole numbers. And this is where the weak point of the conversion system reveals itself, for exact equivalents are rarely in round numbers, and for all practical purposes it is usually assumed that the nearest whole number will suffice. But in Venezuela the tendency appears to be somewhat excessive in that direction, and quite unnecessarily so, for sets of weights, either English or metric, are not so expensive that those of both denominations should not be found in every pharmacy where they are likely to be required. The moral to be derived by English pharmacists from the facts stated above seems to be that they should lose no time in purchasing properly authenticated sets of metric weights and measures, which should be used whenever metric quantities of medicinal substances are ordered in prescriptions or asked for by customers. The fact that errors may easily occur in converting quantities has not been dwelt upon, but it is well known that there is no more fertile source of errors, and as the cause can be removed by the expenditure of a comparatively insignificant sum, there is no valid reason why that cause should be allowed to remain. In everything connected with the dispensing of medicines exactness should be sought after, not approximations, and the only safe rule in weighing and measuring is to use weights and measures of the system indicated.

ANNOTATIONS.

THE CONFERENCE AT BELFAST will have adjourned before another issue of the Journal is in the hands of our readers, and judging from the information in hand, a highly successful meeting will have been recorded. Though the reception and conversazione will not be held until Tuesday evening, next week, instead of Monday as usual, it may be anticipated that the greater proportion of those who propose to take part in the proceedings will have assembled in Belfast by Monday night. Mr. J. C. Nightingale, the Assistant-Secretary of the B.P.C., asks us to announce that a meeting of the Executive Committee will be held at the Grand Central Hotel, Belfast, at 9 p.m. How the time will be spent by the non-official members of the Conference during that meeting and subsequently must be left to the imagination, but presumably it will not be devoted to discussing the new Pharmacopœia or any other strictly pharmaceutical topic. And in any case, a time of quiet contemplation will not come amiss after crossing the ocean, and prior to official welcomes and listening to the presidential address. We understand it is practically decided to devote half a day, during the session of Conference, to a general discussion of the new B.P. That will account for at least a third of the papers to be read, so it may not be so great a puzzle, after all, to find time to read and discuss the numerous papers promised.

THE PHARMACOPŒIA DISCUSSION at the Conference promises to be of especial interest, and it is greatly to be hoped that the Editor of the Pharmacopœia may be able to be present, so as to sum up the discussion. The papers on Pharmacopœia topics approach the main subject from every side, and if, as would be desirable, the discussion takes place on the opening day of the meeting, it ought to prove far and away the most important item in the Conference programme. If for no other reason, the Pharmacopœia papers should be read and discussed on Tuesday because everyone will then be fresh to the work and in the best possible condition for taking part in the proceedings. In addition to that, the earlier the discussion comes on the fuller will be the reports that can be published next week, and consequently the wider the publicity that will be gained. It should be remembered that the full report of the Conference proceedings in next week's Journal will be in the hands of every registered chemist in Great Britain and most of those in Ireland by the end of the week. Such an opportunity has never before presented itself in connection with the annual gathering of the members of the British Pharmaceutical Conference, and it would be a pity if full advantage were not taken of the opportunity. Since, therefore, the new Pharmacopœia is more prominent in the minds of pharmacists than any other technical matter at present, the discussion on it should be as full as possible and as fully reported as press exigences will permit.

THAT SIXTY REGISTERED CHEMISTS should be so lost to all sense of self-respect as to cover companies carrying on the business of a chemist and druggist is greatly to be regretted, yet such is claimed to be the case, in a scandalous circular issued by a company whose ravages are only too severely felt by chemists in the southern counties. The irregular practice of pharmacy rendered possible by registered persons, in the capacity of assistants or managers, covering companies carrying on the business of a chemist and druggist, is the inverse counterpart of the covering of unqualified assistants in medical practice, which has been declared to constitute "infamous conduct," and from that point of view is worthy of the attention of all pharmacists who are desirous of maintaining

the value of their qualification. Those who assist the company referred to, whether there be sixty of them or less, ought to consider seriously what a future they are helping to prepare for themselves. Presumably they do not intend to act as servants of the company for an indefinite period, yet when, if ever, they commence business as chemists and druggists on their own account they will find that they have helped to forge shackles which will impede their progress enormously. Not only that, but so long as they continue to serve the company they are morally responsible for the vile slanders cast upon the rest of the craft in their district by the company whose circular, mentioned above, is as full of misrepresentations as any document could be. Surely the moral sense must be sadly lacking in the case of registered chemists who can stoop to serve such masters!

GRANDMOTHERLY LEGISLATION in the old country is known to be as nothing compared with that prevailing in some of the American States, but it is difficult to conceive of such an absurdity as legislating about the shape of feeding bottles for infants. According to the *Pharmaceutical Era*, however, "the long-necked nursing-bottle question" has stirred up a lot of trouble in Buffalo, where a number of the most prominent druggists have been arrested and charged with selling the objectionable bottle with long rubber tube in direct violation of an ordinance by the Board of Health. One druggist was found guilty and fined, the Court holding that the ordinance was presumptively reasonable, as the bottles in question are detrimental and injurious to public health. The other defendants, backed by the local pharmaceutical association, intend to carry their cases to a higher Court. And now, says the *Era*, "there is a hot time in the old town." The druggists say they are being persecuted, the health officer says the druggists did not sin ignorantly, having been fully informed of the nature of the ordinance, and the physicians are upholding him in the matter. It is allowed that Buffalo's chief health officer, by his methods of sanitation, disinfection, and looking after the public health generally, has secured for that city a record which is the envy of the health boards of other cities. He is described as a fighter who, when he sets out to remedy an evil, usually effects his purpose. It appears that in the present instance no one denies that feeding bottles with long rubber tubes are dangerous, but some think that the health officer has been a little too arbitrary in his action. However, he has the law on his side, and that, observes the *Era*, is a powerful weapon.

THE SCHOOL OF PHARMACY SYLLABUS for the session 1898-99 is now ready, and copies can be obtained by application to the Secretary of the Pharmaceutical Society, 17, Bloomsbury Square, W.C. It gives full particulars of the courses of lectures, laboratory courses, fees, scholarships, etc., and should be consulted by every pharmaceutical student who proposes to attend a college course prior to presenting himself for examination.

DR. J. E. DE VRIJ, C.I.E., whose death is announced as having occurred on July 31, at the Hague, was the latest recipient of the Hanbury Medal. He began life as a pharmacist and was more or less associated with pharmacy throughout his long life, but he gained distinction as an investigator in connection with the chemistry and natural history of drugs, more especially cinchona, or as the *Times* puts it, somewhat strangely, "the pharmaceutical properties of quinine" (*vide P. J.*, lix., 30). The Hanbury Medal was awarded to Dr. De Vrij in July of last year, and presented at the inaugural meeting in October last, when the worthy recipient was unfortunately unable to be present. He died after a very short illness at the advanced age of 85 years.

SECONDARY EDUCATION may possibly receive the attention it deserves in the next session of Parliament, the Duke of Devonshire having formally directed the attention of the House of Lords to the subject on Monday by introducing two Bills relating thereto. He pointed out that the Department of Science and Art is now maintaining central organising authorities at a cost of about £26,000 a year, and also distributing the public grant of £276,000, divided amongst local institutions, some of which profess to give the highest scientific and artistic teaching. Parliament is also responsible for other amounts, and altogether there is a sum of not less than a million expended on certain branches of secondary education in various schools and institutions. In addition, there is a large number of private schools all over the country which would probably be quite willing, in return for some public recognition, to come into a general scheme of education, and the Lord President of the Council is of opinion that, by supporting such agencies from public funds, the direct administration of them might and should be brought under the consideration of Parliament, through a Minister who shall be understood to be responsible for the direction given to secondary as well as elementary education.

THE MINISTER OF EDUCATION will preside over a Board of Education, on the model of the Board of Trade, the Local Government Board, and the Board of Agriculture, the present Education Department and Department of Science and Art being brought together and placed under the control of one permanent secretary. If the Minister of Education should be in the House of Lords, the President of the Council will be President of the new Board, and he will be represented by the Vice-President in the House of Commons. If, on the other hand, the Minister of Education should be in the House of Commons, he will have the office of President of the Board of Education, and there will be no Vice-President, the new department being represented in the House of Lords by some other arrangement. The present Education Department is to be entirely reorganised, as well as the Department of Science and Art, but the details of the reorganisation remain as yet to be worked out by the departments concerned. It is thought that the proposed changes will tend to economy, no less than to increased efficiency, and the new departure should be cordially welcomed by all friends of systematic advanced education. Experiments in this direction, on a larger or smaller scale, have been carried on all over the country at a great cost to the public for some years past, but if both successes and failures prove useful in facilitating the evolution of a perfect scheme of general education the expense will have been wisely incurred.

THE FLORA OF TROPICAL AFRICA, which is being issued by the scientific authorities of the Royal Gardens at Kew, is progressing, volume 4 being in an advanced state of preparation, though very little of it appears yet to be in type. Two other volumes, Nos. 7 and 5, are being printed first, the third and last part of volume 7 being nearly ready. There have been certain difficulties as to the printing of volume 5, but the publishers have now declared themselves ready to proceed with it.

DR. MORRIS, Assistant Director at Kew, is to be Director of a special public department to be established, in connection with the West Indies, for the purpose of dealing with all questions of economic plants and botanic stations in all the islands. He possesses special qualifications for the post, since he has special acquaintance with the West Indies, in addition to the scientific and other knowledge required. As was stated by Sir Edward Grey in the House of Commons on Tuesday last, he will bring to

the discharge of his duties a knowledge of tropical produce and the possibilities and conditions of the cultivation of that produce such as cannot be surpassed by anyone. He will also bring to the administration of the new department the greatest ability, energy, enterprise, and devotion to work, and his labours as head of the department should prove of the highest value to the West Indian Islands.

THE NEW CANADIAN TARIFF is exceptionally favourable to the products of all other British territories, allowing as it does a reduction of one-fourth from the general tariff rates of duty. The preferential tariff applies to all articles except wines, malt liquors, spirits, spirituous liquors, liquid medicines and articles containing alcohol, tobacco, cigars and cigarettes, imported into Canada from the United Kingdom, Bermuda, the British West Indies, British Guiana, British India, Ceylon, New South Wales, and the Straits Settlements. The tariff may also be extended by Order in Council to any other British colony or possession, if the local Customs tariff is, on the whole, as favourable to Canada as the British preferential tariff of Canada is to such colony or possession.

MR. J. A. R. NEWLANDS, to whom, equally with Mendeléeff credit is due for the discovery of the "periodic law" in chemistry, died at Clapton on Friday, July 29, aged 60 years. He was about only a few weeks ago, and his death will be greatly regretted by a large circle of friends and acquaintances. Mr. Newlands was privately educated by his father, a Presbyterian minister, though claimed as a City of London School boy. His work on the periodic law was but tardily recognised in this country and, in fact, practically ignored until Mendeléeff had given the subject prominence.

SIR FREDERICK ABEL offers to those who desire to inform themselves correctly regarding the important matter examined into by the Petroleum Committee, the excellent advice that they should not be guided by *ex parte* statements, but should examine for themselves. But the task is somewhat difficult, for unfortunately the truth about petroleum and the flash point of lamp oil lies at the bottom of a very deep well; it has been sounded by Sir Frederick and by Dr. Atfield, but without either having brought to light the real reason for adopting the 73 degree standard. However, the adoption of a higher flash point is now so probable that there is practically no need for raking up ancient history that few are acquainted with.

THE NATURAL HISTORY MUSEUM at South Kensington is to be in charge of Professor E. Ray Lankester, F.R.S., Linacre Professor of Human and Comparative Anatomy of the University of Oxford, who has been appointed Director in the room of Sir William Fowler, who retires at the end of September next. Professor Ray Lankester holds the degrees of M.A., LL.D., F.R.S., and is a Fellow of Merton College and Hon. Fellow of Exeter College, Oxford. He was Professor of Zoology and Comparative Anatomy at University College, London, from 1874 to 1890, became Regius Professor of Natural History, Edinburgh, in 1882, Royal Medallist of the Royal Society in 1885, and Vice-President of the Royal Society in 1896. He founded the Marine Biological Association (Plymouth Laboratory), of which he subsequently became President, in 1884. He is a corresponding member of the Imperial Academy of Sciences, St. Petersburg, a foreign member of the Royal Bohemian Society of Sciences, and has edited the *Quarterly Journal of Microscopical Science* for many years, besides publishing numerous works on zoological science.

BYE-LAWS OF THE PHARMACEUTICAL SOCIETY.

For the convenience of readers the existing bye-laws of the Pharmaceutical Society and the proposed bye-laws are here presented side by side for comparison.

Present Bye-Laws.

PRELIMINARY.

In the following Bye-laws words importing the singular number shall include the plural number, words importing the plural number shall include the singular number, and words importing the masculine shall include the feminine, unless there be something either in the subject or context repugnant to such construction. By the expression, "the Charter," shall be meant and intended the Royal Charter of Incorporation of the Society. By the expression, "the Statute, 1852," shall be meant and intended the Statute, 15 and 16 Vict., cap. 56, intituled "An Act for regulating the qualifications of Pharmaceutical Chemists;" and by the expression "the Act, 1868," shall be meant and intended the Statute, 31 and 32 Vict., cap. 121, intituled "An Act to regulate the Sale of Poisons, and alter and amend the Pharmacy Act, 1852." All the Bye-laws heretofore passed are hereby repealed.

SECTION I.

QUALIFICATIONS, ELECTIONS, AND SUBSCRIPTIONS.

1. Persons who have become Members and Associates pursuant to the Charter, the Statute, 1852, or the Act, 1868, may continue to be such Members, or Associates accordingly. Persons who have become Apprentices or Students, pursuant to the Charter and the Statute, 1852, may be registered as Students, and all the said Members, Associates, or Students, shall respectively so continue, subject to the Bye-laws in force for the time being.

2. Persons qualified to be elected Members, Associates, or Students of the Society, shall at a meeting of the Council be proposed and seconded by Members of the Council. The qualification of the proposed Member, Associate, or Student, shall be stated in a written resolution, which, when proposed and seconded, shall be submitted to the Council, and when passed, shall confer the right of becoming a Member, Associate, or Student.

3. Persons registered as Pharmaceutical Chemists under Section 10 of the Statute, 1852, and desirous of becoming Members of the Society, shall make application to the Council in that behalf.

4. Persons who, at the time of the passing of the Act, 1868, were or had been in business on their own account as Chemists and Druggists, who have been registered as Chemists and Druggists, and are desirous of becoming Members of the Society, in exercise of the privileges conferred by Sections 18 and 19 of the Act, 1868, shall make application to the Council in that behalf.

5. No persons other than those who have previously been registered as Pharmaceutical Chemists, or those who, at the time of the passing of the Act, 1868, were or had been in business on their own account as Chemists and Druggists, and have previously been registered as Chemists and Druggists, shall be elected Members, unless as Honorary Members or as Corresponding Members.

6. Persons registered as Chemists and Druggists, by reason of having obtained certificates of qualification from either of the Boards of Examiners, and desirous of becoming Associates of the Society, under Section 20 of the Act, 1868, shall make application to the Council in that behalf, and no other person shall be elected an Associate.

7. Persons registered as Apprentices or Students under Section 10 of the Statute, 1852, shall be eligible for admission as Students

Proposed Bye-Laws.

PRELIMINARY.

All the Bye-laws heretofore passed are hereby repealed, and the following shall be the Bye-laws of the Society.

In the following Bye-laws:—

Words importing the singular number shall include the plural number, words importing the plural number shall include the singular number, and words importing the masculine shall include the feminine, unless there be something in the subject or context repugnant to such construction.

"The Society" shall mean and intend the Pharmaceutical Society of Great Britain.

"The Charter" shall mean and intend the Royal Charter of Incorporation of the Society.

"The Statute, 1852," shall mean and intend the Statute 15 and 16 Vict., cap. 56, intituled "An Act for regulating the qualifications of pharmaceutical chemists."

"The Act, 1868," shall mean and intend the Statute 31 and 32 Vict., cap. 121, intituled "An Act to regulate the sale of poisons and alter and amend the Pharmacy Act, 1852."

"The Council" shall mean and intend the Council of the Society.

"The Secretary" shall mean and intend the Secretary of the Society, and

"The Registrar" shall mean and intend the Registrar appointed under the provisions of the Statute 15 and 16 Victoria, cap. 56, and of the Statute 31 and 32 Victoria, cap. 121.

SECTION I.

QUALIFICATIONS, ELECTIONS, AND SUBSCRIPTIONS.

1. Persons who have become Members may continue to be such Members. Persons who have become Students shall become and be registered as Student-Associates, and all the said Members and Student-Associates shall be subject to the Bye-laws of the Society in force for the time being.

2. Every person who on the 25th day of July, 1898, was an "Associate in Business" may be elected by the Council a Member of the Society without special application in that behalf, and such persons shall be exempt from further contribution to the Society in respect of the year 1898, and save as appears hereby persons qualified to be elected Members, or Student-Associates, shall, at a meeting of the Council be proposed and seconded by Members of the Council. The qualification of each proposed Member or Student-Associate shall be stated in a resolution, which, when proposed and seconded, shall be submitted to the Council, and when passed, shall confer the right of becoming a Member or Student-Associate.

3. Persons registered as Pharmaceutical Chemists or as Chemists and Druggists, and desirous of becoming Members, shall make application to the Council in that behalf, and no persons other than Pharmaceutical Chemists or Chemists and Druggists shall be elected Members, unless as Honorary Members or as Corresponding Members.

To be repealed.

Incorporated in Clause 3.

To be repealed.

4. Persons registered as "Apprentices or Students" shall be eligible for election as Student-Associates, and, if desirous of being

Present Bye-Laws.

of the Society, and, if desirous of being admitted accordingly, shall make application to the Council in that behalf.

8. All persons on election as Members, Associates, or Students, shall sign a written declaration, stating their full names and addresses, and their willingness to comply with the regulations of the Society.

9. All Subscriptions for the current year shall become due upon election, and all annual subscriptions shall become due on the first day of January in every year; and if any Member, Associate, or Student shall not have paid his annual subscription before the first day of May in any year, his name shall be omitted from the Register of Members, Associates, and Students of the Society, certified by the Council at the Annual Meeting. It shall be competent to the Council to restore any person whose name has been so removed to his former status in the Society on payment of his subscription for the then current year, and a sum to be determined by the Council, and being not less than one shilling nor exceeding one guinea, as for and in commutation of his arrears of subscription.

10. All persons who have become Life Members of the Society pursuant to Bye-laws which have heretofore from time to time been in force, shall be exempt from further contributions to the funds of the Society.

11. All Members of the Society, except Life Members, Honorary Members and Corresponding Members, shall pay an annual subscription of one guinea.

12. All Members of the Society, and all persons qualified for election as Members of the Society, shall have the option of becoming Life Members exempt from further contribution on payment of a life composition of ten guineas.

13. All Associates and Students, other than Associates who are in business on their own account, shall pay an annual subscription of half a guinea.

14. All the Associates who, under Section 20 of the Act, 1868, are entitled to continue, and are desirous of continuing as such Associates, being in business on their own account, shall give notice to the Secretary in that behalf, and shall, in accordance with the same section, contribute to the funds of the Society the same subscriptions, whether annual, life, or otherwise, as Members, and in default thereof shall cease to be Associates.

SECTION II.

HONORARY AND CORRESPONDING MEMBERS.

1. The Council shall at their discretion elect as Honorary Members, or as Corresponding Members of the Society, such scientific men as have distinguished themselves in any of the branches of knowledge embraced in the educational objects of the Society.

2. The Council shall from time to time determine the number of persons to be Honorary Members, and the number of persons to be Corresponding Members. There shall be books kept by the Secretary, in which Members of the Council shall enter the names of persons whom they may consider eligible for election as Honorary Members or as Corresponding Members, and at the meeting of the Council in April of every year names shall be selected from the books so kept, not exceeding in number the vacancies in the lists of Honorary Members or of Corresponding Members respectively, and the names of the persons so selected shall be exhibited in the Library, until the meeting of the Council in the ensuing month, when the Council shall proceed to the election.

SECTION III.

COMMON SEAL.

1. The Common Seal of the Pharmaceutical Society of Great Britain shall consist of the armorial bearings, crest, and motto, registered in her Majesty's College of Arms.

2. The said seal shall be deposited at the House of the Society, in a box having a lock and two keys, one of which shall be in the custody of the President, and the other in that of the Vice-President.

3. The Common Seal may be set or affixed to any deed, instrument, or writing, in pursuance of an order or minute of the Council entered in their minute book, and in the presence of the President, or Vice-President, or two Members of the Council, and not otherwise.

SECTION IV.

BYE-LAWS AND REGULATIONS.

The making, altering, or abrogating of any Bye-law or any Regulation, to be prescribed by the Society, in accordance with any statute, shall be in the following manner:—

Proposed Bye-Laws.

elected accordingly, shall make application to the Council in that behalf.

5. All persons on election as Members, or Student-Associates, shall leave with the Registrar a signed declaration, stating their full names and addresses, and their willingness to comply with the regulations of the Society.

6. All Subscriptions for the current year shall become due upon election; and all annual subscriptions shall become due on the first day of January in every year; and if any person shall not have paid his annual subscription before the first day of May in any year, his name shall be omitted from the Register of Members or of Student-Associates. It shall be competent to the Council to restore any person whose name has been so omitted to his former status in the Society on payment of his subscription for the then current year.

7. All persons who have become Life Members or Life Associates pursuant to Bye-laws which have heretofore from time to time been in force, shall be exempt from further contributions.

8. All Members, except Life Members, Honorary Members, and Corresponding Members, shall pay an annual subscription of one guinea.

9. All Members, and all persons qualified for election as Members shall have the option of becoming Life Members exempt from further contribution on payment of a life composition of ten guineas.

10. All Student-Associates shall pay an annual subscription of half a guinea.

To be repealed.

SECTION II.

HONORARY AND CORRESPONDING MEMBERS.

1. The Council shall at its discretion elect as Honorary Members, or as Corresponding Members such scientific men as have distinguished themselves in any of the branches of knowledge embraced in the educational objects of the Society.

2. The Council shall from time to time determine the number of persons to be Honorary Members, and the number of persons to be Corresponding Members. There shall be books kept by the Secretary, in which Members of the Council shall enter the names of persons whom they may consider eligible for election as Honorary Members or as Corresponding Members, and at the meeting of the Council in April of every year names may be selected from the books so kept, not exceeding in number the vacancies in the lists of Honorary Members or of Corresponding Members respectively, and the names of the persons so selected shall be exhibited in the Library, until the meeting of the Council in the ensuing month, when the Council shall proceed to the election.

SECTION III.

COMMON SEAL.

1. The Common Seal of the Society shall consist of the armorial bearings, crest, and motto, registered in her Majesty's College of Arms.

2. No alteration.

3. No alteration.

SECTION IV.

BYE-LAWS AND REGULATIONS.

The making, altering, or abrogating of any Bye-law or any Regulation, to be prescribed by the Society, in accordance with any statute, shall be in the following manner:—

Present Bye-Laws.

1. A written formula for any proposed Bye-law or Regulation, or for altering or abrogating any Bye-law or Regulation, being delivered by a Member of the Council to the Chairman, shall thereupon be read, and if seconded and approved, shall be referred to two subsequent ordinary or special Meetings of the Council for confirmation, and then to a special General Meeting of the Members of the Society, and afterwards to the Privy Council, according to the provisions of the Pharmacy Act, 1852, and the Pharmacy Act, 1868.

2. A copy of the Bye-laws shall be given to every Member, Associate, and Student of the Society on his election, and shall at any time be delivered to any Member, Associate, or Student of the Society, on his applying for the same and paying one shilling.

SECTION V.

ELECTION OF COUNCIL AND AUDITORS.

1. Two-thirds of the Members of Council shall go out of office in every year according to the provisions of the Charter: seven of them shall consist of those Members who remained in the Council after the lot was taken in the last preceding year, or their successors; the other seven shall be taken by lot from the remaining fourteen Members.

2. The retiring Members of the Council shall be ascertained and determined at the monthly meeting held in February of every year, and their names shall be published on or before the 10th day of March in every year.

3. Any person qualified to vote desirous of nominating any Member for election as a Member of the Council or as an Auditor, shall on or before the 24th day of March in every year give notice in writing to the Secretary of the Society, with the name and address of the nominee, and if for the Council disclosing whether such nominee be or not a Pharmaceutical Chemist. The Secretary shall on or before the 26th day of March then instant address and send by post to each nominee a notice of his having been so nominated, and inquiring whether he will accept office if elected, and in default of a written reply from such nominee being received on or before the 31st day of March then instant, declaring his readiness to accept office if elected, such nominee shall not be deemed eligible or willing to be elected.

4. The Council shall at their monthly meeting, held in April of every year, prepare a list of all persons nominated for election and eligible and willing to be elected Members of the Council and Auditors for the ensuing year, and disclosing the qualifications of nominees for the Council; and in default of the nomination of a sufficient number of persons eligible and willing to accept office, the Council shall nominate as many as may be required to form a complete list of eligible and willing persons to fill all the vacancies in the Council, and a complete list of five Auditors. No nominations shall be received or made after the 24th day of March, except such as may be made by the Council, in the manner and under the circumstances aforesaid, at the monthly meeting in April.

5. The Secretary shall send by post to every person qualified to vote, not less than ten days prior to the meeting at which members of the Council and Auditors, or either of them, are to be elected, a Voting Paper for such elections. The names and residences of the Members eligible and willing for election, and whether they are or not on the Register of Pharmaceutical Chemists, shall appear in such Voting Papers, and in all Voting Papers for the election of Members of the Council, the names of the Members who remain in office, and whether they are or not on the Register of Pharmaceutical Chemists shall also appear.

6. At all elections of Members of the Council and Auditors, votes may be given by ballot, either by personal delivery of the said Voting Papers at the time of election, or by the said Voting Papers being transmitted under cover to the Secretary, so that the same shall be received by him not less than one clear day prior to the day on which the election is to take place, and the Voting Papers shall be in the following form:—

Voting Paper to be delivered personally on the day of election, May 18, or transmitted under cover to the Secretary, so that it shall be received by him not less than one clear day prior to the day on which the election is to take place. An envelope duly addressed accompanies this.

Proposed Bye-Laws.

1. A form for any proposed Bye-law or Regulation, or for altering, or abrogating any Bye-law or Regulation, being delivered at a Council meeting by a Member of the Council to the Chairman, shall thereupon be read, and if seconded and approved, shall be referred to two subsequent ordinary or special Meetings of the Council for confirmation, and then to a special General Meeting of the Members of the Society, and afterwards to the Privy Council, according to the provisions of the Statute, 1852, and the Act, 1868.

2. A copy of the Bye-laws shall be given free to every Member and Student-Associate on his election, and shall at any time afterwards be delivered to any Member or Student-Associate on his applying for the same and paying one shilling.

SECTION V.

ELECTION OF COUNCIL AND AUDITORS.

1. Seven Members of the Council shall go out of office in every year, and the vacancies shall be filled by election, the retiring Members not being ineligible for re-election if duly nominated for that purpose. The seven Members who so go out shall be the Members of the Council who have been longest in office without re-election, and if and whenever the number of the Members of the Council who have been longest in office without re-election shall exceed seven, the Members of the Council to retire shall be determined from these by lot.

2. The retiring Members of the Council shall be ascertained and determined at the monthly meeting held in February of every year.

3. Any Member qualified to vote desirous of nominating any other Member for election as a Member of the Council or as an Auditor, shall on or before the 18th day of March in every year, give a notice signed by him to the Secretary, with the name and address of the nominee. The Secretary shall on or before the 20th day of March then instant address and send by post to each nominee a notice of his having been nominated, and inquiring whether he will accept office if elected, and in default of a written reply from such nominee being received on or before the 31st day of March then instant, declaring his readiness to accept office if elected, such nominee shall not be deemed eligible or willing to be elected.

4. The Council shall at its monthly meeting, held in April of every year, prepare a list of all Members nominated for election and willing to be elected Members of the Council and Auditors for the ensuing year; and in default of the nomination of a sufficient number of Members willing to accept office, the Council shall nominate as many as may be required to form a complete list of Members willing to fill all the vacancies in the Council, and a complete list of five Auditors. No nominations shall be received or made after the 18th day of March, except such as may be made by the Council, in the manner and under the circumstances aforesaid, at the monthly meeting in April.

5. The Secretary shall send by post to every Member qualified to vote, not less than ten days prior to the meeting at which Members of the Council and Auditors are to be elected, a Voting Paper for such elections. The names and addresses of the Members willing to serve if elected shall appear in such Voting Papers.

6. At all elections of Members of the Council and Auditors, votes shall be given by ballot, either by personal delivery of the said Voting Papers at the time of election, or by the said Voting Papers being transmitted, under cover, by the Member, to the Secretary, so that the same shall be received by him not later than twelve o'clock noon on the day on which the election is to take place, and the Voting Papers shall be as near as conveniently may be in the following form:—

Present Bye-Laws.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

17, BLOOMSBURY SQUARE, W.C.

For the Election of Fourteen Members of the Council.

NAMES OF MEMBERS ELIGIBLE AND WILLING FOR ELECTION.

1*	11
2	P.C.	12
3	13
4*	P.C.	14
5	15
6	16
7	17
8	18
9	19
10	20

The names to which Stars are prefixed are those of Members of the present Council who are eligible for re-election.

The names to which the letters P.C. are prefixed are those of Pharmaceutical Chemists.

The names to which the letters P.C. are not prefixed are those of persons who are not on the Register of Pharmaceutical Chemists.

INSTRUCTIONS FOR VOTING.

Every person voting must erase the names of all the Candidates for whom he does not intend to vote. If more than fourteen names be left, the Voting Paper will be rejected. Section 19 of the Act, 1868, is printed below.

The Voting Paper, after the erasure of names, should be folded up, and must be transmitted under cover to the Secretary, so that the same shall be received by him not less than one clear day prior to the day on which the election is to take place, or delivered by the voter personally at the time of election.

To prevent imposition, the person voting must sign his name and address on the line on the outside of the cover.

The following are the members who remain on the Council :—

- P.C.
-
- P.C.
- P.C.
-
- P.C.

The names to which the letters P.C. are prefixed are those who are Pharmaceutical Chemists.

Section 19 of the Act, 1868, is as follows :—

Every person who is or has been in business on his own account as a Chemist and Druggist, as aforesaid, at the time of the passing of this Act, and who shall become a Member of the Pharmaceutical Society, shall be eligible for election to the Council of the Pharmaceutical Society, but the said Council shall not at any time contain more than seven Members who are not on the Register of Pharmaceutical Chemists.

— is the utmost number of Members not Pharmaceutical Chemists who can be elected on the Council on the present occasion.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

INSTRUCTIONS FOR VOTING.

Every Member voting must erase the names of all the Members for whom he does not intend to vote. If more than five names be left, the Voting Paper will be void.

The Voting Paper must be transmitted, under cover, by the Member, to the Secretary, so that the same shall be received by him not later than twelve o'clock noon on the day on which the election is to take place, or delivered by the Member personally at the time of election.

Present Bye-Laws.

To prevent imposition, the voter must sign his name and address on the outside of the cover.

Form of Address, etc., on Envelope.

VOTING PAPER.

Voter's Signature.....
 Voter's Address.....

To the Secretary of the Pharmaceutical Society, 17, Bloomsbury Square, London, W.C.

The Voting Paper must be returned to the Secretary, so that the same may be received by him on or before the day of May, 18 , or be delivered personally at the time of election.

7. Before the votes are taken, the persons constituting the meeting shall appoint from amongst themselves four or more Scrutineers, of whom four shall form a quorum.

8. The Voting Papers to be delivered personally shall be received at the General Meeting, and the Voting Papers duly transmitted under cover to the Secretary shall be opened by or in the presence of the Scrutineers.

9. The Scrutineers shall ascertain the number of votes given for each Member nominated for election.

10. It being provided by Section 19 of the Act, 1868, that the Council shall not at any time contain more than seven Members who are not on the Register of Pharmaceutical Chemists, the Scrutineers shall, after the voting on any election of Members of the Council, certify to the Chairman of the Meeting whether or not the number of Members not on the Register of Pharmaceutical Chemists nominated for election is more than seven, or more than may with any like Members remaining on the Council make up the number of seven ; and if they shall certify that the number of Members not on the Register of Pharmaceutical Chemists nominated for election is more than seven, or more than may as aforesaid make up the number of seven, then they shall further likewise certify the number of votes given in favour of each of such Members so nominated, and which of such Members so nominated, to the number of seven or the lesser number, sufficient to make up as aforesaid the number of seven, have a majority of votes over the remainder of such Members, and that such of the said Members, as have not the said majority are in a minority of their class.

11. The Scrutineers shall make to the Chairman a return, signed by them, of the names of the Members nominated for election, but in the case of an election of Members of the Council, such return shall be exclusive of the names of such, if any, Members not being Pharmaceutical Chemists as may be certified to be in a minority of their class, and the said return shall disclose the number of votes given for each Member named therein.

12. The Chairman of the Meeting shall declare the result of every election ; and, in cases where there shall have been a poll, shall declare the election to have fallen on the Members who, according to the return of the Scrutineers contemplated by the last-preceding Bye-law, shall appear to have a majority, and in the case of an equality of votes, the Chairman of the Meeting shall have a second or casting vote.

13. The Chairman, at any Meeting for the election of Members of the Council or Auditors, shall have the power of adjourning such Meeting from time to time, with a view to the reception of the Report of the Scrutineers, but no such adjournment shall extend beyond a period of four days.

SECTION VI.
COUNCIL.

1. The Council shall meet at the Society's house on or about the first Wednesday in every month at eleven o'clock in the forenoon, or at such other hour as may from time to time be decided by the Council. Seven Members shall constitute a quorum, and without that number being present no business shall be transacted.

Before other business is entered on, the minutes of the preceding monthly and of any subsequent meetings or meetings shall be read.

2. All motions or proposals shall be written, together with the names of the mover and seconder, and upon being put shall be decided by a show of hands, except in cases of a ballot, which

Proposed Bye-Laws.

The Member voting under cover must write his name and address on the outside of the cover or the voting paper will be void.

Form of Address, etc., on Cover.

VOTING PAPER.

Member's Signature.....
 Member's Address

To the Secretary of the Pharmaceutical Society, Bloomsbury Square, London, W.C.

The Voting Paper must be returned to the Secretary, so that the same may be received by him not later than twelve o'clock noon on the day of May, 18 , or be delivered by the Member personally at the time of election.

7. Before the votes are examined, the Members constituting the meeting shall appoint from amongst themselves four or more Scrutineers, of whom four shall form a quorum.

8. No alteration.

9. The Scrutineers shall ascertain the number of votes given for each Member nominated for election, and shall make to the Chairman a return, signed by them, or four of them, of the names of the Members nominated for election, and the said return shall disclose the number of votes given for each Member named therein.

To be repealed.

Incorporated with Clause 9.

10. No alteration.

11 No. alteration.

SECTION VI.
COUNCIL.

1. The Council shall meet at the Society's house on or about the first Wednesday in every month at eleven o'clock in the forenoon, or at such other day or hour as may from time to time be decided by the Council. Seven Members shall constitute a quorum, and without that number being present no business shall be transacted. Before other business is entered on, the minutes of the preceding monthly and of any subsequent meeting shall be read.

2. All motions or proposals shall be signed by the mover and the seconder, and upon being put shall be decided by a show of hands, except in cases of a ballot, which may be demanded by any Member.

Present Bye-Laws.

may be demanded by any Member. Should the numbers be equal, the Chairman shall have a second or casting vote. It shall be lawful for the Chairman to postpone or adjourn to the next meeting any motion whereof notice in writing has not been given to the Secretary at least six clear days before the meeting.

3. All resolutions carried at the Meetings of the Council, except such as relate to the Bye-laws, shall be acted upon without confirmation.

4. The Council may from time to time in their discretion appoint such Committees as shall appear to them expedient, and shall elect from among themselves a Committee of General Purposes, a Committee of Finance, and a Committee for the Library, Museum, School and House, and may from time to time modify or dissolve any Committee. The President and Vice-President shall be *ex officio* Members of all Committees, and the President shall preside at all Meetings of the Council and of Committees, or in his absence the Vice-President. If the President and Vice-President are both absent, a Chairman shall be chosen by the Members present.

SECTION VII.

COMMITTEE FOR GENERAL PURPOSES.

1. This Committee shall consist of not less than twelve Members, four of whom shall constitute a quorum. The Committee shall meet as often as may be required, and its proceedings shall be reported to the Council.

SECTION VIII.

COMMITTEE OF FINANCE.

1. This Committee shall consist of not less than four Members, two of whom shall constitute a quorum. The Committee shall meet as often as may be required.

2. It shall be the duty of this Committee to regulate and examine the accounts, to check the receipt of all moneys, to examine all bills, and to present at the monthly meetings of the Council such as shall have been approved for payment, with the signature of a quorum attached. This Committee shall also prepare a Financial Statement for the Auditors previous to the annual meeting.

SECTION IX.

THE COMMITTEE FOR THE LIBRARY, MUSEUM, SCHOOL AND HOUSE.

1. This Committee shall consist of not less than five Members, three of whom shall constitute a quorum. The Committee shall meet as often as may be required, and report from time to time to the Council.

2. It shall be the duty of this Committee to superintend the School and the House, the arrangement and preservation of the books, specimens, and apparatus, to inspect the Laboratory, and to make regulations for the admission of visitors and students to the Library and Museum.

SECTION X.

EXAMINERS—EXAMINATIONS—FEES.

1. The Council shall, at their meeting, in December, in every year, appoint such competent persons as they shall think fit, to be Examiners for the year to commence on the then following first day of January, to conduct all such examinations as are provided for or contemplated by the Charter, or by the Statute, 1852, or by the Act, 1868, and the persons so appointed shall, for the time being, constitute and be called the Board of Examiners for England and Wales.

2. The Council shall, at their meeting, in December, in every year, appoint such competent persons in Scotland as they shall think fit to be Examiners for the year to commence on the then following first day of January, to conduct all such examinations as are provided for or contemplated by the Charter, or by the Statute, 1852, or by the Act, 1868, and the persons so appointed shall, for the time being, constitute and be called the Board of Examiners for Scotland.

3. The President and Vice-President of the Society shall, *ex officio*, be members of the Boards of Examiners, and either of them present at any meeting of either such Boards shall preside thereat.

4. The Council shall not appoint any person who has attained the age of sixty-five years at the time of the appointment to be an Examiner.

Proposed Bye-Laws.

Should the numbers be equal, the Chairman shall have a second or casting vote. It shall be lawful for the Chairman to postpone or adjourn to the next ordinary meeting of the Council any motion whereof notice signed as aforesaid has not been given to the Secretary at least six clear days before the meeting.

3. All resolutions carried at the Meetings of the Council, except such as relate to the making, altering, or abrogating of Bye-laws, shall be acted upon without confirmation.

4. No alteration.

SECTION VII.

COMMITTEE FOR GENERAL PURPOSES.

No alteration.

SECTION VIII.

COMMITTEE FOR FINANCE.

No alteration.

SECTION IX.

THE COMMITTEE FOR THE LIBRARY, MUSEUM, SCHOOL AND HOUSE.

1. This Committee shall consist of not less than five Members, three of whom shall constitute a quorum. The Committee shall meet as often as may be required, and its proceedings shall be reported to the Council.

2. It shall be the duty of this Committee to superintend the School and the House, the arrangement and preservation of the books, specimens and apparatus, to inspect the Laboratory, and to make regulations for admission to the Library and Museum.

SECTION X.

EXAMINERS—EXAMINATIONS—FEES.

1. The Council shall, at its meeting, in November, in every year, appoint such competent persons as it shall think fit, to be Examiners for the year to commence on the then following first day of January, to conduct all such examinations as are provided for or contemplated by the Charter, or by the Statute, 1852, or by the Act, 1868, and the persons so appointed shall, for the time being, constitute and be called the Board of Examiners for England and Wales.

2. The Council shall, at its meeting, in November, in every year, appoint such competent persons in Scotland as it shall think fit to be Examiners for the year to commence on the then following first day of January, to conduct all such examinations as are provided for or contemplated by the Charter, or by the Statute, 1852, or by the Act, 1868, and the persons so appointed shall, for the time being, constitute and be called the Board of Examiners for Scotland.

3. The President and Vice-President shall, *ex officio*, be members of the Boards of Examiners, and either of them present at any meeting of either of such Boards shall preside thereat.

4. No alteration.

Present Bye-Laws.

5. No person shall be appointed an Examiner who at the time of appointment is, or who during one year prior to the time of appointment has been, a Member of the Council; and the election of any Examiner to be a Member of the Council shall vacate his appointment as an Examiner.

6. The Board of Examiners for England and Wales shall consist of not more than fourteen nor less than eight persons, exclusive of the President and Vice-President of the Society; eight to constitute a quorum. The Board of Examiners for Scotland shall consist of not more than eight nor less than four persons, exclusive of the President and Vice-President of the Society; four to constitute a quorum.

7. The Council shall from time to time supply any vacancy in the office of Examiner, and may remove any member of the Boards of Examiners, and substitute another person in his place, and may also from time to time appoint a Special Examiner or Special Examiners, to conduct any examination or part of an examination, or to assist the Boards of Examiners.

8. The Secretary shall from time to time submit to the Privy Council for approval, in accordance with the Pharmacy Act, 1868, all appointments of Examiners made by the Council, and shall also give notice to the officer appointed by the Privy Council of all examinations to be held for the purposes of the Act, 1868, stating the times and places at which such examinations will be held, at least three days *prior* to the holding of the same.

9. The Board of Examiners for England and Wales and the Board of Examiners for Scotland shall meet as often as may be required for the purpose of conducting examinations at such times as the Council from time to time shall direct; and shall report the result of every examination to the Council at the monthly meeting immediately following the same.

10. The Boards of Examiners shall conduct all examinations according to the Bye-laws in force in that behalf, and according to such regulations as shall be made or adopted by them from time to time, and as shall have been approved by the Council. Such regulations shall from time to time be inserted in the published Report of the Transactions of the Society.

11. Prior to September, 1900, persons desiring certificates of competent skill and qualification to be registered as Chemists and Druggists under the Act, 1868, shall be examined in their knowledge of the Latin language, in English Grammar and Composition, and Arithmetic, which Examination shall be called the First Examination. Persons intending to present themselves for this Examination shall give to the Registrar notice in that behalf and pay to him a fee of Two Guineas not less than 14 days prior to the day which has been appointed for the holding of the said Examination. All persons who pass the said Examination shall be registered as "Apprentices or Students."

After August, 1900, persons desiring certificates of competent skill and qualification to be registered as Chemists and Druggists under the Act, 1868, shall deliver to the Registrar on behalf of the Board of Examiners a certificate of having passed an Examination in English Grammar and Composition, in the Latin language, and in one Modern Foreign language, and also in Algebra, Arithmetic, and Euclid, conducted by any or either of the examining bodies which shall have been previously approved for the purpose by such regulations as are specified by the last preceding Bye-law, and shall pay to him a fee of Two Guineas, whereupon, if the Board of Examiners shall so see fit, they shall be registered as "Apprentices or Students."

12. Persons intending to present themselves to the Examiners for examination in accordance with the Charter and Statute, 1852, or the Act, 1868, and having been registered as "Apprentices or Students," shall be examined in the translation and dispensing of Prescriptions, in Botany, in *Materia Medica*, in Pharmaceutical and General Chemistry, Physics, and Posology, and in their knowledge of the Law relating to the Sale of Poisons, which Examination shall be called the Minor Examination.

13. Persons desiring certificates of competent skill and qualification to exercise the business, or calling, of Pharmaceutical Chemists shall produce to the Registrar evidence of having been previously registered as Chemists and Druggists, and shall be examined in more extended knowledge of Botany, *Materia Medica*, Chemistry, and Physics, or any two of them, which examination shall be called the Major Examination.

Proposed Bye-Laws.

5. No alteration.

6. The Board of Examiners for England and Wales shall consist of not more than fourteen nor less than eight persons, exclusive of the President and Vice-President; six to constitute a quorum. The Board of Examiners for Scotland shall consist of not more than eight nor less than four persons, exclusive of the President and Vice-President; four to constitute a quorum.

7. No alteration.

8. The Secretary shall from time to time submit to the Privy Council for approval, in accordance with the Act, 1868, all appointments of Examiners made by the Council, and shall also give notice to the officer appointed by the Privy Council of all examinations to be held for the purposes of the Act, 1868, stating the times and places at which such examinations will be held, at least three days *prior* to the holding of the same.

9. No alteration.

10. The Boards of Examiners shall conduct all examinations according to the Bye-laws in force in that behalf, and according to such regulations as shall be made or adopted by them from time to time, and as shall have been approved by the Council. Such regulations shall from time to time be inserted in the *Pharmaceutical Journal*.

11. No alteration.

12. Persons presenting themselves to the Examiners for examination in accordance with the Charter and Statute, 1852, or the Act, 1868, and having been registered as "Apprentices or Students," shall be examined in the translation and dispensing of Prescriptions, in Botany, in *Materia Medica*, in Pharmaceutical and General Chemistry, Physics, and Posology, and in their knowledge of the Law relating to the Sale of Poisons, which Examination shall be called the Minor Examination.

13. No alteration.

Present Bye-Laws.

14. Persons who shall tender themselves to the Examiners for Examination under the provisions of the Act, 1868, excepting only those specified in the next following Bye-law, shall be examined in the Minor Examination.

15. Persons entitled to be registered as Chemists and Druggists on passing a modified Examination, who shall tender themselves to the Examiners for Examination under the provisions of the Act, 1868, shall be required to pass the Modified Examination, which the Council of the Pharmaceutical Society, with the consent of the Privy Council, have declared to be in their case sufficient evidence of skill and competency to conduct the business of a Chemist and Druggist, as the same is set out in the Schedule hereto, or such other modified Examination as may in like manner be declared such sufficient evidence.

16. The Examiners may grant or refuse to such persons as have tendered themselves for the Minor Examination and the Major Examination respectively, Certificates of Competent skill and knowledge and qualification; and lists of such persons shall be delivered by the Examiners to the Registrar.

17. All persons desiring registration as Chemists and Druggists shall in respect of an examination, to take place prior to September, 1900, pay a fee of Five Guineas, and shall in respect of an examination, to take place after August, 1900, pay a fee of Ten Guineas, and shall in either case pass the Minor Examination or the Modified Examination, whereupon they shall be registered accordingly.

18. Persons desiring registration as Pharmaceutical Chemists under the Statute, 1852, shall pay a fee of Three Guineas and pass the Major Examination, whereupon they shall be registered accordingly.

19. Persons intending to present themselves for examination in the Major, the Minor, or the Modified Examination shall give to the Registrar notice in writing of their intention in that behalf on or before the fifteenth day of the month immediately preceding that in which the Examination is to take place.

20. All notices of intention to attend for examination shall be to attend on the next occasion of the Examination being held, and all fees in respect of examination and registration shall be payable on the giving of notice of intention to attend for examination, and in no case shall any fee paid in accordance with the Bye-laws be remitted or returned.

21. All persons shall, at the time of giving notice of intention to present themselves for the Minor Examination, satisfy the Registrar that they have attained the full age of twenty-one years, and have been registered as "Apprentices or Students," and that they have for three years been practically engaged in the translation and dispensing of prescriptions.

22. Persons who have attended and failed to pass an examination shall not be entitled to attend on any future occasion unless and until they shall have given renewed notice of intention to attend an examination, and shall have paid fees as follows:—

(a) *In respect of a Major Examination, Two Guineas.*

(b) *In respect of a Minor Examination, or a Modified Examination, Three Guineas.*

(c) *In respect of a First Examination, One Guinea.*

23. Persons who have given notice of intention to attend an examination and have failed duly to attend at the time appointed for the same, shall not be entitled to attend on a future occasion unless and until they have given renewed notice of intention to attend an examination, and shall in each case have paid a fee of One Guinea,—or if the persons shall have proved to the satisfaction of the Council or the Board of Examiners (by production of medical certificates or otherwise) that the said failure was occasioned by unavoidable and proper causes,—One Shilling.

SECTION XI.

REGISTRAR AND REGISTRATIONS.

1. The Registrar shall receive and, for at least five years, preserve the lists issued by the Examiners, signifying that examinations, or parts of examinations, have been passed.

2. The Registrar shall from time to time make out and maintain a Register of all persons being respectively Members, Associates, and Apprentices or Students of the Society, also a Register of all persons entitled to be registered under the Statute, 1852, and also a Register in accordance with the provisions of the Act, 1868, of all persons who shall be entitled to be registered under that Act, with proper indices of such Registers respectively.

Proposed Bye-Laws.

14. No alteration.

15. Persons entitled to be registered as Chemists and Druggists on passing a modified Examination, who shall tender themselves to the Examiners for Examination under the provisions of the Act, 1868, shall be required to pass the Modified Examination, which the Council, with the consent of the Privy Council, have declared to be in their case sufficient evidence of skill and competency to conduct the business of a Chemist and Druggist, as the same is set out in the Schedule hereto, or such other modified Examination as may in like manner be declared such sufficient evidence.

16. No alteration

17. No alteration.

19. No alteration.

20. No alteration.

21. No alteration.

22. No alteration.

23. No alteration.

SECTION XI.

REGISTRAR AND REGISTRATIONS.

1. No alteration.

2. The Registrar shall from time to time make out and maintain Registers of all persons being respectively Members or Student-Associates of the Society, also a Register of all persons entitled to be registered under the Statute, 1852, and also a Register in accordance with the provisions of the Act, 1868, of all persons who shall be entitled to be registered under that Act, with proper indices of such Registers respectively.

Present Bye-Laws

3. The names of persons registered as Students of the Society, shall, upon their Registration as Pharmaceutical Chemists, Associates, or Chemists and Druggists, be removed from the Register of Students of the Society.

4. The names of persons registered as Associates shall upon their registration as Pharmaceutical Chemists, be removed from the Register of Associates.

5. Persons who have not been examined under the said Statute, 1852, who have been registered as Pharmaceutical Chemists by reason of their election as Members of the Society, and who have not paid life subscriptions, shall pay the annual subscription required from Members; and the names of all such Members as last mentioned who fail to pay their annual subscription before the first day of May in any year shall be omitted from the Register of Pharmaceutical Chemists.

6. The Registrar shall comply with such Orders or Regulations for regulating the Register to be kept under the Act, 1868, as may from time to time be made by the Council.

7. All the said Registers shall be revised annually and laid before the Annual General Meeting of the Society.

8. The Registrar shall, in the month of January in every year, at the expense and for the profit (if any) of the Society, cause to be printed and published, and sold, a correct Register, as required by the Act, 1868, and in so doing shall comply with such rules and regulations as may from time to time be in that behalf made by the Council.

SECTION XII.

TREASURER.

1. It shall be the duty of the Treasurer to take charge of all moneys, to pay such accounts as the Council may order by the signature of six Members of the Council in Council assembled, and to render his account at each monthly meeting.

SECTION XIII.

SECRETARY.

1. The Secretary shall have authority over the clerks and servants of the establishment, whose wages he shall pay. He shall be in attendance at his office during the hours to be from time to time specified by the Council, and be present at meetings of the Council and Committees, General and Special Meetings, and also at the Evening Meetings. It shall be his duty to superintend the affairs of the Society under the direction of the Council and Committees. He shall keep the books of the Society in a neat and orderly manner, shall conduct the correspondence, and issue all summonses, take the minutes of all Meetings for business, and read them, and make a report of all matters that come under his cognisance for the information of the Council and Committees. He shall consult and act on the instructions of the President or Vice-President on any business requiring attention, between the various meetings, and be responsible for the safe custody of all the documents and property belonging to the Society which shall be under his control. He shall find security in the sum of £500, and shall receive all subscriptions, fees and donations, and give a printed receipt for the same, and no other, checking each receipt. He shall promptly pay to the account of the Treasurer at the Society's bankers the amount of moneys so received by him. He shall receive such a sum in advance for current expenses as the Council may order, and account for the same to the Committee for Finance. He shall also superintend the transmission of the Journal and Transactions.

SECTION XIV.

AUDITORS.

1. The Auditors shall meet at least one month previous to the Annual Meeting. It shall be their duty to inspect the Accounts of the Society, and the Financial Statement prepared for them by the Committee for Finance, which must be certified and signed by the Auditors present at the Audit, and presented to the Council not later than at their ordinary meeting in May.

SECTION XV.

SUMMONSES.

FOR ALL MEETINGS OF THE COUNCIL, EXAMINERS, COMMITTEES, OR AUDITORS.

1. Printed summonses shall be issued by the Secretary, with his name attached, and if left at the place of business, or transmitted

Proposed Bye-Laws.

3. The names of persons registered as Student-Associates shall, upon their Registration as Chemists and Druggists, be removed from the Register of Student-Associates.

To be repealed.

4. No alteration.

5. No alteration.

6. No alteration.

7. No alteration.

SECTION XII.

TREASURER.

No alteration.

SECTION XIII.

SECRETARY.

1. The Secretary shall have authority over the clerks and servants of the establishment, whose wages he shall pay. He shall be in attendance at his office during the hours to be from time to time specified by the Council, and be present at meetings of the Council and Committees, General and Special Meetings, and also at the Evening Meetings. It shall be his duty to superintend the affairs of the Society under the direction of the Council and Committees. He shall keep the books of the Society in a neat and orderly manner, shall conduct the correspondence, and issue all summonses, notices and advertisements, take the minutes of all Meetings for business, and read them, and make a report of all matters that come under his cognisance for the information of the Council and Committees. He shall consult and act on the instructions of the President or Vice-President on any business requiring attention, between the various meetings, and be responsible for the safe custody of all the documents and property belonging to the Society which shall be under his control. He shall find security in the sum of £500, and shall receive all subscriptions, fees and donations, and give a printed receipt for the same, and no other, checking each receipt. He shall promptly pay to the account of the Treasurer at the Society's bankers the amount of moneys so received by him. He shall receive such a sum in advance for current expenses as the Council may order, and account for the same to the Committee for Finance. He shall also superintend the transmission of the *Pharmaceutical Journal*.

SECTION XIV.

AUDITORS.

1. The Auditors shall meet at least one month previous to the Annual General Meeting. It shall be their duty to inspect the Accounts of the Society, and the Financial Statement prepared for them by the Committee for Finance, which must be certified and signed by the Auditors present at the Audit, and presented to the Council not later than at its ordinary meeting in May.

SECTION XV.

SUMMONSES FOR MEETINGS.

1. All Summonses, Notices, or Advertisements shall be issued by the Secretary, and Summonses if left at the place of business, or residence, or transmitted by post, addressed to the place of

Present Bye-Laws.

Proposed Bye-Laws.

by post, addressed to the place of business or residence of the person summoned, shall be considered as received.

2. All summonses shall be issued at least three clear days previous to the Meetings, inclusive of the day of issuing the same, except in the case of Special Meetings; and all notices of motion shall be inserted therein, and also notice of such matters as require particular consideration.

3. The Secretary shall issue summonses, notices, or advertisements convening all Special Council or General Meetings. If for the latter, not less than ten clear days' previous notice shall be given; and such summonses, notices, or advertisements shall contain full notice of the business to be discussed at the Special Meeting.

SECTION XVI.

FILLING UP VACANCIES BY DEATH, RESIGNATION OR REMOVAL.

1. In the event of any vacancy occurring in the office of President, Vice-President, or Treasurer, the Secretary shall report the same, and the cause thereof, in the summons for the next meeting of the Council, who shall thereupon find and declare such vacancy, and immediately proceed to elect from their remaining number a proper person to fill such vacant office.

2. In the event of any vacancy occurring in the Council or Auditors, or in the several Committees, during the current year, the Secretary shall report such vacancy and the cause thereof, in the summons for the next meeting of the Council, at which some Member of the Council, or of the Society, as the case may require, shall be appointed to fill up such vacancy.

3. In the event of a vacancy occurring in the office of Registrar or Secretary, the President or Vice-President shall appoint some person, *pro tempore*, to fulfil the duty of the office, and in the summons for the next meeting of the Council the vacancy shall be declared; and some person or persons being proposed and seconded at such meeting the election shall take place, but shall not be final, unless confirmed at the next meeting of the Council.

SECTION XVII.

REMOVAL OF OFFICERS AND MEMBERS.

1. Every Member of Council who shall commit any act or acts which appear to the Council derogatory to the honour of his office, shall give an explanation of the same to the Council, on being required to do so; and in default thereof, or if such explanation be unsatisfactory to the Members present, he shall be liable to the censure of the Council; or if it be deemed expedient, a notice may be given by any Member of the Council for a motion of removal from the Society of the Member so offending, which notice shall be inserted in the summons for the ensuing meetings of the Council until disposed of, and shall be taken into consideration at the first ensuing meeting of the Council at which not less than twelve Members thereof shall be present.

2. If any report be made to the Council by a Member of the Society in writing, with his name attached, that another Member or any Associate has been guilty of any act or conduct which is contrary to, or subversive of, the interests of the Society, or a violation of its laws and regulations, and if the Council be of opinion that the alleged act or conduct is of such character, the Secretary shall write to the Member or Associate so accused for an explanation, and in default of explanation, or if the same be unsatisfactory, two Members of the Council shall be deputed to communicate, personally or by letter, with such Member or Associate, and shall report the result to the Council, when any Member of the Council shall, if he think it expedient, give notice of a motion for the removal of such Member or Associate from the Society. This notice must be inserted in the summons for the ensuing meetings of the Council until disposed of: and be taken into consideration at the first meeting thereof at which twelve members are present.

3. Any Member or Associate, Apprentice or Student, desiring to retire from the Society, shall send notice thereof to the Secretary in writing, together with the certificate or diploma of membership, if any, held by him. No Member or Associate shall be released from his obligation to pay his annual subscription until such time as the certificate or diploma of membership, if any, shall have been returned.

business or residence of the person summoned, shall be considered as received.

2. Summonses, Notices, or Advertisements convening Special General Meetings shall be given not less than ten clear days before the day thereby appointed for the Meeting. All other Summonses, Notices, or Advertisements shall be given not less than three clear days before the day thereby appointed for the Meeting, and in all the said cases there shall appear notice of the general nature of the business to be discussed at the Meeting.

3. Incorporated in Clause 2.

SECTION XVI.

FILLING UP VACANCIES BY DEATH, RESIGNATION OR REMOVAL.

1. In the event of any vacancy occurring in the office of President, Vice-President, or Treasurer, the Secretary shall report the same, and the cause thereof, in the summons for the next meeting of the Council, which meeting shall thereupon find and declare such vacancy, and immediately proceed to elect one of its number to fill such vacant office.

2. In the event of any casual vacancy occurring in the Council or in the Auditors, or in the several Committees, the Secretary shall report the vacancy in the summons for the next meeting of the Council, and at such meeting some member of the Council, or of the Society, as the case may require, shall be appointed to fill the vacancy, but any person so appointed shall retain his office so long only as the member causing the vacancy would have held the same if the vacancy had not occurred.

3. No alteration.

SECTION XVII.

REMOVAL OF OFFICERS AND MEMBERS.

1. No alteration.

2. If any report be made to the Council by a Member of the Society in writing, with his name attached, that another Member or a Student-Associate has been guilty of any act or conduct which is contrary to, or subversive of, the interests of the Society, or a violation of its laws and regulations, and if the Council be of opinion that the alleged act or conduct is of such character, the Secretary shall write to the Member or Student-Associate so accused for an explanation, and in default of explanation, or if the same be unsatisfactory, two Members of the Council shall be deputed to communicate, personally or by letter, with such Member or Student-Associate, and shall report the result to the Council, when any Member of the Council shall, if he think it expedient, give notice of a motion for the removal of such Member or Student-Associate from the Society. This notice must be inserted in the summons for the ensuing meetings of the Council until disposed of: and be taken into consideration at the first meeting thereof at which twelve Members are present.

3. Any Member or Student-Associate desiring to retire from the Society shall send notice thereof to the Secretary in writing, together with the Certificate of Membership, if any, held by him. No member shall be released from his obligation to pay his annual subscription until such time as the Certificate of Membership, if any, shall have been returned.

Present Bye-Laws.

SECTION XVIII.

FUNDS AND PROPERTY.

1. The Council of the Society shall from time to time cause such parts of the funds in the hands of the Treasurer as may not, in their judgment, be required for carrying on the business of the Society, to be invested in Government or real securities in the corporate name of the Society.

2. The property and funds of the Society, other than moneys from time to time in the hands of the Treasurer or Secretary, shall not be disposed of, or otherwise dealt with, except in pursuance of an order of the Council of the Society, signed by six members, at the least, in Council assembled.

SECTION XIX.

BENEVOLENT FUND.

1. The Benevolent Fund shall consist of donations and subscriptions, and such grants as may from time to time be made by the Council from the General Fund towards the particular objects of such Fund, in addition to the sum already invested in respect of the same Fund.

2. Donations* in aid of the Benevolent Fund shall be invested in Government or real securities; and no part of the invested capital of such Fund shall be distributed among the recipients of relief.

3. The interest accruing from the invested portion of the Benevolent Fund, together with annual subscriptions and grants made from the General Fund in aid thereof, shall be applicable, in the discretion of the Council, towards the relief of persons eligible to receive the same according to the provisions of the Act, 1868, and any unapplied portion of the same in any year may be invested and thenceforward form part of the invested Fund.

SECTION XX.

ANNUAL AND SPECIAL GENERAL MEETINGS.

1. The Council shall prepare a Report of their proceedings during the past year, which, together with the Report of the Auditors, shall be read at the Annual General Meeting, and inserted in the published report of the Transactions of the Society.

2. The Council shall meet previous to the General Meeting, and arrange the business to be transacted thereat; and the proceedings of the General Meeting shall be considered perfect in themselves without the necessity of reading or confirming the minutes of the preceding Annual Meeting.

3. No business shall be brought forward at any Special General Meeting but that for which it is convened, and of which due notice has been given to the Members of the Society, pursuant to the preceding Bye-law, No. 3, under Sec. 15.

SECTION XXI.

DIPLOMA AND CERTIFICATES.

1. Every Member of the Society shall be entitled to possess and use a Certificate of Membership.

2. Persons registered as Pharmaceutical Chemists under Section 10 of the Statute, 1852, shall be entitled to possess and use a Diploma stamped with the seal of the Society.

3. All persons examined in the Minor or in the Major Examination pursuant to the Bye-laws may, after having passed their examination and been registered, receive appropriate Certificates.

4. All plates used from time to time for printing the several forms of Diploma and Certificate shall be deposited at the house of the Society, in a box having a lock and two keys, one of which shall be in custody of the President and the other in that of the Vice-President.

5. No print shall be taken from the said plates, or any or either of them, without an express order of the Council. All prints taken shall be in the custody of the Secretary.

* FORM OF BEQUEST.

TO THE BENEVOLENT FUND.

"I give and bequeath the sum of _____ unto the PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, the same to be paid out of my pure personal estate, and to be applied for the purposes of the BENEVOLENT FUND of the said Society.

N.B.—Devises of land and bequests of money savouring of realty, or in other words connected in any way with land, will be void

Proposed Bye-Laws.

SECTION XVIII.

FUNDS AND PROPERTY.

1. The whole property of or under the control of the Society shall be subject to the management, direction, and control of the Council, and may, under the direction of the Council, be invested in or upon mortgage of property or Securities for the time being, from time to time recognised by lawful authority as proper for investment by Trustees.

2. The property and funds of the Society, other than moneys from time to time in the hands of the Treasurer or Secretary, shall not be disposed of, or otherwise dealt with, except in pursuance of an order of the Council, signed by six members, at the least, in Council assembled.

SECTION XIX.

BENEVOLENT FUND.

1. No alteration.

2. Donations* in aid of the Benevolent Fund shall be invested; and no part of the invested capital of such Fund shall be distributed among the recipients of relief.

3. No alteration.

SECTION XX.

ANNUAL AND SPECIAL GENERAL MEETINGS.

1. The Council shall prepare a Report of its proceedings during the past year, which, together with the Report of the Auditors, shall be read at the Annual General Meeting, and inserted in the *Pharmaceutical Journal*.

2. The Council shall meet previous to the Annual General Meeting, and arrange the business to be transacted thereat; and the proceedings of the Annual General Meeting shall be considered perfect in themselves without the necessity of reading or confirming the minutes of the preceding Annual General Meeting.

3. No business shall be brought forward at any Special General Meeting but that for which it is convened, and of which due notice has been given to the Members, pursuant to the preceding Bye-law, No. 3, under Sec. 15.

SECTION XXI.

DIPLOMA AND CERTIFICATES.

1. Every Member shall, whilst a Member, be entitled to possess and use a Certificate of Membership.

2. Persons registered as Pharmaceutical Chemists under Section 10 of the Statute, 1852, shall whilst so registered be entitled to possess and use a Diploma stamped with the seal of the Society.

3. Persons examined in the Minor or in the Major Examination pursuant to the Bye-laws may, after having passed their examination and been registered, receive appropriate Certificates.

To be repealed.

To be repealed.

* No alteration.

Present Bye-Laws.

Proposed Bye-Laws.

6. Every Diploma and every Certificate of Membership shall be signed by the President and Vice-President, and countersigned by the Secretary or Registrar. Every Certificate of Examination shall be signed by the Board of Examiners, or at least four members thereof.

7. Diplomas and Certificates shall be in such form as shall from time to time be determined upon by the Council.

8. Every person ceasing to be a Member of the Society shall forthwith deliver up to such person as the Council shall order the Certificate of Membership furnished to him, pursuant to the preceding Bye-laws.

9. All persons pirating or imitating or improperly using, or inciting any person to pirate, imitate or improperly use, any Diploma, or any or either of the Certificates, or the Common Seal of the Society, or falsely holding themselves forth to the public by means of advertisement, handbills, labels, circulars, or otherwise, as Members or Associates of the Society, or registered under the Statute, 1852, or Act, 1868, will be subject to legal proceedings, and the Council shall from time to time order the same in their discretion.

SECTION XXII.

JOURNAL AND TRANSACTIONS.

1. The *Pharmaceutical Journal* shall be edited, printed, and published in such manner as the Council shall from time to time direct.

2. The Transactions of the Society required by the preceding Bye-laws to be published, shall be inserted in the said Journal, and all notices or advertisements shall be considered duly made or given if inserted therein.

SECTION XXIII.

MEETINGS FOR THE READING OF PAPERS.

1. Meetings of the Society may be held for the reading of papers and discussion of subjects relating to the scientific objects of the Society.

2. Notice of such Meetings shall be given in the *Pharmaceutical Journal* next preceding.

3. All communications intended to be made at such Meetings shall be submitted to the President, or, in his absence, to the Vice-President, or to the Chairman of the Meeting, for his sanction, and without such sanction no subject shall be introduced.

SCHEDULE.

THE MODIFIED EXAMINATION FOR ASSISTANTS UNDER THE PHARMACY ACT, 1868.

Candidates will be examined in the following subjects.

PRESCRIPTIONS.

Candidates will be required to read Autograph Prescriptions, translate them into English, render a correct Translation of the Directions for Use, and detect Unusual Doses.

PRACTICAL DISPENSING.

To weigh, measure, and compound Medicines, write the Directions in suitable language, finish and properly direct each Package.

MATERIA MEDICA AND QUALITY OF SPECIMENS.

To recognise the Pharmacopœia Chemicals in frequent demand, and specimens of Roots, Barks, Leaves, Fruits, Resins, and Gums in ordinary use; the following Plants, either in a fresh or dried state, or from plates:—Belladonna, Stramonium, Hyoscyamus, Conium, Aconitum, Digitalis, and Sabina; also to estimate the quality of each specimen submitted, and its freedom from adulteration.

PHARMACY.

To recognise the Preparations of the Pharmacopœia which are not of a definite Chemical Nature, such as Extracts, Tinctures, and Powders, and give the proportions of the more active ingredients.

Candidates will also be examined in their knowledge of the law relating to the sale of Poisons.

To be repealed.

4. Diplomas and Certificates of Membership and Certificates of Examination shall be in such form as shall from time to time be determined upon by the Council.

5. Every person ceasing to be a Pharmaceutical Chemist or a Member, and every person required so to do by Resolution of the Council, shall forthwith deliver up to the Society the Certificate of Membership furnished to him, pursuant to the Bye-laws.

6. All persons pirating or imitating or improperly using, or inciting any person to pirate, imitate or improperly use, any Diploma, or any or either of the Certificates, or the Common Seal of the Society, or falsely holding themselves forth to the public by means of advertisement, handbills, labels, circulars, or otherwise, as Members, or registered under the Statute, 1852, or Act, 1868, or as Student-Associates will be subject to legal proceedings, and the Council may from time to time order the same in its discretion.

SECTION XXII.

JOURNAL AND TRANSACTIONS.

1. No alteration.

2. The Transactions of the Society required to be published, shall be inserted in the said Journal, and all notices or advertisements shall be considered duly made or given if inserted therein.

SECTION XXIII.

MEETINGS FOR THE READING OF PAPERS.

1. No alteration.

2. Notice of such Meetings shall be given in the *Pharmaceutical Journal*.

3. No alteration.

SCHEDULE.

THE MODIFIED EXAMINATION FOR ASSISTANTS UNDER THE PHARMACY ACT, 1868.

No alteration.

British Pharmaceutical Conference

Presidential Address by Charles Symes, Ph.D. F.L.S.*

A SECOND time in our history has the "Sister Isle" invited the British Pharmaceutical Conference to hold its annual meeting of members on Irish soil, and a second time has it given us the greatest possible pleasure to accept the invitation. Those of us who attended the Dublin meeting just twenty years ago, under the Presidency of the late lamented George Frederick Schacht, will remember the enthusiastic reception accorded to us by our Irish friends on that occasion; the warm and deep interest shown in our proceedings, the large heartedness and fellowship which marked the period of our visit, and the lasting friendships which were formed. To-day this great and beautiful city of Belfast offers us equally friendly greetings and thus assures us of its loyalty to the cause we seek to promote.

Pharmacy and its Advancement.

The science of Pharmacy knows nothing of political differences or diplomatic relations. It simply recognises in the broadest manner the brotherhood of pharmacists, the consolidation of thought, the consensus of opinion of those who practise it, the promotion of whatever conduces to the elevation and advancement of our calling. A more complete knowledge of the materials and the achievement of greater perfection in the appliances with which we have to deal; greater ability to fill our legitimate position as joint labourers with the sanitarians in the prevention of disease, and with the Medical Profession in the noble work of alleviating human suffering and in the healing art. In short, whatever pertains to the real good and the general advancement of the craft. This general advancement is attempted and we believe is, to a considerable extent, accomplished by means which may be divided under several distinct heads, but all bearing close relationship to each other. First and foremost amongst these stands education. Up to the dates of the passing of the Pharmacy Acts every man was a law to himself as to how much knowledge he cared to possess for the conduct of his business, but I am not one of those who believe that in the earlier days a relatively greater proportion of ignorance prevailed in pharmacy than during the early days of other professions. In fact, a little reflection will bring to mind the names of "pharmaceutical giants" who existed before the Pharmacy Act found a place in the Statute books, and whose work will always be recognised as the foundation on which our craft has been built. What, however, has happened is that all who practise our craft must now possess knowledge up to a certain standard, and that standard, determined by the Councils of the Pharmaceutical Societies of Great Britain and Ireland respectively, is applied by the various boards of examiners.

The Influence of Examinations.

Examinations are undoubtedly a stimulus to study and, being conducted largely by men who understand the requirements of the examinees, they are extremely useful, and in great measure accomplish the object contemplated; but the thoroughness with which the knowledge is acquired to pass them, and the way in which that knowledge is afterwards applied, afford the true measure of

their usefulness both to ourselves and to the public. The chief danger of our present system is that men will be content with the minimum of knowledge necessary to pass the qualifying examination, and will then believe that they have done all that is requisite in the way of study to fill the position in life which they have chosen; whereas, in my experience, which now extends over a number of years, the majority of men, when just fresh from their examinations, are then only in a position to learn how to expand, apply, and increase their knowledge for the efficient performance of their duties. This does not apply to pharmacy alone; indeed, so much did it apply to the medical student that, some few years ago, the curriculum was extended to include one year of practical application of the knowledge possessed before registration, by the Medical Council.

The Conference as an Educating Body.

Now, at this point the value of a body like the British Pharmaceutical Conference becomes evident. It at once points out to the so-called qualified man that there is no finality to his knowledge, that he has merely entered by the legitimate portal the field of applied science, investigation, and research; it offers him encouragement to devote himself more closely to the higher branches of his calling, and thus not only to give deeper interest to it, but to sweeten the labour and drudgery attendant on the more commonplace matters which go to make up the daily round of duty. Experts in chemistry, physics, botany, materia medica and other branches of science are busily engaged unfolding the mysteries of Nature, and it is an essential part of the pharmacist's duty to keep himself posted in the advances which are made or he will soon drift behind the times and lose the position which he holds in public opinion. In addition to the foregoing an acquaintance with technical matters is essential. As British subjects we are all amenable to the Imperial laws, but there are some of those which have a special bearing on our calling, and define our relations to the State, to the public, and to ourselves. A knowledge of these is most essential to us, and yet, until recently, no steps were taken either to teach the essential points contained therein or to ascertain if the man who desired a certificate of qualification possessed a reasonable amount of knowledge concerning them. It is gratifying to note that in Great Britain (and I trust the same applies to Ireland), candidates for examination are now required to show that they possess a practical knowledge of the one special Act which regulates their calling. Not only the Pharmacy Acts, but the Statutes relating to the Sale of Food and Drugs, Weights and Measures, Poisoned Grain, Arsenic, Petroleum, and Proprietary Medicines, as well as various Excise Regulations, all have points of special interest for us; indeed, I question whether there is any other calling on which so many Acts of Parliament have such a special bearing.

Pharmacists and the Pharmacy Acts.

Many persons look on the Pharmacy Acts as measures whereby we have voluntarily imposed unnecessary burdens on ourselves. But without going into very ancient dates in the history of pharmacy it may be pointed out that those measures were in the first instance obtained as a means of protection, and of complying with the requirements of public opinion. The Medical Profession

* Delivered at Belfast, August 9, 1898.

on the one hand, and the Government on the other, had from time to time endeavoured to obtain legislation which would materially, and it was feared prejudicially, affect the pharmacist's interests, and he had stood firmly and successfully on the defensive. The time arrived, however, when it was felt that some kind of organisation and legislation was absolutely necessary, and it was thought that it would be better to make an effort to accomplish this for ourselves rather than to leave it to others who could not fully appreciate the requirements and position of our craft. If, therefore, we are at times disposed to complain that the Pharmacy Act is not what we could wish it to be and is defective in some important points, we must bear in mind that it was the result of a compromise, and that had it been left entirely to those outside our calling it would doubtless have been more imperfect than it now is, and we should have been burdened with some oppressive measures from which we are now free. The recently obtained Amendment Act making membership available to all who pass the qualifying examination and giving them a vote in the election of the governing body is calculated to consolidate the Society, and hence is a step in the direction of consolidating the craft.

The Sale of Poisons.

The recent attempt of the Privy Council to pass a "Poisonous Substances" Bill points to the desirability of consolidation for the purpose of opposing such unsatisfactory measures when from time to time the occasion arises. The Privy Council has persistently refused to place carbolic acid, one of those deadly poisons whereby so many lives have been lost, on the Poison Schedule of the British Pharmacy Act, although this has been done in Ireland, and notwithstanding the pressure brought to bear on that body by the Pharmaceutical Society, by coroners, juries, and municipalities. I believe this is due to a great extent to misrepresentations being made as to the restriction of trade and injurious results from monopoly if this were done. As a sort of compromise this Bill was introduced, and without discussion passed the House of Lords, although a crude, imperfect, and erroneous measure. It met with such determined opposition on all hands before its first reading in the Commons that it has been abandoned. This Bill bears in itself the strongest evidence of the impracticability of a Government department attempting to legislate for matters which really belong to pharmacy.

The Desirability of Reciprocity.

The Irish Pharmacy Act, which is of more recent date than that of Great Britain, has most of its clauses based on those of the latter, but so modified as to meet the existing condition of pharmacy in Ireland at the time of its passing. It, too, is the result of a compromise, and leaves something to be desired on the part of our Irish friends. The united action of the two societies, if unable to bring about all the good desired, may do much in that direction. I look forward with hope and confidence to the time when there will be increased unity amongst all English-speaking pharmacists and pharmaceutical societies, and when there will be sufficient uniformity in the various qualifications to enable reciprocity to exist amongst them all. In some of the Colonies it is admitted that something has to be done before this can be accomplished, but it is clearly our duty to do what we can to forward any movement which is calculated to bring about so desirable a consummation.

The Purity of Medicines.

For several years efforts have been made to pass an amended Food and Drugs Act, and it is very generally acknowledged that the present Act requires some amendment. So congested, however, has parliamentary business been that still another session has nearly closed without a prospect of the proposed new measure

becoming law. It is one of the objects of the Conference "to maintain uncompromisingly the principle of purity in medicines." We, therefore, hail with satisfaction anything which contributes to this object, and when we consider how small has been the number of proven cases of deliberate and fraudulent adulteration in recent years under the existing Act, I think the Conference may be congratulated on its good and useful work in investigating and exposing circumstances of this kind during the many years of its existence.

Metric Weights and Measures.

During the past twelve months, the use of the metric system of weights and measures has been legalised for commercial purposes in Great Britain and Ireland. This must be regarded as a step in the right direction, for it previously seemed absurd that a business house could not use actual weights and measures in executing an export order for so many grammes, litres, etc., of an article without committing an illegal act; but so it was. Now, this permissive stage will familiarise the public, slowly, with this system, which is more scientific and, when well known, is more simple than our own. But I have some sympathy with those who would not hastily have its general use made compulsory, as it will take a long time before the public mind is brought to think of quantities in metric terms instead of as now, thinking in our own system, and then converting it into metric equivalents when necessary. If an apple is cut into two equal portions, and again each is equally divided, it seems much more easy to think of one of these as a quarter than as 0.25 of the whole, or, if the division is carried one stage further, an eighth is more easily realised than 0.125. The way in which a number will become fixed in the mind and influence thought is illustrated by the fact that although the decimal system has been used in France (where it originated) for so many years, one still sees in Paris some goods offered in the shops by the "dozen." Some thirty-eight years ago I remember Professor Redwood endeavoured to impress his students with the desirability of thinking in metric quantities, and suggested that those who were familiar with the size of the small dice would be assisted in realising the quantity of a cubic centimetre by regarding them as about equivalent values. Considerable alteration in our coinage will also be required before the decimal system can be rendered general in this country. As pharmacists it is our duty to familiarise ourselves with its use, and thus be prepared to forward a movement which will no doubt sooner or later obtain throughout the country, and is at present used almost invariably for scientific purposes.

Calcium Carbide and Methylated Spirit.

Most of us are not affected sufficiently by the Petroleum Act to call for much comment thereon, but the regulations concerning the storage and sale of benzine have a decided bearing on our calling and calcium carbide, now largely used for the production of acetylene gas for illuminating purposes, has recently been brought under its provisions. The sale of the carbide is a legitimate part of a pharmacist's business, and it is satisfactory that an exemption has been made whereby it may be kept and sold without a licence, so long as it is stored in 1 lb. hermetically sealed canisters and not more than 5 lbs. be kept in stock at any one time. The Inland Revenue regulations affecting us remain the same as they have been for several years past, and we have still to regret that the abuse by a small section of the public of the methylated spirit privilege should have resulted in altered methods of methylating, which inconveniences a much larger section and modifies materially the advantages which we derive from its sale and use. The present kind, methylated with mineral naphtha, becomes turbid on mixing with water and is unsuitable for many purposes for which the old kind containing wood naphtha could be

used. It is true that the old kind can still be obtained under certain conditions for manufacturing purposes, but those pharmacists who formerly supplied pathologists and institutions with it can no longer do so; thus their business suffers without, so far as I can ascertain, any equivalent advantage to any one, I think some strong representation should be made to the Inland Revenue authorities with a view to getting this alteration repealed.

Synthetic Compounds in Medicine.

Turning now to the necessity for keeping up our knowledge of modern chemistry, we have evidence of this from the ever-growing list of physiologically active synthetic organic compounds. Many of these, which have been built up on theoretical considerations, have become valuable medicinal remedies. The fancy names given to them, however, rarely afford any definite idea of their composition, and without this we handle them in a very mechanical way, and lose much of interest that would otherwise attend the dealing with them. The pharmacist knows the nature and qualities, the habitat, process of production, and manufacture of the ordinary drugs and chemicals which he uses, and it is this knowledge, together with care and experience in handling them, which in the eye of the law constitutes qualification for the practice of his profession. It seems only reasonable, therefore, that he should familiarise himself as far as possible with the numerous class of substances which I have mentioned, for although they are of a complex nature, they are capable of much simplification by a consideration of the theoretical constitutions ascribed to them. It will be remembered that Mr. Hodgkin read a very excellent paper on this subject at a meeting of the Conference, held at Leeds in 1890. More recently Dr. Kohn, in an address delivered at a meeting of the Liverpool section of the Society of Chemical Industry, dealt with the relation which exists between the physiological action and the chemical structure of these bodies. I have said that these remedies have been built up, and the term is an appropriate one, as it conveys to one's mind what actually happens. The scientific chemist is now the architect and builder, using certain atoms and molecules to build up chemical structures to meet the wants of the medical profession in the treatment of disease.

Made in Germany.

In Germany, where there are fewer restrictions on experimenting with animals than in this country, the chemist and physiologist work together, the one altering the molecules and molecular arrangement in the chemical, and the other testing, and noting most carefully the effects obtained thereby; hence most of these remedies are produced in that country, and this manufacture has become an extensive chemical industry. I would not be understood to object to the use of fancy names instead of descriptive ones for these synthetic substances, as obviously the use of the latter would in many cases be impracticable. For example, it is much more convenient to speak of or write antipyrin than phenyl-dimethylpyrazolon, and of eucaïne rather than benzoylmethyl-tetramethyl- γ -oxypiperidine-carbonic-methylester. Just as it is more convenient to speak of a cottage, villa, or mansion rather than to use a name which would describe the materials of which either is built and its dimensions. What I hold is that each package or wrapper in which these substances are enclosed should bear a clear and concise description, the formula, and; where practicable, tests should be named whereby it could be identified.

Some New Synthetic Remedies.

Since the publication of Mr. Hodgkin's paper, many new synthetic remedies have been introduced, and it may be convenient here to enumerate some of them, together with their formulæ:—

Agathin— $C_6H_4 \cdot OH \cdot CH \cdot NH \cdot CH_3 \cdot C_6H_5$ —Salicyl-methyl-phenyl-hydrazone. Antirheumatic.

Airol— $C_6H_2(OH)_4CO_2BiI$ —Bismuthoxy-iodo-gallate. Antiseptic.
 Argonin. Silver caseinate. Antiseptic.
 Aristol— $C_{20}H_{14}O_2I_2$ —Di-thymol-iodide. Antiseptic.
 Analgen— $C_9H_5(OC_2H_5)NH(CO \cdot C_6H_5)Na$ —Ortho-ethoxy-ana-mono-benzoyl-amido-chinolin. Antipyretic. Analgesic.
 Antiseptol Cinchonine iodosulphate. Antiseptic.
 Asaprol— $CaC_2H_{14}S_2O_8 + 3H_2O$ —Calcium-beta-naphthol-sulphate. Antirheumatic. Antituberculous.
 Aseptol— $C_6H_4(OH)SO_3H$ —Phenol-sulphonic acid.
 Alumol. Aluminium naphtho-sulphate. Astringent. Antiseptic.
 Benzosol— $C_6H_4(OCH_3)OC_6H_5CO$ —Benzoyl-guaiacol. Antituberculous. Antiseptic.
 Bismal— $4C_{13}H_{12}O_{10}3Bi(OH)_3$ —Bismuth methylene-digallate. Astringent.
 Bromol— $C_6H_2 \cdot Br_3 \cdot O \cdot H$ —Tri-bromo-phenol. Antiseptic and disinfectant.
 Chloralamid— $C_3H_4O_2Cl_3N$ —Chloral formamide. Hypnotic and analgesic.
 Creosol— $C_8H_8CH_3(OCH_3)OH$ —Homo-pyro-catechin-mono-methyl-ether. Antiseptic.
 Diuretin— $C_7H_7N_4O_2 \cdot Na + C_6H_4(OH)CO_2N$ —Theobromine-sodium-salicylate. Diuretic.
 Durol— $C_6H_2CH_3CH_3CH_3CH_3$ —Tetra-methyl-benzol.
 Dermatol— $Bi(OH)_2C_7H_5O_5$ —Bismuth subgallate. Astringent. Antiseptic.
 Eucaine Hydrochloride— $C_{19}H_{27}NO_4 \cdot HCl + H_2O$ —Benzoyl-methyl-tetra-methyl- γ -oxy-tetra-piperidin-carbonic-methyl-ester hydrochloride. Local anæsthetic.
 Europhen— $C_4H_9(CO_3)(O)C_6H_3C_6H_2 \cdot OI \cdot CH_3C_4H_9$ —Iso-butyl ortho-cresol-iodide. Antiseptic. Antisyphilitic.
 Guaiacol Synthetic— $C_6H_4(COH)COH_3$ —Pyro-catechin-methyl-ether. Antituberculous antiseptic.
 Guaiacol Carbonate— $C_6H_4(OCH_3)2CO_3$ —Guaiacol-ester Carbonate. Antituberculous antiseptic.
 Heliotropin. Piperonal. Proto-catechu-aldehyde-ethyl-ester. Antiseptic. Antipyretic. Used in perfumery.
 Hypnal— $CCl_3CH(OH_2)C_{11}H_{12} \cdot N_2O$ —Chloral-hydrate-antipyrin. Analgesic. Antipyretic.
 Hypnone— $C_6H_5CO \cdot CH_3$ —Phenyl-methyl-ketone-aceto-phenone. Hypnotic.
 Iodol— C_4I_4NH —Tetra-iodo-pyrrol. Antiseptic.
 Itrol— $Ag_3C_3H_5O_7$ —Silver citrate. Antiseptic in treatment of wounds.
 Lactophenine— $C_6H_4(OC_2H_5)NH \cdot CO \cdot CH(OH) \cdot CH_3$ —Lactyl-amido-phenol-ethyl-ether.
 Loretin— $C_9H_4NI \cdot OH \cdot SO_3H$ —Ortho-oxychinolin-m-iodo-ana-sulphonate. Antiseptic.
 Lycetol. Dimethyl-piperazin-tartrate. Analgesic. Diuretic.
 Losophan— $C_6HI_3 \cdot OH \cdot CH_3$ —Tri-iodo-meta-cresol. Astringent. Antiseptic.
 Lysidine— $(C \cdot H_2)_2NH \cdot N \cdot C \cdot CH_3$ —Methyl-dihydro-glyoxaline Uric Acid Solvent.
 Malakin— $C_{15}H_{15}O_2N$ —Salicyl-amido-phenol-ethyl ether. Antiseptic. Analgesic.
 Microcidin. Sodium beta-naphtholate. Used in Antiseptic Surgery.
 Nosophen— $(C_6H_2I_2OH)_2 \cdot C \cdot C_6H_4CO \cdot O$ —Iodophen. Tetra-iodo-phenol-phthalein. Antiseptic. Disinfectant.
 Orthoform. Para-amido-m-oxybenzoic-methyl-ester. Local Anæsthetic.
 Phenocoll Hydrochloride— $C_6H_4(OC_2H_5)(NHCOCH_2NH_2)HCl$ —Amido-acet-phenetidid-hydrochloride. Analgesic. Antirheumatic.
 Piperazin— $C_2H_4(NH_2)C_2H_4$ —Diethylene-diamine. Antirheumatic.
 Piperonal. Heliotropine. See above.
 Resorcinol. Iodoform and resorcin. Antiseptic dressing.
 Salophen— $C_6H_4OH \cdot COO \cdot C_6H_4N \cdot H \cdot COCH_3$ —Acetyl-para-amido-salol. Antiseptic. Antipyretic.
 Salipyrin— $C_{11}H_{12}N_2OC_7H_6O_3$ —Antipyrin salicylate. Antipyretic. Analgesic.

Salacetol — $C_6H_4(OH) \cdot COO \cdot CH_2CO \cdot CH_3$ — Acetol-salicylic-ester. Antiseptic. Antirheumatic.

Symphorol N. — $C_8H_9N_4O_2 \cdot SO_3Na$ — Caffeine sodium sulphate. Diuretic. There are also lithium and strontium salts.

Tannalbin. Tannin albuminate. Astringent.

Terpinol — $(C_{10}H_{16})_2H_2O$ — Terpin hydrate derivative. Used in bronchial affections and in perfumery.

Tetronal — $(C_2H_5)_2C(C_2H_5SO_2)_2$ — Di-ethyl-sulphon-diethyl-methane. Hypnotic and sedative.

Thalline Sulphate — $(C_{10}H_{13}NO)_2H_2SO_4$ — Tetra-hydro-para-chinanisol sulphate. Hæmostatic and antiseptic.

Triphenine — $C_6H_4OC_2H_5NHC_2H_5CO$ — Proprionyl-phenetidine. Analgesic. Antipyretic.

Thermidine — $C_6H_4(C_2H_5O)NCO_2C_2H_5COCH_3$ — Acetyl-*p*-ethoxy-phenyl-urethane. Antipyretic. Antiseptic.

Peronine — $C_{17}H_{18}NO_2 \cdot O \cdot C_6H_5 \cdot CH_2 \cdot HCl$ — Benzyl-morphin-hydrochloride. Narcotic.

Creolin, Lysol, Solveol, and Solutol are more or less impure cresol mixtures obtained from coal tar.

Of the fifty substances enumerated, it will be noted that a large percentage possess antiseptic, antipyretic, and analgesic properties; so that their rapid growth would seem to be due more to commercial enterprise than to meeting a real want in medical practice.

Synthetic Odorous Substances.

Another chemical industry, which has considerable interest for the pharmacist, is the production of synthetic esters and odorous substances closely related to the odours of flowers, plants, and animal substances. With artificial musk and vanillin we have been long familiar, as also with the amyl, butyl, and ethyl compounds resembling fruit flavours, but of more recent date we have heliotropine (heliotrope), ionone and iraldine (violet), cumarine (new-mown hay), terpineol (lilac), bergamiol or linaloyl acetate (bergamotte), nerolin (neroly), jasmin oil, anisic aldehyde (hawthorn), geranol (rose geranium), carvol (caraway oil), safrol (oil of sassafras), etc., etc. So much has this industry grown that not only are these products used for toilet soaps, but enter largely into the composition of the essences named after the flowers. They are more persistent than the natural odours, and I am told that the very popular essence of "Parma Violets" is, as a rule, quite innocent of the flowers, and is prepared from ionone mellowed down with small quantities of other extracts, and this the public really prefer. To those, however, who are accustomed to handle delicate perfumes there is not so much difficulty in distinguishing between the artificial and the real, and it still taxes the skill of the chemist and the art of the perfumer to obtain that subtle delicacy of fragrance manufactured and elaborated in Nature's own laboratory.

Paraffins as Medicinal Bases.

Although paraffins, hard and soft, have been much used as applications to the skin, it has generally been recognised that they are not readily absorbed by it, and their use as a vehicle for various medicaments has been objected to on that ground; the addition of lard or wool-fat being considered necessary to obtain the desired result. The great advantage which the paraffins possess of not becoming oxidised by exposure to the air, hence of not becoming rancid, has acquired for them considerable popularity and an extensive use. Of comparatively recent date there has been introduced from Germany a class of liquids which are said to be oxidised paraffin oils, medicated in various ways, and known as valsols. The oxidation is said to bring them into a condition in which they are readily absorbed by the skin, and are therefore valuable vehicles for the medicaments they carry. This statement as to oxidation seems so contrary to our previous notions concerning the paraffins that an investigation into the subject would be of considerable interest, and would form matter for a paper at a future meeting of this Conference. In the meantime I would not wish to question the value of these bodies,

but, so far as I can judge, it is not the pure paraffin which becomes oxidised, but rather the various substances usually found accompanying it in the commercial article.

The British Pharmacopœia, 1898.

In the world of pharmacy, the event of the year has been the publication of the new British Pharmacopœia. The fact that it offers a few alternative formulæ in certain preparations which may be made in or for India and the Colonies cannot be regarded as rendering it Imperial or Colonial, but the appendix which, it is understood, is to be published in about eighteen months or two years, will doubtless render the work complete in this respect. The new Pharmacopœia has already received some adverse criticism from Mr. Howard, Mr. Warrington, Mr. Fletcher, Mr. Umney, Mr. Corder, Mr. Parry, Mr. Bryant and others, and the points raised are well worth consideration, but probably when we become accustomed to the altered formulæ, etc., there will be reason to believe that the work largely represents the advances which have been made in pharmacy since 1885; at least it should do, seeing that it has taken about four and a half years to produce. To judge fairly of the work, it appears to me, we ought to know what was in the mind of the Medical Council when, in December, 1893, it was decided that a new edition of the Pharmacopœia was required. This we are to some extent able to do by reference to an article by Professor Leech in the *Medical Chronicle* of April last, where he writes as follows:—"The propriety of rendering it (the Pharmacopœia) more useful to the colonies and dependencies than it had hitherto been was generally acknowledged, but on other points very diverse views existed. Some, notably Sir Richard Quain, considered but little further change was needed than to add some of the approved new remedies and excise a few of those which had become less used. But the letters and articles which appeared in the medical papers as soon as it became known that a new Pharmacopœia was contemplated, showed that there was a widespread feeling that something more was required. Those who were compelled to make the Pharmacopœia the basis for their teaching, the lecturers on materia medica at the various schools were among the most adverse critics of the Pharmacopœia, pointing out its shortcomings and many errors, while chemists, botanists, and pharmacists, were no less insistent in calling for a thorough revision of all parts of the work. Eventually arrangements were made for such revision."

Pharmacists and the Pharmacopœia.

Here, then, we have the text for what has been attempted, and to the extent to which the work falls short of the object aimed at it is open to fair criticism. I will not enlarge on my oft-repeated objection to the constitution of the Pharmacopœia Committee; it is well known, and I trust in time it will be removed. I am quite aware that the Act of Parliament makes the Medical Council responsible for the publication of the work, but I have yet to learn that the Committee appointed by that body may not consist partly of pharmacists. Without being tedious, let me give you an example of where, I think, the experience of practical pharmacists would have and may come in. Professor Leech tells us in the article quoted that the reason why saffron was retained in decoction of aloes although omitted from tinct. rhei. co., pil. aloes et myrrhæ, and pulv. cretæ aromat., was on the ground that it improves its taste, and that a decoction prepared without it was not so pleasant as that prepared with saffron. But it does not appear to have been taken into account that extract of Barbados aloes, which is more bitter and less aromatic, has been substituted for that of Socotrine, that by keeping for some time, decoction of aloes loses much of its nauseous taste and mellows so as to become almost unobjectionable. It could only be on the

homœopathic principle *similia similibus curantur* that saffron could cure the nauseous taste of anything.

Of Pharmacopœia Publication.

It is not my intention to deal with the criticisms which have been made, as doubtless you are all familiar with them, but I may point out a method of procedure with reference to the publication of the work which would have rendered most of them unnecessary, would have saved much inconvenience and uncertainty, and would probably have secured for it more complete observance than now exists. We are told that the proof was ready in February, and that no material alteration has since been made. Such being the case, why should there have been so much mystery about the publication? Would it not have been better that proof copies should have been sent to the various medical and pharmaceutical journals under certain restrictions, perhaps, but with a view to publicly calling attention to the proposed alterations for the purpose of inviting criticism? Reasonable objections could then have been considered by the Committee. The work could have been issued at the end of May and gazetted, (which legally constitutes publication) at the end of June. I am aware that the able Editor of the *Pharmacopœia* kept a record of the various suggestions for improved processes, etc., which appear from time to time in the various journals, or were made at this Conference, and there is evidence that the 'Year-Books of Pharmacy' and the 'Unofficial Formulæ' have been useful books for reference during the compilation of the official work. There are, however, those engaged in pharmacy who do not publish the many small matters which they observe and think about, but whose opinions on matters of detail would be valuable, and would be ensured by dealing with the work in the manner which I have suggested. Perhaps those in authority would consider that such a procedure would detract from the importance of the work, but Acts of Parliament are not framed and passed in secret, and are not made law before their provisions are known. I do not hold that in Germany they do everything better than we do in this country, but they are certainly in advance of us in their methods of producing a pharmacopœia. In addition to having a properly constituted pharmacopœia committee, they publish from time to time (in fact are now publishing in the *Archiv der Pharmacie*) the suggestions which have been made and the alterations which are contemplated for a future edition of the work, long before it is taken in hand for publication. In this way every detail is considered by all who are concerned and are to be affected by its contents, so that when the work assumes the position of legal authority all are fully prepared to obey its dictates, and it has the endorsement of the entire medical and pharmaceutical professions. We shall all, I think, approve of the more general introduction of the metric system into the work, and there are many other alterations which must commend themselves to us, but I will not anticipate the papers which are to be read at this meeting by entering into details, which will no doubt be ably dealt with by the gentlemen who have them in hand.

In Praise of Ireland.

In view of these interesting papers I am anxious not to weary you with a long address, but I cannot close without referring to the fact that to-day we are the guests of a warm-hearted and generous people, who, like ourselves, are British, and whose interests are closely interwoven with—in short, are identical with, our own. That we are in a country at once beautiful and possessed of great natural resources, capable of much development. The lakes, glens, rocks, rivers, the wild romantic scenery, are all too well known to require comment; but the mineral wealth of Ireland is greater than most people suppose it to be. The coal-

fields of Leinster, Munster, Connaught, and Tyrone; the immense stores of red hæmatite, bog iron ore, and pyrites; the copper mines of Wicklow, Waterford, and Cork. Lead, rich in silver, native silver, arsenic, antimony, baryta, magnesia, etc. To these may be added the gold found in Limerick and Tipperary which, if energetically sought, may prove a veritable Klondike nearer home. The fruitful soil, the climate rendered uniform and less severe than that of England or Scotland by the salutary influence of the Gulf Stream, tend to render the country one which will well repay the expenditure of capital in judicious enterprise. It seems probable that *Eucalyptus globulus* could be cultivated with advantage in the central plains of the island, and that its culture would improve the condition of the soil where excessive moisture exists. In suitable soil it is probable that the climate would be adapted to the cultivation of some herbaceous medicinal plants, such as peppermint, spearmint, etc. Some of the medicinal plants which are grown in North America could doubtless be cultivated with profit in the "Emerald Isle" if a proper selection were made, and their habitat were duly studied. In Belfast we are in a veritable hive of commercial industry, and I know of no legitimate reason why large commercial centres of a similar character should not exist in other parts of this country of so much promise, so well situated and accessible to all parts of the world.

The Late Michael Conroy.

It was my hope that I should have been able to conclude without having to record the death of any member of the Conference during the past year, but such is not my good fortune. Michael Conroy, a former Vice-President, an active member of the Conference, and an Irishman withal, has gone to his rest. He was only fifty-four years of age when he passed away, and we could have hoped to have had his active co-operation, his genial presence, and a continuation of his useful work for some years to come. He possessed a large amount of good reliable information on matters connected with our craft, and took an active part in the discussions at our meetings. He will be remembered by many here as Chairman of the smoking concerts held as part of the social programme at our gatherings for many years, in which his cheerful inspiring cordiality was always exhibited. The Executive Committee have already expressed, through the Honorary Secretaries, their deep sympathy with his widow and family in their bereavement. Personally, I feel his loss to be that of a much-esteemed friend with whom I could always discuss matters relating to chemistry and pharmacy with pleasure and profit.

The Late Dr. de Vrij.

Since this address was written another eminent man has passed away; I refer to Dr. de Vrij, of the Hague. Just fifty-two years ago Dr. de Vrij first visited England as the representative of the "Batavian Society of Experimental Philosophy" at a meeting of the British Association at Oxford, so that in those days he had attained to an eminent scientific position. During his long life his published works and papers and communications numbered over 200, on various scientific subjects. He was the son of a pharmacist, and during the early part of his life he devoted himself to that profession. His chief work which directly affected us was the investigation of the cinchona alkaloids and in connection with cinchona cultivation in Java and India. His work was officially recognised by honours from the Dutch and French Governments and by our Queen, who conferred on him the Order of Companion of the Indian Empire. Last year as your President I had the honour of joining with the President of the Pharmaceutical Society, Mr. Carteighe, and the Presidents of the Linnean and Chemical Societies in awarding to Dr. de Vrij the "Canbury Gold Medal,"

a distinction which he well merited. He was unable to receive it in person, but he wrote a letter expressing his appreciation of the honour, and stating that, although eighty-four years of age, all his senses and his intellectual faculties remained unimpaired. In 1871 he was selected an honorary member of Conference, so that he had been associated with us for twenty-seven years. He was an example of a man of high intellectual ability, devoting his powers to the purpose of serving his day and generation; passing away at a ripe age honoured and esteemed. Last evening your Executive passed a resolution of condolence with his family, which I am sure you will to-day endorse.

THE BASICITY OF QUININE.*

BY DAVID HOWARD AND D. LLOYD HOWARD.

The question suggested for consideration by the Conference as to the basicity of quinine is somewhat difficult to answer, as theoretical consideration would lead to a different conclusion from that indicated by the use of indicators in volumetric testing.

Everything points to the conclusion that the alkaloid is a "diammonia," to use an expressive, if somewhat antiquated nomenclature, that each of the nitrogen atoms of the molecule represents a basic nucleus, one of which is much more powerful than the other.

This is shown by the action of ethyl or methyl iodide or bromide, which very readily give a monethyl or monomethyl base, and with more difficulty a diethyl or dimethyl base.

The formation of quinine salts points to the same conclusion. Sulphuric acid will form three definite crystalline salts; one molecule combining with two molecules of quinine to form the ordinary sulphate of quinine of commerce, with one molecule to form the "soluble sulphate" of commerce; or two molecules of acid will combine with one molecule of quinine to form the little known "tetrasulphate." Similarly the monobasic acids, hydrochloric, hydrobromic, and hydriodic form definite crystalline salts with both one and with two molecules of acid to one of the alkaloid.

Whether the "soluble sulphate" should be regarded as forming a hydric sulphate of the stronger basic nucleus or a neutral sulphate of the "diammonium" must be a matter of opinion; but the tetrasulphate and the acid halogen salts can hardly be regarded otherwise than as the hydric sulphate or the haloid salt of the fully saturated base.

The French chemists have always consistently regarded the "soluble sulphate" as the "neutral sulphate" and the sulphate of commerce as the "disulphate," and similarly they speak of the soluble hydrochlorate as the "neutral" salt and the ordinary hydrochlorate as "basic."

This nomenclature frequently leads to confusion, especially to those who do not recognise the old rule of nomenclature now rarely observed, that gives opposite meanings to the Latin and Greek prefixes. We are careful enough to remember that a kilogramme is one thousand grammes, and that a mille-gramme is one thousandth of a gramme, but we continually find that a disulphate is supposed to be identical with a bisulphate instead of being a basic sulphate, and the exact opposite of a bisulphate. No doubt the risk of this mistake has led to the disuse of the old name "trinitrate of bismuth" for the ordinary subnitrate of the metal.

If, however, we study the salts of quinine by means of the ordinary tests for acidity, we shall arrive at a very different conclusion. Of course, colour indications only show the balance of affinity for an acid or an alkali, as the case may be, of the coloured body. The change from blue to red with litmus only shows that a

free acid has turned the red acid out of its combination with an alkali, and the uncertainty of the change with weak acids is evidence of so slight a preponderance of strength that it required a marked excess to break up the blue salt. This balance of acid strength may be very much affected by temperature and dilution. In a weak and cold solution boric acid has no acid reaction, and borax has been recommended as a means of standardising solutions of test acid. If, however, the borax solution be hot and strong, the boric acid shows a very distinct though indeterminate acid reaction. A colour reaction, therefore, can only show the relative strength of the affinities of the reagents in determining the reaction which causes a change of colour.

As is shown in the paper referred to on the question, in the 'Year-Book of Pharmacy,' 1894, folio 344, this power of the vegetable alkaloids to bring about a colour reaction varies very greatly.

Phenolphthalein gives no indication of the presence of quinine; the acid in a salt may be titrated as if no alkaloid were present. With litmus as an indicator the point of the formation of the older official salts is very well defined, the reaction is almost as well marked as in the case of the formation of the neutral salt of an alkali, and thus as far as indicators go the sulphate of quinine of the British, American, German, and most other Pharmacopœias is undoubtedly a neutral salt. No indicator appears to show the formation of the soluble salt with any degree of certainty. Litmus gives no indication at all, not even the indefinite change to purple caused by the formation of a bicarbonate, and thus the expression "neutral" salt in the French sense expresses a theoretic expression of its composition and not the result of any colorimetric testing, and it is certainly very desirable to avoid an expression which very often proves very misleading.

With methyl-orange the indications are very indefinite; the neutral point is approximately the soluble sulphate. Messrs. Farr and Wright, in their paper on the titration of alkaloids, speak of the end reaction in an alcoholic solution as almost unobservable, but state that in several instances the results obtained by titration were exactly twice as great as those obtained by weighing.

The curious effect of sulphuric acid in increasing the specific rotation of polarised light by solutions of quinine also point to a marked difference in constitution in the different sulphates. Dr. Hesse ('Year-Book of Pharmacy,' page 144, 1874) gives the rotation of quinine $a_j = -166^\circ$, of sulphate of quinine in alcohol as $a_j = -191.5^\circ$, of the quinine in solution as $a_j = -220.4^\circ$. Of soluble sulphate he found the rotation for the contained quinine $a_j = -264.3^\circ$, with $7\frac{1}{2}$ equivalents acid $a_j = -264.7^\circ$, but with still greater excess the rotation of the dissolved quinine may reach $a_j = -287.6^\circ$. It is curious to note that the maximum rotation is not reached immediately on the addition of the excess of acid, but only after the lapse of some time pointing to a slow formation of the tetra-sulphate in the comparatively dilute solutions used.

These results point to the existence in solution of the three crystalline salts, but it would seem that owing to some measure of dissociation in the solutions an excess of acid must be present to keep the tetra-sulphate in solution.

Whatever theoretic conclusions we may form as to the composition of the salts of quinine, there is no doubt of the convenience of the nomenclature adopted by the British, German, American, Dutch, and most other Pharmacopœias, which regards the familiar sulphate as neutral and the soluble sulphate as a bisulphate, but in foreign commerce we must always be on our guard against confusion arising from the French nomenclature, to guard against which the Italian Pharmacopœia gives us the following remarkable trio of synonyms: Bisolfato de chinino = solfato acido de chinino = solphato neutro de chinino.

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

MATERIA MEDICA ANIMALIS.*

BY J. C. MC WALTER, L.R.C.S.I., L.A.H.D., M.P.S.

As official recognition has at length been given to the use of animal substances in medicine by the inclusion of certain preparations of the thyroid gland in our new Pharmacopœia; it may be useful to make a short review of some of the principal remedies of animal origin which have recently been tried for the relief of disease.

At the last meeting of the British Pharmaceutical Conference, it was insisted that glycerin was the most suitable solvent for many of these extracts, and that sterilisation was a most important factor in the production of a satisfactory solution. It is pleasant to find that both of these points have received attention in the directions for preparing the liquor thyroidei of the new B.P.

Nothing within the domain of pharmacology is so difficult as to investigate the therapeutic properties of animal extracts, and in none of the sciences ancillary to medicine has so much ludicrous empiricism been displayed as in the efforts to elucidate these properties.

The difficulty lies, of course, largely in the fact that the problem is largely a biological rather than a chemical one. Dealing with vegetable materia medica, we can generally approximate the active principles, and frequently crystallise them in alkaloids. Any competent pharmacist would confidently offer to exhibit, in the form of extract, tincture, decoction, or elixir, the active principle of any plant submitted to him, but few chemists would claim to be able to bottle in a palatable form the active principles of a calf's brain or a sheep's spleen. We know such organs to have a very complex chemical constitution, and may presume them to be of much therapeutic value in disease of the corresponding organs in the human subject, but what the active principle is, how to discover, extract, and preserve it, constitutes a problem for the scientific pharmacist which should be the more interesting as it is the more difficult, and which has a certain fascination from the fact the solution of it lies on the borderland between the life and death of animal tissues. Continental chemists, who take their duties very seriously, have advocated the establishment of a laboratory where animal extracts and serums could be examined and reported upon, as both physicians and pharmacists are bewildered by the multiplicity of these substances, and confused by the want of any proper standards or tests. The question of the therapy of animal extracts is, indeed, a very proper one for international investigation, but meanwhile something might be done if this Conference were to collect, combine, amplify, and animate the reports of the various scientific bodies throughout the world which are investigating the question. Much of this class of work has already been done in our 'Year-Book of Pharmacy.' But I submit that it would still be desirable if we had some work which would present in a concise and succinct form the present state of our knowledge on any of these animal extracts.

SUCCUS TESTIBUS PARATUS.—Brown-Sequard sterilised extract must be mentioned in any account of organo-therapy. Animated by a belief in its efficacy he tried it in insanity, carcinoma, chorea, cholera, tuberculosis, senile debility, and in various diseases where stimulation of the nervous system is indicated, and in many cases with apparent success.

SPERMINUM.—Spermine is a chemical ferment secreted by most glands, and present in the blood in the normal condition. Professor Poehl discovered that it possesses the curious property of preventing the accumulation in the tissues of certain decomposition products, such as leucomaines and creatine compounds, which cause

auto-intoxication and predispose to infectious diseases. Cases in which the spermine normally present is absent or deficient are relieved by the injection of soluble spermine, prepared in a sterilised solution from fresh animal glands.

CEREBRUM EXSICCATUM PULV.—The modern isopathic movement, which was started by the remarkable cures effected by the thyroid substance, seemed to hold out great hopes of success in the treatment of neurasthenic conditions and mental diseases by preparations from the healthy brains of animals. A dried preparation from the fresh brains of calves was employed for mental troubles, and a subcutaneous injection, liquor cerebri sterilisatus, for neurasthenia. In the latter disease considerable benefit seemed to follow the use of the injection, but for mental diseases the results have been on the whole disappointing. The failures I am inclined to attribute to the methods of preparation. The benefit of cerebral preparations will probably be found to be due to some highly organised and unstable phosphorus compound, which is possibly destroyed in the process of desiccation. The most scientific method, I submit, is to administer the organ in a condition as like the living state as possible. As the brain contains over 70 per cent. of water, drying obviously entails too great a change in its molecular constitution. As we are ignorant of what proportions of its active elements are soluble in glycerin, alcohol, oil, or water, solutions or extracts are out of the question. The only available form seems to be an emulsion, something like Mr. Martindale's pancreatic emulsion. The following will, I think, be found practicable:—Fresh lard, melted, 15 ozs.; distilled water, 15 ozs.; grey substance of brain of recently-killed calf or sheep, 15 ozs.; powdered gum tragacanth, 300 grains; oil of bitter almonds, 15 minims. The brain, freed from membrane and white substance, and hot from the animal, should be dropped into the melted lard, and the mixture strained through a coarse horse-hair sieve. The tragacanth should next be added and the water added *secundem artem* to the mixture in a sterilised mortar. The oil of almonds is to be added last, and the emulsion dispensed in wide-necked bottles. Independent of any specific effect which the brain substance may have in cases of cerebral mischief in the human subject, the emulsion must obviously be of use in checking the excessive waste of tissue which so often accompanies it.

CEREBRUM SICCATUM.—A preparation of the dried grey matter of calf's brains, from which the fat has been removed, has been tried in cases of melancholia and chronic mania. Dr. Robertson has recorded improvement in cases which were treated with daily doses of $\frac{1}{2}$ to 1 drachm.

GLANDULÆ SUPRARENALÆ SICCATÆ PULV.—There is a little gland, shaped like a cocked hat, and perched on the tops of the kidneys of most animals. Its function has long been a puzzle to physiologists. It had been noted, however, that in the curious affection characterised by bronzing of the skin, and known as Addison's disease, that these glands were usually atrophied. Naturally, the fresh and healthy glands from animals have been tried in this affection, and with wonderful results. Drs. Oliver, Sansom, and Jones describe a change in the discoloration of the skin, a rapid increase in weight, and an extraordinary improvement in general health as having followed their use. The internal administration seems to cause great constriction of the arteries, with consequent increase of the blood pressure and stimulation of the heart's action. Hence they seem likely to influence favourably all those diseases which depend on loss of the vasomotor tonus, as neurasthenia and several cardiac affections, some forms of albuminuria, diabetic and Grave's disease. Merck (whose notes I have freely availed of) asserts that the active principle is not destroyed by the gastric juice, and hence they may be given by

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898

the stomach. He advocates the use of a powder prepared from the fresh capsule of which one part is equal to five in the recent state. This is administered in doses of from three to five grains, after meals, two or three times a day. Other investigators claim that glycerin is a satisfactory solvent and recommend a glycerin extract for internal use. This should be made, of course, from the fresh gland.

Altogether the suprarenal capsule seems one of the most promising and interesting resources of organotherapy.

HYPOPHYSIS CEREBRI SICCAT. PULV.—That portion of the brain which rests on the bony structure known as the "sella turcica," and which is called the pituitary body, has been found to be affected in the disease known as acromegaly, in which the extremities are enormously increased in size, and headache with neuralgic pains are distressing symptoms. Dr. Marinesco administered the pituitary body taken from the skull of an ox in three pronounced cases of this disease. The most pronounced effect was a considerable increase in the diuresis, but the neuralgic pains and headache were considerably lessened. It has also been tried in some twenty cases of epilepsy, but so far from relieving, decidedly aggravated the condition. In some cases a new state of exaltation was produced, which presented features entirely different from those which had been observed before.

Iodine has been discovered in the pituitary body, and this fact has lent strength to the belief that it acts vicariously with the thyroid gland. Schiff's investigations have shown that, under certain conditions, the process of elaboration of tissue in the human economy may be influenced by the introduction of preparations of the pituitary body. In healthy young persons no effect is produced, but in an elderly man and a patient suffering from acromegaly the use of this substance produced an intense increase of the total secretion of phosphoric acid, which was not due to the increased metabolism of albumin, as clearly demonstrated by the excretion of nitrogen. Hence the use of the hypophysis cerebri obviously leads to the decomposition of tissue rich in phosphorus but poor in nitrogen, as bone tissue. The causal connection, then, between acromegaly and the pituitary body seems to be demonstrated, and any failure which has attended its use in cases of this disease is probably due to an insufficient acquaintance with the pharmacy of the pituitary substance. It has generally been administered in tablets containing about 2 grains of the dried substance, which is equivalent to about six times as much of the fresh organ, but sufficient care does not seem to have been taken to ensure that the pituitary body was removed sufficiently soon after the death of the animal, or to observe such aseptic precautions as would preserve its active principle from post-mortem changes. Merck favours a preparation which he calls opophypophysinum, and which is made by treating the substance with a saline solution.

MEDULLA OSSIIUM RUBRA.—Modern physiological investigation has shown that the red marrow of the bones is the birthplace of red blood cells. The use of this substance then seems most rational in anæmic conditions. Several British practitioners have examined the properties of bone marrow, and their experiments met with positive success. Dr. Barrs even treated successfully a case of pernicious anæmia which had been made worse by treatment with arsenic; chlorosis and rachitis have also been much improved under its use. On the other side, Dr. Hunt reports in the *Lancet* that he found the preparation perfectly indifferent in three cases of pernicious anæmia in which it had been specially ordered. Most of these reports had been made on a dry preparation of bone marrow, but that obtained by macerating the fresh bones in glycerin gives a far more active solution, which is undoubtedly of

great therapeutic power. Merck points out that it is absurd to use the organs as such, as they are merely vehicles for their useful secretions, much in the same way as nature's metabolism is influenced, not by the tissues, but by their diffusible products. To administer liver for liver complaints, calf's brain for diseases of the brain, etc., is an attempt to enforce the axiom of Hahnemann, *similia similibus curantur*. Modern investigation has shown that the animal tissues, like many microorganisms, may optionally exist under aerobic and anaerobic conditions, and that the anaerobic existence of the tissues has, after the death of the animal, considerable influence in the chemical nature of the tissue fluid. Poehl has proved that by the evaporation, even *in vacuo*, of the glandular extracts, a series of therapeutically important substances vanish, which he ascribes to the anaerobic activity of the glands, since during slow drying processes he found it impossible to avoid this post-mortem function of the glandular cell tissue. Modern medicine requires that only the isolated active components of the organs should be used in practice. Our knowledge of these is very defective; but an element called "spermine" seems common to all organs which are employed for therapeutic purposes, and seems to give them their general tonic effect. Other substances are also present possessing specific therapeutic properties, and these are asserted to be leucomaines—that is, the basic bodies regularly and continuously formed by the physiological processes going on during the decomposition of the protein substances. Since the precipitable albuminoids do not participate in the healing process, their diminution is desirable; moreover, their elimination implies that of a whole group of toxic proteids. Now many of the leucomaines form with chloride or sodium double salts, which are freely soluble in water and highly diffusible. Hence Merck and Poehl have devised a plan whereby the active principle of the fresh gland is represented by a substance prepared with salt, whereof one part is equivalent to ten parts of the fresh gland. Considered from the purely pharmaceutical aspect, the process is an intensely interesting one, while it is claimed that in the short period which has elapsed since their introduction a whole series of successful applications have been recorded.

OVARIA SICCAT.—Without doubt the ovarics, like other glands of the human organism, contain certain internal secretive products which occupy important relations to the entire system. Further, it has long been observed that the cessation of menstruation, either naturally or in consequence of ovariectomy, is followed by a series of disorders which manifest themselves principally in the shape of nervous troubles. The clinical experiences of a number of physicians go to show that the brilliant results which have followed the use of thyroid preparations in cohexia strumipriva, may be rivalled by the success of ovarian medication in climacteric troubles. By the administration of dried ovarian substance, or of an ovarian extract, it has been found possible to repress, for a shorter or longer period, or, in some cases, even permanently, all the symptoms of sympathetic neurosis, such as palpitation of the heart, failure of memory, nightmare, insomnia, ordox fugax, etc. In many of the cases experimented on, other therapeutic measures had already been tried with little effect, hence the beneficial results of the ovarian gland are the more remarkable.

The dried ovarian substance, prepared by removing the fat as far as possible from the entire ovary of the cow, and drying the substance under antiseptic precautions at a temperature not exceeding 40° C., is the preparation introduced by Merck, which has principally been used. A glycerin extract, made by macerating the warm gland in sterilised glycerin, ought to be a far more

active and elegant form for administration. The ovaries vary very much in size, but average about 3 drachms each, but when dried five ovaries weigh about 2 drachms, and of this a daily dose of from 8 to 16 grains suffices, either in tabular or pilular form.

Denaeyer makes a preparation of the ovarian tissue which he terms an albumose. This is made by macerating 20 parts of the fresh tissue in a mixture of 30 parts of water with 3 of active pepsin and 9 part of hydrochloric acid for six hours at a temperature of 40° C. The solution is afterwards brought to the boiling point and neutralised with sodic carbonate, filtered while still warm through a soft filter, which will absorb the fat and the fluid.

RENES SICCATA.—Cases of kidney disease are amongst the most intractable in medical practice, and when we find that one observer noted an improvement in thirty-five nephritic patients, to whom he administered the fresh kidney, or an extract prepared from it, the remedy seems of much value. In these cases the flow of urine was increased, whilst the proportion of albumin diminished or disappeared. In patients suffering from cirrhosis of the kidney with polyuria, the flow was lessened and the general health improved. Uremic symptoms also disappeared under its use. Dr. Donovan reports similar success in a case of nephritis with general dropsy.

According to Brown-Sequard, the origin of trouble in kidney disease is not that substances remain in the blood which ought to be removed, but rather that an internal secretion, which the kidney normally yields to the blood, is absent in these cases. With this view a glycerin extract of kidneys has been subcutaneously injected in chronic and acute inflammations of the kidneys, and generally with a gradual decrease of albumin in the urine and an increase of the diuresis and improvement of the patient's condition. The dry preparation, of which one part is equal to six of the fresh kidney of the pig or sheep, does not seem to be so active as the fresh gland or the glycerin extract. That preparation, procured by peptic digestion and termed an albumose, is a thick, heavy compact powder, unlike the majority of such preparations, which are light and spongy.

Like most other drugs, the renal extract has been essayed in epilepsy. The results were far from gratifying, as the fits became even more frequent, though this was probably due to the cessation of the ordinary bromide treatment. Promising a therapeutic agent as kidney extract seems to be, and large as is the field for its activity, but few reports have appeared in it of late. This is probably due to an attempt to force the use of dried preparations which seem to be of little value.

THYMUS SICCATUS.—This is a peculiar gland situate in the neck of infants, which seems to exercise considerable influence on the development of the body during fetal life and the first years of infancy. As the child grows it gradually becomes functionless and atrophies. This thymus gland is assumed to secrete a fluid which modifies the composition of the blood to a marked extent and which is to some extent antagonistic in its effects to the secretion of the thyroid gland evaporated to dryness in a porcelain vessel.

It is claimed that this method is applicable to any organ, and that the resulting powder represents the active principle in a form which keeps indefinitely if preserved in a sterilised flask. Moreover, it is soluble in glycerin or water, making a solution of a very agreeable flavour, and it can readily be made into pills, tablets, or powders. The strength can be so adjusted that 1 part of the albumose shall be equivalent to 10 parts of fresh tissue. When dissolved in glycerin, and repeatedly filtered, the solution gives no trace of insoluble albuminoids, and will keep indefinitely in a sterilised and sealed flask

Although it is now generally concluded that the therapeutic properties of the thymus gland are opposed to those of the thyroid, it was at first tried as a substitute for the latter in diseases of that gland affecting the human organism. It was found, naturally, to succeed in cases where the thyroid had failed, and to be followed by an increase in the formation and excretion of uric acid. Unlike the thyroid, there were no such secondary effects as decrease of weight, disturbance of the heart's action, etc. The proper use of the thymus gland is in cases where the thyroid is in a state of abnormal activity, as in Grave's disease; whilst the thyroid treatment is obviously proper in cases where there is atrophy and deficient secretion of the gland, as in myxœdema and cretinoid conditions.

The raw gland, fresh from calves or sheep, has been prescribed for defective nutrition in children, and in some cases with marked success. In chlorosis it has also proved beneficial, and is not followed by the feverish symptoms which often accompany the use of the ovarian extract. It has also been tried in anæmia, leucocythæmia, and paralysis infantum.

Many therapeutists attribute the effects of the thyroid extract to the iodine which it is found to contain, Baumann has traced the presence of iodine in the thymus gland, where it probably exists in a state of combination, like that of iodo-thyrin. Abelous and Billard have shown that the important part which the thymus gland plays in the alimentation of the organism depends upon its property of producing, like the thyroid gland and suprarenal capsule, substances which neutralise and destroy the poisons formed in the body by the natural process of metabolism.

The fresh gland itself is probably the most effective form in which to exhibit it, as it does not seem to be followed by any injurious after-effects. A powder, prepared by dessication from the gland freed from fat under aseptic conditions, is prepared by Merck and others, one part of this preparation equals six parts of the fresh gland, and it may be given in doses of 12 to 15 grains in the day.

PROSTATA SICCATA PULVIS.—The prostate gland is situated at the neck of the bladder, and, being peculiarly liable to become hypertrophied in old people, is a fruitful source of trouble by causing strangury, ischuria, etc. The condition was ordinarily supposed to be but little amenable to medical treatment, and the surgical methods employed are always risky and not invariably successful. At the International Congress of Medicine, held at Munich, Dr. Reinert reported that he had tried the effect of the chopped prostate gland of a bull on a patient suffering from hypertrophy of that organ. He administered a quarter of a gland, finely chopped in bread and butter, two or three times a week. After a few weeks the organ had grown considerably smaller, the patient improved in general health, the difficulty of micturition was lessened, there was an absence of sugar and albumin. Failing fresh prostates an extract should be made by macerating the still warm organ from the animal in a saline glycerin solution, according to the formula published by the "Archives of Physiology," that is to say:—

Fresh Gland	2 parts
Sterilised Glycerin	2 "
Saline Solution (50 per cent.)	1 part.

Macerate for forty-eight hours, and filter frequently until clear.

Tablets are also made containing 2 grains of dried prostatic substance. These are taken in doses of five daily. It does not seem to be the best form for administration, as much of the tissue of the gland is of an interstitial character, and probably inert, whilst the parenchymatous tissue, which is probably the active part, must be more or less changed in the drying process. The disrepute into which this remedy seems to have fallen is probably due to the bad pharmacy displayed in the preparations offered in commerce.

THYROIDINUM SICCATUM.—As this preparation is the best known of the animal remedies, and has received the imprimatur of the Pharmacopœia, it is unnecessary to refer further to it. As a result of Hotkin's studies the normal thyroid gland is found to contain two physiologically active bodies: thyroprotein, a metabolic product, which is an active poison, and thyroidin, a specific product of the thyroid cells, which acts as a ferment.

HEPAR.—If the liver be removed from an animal, death quickly follows. A partial ablation of the gland may, however, be effected without an immediately fatal result, but if the quantity removed be considerable, the animal dies in from eight to twelve hours. When an extract prepared with glycerin from the fresh liver tissue is injected into an animal it survives for several days.

This fact proves that the liver secretes a substance which, when introduced into the veins, neutralises the toxic effects of the bile present in the blood, and prevents the formation of toxic albumins. It also shows that the necessary substance can be procured from liver tissue by a simple pharmaceutical process. It becomes at once obviously important to supply, in presence of the morbid conditions of the liver existing with jaundice, the secretion which is absent or insufficient by the injections of a hepatic liquid which will contain the necessary elements of such secretion.

This hepatic juice appears useful in all cases of intoxication by the bile salts or by the colouring matter of the bile. It should also be of extreme value in cases of microbial and alkaloidal intoxication. Thus, Kotlior has demonstrated that when fresh hepatic juice is mixed with hyoscyamine, the latter loses its property of dilation of the pupil. This phenomenon does not take place if we use, instead of the fresh juice, the cooked liver. The hepatic juice has also the property of destroying those ptomaines which are the products of putrefaction, and which give rise to enteric disease if not neutralised by the hepatic secretions.

Some French investigators have attempted to isolate the active principles of the liver, and have extracted from it several albuminoids having a coagulating action on the blood. They have also demonstrated the presence of soluble toxins belonging to the group of soluble ferments. Mairet and Vires have arrived at the conclusion that the introduction of an extract of liver into a healthy person causes the temperature to fall, whilst it increases the amount of urine passed. The secretion of urea and the total excretion of phosphoric acid are also increased, whilst the evacuations are rendered more copious and fluid.

Considering the important function which the liver plays in the formation of sugar, the hepatic extract has naturally been tried in cases of diabetes. It succeeded when used hypodermically in materially decreasing the quantity of sugar, although no change had been made in the diet. In cirrhosis of the liver it has been used with marked benefit, and in this disease the hypodermic injection, and the administration *per os* were attended with the like results, particularly as regarded the marked increase of diuresis. The dose given should be rather large; as much as 3 or 4 ounces of the fresh liver in the day. When the liver is dried under aseptic precautions 1 part of the preparation (*hepar siccatum*) is equivalent to 5 parts of the fresh gland, and about 5 drachms daily is the dose. The aqueous extract is very active, but must be made freshly for each application. The glycerin extract is perhaps the most convenient preparation. It can be given in doses of 4 drachms daily.

An interesting use of this remedy is for hæmorrhage. It has been proved that the liver contains a ferment which has the property of coagulating blood. Hepatic extract and powder have been tried in the cases of five phthisical patients, and have rapidly staunched the hæmoptysis without the use of any other

application. In other forms of bleeding, as epistaxis and metrorrhagia it has likewise been a success.

The experiments of Claude Bernard proved long ago that post-mortem changes take place with immense rapidity in the liver, and whilst it is still apparently fresh and sweet. The importance, then, cannot be exaggerated from the therapeutic point of view of endeavouring to fix and extract the characteristic ferments by impressing the gland in sterilised glycerin and salt solution whilst still hot from the animal, and thus preparing a stable glycerin extract.

LIEN PREPARATUS.—The spleen is the principal organ of the body, in which falls the duty of combating infection. It appears to contain a specific substance which is not destroyed by boiling, and which, when subcutaneously injected, produces a considerably increased proportion of hæmoglobine in the blood, and greatly increases the number of red corpuscles. Some observers believe that these effects may be due to the lecithine contained in the spleen. As splenic extract has also the power of increasing the number of white corpuscles, a nucleinic action is also ascribed to it. From the spleen a body containing iron and iodine, and named by its discoverers "linadine," has been extracted, but the therapeutic properties of this extract have not been yet investigated.

An aqueous splenic extract has been employed in the treatment of anæmia and chlorosis, and succeeded in improving the appetite, re-adjusting the menstrual irregularities, and increasing the weight of the body. In malarial cohexia accompanied by hypertrophy of the spleen, splenic extract and bone marrow have been used with most gratifying results.

LIEN.—There seems to be need of further elucidation of the pharmacy of the spleen, for Dr. Wood, who employed the extract successfully in Grave's disease, found that when the requisite doses were employed that it gave rise to dyspepsia and vomiting, whilst subcutaneous injection gave rise to local inflammation and suppuration. Merck recommends a powder, prepared by drying aseptically, the spleens of sheep or pigs (*lien siccatus pulverisatus*), of which one just corresponds to five of the fresh organ. The dose is from 4 to 12 grains thrice daily in water, gelatin capsules, or tablets.

MAMMÆ.—Dr. Robert Bell has obtained remarkable results by the use of preparations made from the mammary gland of the cow, in cases of uterine fibromata, menorrhagia, and metrorrhagia. He found that the tumour formation was reduced in a remarkably short time, the general conditions of the patient improved, and the pains subsided. The excessive uterine flow was also considerably checked, and in some cases disappeared entirely under the use of the mammary extract, in conjunction with suitable local treatment. The effects are probably due to a secretion from the mammary gland, which, when absent or insufficient in quantity, results in hypertrophy or disordered function of the uterus, and which, when supplied vicariously by means of preparations from the healthy glands of animals, can restore the uterus to its normal condition. The preparation hitherto used has been the powder from the fresh gland, of which 1 part is equivalent to 8 or 9 parts in the recent state. Of this from 5 to 10 grains are given thrice daily. Another preparation which is likely to be of more efficacy is made by treating the glands with saline solution, and is called *opomammium*. Of this from 1 to 2 drachms may be given daily.

PULMONES.—Prepared from the parenchymatous lung tissue of robust young sheep. Dr. Brunet having experimented on animals with extracts of lung tissue, and finding it to possess tonic properties in small doses and toxic effects in larger quantities, felt induced to employ the remedy in the human subject. In ten cases of chronic bronchitis, attended by emphysema, torpid and acute

tuberculosis, phthisis of the lungs and larynx, the use of the remedy was followed by considerable improvement. Brunet accordingly believes this treatment to be applicable to all chronic diseases of the lungs and pleura, pulmonary abscesses, etc. He gave subcutaneous injections of pulmonary juice in doses of about a drachm; or the juice with a little water on an empty stomach every morning. Dr. Grande treated a phthisical patient with the dried powder in doses of about a drachm daily, and effected an increase of the weight and dispelled the fever.

GLANDULÆ BRONCHIALES.—The bronchial glands are credited by physiologists with secreting a substance capable of resisting the entry of bacilli into the air passages. Hence it has been thought that the infected and diseased organism might have its natural healing powers increased by the artificial introduction of the glandular substance. This has accordingly been done in cases of tuberculosis, but the results were disappointing, as in each case fever was produced, with rapid emaciation and loss of strength. Discouraging as this result has been, it yet shows that the preparation is by no means impotent, and that, if pharmaceutical skill be brought to bear on the substance, and a preparation elaborated fell from those toxic albumins which cause the pyrexia, the bronchial gland preparations may yet prove of great value.

EXTRACTUM CORPORIS CILIARIS.—There is a little purplish-black substance in the eye-ball, called the ciliary body, which in its normal condition filters the serum and secretes into the eye a fluid, the aqueous humour, which is almost entirely free from albumin. In certain diseased conditions, such as sympathetic ophthalmia, the aqueous humour fails to be filtered properly, albumin enters it, and becomes deposited on the crystalline lens, thus gravely interfering with vision. Troubles of this kind can be modified considerably by the introduction of an extract from the ciliary body of the ox's eye, to which a little resorcin is added as a preservative. It can be injected under the conjunctiva or dropped into the eye, 1 drop every two hours.

GLANDULA PAROTIS.—A gland is situated in front of the ear, which, when inflamed, gives rise to that condition known as mumps. Frequently when inflammation leaves this parotid gland it settles in the ovaries or testicles. Hence it has been thought that an extract from the parotid might be useful in ovarian disease, and Drs. Bell and McGregor have cured ovarian affections by administering parotid substances. Dr. Bell reports over sixty cases of enlarged and painful ovaries, in which he not only asserted the necessity of an operation, but often effected complete recoveries by the use of the parotid treatment. Parotid gland preparations may be made from the organs of rams or ewes. The dried powder (*glandula parotis siccata pulverisatus*) is equivalent to ten parts of the recent gland, and may be given in 5-grain doses, or the warm gland may be treated with sterilised glycerin to form an extract, or with saline solution.

A few remarks on the general features which should characterise organo-therapeutic preparations may terminate this paper.

Organic juices, and all extracts made by the cold process should present the characteristics of albuminous solutions. They should be coagulable by heat, and be precipitated by strong nitric acid and by solution of potassium ferrocyanide with acetic acid. They give with strong alcohol in excess a precipitate which roughly indicates the strength of the solution, being greatest where the concentration is greatest. They should not give the reactions for albumoses indicated by a precipitation with acetified chloride of sodium, nor should they give the biuret reaction proper to peptones. Most of these preparations can be recognised as to their origin by the smell, or by microscopic examination of the residue evaporated after treatment with alcohol. When in solution they should be

be perfectly limpid and clear, with no trace of bacterial infection, as evidenced by the absence of any odour of putrefaction, though they may show traces of the characteristic odour of the organ with which they are obtained. All vessels containing organic extracts should be thoroughly sterilised, and such substances as tablets or powders should be freed from every trace of moisture and preserved in sealed bottles or in a receptacle containing lime.

Thyroid gland tablets should be suspected, unless they show traces of iodine. Dissolve a tablet in water and add some drops of strong nitric acid, afterwards a few drops of chloroform, which ought to show, after agitation, the characteristic violet tint.

NOTES ON FERRUM REDACTUM, P.B., 1898.*

BY E. SAVILLE PECK, B.A. (CANTAB), PH.C.

The British Pharmacopœia, 1898, describes this as "a fine powder, containing at least 75 per cent. of metallic iron, with a variable amount of iron oxide."

It characterises it as "a fine greyish-black powder strongly attracted by the magnet. It dissolves in hydrochloric acid with evolution of hydrogen and without any smell of hydrogen sulphide, and the solution gives a light blue precipitate with solution of potassium ferrocyanide." It then goes on to describe the method by which the percentage of free metallic iron can be arrived at. It was with a view to ascertaining to what degree commercial samples of ferrum redactum agreed with the tests of the P.B., 1898, that the following investigations were made:—

Fifteen samples were collected from different sources—wholesale houses, pharmacists, hospitals and drug stores. They were mostly received by post—one only being sent out in a bottle (sample X)—and immediately placed in bottles and weighing tubes.

The general appearance was noted in each case, and it will be seen in the subjoined table (B), that with few exceptions the more silvery grey the sample the more free metallic iron it contained. The brown masses mentioned consisted chiefly of ferric oxide (Fe_2O_3).

When treated with hydrochloric acid

- (1) No sample was found to dissolve completely, but left a variable residue of carbon and silica (SiO_2).
- (2) Hydrogen was liberated and in all cases yielded a smell resembling a hydrocarbon such as carburetted hydrogen or an olefine.
- (3) When this liberated hydrogen was passed through filter paper soaked in lead acetate solution, in every sample it caused a brownish to black coloration, due to lead sulphide, according to the quantity of sulphur present. The smell of hydrogen sulphide could not be always detected, being probably masked by the presence of the smell of the hydrocarbon. The presence of the sulphur doubtless points to the use of insufficiently purified hydrogen in the manufacture of the ferrum redactum.
- (4) The solution in hydrochloric acid gave with a solution of potassium ferrocyanide a blue precipitate varying from a light to dark colour.

ARSENIC.—In addition to the above pharmacopœial qualitative tests it was thought desirable to search for arsenic. The means selected was a modification of a test described in Crookes' 'Select Methods in Chemical Analysis,' under the names of MM. Mayençon and Bergeret. One gramme of ferrum redactum was placed in a small flask, and on to it was poured 20 C.c. dilute H_2SO_4 . The neck of the flask was lightly plugged with cotton-wool and tied over with a small filter paper. The latter was then moistened with 2 or 3 drops of mercuric chloride solution and the whole warmed gently. The presence of arsenic was indicated by the appearance of a

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

TABLE B.—Qualitative and Quantitative Analysis of Twelve Samples of Commercial Ferrum Redactum.

Sample.	General appearance.	Wt. taken for analysis.	Free Fe found.	Per cent. of do.	Sulphides indicated by smell.	Sulphides indicated by lead acetate paper.	Arsenic.	Insol. matter, such as silica and carbon.	Test with litmus paper.
A.....	Silvery-grey, slight lustre	·2345	·2080	88·67	Nil	Faint trace	Faint trace	Present	Nil

L.....	Chocolate-grey	·625	·552	88·33	Nil	Faint traces	Absent	"	Alkaline

lemon-yellow coloration, gradually deepening to pale yellowish brown. This is an exceedingly delicate reaction, the presence of 1 part of As_2O_3 in 100,000 parts of water being detected. This test is especially adapted to ferrum redactum, as no zinc is needed to be used, the action of the dilute H_2SO_4 upon the free metallic iron and arsenic generating the arseniuretted hydrogen, and, further, it is unnecessary to prepare a solution of the substance.

Nine samples out of twelve were found to contain traces of arsenic in variable quantities, and suggests the advisability of introducing a limit to its presence in future editions of the P.B.

Its source is probably from the impure zinc used in the generation of the hydrogen used in the manufacture of the sample.

ALKALIES, THE DETECTION OF THE PRESENCE OF.—One gramme of ferrum redactum was well shaken and slightly warmed with 5 C.c. of water, filtered and tested with red litmus paper.

When conducting this obviously simple test it is important that no ferrum redactum itself be allowed to come in contact with the litmus paper, because it was found that even those samples which, when treated in the above manner, yielded no alkaline reaction, yet when placed upon the red litmus paper in the dry state and moistened with a drop of water and exposed to the air, after a short while, turned it blue; doubtless due to the action of the oxygen and carbonic anhydride in the atmosphere.

Five samples were found to give distinctly alkaline reactions.

The presence of alkalies such as carbonates is of considerable importance from the fact that the free iron in samples containing them are more likely to become oxidised in a damp atmosphere.

Their probable source is doubtless insufficient washing of the precipitated hydroxide.

ASSAY.—The British Pharmacopœia, 1898, directs that .25 Gm. be added to a hot solution of 1 gramme of copper sulphate in 15 C.c. of water in a flask that can immediately be well corked, and the whole shaken occasionally during ten minutes. The liquid, after being rapidly filtered with minimum exposure to air and acidulated with sulphuric acid, should not cease to yield a blue precipitate with the solution of potassium ferricyanide until at least 33·7 C.c. of vol. sol. of potassium bichromate have been added.

This makes the minimum standard practically 75 per cent., or, more accurately, 74·9488 per cent.

In working the above method it appeared difficult to obtain concordant results until the following modifications and details were complied with.

(a) The ferrum redactum was finely powdered and intimately mixed until completely homogeneous.

(b) The solution of copper sulphate was tested for ferrous iron, found pure, and made according to the strength stated above.

(c) The ferrum redactum used was weighed out by noting the difference in weight of the corked tube containing it before and after pouring some of it out into a flask.

(d) The copper sulphate solution was added *cold* in the proportion of 15 C.c. to every .25 Gm. ferrum redactum taken. The advantage of adding it cold is that the action does not commence until each little particle of free iron has come into contact with the copper sulphate solution. It was found that when a hot solution was added little masses of iron became coated with metallic copper, and resisted the further action of the copper sulphate solution, and thus gave a slightly lower reading.

(e) The flask used was fitted with a Bunsen valve, this being simply a well-fitting cork pierced with a straight glass tube (about 30 Cm. in length), a small piece of indiarubber tubing with short slit in it, and glass rod to stop the open end. The oxygen of the air cannot enter, but the steam, etc., has free exit.

(f) The flask was then placed upon a water bath and shaken frequently during half an hour.

(g) It was then rapidly filtered, the precipitated copper and the iron oxides thoroughly washed with boiled distilled water, and the whole made up to 100 C.c. Of this 10 C.c. was taken and to it 10 C.c. dilute sulphuric acid added, standard permanganate of potassium solution (N/10 is a convenient strength) was then run in until faint permanent coloration took place. The mean of 3 or 4 determinations was taken, the number of C.c.'s used noted and calculated to percentage. The volumetric solution of potassium bichromate was used in the earlier determinations and was found to correspond with the potassium permanganate, but was afterwards discarded in favour of the latter, which was found more convenient in many ways.

By referring to table A it will be seen the results were satisfactorily concordant. By referring to table B it will be seen that five samples out of the twelve are above the standard of 1898, and six above that of 1885.

It appears therefore that while on the whole the percentage of free iron is fairly satisfactory, the presence of sulphides, carburets and arsenic points to insufficient care being exercised in some of the minor details of manufacture.

DETERMINATION BY MERCURIC CHLORIDE.—It was thought desirable to compare the foregoing results of the P.B., 1898, method with those of some other, and one was found in Berkurt's 'Analytische Chemie,' and this was afterwards found to be practically the same as that employed by the United States Pharmacopœia, 1890. The determination consists in the fact that the free metallic iron is converted by mercuric chloride into ferrous chloride ($FeCl_2$), according to this equation—

but there is evidently an intermediate stage, because mercurous chloride ($HgCl$) is undoubtedly formed and remains present throughout, being filtered off with the metallic mercury and undissolved oxides.

Process.—About .556 Gm. of ferrum redactum was carefully weighed out and placed in a flask with Bunsen valve, and upon

this was poured a solution of 2.5 Gm. mercuric chloride in 50 C.c. water, or in these same proportions, according to weight taken. The flask was then placed in a water bath and frequently agitated during one hour. It was then allowed to cool and made up to 100 C.c. and well shaken. 10 C.c. of the filtered solution was then taken, and to it added 10 C.c. dilute sulphuric acid, and titrated with the same standard solution of potassium permanganate until a faint permanent red coloration appeared, and calculated to percentage of free iron as before, see Table C.

TABLE A.—*Estimations by P.B., 1898, Method.*

Sample.	Weight of ferrum redactum taken.	Weight of free iron found.	Percentage of free iron.
X1266	.2438	91.68
2294	.2706	92.06
Y1263	.1543	58.68
2246	.1479	60.13
3326	.2010	61.65
Z1335	.1404	41.91
23385	.1410	41.66

To confirm the assay the slight red colour left over from above was decolorised by the addition of a few drops of alcohol, then about 1 Gm. of pure potassium iodide free from iodate added, and the whole kept at a temperature of about 40° C. for half an hour in well-corked flask. The liberated iodine was then titrated with standard thiosulphate of soda (N/10 being found convenient), and calculations made. Table C shows that concordant results can be obtained by this method.

TABLE C.—*Estimation of Ferrum Redactum by Mercuric Chloride Method.*

Sample.	Weight of ferrum redactum taken.	Weight of iron found.	Percentage do.	Percentage from thiosulphate confirmation.
X15595	.4795	85.74	—
26320	.5413	85.65	—
Y1579	.2335	41.19	41.20
25835	.2438	41.79	41.85
Z1850	.2722	32.03	32.07
2602	.1876	31.16	31.13
3480	.1527	31.82	31.93

By comparing the two methods, as in table D, it will be readily seen that the copper sulphate method invariably yields a higher percentage of free iron than the mercuric chloride method, but the difference between the two estimations keeps constant.

The reason for this discrepancy appears difficult to tell.

TABLE D.—*Comparison of Copper Sulphate (P.B., 1898), with Mercuric Chloride (U.S.A., 1890) Method for Estimation of Ferrum Redactum.*

Sample.	Percentage of iron by copper sulphate method, P.B., 1898.	Percentage of iron by mercuric chloride method, U.S.A., 1890.	Percentage. Average difference.
X1	91.68	85.65	} 6.18
2	92.06	85.74	
Y1	60.13	41.19	} 19.40
2	60.65	41.79	
Z1	41.91	31.16	} 10.29
2	41.66	31.82	

It was found that the solution of copper sulphate (as is invariably the case) gave an acid reaction with litmus paper, and it is conceivable that this acid formed with the ferrous oxide (FeO) frequently present in black samples such as Y, ferrous sulphate, and so tended to give a higher reading than the correct one. On the other hand, in the mercuric chloride method, the presence of mercurous chloride may have a deterrent effect upon the oxidising action of mercuric chloride upon the free iron present, and so tend to lower the

reading in this case, but up to the present I have been unable to find a satisfactory reason for the discrepancy.

SEPARATE DETERMINATIONS of the different oxides (FeO, if present, Fe₂O₃ and Fe₃O₄) might throw light upon the subject.

In conclusion, I would venture to suggest that in the preparation of ferrum redactum

(a) The ferric hydroxide should be ordered to be thoroughly washed and the hydrogen carefully purified ;

(b) That more stringent tests be added to ensure the absence of sulphides ; of more than 1 per cent. of insoluble residue and of alkaline carbonates ;

(c) That there should be a limit to the amount of arsenic present, and (d) that various modifications be made in the method for estimation.

I have to thank Mr. R. Foster Moore for his valuable assistance in many of the weighings and titrations.

NOTES ON "CONCENTRATED OIL OF LEMON."*

BY T. H. W. IDRIS, F.C.S.

At a meeting held in a city so well-known in connection with the aerated water industry as Belfast, and with which industry I have been connected for the greater portion of my life, it has occurred to me that notes on the two principal flavourings used in that industry would be of interest to pharmacists as well as to mineral water manufacturers.

Under the presidency of a gentleman who has done good work in this direction, I venture to offer some casual observations on the general results of investigations that have been carried on by me in the laboratory of my firm at various times, extending over many years, personally, and in conjunction with Dr. Symons, Mr. R. A. Cripps, Mr. Ernest J. Parry, and Mr. Frank Stephens.

It is not necessary for me to recapitulate the various well-known data respecting oil of lemon, such as the specific gravity, rotation, and boiling points of the oil and its various constituents, which can be found in the text-books on the subject and in the published results of Tilden, Bourchardat, Lafont, Beck, Schimmel, Ladell, Criswell, Hofmann, Doebner, Umney and others, but it may be desirable to remind ourselves that the well-defined constituents of lemon oil consist of limonene C₁₀H₁₆ (a terpene), the aldehydes, citral C₁₀H₁₆O, and citronellal C₁₀H₁₈O, with a small quantity of non-volatile matter. Small quantities of other bodies have been found by different experimenters, and my experience leads me to the conclusion that even pure lemon oil is a much more variable article than is generally supposed, and commonly contains about 4 per cent. of some body or bodies heavier than terpene and which cannot be classed amongst the other constituents mentioned. With a view of elucidating this I hope to carry out more complete experiments and to report the result later on, but this note is not written with the intention of explaining any complex chemical problem relating to the exact constitution or the composition of lemon oil and of the various bodies contained in it, but more with the idea of showing how some easily separable substances can be obtained from lemon oil, and which contain in a concentrated form most of the odoriferous and flavouring principles of the oil. The term concentrated oil of lemon is, of course, a misnomer, as the terpene (limonene) has a flavour and pungency which are peculiar to itself. It is well known that, in addition to the changes which occur from age or from exposure to air, oil of lemon decomposes much more rapidly when diffused in water or aerated water, and this most objectionable occurrence from a manufacturer's point of view renders lemonade made from oil of lemon

* Read at the British Pharmaceutical Conference held at Belfast, August, 1898.

unpalatable in a very short period, and this change is generally, and I think rightly, attributable to a change in the terpene, an odour of turpentine being developed. To obviate this difficulty various tinctures of lemon peel are used by many manufacturers, but lemonade prepared in this way, although having much better "keeping" qualities, is somewhat deficient in the aroma of lemon aldehyde which is desirable in a good beverage.

Essence dealers and manufacturers have accordingly been offering various forms of "concentrated soluble essence of lemon." The first specimens which I came across under this designation were simply oil of lemon with an addition of alcohol, but although the addition of alcohol in a proportion of not less than 10 per cent. absolutely prevents change in oil of lemon, and is consequently a desirable adjunct, the change in the oil when diffused in water is not lessened.

Other samples that I met with contained in addition to the alcohol other flavourings which appeared principally to be additions of small quantities of lemon grass oil or of citral¹ obtained from that oil, and in some cases an admixture of ethers with the oils of lime and orange. All these mixtures are not of much value to the mineral water manufacturer, but the so-called "terpeneless oils" have been an introduction of decided utility. These "terpeneless" oils as sent out by the makers differ considerably, and the principal object of my note is to call attention to a method by which the lemon aldehydes in oil of lemon can be separated without much change and in a state of comparative purity. Fractional distillation of oil of lemon cannot be carried out at the normal pressure of the atmosphere without considerable change in the oil and in the products, but this difficulty is overcome by fractional distillation under reduced pressure. If oil of lemon be treated in this way, and about 85 per cent. distilled at a temperature below 100° C., the distillate will be found to be perfectly white; with a very poor lemon odour, the specific gravity being that of terpene. The distillate will not give any aldehyde reaction. If the remaining 15 per cent. of residue be treated with bisulphite of sodium in the usual way a crystalline mass will be obtained. I find, however, in practice that it is more desirable to distil about 90 per cent. of the original oil. The remaining 10 per cent. is an oily liquid which, on cooling, deposits a white sediment. The gravity is about 0.902 to 0.905, and when mixed with rectified spirit it deposits a dense flocculent precipitate. If distillation of the 10 per cent. residuum is continued under reduced pressure, a very aromatic, colourless oil is obtained, amounting to about 7 per cent. of the original oil; but I find that a better product results from passing steam through the residuum when a pale yellow oil is carried over and floats on the water. This possesses to a very marked extent the pure lemon aroma, and is a very different article from citral. The final yield from most oils operated upon in this manner is approximately 6 per cent. to 7 per cent. of the original oil, and it is found to be very useful in improving the flavour and aroma of lemonade. The residue solidifies on cooling, and only faintly smells of lemon. The terpene from treating considerable quantities of oil of lemon was not thought to be of much value, but I found later on that it could be readily disposed of at about one-third of the cost of oil of lemon, and the eagerness displayed in buying at this price suggested to me that it must be used as an adulterant, and it will be readily seen that it is quite possible to prepare an oil from what appears to me to be the useless residues and the addition of citral from lemon grass oil, which would have the correct gravity, boiling point and rotation of oil and rotation of distillate (B.P., 1898 test), and with or without being mixed with the genuine lemon oil well-nigh impossible to detect, showing even the normal amount of aldehyde. I am also

of opinion that mixtures of lævo-rotatory (French) turpentine or dextro-rotatory (American) turpentine with other oils and citral can be made and are made, so that it is impossible to distinguish them from pure lemon oil by any known chemical or physical test. The question naturally arises, how is it possible to judge of the purity of lemon oil if all the usual tests have proved to be futile? I venture to suggest that the best test of the purity of oil of lemon is treatment in the way that I have indicated, and then to judge of the value of the oil by the flavour and aroma of the separated aldehydes.

Modifications of this process of concentration and subsequent separation under diminished pressure are applicable for preparing terpeneless lime, orange, and many other oils.

THE GALENICAL PHARMACY OF THE 1898 PHARMACOPŒIA.*

BY F. C. J. BIRD.

The storm of adverse criticism which greeted the appearance of the last Pharmacopœia in September, 1885, affords a striking contrast to the comparatively mild protests against alleged defects in the formulæ and processes of the present volume which have as yet appeared. Nor on this occasion has it been found necessary to mar the reputation of the Pharmacopœia by the publication of a lengthy list of errors and corrections—ample evidence of the greater care and more practical knowledge brought to bear upon the compilation. Processes devised in the experimental laboratory, or at the working bench of the retail pharmacy, must be based on thoroughly sound principles if they are to successfully pass through the ordeal of trial on the manufacturing scale, the true test of perfection in any process. Shortcomings in an official formula may, when small quantities are concerned, usually be compensated for by dextrous manipulation, but as soon as grammes give place to kilos any error becomes highly magnified, and the difficulty of successfully carrying out the operation enormously increased.

Sufficient time has now elapsed for exhaustive trials of the new and altered official formulæ, and the fact that so few serious faults have been discovered completely raises the labours of the compilers above that reproach of "easy-chair work" which was thrown, perhaps not quite undeservedly, at the last edition of the Pharmacopœia.

The objects of the present short paper are to briefly convey a general idea of the influence which the galenic pharmacy of the new Pharmacopœia has had upon the work of the wholesale laboratory, and more particularly to elicit the experience and views of fellow-workers from the retail stand-point in the useful discussion which I trust will follow.

Two apparently incompatible incentives are ever present to those who have control of commercial laboratories, viz., excellence of product combined with economy of production. Even a Pharmacopœia cannot afford to neglect these indispensable elements of successful work, and that this has been recognised is evidenced by the fact that some of the most rational and useful of the alterations in official processes are based on the practice of the manufacturing laboratory.

A somewhat revolutionary principle is involved in the omission of a detailed description of processes which can only be conveniently and economically carried out on the large scale. Not so many years ago the man who not only guaranteed the preparations on which his reputation depended, but actually made them himself, was alone considered to be a pharmacist in the highest sense of the

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

word. But as extremes of all kinds are generally bad, the conviction has forced itself upon us that too strict an adherence to the hard and fast lines of ideal pharmacy is fraught with disadvantage. Specialism and division of labour are the tendencies of the age. The conservatism of pharmacy has long and stubbornly struggled against their influence, but the pages of the new Pharmacopœia reflect the result of the unequal contest. The pharmacist of to-day is, by education and training, in a position to guarantee the quality of the chemicals and preparations which he vends. Not that he necessarily has made them himself—the traditional pharmacist of a previous generation may have done so—but with confidence in the source of those preparations which he does not manufacture, supplemented by his own practical knowledge, he may, without diffidence, take the full responsibility of his wares, and continue to occupy that honourable position in the community to which he is justly entitled.

Concentrated infusions, the horror of the pharmaceutic purist, and the theme of many a solemn admonition to the younger generation, have at length insinuated themselves within the pages of our official guide under the guise of Liquores Concentrati. Nor on reflection does it seem unreasonable that the same skill and perception of the idiosyncrasies of a particular drug under treatment which enables the pharmacist to prepare a perfect tincture or liquid extract should also aid him to solve, under somewhat different conditions, a similar pharmaceutical problem.

Uniformity is a dominating idea in the revised Pharmacopœia. The greater precision of language and more accurate definition adopted are welcomed in the laboratory, and will do much to prevent that undesirable variation in the physical character of the product of a given formula emanating from different sources which is always likely to occur when the wording of that formula permits of too much latitude in its interpretation.

It will only be possible in the limited space at my disposal to cursorily glance at the more important classes of galenicals and indicate the direction in which they have been affected by official alterations.

EXTRACTA.—The new and altered extracts are, on the whole, a greatly improved class of preparations. Chief amongst them must be mentioned Ext. Cascar. Sag. Liq., the formula of which is in every way an advance on that of 1885. By the new method the bark is completely exhausted (boiling water removes less than $\frac{1}{2}$ per cent. of tasteless extractive from the marc) and the tedious filtration necessary in the old process can now be dispensed with. The addition of the alcohol throws down an almost negligible precipitate, especially if the aqueous liquid has been carefully decanted before the final evaporation, and considering the enormous demand and large scale on which this preparation is made, the new process comes as a boon to the laboratory worker. Ext. Belladonnæ Alcoholic., whilst now possessing the advantage of a standard strength in alkaloid, cannot be regarded as a perfect galenical; in fact, as far as physical appearance is concerned, its claim to the designation of extract is not apparent. If made sufficiently soft to be of a pilular consistence, hardening occurs at the surface, with consequent variation in potency. Evidently a more suitable diluent is a desideratum. Ext. Belladonnæ Liq.: At the Oxford meeting of the Conference it was suggested that re-percolation might advantageously be adopted as an official process, and this is one of the instances in which the compilers of the Pharmacopœia have considered it applicable. Complete exhaustion of the belladonna root must not be expected by the process as written, for the condensation of the active principles of 2 lbs. of belladonna root in 12½ fl. oz. of product by following the official directions would tax the ingenuity of the most skilful operator. But the application of

heat, which is so detrimental to the colour of the extract, is avoided, and it is always open to the pharmacist to continue percolation (as is usually done) with more menstruum to exhaustion, the weaker fractions being reserved for use in a subsequent operation. Re-percolation gives excellent results with Ext. Sarsæ Liq.; it might also have been extended to Ext. Cocæ Liq. and Ext. Pareiræ Liq. Extractum. Ergotæ, 1885, was unsatisfactory on account of the indefinite expression "syrupy consistence" which occurred in the formula. Just according to the construction placed upon that expression, so the yield and presumably the activity of the product varied, but such a fault is avoided in the new process, which apparently leaves little to be desired. One of the greatest improvements from a laboratory point of view has been effected in the formula for Ext. Glycyrrhizæ Liq.: Made in the old way it was a constant source of trouble, for not only might the undecorticated root be employed for the 1885 preparation (to the detriment of its flavour and sweetness), but the proportion of rectified spirit was quite insufficient to prevent fermentation in hot weather, so that it was absolutely necessary to depart from the literal directions of the Pharmacopœia and evaporate to a higher gravity in order to admit an increased proportion of spirit without interfering with the volume of the product. These faults have now been corrected, and the present formula is an admirable one. Ext. Nucis Vom.: Standardisation with sugar of milk appears to be successful in this case, as unlike Ext. Bellad. Alch. there is sufficient evaporated liquid to take up the sugar of milk and at the same time retain the physical characters of an extract. Ext. Nucis Vom. Liq.: Here re-percolation is inferior to the official method, the whole of the alkaloids being with difficulty removed from the seeds by solvent already partly saturated with extractive matter. Percolation with fresh solvent and distillation as directed easily produce an extract of full strength. Ext. Ipecacuanhæ Liq.: The intention of the compilers was presumably to make this a 1 in 1 preparation, but the alkaloidal standard fixed upon (2.25 per cent.) rarely admits of 16 fl. oz. of extract being obtained from 1 lb. of root. Ext. Pareiræ Liq.: In spite of considerable criticism this process has proved a workable one and the extract deposits less than formerly. But re-percolation would probably have been more suitable, as already mentioned.

The more frequent instruction to "evaporate to dryness" and the introduction of extracts reduced to powder with sugar of milk is a distinct advance in the direction of uniformity, for in these cases the operator is now relieved of all doubt as to the meaning of such indefinite expressions as "suitable consistence," "consistence for forming pills," "soft extract," etc., which were of common occurrence in the last Pharmacopœia.

LIQUORES.—The liquores concentrati rank foremost in interest amongst the numerous additions to this class. Their insertion marks a change in the official attitude which, by many, has long been regarded as inevitable, for they are introduced as the result of many experiments made with the object of preparing decoctions and infusions in a highly concentrated state, which should resemble the liquids termed by manufacturers "concentrated infusions and decoctions." The methods given for the preparation of these liquors, although perhaps not so perfect as those followed commercially in the manufacture of concentrated infusions, are on the whole successful, the liquors sarsæ co., senegæ and quassiæ being amongst the best. Some are deficient in keeping properties, and in those formulæ constructed on the model of liq. chirata conc., it would seem to be more in accordance with the accepted principles of percolation to direct "that the marc be kept covered with menstruum, and the percolate allowed

to flow regularly at such a rate that the whole operation may extend over eight days." Considerable doubt exists as to the manner in which the compilers of the Pharmacopœia intend the Liquores Concentrati to be employed. May I suggest that the idea in their minds was that a medical man when writing a prescription would order the official dose of a liquor in place of the corresponding fresh infusion, and I think this view is supported by the statement in the preface that "the products of their dilution may be prescribed by practitioners in place of the corresponding official infusion." Naturally, in a mixture "Aquæ ad" would give the product of their dilution. Used in this way the Liquores Concentrati would neither interfere with the fresh infusion nor its concentrated representative. Liq. Calumbæ Conc.: Calumba Root is, in this formula, directed to be twice macerated and pressed with given quantities of distilled water, the expressed liquids being afterwards heated to 180° F. and mixed with alcohol. The quantity of expressed liquid obtained from a drug like calumba depends on the power of the press, hence an element of uncertainty exists which is likely to cause variation in the product. This could have been minimised by directing sufficient water to be taken for the second maceration to furnish a definite volume of expressed liquid. Liq. Sennæ Conc.: The product of this formula does not usually measure one pint, as evaporation during the heating of the liquid, precipitation, by the alcohol, and absorption by the filter together tend to make the loss in volume more than the $\frac{1}{2}$ oz. allowed. If the liquid after heating were made up to 16 fl. oz., and the well-drained filter washed, if necessary, with 20 per cent. alcohol to 20 fl. oz. product, greater uniformity would be ensured. Liquor Thyroidei is the herald of a new series of preparations which is probably destined to find a permanent place in future editions of the Pharmacopœia. Scrupulous cleanliness and perfectly fresh and healthy glands, free from cysts, are absolutely essential for the preparation of a reliable thyroid solution; in other respects the process presents no difficulty if the official directions are closely followed. Half per cent. phenol solution in conjunction with glycerin is used as a preservative, but it is doubtful whether this is the most efficient that could have been employed.

SPIRITUS.—The process for Spiritus Ætheris Co. involves distillation of a mixture of alcohol and sulphuric acid at a high temperature. Few ordinary pharmacists, unless possessing special facilities, would undertake the risk of this operation, and under the circumstances a modified formula embracing an outline process, with characters and tests for oil of wine, and directions for its solution in spirit and ether, would have been preferable. Spirit Æther. Nit.: Deficiency of product due to loss of nitrous ether in the old process is now avoided by placing a portion of the alcohol in the receiver, in order to absorb any ethereal vapour which may have escaped condensation. A better yield is thus secured which may still further be increased by conducting the distillation under slight pressure as advised some years ago by Mr. E. H. Farr. The apparatus (all joints of which must be quite air-tight) is set up as usual, but a tube led from the receiver is made to dip under the surface of mercury to an extent dependent on the pressure which the retort, etc., will safely stand.

SPIRITUS RECTIFICATUS.—The change in the strengths of the official alcohols is the most important and far-reaching of any that have affected the characters of the galenic preparations of the new Pharmacopœia. I must confess to not sharing the regret with which the disappearance of proof spirit has been viewed in some quarters. As long as the word "proof" remained on the official page there was always an inducement to use it as a standard of alcoholic strength, but its removal has cleared the way for the

more rational, scientific, and infinitely more convenient centesimal system now happily adopted. Long custom and daily contact with the proof standard have rendered it indispensable to the British Excise, but for pharmaceutical purposes the new method of expressing alcoholic strength has all those advantages over the old which metric weights possess when compared with avoirdupois weights. Forty or fifty over-proof is meaningless to the average mind as an expression of alcoholic strength, whilst the terms 40 or 50 per cent. alcohol at once call up a tangible idea of relative alcoholic value. The ease with which volume-percentage has displaced proof degrees in the routine of the laboratory is surprising, and the compilers of the Pharmacopœia are to be congratulated on having so boldly departed from the beaten track by authorising a system both convenient to work with and widely acceptable. Mixture by weight, where liquids are concerned, is not the general rule of the Pharmacopœia. There are, however, instances in which it has been thought desirable to order liquids in parts by weight; for example, the liquid ingredients of the ointments. This principle, which is particularly applicable when rise of temperature is a consequence of the act of mixing, might, with the view of increasing the usefulness of the formulæ, have been extended to the diluted alcohols and to certain of the diluted acids, for it is obvious that when the components of mixtures have to be measured at 15°·5 C. and the final volume adjusted at that temperature mixture by weight is in such cases both quicker and more accurate.

SYRUPS.—Keen disappointment has been felt at the absence of Syr. Ferri Phosph. Co. and Syr. Hypophosph. Co. These two syrups are manufactured in enormous quantities, but as all makers do not follow the B.P.C. Formulary there is great variation, and authoritative processes for their preparation were eminently desirable. Syrupus Aurantii is improved in flavour by the tincture of fresh peel now used. Syrup. Ferri Iodid. has changed for the better in several respects. The useless and detrimental boiling together of syrup and ferrous iodide solution is omitted, the loss of iodine by volatilisation and absorption in the filter paper, which formerly rendered it impossible to produce a syrup of full official strength, is now prevented by boiling slightly and washing flask and filter with diluted syrup—practical details of great importance. Although the much needed reduction in the quantity of sugar has been effected, the sp. gr. remains about the same on account of the ferrous iodide having been increased to 10 grammes in 100 C.c., probably to bring the syrup into line with the percentage system of the Pharmacopœia. Formulæ for Syr. Ferri Bromidi and Syr. Picis Liquid., two syrups in very general demand, might usefully have been included. It is disappointing that the faults which have so frequently been pointed out in the process for Syr. Rhei are still left uncorrected. Amongst other defects may be mentioned the wasteful procedure (surely unworthy of official sanction) of evaporating an alcoholic percolate. Syr. Rcsæ, an unimportant syrup, also remains unaltered; it might advantageously have been remodelled on the lines of the U.S.P. formula. Syr. Sennæ: This is a great advance on the old syrup. The senna is "extracted by pressure," by which the greater part of the injurious and lengthy evaporation of the old process is avoided, and a product obtained which, although rather thin, is of excellent appearance and aroma. Syr. Papaveris has been omitted without the provision of any adequate substitute. The undesirability of officially retaining a powerful narcotic like Syrup of Poppies, "which is of variable activity, cannot be standardised, and is unfit for medicinal treatment, especially of children," is the alleged reason for its deletion, but although this is certainly consistent with the general principles of the new Pharmacopœia, the preparation in question

being extensively used in domestic medicine, will still be manufactured and sold, and it is doubtful if the object of its omission will be attained. The difficulty might possibly have been overcome by introducing, under some such title as *Syr. Opii Co.*, a formula for a similar syrup, based on a standardised preparation of opium. Would the B.P.C. Formulary Committee consider the suggestion?

TINCTURÆ.—The new and altered formulæ of the tinctures, foreshadowed by the work of Farr and Wright, were finally adopted by the Pharmacopœia Committee of the General Medical Council, after an examination of "some hundreds of tinctures, spirits, etc.," prepared by the Editor of the Pharmacopœia; and the result of the alterations, extensive as they are, has, from a laboratory point of view, proved in most cases entirely satisfactory. *Tinct. Aurantii* is far superior in aroma to the 1885 tincture. The objection that has been raised to the use of the fresh peel, viz, that it can only be obtained at a certain season of the year, can hardly have much weight when it is remembered that many other official drugs (poppy petals, green herbs, etc.) labour under the same disadvantage. *Tinct. Opii*: The well-known faults of the 1885 process have been corrected. The new method is quicker and more easily carried out, exhaustion can be completely effected, and by the final adjustment in strength (a most important improvement) uniformity is ensured. *Tinct. Rhei* is remarkable for the omission of saffron and replacement of part of the 60 per cent. alcohol by glycerin. It is the only tincture prepared by percolation which contains glycerin. The result, however, is in this instance a decided success.

UNGUENTA.—Many improvements have been effected in this group. Experience in the use of the paraffin basis inaugurated in the last Pharmacopœia has had its effect on the present formulæ, and generally they may all be said to be highly satisfactory. Variation in colour of certain of the ointments has been prevented by designating the particular variety of paraffin to be used—a much needed provision, which will ensure uniformity in the future. *Unguentum Hydrargyri Nitratis* apparently still continues an unsolved problem. The formula as it stands does not in all cases give a perfect result, for the ointment is neither of a very good colour when made, nor does it retain its colour for any length of time when kept. Moreover, the high temperature to which the fat and oil are directed to be heated renders the operation a difficult one to carry out, especially on the large scale. A modification of the official process, which yields an excellent product, depends on the fact that lard, either crude or imperfectly oxidised, has a powerful reducing action on nitrate of mercury ointment, whilst olive oil has little or none.

If, therefore, the lard be heated on a water bath with the nitrate of mercury solution to as high a temperature as possible until reaction nearly ceases, and the olive oil then added, the heat being continued for a short time, a product of excellent colour and consistence will be obtained. This process is more manageable than the official one; by completely oxidising the lard with excess of solution of nitrate of mercury the keeping qualities of the ointment are greatly improved. *Ung. Conii*: The boric acid is omitted; this ointment now becomes mouldy on keeping.

The assay processes of the new Pharmacopœia have been found to work well in the analytical laboratory. The one for morphine in opium is now trustworthy and free from error. H. Wilson has shown that in some instances the analytical details may be simplified or shortened, sources of loss eliminated and slightly higher figures obtained; probably with the record of more experience other suggestions will follow. At a certain stage in the *nux vomica* estimation, for example, the

alkaloid is directed to be precipitated in a stoppered flask, the strychnine ferrocyanide transferred to a small filter, washed, and rinsed into a separator, an operation presenting some slight difficulty with the possibility of loss. A more convenient plan is to precipitate the alkaloid in the separator itself (which must have a capacity of 200 C.c.), having previously inserted a minute tuft of cotton wool in the tube of the separator just above the tap. The precipitate is readily kept back by the cotton wool, on which it collects, and the column of liquid in the tube below the tap accelerates the drawing off of the mother liquor and thorough washing of the precipitate. The cotton wool in no degree interferes with the subsequent part of the process.

The standardisation of so many galenicals calls for increased care and more intelligent application of pharmaceutical principles on the part of the laboratory operator, which, however, have their recompense in the comparatively simple processes now given for those preparations which are based on assayed extracts, etc. It cannot be denied that the alterations and improvements in the galenicals are calculated to render them, as a class, more unvarying in activity and more uniform in physical characters than their forerunners in the Pharmacopœia of 1885, whilst the impression gained by a practical experience of the working of the official processes on the large scale since the day of their publication in May last is, that generally speaking, the galenical pharmacy of the 1898 Pharmacopœia is sound, up to date, and thoroughly abreast of the requirements of modern pharmacy.

THE GREEN EXTRACTS OF THE PHARMACOPŒIA.*

BY W. A. H. NAYLOR, F.I.C., AND JOHN J. BRYANT.

The results embodied in this paper are intended to supply data that may assist in framing a reply to question No. 48 of the Conference Blue List, the exact wording of which is as follows:—

"It is obvious that green extract of belladonna, extract of henbane, and extract of stramonium should be standardised. A simple process of assay and definite proposals for standard strengths are desirable."

No mention will be made of extract stramonium, as we have been unable to obtain samples made from the juice of the plant. It may be surmised that the Committee of Revision of the Pharmacopœia refrained from fixing the amount of alkaloidal content until pharmacists could show that what was desirable was also practicable. In the sixteenth edition of Squire's 'Companion' the alkaloidal strength of ten samples of the extract of belladonna are given. No indication of the method by which they were assayed is afforded.

The process we have adopted may now be described:—

From 2 to 5 Gm. of the extract is weighed into a wide mouth flask (for convenience an Erlenmeyer flask is recommended), 25 C.c. of 90 per cent. alcohol is added, and the flask with its contents heated on a water bath under an inverted condenser or other arrangement that prevents loss of alcohol and provides facilities for exhaustion. This operation is twice repeated with two more quantities of 25 C.c. of 90 per cent. alcohol. After each operation the alcoholic solution in the flask is allowed to become cold, and filtered, and the filtrates are united.

To make sure that extraction of the alkaloidal content is complete, the residue in the flask is warmed with a 5 per cent. solution of hydrochloric acid and filtered. The filtrate is then tested with solution of iodine in potassium iodide. We have found that three extractions with alcohol are sufficient for the purpose.

To the alcoholic solution of the alkaloid an equal volume (75 C.c.) of a 5 per cent. solution of the hydrochloric acid of the

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

Pharmacopœia is added, and the mixture shaken up three times successively with 15 C.c. chloroform. After separation and rejection of the chloroformic liquids the acid solution is rendered distinctly alkaline by the addition of solution of ammonium hydroxide and again shaken up three times successively with 10 C.c. chloroform. The chloroformic solutions, after withdrawal, are mixed and evaporated, and the residue dried over a water bath until it ceases to lose weight. The dry alkaloidal residue is titrated as the Pharmacopœia directs in the final stage of the process for determining the proportion of alkaloid as given under *extractum belladonnæ liquidum*.

The chloroformic separations take place quicker and cleaner than is the case in the Pharmacopœia process for liquid extract of belladonna.

It may be noted that the difference between the amount of alkaloid obtained by weighing and that indicated by subsequent titration is less than 0.01 Gm.

The following table gives the exact results obtained from weighing and titration, and shows by difference the amount of impurity in the alkaloidal residue. Two estimations of each sample of extract are given. In the table are included the published analysis, by John Barclay, B.Sc., of the green extracts of belladonna* met with in commerce, and also those given in the seventeenth edition of Squire's 'Companion':—

One great drawback to Barclay's process is, it is unnecessarily complex, inasmuch as it effects the solution of mucilaginous substances which in a subsequent operation have to be precipitated and rejected.

Green Extract of Belladonna.

The extracts of henbane were assayed by the process described and adapted for extract of belladonna, and the results obtained are given in the subjoined table. Two assays of each extract are given:—

We desire to direct attention to the fact that the extracts referred to in both the tables were supplied by growers of belladonna and henbane, who are also makers of the corresponding green extracts, or by makers (not growers) on a larger scale. They are all made from herbs grown in England in localities for

* *Pharm. Journ.* [3], xxiii., pp. 740.

the most part far removed from each other. They may be accepted, therefore, as representative samples, that is, as representing the extracts supplied to dispensing pharmacists by wholesale firms of acknowledged repute. There is no reasonable ground to hope that an examination of samples taken from the dispensing counter of chemists throughout the country would show a much nearer approach to uniformity of strength. They suffice to confirm the observations of others as to the great variation in alkaloidal strength that exists in extract of belladonna,

No.	Amount taken.	Weight of alkaloid.	N/10 acid HCl consumed.	Yield of alkaloid by titration.	Amount of impurity.	Per cent. of alkaloid by weighing.	Per cent. of alkaloid by titration.

and they also show that the variation is proportionately great in the case of extract of henbane. It would be an advantage if growers of these herbs who also make these extracts would supply to the British Pharmaceutical Conference data bearing upon the influence of soil and seasons in respect of yield of alkaloid.

The extracts are widely used, and so long as they find a place in the British Pharmacopœia it is desirable to fix for them a standard of alkaloidal strength. The experience of one of us proves that there is no difficulty in making green extract of belladonna to contain 1 to 1.25 per cent. of alkaloid. Why, then, not fix the strength of the extract at 1 per cent. of alkaloid, using, when necessary, sugar of milk as a diluent, and so bring it into line with the official alcoholic extract? For the extract of henbane we suggest 0.2 per cent. of alkaloids.

THYROGLANDIN.*

BY E. C. C. STANFORD.

There is a pretty general opinion amongst medical practitioners that the various known preparations obtained from the thyroid gland of the sheep leave something to be desired in uniformity of action and in efficiency as a substitute for the raw gland. The absolute cure of a fatal, though fortunately rare, disease, myxœdema, and the importance of its use in commoner complaints, such as obesity and psoriasis, have brought the thyroid gland into prominent notice and into daily extending use. This is shown by the fact that the new British Pharmacopœia has two preparations of it, one, *thyroideum siccum*, is simply the gland dried at a temperature of 90° to 100° F., and the other, *liquor thyroidei*, a glycerin and phenolised cold water extract. There are a number of other preparations in the market, the most important of which is thyroïdin, discovered by Baumann. Probably the most efficient, as well as the most largely used, is the dried gland. The objection to the use of this form is that it is just as dangerous as the raw gland, in that it may introduce into the system bacteria or other matters of foreign origin, which may give rise to disagree-

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

able symptoms, and, indeed, these have been complained of and are already known as thyrioidism. The objection to the glycerin extract is that it does not dissolve out the thyrioidin, and the objection to the use of the thyrioidin alone is that, although perhaps the most active principle, it does not represent all the active constituents of the gland.

Thyrioidin is obtained in destroying the greater part of the gland by boiling for thirty hours in 10 per cent. sulphuric acid (Bayer's Patent, No. 12295, 1895) or by boiling it in 3 per cent. caustic soda solution, and precipitating the thyrioidin by an acid (Bayer's Patent, No. 20827, 1895), or by digesting the gland with pepsin, or by heating it in a close vessel at 180° C. with water (Bayer's Patent, No. 9576, 1896). In each case the gland is destroyed and the thyrioidin only extracted. The thyrioidin is a stable compound and not easily decomposed. It exists, according to Bayer, in small proportion, about 1 in 333 or 3 per mille. The thyroid gland contains two important principles, each containing iodine, iodo-globulin, and thyrioidin. The iodo-globulin in all the above methods is destroyed. I find it can easily be extracted by cold water, and that this solution can be evaporated at 212° F. without in any way impairing its activity. This substance amounts to about 17 per cent. of the raw gland, and is quite active alone. It contains iodine.

The thyrioidin, which is more active, but existing in smaller quantity, can then be extracted from the residual gland, after maceration in cold water, by boiling it with weak caustic soda solution for an hour, and precipitating by an acid. The process I adopt then is as follows:—The thyroid glands, freed from fat, are first minced, macerated in four to five times their weight of cold water (using ice, if necessary, in summer, to keep down the temperature to 50° F.) for twenty-four hours, and this maceration is repeated. The solutions are filtered off and evaporated to dryness at a temperature not exceeding 212° F. The extract is powdered, and represents the iodo-globulin and a small proportion of saline matter. The residue from the cold water maceration is boiled for one hour with a 1 per cent. solution of caustic soda in the proportion of 1 per cent. of caustic soda to the original gland. This solution is allowed to cool, to deposit the fat, and filtered off. The solution is then carefully neutralised with hydrochloric acid and evaporated to dryness at 212° F. The residue, which contains all the thyrioidin, is then powdered and mixed with the iodo-globulin obtained in the first process. The resulting powder is the new preparation to which the name of thyroglandin has been given. The last evaporate may be digested with petroleum spirit to remove traces of fat, but in all ordinary cases the amount is so small that this is unnecessary.

It may be asked why I do not separate the thyrioidin by acid precipitation. The reason is that the precipitation is never complete on account of its partial solubility in the saline mother liquor. Even in Baumann's process of boiling with 10 per cent. sulphuric acid only a portion is thrown down; much remains in the acid solution, and after neutralising it with soda and evaporating the sodium sulphate liquor it continues to deposit even down to crystallisation, and cannot be entirely removed. In four experiments with this process I found an average yield of 3.34 per cent. thyrioidin, of which 0.55 per cent. was precipitated and 2.99 per cent. recovered from the mother liquor.

My experience with acid precipitation from soda solutions is that the thyrioidin is even more soluble and difficult to remove. So I retain it all by evaporation, with the addition of a small quantity of sodium chloride. This addition makes it a palatable preparation, and consequently no objection on the part of the patient is made to taking it in powder. The result gives about

8 per cent. on the gland, so that the usual yield of thyroglandin is about 25 per cent. The gland yields 29 to 30 per cent. of dry matter, so that the dose is rather less than that given in the B.P., which is 3 to 10 grains. The weight of the thyroid gland differs enormously; I have found them vary from 24.2 grains to 136 grains, but the most usual weight is 33.3 grains, or about 3 glands to 100 grains, so that 8.6 grains thyroglandin = 1 gland. The dose, therefore, if half a gland is taken is 4.3 grains, a quantity not too large for ordinary patients to take in powder. Of course it may be compressed into pellets if desired. By one gland I mean one lobe, of which there are two in the animal.

I claim that this preparation does really represent the activity of the raw gland without its disadvantages and dangers, and that it contains the active principles in the form and proportion in which these exist in the raw gland. Considering the raw material used, this preparation is remarkably uniform. This is proved by the cases given by Dr. McLennan, of Glasgow University, in the *British Medical Journal*, July 9, 1898, and by several other observers, whose reports have not yet been published. No unpleasant symptoms were observed in any of the patients who took this preparation.

An outline of the process was given in Dr. McLennan's paper, and it has been criticised in the *British Medical Journal*, July 16, 1898, by Dr. Hutcheson, who naturally prefers a process of his own. This consists in macerating the glands in cold 1 per cent. caustic soda solution, and precipitating the colloids by acetic acid. This would be a convenient method if it were effectual; but the caustic soda in the cold does not dissolve out the thyrioidin, for on boiling the residue with 10 per cent. sulphuric acid much thyrioidin can be extracted. Then the iodo-globulin, which is easily extracted by cold water, is altered by caustic soda, so that the colloid precipitated by acetic acid is not the same as the iodo-globulin dissolved, as might be expected, with such an easily altered body. The precipitation is not complete, for the acetic acid mother liquor, if neutralised and evaporated down, still contains a considerable proportion of the iodine.

My results in this process gave precipitated colloids, 6.67 per cent.

Thyrioidin in residue, 15.25 per cent., very hygroscopic, extracted by boiling in 10 per cent. sulphuric acid

In another German patent the glands are extracted by a $\frac{3}{4}$ per cent. solution of sodium chloride and the solution precipitated by tannic acid, but here a foreign body is introduced into the colloid. The precipitation is not complete, the mother liquor contains iodine, and the residual gland contains thyrioidin.

My results with this process gave—

Colloid tannin precipitate, 16.94 per cent.

Thyrioidin in residual gland, exhausted by boiling in 10 per cent. sulphuric acid, 0.234 per cent.

Here, again, the active principles are not all exhausted, as the sodium chloride does not dissolve out the thyrioidin.

In both these cases more thyrioidin might have been recovered from the saline solution, as only that precipitated is given.

HYDROGOL AND ORANGOSOL.—Schneider gives these names to two solutions of colloidal silver, the first of which is prepared with water and the second with an organic fluid, *i.e.*, alcohol. Colloidal silver is a modification of metallic silver soluble in water obtained by precipitating solutions of nitrate of silver with certain reducing agents. Credé recommends colloidal silver as a substitute for his actol and itrol in those cases where the introduction of silver salt into the circulation produces undesirable effects.—*Pharm. Post.*, xxx., 588.

KIESELGUHR AND OTHER INFUSORIAL EARTHS.*

BY JOHN MOSS, F.I.C., F.C.S.

Infusorial earths having recently come into request by pharmacists, and being very diverse amongst themselves, as well as suitable for a variety of purposes, it may be useful to collect leading facts of special interest concerning them, and to indicate particular applications of which they are susceptible. That is all this short paper professes to do.

KIESELGUHR is the German name for an infusorial earth which is found in Hanover. It means siliceous deposit, and aptly defines a geological formation consisting of the minute fossil shields of diatoms, which is nearly pure silica in those parts nearer the surface, whilst in others lower down it is contaminated with more or less organic matter. In Hanover the deposit is 150 feet thick from the surface downwards. The upper stratum is nearly white, with very little organic matter; lower down it is grey, with very little sand, but more organic matter. The lowest and thickest stratum is, according to Thorpe, from 50 to 100 feet thick and contains up to 30 per cent. of organic matter. We might argue from these facts that a process of oxidation goes on in the upper stratum, which changes the nature of the organic matter, rendering it more soluble and less coloured. A sudden rainfall would effectively wash this stratum, carrying the organic matter downwards to the lower stratum, which, being charged with air to an inferior degree, is less capable of assisting change; indeed, it would seem to have the power of preventing it, hence the accumulation of green colour and organic matter, which are said to be due to extractive from the pine needles strewing the surface of the earth above the deposit. This organic matter, together with the colour, is got rid of by calcining in small furnaces, which are filled with the kieselguhr and then lighted at the bottom. The organic matter suffices to keep the whole in a glow, like peat, and the process is made continuous by raking out below and supplying fresh material at the top. The calcined product consists almost exclusively of silica, and varies from very pale cream to a reddish colour, according to the proportion of ferric oxide present. Beckerhinn found 95 per cent. of SiO_2 and a specific heat of 0.2089. The strongest acids have, of course, no action upon it, but with alkalies it fuses easily, and a variety of soluble glass may be made in this way.

In France there occurs a similar siliceous earth called Randanite (from Randan in the Puy de Dôme).

Other deposits are found in Scotland, near Aberdeen, and in the island of Mull; in Norway, where it is called *bergmehl*; under the city of Richmond in Virginia, in the Bermudas, in Australia, in Algeria, in North Wales, at South Mourne and in many other parts of the earth.

Infusorial earth consists of the siliceous envelope of Diatomaceæ, a family of minute uni-cellular plants, also called "Brittleworts," from the facility with which they may be cut or broken through. The siliceous envelopes, or *diatoms* as they are commonly called, are usually of the most perfect symmetry, and often exhibit elaborately marked patterns of great delicacy, which endow them with extreme interest as microscopic objects. The forms may be simple or intricate, but all are beautiful. There are few objects so attractive to the microscopist as the minute siliceous framework of these low forms of plant-life, and many hundreds of different varieties have been catalogued.

Having regard to the origin of these deposits, diatomite would seem to be a name generally appropriate, and I purpose using it in this sense, as including all the varieties of siliceous earth above referred to. I cannot hope to name every kind of diatom which has

contributed to form each one of the deposits, but having examined several microscopically I may succeed in enumerating some of the more important individuals.

1. KIESELGUHR.—In this the forms recognised are *Surirella*, *Gaillonella*, *Diademesis*, *Pleurosigma*, *Synedra*, *Stephanodiscus*, *Spongolithis*, *Amphora*, *Melosira*, and *Navicula*.

2. SCOTCH DIATOMITE.—This occurs in the Island of Mull and near Aberdeen, and includes amongst other forms *Diatoma*, *Cymatopleura*, *Synedra*, *Gomphonema*, *Cocconema*, *Surirella*, *Primularia*, and *Rhabdonema*.

3. VIRGINIAN.—A stratum 18 feet thick underlies the whole city of Richmond, extending, indeed, over an indefinite and unknown area. It is so compact as to be capable of being carved into small objects, such as the bowls of tobacco pipes, but is at the same time light and friable. It is celebrated for the number and beauty of its forms, including *Coscinodiscus*, *Dictyolampa*, *Rhabdonema*, and *Triceratum*.

4. AUSTRALASIAN.—According to Dr. J. D. Hooker* there is a deposit consisting chiefly of the siliceous loriceæ of Diatomaceæ, not less than 400 miles long and 120 miles broad, at a depth of 200 to 400 feet on the flanks of Victoria Land in 70° south latitude.

5. SCANDINAVIAN.—This is known locally as *bergmehl*, a mountain flour, and contains sufficient organic matter to occasion it in times of scarcity to be mixed with dough in making bread. I have seen no specimen of this, and am unable to describe its appearance, or to name any diatom occurring in it.

6. AUSTRALIAN.—This is a beautiful white fluffy powder, of which specimens came into my hands in 1894, through the kindness of the South Australian Government and others. It consists almost solely of the loriceæ of *Tetracyclus*, with occasional *Pleurosigma*, *Surirella*, *Amphora* and *Diatoma*. There is ground for assuming that this and the Australasian deposit referred to above (which I have not seen) are the same.

The examination of eight different specimens of infusorial earth obtained from as many different sources shows important variations in composition. In no case does the silica (SiO_2) exceed 96 per cent., and it falls as low as 70 per cent., the differences being made up by moisture, organic matter, ferric oxide, and alumina. Moisture varies from 2.64 to 7.8 per cent., the average being 5.73 per cent. Organic matter ranges from 2.43 to 23.6, giving an average of 7.43 per cent. Of the professedly calcined earths, I have met with specimens containing so little as 0.4 per cent. of organic matter, but the proportion usually present is from 2.5 to 3 per cent., showing that the calcining is not perfect. Again, in some earths the iron oxide is as low as 25 per cent., and in others it is as much as 7 per cent.

USES.—Since 1866 diatomite has been largely used in the manufacture of dynamite. This is because it is capable of absorbing a larger proportion of fluid than any other known material that is at all available to the same extent. It will absorb three times its own weight of nitro-glycerin, and then be capable of being pressed into solid blocks.

It is also used to make so-called "dry sulphuric acid." One part of diatomite to 3 or 4 parts of oil of vitriol by weight may be mixed so as to form a mobile powder capable of being worked with iron implements and enclosed in iron drums for export without attacking the metal. I am informed that the success of this expedient is not yet fully assured.

A very important demand for diatomite is for a basis for disinfecting powder, to make which it is charged with 10 or 20 per cent. of carbolic acid or other liquid disinfectant. Such a powder is much lighter than are those with chalk or lime as a basis, and

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

* Carpenter, 'The Microscope,' fourth edition, p. 311.

possesses the advantage of floating on the surface of any liquid upon which it is sprinkled, so that what effluvium arises must pass through the disinfectant. The crudest forms are suitable for this purpose, and one pound occupies the bulk of three pounds of chalk.

Another very important application of diatomite is found in the ease and perfection with which metals may be polished by its means, either in the form of powder or of a paste made with a soft paraffin. For this purpose grit of all kinds must, of course, be carefully removed, leaving a powder of such a degree of fineness as not to scratch gold plate, yet impart a very high polish to it.

I have used diatomite associated with sodium silicate and fibrous material, such as cow-hair, for making an adherent covering for steam boilers, pipes, and pans. Loss of heat by radiation being prevented there is a corresponding economy of fuel, and the temperature of the laboratory is moderated, to the great comfort of those who work in it.

Safe makers take advantage of its non-conductivity in the construction of fire-proof chambers. This property makes it valuable also in the construction of ice houses, and, indeed, wherever it is desirable to prevent too great loss or accession of heat.

Diatomite is said to find its way even into soap, and there is no doubt of its employment in the manufacture of ultramarine and of artificial meerschaum.

Its non-conductivity is not confined to the heat wave. It effectually smothers other undulations, and is therefore equally useful for making walls sound proof, so that the inmates of a class room in a musical seminary may practise without disturbing or being disturbed by similar students in the next chamber.

The properties of diatomite above indicated are naturally suggestive of certain uses in pharmacy. For some of these the absence of gritty particles is absolutely necessary, and freedom from organic matter is desirable for all.

AS A FILTERING MEDIUM.—My attention was first attracted to diatomite for this use. Provided it were possible to obtain or prepare it free from organic matter, it seemed to possess all needful qualities for filtering liquid galenicals and certain solutions of salts and acids. Silica has powers of resistance to solvents far greater than the filtering powders in common use, viz., the carbonates of lime and magnesia, phosphate and sulphate of lime, talc, and asbestos. All these, being compounds, are susceptible of decomposition; indeed, the four first mentioned are of more than doubtful utility, and should be banished from the laboratory for purely filtering purposes. Diatomite, which may be regarded as pure silica, is absolutely indifferent to all but the strongest alkalies at a high temperature—involving a set of conditions which the pharmacist does not have to consider. There is the further advantage that it does not clog up the filtering bag to the same degree as either talc or asbestos, and filtration is consequently more rapid. The benefit of this is not confined to the manufacturer, who is thus able to accomplish more work in the same time, but what is of greater importance, it extends to the preparation also, which must be the better for less handling and exposure. This is not secured at any sacrifice of efficiency. Note may be made of a practical point here. Diatomite does not mix readily with liquids, and should not be dusted on the inner sides of the filter bag in the expectation that it will diffuse through the liquid which is afterwards poured in; nor can it be satisfactorily mixed with the bulk of the liquid. It should be worked down in a mortar with a little of the liquid to be filtered, so as to form a smooth thin paste, which can then be mixed with more of the liquid to set the filter. This takes place almost at once, and but little of the filtrate requires to be returned. Inattention to this

point has occasionally caused failure with diatomite as a filtering medium.

Small though the particles of diatomite may be, they appear to be large enough, and to present irregularity enough, to keep apart the particles of albuminoid or starchy deposit sufficiently for the passage of the still smaller particles of liquid. It is obvious that the diatomite used for filtering must be free from organic matter—a few particles of sand may be disregarded.

DENTIFRICES.—For making these diatomite must be free from sand and also from organic matter, which is apt to suggest a disagreeable earthy taste. It should be as white as possible, so as to exclude interference with the tint of the ingredients. These conditions secured, it may with advantage take the place of ground pumice and cuttlefish bone in all cases, and of precipitated chalk in pastes and powders, which contain other alkaline bodies, such as bicarbonate of soda and borax. If no alkali is present, or if diatomite alone is considered too light, some chalk may be retained in a powder dentifrice with benefit. Diatomite properly refined is not gritty between the teeth, and polishes without scratching the enamel. Bulk for bulk it is half the weight of the lightest precipitated chalk. The formulæ appended* are merely suggestions as to the proportions in which diatomite may be used in dentifrices, and are of course susceptible of an infinity of variation, according to taste and experience.

DUSTING POWDERS.—By virtue of its enormous and unequalled absorbent property diatomite is unrivalled as a dusting-powder basis. It must be the very purest than can be produced, and when absolutely free from organic matter and grit is more smooth and less irritating than any other powder. Unlike vegetable powders it does not contribute to decomposition of the exudation, but keeps sweet for a long time, and may, of course, be associated with antiseptics with equal facility and greater advantage. Smoothness is imparted by the addition of boric acid in very fine powder. Oxide of zinc, kaolin, talc, or Fuller's earth may be added according to circumstances and the object aimed at, as also such antiseptics as salicylic acid, iodoform, thymol, etc. Diatomite as a polisher of metals has already been referred to, and it only remains to say of it in this connection that it is obtainable of all degrees of fineness, suitable for fire irons and fenders at one end of the scale and for the finest gold plate at the other.

IN DISPENSING.—The last suggestion I have to make relative to the use of diatomite in pharmacy is perhaps more debateable than any of the preceding. I mean as a diluent for hygroscopic powders, such as euonymin when made by the late Pharmacopœia process. However carefully this may be prepared according to the official directions, it presents difficulties which are more or less great with different batches of the drug. Being absolutely inert and insoluble in the stomach juices, diatomite cannot react on the drug as chemical powders, like magnesia may, and the mixture is much more easily reduced to powder than when sugar of milk is used; it also remains pulverulent. On the other hand, the question arises as to how far it is advisable to introduce silica however finely divided into the stomach. The quantity at most is a few grains; and may be less than one grain, and when it is remembered that at times of scarcity or famine the Norwegian peasantry have been compelled to eat ounces and even pounds in one week, the doubt is deprived of much of its significance. Further, whole-meal

* Diatomite Tooth Powder.		* Diatomite Tooth Paste.

bread is recommended and largely consumed for the wholesome action of the siliceous particles (much coarser than diatomite) in the grain husk, on the intestinal canal, so that it would seem as if only beneficial effects would be produced by the minute proportion in a dose of euonymin or similar remedy whether given in the form of a powder or of a tablet. The binding power of diatomite under pressure suggests its use in the last-mentioned form for drugs which compress with difficulty.

GLUTEN FLOUR.*

BY VICTOR G. L. FIELDEN, M.B.

The subject of this paper suggested itself to me some time ago when my friend Dr. Whitla asked me to roughly examine a sample of gluten flour which a diabetic patient of his was using, and about which he had suspicions. The iodine test in this sample showed abundance of starch, and microscopic examination revealed myriads of starch granules. I also washed a portion of it in muslin in a stream of water, and was astonished at the small amount of gluten I obtained. I determined therefore to examine at an early date several samples of this substance.

As you all know, gluten flour is used principally, if not exclusively, as a substitute for ordinary flour in making bread, cakes, etc., for persons suffering from diabetes, so that the conversion of starch into sugar in the human laboratory may be reduced to as low a point as possible. The more starchy food that is taken the greater is the production of sugar, and it behoves physicians in treating this disease to administer such a diet that, as far as possible nourishment may be at a maximum and the production of sugar at a minimum. Saccharin can be used as a splendid substitute for sugar itself as a sweetening agent, but a substitute for the staff of life is not such an easy problem to solve. Almond, bran, and gluten in the form of cakes, bread, and biscuits are in everyday use, and it is but right to expect that those who are unfortunate enough to require these necessaries should get them as nearly pure as possible, and chemists who supply the public should see that they are selling a really good article; hence my reason for bringing the subject before a representative meeting of chemists from all parts of the kingdom. Medical men also should know what their diabetic patients are taking, and should examine occasionally the gluten flour to see that it is of good quality. My paper, therefore, will prove, I hope, interesting and instructive to members of my profession also, so that I think I am killing two birds with one stone.

Gluten is the most nutritious part of wheat flour, being equal to that of flesh meat, but its preparations are not by any means so palatable as those made from ordinary flour, therefore its manufacture in agreeable forms has become quite an industry in itself, but I need not dwell on this. The constitution of gluten, however, is such that it possesses very nutritive qualities, and as an article of diet is most useful, and crude gluten is recommended as a fodder. It is contained in many plants, but chiefly in the cereals, wheat being richest in this substance. Hard wheat contains more than soft wheat, and conditions of growth such as soil, climate, temperature, manure and the season when sown greatly influence its amount. The best qualities of wheat contain from 10 to as much as 15 per cent., whilst inferior kinds contain 8 or 9 per cent. Kenwood states that wheat flour contains from 8 to 12 per cent. gluten, and if it contains less than 8 per cent. it is not pure wheat flour. Maize contains a good proportion, whilst barley, rye, and oats have less.

Martin has demonstrated that gluten does not naturally exist in

flour, none being obtained if water at 2° C. be used to wash it. When water of a higher temperature is employed gluten is formed probably by a ferment action on the proteids in the flour.

Gluten is not a definite chemical compound, but consists of three substances, which are closely allied to one another. One—vegetable fibrin—is insoluble in boiling alcohol, and two are soluble, one of which—mucin—separates on cooling, and the other—glutin or gliadin—remains in solution, but is thrown down on addition of water.

Gluten is soluble in alkalis. It is chiefly obtained from the waste products in the manufacture of starch; but it depends upon the process adopted for obtaining the starch how much gluten is recoverable. In one, termed the "sour" process, the starch granules are freed by a process of fermentation which goes on at the expense of the gluten, and in this there is consequently some destruction of this substance. Another process consists in treating the material with dilute solution of caustic soda, which, at least in part, dissolves the gluten, and the starch granules are more readily set free. By this process the maximum amount of gluten can be obtained, for that remaining undissolved with the starch is separated by passing the washed starch through fine sieves, which retain the gluten, and that dissolved in the alkaline solution is recovered by precipitating with an acid.

Wheat starch may also be prepared from wheat flour by making into a dough with water and washing out the starch, the gluten being left in a fine sieve.

A process for the manufacture of maize starch (used largely in America) consists in mechanically separating the husk and germ, which contain the gluten, albuminoids, and oil, from the white starchy portion, any gluten retained in this being removed by washing the powder and straining through a fine sieve.

The old and not economical method used in obtaining potato starch by rasping or crushing the starchy material and subsequent washing need simply be mentioned.

There are several large houses in Britain which supply gluten preparations, and I obtained five samples of flour from different sources for examination. I did not attempt to make a complete analysis of each, but contented myself with assaying those portions which more intimately concerned me, viz., the gluten and the starch together with the sugar. In one sample only, by way of checking myself, I determined the amount of moisture, the most abundant constituent left, and I found that I was able to account for the composition of over 95 per cent. of the sample.

The plan I adopted for assaying the gluten was to wash 10 grammes thoroughly in a bag of close muslin (like this sample) in a stream of water until a small quantity of the washings when boiled gave no blue colour with tincture of iodine. This method I preferred, as being more thorough, to rubbing the flour into a paste in a mortar with water and transferring it to a conical glass, in which it is washed with successive quantities of water. The plastic mass I then dried in a tared dish in this water-oven until it ceased to lose weight when it was weighed and the percentage calculated.

The starch I assayed by converting it into sugar by boiling 2 grammes of the flour with 20 C.c. of sulphuric acid and 200 C.c. of water for three or four hours. Any sugar naturally occurring in the flour was consequently determined at the same time, and, both being equally harmful to a diabetic patient, can conveniently be taken together. After boiling, the liquid was neutralised with caustic soda and made up to a known bulk with water, and the amount of glucose determined by means of Fehling's solution, 10 C.c. of which was equivalent to 0.05 gramme of dextrose or glucose or 0.045

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

gramme of starch. With these figures a simple calculation gave the percentage of starch in the gluten flour.

	A.	B.	C.	D.	E.
Gluten.	76 p.c.	60 p.c.	65 p.c.	8.5 p.c.	66 p.c.
Starch and Sugar.	7.6 p.c.	16.7 p.c.	13.26 p.c.	68.8 p.c.	11.63 p.c.

From the foregoing table it will be seen that with the exception of sample D all contained a large percentage of gluten, ranging from 60 per cent. in B to 76 per cent. in A, samples C and E containing 65 per cent. and 66 per cent. respectively. D contained only 8.5 per cent. of gluten.

With regard to the amount of starch and sugar it will be seen that A again took first place by containing the smallest amount, viz., 7.6 per cent., E came next with 11.63 per cent., then C with 13.26 per cent., and B with 16.7 per cent., whilst D, as was to be expected, contained a very large proportion, viz., 68.8 per cent. This bad sample (D), I learn, is what is sold as crude gluten and is of American origin, and considering that wheat flour, as Kenwood states, contains from 8 to 12 per cent. of gluten, a diabetic gains nothing but rather otherwise by using such a gluten flour as sample D in preference to a good wheaten flour. Sadtler mentions that it has been found that by the process of prolonged boiling with diluted sulphuric acid only 95 per cent. of the starch is converted into dextrose, other non-reducing bodies being formed at the same time. This being so, the percentage of starch would be even higher than my results, as noted in the table, show.

As it is such a simple matter to find out the proportion of gluten by simply carefully washing the flour in a muslin bag and drying, I would suggest that all chemists who sell this article occasionally test their stock, and supply only a good and reliable gluten flour, for the feeding of a diabetic is everything in the treatment of his disease, drugs holding a very secondary place indeed. To feed him on starch is only adding fuel to the fire, which is surely and often rapidly hurrying him to his grave.

Since writing the foregoing, I have been much interested in a leader in the *British Medical Journal*, of July 16, on "The Chemistry of Diabetic Foods." In this article, a paper by Dr. F. Kraus, jun., of Karlsbad, is mentioned, in which, they say, he "illustrates the futility of trusting to the general run of commercial articles sold as diabetic bread by a table showing the carbohydrate contents of most of those used in Germany. Of the nineteen specimens enumerated, only five contain less than 30 per cent. of carbohydrate, four are between 30 and 40 per cent., four between 40 and 50 per cent., two between 50 and 60 per cent., and four over 60 per cent., as against ordinary white wheaten bread, which contains 60 per cent." They also make the statement that they "could produce parallel examples of English diabetic bread and flour in every respect as bad as those made in Germany." A lesson that is desired to be taught is that "it is much better to allow a definite quantity—for example, two to four ounces of potato or toast, than to allow an unlimited amount of 'diabetic bread' of unknown composition."

This warning, coming independently of mine to beware of the quality of diabetic food-stuffs, increases the necessity for care, and I refer to this article so as to still further impress the warning note upon the minds of all.

In conclusion, I beg to thank Professor Letts, of Queen's College, for having kindly lent me most of the apparatus necessary for carrying out the examination of which I have described the results.

THE CHARACTERS AND METHODS OF ASSAY OF THE OFFICIAL HYPOPHOSPHITES.*

BY H. A. D. JOWETT, D.SC.

It is generally recognised that the methods at present known and employed for determining the amount of hypophosphite contained in the commercial salts are unsatisfactory. The object of this investigation was, therefore, to devise an accurate method for such determinations, and having accomplished this, it was thought of interest to supplement its description with an account of some of the properties of the various hypophosphites prepared for the purpose of this inquiry.

Hypophosphorous acid was discovered in 1816 by Dulong, and several of its salts were prepared and their properties examined by Rose. Those of interest to the pharmacist and dealt with in this paper are the potassium, sodium, calcium, barium, iron, and manganese salts. The calcium and barium salts are obtained directly, being obtained by evaporation from the resulting aqueous solution. The sodium and potassium salts are prepared by double decomposition from the calcium salt, and may be purified by crystallisation from alcohol, in which both are soluble. The iron and manganese salts can also be prepared by double decomposition or by general methods, but they are insoluble in alcohol. All the hypophosphites are more or less soluble in water, and are easily oxidised to phosphites and ultimately to phosphates. Impurities may be detected by the ordinary reagents, phosphite being detected by the reaction with barium chloride or lead acetate, since barium phosphite is but slightly soluble in water, and lead phosphite insoluble.

P. de St. Gilles first proposed to assay hypophosphorous acid or its salts by titration with potassium permanganate, stating that the oxidation was easily accomplished, whilst Rose proposed the oxidation of the acid by mercuric chloride, and determination of the amount of hypophosphorous acid present by weighing the calomel formed.

In 1887 Lunan (*P.J.*, 1887, p. 773) in examining the acids rejected the permanganate method and adopted the calomel assay method, but did not give any reason for this, nor are any data given to show the accuracy of the latter method.

In 1889 Moerk (*A.J.P.*, 1889, pp. 326, 386, 459) published a lengthy paper dealing with the qualitative and quantitative examination of hypophosphorous acid and such of its salts as are largely used in America. In addition to the permanganate and calomel methods, he assayed the salts by first oxidising with bromine, and then determining either the hydrobromic acid or the phosphate formed, by general methods. He found the permanganate method unsatisfactory, as a brown precipitate is formed even in acid solution, which only slowly oxidises the phosphite. Good results were, however, obtained with the calomel and bromine methods. No evidence of the accuracy of these methods is given, and apparently impure material was used, as in the course of the paper it is mentioned that unsatisfactory results were obtained owing to "the alkaline hypophosphites containing probably chlorides," and a correction is introduced in a later paper for the impure bromine used for oxidation. Assuming that concordant results were obtained, this is no proof of the accuracy of the methods, and it is not stated that even these were obtained. In the qualitative examination of several salts, phosphite was only met with in one case, viz., a potassium salt stated to contain 13 per cent. of phosphite, and which gave no precipitate with lead acetate and acetic acid. The evidence on which the presence of phosphite was based was a small difference in results obtained by different analytical methods. These results are contrary to pub-

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

lished statements and my own experiments, as lead phosphite is insoluble in water acidulated with acetic acid, and it is only rarely that commercial specimens are met with which are free from phosphite. There are other statements in the paper referred to which require modification, and one is regretfully led to the conclusion that little reliance can be placed on the author's results.

In 1891 Amat (*Compt. rend.*, cxi., p. 676) recommended the calomel method, urging that with permanganate there is a tendency to two errors: (1) By incomplete oxidation of the hypophosphite; (2) by decomposition of the permanganate at high temperatures. He also noted the formation of a brown precipitate during titration with permanganate, which was only completely dissolved on the addition of oxalic acid.

The U.S.P. adopts the permanganate method and makes the curious mistake of requiring the oxalic acid to discharge the "red" colour, whilst in reality it is a brown precipitate which is gradually decomposed by the oxalic acid. No tests are given for phosphites, except in the case of the calcium salt, when the lead acetate test is erroneously stated to detect acid phosphate, a most unlikely impurity. The sodium salt is described as hydrated, that found in the European and American markets (with one exception) is almost anhydrous.

In 1893 Roe (*P. J.*, 1893, p. 473) pointed out that phosphites appeared to be a common impurity in commercial hypophosphites.

In 1897 Tyrer (*P. J.*, 1897, p. 150), in a paper read before this Conference, stated that the permanganate method is unsatisfactory, and pointed out that phosphites are the most likely impurity. He suggested a new method of determination, which was to first precipitate with barium chloride for the removal of phosphates, phosphites, sulphates, or sulphite, to filter, and then to estimate the hypophosphite in the filtrate by the reduction of copper sulphate. Determinations by this method are stated to be very accurate, but as no experimental data are given, it is impossible to say whether the author checked his method by analyses of pure material. It is stated that the U.S.P. method of titration gave good results, as the sulphuric acid in excess keeps the manganese in solution; I am unable to confirm this statement, as I have always found that a brown precipitate is formed as stated by Moerk and Amat. Again, hypophosphites are stated to react with mercuric chloride in the same way whether excess of mercuric salt or of hypophosphite be present, becoming in the cold partially reduced to subchloride, and on boiling reduced to mercury.

I have found that if the mercuric chloride is in excess, calomel only is formed, but if the hypophosphite is in excess, reduction takes place to mercury. That this is so follows from the method proposed by Rose and others, and which depends on the determination of the calomel thus formed. This method is further stated to be unsatisfactory because of a tendency to complete reduction to mercury, but I have found that this is easily remedied by pouring the solution of the hypophosphite into an acid solution of mercuric chloride in excess, when the calomel is obtained quite white and with no tendency to further reduction. Finally, the new B.P. (1898 edition) adheres to the unsatisfactory tests of the old edition, and gives no method of assay, but simply directions to boil a given quantity of the salt with potassium permanganate, when, on filtration, a "nearly" colourless solution should result. It is also stated that the solution of the salt should give little or no precipitate with lead acetate, and it has been repeatedly shown that it is very seldom a commercial salt meets this requirement. Further, the standard of purity required for the permanganate test is not the same as that for the lead acetate test, for a salt that

gives quite a considerable precipitate with lead acetate will yield, when tested as directed, a nearly colourless solution.

In reviewing these proposed methods of assay it will be noticed that no author adduces the necessary proof of the accuracy of the method, viz., analyses of pure material and of mixtures containing a known amount of impurity. Further, in every method except that of Tyrer no notice is taken of the well-known fact that the chief impurity present, viz., phosphite, will behave in a similar manner to oxidising agents as the hypophosphite. Any method, therefore, to be accurate must either be uninfluenced by any impurities present, or the disturbing impurities must first be removed. Since only Tyrer's method fulfils this first essential condition, it is the only one which calls for comment. His method depends for its accuracy on the completeness of the removal of the impurities by barium chloride, since if any phosphite remained in solution it would reduce the copper sulphate in the same manner as the hypophosphite. Barium phosphite, however, is slightly soluble in water, and this can be easily demonstrated by dissolving the barium hypophosphite of commerce and adding a drop of lead acetate solution, when a precipitate of lead phosphite will be thrown down. This being the case, the method cannot be accepted as accurate, owing to the incomplete removal of impurities. It is thus clear that no method of assay previously described can be considered satisfactory.

In the method I propose, the impurities are first removed by lead acetate, lead phosphite and other impurities being insoluble in water. The excess of lead is then removed by hydrogen sulphide, and the filtrate containing the hypophosphite completely oxidised to phosphate, which is determined either gravimetrically or volumetrically by the usual methods of analysis. I have proved the accuracy of this method by the analysis of pure material and of mixtures of pure material with known amounts of likely impurities. In the course of the investigation I have prepared some pure salts and examined their properties, have made some experiments with the hypophosphites of iron, and have finally made a complete examination of the principal salts of the leading British and American manufacturers, which has afforded some interesting results.

EXPERIMENTAL.

SODIUM HYPOPHOSPHITE.—The commercial salt was purified by boiling a portion with strong alcohol, filtering, and allowing the filtrate to cool, when long, transparent, prismatic crystals, sometimes an inch in length, separated. The purity of the salt was proved by taking a concentrated aqueous solution and adding a drop of acetic acid and then a few drops of lead acetate solution. If the liquid remained quite clear it was regarded as pure, freedom from other ordinary impurities having been previously ascertained. These crystals were found to contain one molecule of water of crystallisation and to be extremely deliquescent, apparently much more so than the granular salt of commerce. Experiments were made to see if the salt could be dried without decomposition. The pure salt was heated for two hours at 100°, and afterwards for one hour at 110°, when it had ceased to lose weight, and on testing with lead acetate was found to be quite pure. Experiments were made also to see if a solution of the salt in air free water could be boiled without decomposition. This was found to be the case if the water is boiled for at least ten minutes and the salt quickly added, it then suffers no decomposition on further boiling. In the following experiments the salt was dried for one hour at 110°, experiments showing that this procedure dried the salt completely, and without decomposition. The first experiments were made with the permanganate method as follows:—About 0.1 gramme of the dried salt was

dissolved in a convenient quantity of water, 1 C.c. sulphuric acid and 50 C.c. N/10 potassium permanganate added, and the mixture boiled for fifteen minutes, then N/10 oxalic acid added till colourless, and finally N/10 permanganate till the faintest pink coloration is evident. If, on standing five minutes, the coloration is unchanged, the calculation is made from the data in the usual way. If, however, the pink coloration fades or changes to a brownish tint, the hypophosphite has not been completely oxidised, and more permanganate must be added, and the operation repeated.

The following results were obtained :—

(1) 0.072	gramme pure salt required	33.1 C.c. N/10 KMnO ₄	= 101.1 per cent.
(2) 0.0874	" "	40.2 "	= 101.1 "
(3) 0.1296	" "	58.7 "	= 99.6 "

The last experiment required an hour's boiling for complete oxidation. The method not giving accurate results, experiments were made to determine the cause of error. A blank experiment showed that, under these conditions,

proving that a portion of the permanganate is decomposed on boiling. This fact and the difficulty of completely oxidising the hypophosphite caused me to abandon this method. In addition to these two errors, there is a third, due to the presence of chlorides, which are frequently found in the commercial salt, and which reduce permanganate. As these errors give respectively too high or low results, it is possible that under certain conditions they might balance each other and give an apparently correct result.

The calomel method was next tried, though there is an initial difficulty by this method in properly drying the calomel. The solution of the pure salt was poured into a solution of excess of mercuric chloride acidulated with hydrochloric acid and the mixture heated on a water bath for one hour, and the calomel separated and weighed.

0.0438	gramme salt gave	0.4746	gramme calomel	= 101.4 per cent.
0.0934	" "	1.0092	" "	= 101.2 per cent.

These results and the difficulties of the method led to its abandonment.

The next method tried was that of oxidation and subsequent determination as phosphate. The oxidation is carried out by bromine, or better, by potassium chlorate and hydrochloric acid in the usual way, and the resulting phosphate estimated gravimetrically or volumetrically by the usual analytical methods. The results thus obtained were very accurate.

0.3096	gramme pure salt gave	0.3924	Mg ₂ P ₂ O ₇	= 100.25 per cent.
0.3176	" "	0.388	" "	= 99.76 per cent.
0.298	" "	req. 48 C.c. standard	uranium acetate solution (1 C.c. = .005 P ₂ O ₅)	} = 99.88 per cent.

This method having been proved accurate on pure material, it was consequently adopted.

The next experiments were made on a mixture of pure sodium hypophosphite with sodium phosphate.

This sodium phosphite on analysis was found to contain—

Sodium Phosphite.....	61.33 parts.
Sodium Phosphate	11.00 parts.
Sodium Carbonate.....	27.67 parts (by difference).

The mixtures thus made would approximate closely to the commercial article, and any other impurities present would either be removed by the lead acetate or would not interfere with the phosphate determination.

After many experiments the best way of carrying out the analysis was found to be as follows :—

About 0.3 gramme of the dried salt is dissolved in 10 C.c. of water, 3 C.c. of a 10 per cent. solution of lead acetate added, and

the mixture allowed to stand twelve hours. It is then filtered, the precipitate thoroughly washed, and the washings added to the filtrate, which is acidified with hydrochloric acid, and then saturated with hydrogen sulphide, boiled, filtered, and the lead sulphide thoroughly washed.

The mixed washings and filtrate are then evaporated to a low bulk and 5 C.c. hydrochloric acid and 1 gramme potassium chlorate added and gently heated for half an hour, then concentrated to about 20 C.c., and the phosphate finally determined either gravimetrically or volumetrically by the usual method. The results were as follows :—

Composition of the Mixture.		Found.
Per cent. of NaPH ₂ O ₂ present.....	{ 90.96	90.38
	{ 98.56	93.30

The method having been thus proved accurate within the usual limits of experimental error, the method of qualitative examination was investigated.

The usual tests were made for metallic impurities, calcium, carbonate, sulphate, and phosphate. With regard to the latter, it must be remarked that the absence of a precipitate with magnesia mixture does not necessarily imply that no phosphate is present, as the test is not so delicate, but that it is certainly not present in more than traces. Attention is also directed to the test for chlorides. Contrary to general statements, it is not easy to completely oxidise this salt by means of nitric acid, and it is therefore necessary in carrying out this test to boil for at least five minutes with nitric acid, then add the silver nitrate and boil for another five minutes if any precipitate is formed. Phosphites and sulphites were tested for in the precipitate produced by lead acetate by the method described by Tyrer. Carbonate and moisture were estimated in the usual way. A series of parallel experiments were made on a sample of commercial sodium hypophosphite, using different methods of assay.

Method.	U.S.P.	Calomel.	Magnesia.	Uranium.
Pure Salt.....	101.1	101.3	99.76	99.63
Coml. Salt.....	92.85	92.69	91.40	91.65

} per cent.

Whilst the results obtained by the uranium and magnesia methods agree, those obtained by the other methods show a higher percentage, due to errors of the method, and also to the presence of phosphite, which would give a high result.

POTASSIUM HYPOPHOSPHITE.—This salt is anhydrous and can be purified in a similar manner to the sodium salt, but this purification is a little more difficult, due to the limited solubility of the salt in alcohol. The quantitative and qualitative examination of this salt is carried out in a similar manner to the sodium salt, except that in the case of this hygroscopic salt the moisture is not determined.

The assay of a commercial sample by different methods gave a similar result to the sodium salt.

U.S.P. method.....	95.5 per cent.
Calomel "	97.3 "
Magnesia "	94.82 "
Uranium "	94.42 "

CALCIUM HYPOPHOSPHITE.—This salt is not easily obtained pure, and some commercial specimens do not form a clear solution with water. When the salt is crystallised from water by evaporation *in vacuo* at the ordinary temperature three separate fractions gave the reaction with lead acetate, consequently it is not possible to purify the salt by recrystallisation. It may, however, be prepared quite pure in the following manner :—To the aqueous solution is added lead acetate in slight excess, the mixture then filtered after standing twenty-four hours, and the filtrate saturated with

hydrogen sulphide and filtered. The hydrogen sulphide is then removed by a current of air and the salt precipitated by the addition of alcohol to the aqueous solution. The pure salt crystallises in pearly flakes, which give no reaction with lead acetate.

Several contradictory statements have been made regarding the solubility of this salt in water. The U.S.P. gave 1 in 6.8, Tyrer 1 in 7.2, B.P. 1 in 8, and various text-books 1 in 6, but it is not clear whether these statements refer to the commercial article or the pure salt. Having in my possession a quantity of the pure salt, I determined its solubility and found it to be 1 in 6.43 parts of water at 20°. Of the commercial specimens examined, one only was soluble in 8 parts of water, and some did not form a clear solution even in 14 parts of water. Experiments of heating at 110° and boiling in pure water similar to those made with the sodium salt having shown that the calcium salt is quite stable under these conditions, the effect of evaporation of an aqueous solution of the pure salt under ordinary conditions was noted. A 10 per cent. solution of pure calcium hypophosphite was evaporated on a water bath to dryness, and the residue on analysis gave 97.73 per cent. of calcium hypophosphite. This may be a cause of the phosphite present in many commercial specimens. The specimen of the pure salt obtained commercially had an appearance which suggests precipitation from aqueous solution by alcohol. Another method of preventing this decomposition would be by evaporation *in vacuo*.

The method of analysis has to be slightly modified for the calcium salt on account of the insoluble calcium phosphate formed. If weighed as $Mg_2P_2O_7$, the best method is to proceed as with the sodium salt, then remove the lead and calcium as sulphate by precipitating with dilute sulphuric acid and adding alcohol. The further operations are the same as with the sodium salt. A better method is to determine volumetrically by uranium acetate, following the usual precaution observed in the presence of calcium and carefully standardising the solution against pure calcium hypophosphite. Good results were obtained by both of these methods on the pure salt.

Found by $Mg_2P_2O_7$ method	100.35 per cent.
Found by Uranium method	99.77 per cent.
Found by U.S.P. ($KMnO_4$) method ..	97.7 per cent.

With this salt the permanganate method gives results lower than the actual value.

COMMERCIAL CALCIUM HYPOPHOSPHITE—

Found by $KMnO_4$, U.S.P. method	95.97 per cent.
Found by $Mg_2P_2O_7$ method	97.49 per cent.
Found by Uranium method	97.56 per cent.
Found by Calomel method	97.3 per cent.

BIARIUM HYPOPHOSPHITE.—This salt can be assayed in the same way as the calcium salt, omitting the alcohol in the removal of the barium. The permanganate method here gives results higher than the actual value, as in the case of the sodium and potassium salts.

In a commercial specimen I found :—

By $KMnO_4$ method	98.6 per cent.
By $Mg_2P_2O_7$ method	97.25 per cent.
By Uranium method	97.29 per cent.

As the last two salts are used for the manufacture of hypophosphorous acid it follows that the acid will contain the same impurities as are present in them, such as phosphorous acid, etc. The acid can be determined by neutralising with sodium hydrate and proceeding as with sodium hypophosphite.

MANGANESE HYPOPHOSPHITE, $Mn(PH_2O_2)_2 \cdot H_2O$.—This salt is easily prepared by dissolving manganese carbonate in the equivalent quantity of hypophosphorous acid and crystallising from the hot aqueous solution. The purity of the salt will depend on the

acid used. It crystallises with one molecule of water, and is somewhat difficult to determine. It cannot be done by the magnesia method, as the manganese cannot be completely removed, but good results were obtained with the uranium method by proceeding as with the calcium salt, but first removing the lead and most of the manganese by ammonium carbonate and ammonia.

In a sample prepared by myself from the commercial acid, I found 98.61 C.c. of manganese hypophosphite.

IRON HYPOPHOSPHITE.—This salt is official only in the U.S.P., and can be prepared by two distinct methods: (1) From ferrous sulphate and calcium hypophosphite by double decomposition, filtration, and evaporation of the filtrate, when a mixture of ferrous and ferric hypophosphites and phosphites with calcium sulphate is obtained; (2) from a soluble ferric salt and a hypophosphite by double decomposition, filtration, washing, and drying of the precipitate obtained. This product is chiefly ferric hypophosphite with a varying amount of impurity dependent on the purity of the materials used and the thoroughness of the washing. The qualitative and quantitative examination of these salts was carried out as follows:—The tests for calcium, sulphate, carbonate, and chloride, were made in the usual way, observing the precautions necessary, and detailed under sodium hypophosphite. Phosphite was detected by shaking up 0.5 gramme of salt with 10 C.c. of a 5 per cent. solution of sodium hydrate in the cold, filtering, acidifying the filtrate with acetic acid, and adding lead acetate. If much sulphate is present, it is necessary to further test the lead precipitate by reduction. Unfortunately I was unable to devise a method of determining the amount of hypophosphite present in this salt without introducing the error due to phosphite, but this can be partly remedied by noting the amount of lead precipitate in the test above detailed. The determination is then carried out on about 0.3 gramme of salt by first oxidising with potassium chlorate and hydrochloric acid in the usual way, then adding 0.5 gramme of sodium citrate and finally excess of pure sodium hydrate. The precipitate is washed thoroughly, the iron contained in it determined iodometrically, and the phosphate contained in the filtrate by the usual analytical methods. A blank experiment performed in this way on a mixture of pure ferrous sulphate and sodium hypophosphite gave—

	Calculated.	Found.
Iron	20.14 per cent.	20.35 per cent.
Ferric Hypophosphite ..	100.00 per cent.	99.92 per cent.

These results prove the accuracy of the method, and it may be noted that the presence of phosphite would affect both the iron and phosphate determinations.

Being thus in the possession of a reliable method of assay, I made some specimens of ferrous and ferric hypophosphites by different methods and examined the resulting product.

I first prepared a salt by mixing solutions of equivalent proportions of ferrous sulphate and calcium hypophosphite, filtering and then evaporating to dryness on a water bath. In this way a greenish-grey powder was obtained which contained ferrous and ferric hypophosphite with some phosphite and calcium sulphate.

On analysis the salt gave :—

Ferric Hypophosphite	71.02 per cent.
By U.S.P.	74.95 per cent.
Iron	22.06 per cent.
Calcium Sulphate	13.8 per cent.

This was obviously a very unsatisfactory product, so the calcium hypophosphite was replaced by the barium salt, and a reddish powder was obtained which on analysis gave :—

Ferric Hypophosphite	91.52 per cent.
By U.S.P.	89.5 "
Iron	28.88 "
Barium Sulphate	nil.

If these results are calculated as ferrous hypophosphite the amount present is 102.26 per cent., so that the product consists of ferrous with a little ferric hypophosphite, and some phosphite. This preparation would appear to be satisfactory but for its indefinite composition; recourse was had, therefore, to the ferric salt. This salt was prepared by double decomposition of ferric sulphate (iron alum) or ferric chloride and sodium hypophosphite. The precipitate was washed, but it is very difficult to wash thoroughly without a very serious loss of the hypophosphite, and the salt therefore generally contains a certain amount of this impurity dependent on the salts used. If calcium chloride is present, the salt will be deliquescent, as stated by Tyrer, but some prepared by myself from iron alum was quite stable in the air. The results of the examination of several commercial specimens showed that both the sulphate and chloride are used in the manufacture of this salt.

A sample prepared from ferric sulphate gave on analysis:—

Ferric Hypophosphite.....	94.25 per cent.
U.S.P. method	88.25 "
Iron	22.27 "
Sodium Sulphate	4.17 "

This sample contained no ferrous iron, and was a white amorphous powder. The above experiments show that the permanganate method of the U.S.P. does not give accurate results, whilst its use is inadmissible with the ferrous salt. It is clear from these experiments that the best salt is the ferric hypophosphite, which should be used, and not the mixture prepared from a ferrous salt.

EXAMINATION OF COMMERCIAL SPECIMENS.—Having worked out a satisfactory and accurate method of assay for these salts, specimens of the sodium, potassium, calcium, and iron salts were obtained from two leading English manufacturers and also from three leading American houses, and examined according to the method previously detailed.

The English manufactured products are designated B1, B2, and those of American manufacture A1, A2, A3. Of these A1 was sold as purified, the others had the name of the salt only on the label.

SODIUM HYPOPHOSPHITE.

Sample.	Na ₂ CO ₃ .	Moisture.	NaPH ₂ O ₂ per cent. of dried salt.	Impurities.
B1	0.16	3.19	91.52	Phosphite, traces Ca, ¹¹ SO ₄ , ¹¹ Cl, ¹¹ CO ₃ . Phosphite, traces Ca, ¹¹ SO ₃ , ¹¹ SO ₄ , ¹¹ Cl, ¹¹ CO ₃ . Traces phosphite, ¹¹ CO ₃ , ¹¹ Cl, ¹¹ SO ₄ Phosphite, traces, Ca, ¹¹ SO ₄ , ¹¹ Cl, ¹¹ CO ₃ ditto
B2	0.08	9.92	96.97	
A1	0.09	14.41	99.78	
A2	0.79	1.32	96.53	
A3	0.36	4.09	98.26	

Of these specimens A1 is pure and represents the hydrated salt the others contain varying amounts of moisture and impurities, the chief being sodium phosphite. The traces of calcium, sulphate, chloride and carbonate present are no doubt derived from the sodium carbonate and calcium salt used in the manufacture.

POTASSIUM HYPOPHOSPHITE.

Sample.	K ₂ CO ₃ .	KPH ₂ O ₂ . Per cent. of dried salt.	Impurities.
B1	2.8	94.62	Phosphite, traces Ca, ¹¹ SO ₄ , ¹¹ Cl Phosphite, traces Ca, ¹¹ Cl, ¹¹ SO ₄ , ¹¹ SO ₃ Phosphite, traces ¹¹ SO ₄ , ¹¹ Cl Phosphite, traces ¹¹ SO ₄ Phosphite, traces Ca, ¹¹ Cl
B2	0.4	98.06	
A1		98.11	
A2	3.72	92.52	
A3	0.68	98.51	

Here the impurities present are similar to those found in the sodium salt, but there is an excessive amount of K₂CO₃ in two samples. No sample is as pure as the A1 sodium salt, which must

be due to the mode of manufacture. I have before noted that this salt is not so easily purified as the sodium salt. Sulphites, about which some contradictory statements have been made, were present in one sample only, viz., B2.

CALCIUM HYPOPHOSPHITE.

Sample.	Per cent. of Ca(PH ₂ O ₂) ₂ .	Impurities.
B1	97.50	Phosphite and sulphate. Traces iron, phosphite, and sulphate. Traces phosphite. Phosphite and sulphate. Nil.
B2	98.18	
A1	99.37	
A2	97.64	
A3	99.61	

Of these A3 was perfectly pure and readily soluble in 8 parts of water; the others were not soluble in this amount, and B1 and A2 did not give a clear solution even with 20 parts of water. B2 contained an appreciable trace of iron, the only metallic impurity met with in the whole series.

IRON HYPOPHOSPHITE.

Sample.	Iron. per cent.	Ferric Hypophosp. per cent.	Impurities.
B1	22.34	84.12 (Ferrous)	12 p.c. CaSO ₄ , phosphite and Cl ¹ Phosphite, traces Ca, Cl ¹ Phosphite, traces Ca and SO ₄ ¹¹ Phosphite, traces Ca and SO ₄ ¹¹ 9 p.c. Na ₂ SO ₄ , phosphite and Cl ¹
B2	21.96	89.84	
A1	22.54	98.84	
A2	23.00	95.02	
A3	20.20	87.58	

B1 was chiefly ferrous hypophosphite, and had evidently been prepared from ferrous sulphate and calcium hypophosphite, and agreed closely with that prepared by myself. The others were true ferric hypophosphite, B2 apparently prepared from ferric chloride, and the others from a ferric sulphate. A3 was very insufficiently washed, and compared very unfavourably with the other salts of this make.

As a result of this work, I would suggest as worthy of the consideration of various Pharmacopœia Revision Committees the necessity of a thorough revision of the tests for these salts and the need of fixing some standard which might be as follows:—For the calcium and barium salts, 98 per cent.; for the sodium and potassium salts, 96 per cent.; for ferric salt, 95 per cent. As a suggestion for the tests, I give below those for sodium hypophosphite, based, it will be seen, on the system of the U.S.P., which I consider preferable, on the whole, to that of the present B.P.

SODIUM HYPOPHOSPHITE, NaPH₂O₂.—5 C.c. of a 5 per cent. solution (to be used of this strength in the following tests) should yield, with 1 drop AmHS, no colour or turbidity (absence of metallic impurities).

5 C.c. with 1 C.c. Am₂C₂O₄ test solution, and 1 C.c. acetic acid, should yield not more than a slight opalescence (limit of calcium).

5 C.c. with 1 C.c. BaCl₂ test solution, and 1 C.c. HCl, and boiled for two minutes, should yield no precipitate (limit of sulphate).

5 C.c., boiled for five minutes with 5 C.c. HNO₃, and then 1 C.c. AgNO₃ test solution added, and again boiled for five minutes, should yield no turbidity (absence of chloride).

5 C.c., with 5 C.c. magnesia mixture, and well shaken, should yield no precipitate (limit of phosphate).

1 gramme of the dried salt, dissolved in water, to which is added 0.5 C.c. of N/10 H₂SO₄, with 1 drop of phenol-phthalein solution, should remain colourless (limit of carbonate=0.2 per cent.).

When analysed as before described, should yield 96 per cent. of sodium hypophosphite.

A simple test which could be used would be the following:—To 1 gramme of the dried salt, dissolved in 10 C.c. of water, add 9 C.c. of a 1 per cent. solution of lead acetate, allow the mixture

to stand for half an hour, and filter. On adding lead acetate to the filtrate the liquid should remain quite clear. This corresponds to about 96 per cent. of pure sodium hypophosphite.

In conclusion, I have added a list of the factors necessary in making analyses by these methods and the corresponding logarithms, these being based on the atomic weights of Meyer and Seubert, in the hope that they may be useful to any who may use these methods of analysis.

TABLE OF FACTORS FOR USE IN ANALYSIS.

Salt.	M. Wt.	Mg ₂ P ₂ O ₇ .		1 C.c. Uran. Sol. = 0.005 P ₂ O ₅ .	
		Factor.	L. Factor.	= grammes.	L. grammes.
Sodium hypophosphite ..	87.88	0.79085	7.89810	0.0062	3.79246
Potass. " ..	103.91	0.9351	7.97087	0.0073	3.86523
Calcium " ..	169.67	0.76346	7.88279	0.006	3.77714
Barium " ..	266.66	1.11999	0.07914	0.0094	3.97350
Manganese (hydrated) " ..	202.52	0.9113	7.95965	0.0071	3.85401
Ferric " ..	501.04	0.7515	7.87593	0.0077	3.77029
Ferrous " ..	135.64	0.8353	7.92185	0.0065	3.81621
Hypophosphorous acid ..	65.88	0.5929	7.77297	0.0046	3.66732
Anhyd. Mn. (PH ₂ O ₂) ₂	184.56	0.83045	7.91932	0.0065	3.81368

The above experiments were carried out in the Wellcome Research Laboratory, London, E.C.

SOME COMMERCIAL VARIETIES OF DILL FRUITS AND THEIR ESSENTIAL OILS.*

BY JOHN C. UMNEY.

Although the dill fruits obtained from different countries do not show such marked difference in appearance as the fennel fruits from various parts of the world, which I have already described (see *P. J.*, March 13, 1897), yet the differences are probably of greater medicinal importance.

I have shown that the varieties of fennel fruits differ considerably in size and also in the size of their vittæ, but that in all probability they are derived from the same species, whether cultivated in England, Germany, Roumania, Russia, Persia, India, or Japan. In the case of dill fruits, however, the evidence points strongly to the fact that the fruits are not derived from the same species, and although they are only used for the preparation in this country of dill water and for the distillation of the essential oil, still, the differences are of considerable importance, and appear to be worth placing on record.

The English and Indian dill fruits are those which have up to the present been used entirely in this country, the latter being very largely imported and employed for the distillation of essential oil. Those cultivated in Germany are also largely distilled for purpose of liqueurs, and a Spanish variety is I believe also distilled in Southern Germany.

The English and German fruits are exactly alike, the two mericarps being usually separated from the pedicel, each of them being oval and about one-sixth of an inch long and one-tenth to one-eighth of an inch broad, a decided brown in colour, the dorsal ridges being inconspicuous, but the lateral much prolonged into the form of wings. Six vittæ are seen in each mericarp in transverse section.

In the case of the Indian variety the same number of vittæ (except in a few cases) are observable, but the lateral ridges are not so prolonged and the colour of the fruits is a paler brown, the mericarps being usually not divided.

In describing the different varieties of dill fruit, Flückiger and Hanbury ('*Pharmacographia*,' p. 292, edition 1874) write "that dill, under the Hindustani name of Suva or Soyah,

is largely grown in various parts of India. On account of the slight peculiarity in the fruit, the Indian plant was regarded by Roxburgh and De Candolle as a distinct species, and called *Anethum sowa*; but it possesses no botanical characters to warrant its separation from *Anethum graveolens*." It is doubtful whether this opinion is a correct one, as the difference between the essential oils appears to be far greater than would be associated in all probability with the oils of the same plants grown even in such widely different districts.

A considerable consignment of Japanese fruits has recently reached this country, I believe, for the first time, and in botanical characters they agree so closely with the Indian variety that an examination of them seemed of some importance.

I have already called attention to the fact (*P. J.*, May 4, 1895) that the oil of the Indian variety, which, until recently at any rate, was that very largely met with in commerce in this country, differs considerably from that distilled from the English variety, the percentage of carvol being considerably less, and the specific gravity of the oil considerably higher, due to a body heavier than water. This body has been subsequently examined by Ciamician and Silber, who state that it has all the characters of apiol separated from the oil of parsley.

The oil distilled from the Japanese variety has a specific gravity of .964, and an optical rotation of +50.5° in a tube of 100 Mm.

The relative proportions of carvol (b.p. 224-226° C.) contained in the oils can be best seen by reference to the table of percentages obtained at varying temperatures of fractionation.

None of the methods hitherto put forward for the estimation of carvol appear to be completely satisfactory, although approximate results may be obtained by the hydroxylamine method (Kremers and Schreiner).

	Sp. gr.	Opt. Rot.	Below 200° C.	200°-210 C.	210-220° C.	220-230° C.	Above 230° C.
English distilled from fruits grown at Market Deeping.	.9143	+72.25°	22	14	12	50	2
English distilled from fruits grown at Canterbury.	.9146	+80.25°	21	19	12	46	2
German.	.9002	+70.25°	53	13	12	17	5
Indian.	.9486	+47.5°	24	17.5	7	10.5	39
Japanese	.9643	+50.5°	21	12	10	8	49

The oil distilled from the German fruits has practically the same characters as that distilled from the English fruits, provided that no separation of carvol has taken place, as in sample No. 3, a practice adopted to some extent on the Continent.

I have not been able to obtain a sample of the Spanish fruit for distillation, but have examined an oil reported to be distilled from Spanish fruit which possesses practically the same characters as the German oil.

It is evident, from the characters of the essential oils, that the Indian and Japanese varieties, although agreeing amongst themselves, differ very considerably from the English and German, and it cannot be supposed that the apiol-like body already referred to is devoid of powerful physiological action. It is imperative, therefore, that the English or German dill fruits should be employed for the distillation of dill water, and that the characters of the essential oil prescribed by the new Pharmacopœia should be rigidly adhered to, thus excluding the Indian and the Japanese varieties.

* Read at the British Pharmaceutical Conference, held at Belfast, August, 189 .

PHARMACISTS AND THE PHARMACOPŒIA.*

BY PETER MAC EWAN, F.C.S.

Why should British pharmacists trouble about the British Pharmacopœia as we are doing now? The State does not recognise us as fit and proper persons to entrust with the publication of the work, and the General Medical Council, which is so honoured, has not been too eager to take counsel with the representatives of pharmacy in regard to its preparation.

There are few greater anomalies in this country than the British Pharmacopœia. It may first be noted that, although the General Medical Council is by the Medical Acts of 1858 and 1862 constituted the publishers of the book, the Legislature has been careful to give instructions in such wide terms that the Council is not compelled to prepare the work, but "shall cause to be altered, amended, and republished such Pharmacopœia as often as they shall deem it necessary." Under this provision the Medical Council has since the first British Pharmacopœia was published excluded any but its own members from final decisions upon what should and what should not be included in the British Pharmacopœia; so that pharmacists, who are best qualified to decide upon pharmaceutical matters, and to whom pharmaceutical standards are of commercial as well as professional interest, have practically no voice in the decisions.

Secondly, we may note that the publishers of the book seem to lack organisation for continuous revision—in fact, until they appointed a pharmacist, Dr. John Attfield, as a reporter, there was no provision by the Council for watching the progress of pharmacy and medical treatment so far as such progress affected the Pharmacopœia.

In the third place, we may take it as a fact that the new British Pharmacopœia is chiefly or essentially the work of pharmacists who were appointed by the Pharmaceutical Society of Great Britain to assist the publishers. They did their work well, but I believe I am right in saying that these workers were in such an unsatisfactory position that they could never be sure that their expert opinions would be accepted as final. Which is the greatest anomaly of the whole matter.

In France, Germany, and the United States the compilation of the national Pharmacopœias is entrusted to representative committees of medical men and pharmacists, with associate helpers. None of these countries, however, strictly compares with our own. In France the Government of the day selects the committee of revision, placing upon it men of all interests—medicine, pharmacy, chemistry, and botany—but the burden of the work and the greater part of the honour of revising the 'Codex' falls upon the pharmaceutical representatives. The conditions are almost similar in Germany, the *Arzneibuch* Commission being appointed by the Emperor; and here, again, medicine, pharmacy, and chemistry are represented, and veterinary surgery is also recognised. In the United States matters are different. The Pharmacopœia of that country is practically a private publication; its authority is like that of our 'Unofficial Formulary'—it is tacitly recognised as an authority, but is not by Statute a compulsory standard, although each State in the Union may so decree in its Legislature.

In spite of its unsatisfactory recognition the United States Pharmacopœia is revised in a manner little short of perfect. Once every ten years all medical and pharmaceutical associations in the Union send delegates to a Convention held in Washington. The Convention appoints a committee to revise the work. The nation is recognised by the appointment of representatives of the Army and Navy medical services. As constituted the committee represents all directly interested, but in practice the work is done

by pharmacists, some of whom, however, hold medical qualifications. With the publication of a new edition the work of the committee does not end. This committee is so largely composed of leaders from our kindred body, the American Pharmaceutical Association, that year by year preparation for revision goes on by research committees, individual work, and reports on special subjects which small committees have been appointed to consider. The details of the scheme are of great interest, but it would be out of place to epitomise them now. Suffice it to say that they embrace consideration of every branch of the current literature of the world connected with a Pharmacopœia, and research on criticisms directly affecting the existing work. Be it noted that all this is done without statutory obligation. The committee are the publishers of the work, and the revenue obtained from it pays the out-of-pocket expenses.

Is it possible for British pharmacists to do something on similar lines? At present, year by year, an immense amount of work is done in our country which bears upon Pharmacopœia revision, and, saving the annual report to the Medical Council, which is a clever piece of literary craftsmanship, there is no adequate means of utilising this work. The Pharmaceutical Societies cannot be expected to look after such things, because their functions are becoming more and more concentrated upon the administrative side of pharmacy, I suggest that the British Pharmaceutical Conference should take the matter up. It represents the British Empire—England and Wales, Ireland, Scotland, Canada, India, and the colonies. Its object is to improve the practice of pharmacy. It is free from the burden of Acts of Parliament, and especially of official red-tape. It has already in the Formulary Committee given evidence of its ability in Pharmacopœia pioneering. We only require to reorganise the committee to make it suit the purpose. It should be representative—

First, of the more important centres is the three kingdoms, preferably through the local pharmaceutical associations.

Second, of the Pharmaceutical Societies of Great Britain and Ireland.

Third, of every pharmaceutical association and society of interest in Canada, India, and the colonies.

This would form a grand committee equivalent to the American Convention. From it would be appointed a smaller working committee, whose suggestions would be submitted to and voted upon by the grand committee before recommendation to the Conference, with reservations in regard to matters requiring expeditious decision.

The working committee's duties can better be imagined than described. It should be so constituted and have such powers that the director of it should be able to freely instruct or correspond with his colleagues regarding any B.P. subject. It should secure the co-operation of the Pharmaceutical Research Laboratory and of any similar institution in the kingdom or abroad. There is much assistance latent in the senior pupils of schools of pharmacy, in the laboratories of wholesale houses, and in our university colleges, apart from which there are many young pharmacists who would be only too thankful to apply to a central authority for work to do, if they knew that their assistance would be welcomed. You will all have noticed that the progress of pharmacy is made by potential examiners, who too frequently retire into their scientific coffins when they receive their appointments.

If a scheme of revision such as that I have outlined were carried out, new life would be infused into this Conference, and we should never lack pabulum for our discussions. Beyond which it might be possible for the Conference to publish a more comprehensive work than the "Formulary"—one rivalling the British Pharma

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

copœia itself; and, should the time ever come when pharmacists obtained statutory recognition as revisers of the Pharmacopœia, the organisation for the work would be ready.

Finally, pharmacists may well consider whether it is of their advantage to give their services under the present law so humbly to the General Medical Council as they do. I understand that the Council claims that it must adhere to the Statute, and that it may not delegate its powers to pharmacists. True, but as the assistance which pharmacists have hitherto given is legal, it would be quite as legal for the Council to give the representatives of pharmacy voting-power in the preparation of the work and remuneration for expenses incurred. Perhaps the Pharmaceutical Societies could not insist upon this, since there is a kind of brotherhood between all official executive bodies, but the Societies could say to the Medical Council, "Gentlemen, like yourselves, we have many executive functions to perform, and these practical pharmaceutical investigations which you suggest to us are not in our direct line of work; but the British Pharmaceutical Conference has had a Pharmacopœia Committee working for some time; we are represented upon it. Better try the B.P.C." The Conference would be able to state its terms, and if these were not agreeable to the Medical Council, then let the Council itself carry out its statutory duties without pharmaceutical assistance.

NOTE ON EXTRACT OF GINGER.*

BY T. H. W. IDRIS, F.C.S.

It is well known that alcoholic extract of ginger, commercially known as "gingerine," does not contain all the aromatic principles of the root, as most of the essential oil is carried over with the recovered alcohol.

In the course of experiments to produce extract of ginger that would contain the whole of the flavouring and odorous principle, it was found that acetone was the most suitable solvent, boiling as it does at 56° C. and being miscible with water in all proportions. The apparatus used consists of a modification of a Soxhlet on a manufacturing scale. If some powdered ginger be exhausted in a Soxhlet with acetone, and afterwards with alcohol, we find that the whole of the aromatic and pungent principles have been removed by the acetone, showing that it compares favourably with alcohol as a solvent. The acetone extract does not appear to have lost any of its volatile oil in the process of recovery, as is so markedly the case when using alcohol, while the last trace of acetone is easily removed by agitation with a little water. This acetone extract is a dark brown substance of a treacly consistency, intensely pungent and at the same time possessing a full ginger aroma, the quality of which largely depends on the variety of ginger used.

It is readily soluble in alcohol, forming a deep brown liquid. If steam be passed through the extract and then condensed it carries over a quantity of the volatile oil with it. This oil floats on the surface of the condensed water, forming a yellow layer, and can be easily removed. The difference in aroma of the various kinds of ginger, though noticeable enough when examining the rhizome, is much more apparent when dealing with the oils themselves, and in this way a method of distinguishing the variety of ginger used is obtained. The various tinctures and essences of ginger may be very conveniently and readily prepared from this extract without the usual loss of alcohol, and syrup may be flavoured with it by proper diffusion at a suitable temperature without the use of any spirit, and a further saving may be thus effected in manufacturing ginger-flavoured beverages.

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

THE GALENICALS OF THE NEW PHARMACOPŒIA.*

BY H. WIPPELL GADD.

The publication of a new Pharmacopœia inevitably provokes much criticism—some sympathetic, some severe, some savage. Fault-finding is proverbially easy, and grumbling the prerogative of Englishmen, whilst no patriotic Irishman is happy without a grievance.

On the other hand, it is manifestly unfair to condemn hastily products or processes which have been put forward by a body of experts after long deliberation and many experiments.

In these notes it is my object not so much to criticise as to bring forward points and apparent difficulties which have been noted in the course of manufacturing work, in the hope of provoking a good discussion rather than of imparting information.

In the first place, it would appear that in spite of the small quantities named in its processes, its lordly indifference to the needless dissipation of spirit, and the undoubted orthodoxy of its compilers, the Pharmacopœia of 1898 is essentially a wholesalers' Pharmacopœia.

That is to say, the stringent nature of its tests, the number of spirits of varying strengths employed in its processes, and its insistence on standardisation will make it more and more difficult for the official galenicals to be made economically and efficiently on the small scale. And, that being so, it is surely not too much to ask that those whose products will be examined, not by an ignorant public, but in the fierce light which comes from the coloured carboys, should know exactly what is required of them, and what body is better able to interpret the official directions than this Conference?

To mention the solvents first, it is satisfactory that, the tests being more stringent, "engine waste" can no longer be described as "aqua distillata." The changes in alcoholic strengths, which at first appeared revolutionary, present no great difficulty in practice, and as the drugs are doubtless better exhausted they may be looked on as advantageous.

Of the new and altered preparations I have made notes concerning the following:—

Effervescing citrate of caffeine.—A satisfactory formula, its only drawback being that the strength (4 per cent.) bears no simple relation to the dose.

Resin plaster.—The directions for melting each ingredient separately are impracticable in the case of the soap.

EXTRACTS.—Liquid extract of belladonna, which is the basis of all the belladonna preparations, with the exception of the green extract.

The pharmacopœial process, with slight practical modifications, appears to be satisfactory, although it has been shown by Bryant not to exhaust the alkaloidal strength of the root.

The latter's process, however, materially alters the appearance of the extract, which difference is particularly noted in making the official ointment.

And here I should like to call your attention to some samples of belladonna extract met with in commerce, all of which are guaranteed to be B.P. 1898, but which show striking variance in physical characters.

The solid extract is made from the liquid by evaporating, adding sugar of milk and then further concentrating, a process not free from difficulties, and which becomes objectionable when the extract is used for making suppositories.

For the latter, I would suggest that, instead of taking 18 grains of the solid extract as the Pharmacopœia directs, 30 minims of the liquid extract be taken.

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

I submit samples made by the two methods. With regard to the ointment, it has already been pointed out by Umney that it would be better to evaporate the liquid extract to a quarter instead of an eighth of its bulk. The standardised liniment is also advantageous, but its logical outcome, the standardised methylated liniment, savours somewhat of a *reductio ad absurdum*.

Liquid extract of ipecacuanha, with its products, the official vinegar and wine, are things to be thankful for, the only drawback being that whilst the Carthagen root is not sanctioned, there is nothing in the estimation process to show the nature of the total alkaloids and consequently the source of the drug employed.

The liquid extract of nux vomica being estimated for strychnine only, and the consequent alteration of the strength of the solid extract and tincture, are very important points. I have found the separation of the strychnine and brucine by means of potassium ferrocyanide difficult.

No amount of washing appears to free the precipitate absolutely from brucine, whilst the bitter taste persists in the filtrate. Prolonged washing, moreover, causes a considerable diminution of weight, with a probable loss of strychnine. Would not a reprecipitation process, as suggested by Dunstan and Short in their original paper, be better? I should much like to hear the experiences of others in this connection.

Extract of strophanthus is curious as being made by successive percolation with ether and alcohol (90 per cent.), whilst percolation with alcohol (70 per cent.) alone suffices for the mixture. Concerning the remaining extracts little need be said, except that it would be well if the directions evaporate "to a soft extract," "to dryness," "to a firm extract," as the case may be, could be replaced by directions to concentrate to a given weight.

Ext. coloc. co. and extract of cascara sagrada would be better in the form of powder.

With regard to extract of Calabar bean, the product will vary in accordance with each manufacturer's idea of what is "a very soft extract."

This is a matter of some importance with so potent a drug, and I would suggest that a similar process to that for extract of strophanthus, in which the final product is directed to be of a definite weight, would be preferable.

Glycerin boric acid, when made by the Pharmacopœial process, turns pink.

Perhaps one of the best features of the new Pharmacopœia is the use of metric equivalents, but compromises are always unsatisfactory, and one's loyalty to the decimal system is somewhat strained by the awkwardness of the concentrated liquors 1 in 10. This is, however, more a point for dispensers than for manufacturers.

The amount of menstruum ordered in making liq. calumb. conc. is quite inadequate, whilst the maceration and pressure method, which has obvious disadvantages for this drug, does not yield a better result than slow percolation alone.

The process by which the concentrated solutions of chiretta, cusparia, krameria, quassia, rhubarb, senega, and serpentary are prepared is elaborate and troublesome, but does not exhaust the drugs.

Liq. hamamelidis not being able to be made on this side of the Atlantic, it would have been better if characters and tests had been given instead of a process of manufacture.

Liq. sarsæ co. conc.—If the mixed infusion and decoction be concentrated to sixteen fluid ounces a pint of filtered product cannot be obtained. It should be concentrated to 18 fluid ounces.

The powders, with the notable exception of aromatic chalk powder (from which the saffron is deleted), are little altered, but it may

be noted that the trade custom of using decorticated liquorice for compound liquorice powder is now officially enjoined.

Of the syrups, syr. ferri phosphatis cum quinina et strychnina is unsatisfactory, the precipitation process giving a much better product.

Syr. cascarae aromat. is not an elegant preparation, as it quickly deposits.

Syrup of lemons, containing as it does a strong tincture of the fresh peel, is a decided improvement.

It seems a pity that specific gravities are not given for the syrups, forming, as they do, useful and ready tests.

The tinctures are the class of galenicals which have been subject to most alterations, on the whole with satisfactory results. It may be doubted, however, if a slight improvement in flavour and a possible reduction in the price of marmalade are worth the trouble caused by the preparation of tincture of orange from the fresh peel. Here again the indirect result is to take the manufacture out of the retailer's hands.

If medicine requires tinctures of uniform strengths and doses, pharmacy can supply them, and has no cause to complain, but the changes in those made from potent drugs should be notified as widely and as fully as possible.

These are briefly:—Tincture of aconite, two-fifths the strength of the 1885 tincture; tincture of belladonna, about double the strength of the 1885 tincture; compound tincture of chloroform and morphine, four times the strength of hydrochloride of morphine, and a totally different preparation; tincture of nux vomica, nearly twice the strength of the 1885 tincture; tincture of podophyllum, nearly double the strength of the 1885 tincture; tincture of strophanthus, only half the quantity of drug is used, but being better exhausted the alkaloidal strength may not be very different. It would be interesting to have results of analyses of the last-named tincture.

With regard to the compound tincture of lavender and also the spirit of lavender, it has been noted that foreign oils are not now excluded from the Pharmacopœia, but as it is difficult to meet with an *ol. lavand. exot.* which conforms to the official tests, the concession does not appear to amount to much.

Tincture of rhubarb without saffron differs so little from the old tincture that this economical change would appear to be an unmixed blessing. Concerning the tinctures as a whole, it seems a pity definite characters such as specific gravities or amount of extractive are not given, when more exact standardisation is not feasible.

The lozenges are hardly galenical preparations, but it may be noted in passing that trochisci acid. carbolicci appear to be excessively strong.

Of the ointments, the process for that of nitrate of mercury is a decided improvement.

Paraffin ointment has been complained of, but the allowance of variance in accordance with temperature meets this objection.

Ung. staphisagriae would be better made from the oil.

In the wines, the test for freedom from salicylic acid is useful, and the great improvement in ipecacuanha wine has already been noted.

Viewing the galenicals as a class, I cannot but consider that the new Pharmacopœia is in advance of the previous ones, the weakest point being the processes, and one wonders if in some future book, when pharmacy approximates more closely to an exact science, and the present tendency towards factory-made preparations has advanced still further, the galenicals may be treated as the chemicals are now, processes being omitted and tests extended.

THE CHEMISTRY OF THE 1898 B.P.*

BY P. KELLY, PH.C.

My object in reading this paper is with a view to inaugurate a discussion on the chemistry of the new B.P., and thereby elicit the opinions of the members of the Conference which may tend to the mutual benefit of all concerned.

It is held by some that the Pharmacopœia is not intended to be a teaching book. To my mind it cannot be separated from that object, and, moreover, that it is not only a teaching book, but one that we all should look to both as a standard in scientific work, as well as a standard in manufacturing operations, and so should be the guide-book alike both of the youthful apprentice, without a thorough knowledge of which he cannot either become a competent assistant or a successful candidate at his examinations, and to the matured pharmacist it should be the chart by which he is expected to steer, the guide-book of his every operation, to produce substances in keeping with the standard of its requirements.

Now, this being so, how necessary it is that its contents should enlighten us as to the best methods for the detection of, or exclusion of, suspected impurities; that the tests used for this purpose should be the most reliable known, and the directions for their application should be explicit, thoroughly practical and free from laxity.

Let me first draw your attention to the atomic weights of the elements, which to me seems the most radical change in the whole volume, as it affects every chemical substance in it, altering the molecular weights of all chemical compounds contained in it, and in this way it is accountable for the most numerous, if not the most important, changes, every one of them being altered, with the exception of that one, to alter which, as it is the standard, would destroy unity, and upset the bases upon which we work; I mean the platform constructed by Dalton, the atomic theory, and I allude to hydrogen.

The cause for such sweeping alterations, I suppose, must be due to the scientific progress in the method of determining them.

But passing on from hydrogen, all the remainder are, like the ladies, growing younger every year.

Now take antimony, before 1885 its atomic weight was 122; in 1885, 120; and in 1898, 119; and so with them all, that one does not know where they will stop, and begins to fear for the stability of the periodic law (as I believe the discovery of argon has even puzzled Mendelejeff himself).

And so one is surprised at the diversity of opinion which exists between the most expert experimenters with regard to the atomic weights of the elements.

Then with regard to the introduction of structural and constitutional formulæ, I would say, from a scientific point of view, it is well to give us an idea of the internal arrangement of the atoms in organic compounds, which enable us for one thing to account for the different physical and chemical properties of isomeric bodies. Yet from a practical point of view I would say the empirical formulæ would be less strain on the memory and more useful for writing an equation.

For instance, take oleic acid. The empirical showing its monobasic character would be $H \cdot C_{18}H_{33}O_2$, whilst its constitutional would be $C \cdot H_3(CH_2)_7C \cdot H : C \cdot H (C \cdot H_2)_7C \cdot O \cdot O \cdot H$.

I consider these complex formulæ, which are wrapped up in so much mystery, or at least theory, should be left to the writers of scientific text-books, and for practical purposes use the empirical formulæ only in the B.P.

I consider the changes in nomenclature are an improvement,

especially the acids being now expressed as salts of hydrogen, as sulphuric acid, now termed hydrogen sulphate, and the hydrates, now termed hydroxides, is a decided step forward.

With regard to inorganic acids, there are a few changes in them, notably acid hydrobromic dilute, which is now prepared, or, as the B.P. says, "may be obtained," by the distillation of potassium bromide with concentrated phosphoric acid, which I consider a great improvement on the '85 process, viz., with bromine and hydrogen sulphide, and also on the Fothergill process; its strength is determined volumetrically by vol. sol. silver nitrate, new, and by vol. sol. of sodium hydroxide. There are three methods by which sulphurous anhydride may be obtained, viz., combustion of sulphur in air or oxygen, boiling sulphuric acid with copper, mercury, or carbon. The first three are new in the B.P.; the sulphuric acid plus carbon is the '85 process, which being faulty might be left out.

Amongst organic acids, citric gets the lion's share of attention, and deservedly so, as it is used so much in medicine and also for domestic purposes. There are several tests to detect impurities and two tests to detect tartaric acid, which you would scarcely expect to find now as an adulteration, the commercial value being so nearly equal. Tartaric acid has also an increase of tests, one a very pretty reaction. I mean where you take a solution of tartaric acid to which you add a drop of solution ferrous sulphate, and a few drops of hydrogen peroxide, and solution of potassium hydroxide in excess, which gives a very pretty purple or violet colour.

The mirror, or reduction test (as there are so many organic bodies which produce similar results), I would be inclined to dispense with. Phenol, commonly called carbolic acid, has also its alterations, especially its boiling and melting points. Salicylic acid is also slightly changed in its mode of preparation, also its melting point, and a new test (uranium nitrate) is introduced to detect or exclude carbolates and sulpho-carbolates.

In a short paper like this it is impossible to deal at any length with the numerous changes in constants, and the increased number of tests which involve an increased number of reagents.

The standardisation of the preparations of potent drugs, such as extracta, nucis vomicæ, belladonnæ, ipecacuanha, as to their alkaloidal strength, is both from a therapeutic and chemical point of view a great improvement.

This should be valuable information to the medical man who prescribes according to the B.P.

That the 1898 B.P. is an improvement upon its predecessors (in many respects) is unquestionable, especially in its chemistry. Yet there is still room for improvement, and though in the preface the onus is thrown a good deal on the one hand on the prescriber, and on the other on those who are supposed to be duly trained, thus ridding the editor of almost all responsibility from the position the book occupies, this cannot be. If you are to be obedient to its dictates it should supply you with the necessary information to carry them out. I do not think this has been done in the part devoted to the preparing of the volumetric solutions.

Comparing it with '85 B.P., there are still six in number, sulphuric acid being substituted for oxalic. All the molecular weights of the substances used are altered on account of the alteration in the atomic weights but potassium bichromate, which is completely altered, its molecular weight being now 292.3, as compared with 295, and 4.87 grammes dissolved in 1000 C.c. instead of 14.75 grammes in 1000 C.c., which was in the '85 B.P.

The change is an improvement, but what I consider cause for complaint is, those changes are not even alluded to in any way, footnote or otherwise. There is no information as to the use of

indicators, except in the case of sodium thiosulphate solution, where you are told to use mucilage of starch and sodium hydroxide litmus.

Now on page 8 of the preface you find written that it is desired that the B.P. should afford to the members of the medical profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide, whereby the nature and composition of substances used in medicine may be ascertained and determined. This is why I say standard strength should be explicitly stated, and so be what an authorised book should be—a guide alike to the youth learning his business as well as to the duly trained chemist. And as it is assumed that the chemistry of the 1898 B.P. is the emanation from (shall I say) the blended brains of practical English and Scotch chemists, should we have any hesitation in expecting it to be a standard in scientific manipulation, and if such is not the case, might I suggest that it was due to the need of the presence of an Irishman in their deliberations?

AMOUNT OF CARBONIC DIOXIDE AVAILABLE IN THE OFFICIAL GRANULAR EFFERVESCENT PREPARATIONS.*

BY C. S. DYER, A.P.S.

Supplementary to the investigation suggested by the title of this paper is the examination and comparison of certain commercial specimens on the same point with a view to obtaining an official standard.

Of course the quality of a non-medicinal granular saline consists solely in the extent of its effervescence, or, in other words, the object aimed at is to get as large an amount of carbonic acid gas as possible with the least quantity of dissolved salt.

The only practical method of determining the amount of gas was to measure the carbon dioxide volumetrically.

The apparatus used was an ordinary Lunge nitrometer with the urea determination arrangement attached. The nitrometer was filled with water, and to avoid absorption of CO₂ a little benzene was floated on the surface in the measuring tube, the resulting presence of the mixed benzene and aqueous vapour caused the amount of gas evolved to exceed the theoretical yield by about 10 per cent., so eventually mercury was employed, this giving in every way satisfactory results.

The different samples were moistened with an equal quantity (2 C.c.) of water. This would at same temperature and pressure absorb the same amount of gas, which would not exceed 2 C.c.

Several specimens of commercial sodium bicarbonate were first tried, and were found to give almost identical results, all showing almost exactly the theoretical amount of CO₂.

Then to ascertain whether the loss of gas on granulating is due to the heating of the bicarbonate, *per se*, the same samples were exposed to a temperature of 100°-105° C. for ten minutes; that is, under the same conditions so far as heat is concerned as in the process of granulation. The resulting loss in weight amounted to about 2 per cent., this is apparently water, the same quantity of gas being evolved.

The ingredients of the P.B. sodii citro-tart. effervescens were then carefully weighed out and well mixed.

1. Part of this mixture was immediately tested for quantity of CO₂.

2. Part was dried below 54° C. without granulating (for comparison with No. 3) to see how much loss the necessary high temperature caused, and

3. The rest was passed through the P.B. process, granulated, and dried.

The two latter parts both lost about 10 per cent. in weight as

the P.B. states, but that portion not heated much showed a higher percentage of gas available.

Now, citric acid loses nearly 9 per cent. of its weight in water of crystallisation, and the amount present of citric acid is only 16 per cent. The other ingredients only lose about 2 per cent. in weight on treating. How is this 10 per cent. to 12 per cent. loss accounted for? The following paragraph will, I think, make this clear.

Sodium bicarbonate on combining with an acid of course produces CO₂ and H₂O, which is lost on drying. This amounts to 62 per cent. of the weight taken, and as the quantity present is about 46 per cent., the total possible loss in this way would be—

$$\frac{46 \times 62}{100} = 28.5 \text{ per cent.}$$

The observed decrease in weight is about one-third of this, roughly indicating that about 30 per cent. of sodium bicarbonate and acid has combined during the process. To see how far this is actually the case, the following figures will show.

Use mercury in the nitrometer; if using water place a little benzene on surface, and remember the results will be 10 per cent. higher.

Substance experimented on.	Quantity used.	No. of C.c. of CO ₂ evolved at N. T. and P.
1. Sodium bicarbonate15 gramme	41.6 C.c.
	.15 gramme	41.8
2. Ingredients of P.B. eff. citro-tartrate immediately after mixing3 gramme	39.24 C.c., slight loss
	(46 p.c. NaHCO ₃)	
3. Ditto dried below 54° C., not granulated3 gramme	33 C.c. = 21 p.c. loss gas
P.B. process carried through3 gramme	27 C.c. = 32 p.c. loss gas
5. Good commercial sample by well-known maker3 gramme	26.8 " " "
6. P.B. eff. sodii sulphas3 gramme	21.8
7. P.B. mag. sulph. eff.3 gramme	15 C.c.
	(contains only 36 p.c. soda)	
8. Sample of mag. cit., commercial..	.3 gramme	15 C.c.

No. 2 shows a slight loss, the powder being very damp.
 No. 3 shows nearly as much loss as in the final operations.
 No. 4, 32 per cent. loss; this agrees with the loss in weight mentioned before.
 No. 6, a comparatively old sample.
 No. 7, this preparation contains only 36 per cent. of soda, against 50 per cent. of No. 6; the relative yield is therefore the same.
 No. 8 contains about 33 per cent. sodium bicarbonate; result fair.

To summarise the above, it appears that good commercial specimens of the P.B. article and carefully made samples, unless absolutely fresh, exhibit only about 60 to 70 per cent. of their sodium bicarbonate available for effervescing purposes. This, to me, surprising result shows that fully 30 per cent. of the acids and sodium carbonate combines during the process of granulation.

1. Now this 30 per cent. loss of sodium carbonate is nearly sufficient to neutralise the amount of citric acid present.

2. The citric acid causes the mass to flux, because it (the acid) melts at about 100° C.

It is evident, therefore, that at the same time practically the whole of it combines with the carbonate so brought into molecular contact with it, leaving the eventual effervescence entirely to the tartaric acid.

The above method is very useful when desiring to compare many samples of salines at about the same prices as after weighing; only about two minutes is required to complete the operation, so a good many can be tested with a very moderate expenditure of time.

I would throw out the suggestion that the Pharmacopœia ought among the characters and tests of those preparations to state the least amount of CO₂ which each should yield on the above treatment. Any sample which does not show, say, 50 per cent. of its bicarbonate available for producing effervescence should not find its place in modern pharmacy.

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

THE STUDENTS' PAGE.

THE STUDY OF THE B.P.

INTRODUCTORY.

THE British Pharmacopœia is not a text-book, but it is, nevertheless, a book with the contents of which pharmaceutical students should be familiar, from cover to cover. Moreover, it is not sufficient that the statements contained in the book should be committed to memory; the work must be studied with a due sense of the reasons for so doing, and not a single statement should be passed over by the student until he has thoroughly grasped its full import. He will find then that the whole of his work circles round the Pharmacopœia, frequent reference to text-books of physics and chemistry, botany and pharmacography being required in order to secure that thorough grasp of the import of official statements already referred to. Whilst, therefore, the study of the Pharmacopœia cannot be entered upon too early in the pupil's career, he must, sooner or later, take up the study of the sciences mentioned if he desires to master all the details of the national medicine book. Accordingly, it will be assumed in the following notes that the student possesses an elementary knowledge of the general principles of chemistry, botany, and pharmacy.

PLAN OF WORK.

It is proposed in these notes to take the substances in the new Pharmacopœia seriatim and furnish explanations for such statements as seem likely to present difficulties to the student. It will obviously be unnecessary to repeat the information contained in the series of explanatory notes just concluded and relating to the 1885 B.P., edition, since the journals containing them are of recent date, and should be readily available for reference by the student. In what follows, therefore, it will be assumed that the reader will have by his side the "Students' Page" of those back numbers which contain the previous monographs dealing with the substances under discussion. By adopting this plan, unnecessary repetition will be avoided and space saved; at the same time there will arise numerous opportunities for comparison between the 1885 and 1898 editions of the Pharmacopœia. Those comparisons will be particularly profitable during the present transitional period, whilst the old B.P. is being superseded by the new. And although for examination purposes only a knowledge of the new Pharmacopœia will later be demanded from candidates, the student engaged in the practical business of pharmacy will for some time to come find it necessary to possess a general acquaintance with the contents of the superseded work, in order to avoid errors and difficulties likely to be encountered in dispensing prescriptions written before the issue of its successor.

SOME PRELIMINARY CONSIDERATIONS.

Before commencing the study of the details of the Pharmacopœia, it will be well to devote some consideration to the methods which experience suggests as the best to be followed in dealing with a work of such extended range. The articles mentioned in the Pharmacopœia will then be considered in order, care being taken to expand and explain the statements made in each monograph, whilst an endeavour will be made always to use such explanations as illustrations of the principles involved. In this way

it is hoped that the student will acquire the habit of applying his knowledge intelligently and usefully to the elucidation of problems of allied nature. The explanations offered will be as full as is consistent with the above remarks; at the same time the student should not rest content with anything less than the ability to explain every statement made in the Pharmacopœia. It may therefore happen at times—perhaps more particularly in the case of an apprentice who has not had the opportunity of a systematic course of study—that some explanation may be omitted which appears simple but is not self-evident to the beginner. Under such circumstances the student is invited to communicate his difficulty to the Editor, observing the rules for correspondents, and an endeavour will then be made to remove it.

INTELLIGENT STUDY PREFERABLE TO CRAM.

With regard to the chemistry of the Pharmacopœia, there are numerous instances where the knowledge involved extends considerably beyond the chemistry of the Minor syllabus. It is in such cases that information can very profitably be supplied, which is probably not contained in the text books used by the student. It is also quite common to hear students speak of "getting up" the Pharmacopœia, as a colossal task involving an enormous amount of memory work, particularly in connection with the formulæ for galenical preparations. It cannot be too strongly impressed upon students at the beginning of their studies that this is quite wrong. To commit to memory such formulæ is to encumber the mind with information which is not demanded of them by the examiners (*vide* Syllabus of Pharmacy for the Minor Examination); it is also useless for any practical purpose. A knowledge of this sort may be acquired without effort by one engaged in manufacturing the things continually, but sufficiently extended opportunities are seldom available for the average student. To acquire, by mere reading and effort of memory, a store of information which is useless for any practical purpose and rapidly forgotten is obviously more than a waste of time. There is, however, a small amount of memory work required in the Minor Syllabus in Pharmacy, viz., the proportion of active constituent present in the preparations of the more toxic drugs. But it is essential to note carefully that this knowledge is practically useful, because it enables the pharmacist to check accurately the doses of substances contained in prescriptions submitted to his care. For example, knowing that the lozenges of morphine and ipecacuanha contain 1/36th grain of morphine hydrochloride in each, he realises at once that eighteen lozenges contain the maximum dose of the morphine salt. Moreover, knowing the dose of the original drug and the proportion of it contained in its preparations, he is provided with a check upon his memory, with regard to doses, in just those cases where it is absolutely essential that his memory should never be at fault. Beyond this, such extended knowledge should not be attempted by mere reading; it can only be usefully and permanently acquired by practical work in pharmacy. Let the student acquire as much detailed information as he can in this manner—the more the better—but in his reading let him devote his attention to the principles of processes. To give a concrete example, the man who knows why water acidulated with hydrochloric acid is used in making liquid extract of cinchona is in possession of much more valuable information than the one who knows that he must use five fluid drachms of hydrochloric acid in the official formula, but does not know why it is employed. It will be seen therefore that the pharmacy of the Pharmacopœia, approached in this way, no longer possesses the terrors which it often has had for the tiro labouring under a misconception as to the information he is expected to possess.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, AUGUST 13, 1898.

THE "OPEN DOOR" FOR UNION.

As this number of the Journal will be sent to every person on the Register of Chemists and Druggists in Great Britain, a convenient opportunity is afforded for repeating the admonitory appeal addressed by the President of the Pharmaceutical Society more especially to the members of that body. Various circumstances connected with the passage of the Pharmacy Acts Amendment Bill through both Houses of Parliament have incidentally given increased significance and importance to the simple measure designed for the purpose of broadening the foundation of the Society and establishing that solidarity of the body it represents which has always been desired. The past history of the Society and of pharmacy legislation, bears indications of a continuous struggle in which the efforts to create a qualification for the practice of pharmacy, as a professional occupation, have been counteracted by influences referable to those parts of the business of chemists and druggists which partake more of trade. That has been a natural consequence of the mixed nature of the business and while the only qualification was that of pharmaceutical chemist, the comparatively limited membership of the Society was not surprising. At a later date, when there was a general demand for incorporation of the entire body, pharmaceutical chemists resisted—without reason, though perhaps without sufficient liberality—the admission of others to membership of the Society. The compromise eventually made was not a happy one for either section, for though incorporation was effected from the point of view of the public interest, there was a lack of harmony within the craft, as to the need for education which left room for manifestations of dissatisfaction, real or affected, on the part of the trade, a somewhat vague entity still assumed to be hostile to the Society. The unfortunate exclusion of persons qualifying by examination under the Act of 1868, has augmented that feeling and it has, no doubt, been one reason why so many have abstained from joining the Society. Hence the attempt, commenced more than twenty years ago, to rectify that mistake as to membership. The successful result now attained ought to remove any objection that has hitherto been made to connection with the Society. It is no longer necessary to take a qualification for the practice of pharmacy which many consider to be beyond their requirements. Membership of the Society is now open to all who possess the qualification "to sell or keep open shop for or retailing, dispensing, or compounding" the articles declared

to be poisons within the meaning of the Pharmacy Act, 1868. The title of pharmaceutical chemist is protected for those who voluntarily take it, but otherwise all the privileges of membership will be equally shared. Full opportunity will therefore be afforded for the exercise of self-government, for protecting individual qualification and for promoting the general interests of registered chemists and druggists.

There ought no longer to be any reticence nor any disposition, such as that mentioned by the PRESIDENT last week, to stand aside inert, until advantages have been gained and then to be ready to share them. If the position of the craft is to be improved, that result will be attained only by hard fighting that must be done by the Society constituted of such a large majority of registered persons as will be practically representative. The unexpected reference to company trading, which is the especial sore point with registered chemists, the favourable expression of opinion that there is need for amendment of the Pharmacy Acts and the similar tendency of the recent discussion in the House of Commons, are all indications that, at the present moment, there is an opportunity which should be vigorously taken advantage of by all who are concerned in defending their position. For that purpose the Society is the only medium through which an effort can be made and therefore, we repeat the appeal of the Society's PRESIDENT to all who are unconnected with the organisation to come forward and do their part in the work to be undertaken.

As pointed out by Mr. BOTTLE, Mr. CARTEIGHE, and several other members of Council, resistance to the invasion of the chemist's business by companies is not to be undertaken rashly or without careful consideration. For our own part we believe that the decision of the House of Lords in the London and Provincial case has been taken as going much further than it really did go. The very important qualification in Lord SELBORNE's judgment, that there would, under certain conditions, have been an extremely strong argument against a corporation being permitted to carry on the business, does not appear to have been sufficiently considered. In any case, the decision does not seem to warrant the conclusion that a company may carry on the business provided a qualified person is engaged as the seller. If that inference were correct, there would be no reason why an unqualified individual should not carry on the business with a qualified assistant. We are more disposed to think it is maintainable that, in regard to the Pharmacy Act, 1868, company trading is altogether unlawful in itself and the support of it by registered persons a disloyal complicity in a breach of the law. No less position can be taken, for as a company is held to be outside the scope of the Act because a company is not a person that can comply with the statutory requirement of being examined, the argument should be equally conclusive that a company cannot lawfully perform the functions of selling or keeping open shop for retailing, dispensing, or compounding poisons, etc., in respect of which individual qualification is declared to be essential for the purposes of the Act. Since that requirement "is expedient for the safety of the public" no exception can be made without sacrificing that object of the Act and at the same time inflicting injustice on the persons who have satisfied the demand of the law. As for any degree of acquiescence in the practice of store trading, there does not appear to be the slightest reason, nor has there been—as Mr. CARTEIGHE reminded the Council last week—any indication that it would be entertained, or regarded as tolerable, by any portion of the registered chemists and druggists of the country.

THE PRESIDENTIAL ADDRESS AT BELFAST.

THE address delivered by Dr. SYMES at Belfast resolved itself on this occasion into a fairly comprehensive survey of the numerous problems, small and great, which have of late years troubled the pharmacists of these islands in a greater or less degree. Education is regarded by Dr. SYMES, who appears thus to overlook the supreme importance of organisation, as being first and foremost amongst the means which have helped in the general advancement of the craft. Examinations he might be thought to honour too much by remarking that they are undoubtedly a stimulus to study, but for the fact that he recognises the danger of men being content to acquire the minimum of knowledge necessary to pass the qualifying examination of the Pharmaceutical Society, and then believing that they have done all that is requisite in the way of study to enable them to do justice to the position in life which they have chosen to aspire to. As a partial remedy for this state of affairs, Dr. SYMES points to the existence of the body of which he has for the last two years been President, but it is greatly to be feared that not even the work of the British Pharmaceutical Conference will prove effective in persuading the "so-called qualified man" of the extent of his ignorance.

The reminder that pharmacists are directly interested in the operation of many Acts of Parliament that do not concern the ordinary individual is a timely one, for every member of the craft should consider it incumbent upon him to possess an acquaintance with certain provisions of all the Statutes mentioned by Dr. SYMES and of one or two others. But, unfortunately, too few have even taken the trouble to acquire a definite knowledge of the Pharmacy Acts, and it is not surprising, therefore, that chemists and druggists are continually finding themselves at a disadvantage because of their ignorance of the exact bearing of some Statute or another upon their business. The Poisonous Substances Bill, recently deceased, naturally came under review in the address, Dr. SYMES being strongly of opinion that it is impracticable for a Government department "to legislate for matters which really belong to pharmacy." That is a pretty common view in pharmaceutical circles, but, in view of the probability of the objectionable measure being resuscitated next session, attention cannot too often be directed to the fact.

The metric system and the difficulties attending its general use were briefly referred to, and pharmacists urged to familiarise themselves with the system, so that they may help to forward its universal adoption. Allusion was also made to the special regulations bearing on the sale of calcium carbide and methylated spirit, the restrictions in connection with the latter being held to be unnecessarily severe and tending to operate in restraint of trade. Synthetic compounds used in medicine and for industrial purposes were then referred to at some length, after which attention was devoted to the new British Pharmacopœia. Dr. SYMES reiterated his oft-repeated objection to the constitution of the British Pharmacopœia Committee of the General Medical Council, protesting against the exclusion of pharmacists from that body when the bulk of the work of revision must of necessity be done by pharmacists. Exception was also taken to the manner in which the book was published, the arrangements adopted in Germany being instanced as much superior. In addition to having a properly constituted Pharmacopœia Committee, our Teuton cousins publish from time to time the suggestions made and

alterations proposed in connection with the national medicine book, so that anyone may criticise the work of the revisers, and further suggestions be embodied. A new German Pharmacopœia, when it is published, is thus as nearly perfect as the state of medical and pharmaceutical knowledge will permit. In conclusion, Dr. SYMES paid the Irish hosts of the Conference and their country some pretty compliments, and gave utterance to a brief but well-merited encomium on the late MICHAEL CONROY, a warm-hearted Irishman, and a highly-esteemed member of the Conference, of which he was at one time Vice-President.

WORK RECORDED AT THE CONFERENCE.

Fielden on Gluten Flour. A sample of so-called gluten flour having been found to contain abundance of starch and but a small amount of gluten, V. G. L. FIELDEN subjected five commercial samples to detailed examination. With one exception all but one proved to contain a large proportion of gluten, ranging from 60 to 76 per cent. The fifth sample—of American origin—contained 8.5 per cent. only. As regards starch and sugar, the four samples rich in gluten yielded from 7.6 to 16.7 per cent., whilst the one containing little gluten consisted of starch and sugar to the extent of 68.8 per cent., so that diabetic patients would gain little by using it instead of good wheaten flour. Since the proportion of gluten in flour is readily determined by simply washing a sample in a muslin bag and drying, the author suggests that all chemists who sell gluten flour should occasionally test their stock (p. 170).

Gordon Sharp on Albumins. As the result of an examination of hard-boiled egg-albumin and dried serum-albumin, Dr. GORDON SHARP arrives at the conclusion that peptone is absent from both. Egg-albumin is said to yield unaltered albumin, alkali albumin, proto-albumose, a little hetero-albumose, and some crystalline matter of an alkaloidal nature; serum-albumin differs in yielding more hetero-albumose, together with a little deuterio-albumose. Papain was found to digest serum-albumin much more readily than egg-albumin, yielding traces of proto and hetero-albumose, abundance of deuterio-albumose, but no peptone. With pepsin, in both cases, the digestive process was carried further, traces of true peptone being found. In the presence of yeast, as in the maturing of koumiss, the albumin is milk is partly changed into the higher proteids, but the peptone stage is never reached (p. 197).

Dyer on Granular Preparations. Having prepared and examined some granular effervescent sodium-citro-tartrate, C. S. DYER concludes that fully 30 per cent. of the acids and sodium bicarbonate used in making the preparation combines during the process of granulation, leaving between 60 and 70 per cent. available for effervescing purposes. He assumes also that the 30 per cent. of sodium bicarbonate so lost combines exclusively with the citric acid during the application of heat in the granulating process. In that case it is evident that the eventual effervescence must be left to the tartaric acid. It is suggested that in official statements of the characters and tests of granular effervescent preparations it should be stipulated that at least 50 per cent. of the bicarbonate present should be available for producing effervescence (p. 181).

Moss on Diatomite. The leading facts of special interest concerning the various infusorial earths—diatomite—in common use have been brought together by J. MOSS, who also indicates particular applications of which those earths are susceptible. As a filtering medium, diatomite freed from organic matter is absolutely indifferent to all but the strongest alkalies at a high temperature, it does not clog up the filtering bag to the same degree as talc or asbestos, and its particles are sufficiently large and irregular in shape to keep apart the particles of albuminoid or starchy deposits, and so allow liquids to pass readily. White diatomite, free from sand and organic matter, makes an excellent basis for dentifrices, and by virtue of its enormous and unequalled absorbent property it is unrivalled as an ingredient of dusting powders. Finally, its use is suggested as a diluent for hygroscopic powders and for binding together drugs that compress with difficulty (p. 168).

MacEwan on the Pharmacopœia. The British Pharmaceutical Conference should, in P. MACEWAN'S opinion, take upon itself the task of revising the Pharmacopœia. He would have the Formulary Committee reorganised so that it should be representative (1) of the more important centres in the three kingdoms, preferably through local pharmaceutical associations; (2) of the Pharmaceutical Societies of Great Britain and Ireland; and (3) of every pharmaceutical association and society of interest in Canada, India, and the Colonies. This Grand Committee should appoint a smaller working committee, which should secure the co-operation of the Pharmaceutical Research Laboratory, and of any similar institution at home and abroad. Pharmacists would thus take the lead in the matter of pharmacopœia revision, and might stipulate for more satisfactory conditions than now prevail when asked by the General Medical Council for assistance (p. 177).

Jowett on Mydriatic Alkaloids. The descriptions and tests of mydriatic alkaloids given in the new Pharmacopœia are considered by Dr. H. A. D. JOWETT to be generally unsatisfactory, and in some cases misleading and inaccurate. In the case of atropine and its salts he thinks the insertion of the colour test with fuming nitric acid and potash is quite unnecessary, and he suggests that to ensure pure products, such as might reasonably be expected from manufacturers, reference should be made to the melting point, formation and melting point of the aurichloride, optical inactivity, and freedom from ash on ignition. It is suggested that the melting point of hyoscyamine should not be lower than 200°, that scopolamine or hyoscyne hydrobromide should have its solubility given as 1 in 4 rather than 1 in 1, and that the melting point given for the dehydrated salt should also be modified (p. 195).

Dowzard on Strophanthin Assay. A quick polarimetric method for approximately determining the amount of strophanthin in the official extract and tincture, described by E. DOWZARD, consists in reducing the preparation to be assayed to a small bulk, then heating with a little basic lead acetate, evaporating the filtrate and washings to a definite volume, and noting the optical rotation of the liquid in a 200 Mm. tube, using an instrument of the Laurent half-shadow type (p. 199).

McWalter on Animal Extracts. In a lengthy paper, J. C. MCWALTER deals with the recent animal materia medica. The tendency of the paper is medical rather than pharmaceutical, on the whole, and no adequate summary could be presented here, in the limited space at disposal for that purpose. Suffice it to say, therefore, that the exhaustive notes on animal extracts of all kinds should prove extremely useful for reference (p. 155).

Jowett on Hypophosphites. An investigation of hypophosphites by Dr. H. A. D. JOWETT has had for its object the discovery of an accurate method for determining the amount of hypophosphite contained in commercial salts. In the method suggested, the impurities are first removed by the addition of lead acetate, the excess of lead is then removed by hydrogen sulphide, and the hypophosphite contained in the filtrate completely oxidised to phosphate, which is then determined either gravimetrically or volumetrically. The author suggests a thorough revision of official tests for hypophosphites and the need of fixing standards of purity for the same—for the calcium and barium salts, 98 per cent.; for the sodium and potassium salts, 96 per cent.; for the ferric salt, 95 per cent. (p. 171).

Umney on Dill Seed and its Oil. The dill fruits obtained from different countries by J. C. UMNEY do not show such marked difference in appearance as the fennel fruits from different parts of the world, but the differences are probably of greater medicinal importance. English, Indian, German, and Japanese dill fruits are described, and analytical data given concerning their oils. The use of English or German fruits is recommended for the preparation of dill water, and preference for pharmaceutical purposes is given to the oils of the same varieties (p. 176).

Umney and Swinton on Lemon Oil. In examining lemon oil, J. C. UMNEY and R. S. SWINTON have separated an ester of geraniol, and they consider that the presence of this compound has an important bearing upon the odour and taste of lemon oil, and that a concentrated lemon oil must contain the ester in normal proportions, in addition to citral and citronellal, before it can be said to represent in a concentrated form the true odour and taste of the natural oil (p. 169).

Naylor and Bryant on Green Extracts. The results embodied in the paper by W. A. H. NAYLOR and J. J. BRYANT are the outcome of an investigation as to the feasibility of devising a simple process of assay for the green extracts of belladonna and henbane, and supply data that may assist in arriving at a satisfactory method of standardising those preparations. It is suggested that the strength of extract of belladonna should be fixed at 1 per cent. of alkaloid and that of extract of henbane at 0.2 per cent. (p. 165)

Idris on Concentrated Lemon Oil. Concentrated oil of lemon is a misnomer, according to T. H. W. IDRIS, as the terpene of the ordinary oil has a flavour and pungency which are peculiar to itself. Some "concentrated soluble essence of lemon" has been found to consist simply of oil of lemon to which alcohol has been added. Other samples contain added lemon-grass oil or citral, or an admixture of

ethers with the oils of lime and orange. Such mixtures are of but little value to mineral water manufacturers, but "terpeneless" oils are of decided utility. Those oils differ considerably, however, and the author of this paper shows how the aldehydes in oil of lemon can be separated without much change and in a state of comparative purity by fractional distillation under reduced pressure. After distilling off about 90 per cent. below 100° C., an oily liquid is left, which deposits a white sediment on cooling. By passing steam through this residue, a pale yellow oil is carried over, which possesses to a very marked degree the pure lemon aroma and is very different from citral (p. 161).

The insoluble compounds formed with **Stanford on** alginic acid and some of the metals **Alginoids and on** are suggested by E. C. C. STANFORD as **Thyroglandin.** a new series of therapeutic agents that would probably give rise to new developments in medicine and add considerably to the physician's weapons in attacking disease. Alginoid iron, prepared by adding sodium alginate to ferric chloride, can be administered when other preparations of iron would not be tolerated, as it is quite tasteless, has no astringent effect on the bowels, and is rather laxative than constipating (p. 199). Thyroglandin is a preparation made from the thyroid gland, and is claimed to represent all the active constituents of the gland (p. 166).

The objects of the paper by F. C. J. **Bird on B.P.** BIRD are to convey a general **Galenicals.** idea of the influence which the galenic pharmacy of the new Pharmacopœia has had upon the work of the manufacturing laboratory, and also to elicit the experience and views of other workers from the retail standpoint. The paper is an extremely useful contribution to the literature of the subject of which it treats, and served as an excellent introduction to the general discussion on the B.P., 1898. It is satisfactory to note that, in the opinion of the author of this paper, the new official formulæ on the whole afford little ground for serious criticisms (p. 162).

With similar objects to BIRD's paper **Gadd on B.P.** that by H. W. GADD shows that opinions **Galenicals.** may differ even when a new Pharmacopœia is regarded by two critical observers from a practically identical point of view. The weakest point of the galenic pharmacy of the new B.P. is stated in this paper to be in the processes, and the question is asked whether in some future pharmacopœial processes may not be omitted and tests extended (p. 178).

The salient features of the Irish flora **Druce** serve as the text of the paper by G. C. **on the** DRUCE, who observes that to the phytogeographer Ireland presents difficulties owing **Irish Flora.** to its insular position, its contiguity to the ocean, and the effects of the Gulf Stream, which surrounds the whole coast. The species of flowering plants are relatively much fewer in number in Ireland than in England, and to a certain extent Ireland is also deficient in large, bright-coloured flowers, such as are found in the Compositæ, Labiatae, and Leguminosæ. There is also a great falling-off of Germanic types in Ireland, and the Scandinavian types are only about one-third as many as in England. But there appears to be much work to be done at the Irish flora before it can be said to be known in the same sense as that of Britain (p. 200).

Parry on
Oil of
Eucalyptus.

Whilst in Western Australia last year, J. PARRY visited most of the eucalyptus districts, and was able to secure a supply of oil distilled from the leaves of *Eucalyptus toxophleba*, the York gum. The oil is described as having a most obnoxious and irritating odour, its specific gravity is 0.8828, and it is faintly dextro-rotatory. It contains about 15 to 20 per cent. of cineol, together with phellandrene, aldehydes, and ketones (p. 198).

Peck on
Ferrum
Redactum.

As the result of a careful examination of fifteen commercial samples of reduced iron, E. S. PECK suggests certain alterations in the B.P. directions for the preparation of the substance, and that the tests should be modified so as to ensure the absence of sulphides, of alkaline carbonates, or of more than 1 per cent. of insoluble residue. He proposes also to limit the amount of arsenic present and to vary the details of the official assay process (p. 159).

Kelly on
B.P.
Chemistry.

In the opinion of P. KELLY, not only should the Pharmacopœia be regarded as a text-book, but it should be a work that can be looked upon as a standard both in scientific work and in manufacturing operations. Changes in atomic and molecular weights, the introduction into the B.P. of structural and constitutional formulæ, alterations in nomenclature, modifications of tests, and the standardisation of preparations of potent drugs, are referred to in this paper, the author of which sums up by remarking that the 1898 B.P. is an improvement on its predecessors, especially as regards its chemistry (p. 180).

The alcoholic extract of ginger, **Idris on Ginger** known in commerce as "gingerine," **Extract.** does not contain the essential oil of the root, but by using acetone as the extracting menstruum, T. H. W. IDRIS has been able to remove the whole of the aromatic and pungent principles of ginger. The acetone extract is dark brown in colour, of a treacly consistence, intensely pungent, and possesses a full ginger aroma, varying according to the variety of ginger used. It dissolves readily in alcohol, and syrup may be flavoured with it by proper diffusion in a suitable temperature without the use of any spirit (p. 178).

This question, suggested for consideration in the Conference Blue List, has **Messrs. Howard** been found by DAVID HOWARD and DAVID **on the Basicity** LLOYD HOWARD somewhat difficult to **of Quinine.** answer. Theoretical consideration points to the conclusion that as each of the nitrogen atoms of the quinine molecule represents a basic nucleus, quinine is bi-basic. The formation of quinine salts, such as the ordinary commercial quinine sulphate, "the soluble sulphate," and the tetra sulphate, is also in favour of that view; but this is not confirmed by the use of indicators in volumetric testing, which show that the quinine sulphate of the British and most other Pharmacopœias is undoubtedly a neutral salt. Whatever may be the theoretical conclusions, there is no doubt of the convenience in regarding the familiar sulphate as neutral and the soluble sulphate as a bisulphate (p. 154).

DORAN on "The Chemistry of the Pharmacopœia," and EVANS'S "Short Note on Lime Water" completes the list of papers.

ANNOTATIONS.

CONSISTENCY IS A VIRTUE that may tend towards viciousness if too rigidly adhered to, but the following irreconcilable quotations from an enterprising contemporary cannot be said to indicate an excess in that direction :—

C. and D., August 10, 1895.

"It is gratifying to find that the evil we have so often complained of has been recognised in such an influential quarter, and we gladly bear testimony to the promptitude and ability with which the grievance was represented to the Committee by the Council of the Pharmaceutical Society."

C. and D., August 6, 1898.

"The judgment of the House of Lords, establishing the contention that the 15th Section of the Pharmacy Act did not apply to companies, was given on July 20, 1880—eighteen years ago. From that day to this the Council of the Pharmaceutical Society have done nothing to remedy the acknowledged evil."

The occasion on which the first statement was published was immediately after the Departmental Committee of the Board of Trade, appointed to inquire what amendments are necessary in the Acts relating to joint-stock companies incorporated with limited liability, had issued its report, three years ago. The cause of the second outburst was, of course, the passing of the Pharmacy Acts Amendment Act, 1898, and the alleged "betrayal" of the trade by the Council of the Pharmaceutical Society, because that body declines to accept, in any shape or form, the legislative recognition of company pharmacy.

ALL CHEMISTS AND DRUGGISTS IN GREAT BRITAIN are now eligible for membership of the Pharmaceutical Society, and, as members, entitled to attend all meetings of the Society and to hold office as Members of the Council or as Auditors. Members also have the use of the Museum and Libraries of the Society in London and Edinburgh, they receive the *Pharmaceutical Journal* regularly as published every week, have votes for the election of the Council and Auditors, and also for the election of Annuitants on the Benevolent Fund. The annual subscription for membership is one guinea, or the payment of ten guineas in a lump sum entitles the member to all the privileges enumerated above for life. Students who have passed the Preliminary examination or its equivalent may be elected Student-Associates of the Society. They pay an annual subscription of half a guinea, and are entitled to attend the Evening Meetings of the Society, to use the Museums and Libraries, and to receive the *Pharmaceutical Journal* every week.

THE 'SYNOPSIS OF THE BRITISH PHARMACOPEIA, 1898,' published at the *Pharmaceutical Journal* Office, 5, Serle Street, W.C., will soon be out of print, and those who have not yet obtained copies of this compact little guide to the changes in the official work should do so at once. In connection with the formulæ and processes, the whole of the alterations, additions, and omissions are clearly shown, and full workings are given, so that the little book serves as a practical laboratory guide. Pharmacists, medical men, and students preparing for examination will find the Synopsis equally useful and, to a great extent, indispensable. Single copies can be supplied by the publishers at fourpence each, or, in cloth covers, at a shilling each.

THE 'PHOTOGRAPHIC TOURISTS' GUIDE' is another useful aid to the business of the chemist and druggist. It includes a concise gazetteer, with a list of dark rooms and dealers in photographic materials, and has been highly commended by the editors of all the important photographic papers published in this country. A calendar, blank pages for memoranda, hints to photographic tourists, notes on exposure and exposure tables are also included,

rendering the Guide a most handy *vade mecum* for amateur photographers. Chemists who sell or give away copies of the Guide will find it an admirable aid to business. Further particulars regarding it will be found in our advertisement pages.

THE 'METRIC CONVERSION TABLES,' also published at the Office of this Journal, constitute the most convenient means of determining the exact equivalents of both Imperial and Metric weights and measures yet issued to the public. They have been especially designed to meet the requirements of chemists and druggists, and deal, therefore, with apothecaries weights as well as avoirdupois weights. All the equivalents given are based on the Board of Trade Standards, which alone are official in the United Kingdom. Extended thermometric tables are also included in the book, one or more copies of which should be found in every pharmacy in the country.

FOREIGN-MADE CACAO BUTTER has again engaged attention in the House of Commons, Mr. Lowles having asked the Chancellor of the Exchequer whether he could state the amount of public revenue obtained by the duty on foreign-made cacao butter from August 7, 1896 (when it was imposed), to July 31, 1898, and what proportion thereof was obtained between August 1, 1897, and July 31, 1898; and whether he had received any legitimate complaints as to the effect of the incidence of the duty from manufacturers or artisans in the United Kingdom. The Chancellor of the Exchequer replied that the revenue obtained by duty on foreign-made cacao butter from August 7, 1896, to July 31, 1898, was £9320, of which £5866 was obtained from August 1, 1897, to July 31, 1898. The answer to the second paragraph of the question was in the negative.

THE BRITISH PHARMACEUTICAL CONFERENCE has met once more, and under the most favourable auspices. A very large number of members attended from England and Scotland, together with many more ladies than usually attend similar meetings nearer home; the voyage across the Irish Channel was, in most cases, uneventful and pleasant; and though rain fell heavily on Monday and the outlook for the week seemed anything but cheerful, the actual opening of the meeting was heralded by glorious sunshine. The library at Queen's College, Belfast, was fairly crowded when the addresses of welcome were given by the Lord Mayor and others, and even after Dr. Symes had delivered the presidential address and had been cordially thanked for the same, there was a not inconsiderable audience. The ladies, of course, did not remain to hear the papers read, but were taken in carriages to visit the premises of Messrs. Robinson and Cleaver and Marcus Ward and Co. Luncheon was served later in the examination hall at Queen's College, and subsequently the reading of papers was resumed, whilst the ladies paid more visits. Then came tea, followed by a pleasant drive and the usual reception and conversazione.

THE PHARMACOPEIA DISCUSSION could not, unfortunately, be taken until Wednesday morning, and the report in this week's Journal is therefore of necessity brief. Since, however, the subject is one of considerable importance, it is proposed to publish a detailed report in our next issue. As will be seen, the number of papers presented was very large, much too large, in fact, for it was physically impossible to consider them satisfactorily in the limited time at disposal, and with so many other inducements to occupy that. A certain lack of consideration was also shown by the authors of some papers in deferring the delivery of

their manuscripts until the last minute, the result being that those papers had to be abstracted and put in type after being read on Tuesday and Wednesday, without the possibility of correction by the authors. The Hon. Secretaries are quite unnecessarily worried about this matter, and they should be authorised to refuse to receive any papers sent to them after the Saturday immediately preceding the meeting. If the subject of a paper is worth discussing at the Conference, the paper should be worth finishing, and should be delivered at a reasonable time in advance; on the other hand, rubbishy papers of a type sometimes submitted are not worthy of consideration at the annual meeting on any terms. We hope that before the Plymouth meeting next year steps may be taken to prevent this delay in delivering papers, which is fast becoming a serious abuse.

THE ULSTER EXECUTIVE COMMITTEE must be warmly congratulated on the success attending their arrangements. The members, on arrival, found that everything practicable had been done for their comfort, and the unavoidable dispersal of the visitors in a number of different hotels was rendered as slight an inconvenience as possible. The Official Programme presented to those attending the meeting was an excellent and useful production. It was in reality a guide to Belfast and the Conference proceedings, arranged on the plan rendered familiar by the similar guides presented to the members on former occasions by the Editor of the *Pharmaceutical Journal*. As regards the *personnel* of the committee which had all the arrangements in hand, it may be permitted, without seeming invidious, to single out for special reference the labours of the indefatigable hon. secretary, Mr. R. W. McKnight, who is credited locally with having spent many sleepless nights whilst endeavouring to secure a maximum of happiness for two or three hundred pharmacists and their lady friends during the best part of a week. Much credit is also due to Mr. J. C. C. Payne, the chairman of the local Executive Committee and president-elect of the Conference, as well as to all other Ulster pharmacists who did what they could to add to the comfort and pleasure of their numerous visitors.

THE CHEMICAL CONGRESS AT VIENNA has been marked by a sensational report respecting an alleged synthesis of albumin. On the closing day of the Congress a paper was read by Dr. Leo Lilienfeld, in which he stated that, by the condensation of phenol and amido-acetic acid with phosphorus oxychloride, he has succeeded in producing peptone and then albumin. It is also reported that in order to dispel any doubt as to the possibility of thus making artificial albumin the lecturer carried out the entire process in the presence of the assembled chemists, and then demonstrated the identity of artificial and natural albumin by means of reactions.

THE STUDY OF BACTERIOLOGY is likely to be encouraged by the London County Council, the Public Health Committee of that body having had under consideration the question whether the Council shall apply to Parliament for power to establish a bacteriological laboratory and appoint an expert in connection therewith, or to otherwise make arrangements whereby medical officers of health and practitioners in London can obtain, at the expense of the county, the examination by a competent bacteriologist of material from suspected cases of infectious disease, with a view to aiding in the diagnosis. A circular letter has been issued on behalf of the Committee to the various local authorities of London, inquiring their views on the question.

THE CHEMISTS' ASSISTANTS' UNION OF GREAT BRITAIN has issued its rules, and we note that rule nineteen runs as follows:— "No qualified member of this Union shall be recommended to sell his services to any company whose directors and shareholders are not duly qualified chemists, or which, in the opinion of the Council, is improperly constructed." But why not make the rule more stringent and insist that no member of the Union shall be permitted to act in the manner referred to? Copies of the rules and particulars regarding the Union may be obtained from the Secretary, Mr. C. E. Pickering, Horse Shoe Hotel, Tottenham Court Road, London.

THE DEATH of a successful "coach," who, it has been said, could easily earn £5000 a year by his efforts, seems to have led the general Press into a species of glorification of the art of "cramming." According to the published statements in a great London daily newspaper, the "crammer" fills a long-felt want, and is now firmly established in London. To those who might be disposed to say "so much the worse for London," the *Daily Telegraph* offers the crammer's own definition of his labours. "What we do," the representative of the educational tipsters is made to say, "is to put into shipshape the work of the teacher who affects to look with contempt on examinations. We keep the student off the mass of burdensome and unnecessary matter, which he learns with difficulty and forgets with promptitude." This sounds very plausible and not unreasonable, but when one examines the process by which the "coach" arrives at what is unnecessary, a rather unsatisfactory condition of affairs is revealed. The fraternity is bound to admit that the knowledge imparted is carefully selected according to the idiosyncrasies of particular examiners. The examiner is studied and his peculiarities discovered, so that his style of question may be diagnosed. In fact, the avowed object is not so much to educate the candidate in the subjects of examination, but rather to show him the weak side of the individual examiners. This may be a paying game to the operator and secure certain candidates a "pass," but it is not education, and is not the sort of thing likely to fit the young men of Great Britain to compete with their better trained contemporaries abroad. Possibly the examination system is at fault, and in this connection it is as well to remember that a serious responsibility devolves on those examining bodies which have hitherto accepted candidates for technical or professional examinations without demanding as a preliminary formality evidence of adequate training in an approved school or university. We should not be sorry to see a newspaper discussion on this topic, for it may have some influence on the coming Teaching University. That much-wanted institution should be a real teaching centre, and should not become the outward and visible sign of the apotheosis of cramming.

THE BRITISH PHARMACEUTICAL CONFERENCE is evidently a "teaser" for the ordinary reporter. In the accounts (generally admirably done, by the way) furnished to the newspapers, the Belfast meeting is variously described as "The 35th Annual Conference of the British Pharmaceutical Association," "The meeting of the Chemists' Congress," and "The annual meeting of the British Pharmaceutical Society." But what's in a name? The Conference by any other name is just as admirable in its aims and in its work, and if the public Press fails to give its right description, there seems to be no failing in recognising the public value of the ministerial statement of its President.

THE PHARMACY ACTS AMENDMENT ACT, 1898.

WITH the enactment of the Pharmacy Acts Amendment Bill, 1898, the possibilities of effective progress in the calling of pharmacy have been immensely widened; it is not therefore unjustifiable or bombastic to claim that the modest measure which has survived a thousand gibes and eluded the enmity of a host of foes, will prove of far more practical value than a mere unthinking perusal of its clauses would convey. Naturally the "true inwardness" of things in general and of Pharmacy Acts in particular, is not apparent to those who, either from indifference or interested wilfulness, do not look for or desire to find it. The journalistic wisdom which brings its blind eye to the task will airily pronounce that the new order of things is of little or no use to "the trade." But that dictum is hoary and custom has staled its efficacy; for, according to the same press oracle, it would appear that nothing outside its own editorial movements, ever has been or ever will be, of benefit to that Harris-like entity, "the trade." As we view it, the new Act places in the hands of registered chemists and druggists the means of making themselves a powerful body, potent for advancement as well as for defence and, from that standpoint, its addition to the Statute Book appears to merit more than passing attention. An additional reason for marking the occasion in a somewhat special manner is found in the fact that nearly thirty years have elapsed since the previous item of pharmaceutical legislation figured in the list of Statutes. We propose, therefore, to place upon record the main features in the history of the Act of the present session and to offer some comment concerning the immediate and prospective effects by which this Act may be made of far greater utility and importance than the Act of 1868.

The Objects of the Act, which is printed in full on page 194 of this issue, are four in number:—

Clause 2 (a).—The conversion of the "Student" class of subscribers into "Student-Associates"—a purely verbal amendment, of little more than infinitesimal import. Perhaps the new name is rather less incorrect than the old one, and there is something in the claim that it is more descriptive of persons in the student stage who are *associated* with the Society; but the double-barrelled dignity will carry no extra privileges or semblance of qualification. It is simply an alteration of name which was inspired by the consciousness that to dub a person who had never been in the Society's School a "Student of the Society," might sometimes be productive of misunderstanding.

Clause 3 (b).—The emancipation of the chemist and druggist from the disabilities which kept him from direct representation on the governing body of the Society. That object was the especial *raison d'être* of the Act, and further reference will be made to it later on.

Clause 4 (c).—The abolition of retirement from the Council by lot and the substitution of the more reasonable, though perhaps less sportive, procedure of regular rotation. In 1899, instead of 14 members of Council retiring, half by rotation and half by the hazard of a species of toss-halfpenny game, *seven* only will retire and they will be the seven members of Council who have been longest in office without re-election—to wit, those gentlemen who in May last remained in office by lot. This may be regarded as a sensible change, for it not only removes an objectionable form of procedure that might, in the hands of unscrupulous officers, be misused, but also does away with the undesirable possibility of any one member

of Council having to face his constituents every year. No difficulty will ensue under the new *régime* in dealing with cases of co-opted members, for they would be deemed to inherit the precise liability to retirement left by the councillors whose places they filled. Thus if A—a member of Council due to retire in May—died, resigned, or was removed in January of the same year, anyone called upon to fill the vacancy would have to retire in May, exactly as though he were the deceased or resigned A. It may be interesting to note that the first batch of Councillors to retire under the new procedure will consist of Messrs. Bottle, Carteighe, Hampson, Harrison, Park, Southall, and Young. Council elections in the future should be rather more interesting than some of them have been in the past; for with the vacancies reduced to one-half, a salutary increase of competition should be engendered, and the law of the "survival of the fittest" will have the fullest scope to operate for the benefit of the Society.

Clause 5 (d).—The extension of the time during which voting papers for the election of Council and Auditors may be received by the Secretary. This is quite a minor reform, but it gives tardy electors an extra day in which to make up their minds. The present Bye-laws prescribe that voting papers, if transmitted, must reach the Secretary one clear day prior to the day of election. The Act removes this time limit, and in future no distinction will be drawn between personally delivered voting papers, and those forwarded by post or messenger. All the fateful documents must be in the hands of the Secretary by the advertised time of assembly of the Annual General Meeting, and no other restriction will be imposed. Members who have been in the habit of putting their voting papers into the ballot box at the close of the annual meeting would be well advised to make a note of the alteration.

History of the Act.—Clause 3, it is clear, is the essential part of the Act—the point around which the chief interest lies. It remedies an injustice and its history carries one back to the remote days when chemists and druggists first obtained a statutory existence. Very soon after 1868 the disabilities of examined chemists and druggists became manifest. Unexamined persons who, fitly or unfitly, were in business in pre-Pharmacy Act days, were admitted to membership of the Society and they might, with certain limitations as to number, attain the dignity of Pharmaceutical Councillors; whereas those unfortunate individuals who had to acquire their qualification painfully through the medium of examination were ineligible for membership and could never aspire to the Council however eminently fitted for the position they might be. Gradually the feeling grew in intensity that this state of affairs, as pointed out by Mr. Bottle, was not only hard on the examined man but bad for the Society. Practically the Society stood in danger of becoming a close borough of pharmaceutical chemists and of sharing the ultimate fate of all institutions run on narrow or too exclusive lines. But though this feeling existed in 1870, it was not until thirteen years later that anything like an attempt was made to devise a remedy. In 1883 the Council, having been asked by the Privy Council to formulate its views as to poison legislation, drafted a very thorough Bill, which dealt with pretty well every pharmaceutical grievance then in existence. It displayed an astounding lack of perception in relation to poisonous proprietaries, it would have settled company pharmacy, created a third schedule of poisonous substances, regulated branch businesses, registered proprietors, established a curriculum and generally put everything right—in intention that is. No measure ever merited more the name of "Omnibus," by which sobriquet posterity will know it. But it had some good points and the following clause,

which is, if we remember rightly, mainly due to Mr. Hampson, was one of them :—

Every person . . . registered as a chemist and druggist by reason of having obtained a certificate of qualification from the Board of Examiners shall be eligible to be elected a member of the Pharmaceutical Society according to the Bye-laws thereof, but no person shall in respect to membership acquired by reason of this clause be placed on the Register of pharmaceutical chemists.

This was the first embodiment of the desire to consolidate the ranks of the Society and to open up the membership to all persons possessing the statutory qualification to practise pharmacy. It differs very little from the clause which has now been enacted, being identical in spirit, though a trifle more diffuse in phraseology. The Bill of 1883, as every student of Bloomsbury history knows, was never launched on parliamentary waters. It was sent to the Privy Council office, but the air of Whitehall did not agree with its overloaded frame and it died in one of the famous departmental pigeon holes. On its ashes rose the Poisons Bill of Lord Carlingford *circa* 1885, which retired into oblivion precisely as its descendant the Duke of Devonshire's Bill did in the present year of grace. Thus history repeats itself.

Consolidation was then dropped until June, 1890, when the idea was revived, probably owing to the continual increase of Minor men and the corresponding relative decrease of pharmaceutical chemists. This time the Council appears to have been somewhat influenced by the pharmaceutical chemists' point of view; for the offer of membership was coupled with a condition that not more than ten chemists and druggists should be on the Council at one time. Even that restriction was not felt to be stringent enough, for the number was subsequently reduced to seven. Nothing came of this draft, there is indeed reason to doubt whether it was seriously intended. What other deduction can one make from parliamentary proposals started in June? In the following March attempt No. 3 was made by the introduction into Parliament, under the pilotage of Sir Henry Roscoe, of a popular modification of the "omnibus" variety of Bill. There was the curriculum idea cheek by jowl with exemption from juries, whilst the restriction to registered men of the dispensing of medical prescriptions was closely associated with provisions for the more regular rotation of the Council. The consolidation clause was also present, but it wore a new dress. Registered persons over twenty-five years of age, or in business for themselves, were to be eligible for membership and for seats on the Council to the extent of ten out of twenty-one, but the younger men who had just passed their examinations and might be supposed to experience some financial tightness, were to be permitted to join the Society as half-guinea associates as heretofore.

Many experts who have thought over the subject hold the opinion even now that the consolidation clause of Mr. Carteighe's 1891 Bill was a wiser remedy than Clause 3 of the Act concerning which we are writing. That, however, is a matter of opinion. The 1891 Bill speedily became a Parliamentary memory, after the manner of its kind, and the claims of "associates in business" remained in abeyance for another three years. In April, 1894, another draft Bill was made public. This time consolidation, pure and simple, was the object and all other considerations were thrown overboard. The age qualification for membership was dropped, as well as the condition relating to being in business, and the essential clause more nearly approached in form the original proposal of 1883. The restriction as to the number of chemists and druggists to be admitted to the Council was, however, still retained and one could not help feeling that the desire to do justice was still tempered by distrust. The Bill was received with indifference by the majority of registered men in spite of official assurances that it was a desirable measure

and one that had a chance of passing into law owing to its innocent character. But the futility of starting the manufacture of enthusiasm towards the end of a parliamentary session is usually apparent to anyone of ordinary judgment and it was practically manifested when the draft of 1894 followed into obscurity the other abortive attempts to amend the Pharmacy Acts. Its disappearance marked the close of the long period of misfortune and unappreciated draftsmanship which had characterised the efforts of the Council. There are some who are inclined to attribute those failures to other causes than the influence of malignant stars, but on the other hand there are others who conceive the fault to be rather the unripeness of the times and are disposed to quote authoritatively—

What fates impose, that man must needs abide,
It boots not to resist both wind and tide.

At any rate, the period of failure is over. Late last autumn the Council, under the presidency of Mr. Walter Hills, resolved to boldly grasp the nettle. The disproportion between those taking the Minor examination and those going on for the Major had become so accentuated that the majority of the persons constituting the Society were those who could have no personal voice in its management; or, to state the same thing another way, two-thirds of the whole calling were unable to have any direct part in shaping the destinies of their craft. Mr. Hills considered that the Council was pledged to remove the anomaly, and that there would be little difficulty in these democratic days in getting Parliament to back up a proposal for making equal representation follow equal subscription. This belief found expression in the Bill, which has now become an Act.

Passage Through Parliament.—The Bill entered the House on February 24, in charge of an escort captained by the Hon. W. F. D. Smith (Strand), and comprising the following gentlemen:—

Mr. Brodie Hoare	Hampstead.
Dr. R. Farquharson	W. Aberdeenshire
Mr. Boulnois	E. Marylebone.
Mr. Thomas Shaw, Q.C.	Hawick Burghs.
Mr. Brookfield	Rye, Sussex.
Mr. Kearley	Devonport.
Mr. Schwann	N. Manchester.

It bore its explanations on its first page in the shape of a concise memorandum of reasons and its promoters determined to deserve success by distributing these reasons, together with an appeal for support, to all the associates in business of the Society, as well as to all local secretaries. Thus it happened that very shortly after the appearance of the Bill in the House members of Parliament had an exceedingly busy time of it with their constituents. And was there no opposition during the initial stages? Mr. S. R. Atkins, speaking at the Council meeting which approved the Bill, said it was almost inconceivable that anyone could oppose so harmless a project, but perhaps he was expressing his hopes rather than his thoughts, for no human proposal, however mild and innocent, is ever likely to escape the adverse criticism of some member of the race. So the Pharmacy Acts Amendment Bill betrayed its human origin by experiencing the usual amount of initial difficulties. Quite logically, certain of the younger pharmaceutical chemists expressed strong dissent, because they conceived that the proposed change might result in a lowering of the educational standard. They fancied they saw the thin edge of the wedge and they feared the eventual disappearance of the Major qualification. They argued that if Minor men were made "members," Major men should be made "fellows." The argument was just, though the basis was false, but it is to the credit of the objectors that when it was pointed out that the relative position of Major and Minor men was not altered by anything in Clause 3, they withdrew their opposition. Doubtless the fact that the Privy Council approved the Bill may have had something to do

with allaying their fears. After some trouble with the hon. member for Mid. Cork (Dr. Tanner) who opposed "on principle" the Bill obtained a second reading on March 7. Then came into the field the most serious opponent, Mr. Alexander Cross (Camlachie), a Glasgow seedsman, who had come into conflict with the Pharmacy Act, 1868 and saw an opportunity for revenge. He placed a series of amendments on the paper and, thus, for weeks, kept the Bill out of the Committee stage. His chief object was to wreck the Bill and he thought the best way of doing so was to raise the cry of monopoly. He claimed that agricultural preparations should be exempt from the operation of the Act regulating the sale of poisons. It was a plausible line to take and it even imposed upon Mr. Long (of muzzle fame) as well as other members interested in agriculture. Personal arguments would not weigh with Mr. Cross. He knew his advantage and determined to maintain it. Glasgow chemists tried their best to move him and failed. Edinburgh exerted its influence without effect, and the whole artillery of Bloomsbury could make no hole in his armour. Things looked still more black for the pharmaceutical bantling, when additional amendments were tabled by Mr. Weir (Inverness) and Mr. Yoxall (Nottingham), but the splendid generalship of Mr. Smith with the active help of friends in Nottingham and Inverness eventually triumphed. One quiet Wednesday in June the Committee stage was taken and the opposition collapsed like a house of cards. The skilful management of Col. Brookfield, during Committee, and the inherent inconsistency of the attempt of Dr. Clark (Caithness) to move the inclusion of Mr. Cross's exemption clause, are fully set out in the *P. J.* for June 11, page 552. It would be worth while perusing that account for the purpose of becoming acquainted with the interesting discussion on the sale of poisons which took place in Committee. The attitude of Mr. John Burns was particularly significant, inasmuch as it indicated that he, at any rate, is quite willing that the sale of dangerous substances should be confined to persons having competent qualification. The third reading was taken, amid cheers, on the same day (June 8) and the whole calling distinctly gained by the publicity which was given to the discussion incidentally invoked.

IN THE HOUSE OF LORDS the Earl of Morley formally introduced the Bill and, after considerable delay due to the promoters' want of acquaintance with the procedure, Lord Hardwicke took charge of the measure. But even to the last, opposition dogged its steps. The second reading was passed on July 8 and Committee on the 11th. Standing Committee promised to be short and uneventful, when the Lord Chancellor and Lord Herschell startled the whole pharmaceutical world by suggesting that what apparently was intended to be a companies' prohibition clause, should be tacked on to the innocent Domestic Reform Bill. For three years the Society had been urging the Lord Chancellor to amend the Companies Acts so that corporate bodies should not evade the Pharmacy Acts and lo, here, after many days, was found the bread on the waters. True it was found to be very bad bread, when closer acquaintance with its nature became possible, but *que voulez vous*, it had been a long time on the voyage. The Council had a difficult choice to make. Either to urge their Lordships not to press the inopportune amendment, or submit to an addition and, thus, run the risk of losing the Bill. The first and as it seems to us, the proper course was chosen. The Bill had passed the Commons and had received the approval of the Privy Council because it dealt solely with the internal matters of a voluntary society. It seemed very much like a betrayal of confidence to acquiesce in the addition of the most highly contentious matter in the whole realm of pharmaceutical politics. Happily the Lord

Chancellor took that view and withdrew his clause, in which defects were more numerous than virtues, leaving the Bill to get its third reading on July 21 and its finishing touch of Royal approval four days later.

The Effects of the Act.—The Society will now comprise only two grades of supporters, viz., "Members" and "Student-Associates." That is to say, persons possessing a statutory qualification and those who are training in the hope of obtaining it. Registration under the Pharmacy Act, 1868, is made the only basis for membership and membership is declared to be the only qualification necessary for a person who desires to offer himself as a candidate for the Council. Thus the fifteen thousand persons whose names appear on the Register have at their disposal the means of perfecting their incorporation and of becoming a great political power. Through the medium of a Society whose policy they can mould into any form deemed to be most expedient or most satisfying, they may now co-operate and there is no reasonable demand they might formulate which could not be had for the asking. Now is the time for combined action to take the place of torpid incoherent grumbling. Let the able men of the calling stand forward and come on the Council; let us have no more outside criticism, which henceforward would indeed be, more than ever, mere self-condemnation. There is no let or hindrance now, the Council can be replaced in due time by twenty-one chemists and druggists if the electors can secure them and they think them the best men. The pharmaceutical chemists have undertaken to risk that contingency: they will have to take care of themselves and their order, and their broad-minded attitude might surely be imitated by all registered men. Possibly we may be open to the captious charge of "touting for guineas." Well, if a battle is to be fought it is desirable to be well provided with powder and if urging chemists to protect themselves with the weapon just fashioned, is "touting," we must plead guilty to the impeachment. What organisation ever wrested privileges from an indifferent public or a hard-hearted Legislature without spending money; what great good has ever been promoted or terrible wrong righted without the power derived from combined effort and associated capital? Imagine a Society of 14,000 chemists each subscribing one guinea a year, and think of the potentiality of the combination before condemning anyone who seeks to bring about such a consummation. That a critical time for the interests of pharmacy and of all registered chemists and druggists is approaching is doubtless patent to many observers. It is, therefore, more incumbent upon those engaged in every branch of the calling to associate themselves with the one organisation by which those interests can be defended or promoted and, thus united, to neglect no means of preparing themselves for the coming struggle. During the past session fortune has seemed to be in a merry mood, ready to give us anything; the temper of the Commons on the question of poison and of the Lords respecting company trading was excellent; but if anything satisfactory is to come out of that position next session, it must be as the result of work done by more than a handful of pharmacists. The continued abuses of the Companies Acts constitute the gravest danger that chemists and druggists have to face. The Lord Chancellor is greatly impressed with the injustice already wrought; apparently he would be prepared to aid in staying its further progress. There is the chance, what we ask is, Will not the rank and file of the craft be willing to make some sacrifice to enable the Society—that is themselves—to shake off chronic inaction, to formulate a remedy and to carry it into execution? Can they not, with that object, rise to the position of being entitled to have leaders and of being able to insist upon definite action on their part?

A BRIEF HISTORY OF POISON LEGISLATION IN THE UNITED KINGDOM.

THE earliest attempt to regulate the sale of poisonous substances in this country would appear to be the introduction into Parliament in 1819 of "a Bill for establishing regulations for the sale of poisonous drugs, and for better preventing the mischief arising from inattention or neglect of persons vending the same." What the provisions of that Bill were is not mentioned by Bell in the "Progress of Pharmacy," but it is there stated that as some of them appeared "likely to embarrass the dispensing of medicines, and not calculated to effect the object intended," the chemists and druggists of that day determined to oppose the measure. A petition was therefore drawn up and presented to the House of Commons, a representative Committee was subsequently favoured with a hearing before the Committee of the House to which the Bill was referred, and shortly afterwards the Bill was withdrawn.

No further step in this direction seems to have been taken until after the formation of the Pharmaceutical Society, but about 1849 the question of the sale of poisons was occupying the attention of the Government, of the medical profession, and of the public generally, and two years later the sale of Arsenic Act was passed without any serious opposition. At that time more than one-third of the deaths by poisoning reported were caused by the use of arsenic, and the Pharmaceutical Society took an active part in collecting evidence on the subject. As there was at that date no legal definition of the terms "chemist and druggist" and "pharmaceutical chemist," it was found impossible to limit the sale of arsenic to a class of men possessing a special knowledge of its properties, but the fact that some such limitation was desirable in the public interest encouraged the Society to introduce a Pharmacy Bill into Parliament, and in 1852 the first Pharmacy Act was passed.

In that Act, however, no allusion is made to poisons, the fact of the matter being that the leaders of the Society were in no degree anxious to deal with the question of the sale of poisons. They took up the position that the qualification of the dispenser was the thing to define, and it was felt that any attempt to interfere with the drug trade by legislation without defining the qualification of dispensers must of necessity be insufficient to effect the desired end and should be consistently opposed. That fact must be borne in mind when it is noted how frequently the Council of the Pharmaceutical Society has been in opposition to the Government in regard to proposed legislation on the poison question. Even now the qualification of the vendor must be held to be of much greater importance than the imposition of regulations as to the storage and sale of poisons.

Three years after the passing of the Pharmacy Act a succession of cases of criminal poisoning occurred, which greatly agitated the public mind and forcibly directed attention to the unguarded manner in which poisons were supplied to those who required them, but the only immediate result of the discussions that took place was that a supplement to the Dublin Pharmacopœia was issued in 1856, in which it was ordered that medicines possessed of dangerous qualities should invariably be kept and sold in bottles or vessels of angular shape. English pharmacists, however, concurred in disapproving of these "Irish poison regulations," as they considered them to be impracticable and useless for the purpose intended.

Early in 1857 a Bill was introduced into Parliament, which

provided that no poison should be sold unless the sale was made to a person of full age and in the presence of a witness of full age, who was known to the seller and to whom the purchaser was known. A record was to be kept of all sales; all colourless poisons were to be coloured with soot, indigo, or archil; and all poisonous substances were to be kept under lock and key in a closet set apart for that purpose. Poisons wrapped in paper were to have an outer wrapper of tin-foil, with the word "Poison" in conspicuous letters; liquid medicines for external use, and all others containing any poison were to be supplied in quadrangular blue glass bottles, labelled in conspicuous capital letters, white on a black ground, "Poison" or "For External Use," and with the same words cast or moulded in raised letters in the glass on the four sides of the bottle. Opposition to this Bill by the Pharmaceutical Society resulted in considerable modification of its provisions, but as it was proposed to create a new qualification—that of "licensed druggist," the examination for which should be conducted by a mixed board of six examiners, only one of whom would represent pharmacy—the opposition was actively continued, and in the end the Bill was withdrawn. Early in 1859 it was re-introduced with its most objectionable provisions omitted, but further opposition by the Pharmaceutical Society was felt to be necessary, more concessions were made by the Government, and the Bill was ultimately so emasculated that it was not thought worth while attempting to carry it. It was, therefore, finally withdrawn.

A Bill to prohibit the sale and use of poisoned grain was introduced in 1863, and as originally drafted would have rendered it penal to sell or use any poison for the destruction of rats, mice, or other vermin, or of any domestic animal which it might be desired to destroy speedily and easily; it would also have interfered with the dressing of seed-wheat with poisonous salts for the preparation of smut. The Council of the Pharmaceutical Society decided, therefore, to petition Parliament against those provisions, and as the result of that and similar representations the Bill was suitably modified before it was passed. A Poisoned Flesh Prohibition Act, passed in 1864, may be regarded as complementary to the Poisoned Grain Prohibition Act. It provides that no one shall expose flesh which has been treated with poison in such a manner as to make it liable to destroy life.

In 1864, a Bill was promoted by the United Society of Chemists and Druggists, in which it was proposed that all chemists and druggists should be registered, and that none but registered persons should be able to recover in courts of law any charges accruing from the sale of certain scheduled active poisons and dangerous drugs; further, it was provided that certain specified regulations should be observed in the sale of active poisons. In the Bill promoted by the Pharmaceutical Society earlier in the same year there was no reference to poisons, the intention being simply to secure the registration of all chemists and druggists, and to restrict to registered persons the compounding of the prescriptions of duly qualified medical practitioners. The two Bills were referred to a Select Committee of the House of Commons, which found itself unable to decide between the conflicting claims of the promoters, and ultimately a report was agreed to which recommended that neither of the Bills should be proceeded with, but that the Government should bring in a Bill embodying restrictions on the sale of poisons. It was thus rendered evident that there must be a union of the pharmaceutical forces before anything satisfactory could be done; after prolonged and careful consideration, therefore, the Pharmaceutical Society made certain concessions to the United Society of Chemists and Druggists, which thereupon agreed to support the Society's amended Bill, the Government

was conciliated by the insertion of poison clauses, and in 1868 the Bill was passed. Henceforth a register was kept of all chemists and druggists, and none but registered persons were permitted to keep open shop in Great Britain for retailing, dispensing, or compounding poisons scheduled under the Act.

Ireland obtained protection in the matter of the sale of certain poisons in 1870, the Sale of Poisons Act then passed being drafted on the same lines as the poison clauses of the British Act of 1868. At first there was no restriction of the trade in scheduled poisons to any special class, but in 1875 the Irish Pharmacy Act was passed, and limited the compounding of medical prescriptions and the sale of scheduled poisons in Ireland to licentiates of the Pharmaceutical Society of Ireland and licensed apothecaries. An amending Act passed in 1890 provided for the registration of "chemists and druggists" and "registered druggists," who, as well as "pharmaceutical chemists" and "licensed apothecaries" are now entitled to sell poisons in Ireland.

A Bill for amending the law relating to the sale of poisons in Great Britain, and to the administration of poisonous drugs to horses and other animals, was introduced into the House of Lords by the Duke of Richmond late in the parliamentary session of 1881. It proposed to add mineral acids, hellebore, butter of antimony, and salts of copper to the list of poisons contained in Part I of Schedule (A) to the Pharmacy Act, 1868, and would have imposed more irksome restrictions on the sale of those substances than any previously in force. The purchaser was to be liable to a fine not exceeding ten pounds for giving a false name or address, or for knowingly and wilfully making to the seller a false statement of the purpose for which the poison was required; the seller would have been equally liable for selling a scheduled poison to any person known or appearing to be under the age of twenty-one years. Further, no servant was to be supplied with poison without a written order from the master, and the seller was to send by post to the master a copy of the entry made in his poison book. Finally, the poison book was to be open to the inspection of any justice, constable, or peace officer, at all reasonable hours in the daytime. The provisions of this Bill were, as might be expected, considered by registered chemists to be extremely objectionable, but nothing more was heard of it after its introduction.

Early in the following year, however, the Home Secretary invited the Pharmaceutical Society to lay before him any suggestions it might have to make for the amendment of the law relating to the sale of poisons. In response, the Council of the Society intimated that further restrictions on the sale of medicine containing poisons dispensed from ordinary prescriptions were neither necessary nor practicable, though it was desirable that the sale by wholesale of poisonous vegetable alkaloids and their salts should be placed under greater restrictions, and that proprietary and so-called "patent" medicines should be subject to the same restrictions as other medicines containing poisons. Subsequently a deputation from the Council waited by invitation upon the Home Secretary, and in accordance with a suggestion then made, the views expressed by the deputation were embodied in a series of propositions, which were forwarded to the Home Office for consideration. About the same time a communication was received from the Privy Council on the same subject, and in response to the invitation of the Lord President of the Council, the views of the Society in regard to the sale of poisons were submitted for consideration in the form of a draft Bill to amend the existing law.

The chief feature of that Bill, published in the *Pharmaceutical Journal* of February 10, 1883, was the proposal to include mineral acids, carbolic acid, and butter of antimony in a "Schedule of

Poisonous Articles." Those substances were to be distinctly labelled with the name of the article, the word "poisonous," and the name and address of the seller, but the seller was not of necessity to be a registered chemist. It was also proposed to regulate the sale by wholesale of poisons in Part I of Schedule (A) to the Pharmacy Act, 1868, and the sale of proprietary medicines containing scheduled poisons. The draft Bill included, in addition, such amendments of the Pharmacy Acts as were considered desirable, and was received with general approval by the members of the Society and the trade at large, but it was not introduced, and in reply to an inquiry the Government intimated in 1884 that it was not proposed to deal with anything more than the sale of poisons, and that a Bill would be introduced shortly.

The Government Bill was actually introduced in the House of Lords in March, 1885, and was then found to propose great alterations in the Pharmacy Act of 1868, and to apply to Ireland as well as to Great Britain. Thus it was provided that the strong mineral acids, carbolic acid, butter of antimony, and chloride of zinc should be included in a third part of the Schedule, but the sale of those substances was to be unrestricted so long as they were labelled with the name of the substance, the word "poison," and with the name and address of the seller. Other scheduled poisons were only to be sold by registered chemists or medical practitioners, as at present, but were not to be sold to any person under the age of seventeen years. Companies were to be permitted to sell any poison through the agency of a legally qualified manager; wholesale dealers were to label all scheduled poisons sold with the name of the substance and the word "Poison"; and medicines containing poisons were to be labelled "To be used with caution" if they were likely to produce poisonous effects when taken otherwise than directed. Last, and worst of all, the power of making regulations as to the keeping, dispensing, and selling of poisons comprised in the first and second parts of the Schedule were to be henceforth vested in the Privy Council so far as registered chemists were concerned. The Bill was duly read a second time in the House of Lords, on the motion of Lord Carlington, but petitions against it having been presented by the Pharmaceutical Societies of Great Britain and Ireland, and by the chemists of various large towns, it was referred to a Select Committee and heard of no more.

For a period of thirteen years since that Bill was lost sight of no further attempt was made by the Government to regulate the sale of poisons. But quite recently a hastily drawn Poisonous Substances Bill was rushed through the House of Lords, the ostensible object of the measure being to protect the public, though there is little doubt that it represented a veiled attack upon the privileges of registered chemists in Great Britain and Ireland. It was proposed in the Bill that strong mineral acids, butter of antimony, carbolic and cresylic acids and their preparations, chloride of zinc, sugar of lead, and substances used for the purpose of poisoning insects or vermin, should not be sold unless distinctly labelled with the name of the substance, the word "poison," and the name and address of the seller. No attempt was made to restrict the sale of the substances, to any special class but if they were supplied for internal use by medical men or chemists they were to be labelled "To be used with caution," and a record of each transaction entered in a book. In addition an attempt was once more made to place registered chemists directly under the control of the Privy Council by empowering that body to prescribe regulations for the keeping, dispensing, and selling of poisons. As on the former occasion, however, the attempt failed; for by the

well-timed action of the Council of the Pharmaceutical Society, backed up by chemists all over the country, such an effect was produced that, though the Bill had passed through all its stages in the House of Lords, it was decided by the Government not to introduce it into the House of Commons. Whether that Bill or a similar one is likely to be brought forward in the next session of Parliament remains to be seen, but in the improbable event of that happening, all registered chemists throughout Great Britain and Ireland should be prepared to repel the attack, and if they will but act together as well as has recently been done there need be little fear of the result. Any further amendment of the pharmacy and poison laws of the country should only be proceeded with by the Government after consulting those who are most deeply interested in the matter, and in any case it should ever be borne in mind that the education and proper qualification of the vendor cannot be improved upon as a means of protection for the public in connection with the sale and dispensing of poisons.

PHARMACY ACTS AMENDMENT ACT, 1898.

61 & 62 VICT., CAP. 25.

An Act to amend the Pharmacy Acts, 1852 and 1868.

[July 25, 1898.]

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. INTERPRETATION.—In this Act the term "chemist and druggist" shall have the same meaning as in the Pharmacy Act, 1868, and "the Society" shall mean the Pharmaceutical Society of Great Britain.

2. "APPRENTICES OR STUDENTS" ELIGIBLE TO BE ELECTED "STUDENT-ASSOCIATES." 15 and 16 VICT. c. 56.—Every person who at the time of the passing of this Act shall have been duly registered as an "apprentice or student," and who, under the provisions set forth in section ten of the Pharmacy Act, 1852, has been admitted to and at that time remains in the Society as a "student," shall be registered as a "student-associate" of the Society; and every person who at the time of the passing of this Act shall be duly registered, or who thereafter shall become registered as an "apprentice or student," shall be eligible to be elected a "student-associate" of the Society according to the Bye-laws thereof.

3. REGISTERED CHEMISTS AND DRUGGISTS ELIGIBLE TO BE ELECTED "MEMBERS."—Every person who at the time of the passing of this Act shall have been registered as a chemist and druggist, or who shall hereafter become registered as a chemist and druggist, shall be eligible to be elected a "member" of the Society according to the Bye-laws thereof.

4. RETIREMENT OF MEMBERS OF THE COUNCIL BY ROTATION.—In lieu of the provisions contained in the Royal Charter of Incorporation of the Society, whereby it is provided that two-thirds of the members of the Council shall in every year go out of office, the following provisions shall, after the passing of this Act, have effect:—

1. On the ordinary day of election of members of the Council in every year seven members of the Council shall go out of office, and the vacancies shall be filled by election, the retiring members being eligible for re-election.
2. The seven members who go out shall be the members of the Council who have been longest in office without re-election.

3. If and whenever the number of the members of the Council who have been longest in office without re-election shall exceed seven, the members of the Council to retire shall be determined from these by lot.

5. VOTING PAPERS FOR ELECTION OF OFFICERS.—At all meetings of the Society at which votes shall be given for the election of officers, all or any of the votes may be given either personally or by voting papers, in a form to be defined in the Bye-laws of the said Society, or in a form to the like effect, such voting papers being received by the Secretary, under cover, not later than twelve o'clock noon on the day on which the election takes place.

6. EXTENT OF ACT.—This Act shall not extend to Ireland.

7. SHORT TITLE OF ACT.—This Act may be cited as the Pharmacy Acts Amendments Act, 1898.

8. REPEAL.—The enactments mentioned in the schedule to this Act to the extent specified in the third column of that schedule are hereby repealed.

SCHEDULE.

Enactments Repealed.

Session and Chapter.	Short Title.	Extent of Repeal.
15 and 16 Vict. c. 56	Pharmacy Act, 1852	In Section ten, the words "and every such person duly registered as an Assistant shall be eligible for admission as an Associate of the said Society."
31 and 32 Vict. c. 121	Pharmacy Act, 1868.	Sections eighteen, nineteen, twenty, and twenty-one.

SELECTED FORMULÆ.

APPLICATION FOR SORE NIPPLES.

Vomacka prescribes the following:—Ol. olivar, 12; ichthyol, 2; salol, 3; Peru balsam, 3; gum arabic, 10; orange-flower water, 12; lime water to produce 100. Ft. emuls. Sig. For external use.—*Deutsch. Amer. Apoth. Ztg.*, xviii., 143, after *Rundsch.*

MURREL'S LINIMENT

For rheumatism, lumbago, etc., is stated to be composed of sod. salicylic, 15; ol. cajeputi, 2; ol. eucalypt., 1; liniment sapon. ammon., 15; spirit vini, 200.—*Pharm. Post*, xxxi., 66.

HÆMOGLOBIN AND ITS PREPARATIONS.

Pure hæmoglobin is a light to brick-red crystalline powder, which, exposed to the air, darkens a little, due to formation of methæmoglobin. According to Donet, its solubility is 8 to 10 per cent. in water, 10 to 5 per cent. in alcohol, 4 per cent. in white wine, 3 per cent. in red wine. The addition of glycerin increases its solubility. The author gives the following formulæ for pharmaceutical preparations:—*Vinum Hæmoglobini*: Hæmoglobin, 30; vini albi, 1000. A tablespoonful of this wine contains 0.45 gramme of hæmoglobin. *Syrupus hæmoglobini*: Hæmoglobin, 20, to be suspended in equal parts of cold water. Syrup simpl., 1000. A tablespoonful contains 0.40 gramme of hæmoglobin. *Elixir Hæmoglobini*: Hæmoglobin, 40 grammes; aquæ destil., 500; syrip. cort. aurant., 400; tinct. cocæ, 100. *Pilule Hæmoglobini*: Make a solution of hæmoglobin with the addition of glycerin and water and evaporate to the consistence of an extract. Add excipient and roll out into pills each of which contains 0.1 gramme hæmoglobin.—*Pharm. Centralh.*, xxxviii., 512.

SULPHUR AND ZINC OINTMENT.

Sulphur precipitat., 6; zinci oxid., 4; terr. siliciæ (alb. subtil. pulv.), 2; adip. lanæ, adip. benzoat., āā 14.—*Pharm. Centralh.*, xxxix., 92.

NOTE ON THE MYDRIATIC ALKALOIDS.*

BY H. A. D. JOWETT, D.SC.

That some confusion should have arisen in the past regarding this group of alkaloids is not altogether surprising, considering that there was on the market a variety of products designated daturine, duboisine, heavy and light atropine, etc., and that the literature of the subject was in a most unsatisfactory condition. The work of Schmidt and others has, however, removed these discrepancies, and it is now possible to obtain in commerce products of definite chemical composition of a high degree of purity. A paper read by Dr. G. Sharpe at last year's Conference (*P. J.*, 1897, p. 160) contained several statements and conclusions which are not in accord with our present knowledge of this subject, and in the 1898 B.P. the description and tests of the official members of this group are generally unsatisfactory, and in some cases misleading and inaccurate. I therefore thought that it would not be without interest to the members to contribute a short note on the subject.

As Dr. Sharpe says, the several names which have been used for a mixture of these alkaloids, as daturine, duboisine, light atropine, etc., should be once and for all abandoned, as they only represent a variable product obtained from a particular plant, the composition of the product depending on the process of manufacture, but consisting chiefly of atropine or hyoscyamine. The only alkaloids belonging to this group which can at present be definitely considered as chemical entities are atropine, hyoscyamine, and scopolamine. These are bodies of definite composition, whose chemical and physical properties have been carefully studied. In addition to these bases pseudo-hyoscyamine, from *Duboisia myoporoides*, isomeric with atropine and hyoscyamine, has been described by Merck, but its relation to its isomers has not yet been worked out.

ATROPINE.—Atropine can be prepared either synthetically from tropine and tropic acid by the elimination of water, or by isomeric change from hyoscyamine. The alkaloid contained in belladonna root and other solanaceous plants is primarily hyoscyamine, which, during the processes of extraction, precipitation, etc., becomes converted into atropine by the action of the heat and alkali used. Atropine itself is present in only a very small amount, if at all, in these plants. Dr. Sharpe states that "the relationship of these two bases can hardly be said to be understood," but this statement requires a little modification. Though the nature of the isomerism of these two bases is not at present known, their properties are such as to differentiate them sharply from each other, and it is certainly within the ability of the chemist to detect these differences.

The best and simplest test for determining the freedom of atropine from hyoscyamine or scopolamine is its optical inactivity, both the other bases and their salts being optically active. The presence of a small amount of these likely impurities would thus be at once detected. The new B.P., in the tests for atropine and the sulphate, makes no mention of this fact, but it is stated amongst the characters and tests of aconitine that it is dextro-rotatory, which is perfectly true, but the object of this statement is not apparent, as this property is no test of either its identity or purity. Beyond the melting points the B.P. gives no test for the presence of organic impurities in atropine or its sulphate. That of the base (115.5°) is correct for a pure product, but that given for the sulphate (183°) is open to criticism. Will (*Ber.*, 21, p. 1724) gives it as 196°, the U.S.P. 187°, Hesse (*A.*, 271, p. 102), 180°-181°, Merck 189°-191°, whilst a salt, proved to be optically inactive, prepared by myself from pure atropine melted at 190°. A good commercial

specimen melted at 190°, so that there is no doubt but that the B.P. melting point is too low.

The sulphate can always be obtained quite white, but has generally an amorphous appearance though really crystalline, and here again the pharmacopœial description requires modification. The melting points of the aurichlorides of this group form a very easy way of identifying the alkaloid and also afford some criteria as to its purity. The B.P. recognises these salts and gives the melting point for scopolamine aurichloride, but by a strange inconsistency not those of atropine and hyoscyamine, where it relies on the appearance of the salt, of which again a misleading account is given. They are best prepared by dissolving the base in excess of hydrochloric acid, then adding auric chloride and crystallising from the hot solution. The B.P. gives an impracticable method of preparing it from an aqueous solution of atropine. The appearance of the two salts is very characteristic; the atropine aurichloride separates first as an oily clot, which solidifies to a crystalline mass, the hyoscyamine salt comes down in brilliant golden-yellow crystals. The melting points are very sharp and separated by 23°. Atropine aurichloride melts at 137°, and hyoscyamine aurichloride at 160°. The B.P., therefore, requires in this respect amendment and addition. The insertion of the colour test with fuming nitric acid and potash is quite unnecessary, and as tests for identity and purity of the base and salts I would suggest—

1. Melting point.
2. Formation and melting point of the aurichloride.
3. Optical inactivity.
4. Freedom from ash on ignition.

These tests would ensure a pure product, and one which can reasonably be expected from the manufacturer.

HYOSCYAMINE.—This base is actually found in many solanaceous plants, including belladonna, scopol, etc., and not "possibly" as the B.P. states. It is optically active, and can be converted quantitatively by heat or by treatment with alkali into atropine. It is not, however, only an optical isomer of atropine, as lævo-atropine has been prepared synthetically and is not identical with hyoscyamine. It is distinguished from atropine by its optical activity and by the melting point of its aurichloride (160°). The melting point of the sulphate as it occurs in commerce is about 200°, whilst I have found the pure salt to melt at 204° and not, as stated in the B.P., at 206°. I would suggest a melting point of not lower than 200°.

SCOPOLAMINE (HYOSCINE).—This base is found accompanying hyoscyamine in very small quantity (0.03 per cent.) in many solanaceous plants, its chief source being *Scopola atropoides*. It is distinguished from both atropine and hyoscyamine by several well-marked characteristics, the most important of which are its percentage composition, its products of hydrolysis, and the melting points of its salts, particularly the aurichloride. Lately Schmidt has shown that it exists in stereo-isomeric forms, differing in optical activity and slightly in melting points, but not in their physiological action.

It is identical with the base called hyoscine, prepared from hyoscyamus seed, but this is not the source of the commercial article, which is preferably called scopolamine. This question has, however, been very recently discussed by Schmidt, Hesse, and Merck, and may be considered satisfactorily settled. The characters and tests given for the hydrobromide in the B.P. are very unsatisfactory.

The solubility in water (1 in 1) is incorrect. The U.S.P. gave 1 in 1.9, and Hesse gives 1 in 4, which is more correct. The hydrated salt, when heated (in a capillary tube) to 100°, forms a clear liquid, and no alteration can be observed on further heating

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

to 181° (the melting point of the dehydrated salt). The statement in the B.P., therefore, is somewhat misleading.

The melting point of the dehydrated salt as there given (193°-194°) requires modification. According to Schmidt (*Arch. Ph.*, 236, pp. 47, *et seq.*) the scopolamine hydrobromide of commerce consists of a varying mixture of lævo (or normal) and inactive scopolamine in proportions dependent on the source of the alkaloid and the mode of manufacture. The commercial salt has a specific rotatory power of about -13°, and melts at 181°. The purified lævo salt melts at 193°, and the inactive modification at 180°, but it has been shown that there is no difference in the physiological action of these salts. The tests and characters of the official salt should therefore be given for the pure product as it appears in commerce, which is a mixture of the stereo-isomers, melting at 181°. This is the melting point given by Hesse and confirmed by my own experiments. It would be interesting to know if the compilers of these tests have met with a salt in commerce of the melting point given (193°-194°).

With auric chloride the salt is stated to give a crystalline salt melting at 198°, which is not correct. As I have previously shown (*J. C. S.*, 1897, p. 679), an additive compound is formed under these conditions of the formula $B \cdot HBr \cdot AuCl_3$, which melts at 215°. The aurichloride, when prepared in the usual manner, melts sharply at 198°, thus differentiating it from atropine and hyoscyamine. There does not seem to be any reason why the salt should not be neutral to litmus, as a properly prepared salt will conform to this condition. The statements of Dr. Sharpe regarding hyoscyne and scopolamine show that he has confused these bases, but if the investigations made in recent years be considered, it will be found that our knowledge of this group of alkaloids is quite definite and satisfactory.

A NEW CONSTITUENT OF LEMON OIL.*

BY JOHN C. UMNEY AND R. S. SWINTON.

From the very time that citral was first stated to be the odorous constituent of lemon oil, various theories have been put forward to account for the difference in both taste and odour between a natural lemon oil and a mixture of the terpene of lemon oil with citral in the relative proportion in which they were understood to exist.

It was subsequently found that citronellal was associated with citral, and had some influence upon the taste and odour of the oil, and mixtures of these two aldehydes obtained from their most economical sources were suggested as a still more efficient substitute for natural concentrated lemon oil.

It was found, however, that no blend, no matter in what proportion the citral and citronellal existed, possessed the same peculiarly sweet character as the natural oil.

Several methods of estimation of these aldehydic constituents have been put forward, dependent upon the formation of compounds with phenyl hydrazine, hydroxylamine, and also other characteristic crystalline compounds.

Garnett (*P.J.*, Vol. 56, p. 323) subsequently proposed the estimation of citral by reduction to geraniol, but the accuracy of this method was at once contested by one of us (*P.J.*, Vol. 56, p. 360) as a result of experiments already conducted very much on the same lines as that worker had followed. Messrs. Schimmel and Co. some months later also detailed in their annual report (Oct., 1896) very many experiments to disprove the correctness of Garnett's assertions. These processes, however, for the determination of the odour-value of lemon oil consist solely in estimation of the aldehydic constituents.

We have noted, however, that a simple concentrated lemon oil, in which every care has been taken to free the product from stearoptene and resinified products, has a pleasant odour which is not associated with a concentrated oil separated by chemical means and consisting practically entirely of mixed aldehydic constituents. We have therefore sought to determine to what this difference is due, and, we think, with a result that may be of some importance.

For the purpose of our experiments we concentrated under reduced pressure, 2000 C.c. of lemon oil to 200 C.c. and lest any of the odorous constituents should have been carried over, again concentrated the 1800 C.c. of distillate to 100 C.c., which also was reserved. The aldehyde was removed from these concentrated oils by repeated treatment with solution of acid sulphite of sodium of 30 per cent. strength, when a considerable quantity of uncombined oil was separated which possessed an odour recalling geranyl acetate.

Advantage was now taken of the knowledge that both citral and citronellal when thoroughly acetylated form alkali absorption bodies (citronellal reacting quantitatively, citral only approximately) to get an idea as to the total amount of acetylatable bodies present.

The concentrated oil after acetylation for two hours was found to contain 68 per cent. alkali absorption bodies, which corresponds to about the same percentage of aldehydes. An attempt was made to check this result by estimating the concentrated oil with acid sulphite of sodium in a Hirschsohn flask, and though the reading was almost impossible owing to the separation of the insoluble citronellal bisulphite compound, yet it could be taken near enough to show that bisulphite did not indicate this amount of aldehyde, and that in all probability the difference was due to the presence of an aromatic ester.

This conclusion was confirmed when the aldehydes were completely destroyed by saponification with alcoholic potash solution, the alcohol dissipated and the residue distilled. This distillate was again treated with excess of alcoholic potash solution until no trace of saponifiable bodies was left. The product was then distilled under reduced pressure, and then subsequently carefully fractionated under ordinary pressure, that portion distilling between 230 and 250° C. being reserved for examination.

This was found to possess the characteristic odour of geraniol, and by repeated fractionation the alcohol was separated having characters in the closest agreement with those of pure geraniol.

Considerable difficulty was experienced in determining the nature of the acid combined with this geraniol in the form of ester in the original oil on account of the decomposition products formed in the oil, the evidences of acetic acid which were obtained probably arising from a decomposition of the ester, and pointing strongly to the fact that the ester of that alcohol is the one present.

In order to get an approximate idea of the quantity present, and also to determine whether there was any difference in the proportion present in the normal pure oils of Palermo and Messina variety, large quantities of the oils were operated upon by a slight modification of the process already detailed. Quantities of alcohol corresponding to from 1.2 to 1.4 per cent. of ester were obtained; no constant difference in quantity could be said to exist in the two varieties. It does seem, therefore, that up to the present a constituent which has an important bearing upon the odour and taste of lemon oil has been disregarded, and that it is necessary that a concentrated lemon oil shall contain not only citral and citronellal, but also this ester of geraniol, in normal proportions before it can be said to represent in a concentrated form the true odour and taste of lemon oil.

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

ALBUMINS AND SOME TYPES OF PROTEID DIGESTION.*

BY GORDON SHARP, M.D. (EDIN.).

The following fragment is the result of some work done four years ago. It was my intention at that time to carry out a somewhat more ambitious scheme, which, however, pressure of other duties has prevented me from even attempting. The incomplete character of my experiments renders this explanation necessary.

PROBABLE CONSTITUTION OF THE ALBUMINS.

Although nothing definite is known regarding the constitution of the proteid matter called albumin, it is believed to be in reality an albuminate; that is, the proteid matter of albumin is looked upon as playing the part of an acid, the base being either sodium, potassium, or calcium and ammonium. This point, it must be admitted, has not been accurately determined, but it has been found that however carefully albumin is freed from extraneous matter, a certain proportion of metallic substance is found in the ash. For example, white of egg or egg-albumin, when incinerated, yields calcium, and serum-albumin yields sodium and perhaps some potassium. One then may regard egg-albumin as albuminate of calcium, and serum-albumin as albuminate of sodium. Another point lends some support to this view, and that is the relative solubility and measure of decomposition of the two albumins. Serum-albumin is readily soluble and easy of digestion, being broken up by such a weak ferment as papain. Now, as we have just supposed, serum-albumin is a sodium-albumin, and, as is well known, sodium salts are highly soluble. On the other hand, egg-albumin is not readily soluble, and is almost untouched by a weak ferment, such as papain. Albumin we suppose to be a calcium-albumin, and, generally speaking, calcium salts are much less soluble than sodium salts. We might even carry this comparison further, and reflect for a moment on the possible reason why the powerful ferment pepsin has almost no effect on egg-albumin unless a certain proportion of hydrochloric acid be present. The reason may in great part be because the acid is necessary to unlock the calcium salt from its combination with the albumin, and thereby form a soluble calcium salt. On the other hand, an acid is a less necessary adjunct to pepsin in the digestion of serum-albumin. Further, pancreatin, which is an alkaline ferment, has very little action on egg-albumin, and this may be because it has no action in the way of rendering the calcium base soluble. Contrariwise, pancreatin, the alkaline ferment, acts powerfully on serum-albumin, the sodium-albumin.

PUTREFACTIVE DIGESTION.

When we extend our inquiries into other fields, as, for example, the digestion by putrefaction, we find the comparisons instituted above hold good. Serum-albumin readily yields; egg-albumin is much more difficult of decomposition. This is how Nature safeguards herself, for if the egg were surrounded by a zone of albumin easy of digestion we should find an enormous destruction of eggs by simple putrefactive digestion.

In the experiments I am about to detail I wish to compare the behaviour of egg and serum-albumin in their behaviour towards putrefactive digestion, and more particularly as to the proteoses (albumoses) present. And at the end we can compare these proteoses with those found in papain and pepsin digestions and with the digestion produced by yeast.

METHODS EMPLOYED.

In the present investigation hard boiled egg-albumin was employed on the one hand, and dried serum-albumin, prepared from meat, on the other. They were both exposed in the same manner, and as follows: In both, 5 grammes of albumin were employed. The

egg-albumin was boiled hard and broken up into a pulpy mass, and mixed with 30 C.c. of water. The serum albumin which had been boiled and dried so as to be ready for other experiments was simply placed in 30 C.c. of water. In order to hasten the digestive process a small particle of dried gelatin containing bacteria, causing liquefaction, was added to each bottle. The gelatin used was prepared by exposing a plate of that substance, newly run, to the air, noting when colonies settled on it, causing softening, at which period it was quickly dried and preserved. By merely exposing the specimens of albumins and water to the air in uncorked bottles at a moderate temperature (25° C.), as I did, one might expect putrefaction and softening to go on, still the immediate presence of bacteria could not but hasten the process, hence the reason for adding the gelatin. The bottles were kept at 25° C. for one week, after which they were simply left in a room for several weeks at a temperature of never less than 16° C. At the end of that time both albumins were examined. The serum-albumin was quite digested, but the egg-albumin showed a considerable sediment at the bottom of the bottle. A portion of both fluids was thrown on separate dialysers, and the liquids passing through were in both faintly alkaline, and both gave a precipitate with Thresh's alkaloid reagent. With egg-albumin dialysis continued for thirty-six hours, the fluid passing through gave no precipitate with solution of phospho-tungstic acid nor did it give the biuret reaction, so peptone was absent, and probably also deuterio-albumose. From the fact of serum-albumin being more ready of digestion than egg-albumin a portion of the dialysate from the serum-albumin preparation was examined at the end of one hour, when it was found to give no precipitate with solution of phospho-tungstic acid, nor did it give the biuret test, showing absence of peptone.

To confirm this, a portion of the original serum-albumin solution was taken, filtered, and then treated with great excess of ammonium sulphate, allowed to stand over night and filtered. The filtrate was treated with excess of caustic soda solution and a trace of copper sulphate solution, but no reaction took place. At the end of thirty-six hours the dialysate, however, gave a deep pink with the biuret test, pointing to the probable presence of deuterio-albumose, peptone having been just shown to be absent. It is well known that deuterio-albumose can after many hours pass through an animal membrane, more especially if the fluid is slightly alkaline. A portion of the original egg and serum-albumin preparations after being filtered through paper and boiled became cloudy, pointing to the presence of some unaltered albumin and globulin. Another portion of the same filtrates (slightly alkaline) gave a precipitate on neutralisation, showing some alkali-albumin. With excess of magnesium sulphate the filtrates give cloudy precipitates very small in amount (globulin). On filtering off these precipitates, diluting with distilled water and dividing each into two, one of each with a drop of dilute nitric, gave a precipitate of albumoses. The second portion of each was next treated with dilute acetic acid and excess of sodium chloride, and in both a precipitate resulted (proto- or hetero-albumose or both). Both fluids were largely diluted with distilled water, whereupon both precipitates dissolved. Portions of each were thrown on two dialysers and left for twenty-one days in a very cold place, the water in the outside vessels being changed every day. The egg-albumin preparation only showed the merest trace of precipitate in the inner vessel (hetero-albumose) thus the precipitate produced by acetic acid and sodium chloride as shown above must be mostly composed of proto-albumose. The case, however, is different when we come to look at the serum-albumin, for the inner vessel contains a bulky precipitate, showing

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

that the acetic acid and sodium chloride precipitate is largely composed of hetero-albumose.

To still further confirm the presence or absence of deuterio-albumose the precipitates thrown down by the acetic acid and sodium chloride were filtered off from a portion of both albumins, the filtrates largely diluted with distilled water, and excess of ammonium sulphate added to each. The egg-albumin fluid remained clear (absence of deuterio-albumose), while the serum-albumin one showed a precipitate (deuterio-albumose). Thus the digestive process due to simple putrefaction is more readily effected in the case of serum-albumin than in the case of egg-albumin, and the albumoses formed would appear to be higher in the series in the former than in the latter.

The absolute alcohol extract was next examined in the following manner:—A portion was taken from each bottle, evaporated to dryness at water-bath temperature, treated with freshly prepared absolute alcohol and filtered, the alcohol evaporated off at ordinary temperature, the resultant extract again treated with absolute alcohol, filtered, and allowed to slowly evaporate. The extract from both albumins is a yellow mass, that from the egg preparation being the darker. Both extracts are sparingly soluble in ether and chloroform, and the latter agent bleaches the colour very largely. The egg-extract is perceptibly less soluble in ether and chloroform than the serum one. Alcoholic solutions of both extracts give a turbidity with Thresh's (bismuth, etc.) alkaloid reagent. Microscopically both show a few crystals (leucine and tyrosine most probably) with a yellow substance in great abundance in the form of drops, warty crystals, and pentagonal plates. Both extracts are only sparingly soluble in water. The nature of both extracts is probably in great part alkaloidal. The amount of extract from egg-albumin is relatively much smaller than that from serum-albumin. To sum up:—

Egg-albumin gives— Unaltered albumin. Alkali-albumin, Proto-albumose, Hetero-albumose (little), Alkaloid and crystals.	Serum-albumin gives— Unaltered albumin, Alkali-albumin, Proto-albumose, Hetero-albumose (much), Deuterio-albumose (little), Alkaloid and crystals.
---	--

Peptone is absent from both.

PAPAIN DIGESTION.*

Digestion by papain in either acid or alkaline preparations gives—

Proto-albumose	} traces.
Hetero-albumose	
Deuterio-albumose	

Peptone is absent.

Papain readily digests serum-albumin, but has infinitely less action on egg-albumin.

PEPSIN DIGESTION.

This is perhaps the most complete form of digestion, and we find chiefly the higher albumose, namely deuterio-albumose, and strange though it seems, only traces of true peptone; that is, the digestion has gone beyond the proto- and hetero-albumose stage, and only just reached the peptone stage. This applies to both egg and serum-albumin.

DIGESTION IN PRESENCE OF YEAST.†

In the maturing of koumiss, when the fermentation has been started by the yeast plant, we find the albumin of the milk becomes in part changed into the higher proteids. The digesting agents here are probably the acids which are generated during the alcoholic and acetous fermentations. The peptone stage is never reached, and most probably the bulk of the albumoses produced belongs to the proto and hetero series.

In all these types of digestion we find tyrosin, leucin, urea, etc., none of which interests us at the present time.

In another paper I hope to give the result of some experiments on digestion carried on with sundew (*Drosera rotundifolia*), and also on the behaviour of egg-albumin towards the products of yeast fermentation.

NOTE ON EUCALYPTUS OIL.*

BY E. J. PARRY.

There are some fifty or more species of eucalyptus already identified in Western Australia, many of which are not found in the other parts of Australia. During a visit last year to this colony I went through most of the eucalyptus districts, going some 800 miles into the interior of the Continent. I was struck with the overpowering and not altogether pleasant odour of the bruised leaves of some of these Western Australian eucalypts, and asked Mr. Ednie-Browne, the conservator of forests, if he could get me any oil distilled from any of them. He was able to get about 60 or 70 C.c. from the leaves of *Eucalyptus toxophleba*, which he kindly sent me, an incomplete examination of which is the subject of the present note.

The tree is known locally as the York gum, no doubt on account of its being one of the most common eucalypts found in the neighbourhood of the town of York. It grows chiefly in companionship with *Eucalyptus redunca* (the wandoo), but peculiarly enough, whilst it flourishes on the eastern slopes of the Darling range, there is a thick eucalyptus forest on the western slopes, in which not a single specimen of *toxophleba* is to be seen. I have seen plenty of it, however, all through the forest districts between Albany and Perth, especially in the neighbourhood of York, Beverley, and Pingelly. It forms a fine straight tree, of 70 to 100 feet in height, with a diameter of 18 inches to 3 feet at the base. The bark is rough and dark-coloured, and the leaves, which are tapering, have a peculiar oblique venation. It grows on any soil, and its wood is very hard, almost, indeed, as hard as that of the famous jarrah (*Eucalyptus marginata*), and finds employment for all kinds of wheelwrights' work. The aborigines value it much, as it is the finest wood for making their spears with. Unfortunately the small amount of oil at my disposal only allowed me to make a very incomplete examination, but I hope to be able to obtain a further supply of it, and to go further into the chemistry of the oil.

It has a most obnoxious and uninviting odour, and when inhaled induces violent coughing. Its specific gravity at 15.5° is .8828. It is faintly dextro-rotary, about $.5^{\circ}$ for 100 Mm. On fractionation it yielded the following results. It began to boil at 160° , rising rapidly to 168° . The fractions collected were:—

168° - 171° ..	68 per cent.
171° - 176° ..	14 ,, "
176° - 182° ..	2 ,, "
182° - 187° ..	8 ,, "
Residue ..	8 ,, "

With phosphoric acid the oil simply became syrupy. The first fraction was almost free from cineol, whereas the 8 per cent. distilling between 176° - 182° was almost entirely cineol. A determination of this body in the fractions, which was necessarily only approximate, showed that the oil contains only about 15 per cent., certainly not more than 20 per cent., of cineol. Whilst phellandrene was present, as identified by its nitrite, it did not form anything like the remaining 80 per cent. of the oil; I was unable to search for any other bodies except aldehydes and ketones, the presence of which was indicated by an absorption by sodium bisulphite of about 10 per cent.; and for amyl alcohol, which has been identified in traces in some specimens of oil of *Eucalyptus globulus*. I was unable to find any trace of this body, however.

I hope to be able to examine this oil further.

* For further details see under "Papain Digestion" (*Ph. J.*, February 3, 1894)
† "Koumiss" (*Ph. J.*, December 24, 1892).

ALGINOID IRON, AND SOME OTHER ALGINOIDS.*

BY E. C. C. STANFORD.

The property of passing through the stomach unchanged is possessed by few if any medicines, hence where this is desired, it is usually necessary to cover the medicament with such a body as keratin, on which the stomach has no action. A complete series of therapeutic compounds having this general property would be new to medicine, would probably give rise to new developments, and add considerably to the physicians' weapons for attacking disease. Such a series appear to be presented in the alginates. As far as has been ascertained, alginic acid and its insoluble medicinal salts, iron, zinc, mercury, bismuth, lead, silver, antimony, arsenic, etc., are unacted on by the gastric digestion, and pass the stomach unchanged. Hence the action of these metals may be expected to present some differences or variations of the ordinary effects when presented in this form, and for a distinctive and expressive name I call these "Alginoids."

I have represented the chemical formula of alginic acid as $C_{76}H_{80}N_2O_{22}$.† It is a strong acid evolving carbonic acid from the alkaline carbonates in the cold; however it is assimilated and it is known to be a nutritious food. The soluble alginates are those of the alkaline metals and of magnesium. The insoluble salts are of the other alkaline earths and of the heavy metals.

ALGINOID IRON OR FERRIC ALGINATE.—Ferrous salts are not precipitated by sodium alginate, the ferric salt is obtained by decomposing ferric chloride with sodium alginate, both in solution. A gelatinous brown precipitate is obtained. When dry it forms a tasteless insoluble brown powder, having a composition leading to the formula $C_{76}N_{77}Fe_3N_2O_{22}$. It contains 10.97 per cent. of Fe.

It is soluble in ammonia, forming a deep reddish-brown solution, which on evaporation becomes insoluble in water, so that the alginoid iron can be administered in a liquid form.

The dry powder has, however, been mostly administered, and in all cases of anæmia and chlorosis, even where gastric ulceration was present, it has been well borne, and showed a sedative action by arresting vomiting and sickness. It can be employed, therefore, when other preparations of iron would not be tolerated. Being quite tasteless it is readily taken by children. It has no astringent effect on the bowels, and does not produce constipation, on the contrary the effects are slightly laxative. It is given in doses from 2 to 15 grains. Some physicians have found the former dose quite effective.

I shall only now shortly refer to some other alginoids, specimens of which are on the table. The therapeutic trials of these are not yet complete, and this is therefore only a preliminary notice.

ALGINOID BISMUTH OR BISMUTH ALGINATE.—This compound is a yellow powder containing 32 per cent. of Bi. It is prepared by decomposing bismuth nitrate by sodium alginate, both in solution. It is soluble in ammonia, remaining soluble on evaporation, and this gives us another form of liquor bismuthi, miscible with water.

ALGINOID MERCURY OR MERCUROUS ALGINATE is obtained by decomposing mercurous nitrate with sodium alginate both in solution. This compound presents a grey powder containing 33 per cent. of Hg, or about the same as the officinal grey powder and blue pill. It is blackened by ammonia. It is expected that this preparation will not derange the stomach and digestion.

MERCURIC ALGINATE.—Mercuric chloride in solution is not precipitated by sodium alginate, a distinction from albumin. But mercuric nitrate in solution is precipitated, and the mercuric alginate so obtained is a whitish grey powder soluble in ammonia. This solution does not affect steel instruments.

ALGINOID ANTIMONY OR ANTIMONY ALGINATE is a white powder containing 4.5 per cent. of Sb. It is prepared by precipitating antimony chloride with sodium alginate, both in solution. It is soluble in ammonia, giving therefore another solution of antimony, miscible with water. The residue on evaporation remains soluble in water.

ALGINOID ARSENIC is a white powder prepared by precipitating arsenic chloride with sodium alginate. It is soluble in ammonia, affording another liq. arsenici, which may have some advantages. The residue on evaporation remains soluble in water.

ALGINOID ALKALOIDS (morphia, 35 per cent.; strychnine, 50 per cent.).—All the alkaloids combine with alginic acid, and the salts are soluble in water—for instance, we may have another liquor strychninæ alginatis which certainly will not crystallise, all the alginates being gelatinous.

ALGINOID MAGNESIA.—It is remarkable that this is a soluble salt; the two insoluble compounds, alginic acid and magnesia, combine in the presence of water to form a clear solution. If magnesium carbonate be used, carbonic acid is evolved. The formula is $Mg_5(C_{76}H_{77}N_2O_{22})_2$. It contains 4.2 per cent. of Mg. In a 40 per cent. solution it makes a good gum for adhesive purposes.

All the alginoid solutions keep perfectly.

I hope to refer more fully to these and to some other alginoids in a future communication. However, I have sufficiently indicated the character of these preparations to lead to some of those valuable suggestions which are so often obtained from the members of this Conference.

A QUICK POLARIMETRIC METHOD FOR THE DETERMINATION OF STROPHANTHIN IN THE B.P. EXTRACT AND TINCTURE.

BY EDWIN DOWZARD, F.C.S.

The following method will be found useful as a means of approximately determining the amount of strophanthin in the B.P. tincture and extract:—

100 C.c. of tincture is evaporated down to about 20 C.c. on a water bath, 2 C.c. of a solution of basic acetate of lead then added, the mixture heated for a few minutes, and filtered, the precipitate being washed twice with warm water. The filtrate and washings are evaporated to about 10 C.c. and made up to exactly 20 C.c. with water, a portion of which is passed through a dry filter. The optical rotation of the filtrate is then taken in a 200 Mm. tube, using an instrument of the Laurent half-shadow type.

One minute is equivalent to .03 gramme strophanthin per 100 C.c. of the liquid examined.

Example:—

100 C.c. of the 1885 tincture were treated as above; the rotation equalled $+0^{\circ}30'$.

$$\therefore \frac{0.03 \times 30}{5} = 0.18 \text{ gramme strophanthin in 100 C.c. tincture.}$$

It is necessary, of course, to divide the rotation by five, as the liquid is five times stronger than the original tincture.

In the case of the extract, the determination must be made before the reduction with milk sugar.

1 gramme of extract is dissolved in 5 C.c. warm water. 2 C.c. solution of basic acetate of lead are then added, the mixture heated for a few minutes and filtered, the precipitate is washed with warm water until the filtrate and washings measure 20 C.c. The rotation is then observed, and the amount of strophanthin calculated therefrom as in the tincture.

ON THE SALIENT FEATURES OF THE IRISH FLORA.*

BY G. C. DRUCE, M.A., F.L.S.

Last time I had the privilege to address the members of the Conference, I was permitted to draw their attention away from the more strictly scientific and practical side of our calling to a subject which was once considered to have interest to all pharmacists, at any rate for that short period of their existence which was spent in preparing themselves for the qualifying examination of a pharmacist, but which, alas! is now being pushed more and more out of our pharmaceutical curriculum; I mean the systematic and morphological branches of that huge and unwieldy science known as botany. Such names as Bentley, Daniel Hanbury, Stoddart, Brady, Henry Groves, and Deane we know placed a high value on that portion of pharmaceutical training known as field botany. Therefore I welcome the kind offer to spare me a few minutes while I endeavour to sketch the salient features of the Irish flora. Those who had the misfortune to be present when I traced the special characteristics of the Scottish flora last year may perhaps remember that I pointed out that it was the alpine flora which was especially represented in Northern Britain, and its chief similarities and alliances were to be found in the Scandinavian flora, of which the Scottish appears at one time to have formed a part. I then said that I believed I had been fortunate enough to prove the presence of another Scandinavian sedge on the Breadalbane Mountains. That the plant I gathered then is the true *Carex helvola* I have since demonstrated to the Linnean Society. Moreover, a new species of grass named *Poa cenisia* var. *flexuosa*, and a new variety of *Ranunculus acris*, known previously only from Greenland, were also gathered by me in Perthshire last year.

Politicians have found Ireland a troublesome nut to crack, and to the phytogeographer Ireland also present its difficulties. Owing to its insular position, its contiguity to the melancholy ocean, and to the effect of the Gulf stream, which surrounds the whole coast, the climate of Ireland is, especially in the west, more moist and equable than Britain, or, in fact, any part of Europe in the same latitude. I have not attempted to prepare a table showing the rainfall of Ireland, nor can we trust the statements made by British tourists, since I believe the most accurate of them peril their hopes of salvation by the statements they make regarding the rainfall of Connemara, but it will be safe for me to say that the rainfall on the western side is higher than that of the western side of Britain in the same latitude (I am excluding from this the Lake district of England) and that the rainfall on the western side of Ireland is very nearly three times as much as that on the eastern shores. The mean temperature of the summer months is about two degrees lower than in Britain, and although this sounds only small, yet this trifling variation has very great and far-reaching effects on the vegetation, rendering, indeed, wheat cultivation, which in England is not indeed a more lucrative occupation than our own much suffering business, a most precarious crop, so that over a large portion of Western Ireland it is unknown.

Not only, therefore, have we in Ireland a lower summer temperature, a heavier rainfall, but we have a more humid atmosphere and a smaller amount of sunshine than in England. All these are factors in producing a flora whose elements differ considerably from that of the adjacent island.

From the table, which is only approximately accurate, it will be noticed that the species of flowering plants are relatively much fewer in number than in England, that is, in the proportion of 18 to 10, while England is poorer by nearly three times than Spain. As compared with Spain, and to a certain extent with

England, Ireland is especially deficient in large, bright-coloured flowers such as are to be found in the Compositæ, Labiateæ, and the Leguminosæ, which essentially depend for their fertilisation upon butterflies and other insect visitors, while it will be observed

European Species, roughly 10,000.

English British.....	931	737	785
Scottish	117	3	66
Scandinavian or Highland.....	120	—	40

I now direct your attention to a table which shows the distribution of certain types. By this it will be seen that, as might be expected, there is a great falling off in the occurrence of what are called Germanic types, which in England attain their maximum of development in the Eastern counties, and belong to a central European type of distribution. Out of the 130 possessed by England, only about 20 are found in Ireland, and several of these are not native. In the Scandinavian or high alpine species, of which Great Britain has 130, only about 40 are recorded for Ireland; these latter occur chiefly in the north and west of the Island. I remember the first time I ascended Mangerton, in Co. Kerry, I said, having in mind the Cairngorms and Breadalbanes, "Why, here is a mountain without alpine plants, and although it does possess some, they are few, not only in number of species, but also of individuals, either on that mountain or on the higher and more cragged Carran Tual. But it must not be imagined, from the negative qualities I have mentioned, that to the botanist Ireland is a desert. Such is by no means the case. I shall leave the north, whose acquaintance I now make for the first time, but as long ago as 1875, I worked the west coast and walked from Westport to Galway over a country made up to a great extent of dreary moorland and bog, but in which there were oases of great natural beauty in which I gathered many interesting plants, some of which are found nowhere else in the British Isles. I shall now proceed to enumerate the chief of these plants which are peculiar to Ireland, and to glance at the types of distribution to which they belong. We have seen that over 800 species found in Great Britain find the Irish Channel too wide a streak for them to cross. On the contrary about twenty-three species occur in Ireland which are not found in Great Britain. These consist of a rock rose, *Helianthemum guttatum*, growing in Galway and County Cork, which, although common in the Channel Islands* exists only as a variety or sub-species in Anglesey, this variety, being also found in Ireland at Inishbofin. Curiously enough the common yellow rock-rose, so frequent on the English chalky hills

* With which I am assuming the Cork plant to be identical; if not, and it is the same as *H. breweri*, we must delete it from the list as *H. breweri* is found in Anglesey.

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

and limestone pastures, is very rare in Ireland. In Sligo, a Caryophyllaceous plant, the *Arenaria ciliata*, is found near Ben Bulbin, at an elevation of some 1500 feet. This rare and local species is common in some parts of the European Alps, and I have gathered it near the juncture of the Austrian and Italian frontiers, on the Stelvio pass, at nearly 8000 feet. A closely allied species, or possibly a variety, is found in Sutherland and the Shetland Isles, and is known as *Arenaria norvegica*. Two species or varieties of the genus *Rubus* have been described recently from the West of Ireland. The order Saxifragaceæ is well represented in Ireland, both in species and number of individuals; four or five species occur which are not native in Britain. One of these, the common London pride of our gardens, the *Saxifraga umbrosa*, is abundant in the Killarney mountains, and is found from Donegal to Waterford. Two nearly allied species, *S. hirsuta* and *S. Geum*, are more local and rare, being confined to Cork and Kerry. Two cut-leaved species are also found in the south-west, namely, *S. Sternbergii* and *S. hirta*. The great order Compositæ only yields a single species which does not occur in Britain,* namely, the singular *Inula salicina*, which is found on the north-west shore of Lough Dearg, in Galway, and probably two or three varieties of the hawkweed genus may be endemic. The Heath order affords four species, namely, the *Mediterranean heath*, which is local in Galway and Mayo, and *E. Mackaii* occurs in the neighbourhood of Roundstone. The latter is considered to be a hybrid of *E. ciliaris* and *E. Tetrix* by some botanists, but in our more recent books it is given specific rank, and it is certainly not identical with undoubted hybrids of the two plants which I have gathered near Truro. The third species of the Ericaceæ is the St. Dabeoc's heath, now scarcely recognisable under the name *Boretta cantabrica* (the name is not derived from the biretta used in the same district). This St. Dabeoc's heath is one of the most beautiful of our native plants, as it has large bells of a charming purplish-red colour, and leaves whose upper surface is of a dark glossy green, but are silvery white underneath, and when seen growing by some trench where the *Osmunda* luxuriates it forms a sight which will scarcely be effaced from the recollection of the plant-lover. The fourth species is the strawberry tree, *Arbutus Unedo*, whose wood is to the Killarney shops what the olive-wood is to those of the Southern Littoral. The arbutus forms a small but handsome tree, having beautiful effects of foliage, and is especially noticeable in that portion of the drive from Glengarriff to Killarney, after one has passed the summit level, down to the lakes, a drive which, in my opinion, affords the most beautiful combination of lake and mountain scenery, and of exquisite variety of foliage, which is to be found in the British Isles.

In the same district of Cork and Kerry is to be found a Lenticulariaceæ insect-eating plant, the great Irish butterwort—*Pinguicula grandiflora*, whose magnificent blue flowers are a striking sight. This was planted near Penzance, and has now become naturalised there. Two species of the Orchidaceæ are found only in Ireland, one, the *Habenaria intacta*, which was discovered by Miss More, the sister of my late friend, the joint author of 'Cybele Hibernica,' in the limestone pastures of Galway, Clare and Mayo, near Lough Corrib and the other still more interesting species, the Irish lady's traces, *Spiranthes Romanzoffiana*, which was first discovered by Mr. Drummond at Berehaven, near Cork, in 1810, and which has recently been found in the north of Ireland, in Armagh and Derry, but is known for no other European locality. The order Iridiaceæ affords *Sisyrinchium angustifolium*, which grows in meadows near Woodford in Galway,

* *Theracium hibernicum* is said to be extinct.

and also in Kerry, and has blue flowers, and in 1896 my friend the Rev. E. S. Marshall found on the eastern coast of Ireland, in Wexford, the yellow-flowered *Sisyrinchium californicum* in large quantity and completely naturalised, but of whose indigenuity I am not yet convinced. One plant of the Pondweed order also occurs in Ireland only in the United Kingdom, namely, *Potamogeton sparganifolius*, which is found in Galway. One sedge, *Carex rhyncophysa*, has recently been added to the Irish flora from the central part of Armagh, where Mr. Praeger found a single tuft near Mullaghmore Lough. Two horsetails, one a species *Equisetum Moorei*, so named after the well-known botanist of Glasnevin, occurs in Wicklow, and the other one, a variety of *E. variegatum* called *Wilsoni*, has a wider range of distribution. A single hybrid fern, *Asplenium Clermontæ*, has been found, and three species of Characeæ, *C. denudata*, *C. tomentosa*, and *Tolypella nidifica*, complete the list of plants which occur in Ireland only in the United Kingdom. Most of these will be found to belong to the Peninsular group, so called from the fact that these plants have their headquarters in the Spanish Peninsular, and by some authorities are said to suggest a former continuity of land between the two countries. In addition to the special species mentioned there are some other species of the Peninsular group which occur in Ireland, such as *Erica ciliaris*, *Trichomanes radicans*, *Adiantum Capillus-veneris*, *Simethis bicolor* (now almost destroyed at Bournemouth), and *Euphorbia hiberna*.

I said that these Irish plants belonged to different types of distribution; by far the greater number belong to the Peninsular group, but *Arenaria*, *Inula*, and *Carex rhyncophysa* are somewhat anomalous. Three belong to a group we should not expect to be represented in the British Isles, and that is the American group; to this belong the *Spiranthes* I have already alluded to, and this is found chiefly on the western side of North America and in the Rocky Mountains, but not elsewhere in Europe. The second is the blue-flowered *Sisyrinchium angustifolium*, which is only of adventitious occurrence elsewhere in Europe; the third being the yellow-flowered *S. californicum* from the western side of North America, is a doubtful native of Ireland. A fourth member of this American group is abundant on the margins of lakes in Connemara and elsewhere on the west coast of Ireland, but, unlike the first three members of the group, *Eriocaulon septangulare*, extends its range to Skye and the Western Hebrides in Scotland, where it is very local. This plant may have been introduced to Ireland from America by the agency of birds.

I have thus briefly glanced at the salient features of the Irish flora, and can promise any botanist who may have leisure that there is an enormous amount of work to be done at the Irish flora before we can say that it is known in the same sense as that of Britain. To those who have time and energy a pleasant task awaits them in exploring some of the wild and beautiful scenery of the Emerald Isle, which always offers a hearty and cheering welcome to any visitor to its shores.

IODOL IN THE TREATMENT OF ANGINA.—In daily doses of 60 centigrammes, iodol has been given by Maldarescu with good results in angina pectoris. The attacks of pain, which had occurred daily and had not yielded to treatment with any other drug, disappeared entirely after the fourth day of treatment with iodol. Iodol was also found to be of great value in acute paracetritis, causing rapid re-absorption of the local exudation. The remedy may be safely given during pregnancy.—*Bull. Gén. de Thérap.*, cxxxiii., 474, after Vratch.

A NOTE ON THE BOTANICAL NOMENCLATURE OF THE BRITISH PHARMACOPŒIA.*

BY G. CLARIDGE DRUCE, HON. M.A. (OXON), F.L.S., ETC.

The botanical names for the plants yielding the various drugs which are included in the British Pharmacopœia have in some cases undergone alteration from those employed in the last edition, but the changes in almost all cases are made in the right direction, and the compilers are to be heartily congratulated on the result of their labours. The selection of the names is evidently based on the law of priority of publication, and the date 1753 (which I suggested in the *Pharmaceutical Journal*, March 26, 1892, p. 789) appears to be taken for the citation of both genera and species, this has a distinct advantage over the dates of the publication of Linnæus 'Systema' of 1735 and of the first edition of the genera of 1737.

In a few instances it appears to me that the law of priority has not been complied with, and I venture to point them out, rather with a view to elicit the reasons which led to the choice of the names employed than to claim absolute authority for those which are here suggested.

CITRUS AURANTIUM, VAR. BIGARADIA, Hook. fil., is now adopted for the bitter orange. May I suggest that Linnæus, in his first edition of the 'Species Plantarum,' described it as *C. Aurantium*, and gave as a var. *b*, the sweet orange, so that it appears *C. Aurantium*, Linn., would have been sufficient to distinguish the bitter orange. If a name exclusively referring to it were needed, it would seem that *C. vulgaris*, Riss. (published in 'Ann. Mus. Par.,' xx., 1813, p. 190) has precedence over *C. Bigaradia*, which appears to have been first published in Loiseleur's edition of Duhamel's 'Traites des Arbres et Arbustes,' vol. vii., 1819, p. 99.

ARARоба.—According to strict priority the name *Andira* is superseded by Aublet's genus *Vouacapoua*, published in the 'Histoire des plantes de la Guiane Française Suppl.' p. 9, t. 373 (1775), while Lamarck's genus *Andira* only dates from the 'Encyclopédie Méthodique,' vol. i. (1783), p. 171. In the 'Revisio Generum Plantarum,' Otto Kuntze chose Aublet's name, but altered the spelling to *Vuacapua* in order to bring Aublet's vernacular name closer to classical rule. Since other vernacular names are adopted, with the spelling unchanged, in the 'Genera Plantarum' of Bentham and Hooker, it would appear better, assuming that Kuntze is correct in his statement that Aublet's genus is valid, to follow the original spelling and write *Vouacapoua Araroba* (Aguiar).

BALSAMII PERUVIANUM ET TOLUTANUM.—The generic name *Toluiifera* of Linnæus' 'Species Plantarum' of 1753 (which he also used in the 'Materia Medica' of 1749 and his 'Genera' of 1742), has precedence over *Myroxylon*, which appears to have been established in 1781 by the younger Linnæus in his Supplement. I would suggest the name *Toluiifera Pereira*, 'Baillon Hist. Plantes,' vol. ii. (1869), p. 383, and *Toluiifera Balsamum*, 'Linn. Sp. Pl.,' p. 384 (1753), for the plants yielding Peru and Tolu balsam.

GAMBOGE.—The original spelling of the gamboge plant in the *Journal of the Linnean Society* for 1875, vol. xiv., p. 485, was *Garcinia Hanburyi* not *Hanburii*.

CAPSICUM.—Flückiger and Hanbury say that Farr has ascertained that the official plant is identical with *Capsicum frutescens*, Linn., 'Sp. Pl.,' p. 189 (1753). If this be the case, should it not be substituted for the name *C. minimum*, Roxb.? There is also a *C. minimum* of Blanco from the Philippines, which appears to be a different species. The fact that the plant referred to in the 'Hortus Cliffortianus' by Linnæus is not identical with *C. frutescens*

of the 'Species Plantarum' does not appear to be a sufficient reason for rejecting the latter name.

CATECHU.—In this case there is an earlier name which was given to the genus *Catechu* by Aublet in the 'Histoire des Plantes de la Guiane Française' of 1775, p. 177, t. 68. Otto Kuntze, in the 'Revisio Generum Plantarum,' vol. i., p. 201, took up Aublet's genus, but, as in the case of *Vouacapoua*, altered the spelling to *Uruparia*. Schreber's genus *Uncaria* only dates from the 'Genera' of 1789. Assuming that Aublet's publication is valid, our plant should be *Ouroparia Gambier* (Roxburgh) = *O. Gambir*, Baill., 'Hist. Plantes,' vol. vii., p. 350.

CIMICIFUGA RACEMOSA, Elliott.—The date of the publication of 'A Sketch of the Botany of South Carolina and Georgia' where this plant is mentioned by Elliott, is 1824 (see vol. ii., p. 16), but the 'Kew Index' gives an earlier authority, namely, Nuttall's 'Genera of North American Plants,' vol. ii., p. 15 (1818).

COPAIBA.—The name of the genus of plants yielding our drug is given as *Copaifera*, which dates from the second edition of the 'Species Plantarum,' which was published at the end of 1762 or the beginning of 1763. In 1760, however, Jacquin in the 'Enumeratio systematica plantarum, quas in insulis Caribæis vicinaque Americæ Continente detexit novas,' gave the name *Copaiva*. Should this be a valid publication the official plant will have to be called *Copaiva Landsdorffii*, Desf. in 'Mém. Mus. Par,' vol. vii. (1821), p. 377. Among the other species yielding copaiba are *Copaiva officinalis*, Jacq. l.c., p. 21 (1760); *Copaiva coriacea* 'Mart. Reise Brasil,' p. 285; *Copaiva guyanensis*, Desf. in 'Mém. Mus. Par.,' vol. vii. (1821), p. 376; *Copaiva multijuga*, Desf., l.c., rests on rather uncertain identity, since it is said a fragmentary specimen only exists.

CUSO.—In the Pharmacopœia of 1885 the name *Brayera anthelmintica* was displaced by that of *Hagenia abyssinica*; now the former name is restored, but I fail to see the reason. Bruce first described the plant in his 'Travels in Abyssinia,' vol. v., 1790, p. 22-3. In the text it is called *Banksia abyssinica*, but on the plate dated December 1, 1789, it is spelt *Bankesia*. The name, whichever spelling be followed, is invalid, owing to there being an earlier genus, *Banksia* in the Proteaceæ. In the 'Systema' of 1791, p. 613, J. F. Gmelin therefore named the Cusso *Hagenia abyssinica*, and this name was adopted by Willdenow in the 'Species Plantarum,' vol. ii., p. 331, of 1799. The earlier *Hagenia* of Mönch is not a competing name, since it is now sunk in *Saponaria*. The genus *Brayera* was not established by Kunth until 1824, when he published it in Brayer's 'Notice sur une Nouvelle Plante de la Famille des Rosacées.' In passing I may say that Bruce spelt the name of the drug "cusso."

FILIX-MAS.—The name of the male fern is given as *Aspidium Filix-mas*. In most works on English botany *Lastrea* is the name used for the genus, and this was established by Presl in 1836 as distinct from *Aspidium*. The oldest name for the genus appears to be *Dryopteris*, which was used by Adanson in vol. ii., p. 20, of his 'Famille des Plantes' of 1763, and where he diagnoses the genus. Our plant is *Dryopteris Filix-mas*, Schott, 'Gen. Fil.,' sub. t. 9 (1836).

FŒNICULI FRUCTUS.—The name *Fœniculum capillaceum*, Gilibert, 'Flora Lituan,' vol. ii. (1782), p. 40, is retained, but the oldest name is *F. vulgare*, Miller, 'Gardener's Dictionary,' ed. 8 (1768).

MENTHOL.—*Mentha arvensis*, D.C., is stated to be one of the plants yielding it, but the authority for *M. arvensis* is Linnæus in the 'Species Plantarum' of 1753, p. 577, not De Candolle. *M. piperita*, Smith, should be cited as of Hudson, since he described it in the 'Flora Anglica' of 1762, long before Sir J. E. Smith. Linnæus also gives a *Mentha piperita*, but there is some doubt as to the exact

identity, since Sir J. E. Smith says it is represented in the Linnean Herbarium by a form of *Mentha aquatica*.

MYRRHA.—It is a pity that the name *Commiphora* which is adopted by some continental pharmacopœias for the plant yielding myrrh should not have been chosen, since it was established by Jacquin in the 'Plantarum rariorum horti cæsarei Schonbrunnensis descriptiones et icones,' vol. ii. (1797), p. 66, and has considerable priority over the name *Balsamodendron*, which was not founded until 1824 by Kunth in the 'Annales Sciences Naturelles, sér.' i., vol. ii., p. 348. The name of the myrrh plant is *Commiphora Myrrha*, Engler, in D.C. 'Mon. Phan.', vol. iv., p. 10.

OLEUM MENTHÆ VIRIDIS.—In the first edition of the 'Species Plantarum,' the spearmint was described by Linnæus as *Mentha spicata*, var. *viridis*. In the second edition of 1762, he gave it specific rank as *M. viridis*. Meanwhile, Hudson, in his 'Flora Anglica,' had previously described it as a species under the name *M. spicata*. It is a question, therefore, whether the name should not be *M. spicata*, Huds.

OLEUM ROSÆ.—The authority for *Rosa damascena* is not Linnæus but Miller, who first described it under that name in 'Gardener's Dictionary,' of 1768.

PAREIRÆ RADIX.—The name of the plant is given as *Chondrodendron tomentosum*, but it is spelt, against etymological rule, *Chondodendron* by Ruiz and Pavon in the 'Syst. Veg.,' p. 261.

QUILLAIÆ CORTEX.—The specific name should be spelt with a capital, as *Q. Saponaria*, as should *Citrus Medica*.

SINAPIS NIGRÆ SEMINA.—The name of the black mustard is given as *Brassica nigra*, Koch, which was founded in Roehl's 'Deutsch. Flora,' ed. 3, vol. iv., p. 713, of 1833, but Roth, in his 'Manuale' of 1830, vol. ii., p. 957, had previously called it *Brassica sinapioides*, and until British botanists accept the permanence of the specific names as a rule of nomenclature, the latter name should be adopted.

THE CHEMISTRY OF THE PHARMACOPŒIA.*

BY ARTHUR L. DORAN, M.P.S.I.

The request to write an introductory paper on the chemistry of the British Pharmacopœia, for Conference, was received early in July with mixed feelings. For, on the one hand, was it not a pleasant proof that all the leaders of pharmacy in the adjacent island did not endorse the opinion so recently expressed post-prandially and euphemistically by a well-known English professor to the President of the Pharmaceutical Society of Ireland? For which see, *mutatis mutandis*, Nathanael's reply to Philip. And again, on the other hand, it is equally plain that so soon after publication there are only two kinds of critics adequate to the proposed task—the purely professional chemist engaged constantly in devising, testing, and teaching processes, hence fully cognisant of the historical data of any given question; and the technical chemist in the wholesale laboratory, whose science, though not necessarily less pure than that of the former, is often limited by the exigencies of commercial dispatch and by a less ample dower of apparatus.

It is surely to be regretted that the wholesale houses on this side of the water are so neglectful of similar work, of which it may be at once stated that it is not only an ethical duty, but also a business investment of the soundest character. In some of the criticism already published one may be excused for detecting an apparent desire to say something detrimental at an early date rather than the better part of selecting for commendation undoubted advances and improvements on the previous edition. In general,

we may say that the chemistry of the new B.P. presents nothing particularly novel, and has been familiar to most of us for a long time, although a good deal of it escaped incorporation in the revision of 1885. Changes in chemical nomenclature and a militant metric system becoming triumphant—indeed, reigning alone in the purely scientific work—were to be expected, while the deletion of technological matter, removal of common reactions to the appendix, and adoption of a principle of limits for purity tests, are natural results of having so illustrious a triad of "referees," one of whom we delight to honour as *homo clarissimus Dublinensis*.

I cannot agree with the strictures that have been passed to the effect that the instructions given for testing are superfluous to the brained analyst and insufficient to the tyro. The chemical instructions of the B.P., I take it, are intended for the average man who may well need a mnemonic, be he an M.D. some time removed from his College course, or a chemist made in the Square or at Mount Street. It should be remembered that in the vast majority of cases it is good negative evidence alone that will be requisite, and that if impurity or adulteration be indicated it will have to be proved by more than one method, and for this long apprenticeship to the science together with considerable aptitude will as a rule be necessary.

The introduction of reasonable standards of purity, conforming to good commercial specimens, is of the greatest importance at a time when the usage of citing the B.P. as a legal standard under the Foods and Drugs Act has become well-established. In so comprehensive a work as the B.P., doubtless after a time some of the standards adopted will be found open to objection and in need of revision, and it is especially here that I think the services of many able and willing pharmacists throughout the United Kingdom might be enlisted to work, either alone or in conjunction with a local association in such a manner that a maximum number of observations and determinations would become available on such questions arising.

As an example may be mentioned a recent experience of my own in the case of a newly-introduced compound—bismuth salicylas. Of a number of specimens examined, not one failed to give more or less violet coloration when test solution of ferric chloride was added to the 90 vol. alcohol washings. One specimen was so grossly impure that salicylic acid was deposited on the funnel on filtration, and I merely mention this to draw attention to the fact that the therapeutical reputation of this chemical would necessarily be ruined by such a mixture.

By the statement in the Preface—that constitutional formulæ are given rather than empirical for organic chemical substances, and that the revisers were only stopped short of graphic representation by the limitations of page area—attention is obliquely drawn to the great importance of these latter, constituting as they do a chemical shorthand that not only informs one of their probable chemical behaviour but in many instances of their physiological action. A single example must suffice of the way in which these formulæ must be applied to working out an answer to such a question as "What is exalgine?" Diagrammatically thus:—

and recollecting that it is a characteristic of amidogen substituted derivations of the aromatic group to exhibit antipyretic properties, we see why the second last of these compounds finds a place

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898

in medicine. Moreover, the substitution of an alkyl group, particularly methyl, in the amidogen powerfully modifies the properties of the compound in the direction of conferring analgesic power, hence we expect and find that exalgine or methyl acetanilide possesses such power. And every correct instance of this sort is a step nearer to that great object of modern chemistry—the synthesis of bodies possessing properties primarily determined on.

I beg to close this cursory review of impressions and convictions with the hope that in any future Pharmacopœia revision the General Medical Council will pursue still further the wise and dignified policy of delegating detailed work to the hands best suited to properly execute it, being mindful of the Napoleonic dictum, *La carrière ouverte aux talens*, so that we may come to possess at last a work resting firm and unassailable on the triple support of expert, commercial, and officinal knowledge.

A SHORT NOTE ON LIME WATER.*

BY E. J. EVANS.

A few experiments were attempted with the above subject in view of the late prosecutions under the Foods and Drugs Acts.

1. Lime water was made with 2 oz. freshly slaked lime to the gallon, and allowed to stand 24 hours.

100 C.c. of this solution filtered required 49 C.c. N/10 vol. HCl.

2. Lime water made with the same quantity of lime hydrate, but the lime washed with a little water previous to using.

100 C.c. filtered required 49.5 N/10 vol. HCl.

3. Ordinary shop solution.

100 C.c. required 48 C.c. N/10 vol. HCl. This solution had been kept about a month in contact with the slaked lime.

4. No. 1 solution kept in a flask covered with a chip box lid in contact with the excess of lime for a week and then tested.

100 C.c. required 47.5 C.c. N/10 vol. HCl.

5. No. 2 solution was kept in a flask covered with a funnel, in contact with the excess of lime.

100 C.c. required 48 C.c. N/10 vol. HCl.

6. Lime water was made with water to which 16 grains of $MgSO_4$ per gallon had been added.

100 C.c. required 50.7 C.c. vol. N/10 HCl. A week later 100 C.c. required 50.5 C.c. vol. N/10 HCl.

7. Lime water made by water containing 16 grains of alum to the gallon.

100 C.c. required 50.2 C.c. N/10 vol. HCl. A week later 100 C.c. required 50.25 C.c. N/10 vol. HCl.

8. Lime water made and tested fifteen minutes after mixing.

100 C.c. required 51.0 C.c. vol. N/10 HCl.

9. No. 8 solution after fifteen minutes longer.

100 C.c. required 51.7 C.c. N/10 vol. HCl.

B.P. requirement—

100 C.c. require 42.0 N/10 HCl or H_2SO_4 .

10. Lime water made with water contain 1/10 vol. of CO_2 .

100 C.c. required 49.0 C.c. N/10 HCl vol.

11. Lime water made with water contain 1/2 vol. of CO_2 .

100 C.c. required 39.0 C.c. N/10 vol. HCl.

Two ounces of lime hydrate is too large a quantity to use if the lime used is fairly pure.

Theoretically 96 grains or 6.2 grammes would be required.

Experiments with and tested an hour after :—

(a) Solution 72 grains to gallon required 30 C.c. vol. N/10 HCl per 100 C.c.

(b) Solution 96 grains to gallon required 37 C.c. vol. N/10 HCl per 100 C.c.

(c) Solution 120 grains to gallon required 40 C.c. vol. N/10 HCl per 100 C.c.

After twenty-four hours 41.5 C.c. N/10 vol. HCl per 100 C.c.

(d) Solution 144 grains to gallon required 43.0 C.c. vol. N/10 HCl per 100 C.c.

After twenty-four hours, same.

From these experiments it would seem that lime water can be made in a few minutes, if a fairly pure caustic lime be recently slaked before using. Also that when intended to be kept, the lime water should be in contact with the excess of lime used.

LEGAL INTELLIGENCE.

PROCEEDINGS UNDER THE FOOD AND DRUGS ACT.

At the Abergele Petty Sessions, North Wales, on Saturday, August 6, Superintendent Jones, of the Denbighshire County Police, summoned Mr. Thos. Williams, grocer and baker, Pensarn, Abergele, for selling tincture of rhubarb and sweet spirits of nitre, which were not of the quality and nature demanded.

The defendant was represented by Mr. E. A. Crabbe, solicitor, Abergele. The sale of the articles was admitted.

Superintendent Jones produced the certificate of Mr. Lowe, Chester, county analyst, which showed that the tincture of rhubarb was as follows :—Specific gravity at 60° F., 0.95; alcohol (by weight), 34.56 per cent.; extract, 4.76; water, 60.68. The words added by the analyst to the above were: "Only about three-quarters of amount of alcohol ordered by the British Pharmacopœia." The analysis as to the sweet spirits of nitre was as follows: "Specific gravity at 60° F., 0.85; ethyl nitrite, 0.32 per cent. Only about one-sixth of the amount of active principle, ethyl nitrite, ordered by B.P."

For the defence Mr. Crabbe said that the defendant had acted in ignorance. He kept the tincture of rhubarb for the convenience of the residents of Pensarn, which did not possess a chemist's shop. It was bought from Messrs. Bell and Son, Liverpool, and defendant was assured that it complied with the legal requirements. He produced the bottle in which the tincture of rhubarb was sent to defendant, the label bearing the words: "Tincture of Rhubarb, B.P." The wholesale firm now admitted that it was not up to the British Pharmacopœia strength, and that it was mixed with other ingredients to make it more palatable. Under the circumstances he was bound to plead guilty with regard to the tincture of rhubarb, but he had a defence as to the sweet spirits of nitre.

Dr. Wolstenholme (a magistrate) pointed out that the tincture was kept in a bottle with an ordinary cork. It was clear that the defendant had been deceived. Messrs. Bell and Son should certainly make it good to the defendant, who he was sure would not knowingly commit an offence, but had kept the tincture for the benefit of the public.

Superintendent Jones remarked that defendant had his remedy against Messrs. Bell and Co.

Mr. Crabbe replied that unfortunately that was not so, as it had been invoiced to the defendant as "Compound tincture of rhubarb."

The Chairman of the Bench said it was a hard case, and, unfortunately for defendant, the costs were heavy. Defendant could not be said to be responsible, but the analyst's certificate was conclusive. As the costs in the tincture of rhubarb case came to 18s., defendant would be fined the nominal sum of 6d.

The case of the sweet spirits of nitre was then taken, and Mr. Crabbe argued that defendant was entitled to a dismissal, as he did not know that the spirit would evaporate. He had kept it in a large bottle, and as a customer asked for it he served it out. Defendant should have sold the spirit in small stoppered bottles as he received it. It was really ignorance of the nature of the spirit that had caused the evaporation.

The Chairman pointed out that there was no charge of adulteration.

Superintendent Jones replied that he did not charge defendant with adulteration. He complained that the sweet spirits of nitre were not of the nature and quality demanded. It was robbing the public.

The Chairman said it was hard on defendant, who was fined 6d. and 18s. costs.

* Read at the British Pharmaceutical Conference, held at Belfast, August, 1898.

SESSIONS OF CONFERENCE.

FIRST DAY'S BUSINESS.

The thirty-fifth Annual Meeting of the British Pharmaceutical Conference commenced its sittings on Tuesday, August 9, in the library of the Queen's College, Belfast, under the presidency of Dr. CH. SYMES, of Liverpool. The commodious hall was well filled, a large number of ladies being present.

The proceedings began with an address of welcome by the LORD MAYOR OF BELFAST, who said he was delighted that the Conference had selected Belfast as its place of meeting this year. Since he had had the honour of holding the office he did, he had the pleasure of welcoming many bodies to that city, but in no case had he done so with greater pleasure than on the present occasion. He had noticed in the transactions that some years ago a resolution was proposed by Mr. Payne, who occupied a very important and honourable position in Belfast, that the meetings of the Conference should not in future necessarily take place at the same time and place as the meetings of the British Association. He thought this a very wise resolution, and he was glad that it was carried, otherwise the Conference could not have met in Belfast this year. It was not necessary to say anything about the city itself, as he trusted its visitors would soon make acquaintance with it for themselves, but he could assure them all of a hearty welcome, not only by the Corporation of which he was the head, but by the various public boards and by the people at large.

Rev. Dr. HAMILTON (President of the Queen's College) also welcomed the Conference to Belfast. It afforded him the greatest pleasure to be able to place the College at the service of the Conference. They had had the honour of receiving many learned and important bodies in the College at different times, but to no body could they give a heartier welcome than to the British Pharmaceutical Conference.

Dr. NELSON (President of the Ulster Medical Association) also briefly welcomed the Conference to Belfast.

Professor WHITLA; in adding his welcome on behalf of the medical profession, said he was regarded as a sort of missing link between the scientific pharmacist and the practising physician. There was no city in the British Empire where there was a closer and more friendly relationship existing between the medical faculty and the pharmacist. In the northern capital of Ireland it had long been recognised that the pharmacist prepared, sometimes discovered, and sometimes even, out of nothing, created the weapons with which the doctors had to fight their battle against disease, and they regarded the pharmacist as a co-worker.

The Presidential Address (see page 149) was then delivered.

Sir JAMES HASLETT, M.P., in moving a vote of thanks to the President for his address, commenced by joining on behalf of the citizens of Belfast in the welcome which had already been extended to the Conference. He was glad to find that this visit had helped to remove any little points of difference which might have existed between various phases of the calling in Ireland, and hoped that the leading differences which existed between the Irish and English practice would soon pass away too, and that there might be one general system of examination and qualification for all, so that the trade might be common to all in England, Ireland, and Scotland. He was aware that there were difficulties in the way, but if the members of the Conference helped to remove them he should be glad. He did not like Irishmen to go to England with any badge of inferiority, because they were equal to most men and superior to all. He hoped some of their good friends who had come over would lose their return tickets, as had happened before to some of their Scotch friends. He did not sympathise with a remark he recently heard that these people would come and spy out the land, set up in opposition, and get all the business. He had no fear of that, for it was cut so fine that there would be no living for an Englishman, and even Irishmen sometimes found it difficult to get potatoes and salt. The President had referred in his address to the question of scheduled poisons, and especially to carbolic acid, which was largely used in committing suicide; but the difficulty in putting such an article on the schedule was no doubt the large extent to which it was used in industry. With regard to methylated spirit his own view was that anyone who could drink it ought to be allowed to do so, and he did not think further legislation was required to prevent them. With regard to the metric system, he feared he was too old to

change his mode of calculation, but he felt quite sure that for young men who could master it, it possessed a simplicity far in advance of the present system. With regard to the connection between medicine and pharmacy, it was as close and intimate as that between the organist and the organ blower, and both parties were equally entitled to claim a share in the result produced. With regard to the Pharmacopœia, no doubt it would have been more satisfactory if practical men had had more to do with it; he could only express his own opinion that it was infinitely inferior to Dr. Whitla's edition. That was by no means such dry reading as the present one, in fact he could bear living testimony to the fact that it was actually fire-proof, for when their premises in North Street were burnt down, it was almost the only thing that escaped destruction, and it still remained, burned outside, but intact within, and he could cordially recommend it for the information it contained. He concluded by an eloquent and sympathetic reference to those who had passed away, suggesting the lesson that all should so fulfil their duties through life that, when called away, they would also be mentioned in similar terms of regret.

Mr. J. C. C. PAYNE, J.P., had much pleasure in seconding the vote of thanks so ably proposed by Sir James Haslett, M.P.

Mr. S. R. ATKINS, J.P. (Salisbury), in putting the vote of thanks to the meeting, said Dr. Symes had given them that day an address full of practical importance.

The resolution having been carried,

The PRESIDENT said he had been somewhat overwhelmed by the manner in which the resolution had been proposed and received. He could only thank the meeting for the attention they had given to his address.

The Lord Mayor then retired:

Letters of regret for inability to attend the Conference had been received from Mr. T. B. Groves (Weymouth), Mr. N. H. Martin (Newcastle-on-Tyne), Mr. F. B. Bengier (Manchester), Mr. Charles Umney (London), Mr. R. Wright (Buxton), Mr. Walter Hills (London), Mr. T. Tyrer (London), Mr. R. Reynolds (Leeds), and Dr. Attfield (London). Professor Remington, of Philadelphia, had also telegraphed his congratulations and well-wishes to the Conference.

Amongst the letters of apology the following were read:—

Leeds,

August 4, 1898.

Dear Mr. Naylor,—Although I cannot have the pleasure of being present at the meeting of the British Pharmaceutical Conference at Belfast, I hope that I may be permitted to express my gratification at the period of vigorous existence which our institution is now enjoying. There is reason to think that the too abundant blows that have fallen upon those who practise pharmacy have had the result of welding their social instincts. The latest illustration of this is a very recent episode in attempted legislation affecting both British and Irish pharmacy. Had this danger threatened longer, we know that with a good cause our united parliamentary forces would have been invincible. Wishing you a very successful meeting,

I am, yours faithfully,

RICHARD REYNOLDS.

Ashlands, Watford,

August 6, 1898.

Dear Dr. Symes,—After making all arrangements to be present at Belfast next week, I am much disappointed at being compelled to forego the pleasure. The sudden rupture of a large cyst that has latterly disfigured my head has placed me temporarily in the hands of the surgeon. Now the resources of surgery, medicine, and pharmacy are fit subjects for the brain of an Editor of a British Pharmacopœia; but when they take the tangible shape of an ugly mass of cotton-wool, phenol, and sticking-plaster on his scalp, they unfit him for the platform of a Pharmaceutical Conference. I am the more sorry because nearly every one of the announced papers has great interest for me. Please convey my regrets to my many friends and accept my congratulations on the apparently assured success of the meeting in both its scientific and social aspects.

Yours faithfully,

JOHN ATTFIELD.

The HON. SECRETARY (Mr. Ransom) then read the following list of delegates to the Conference:—

Pharmaceutical Society of Great Britain.—Mr. W. Hills (President), Mr. G. T. W. Newsholme (Vice-President), Messrs. Atkins, Bateson, Carteighe, Grosch, Johnston, Martindale, Park, Symes, Warren, Young, and R. Bromridge (Secretary).

Pharmaceutical Society of Great Britain (North British Branch).—Messrs. J. Laidlaw Ewing (Chairman), W. L. Currie (Vice-Chairman), J. Bowman, G. Coull, A. Davidson, Fisher, Lunan, Kerr, McLaren, Moir, and Nesbit.

Pharmaceutical Society of Ireland.—Messrs. R. J. Downes (President), G. D. Begg (Vice-President), Connor, Conyngham, Kelly, Montgomery, O'Sullivan, Wells, jun., Professor Tichborne, and Dr. J. A. Walsh.

Brighton Association of Pharmacy.—Messrs. Ashton, Costerton, Gibson, Savage, Weston, and Yates.

Bristol Pharmaceutical Association.—Messrs. Keen and Pitman.

Cambridge Pharmaceutical Association.—Mr. E. Saville Peck.

Edinburgh Chemists' Assistants' Association.—Messrs. Lunan and McLaren.

Forfarshire and District Chemists' Association.—Messrs. C. Kerr (President), Anderson, Davidson, Ferrier, and Naysmith.

of Dorpat, has contributed much to the promotion of pharmaceutical research. By the death of Mr. Michael Conroy, F.C.S., who was a Vice-President at the Liverpool Meeting in 1896, the Conference has lost one of its most able and frequent contributors. His ability and practical experience in technical pharmacy were evidenced in the papers which he contributed and in the part he took in the discussions, while his genial nature brought him into equal prominence in the social functions of our meetings. Amongst others who have passed away, reference must be made to Mr. E. Beynon, whose death followed shortly after his resignation already referred to; Mr. Thomas Glaisyer, who acted as honorary local secretary at the meeting of the Conference in Brighton; and Mr. W. Willmott, who has contributed several papers of interest.

"At the moment of completing this report there comes the sad intelligence of the death of J. E. De Vrij, Ph.D., C.I.E., at the advanced age of 85. As a quinologist he had attained a reputation which gave him rank amongst the greatest authorities in this branch of knowledge. He was also early distinguished as a pharmacist, and later as a naturalist. For twenty-seven years he has been an honorary member of the Conference, and in the 'Year-Books of Pharmacy' are to be found references to twenty-five of his many papers on cinchona bark or its alkaloids. Your Committee desires to pay its tribute of grateful acknowledgment to the memory of him who by his invaluable researches has greatly enriched our knowledge of a most important drug.

"The loss which has annually to be recorded of so many of our active members should stimulate all those who remain to increased energy, and your Committee trusts that the disinterested loyalty which so characterised the founders and early supporters of the Conference may continue to inspire those upon whom the duty devolves to maintain the success of the Association.

The adoption of the report passed unanimously."

FINANCIAL STATEMENT.

Mr. F. R. RANSOM then read the financial statement (see page 206)

Mr. DRUCE (Oxford), in moving the adoption of the report, expressed his regret at the retirement of Mr. Moss.

Mr. BRANSON (Leeds) seconded the resolution, which passed unanimously.

REPORT OF THE UNOFFICIAL FORMULARY COMMITTEE.

Mr. W. MARTINDALE read the report of this Committee as follows:

"In presenting their report the Unofficial Formulary Committee have to inform the Conference that as some of their members were engaged in assisting the General Medical Council in the revision of the British Pharmacopœia during the last three years, it was considered advisable that the Formulary work should be in abeyance until the new Pharmacopœia was published. They have much pleasure in reporting that the Official Pharmacopœia has absorbed eighteen formulæ that were devised by the Unofficial Formulary Committee (some with slight modification). The Committee should now resume active work, and would suggest their reappointment."

Mr. COLLYER (London) proposed the adoption of the report.

Mr. E. SAVILLE PECK (Cambridge) seconded the resolution, which passed unanimously.

The first paper read was by Mr. JOHN MOSS, F.I.C., F.C.S., on

Kieselguhr,

which is printed at p. 168.

Mr. Moss was able to submit a specimen of Australian diatomite in the natural condition as it occurs at Talbot, Victoria, and at Cooma, in New South Wales. They are of different degrees of hardness, but not so hard as the Virginian kind. There were also specimens from Llyn cwm Bychan, in Wales, which are softer still and darker in colour, and a most interesting specimen from the Government Geologist of South Australia, who labels it diatomaceous rock from Port Darwin. The piece was very hard and rocky, and can with difficulty be worn by scraping it with a knife, and it illustrates in a marked manner how sharp the line of demarcation may be between the white unsullied rock and the same rock stained by infiltration of some dark impure liquid.

The PRESIDENT, in inviting discussion, said Mr. Moss told them that a diatom was a plant, which was no doubt true, though in his early days it was termed an animal. It was just on the borderland. In those days one had to go through a long and tedious process to obtain any quantity of diatoms for examination, and he remembered boiling many samples of guano with nitric acid, sulphuric acid, and then nitro-hydrochloric acid, and finally in sulphuric

acid with the addition of a little chlorate of potash; and if any diatoms survived that treatment you might assume it was a very hardy skeleton, and would form an inert powder not likely to be easily acted upon.

Mr. STANFORD asked if Mr. Moss had any experience of the use of kieselguhr as a filtering medium for the exclusion of bacteria. He understood that some filters were made with it.

Mr. RANSOM said he had used the kieselguhr as a filtering medium and found it very excellent, the darker kinds, however, being better than the lighter, presumably because the diatoms in the latter were more broken up, or belonged to the smaller species. Examined under the microscope they differed in size as much as from 1/40 to 1/1000 in. There was no doubt now that diatoms belonged to the algæ and had the characteristics of vegetables.

Mr. MARTINDALE thought kieselguhr would be rather harsh as a dusting powder and seemed to have rather a sticky nature. He did not think it would compare for this purpose with kaolin or talc, except for its absorbent properties, which in some cases would be useful.

Mr. Moss in reply said anyone who had to do much filtering of galenical preparations must sometimes require to filter out bacteria which developed in them, as well as in organic preparations, and he had found kieselguhr most useful for that purpose. His experience coincided with Mr. Ransom's as to the efficacy of these powders; the darker ones did filter a little more readily than the purer ones. The Australian powders consisted almost of one variety, as stated in the paper, whilst there were an immense number of forms of larger size to be found in the ground. He should not describe the infusorial earth as harsh or sticky; it was better as a dusting powder for surfaces which were apt to have exudations than where two were rubbed together as instanced by Mr. Martindale. A little of the infusorial earth mixed with talc or Fuller's earth improved its absorbing properties without interfering with the antifrictional properties.

A vote of thanks to Mr. Moss was passed unanimously.

The next paper was read by Mr. E. J. PARRY, B.Sc. F.I.C., on

Oil of Eucalyptus,

printed at p. 198.

A vote of thanks was passed to Mr. Parry for his paper.

The next paper (see p. 170) was by Dr. FIELDEN on

Gluten Flour and its Analysis.

The PRESIDENT said this paper was very valuable at the present time, when so much attention was given by the medical profession to food for diabetic patients. Some years ago Dr. Pavy had a number of samples of diabetic bread and biscuit examined. He thought that they should contain at least 75 per cent. of gluten, and it was very important that such articles should not contain so much starch as 50 or 60 per cent.

Mr. COLLIER said he belonged to the hospital with which Dr. Pavy was many years associated, and was aware that gluten bread always contained a notable quantity of starch. You could not obtain gluten flour free from starch, and he always attributed that to the mode of preparation. The mere washing out of the starch with water was not sufficient, and he should like to know if Dr. Fielden had any experience of a method which had been suggested of treating the flour with a certain amount of extract of malt, which, by its diastasic action, rendered the starch soluble. A short time ago he examined a French specimen of gluten bread which had received high testimonials, and found it contained nearly 40 per cent. of starch. The general impression amongst medical men was that gluten bread was practically free from starch, and it was very desirable that the facts should be generally known.

Dr. B. H. PAUL could confirm what had been said with regard to the almost invariable presence of a large proportion of starch in the so-called diabetic food, gluten biscuits, and such preparations. Two or three years ago he examined a large number of these preparations for a sufferer from diabetes, and there was scarcely one of them which was not found to contain such large proportions of starch as to make them delusive as diabetic food.

Mr. MARTINDALE said he had been informed by a dealer in gluten flour in London that it was impossible to get it free from starch, and also that it was invariably an imported article, being either of Swiss or French manufacture. He considered that as a pleasant change for diabetic patients bran or almond biscuits would be found very suitable.

Mr. ATKINS said the paper was of great practical importance, and the Conference were greatly indebted to the writer. He was amazed at the large percentage of starch present in the gluten bread, especially in sample D. It seemed to him that a very cruel course was unconsciously being pursued in the sale of this bread; patients were compelled to eat this most obnoxious form of bread under medical advice, and surely there ought to be some means by which an honest article could be supplied to them, and he trusted that that would be one of the results which would follow from the reading of the paper.

Mr. NAYLOR said gluten was extremely difficult to manipulate, and he should like to suggest that that was possibly one reason why gluten flour always contained a proportion of starchy matter, though it did not account for the large proportion that had been disclosed.

Dr. FIELDEN thanked the Conference for their reception of the paper. In reply to Mr. Collier, he said this was the first time that he had attempted to examine gluten preparations; he had confined himself solely to the flour, and did not examine any gluten bread. Each of the samples he had examined were obtained from different sources.

The PRESIDENT, in proposing a vote of thanks to Dr. Fielden, said there were differences of opinion about gluten bread, but he thought everybody would agree that it would require a good deal of beating.

The vote of thanks passed unanimously.

Mr. STANFORD next read a paper on

Thyroglandin,

which is printed at p. 166. Specimens of the preparations referred to were exhibited

The PRESIDENT said this was a subject which Mr. Stanford had made his own, having been working at it for some time, and he had evidently, since last year succeeded in meeting some of the difficulties which presented themselves, and producing a very excellent preparation.

Dr. McWALTER said Mr. Stanford was such an authority on this subject that he only ventured with diffidence on any criticisms; but it seemed to him that the preparations of the thyroid gland had long been a reproach to pharmacy, inasmuch as very few at all represented the active principle. The first difficulty was to know what really was the active principle, but as far as he could make out it was generally admitted that there were two, and possibly three—viz., thyroiodin, a metabolic product, some thyro-proteid, and a third, described by Mr. Victor Horsley, which was of the nature of an internal secretion, the approximate chemical character of which had not yet been determined. He did not think sufficient stress was laid on the importance of employing the gland while still warm from the animal, because *post-mortem* changes took place with great rapidity. No doubt Mr. Stanford used them fairly fresh, but he did not think he was sufficiently definite on that point; they ought to be used, if possible, within thirty minutes of removal. With regard to the glycerin process, though Mr. Stanford did not approve of it, he understood that since last year Dr. Murray, of Newcastle on-Tyne, who was then quoted in favour of dried preparations, had expressed himself as a convert to the use of glycerin, and even claimed the new pharmaceutical preparation as his own. Although Mr. Stanford had quoted Dr. McLennan, who was an undoubted authority, in favour of his preparation, he thought further experience was desirable before it could be accepted as being entirely satisfactory. They were all, however, much indebted to Mr. Stanford for his very valuable paper.

Dr. SIEBOLD asked the relative proportion of iodo globulin and iodo-thyroidin in the preparations Mr. Stanford had made, and if there was any difference in the proportion of iodine in the two.

Mr. MARTINDALE asked if it had really been decided that the efficacy of the gland was due to the iodo-compounds found in it. If it were chiefly due to the iodine, no doubt Mr. Stanford could obtain that body much more cheaply from other sources, but he was somewhat doubtful about its efficacy. The use of a preparation of idio thyroiodin had not been carried far in London, where a dried preparation of the gland, and in some cases the glycerin extract, was preferred, though the latter was not much demanded, probably because it did not keep well. The pharmaceutical preparation made by exhausting the gland with petroleum spirit kept reasonably well; but there was the danger that the gland, unless quickly dried and freed from fat, was apt to undergo decomposition. These preparations of Mr. Stanford were not unpleasant in odour, but there was a trace of a pepsine-like smell which a fastidious patient might object to.

Mr. KELLY said if *post-mortem* changes took place in the gland the patient might be swallowing ptomaines instead of the thyroid gland; he thought, therefore that some test for ptomaines should be included in the Pharmacopœia process, so as to provide for cases where decomposition might have commenced.

Mr. BALL asked what was the real difference between the production obtained by Dr. Hutcheson's method and by Dr. McLennan's. He rather gathered the difference was that in Dr. Hutcheson's process the gland was not so completely exhausted.

Mr. STANFORD, in reply, said Mr. Ball was right; Dr. Hutcheson's preparation did not represent the gland, because it was not all exhausted. He could not go into the question of the medical action of the thyroid gland, for anyone who would go into the literature of the subject would find not only that it was very voluminous, but that opinions varied very greatly as to what was the active principle. He only claimed for this process that it was the first attempt to get a good chemical process, giving a product which had no decomposing matter in it. All the others, except the thyroiodin were liable to be contaminated by any disagreeable substances which might be contained in the raw gland. The two tubes he had shown would partly answer Dr. Siebold's question, but he could not give the exact iodine contents then, though he hoped to add this information later. With regard to glycerin preparations he thought that they were the ones which were generally complained of as producing unpleasant symptoms. A vote of thanks was passed to Mr. Stanford.

A paper on

A Quick Polarimetric Method for the Estimation of Strophanthin in the B.P. Tincture and Extract,

by EDWARD DOWZARD, F.C.S., printed on page (199), was then read by Mr. Naylor.

The PRESIDENT, in proposing a vote of thanks, said this was a very interesting paper. He hoped this method would be found to apply to other substances besides strophanthin.

The resolution passed unanimously.

The next paper was by Mr. W. A. H. NAYLOR, and Mr. J. J. BRYANT, on

Green Extracts of the Pharmacopœia,

printed at page (165).

The PRESIDENT said Mr. Naylor, in a very few words, gave the result of a very useful and general work. With his accustomed modesty he always attributed less importance to his work than it deserved, but when they came to study the paper they would see that it had involved very careful work. This paper might be taken to be not only reliable work, but also representative.

Mr. MARTINDALE thought the green extracts were not up to date. They were largely in demand, but the preparation of them entailed a good deal of pressure of work at a limited season that would be very much better done if the extracts were prepared from carefully dried plants. He did not think there was any civilised country that used such a preparation as was used in Great Britain. For his part he should prefer to have the plants carefully dried and alcoholic preparations made from them. The prices would vary with the time of year at which they were collected; if they were collected in a wet season the amount of alkaloid in the juice would vary, and the extracts would also vary.

Mr. J. C. UMNEY asked whether Mr. Naylor had made any experiments as to the proportion of alkaloid got from the same district in the case of belladonna at different seasons. Making experiments on a large scale he noticed that the extracts at the end of July or the beginning of August were better than those made early in the season. He made no experiment on their alkaloidal value.

Mr. FARR said in conjunction with Mr. Wright he had examined a number of green extracts. They had examined them for the mucilaginous as well as the alkaloidal constituents, and found they contained a very large proportion of inert matter. After working on the subject for a month or two they came to the conclusion that if you wished to get a really active preparation it was necessary to work upon the dry material, and make a more or less alcoholic preparation. He was pleased to hear Mr. Naylor advocate the standardising of these preparations, as he thought he was not always in favour of it.

Mr. NAYLOR said they had not considered in the short note the advisability of using dry material. They had simply hoped that what they had there given would be some little contribution on

the question. In reply to Mr. Umney he must say that he and his colleague had not considered the question he referred to, but he did think that they were able, to a very considerable extent, to determine whether they should have an extract which should contain a fair proportion of alkaloids, or one which should contain a much smaller proportion. Of course, they took the green herb, which was very stalky, and especially if it contained a lot of the thick stalk, they would have an extract which would contain more mucilaginous matter, but less alkaloid. If they were careful in the choice of the green herb and took the leafy portion, then, independently of soil and season, they would be able to obtain an extract which would contain not less in the case of belladonna than 1 per cent. It was quite clear that there was a great variation in the percentage yielded by these extracts, and the only sound conclusion they could come to was that, so long as they were retained in the Pharmacopœia, they should be standardised.

The PRESIDENT, in putting the vote of thanks, said there was one particular case in which they had returned to the use of green leaves in obtaining cocaine. When cocaine was very scarce, it was found that in bringing the dry leaves to this country four-fifths of the cocaine was lost, and they owed the fact of the low price of cocaine to it being now obtained from the green leaves on the spot.

The next paper read was by Mr. E. C. C. STANFORD on

Iron and other Alginoids.

It is printed on page 199.

The PRESIDENT said Mr. Stanford had introduced a new class of substances which appeared to possess certain advantages. He would first ask if these solutions kept well; if they did some of them would be very useful; antimony, for instance, as antimony wine was very liable to change. They all knew the difficulty in coating certain drugs in such a manner as to prevent their action until they had passed from the stomach into the intestines, and if this class of preparation could be relied upon for this purpose it would be very useful.

Mr. BIRD asked if the magnesium alginate could be used for emulsifying purposes. Some years ago Mr. Stanford sent him some sodium alginate, which he tried for that purpose, but found it too gelatinous. These compounds were very interesting, and the iron alginoids in particular appeared likely to be very useful.

Mr. MARTINDALE thought these preparations offered a means of administering metallic compounds which would be of great service. He might refer especially to the bismuth compounds, which in many diseases were very valuable, but which were very irritating to the stomach. The same with regard to arsenic, it could hardly be borne by the stomach in large doses, but was chiefly absorbed in the bowels. The ferric alginate might also prove of some service, as the big doses required in some cases of chlorosis were very irritating to the stomach, and could not be borne by some patients. The taste was not disagreeable, and if it could be diluted with wine without precipitations he thought it would be an agreeable medicine for children. The mercurous alginate also might be very useful in certain cases. He should like to know if the alginate compounds were as useful for coating pills as keratin, and also if the antimony alginate would keep stable without the development of fungi. He feared the preparation of bismuth was too weak to act as bismuth, but merely as a sedative.

Mr. STANFORD, in reply, said one of the difficulties about the introduction of the sodium alginate was its extraordinary viscosity, a 2 per cent. solution was an extremely viscous fluid. The alginate of magnesium was the only one which would be at all likely to be used for pill coating, and he did not know that he should recommend even that for that purpose. The bismuth preparation was only brought to show that another solution of that metal could be produced; no doubt it would be too weak to be of much use. The alginate of iron, however, had been thoroughly tried, and the origin of it was rather singular. There was a girl who had been discharged from the Glasgow Royal Infirmary as incurable, suffering from acute anæmia and gastric ulcer. She got the local doctor to give her this preparation, and much to the astonishment of the physician of the Infirmary, who had pronounced her incurable, within about a month she was perfectly cured. He believed they all kept perfectly well, and did not give rise to any growth.

A vote of thanks was passed to Mr. Stanford.

Two papers were next taken—

A New Constituent of Oil of Lemon

(printed on p. 196), by J. C. UMNEY and R. S. SWINTON, and

Notes on Concentrated Oil of Lemon

(printed on p. 161), by T. H. W. IDRIS, F.C.S., the latter paper being read by Mr. J. PARRY.

The PRESIDENT, in moving a vote of thanks to the authors, regretted that Mr. Idris was not present, as his paper was one of great interest.

Mr. E. M. HOLMES said he had listened with considerable interest to both these papers. As the result of experiments he had made with the citral and sugar, he had come to the conclusion that the citral could not be the actual flavouring of the lemon, but that there must be other essences which would add to the flavour. One of the specimens that Mr. Umney had submitted to him he certainly thought represented the exact flavour of lemon peel. He was curious to know what this was due to, and was glad to hear that there was another ingredient present in the lemon which modified its flavour. He was not quite sure that Mr. Umney had got out everything which represented the lemon. Most of their essential oils did not represent in any one ingredient the actual flavour of the drug itself. He hoped Mr. Umney would still further extend his observations, as he was sure there was a great deal more to be learnt as to the other ingredients present.

Mr. PARRY said no progress had been made in the chemistry of oil of lemon for some time. The whole attention of those interested in essential oils had been directed to the aldehyde constituents. In one of Schimmel's reports it was said that the question of lemon oil could not be regarded as being definitely solved until there was a reliable method of estimating the citral and oil of lemons, but Mr. Umney's paper had disproved this. It was so easy to add a little citral to oil of lemons that it was now the common practice.

A vote of thanks was then passed to the readers of the papers.

The next paper was by Mr. JOHN UMNEY on the

Commercial Varieties of Dill and their Essential Oils.

It is printed at page 176. The following discussion took place.

The PRESIDENT asked if the rotatory power of Indian and Japanese oils had been determined, as compared with that of oil from English grown seed.

Mr. HOLMES said botanists and horticulturists somewhat differed in their ideas as to whether two plants should be called distinct species or only varieties. The different varieties of the apple had very different flavours, and the amount of acidity and stringency varied considerably, but botanists classed them all as the same species. The Indian dill and English dill, although very similar in flavour, had been shown by Mr. Umney to differ in their chemical constituents, and as far as he could judge from seeds he had succeeded in growing, the fruit was more convex and narrower than the English, but apparently botanists did not consider these differences sufficient to warrant them as regarding it as a distinct species. It appeared, therefore, that two plants which only differed slightly might contain very different bodies, and might act in a very different way, and that the apiol was practically poisonous. This showed the importance of limiting the drugs used in the Pharmacopœia to particular forms so as to ensure uniformity both in constitution and strength. He should like to know whether the amount of apiol present in the Indian oils had been ascertained.

Mr. DRUCE said there was an instance in the Umbelliferae, *Cicuta virosa*, which in the south of England was considered a dangerous poison, but when grown in the neighbourhood of Edinburgh had no noxious property. At the same time botanists did not consider the plants different.

Mr. BRODIE said he remembered the late Professor Henry Roger, of Glasgow, making a remark to a similar effect, and mentioning the names of certain plants, though he had forgotten what they were. He said it was a well-known fact that many plants grown in England elaborated poisonous properties, which, when grown in Scotland, were harmless.

Mr. J. RUTHERFORD HILL said there was a paragraph some time ago in one of the medical journals stating that *Conium maculatum* grown in England was poisonous, but that when grown in the neighbourhood of Edinburgh was not so, and he had the curiosity to test the truth of the statement. The result was that fruits carefully collected in the neighbourhood of Edinburgh were found to contain a larger percentage of the alkaloid than similar fruits

collected in England. He took it, therefore, that all such statements required careful investigation.

Mr. MARTINDALE said he thought the statements referred to had gained currency on the authority of Professor Christison.

Mr. J. C. UMNEY, in reply, said the oil from Indian seed showed an optical rotation of 47.5° in a tube of 100 millimetres and Japanese 50.5° . The limit allowed by the Pharmacopœia was 70° . He could not say the amount of apiol present in the Indian and Japanese oil, but from 35 to 40 per cent. of crystalline apiol distilled over at 230° .

A vote of thanks was passed to Mr. Umney for his paper.

Mr. G. C. DRUCE read the concluding paper of the afternoon, on

The Salient Features of the Irish Flora

(which is printed at p. 200).

The PRESIDENT said the paper was full of information and would well repay perusal, but hardly called for any discussion, and he would therefore at once propose a vote of thanks to the author.

This was carried, and the Conference adjourned till the following morning.

The Conversazione at the Queen's College in the evening was a great success in every way, the various halls and galleries being artistically decorated for the occasion, and a capital programme of music and recitations provided.

SECOND DAY'S BUSINESS.

On Wednesday morning the Conference resumed its sittings at ten o'clock.

Mr. IDRIS's paper a

Note on Extract of Ginger,

which is printed at page 178, was read by Mr. NAYLOR.

Mr. J. C. UMNEY asked if the author gave figures showing the amount of extractive obtained by acetone and by strong alcohol respectively.

Mr. NAYLOR replied in the negative.

A vote of thanks was passed to Mr. Idris.

Dr. McWALTER's paper on

Materia Medica Animalis,

which is printed at page 155, was read in abstract by the author.

The PRESIDENT said Dr. McWalter had placed before the Conference a great many facts with regard to these animal extracts which were now becoming so very numerous, and which, no doubt, were believed to be useful in some cases. Some thought they were returning to those days when a great many animal substances were given internally in a manner which had been indicated as absurd; but there was no doubt the paper would be perused with great interest.

Mr. STANFORD said they were much indebted to Dr. McWalter for his elaborate paper, and he was quite sure it would be read in the Journal with very great profit. He would only remark that they knew very little about the chemistry of any of these bodies. He had attempted to show something about the thyroid gland, and there could be no doubt that whatever the active principle might be the iodine had something to do with it, and with that view Dr. McWalter seemed to agree. With regard to the paper that he (Mr. Stanford) read on the previous day, he should like to say now that thyroiodin was extracted from the glands after Dr. Hutcheson's colloid had been precipitated from them, which was a positive proof of what he had said on the previous day.

A vote of thanks was passed to the author.

Mr. E. SAVILLE PECK read the next paper entitled

Notes on Ferrum Redactum, B.P., 1898,

which is printed at p. 159.

Mr. MARTINDALE spoke of the difficulty of avoiding the presence of arsenic and sulphur in these preparations, and referred to the imperfection in respect of the new B.P. test.

Dr. SIEBOLD and Mr. J. C. UMNEY having referred in terms of commendation to the iodine test for ferrum redactum, Mr. Howard mentioned Marsh's test.

Mr. PECK having briefly replied, a vote of thanks was passed.

Dr. JOWETT read a paper on

The Characters and Methods of Assay of the Official Hypophosphites,

which is printed at p. 171, a brief but interesting discussion

followed, in which Mr. NAYLOR, Mr. BIRD, and Mr. LUNAN took part.

A short paper by Messrs. DAVID and D. LLOYD HOWARD on the
Basicity of Quinine.

which is printed at p. 154, was then read by Mr. D. LLOYD HOWARD.

Mr. BRODIE suggested that it would be very useful if the scattered information could be codified, and a vote of thanks was passed to the author.

Dr. JOWETT read a paper on

Note on the Mydriatic Alkaloids,

which is printed at p. 195.

Mr. MARTINDALE having made a few remarks on the paper, Mr. SIEBOLD offered some observations dealing chiefly with the paper read last year by Dr. Sharpe, and Dr. Jowett did not find it necessary to reply.

The following papers were read:—

Pharmacists and the Pharmacopœia,

by Mr. P. MACEWAN, which is printed at p. 177.

The Galenical Pharmacy of the 1898 Pharmacopœia, by Mr. F. C. J. BIRD, which is printed at p. 162.

The Galenicals of the New Pharmacopœia, by Mr. H. W. GADD, which is printed at p. 178.

The Chemistry of the 1898 B.P.,

by Mr. P. KELLY, which is printed at p. 180.

The Pharmacopœia Chemically Considered,

by Mr. A. L. DORAN, which is printed at p. 203, after which Mr. G. C. DRUCE read a paper on

The Nomenclature of Certain Drugs of the Pharmacopœia,

which is printed at page 202, the discussion upon them being adjourned until after the adjournment for luncheon. Whilst the members were assembling a short paper on

Lime Water,

by Mr. E. J. EVANS, was read (p. 204).

A vote of thanks was accorded to the author.

A paper on

The Amount of Carbonic Dioxide Available in the Official Granular Effervescent Preparations,

by Mr. C. S. DYER, which is printed at p. 181, was also read.

Mr. MARTINDALE suggested that the proportion of citric to tartaric acid should be varied to suit the various compounds in which it was used.

The PRESIDENT added a few words, and then after passing a vote of thanks, the Conference proceeded to discuss the paper dealing with the new Pharmacopœia.

Mr. ATKINS commenced by expressing the opinion that pharmacists ought to occupy a more important, in fact, a statutory position with regard to the compilation of the Pharmacopœia. He agreed in great part, but not entirely with, Mr. MacEwan, and thought the Pharmaceutical Society rather than the Conference should be the body entrusted with this duty.

A long and interesting discussion on points raised by the various papers ensued, of which a full report will appear next week. Messrs. J. C. Umney, Howard, Wardleworth, Wells, Clague, Farr, Rutherford Hill, Cowley, Martindale, and the President took part in this discussion, and a few words were added in reply by Mr. Bird.

Mr. MACEWAN hoped the Executive Committee would seriously consider the proposals which had been put forward, and that some definite course of action would be put before the Conference next year.

Mr. GORDON SHARPE's paper on

Albumin and Some Types of Proteid Digestion,

which is printed on p. 197, was taken as read.

PRESENTATION FROM THE BELL AND HILLS FUND.

The PRESIDENT, in making the usual presentation of books, said it was the custom to present the books to the local association of the town in which the Conference met, but as there was no such

body at present existing in Belfast, the authorities of the public library had been good enough, through the influence of the Lord Mayor, to accept the books in custody pending the formation of the association, which, it was hoped, would be the outcome of the visit of the Conference.

ELECTION OF THE FORMULARY COMMITTEE.

The PRESIDENT announced that letters had been received from Mr. T. B. Groves and Mr. R. Reynolds, resigning their position as members of the Formulary Committee. Although these gentlemen were resigning, their sympathies would always be with the work of the Committee.

Mr. F. R. BRANSON moved the election of the following gentlemen as the Formulary Committee for the ensuing year:—

Formulary Committee.—W. Martindale, F.C.S. (Chairman); W. A. H. Naylor, F.I.C., F.C.S. (Secretary); A. C. Abraham, F.I.C., F.C.S.; H. G. Greenish, F.I.C.; F. C. J. Bird; T. Maben, Ph.C.; N. H. Martin, F.L.S., F.R.M.S.; F. Ransom, F.C.S.; Harold Wilson; C. Symes, Ph.D.; R. Wright, Ph.C., F.C.S.

Mr. T. MALTBY CLAGUE seconded the motion, which was at once carried.

PLACE OF MEETING IN 1899.

Mr. C. PARK (Plymouth) invited the Conference to visit Plymouth next year. It was over twenty years since the Conference honoured the town. There were plenty of facilities of visiting Plymouth by water for those who cared to avail themselves of them. He wished to thank the Brighton chemists for the way in which they framed their prior invitation.

Mr. J. D. TURNEY, in seconding the motion, said a hearty West Country welcome would await the Conference at Plymouth, a centre where he was sure its visit would produce very good results on the whole district. Plymouth was not a wealthy city like Belfast; but the natural beauties of the neighbourhood were very varied, and he was sure would be appreciated.

Mr. SAVAGE (Brighton) said circumstances had convinced the chemists of Brighton that Plymouth had a prior claim on this occasion, and that a visit should be paid to Brighton on a future occasion. Possibly a day's visit could be arranged in 1900, when he believed the Conference would meet in London. He therefore moved that the Conference meet next year in Plymouth.

Mr. BIRD seconded the motion, which was unanimously agreed to.

ELECTION OF OFFICERS.

The following were unanimously elected:—

President.—J. C. C. Payne, J.P., Belfast.

Vice-Presidents.—Walter Hills, F.C.S., London; R. J. Downes, Dublin; John Moss, F.I.C., F.C.S., London; C. J. Park, Plymouth.

Treasurer.—J. C. Umney, F.C.S., London.

Hon. General Secretaries.—W. A. H. Naylor, F.I.C., F.C.S., London; F. Ransom, F.C.S., Hitchin.

Hon. Local Secretary.—Davy Turney, Plymouth.

Other Members of the Executive Committee.—Leo Atkinson, London; G. Breeze, J.P., Devonport; F. C. J. Bird, London; H. Collier, London; G. C. Druce, M.A., F.L.S., Oxford; Professor Greenish, F.I.C., London; R. W. McKnight, Belfast; Edmund White, B.Sc., London; R. Wright, F.C.S., Buxton.

Auditors.—D. W. Elliot, Belfast; F. Maitland, Stonehouse, Plymouth.

VOTES OF THANKS.

Mr. LAIDLAW EWING moved a hearty vote of thanks to the President of the Queen's College for the use of the building, which was seconded by Mr. WARDLEWORTH, and carried unanimously.

Dr. FIELDEN briefly acknowledged the vote, saying it had given the authorities great pleasure to be of service to the Conference.

Mr. J. C. C. PAYNE, as Chairman of the Ulster Committee, had much pleasure, on behalf of the pharmaceutical chemists and chemists and druggists of the North of Ireland, in accepting the present of books. At present neither body had a home of their own, but through the intervention of Sir Jas. Haslett, M.P., Mr. Elliott (Librarian of the Public Library) had kindly undertaken to take charge of them for the present.

Mr. ELLIOTT confirmed this statement, and mentioned the hours when the books would be accessible.

Mr. MARTINDALE moved a vote of thanks to Mr. Moss for his services as Treasurer to the Conference for the last five years, with an expression of regret at his resignation.

Mr. JOHN C. UMNEY seconded the motion, which was at once carried by acclamation, and briefly responded to by Mr. Moss.

Mr. ATKINS moved "That the cordial thanks of the non-resident members of the Conference be accorded to the local Committee, and especially to Mr. J. C. C. Payne (the Chairman), to Mr. R. W. McKnight and Mr. W. J. Rankin (the Honorary Secretaries), to Dr. Fielden and Mr. Gibson (the Treasurer), for the very success-

ful manner in which the various arrangements connected with the Belfast meeting have been carried out."

Mr. DRUCE seconded the motion in his usual felicitous manner, and it was at once carried unanimously.

Mr. J. C. C. PAYNE briefly acknowledged the vote, and alluded to the honour just done him by his election as President, in which office he would endeavour to emulate the successful efforts of his predecessors.

Mr. MCKNIGHT, in response to loud calls, also responded, and Mr. GIBSON added a few words of thanks. He was especially proud to find that so many ladies had attended the meeting.

Mr. STANFORD then moved a vote of thanks to the President for the able and courteous manner in which he had conducted the business of the meeting. He had presided over two record meetings, one in Scotland and one in Ireland, and had given immense satisfaction in both cases.

Mr. W. F. WELLS had great pleasure in seconding the vote, and thought the words "able and courteous" were hardly strong enough to meet the case.

The motion was put by Mr. ATKINS as senior Vice-President, who added a few words in support, and was carried by acclamation.

The PRESIDENT, in responding, acknowledged the help he had received from the Executive Committee, the Hon. Secretaries, and the members generally, and expressed his great satisfaction at finding the Conference still retaining so much vigour and enthusiasm. He concluded by moving a hearty vote of thanks to Mr. Naylor and Mr. Ransom, the Hon. Secretaries, to whose efforts the success of the meetings was mainly due.

Mr. MARTINDALE seconded the motion, which was carried unanimously, and briefly acknowledged by Mr. NAYLOR and Mr. RANSOM, which concluded the proceedings.

A garden party given by the Lord Mayor of Belfast and the Lady Mayoress, which took place immediately on the conclusion of the business, was eminently successful, the weather being all that could be desired.

The excursion to Garron Tower, Glenariff, and Parkmore took place on Thursday, and Friday was devoted to sight-seeing generally.

PHARMACEUTICAL SOCIETY OF IRELAND.

The monthly meeting of the Council was held on Wednesday, the 3rd inst., at 67, Lower Mount Street, Dublin. The PRESIDENT, Mr. R. J. Downes, occupied the chair, and the other members of the Council present were the Vice-President (Mr. Beggs), and Messrs. Wells, Bernard, Kelly, Professor Tichborne, Porter, Ryan, Hayes, and Dr. Walsh.—The PRESIDENT said that since they last met they had had as providential a deliverance as the British nation had from the Spanish Armada. On the last occasion they had before them the Poisonous Substances Bill, introduced by the Government, and they directed that steps should be taken to have circulars issued to Members of Parliament and to their licentiates and others calling on them to give the strongest opposition to the measure. That was done, and after the circulars had been printed the Government announced that they were not going to proceed with the Bill. He therefore thought that it would be useless to go to any further expense in the matter, because what would be done would be out of date by the time that the new Bill, which he was informed the Government intended to introduce next Session would come on. They also anticipated the action of the Lord Chancellor of England in connection with his proposed amendment of the English Pharmacy Acts Amendment Bill. He (the President) thought there would be considerable difficulty in making the proposed clause applicable to the purpose which the Society required, because he did not see how an amendment of the English Act could be extended to Ireland. He accordingly wrote to the Lord Chancellor of England, pointing out those difficulties, and he had no doubt that that representation weighed with him, for in his address he mentioned that one of the difficulties was the extension of the clause to Ireland. The English Society also objected to having the clause put into their Bill, particularly as it was one that did not suit their purposes. He (the President) was astonished when he saw the draft of the clause. It gave absolute authority to the limited companies to carry on business; and one of the difficulties that the Lord Chancellor saw was that as he had drafted the clause—which was simply an adoption of what had been improperly called the "widows clause"—it did not provide for the placing of the companies upon the Society's register. Altogether it appeared to him that the Lord Chancellor completely misjudged what he

intended to do or thought could be done by the clause which he proposed. It was a clause that would have given the Society completely away, and he suspected that there was an earnest desire on the Lord Chancellor's part to get pharmacy out of the way, treating it as a trade, so that he could deal with the claims of the medical profession afterwards, for if once the pharmacists were tied and bound, they could not interfere with the privileges extended to the medical profession. He felt bound to notice an article contained in the *Chemist and Druggist*, which was the organ of the Society, and to dissociate the Council from the remarks contained in it. He did not approve of the remarks in the article as regarded the English Society or the tone of them. He entirely dissented—and he thought the Council would dissent—from the views of the writer. That article said: "We suspected last week, and it is now admitted, that the most influential objection to the Lord Chancellor's proposal to amend the Pharmacy Act by a clause to provide against its infringement by companies came from the Council of the Pharmaceutical Society." He (the President) was certainly pleased to know that the English Society did use its influence to oppose the clause. Then the writer said, referring to particular Acts: "It means that the Council and their intimate friends were so eager to get their paltry little Bill passed that, rather than risk it, they preferred to reject the assistance which the Lord Chancellor and Lord Herschell spontaneously offered them towards the accomplishment of what has always been professed as the ultimate purpose of the measure." Whatever the Lord Chancellor proposed to do, he did not see that his clause would have compassed what the Society wanted. "But could not the representatives of pharmacy have laid such arguments as this before the Lord Chancellor? He clearly enough withdrew his amendment with reluctance; his warmest support, we gather, came from Ireland." Now he (the President) did not know what was the authority for that statement. Certainly, as far as that Society was concerned, whilst they wanted their own clause they were not supporting the Lord Chancellor in the amendment he was proposing, and of which they had no cognisance.—Mr. BERNARD: In an Act which did not apply to us.—The PRESIDENT said the article went on: "And he was undoubtedly willing to do what reasonably could be done to secure for pharmacy its rightful position. We are afraid it was impossible to ask at this date that companies should not be allowed to own chemists' and druggists' businesses. Twenty years ago that could have been pressed with much more chance of success than now. But it might still have been feasible to exact that no unqualified person should be entitled to be a director of a company formed for the object of carrying on a pharmaceutical business. If for any reason which does not occur to us so much seemed impracticable, it might at least have been required that the managing director of any such company should be qualified. His qualification is of infinitely greater importance to the public than is that of the assistant who merely carries out his commands. Either of these provisions would go a long way towards remedying the grievance of which we complain. It is likely enough that the Lord Chancellor would have adopted one such amendment of his clause, and it is far from certain that the Houses of Parliament would have rejected it. At all events, the opportunity was offered to test the opinion of our legislators, and it has been declined by the Pharmaceutical Society of Great Britain." His (the President's) contention was that that was giving away the whole question. The Society's contention was that the proprietor or proprietors of establishments should be qualified men. That was the law at the present time, and it was at that point that they wanted to keep it. Qualified directors, or even a qualified managing director, would not be sufficient to protect the public; but worse, it would be a giving away of their position altogether. The article then said:—"The pharmaceutical associations of the country gave loyal and invaluable aid to the Pharmaceutical Society in the matter of this amending Bill. But the large majority of the members voted for it on the explicit or implied assurance that it was to pave the way for some legislation that would be of substantial value. If they maintain their enthusiasm in the face of this betrayal—for the conduct of the leaders deserves to be so designated—they are simply impervious as to facts." As President of the Society—or rather as an individual—he (Mr. Downes) protested *in toto* against that article, and he asked the Council to dissociate itself from it; because it appeared in the organ of the Society and the Council would be credited with what was said if it did not do so. The position was that unqualified persons kept open shop, and that when they were meddled with they protected them-

selves by going under the cover of the Companies Acts. The amendment proposed by the Lord Chancellor would have simply amounted to providing that if those persons registered themselves they would have full qualification and a full right to carry on a business for the carrying on of which individually they would have been prosecuted. If that was his intention there was not the least use in meddling in the matter. The Council's contention was based on the fact that the poison laws of the kingdom from first to last had recognised it as obligatory that the proprietors of establishments selling poisons should be qualified persons; and if they departed one inch from that they gave away their whole ground.—Mr. WELLS said he was very pleased indeed that the President had acted as he had. He (Mr. Wells) was very much astonished when he read the article which had been referred to; and he should be very sorry if it were not replied to, for it undoubtedly represented the Council as in favour of what the Lord Chancellor wanted to do. He should like the licentiates to know that they were not in favour of it; they would be traitors if they were. What they wanted to get was a very different thing, and he quite agreed with the President that the object of the Lord Chancellor was to get them provided for so as to satisfy certain Members of Parliament and others, and then to do what he would perhaps have to do, whether he liked it or not, namely, to give the medical profession what they were asking for.—The PRESIDENT: And which we are asking.—Mr. WELLS: And which the President has been the means of starting. It was all due to his action, and when the medical bodies should take the matter up they would perhaps have some weight with Parliament. If a clause should be put in for them it would cover the Society also. At all events it was due to their licentiates that the Council should dissociate itself from any sympathy with such an amendment. If such law should be passed, he, for one, would not bother himself about the carrying out of pharmacy law any longer. It would be a dead letter and a dead letter let it be. But although the matter had dropped for the present, they ought to keep working it up. The Council should induce the licentiates to speak to their Members of Parliament on the subject. The article said that it was not likely they would get the protection they were asking for so late in the nineteenth century. But were not bricklayers and masons from one end of the country to the other getting the protection that they (the Council) were asking? He read in a police report that a workman was thrown out of employment because he would not join a trades union; and they were told by high judges in the land that that was legal, and that people were within their rights in coercing workmen to join unions. If barristers and tradesmen were to be protected, the Society should be protected. It would be more for the benefit of the public that they should receive protection than in the other cases.—VICE-PRESIDENT: Has he not promised to bring in a fresh Bill? The PRESIDENT: He has promised to bring in a Bill to cover the whole ground.—Mr. WELLS: In the meanwhile we ought to work up all our members.—Mr. KELLY said they should give a flat denial to the article in the *Chemist and Druggist*. Honesty in high places seemed now a rare thing. Having regard to the education that was necessary to qualify a man even to sell poisons, it was a very wrong thing on the part of the organ of the Society to put words into their mouths which were certainly the very opposite to what they wished. They were too quiet in this matter, and in every other, and they must make themselves felt if they wanted to get redress. If they were to be made to register men who had never spent an hour at the business so as to enable them to do what, as individuals, they could not do, it would amount to a lack of honesty in high places.—The subject then dropped.—A letter from the Decimal Association enclosed a form of petition to the Government in favour of the adoption of metric weights and measures in this country.—A letter from the Lord Chancellor of England acknowledged the receipt of a letter which had been addressed to him by the President, protesting against his Lordship's lately proposed amendment of the English Pharmacy Bill.—The REGISTRAR read a letter which has already been published.—The VICE-PRESIDENT: I think we ought to approve of the President's letter.—On the motion of the VICE-PRESIDENT, seconded by Mr. PORTER, the letter was approved.—A letter from Dr. A. B. Griffiths, Principal of the Brixton School of Chemistry and Pharmacy, applied that certificates of attendance at the chemistry, botany, and materia medica lectures of that school should be recognised.—Mr. HAYES: Have we not an order on the books that for the present we will not increase the number

of schools whose certificates we recognise? I think we had better adhere to it.—A donation was received from the Pharmacy Board of Victoria and a copy of their report for 1897, and thanks were voted to the donors.—The PRESIDENT moved, "That a special meeting of the licentiates of the Society be called in Belfast during the Conference week to protest against the amendment proposed by the Lord Chancellor in connection with the English Pharmacy Bill, and also to form a Parliamentary Committee to raise a special fund and to co-operate with the Council in promoting the interests of the Society in Parliament." He brought forward this motion in order that its merits might be discussed. It occurred to him that they would be able to obtain a larger and more representative meeting of members of the Society during the Conference week in Belfast than they could possibly get on any other occasion; and that it would be advisable to have such a meeting in order to voice their protest. It would include members from all parts of the country. He had written to Mr. Montgomery as to the time and place for the meeting, but had not yet received a reply from him.—Professor TICHBORNE: Would the meeting be in connection with the Conference?—The PRESIDENT: Certainly not. It would be a meeting of our own Society. I would not mix it up with the Conference at all.—Mr. WELLS remarked that it had been suggested at more than one Conference that a day should be set apart for pharmaceutical politics, but the idea had never been carried out. The difficulty he saw about this proposal was that the time would be so fully occupied with the business of the Conference that gentlemen would not be able to find time for the meeting. No doubt the Society had a fair number of members in Belfast. As to the proposal of a fund, he would prefer not to look for outside help. They would not find it so easy to get up a guarantee fund. If people would not give £1 a year for membership of the Society they would not give it to a guarantee fund.—Mr. BERNARD: It is a case of never venture never win. We must do something. Another advantage will be that you will have a large number of representatives of the English press at Belfast.—Professor TICHBORNE seconded the motion of the President, which was altered so as to read "that a special meeting may be called in Belfast," and by adding words at the end leaving the arrangements for the holding of such a meeting in the hands of the Vice-President.—In that form it was unanimously agreed to.—The election of an Examiner in Pharmaceutical and General Chemistry for the Licence was postponed until the next meeting.—Other business was not disposed of owing to the retirement of members not leaving a quorum.

OBITUARY.

PARKES.—On August 5, at Stoke Newington, John Prior Parkes, Pharmaceutical Chemist and Life Member of the Pharmaceutical Society. Mr. Parkes had been a loyal supporter of the Society's work for more than forty years.

SEELY.—On August 4, Herbert William Seely, Chemist and Druggist, Halifax. Aged 35. Mr. Seely was an Associate of the Pharmaceutical Society, a native of Lincoln, and the Hon. Secretary of the Halifax and District Chemists' Association. He was well known and a general favourite in Halifax, where he had been in business about nine years. His death was totally unexpected, he having been called, after business hours, to his shop to make up a preparation, and was discovered the next morning lying dead behind the dispensing counter, death being due to heart disease. Much sympathy is expressed for his widow and young son.

CANT.—On July 13, John Reymer Cant, Chemist and Druggist, Cardiff. Aged 54.

STEPHENS.—On July 17, John Harris Stephens, Chemist and Druggist, Plymouth. Aged 85.

SNAITH.—On July 31, Fishy Snaithe, Chemist and Druggist, Boston. Aged 78.

HILL.—On August 2, Richard Christopher Hill, Chemist and Druggist, late of Plymouth. Aged 60.

JAMES.—On August 4, Joshua James, Chemist and Druggist, Carmarthen.

TUCKER.—On August 5, Henry Symons Tucker, Chemist and Druggist, Birmingham. Aged 73.

EXTRACTS FROM CONSULAR REPORTS.

THE BORAX INDUSTRY OF PERU appears to be assuming some importance, the export during 1897 exceeding that of 1896 by some 5114 tons, value £22,450, the totals being 7350 tons, value £36,970, in 1896 and 12,464 tons, valued at £62,420, in 1897. The deposits are found some twenty miles in the interior from Arequipa, the supply of borax apparently being inexhaustible.

THE RUTHLESS DESTRUCTION OF VALUABLE TREES, such as the cinchona and gum-trees, and of numberless medicinal plants in Peru, is the subject of a pamphlet published by Mr. Billingham, the first Vice-president of the Republic. He desires that the present system should be checked, but the difficulty of controlling the gatherers, who penetrate into the forests, where supervision is almost impossible, is in itself an insuperable obstacle. Owing to the destruction of the trees on accessible lands, the export of cinchona from Peru and neighbouring Republics, according to Mr. St. John, is now insignificant, but he thinks the cultivation of the bark trees could still be resorted to with every prospect of success in accessible regions.

AN "EXPORT AND COLONIAL ACADEMY" is about to be established in Vienna, which is to be solely devoted to the education of young men destined to enter upon mercantile careers. According to competent authorities, the younger generation of Austrians do not aspire to commercial pursuits, preferring the army or civil service, and in view of this circumstance it is proposed to found the institution referred to. The project has official support as well as that of many prominent merchants and manufacturers. In addition to foreign languages, the curriculum will include a course of lectures on the commercial conditions prevailing at home and abroad, and will embrace every subject likely to be of future use to a business man. It is anticipated that all arrangements will be completed in the autumn of this year, and that studies will then commence.

THE EXPORT OF OTTO OF ROSES from Sofia, Bulgaria, during 1897 amounted to 3192 kilos, value at £71,278. Of this quantity France took 1151 kilos, value £25,683; Great Britain came next with 686 kilos (£15,412), Turkey taking 680 kilos (£15,155), while Germany received 583 kilos, valued at £12,992. Of the remaining 92 kilos no mention is made in the report as to its destination. Otto of roses forms an important product of Bulgarian agricultural industry, the district of Kezanlık being chiefly interested in the trade. The manufacture of wine is increasing in the country, and the cultivation of the vine is carried on in most districts, and promises to become a more important branch of export trade from year to year.

THE AMMONIA-SODA FACTORY at Lukavica (Austria-Hungary), Consul-General Freeman reports, has declared a dividend at the rate of 11 per cent.

THE FIRST AEROLITE which has been found in Bosnia (Austria-Hungary), according to a recent report, fell shortly before noon on August 1, of last year, at Zavid, near Rozanj in the district of Zvornik. Eye-witnesses of the fall of the meteorolite stated that it was accompanied by a noise like thunder lasting several minutes and audible a long way off. It left a fiery streak behind, which, a short way above the horizon divided in two, and above this streak or tail was a thick cloud of smoke. It buried itself a yard deep in the ground. It was broken in several pieces by the fall, but these have been joined together again, and the meteorolite, measuring 55 by 35 by 28 centims, is now in the museum of the town.

A **CHINESE SCHOOL** for the teaching of English has been established at Wuchow, with Chinese teachers from Canton. Boys are taught during the day, and there are evening classes for men.

MOXA SMELLS STRONGLY OF CAMPHOR, and is reported to be frequently described as crude camphor. It is a greyish-white powder, and is not derived from *Cinnamomum camphora*, Fr. Nees, but is distilled from *Blumea balsamifera*, D.C., the centres of export being Nan-ning and Po-sé. It is a valuable product of Kwangsi, costing as much as 200 taels a picul (133½ lbs.), and is used in medicine, perfumery, and in Hong Kong it is stated to be converted into camphor oil.

PARLIAMENTARY NOTES.

THE PETROLEUM BILL OF MR. URE, the high flash-point advocate and member for Linlithgow, is a very short and direct measure. Its sole object is to carry out the recommendations of the majority of the Select Committee in respect to raising the "deadly" 73° to the absolutely innocuous minimum of 100°. The change is proposed to be effected by repealing sections 2 and 6 of the Petroleum Act, 1879, and the second Schedule to that Act. The effect of such repeal, as anyone consulting the Society's Calendar may discover, will be to restore the *statu quo ante* 1879; that is to say, the original Act of 1871 with its 100° test will become re-enacted, though with an important difference. In 1871 the test was the inaccurate, or at any rate scarcely reliable, "open" test, but if Mr. Ure's Bill should pass, the 1879 "close" or Abel test will still apply to the minimum flash-point of 100° specified in the 1871 Act. Thus the word petroleum would receive a wider meaning at Mr. Ure's hands, for it would cover all oils flashing at a lower temperature than 100° Fahrenheit. Apparently, the honourable promoter of the Bill and his backers (all members of the triumphant party of the Select Committee) deem the Petroleum Acts, apart from the flash-point, to be legal perfections, for they do not suggest a single alteration. Yet it is not so long ago that the late Sir V. Majendie revealed to the Committee strong evidence of the inadequacy of the law, and the difficulties in the way of efficiently administering it.

THE PRIVY COUNCIL OFFICE was somewhat fortunate on Monday in escaping the criticism of the economical Mr. Caldwell and the wrathful Mr. Bayley. Supply is the delight of parliamentary wind-bags, for it is possible to drag any subject into the Committee proceedings; in fact a number of legislators who have been unable to deliver their speeches in the House are always eager to seize such an opportunity of unloading their minds as Committee of Supply affords. The natural result is that the proceedings are unduly prolonged over minor items, and eventually the important votes have to be rushed through under pressure of the closure. This is what happened on Monday. After unmeaning growlings about muzzles, Cyprus, swine fever, and vivisection, the debate was compulsorily closed, and such important votes as the Privy Council, Board of Trade, together with the items under the Companies Winding-up Act, 1890, on all of which interesting and possibly useful discussion might have been raised, were carried through in silence.

THE ROYAL SOCIETY was somewhat roughly handled by the economists under Dr. Clark when the vote for scientific investigations came up on Friday, the 5th. It seems that £15,300 is granted to the Royal Society for meteorological purposes, and that the Government having handed over the money do not care two straws how it is spent. Now, Dr. Clark does care, and he says he has discovered that the Committee of the Society commence their meteorological observations by voting £1000 to themselves for services and another £800 to one of their number for acting as Secretary. This seems a grave charge against the Meteorological Council and the Royal Society, but it must be taken with large reservations. Dr. Clark does not mean to say that this public grant or any portion of it is diverted to private uses, but he simply desires to convey that Scotland does not get enough of the grant and cannot carry on its Ben Nevis observatory—a valuable work—owing to lack of support from the Meteorological Council. He achieved his object in the end, for Mr. Hanbury promised to bring pressure to bear on the distributors of the grant, with a view to screwing out more bawbees for Scotch observatories. Mr. Pirie will ask on the 11th inst. (just as we go to press) whether the pressure promised has been exerted, and with what result.

GENERAL LAURIE (Pembroke and Haverfordwest) has given notice that when the University Degrees Bill comes on for second reading (which will not be this year) he will move its rejection on the ground that it discriminates adversely against universities outside the United Kingdom, and is an implied insult to the Universities of British Colonies. Mr. Sidebotham, the introducer of the Bill, evidently overlooked Imperial Federation as a factor in Imperial politics.

LETTERS TO THE EDITOR.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London, W.C., and not in any case to individuals supposed to be connected with the Editorial Staff no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ELEGANT PHARMACY?

Sir,—Having regard to the growing custom of supplying pills of the P. B. and others ornamented with all the colours of the solar spectrum, especially at the cheap and nasty drug stores where they do not make their own pills, is it not possible some watchful analyst may find the presence of some ten per cent. of extraneous and probably hurtful matter an adulteration. The P. B. sanctions no coating whatever.

London, July 27, 1898.

E. WARRELL.

COMPANY PHARMACY.

Sir,—The decision by Judge Shortt at Grimsby County Court, as reported in your issue of the 6th inst., whereby the defendant was fined £5 for assuming the title "manufacturing chemist," is one of considerable importance to chemists, as it indicates legal opinion regarding the unlawful use of titles by wholesale or retail dealers. One would think that one or two more such decisions would tend to clear the country of pseudo-chemists and all the so-called "manufacturing" and "cash chemists," and restrict the use of such titles to those who have earned them. Now the difficulty has hitherto been with "companies;" they shelter themselves under the plural number, and having adopted the motto "Union is strength" they limit their liability by incorporation. By appropriating all that is worth having in the Pharmacy Act, these companies have induced the popular notion that they are bodies of qualified chemists that have broken away from the restraints of traditional policy and by dint of business acuteness have gained for themselves in many cases the cream of the pharmaceutical trade. It is unfortunate, sir, as you have already pointed out, that so many qualified men are ready to sell themselves as slaves to their enemies. "Companyism" prefers to be free from the trammels of pharmaceutical education, directing its concerns from without with a zeal and persistency worthy of a worthier cause. But surely recent events in Parliament and the courts of law are but the harbingers of the dawn of a better day. According to Section 15 of the Pharmacy Act I submit that the Pharmaceutical Society has two causes of complaint against companies who seek to evade the Pharmacy Act, for taking or using in any way the title "chemist." Section 15 reads thus: "Any person who shall . . . take, use, or exhibit the name or title of chemist and druggist or chemist or druggist, not being a duly registered . . . chemist and druggist . . . shall be liable to a penalty of £5 . . . etc. Judges have ever experienced a difficulty in reading "person" into corporation, but the historic decisions of some ten years ago applied to the conducting of a dispensing business by companies, and not to the use of the title "chemist," etc., and the first ground of complaint which the Society has is against each individual of the "company" who is personally interested, and therefore personally responsible, for using a title which Section 15 declares to be a personal one denied to unregistered persons. The second ground of complaint is against "companies" as such. According to former decisions, not being a "person," these companies cannot use a personal title. A limited company may have limitations in monetary matters, but it is responsible for using a title which Section 15 expressly says does not belong to it. Until the Act is satisfactorily amended it is for chemists to protest against the dishonest use of titles indicating qualifications which are not possessed.

Edinburgh, August 8, 1898.

W. S. GLASS.

CHEMISTS AND THE SALE OF FOOD AND DRUGS ACT.

Sir,—The case reported in your issue of 23rd instant about a chemist being fined a penalty of 20s. and 42s. costs for selling lime water deficient in lime is just one of those cases which serve to hold up to contempt the Sale of Food and Drugs Act. That Act was passed expressly to protect the consumer being supplied with food and drugs that in any way injure him. Now, out of the one in ten thousand persons who use lime water, how much

injury would a deficiency of lime injure the partaker? Moreover, I should like to know whether lime water is a drug or a food? Speaking from experience in my own district, the Act for guarding the public against fraud is a dead letter. I have no hesitation in saying that it is next to impossible to buy pure butter or pure lard in this district, to say nothing about fine oatmeal being adulterated with haricot beans, lentils, and pepper with cayenne ("hot dust"), bread with potato parings, flour with bone meal, tea consisting of leaves apparently gathered up from wayside hedges, and a host of other impurities in the way of food-stuffs. Now, all such articles as these are consumed in quantities a thousand times more than lime water, milk of sulphur, or any such articles. If the inspectors under the Act would make frequent and periodical visits to these places and take samples of such articles as those mentioned, I believe Erdington would not only be a healthier place, and thereby require fewer doctors, but the inhabitants would be plumper and not so cadaverous featured, for apparently the majority of them look as if they had no flesh on their bones, due chiefly to the inferior quality of food-stuffs sold in the district. Of course, while the law is satisfied by the public analyst performing a prescribed number of analyses during the year, it would not be human to suppose he would willingly select those subjects for analysis which give him most trouble or are difficult to detect. Consequently the inspector under the Act confines his attentions to only such articles as can be easily and readily analysed, and which a sure conviction can be obtained. I think it a disgrace to modern civilisation that the informer should share the fines obtained from a conviction. Now what is wanted to make this Act effectual is a more frequent inspection of every district or a systematic one fortnightly, weekly, or monthly, and every class of food-stuff should be analysed, not only from one shop but from every one in each district. Then, and then only, would the Act give protection to the consumer, which it does not do now. A 40s. fine even in a twelvemonth for a man who sells 4*l.* margarine as 1*s.* butter is a mere trifle and not likely to cause him to forego such a lucrative sale; while as for lard, flour, and the other articles named above they seem to be left severely alone by the inspector. The Board School inspector performs his perambulations daily, and why should not the inspectors under the Sale of Food and Drugs Act be also a daily visitor to every district? Of course, such a procedure would necessitate a large increase in the inspectorial staff, but better that than that the Act should remain a mere farce, which it is now. Can any reader point out any decrease in the amount of adulterated food since the passing of the Act? If so I should like to know of it.

Erdington, Birmingham,
July 25, 1898.

H. C. STANDAGE.

CAMPHOR IN PILLS

Sir.—With reference to Mr. F. C. Barton's letter, *re* quinine, belladonna and camphor pills (of July 30), I have found the following method answer perfectly. Make into a soft mass the finely powdered camphor and extract belladonna by means of glycerin, mucilage of gum acacia and alcohol, 90 per cent. (equal parts), then add the quinine, also powdered finely, and the result will be a mass easily rolled out and forming satisfactory pills. It is useless attempting to mix powdered camphor and quinine, as on rubbing together it agglomerates at once, rendering it unworkable. I may also remark that the excipient above referred to will be found exceedingly useful for almost any pill mass, or at any rate for a large number. So useful and such excellent results have I obtained with it that I have named it the "universal excipient."

4, St. Stephen's Road, Lewisham, S.E.
August 1, 1898.

GRAHAM BOTT.

Sir,—With regard to Mr. Barton's letter *re* camphor in pills, I should like to mention that I have frequently dispensed similar pills—using glycerin of tragacanth—which turned out a good pill without materially affecting their size.

London, August 3, 1898.

A. A. W. (139/5.)

AQUA SPIRÆA ULMARIÆ.

Sir,—Twenty-four years ago to-day—being Bank Holiday, and having a little more leisure—I picked in the morning a good handful of the flowers of meadow-sweet, and later in the day distilled them in a glass retort. The distillate had a strong smell resembling that of the flowers. From curiosity I have kept this ever since, and to-day it is just as fresh as when first distilled, clear and bright, with the odour unaltered, which, of course, would

not be the case with water distilled from the flowers of elder or rose. Can anyone tell if aqua spiræa ulmarie has ever been put to any use?

High Street, Odiham, August 3, 1898.

G. WOODMAN.

THE ATTACK ON VESTED INTERESTS.

Sir,—In a letter recently addressed to the Editor of the *Daily Mail*, but which did not appear, I referred to some correspondence lately started, under the above heading, and asked, Was ever a cry more groundless? What are the "vested interests" which are assailed? They amount to nothing more than the claim of a right to do, without qualification, what the law says may only be done by those who hold the qualification required by law. To quote the address of Mr. Godden, the President of the Incorporated Law Society, at Sheffield, last year: "When the Crown surrendered its prerogative and Parliament gave up its control over the creation of corporations, individuals were allowed to incorporate themselves at pleasure for any lawful purpose." That is the limit of their freedom; but, unfortunately, no method was provided, nor has any yet been provided, by which persons incorporated for an unlawful purpose can be proceeded against. Every care has been to protect the members and creditors of the company; but it never was intended that it should be competent for seven unqualified persons to do what six unqualified persons or any unqualified individual could not do. The cry of "vested interests" now raised is nothing less than that of the rogue who holds property belonging to others by the simple reason that the rightful owner has lost the title deeds and claims that "possession is nine points of the law." Those "vested interests" exist only by reason of a defect in the law, which leaves aggrieved persons unable to prove against them. This has now been pointed out and Parliament is asked to provide the remedy. Capitalists, through incorporation, have usurped a position which has been left so long unquestioned that now they try to obtain the sympathy of the general public by alarming company shareholders into the idea that they are about to be deprived of a lawful right. The professions—one and all—are equally affected. Parliament has defined their status and rights. Parliament has said, that for the protection of the public and with a view to public safety, certain callings may not be followed except by persons who have proved their competence by education and examination. Persons, expecting that restriction to be respected and maintained, have, at expense of time, labour, and money, gone through all the stages necessary to prove themselves qualified to practise in a particular calling. Have they not a vested interest to be respected? The question is, Which vested interest is to be maintained, that acquired by the law or that seized by a lapse of law?

Dublin, August 5, 1898.

ROBERT J. DOWNES,
President Pharmaceutical Society of Ireland.

LIQUORES CONCENTRATI.

Sir,—It is most amusing to read Mr. J. C. Hyslop's defence of the liquores concentrati, especially when he tells us that Nature abhors uniformity. Alas for his argument, the liquors are uniformly 1 to 9. Where was Nature when the tinctures were being juggled with, "First, to arrange for greater uniformity of dose," as per preface, page xvi.? Surely it is just as easy for the imitation science to produce liquors 1 to 7 as to vary the strength of the tinctures. Nature apparently does not abhor uniformity when it is decimal, but only when it is octaval and convenient, which is equivalent to saying that Nature abhors common sense—a truly ludicrous conclusion. Why not tell the truth, and say that it is an attempt to pave the way for the metric system—a system we have but one objection to, that it is not the system by which we dispense at present. As it is we have liquors made in decimal concentration, which we use by octaval measurements, and so crown all so-called centesimal liquors which are prescribed and measured by a centi-vigintal scale. And when—the pride of the B.P.—the centesimal scale turns out to be so accurately inaccurate that it is centi-decimal, science should hide its diminished head. What we object to is the false standard set up, which false standard is due to the straining after the metric system. The compilers of the B.P. having harnessed their Arabian colt in dray-horse harness, in the name of scientific accuracy, Mr. J. C. Hyslop blames Nature's abhorrence of uniformity for the misfit. That it is a misfit, witness the doses of the liquors of the alkaloidal salts. Is not the dose of morph. hydrochlor. from $\frac{1}{8}$ to $\frac{1}{2}$ gr. equivalent to 13.75 μ to 55 μ of the liquor whose dose is given as from 10 to 60 μ ; and is not the

dose of strychnin. hydrochlor. from 1/60th to 1/15th gr. equivalent to 1.83 m to 7.3 m of the liquor whose dose is from 2 to 8 m? And this is science! Is it not highly ridiculous to strain after accuracy with the one hand—misnamed science—and yet be content with the despised “*numero redondo*,” the “nearly and about,” which is all that the other hand (be it art or commerce) can attain to. If we are to dispense by the metric system, good and well, but while we have to dispense by fluid drachms, ounces, and grains, let us make our preparations accordingly, and not have to work the two incompatible systems together, making an entirely new system which is neither flesh, fowl, nor good red herring. Perhaps, however, Mr. J. C. Hyslop has over-taxed his inventive genius, and has mixed up his argument for *liquores consecrati* with those intended to defend the prolixity of spirituous media. If that is so, and whether or not, in the name of common sense let us have no more “nonsense” about science and Nature’s abhorrence.

August 6, 1898.

FLUID DRACHM (139/13).

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the ‘Pharmaceutical Journal’ will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed “Editor, 17, Bloomsbury Square, London, W.C.,” and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on separate slips of paper, each of which must bear the sender’s initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

BOOK ON GOVT.—It is published at the *Lancet* office, 423, Strand, London, W.C. [Reply to GOVT.—14/21.]

BOTANICAL.—1. *Cornus sanguinea*; 2. *Circaea lutetiana*; 3. *Hypericum hirsutum*. [Reply to J. L. J.—13/20.]

SYR. EASTONII.—If it be taken for too long a period, it is quite possible that effects may be produced resembling those it is desired to remedy. [Reply to APPRENTICE.—14/19.]

QUALIFICATION AS DISPENSER.—To obtain a “qualification” as a dispenser in Great Britain you must pass the Minor Examination of the Pharmaceutical Society. [Reply to G. T.—14/24.]

PERCENTAGE OF PASSES.—We are not in possession of the figures you ask for, but understand that the percentage of passes at the first attempt is very high. [Reply to S. P. S.—14/22.]

BOOKS FOR ADVANCED STUDY.—There is no single book which deals at all exhaustively with organic chemistry as limited to materia medica. ‘Pharmacographia’ is the text-book on the subject, but the chemistry of this work is considerably out of date. Probably Maisch’s ‘Materia Medica’ will be a useful book to you. Another book, if you read French, will be Collins’ ‘Guide Pratique pour la Determination des Poudres Officinales.’ This will give you help in microscopic work. For general reading you will get a good idea of the latest work from the pages of the *P.J.* If you bind these you will find the volumes most useful for reference. The ‘Year Book of Pharmacy’ also gives a good current digest of work in the domain of pharmacy. [Reply to SYRUPUS.—14/17.]

DETERMINATION OF THE ALKALOIDS IN QUININE WINE, COCA WINE, AND IN LIKE PREPARATIONS.—The alkaloids are best obtained by treating, say, 100 C.c. of the wine with ether and ammonia separating the ether, taking special precaution that none of the alkaline liquor is run off with the ethereal solution; then evaporating the ether to dryness and weighing the residue. Kola-coca wine presumably containing caffeine, theobromine and cocaine should be treated with chloroform instead of with ether. The identification of the alkaloids requires much experience in alkaloidal work and can only be done satisfactorily by an expert. Allen’s ‘Commercial Organic Analysis,’ Vol. III., Part II., may be consulted with the latter object; also Vol. I., for the determination of carbolic acid in samples of carbolic disinfectants and soaps. [Reply to BROCKLEY.—14/27.]

EGYTRACUM.—This is an old name for linimentum æruginis. [Reply to J. J.—14/33.]

SOFT HEARTH-STONES.—Hearth-stones are scarcely within our province. Ask a wholesale drysalter for the name of the maker. [Reply to J. J.—14/33.]

TO DECOLORISE ESSENCE OF RENNET.—Filtration through animal charcoal is the best means both to decolorise and to brighten essence of rennet; but if properly prepared it should be almost colourless. [Reply to D. M.—14/26.]

DECORTICATED CRUSHED LINSEED.—No, there is no great advantage in having husks of the linseed removed for the purpose of poultice making. [Reply to D. M.—14/6.]

GOVERNMENT LABORATORY APPOINTMENTS.—To obtain an appointment in the “Somerset House” Laboratory, you must first enter the Excise in the ordinary way, and then apply for entrance to the laboratory; as vacancies occur they are filled from applicants in the Inland Revenue service. You will obtain full particulars of these appointments by application to the Civil Service Commissioners, Cannon Row, Westminster, S.W. [Reply to CHEMICAL DERBY.—14/28.]

WATERPROOFING FABRIC.—You do not now tell us what the “inside fabric” is. Probably a sort of canvas. Probably a wash over first with weak copper sulphate solution, and then with soap solution, will have the desired effect; but the surface ought to be thoroughly dry before the article is put away. This will be somewhat difficult to effect in this instance. [Reply to G. W. M.—14/13.]

ASSOCIATES.—The grade of “Associate” is abolished by the new Act, but all registered chemists desiring to be connected with the Society are eligible as “Members.” They will possess exactly the same privileges in connection with the Society as existing members—whether “Major” men or not—and should not therefore deem it a hardship to be expected to pay the same subscription. [Reply to F. W. C.—139/2.]

ACTION OF SUNLIGHT ON SYRUP FERRI IODID.—No, the syrup does not become weaker if kept in bright sunlight. On the contrary, it maintains its full strength in ferrous iodide better than if kept in the dark. The actinic rays act as a reducing agent, for, if some syrup which is discoloured be so exposed, it will be restored to its normal colour after a time, provided it has not gone too far. The same applies to the strong *Liquor ferri iodii pro syrupo* and its congener the solution of ferrous bromide. Both these solutions keep excellently if exposed to bright sunlight. [Reply to IRON SYRUPS.—14/16.]

LEGAL QUERIES.—I. It is unlawful under the Pharmacy Act, 1868, for any unregistered person to take, use, or exhibit the title “druggist.” II. Duly qualified apothecaries and duly qualified medical practitioners who, in order to obtain their diplomas, have passed an examination in pharmacy, are not amenable to the first fifteen sections of the Pharmacy Act, 1868. The answer to your query depends upon certain particulars with which you have not furnished us. Write to the Registrar, 17, Bloomsbury Square, giving particulars. [Reply to B. G.—14/29.]

PRESERVING VEGETABLES.—Obviously it is impossible to tell from a mere description what has been used to preserve the vegetables you speak of. Examine some of the liquor; it may contain boric acid, or salicylic acid, or formaldehyde. You should be able to detect either of these. On the other hand, it is very likely nothing but what you say it seems to be—water. Such vegetables are often preserved in water thus: they are immersed in cold water in previously sterilised bottles, which are stood, with the mouths plugged with cotton wool, in a capacious water bath filled with cold water. This is gradually heated to boiling, and maintained at that temperature for some time. The wool is then removed, and the bottles corked before withdrawal from the bath. This method requires care, but is often successfully carried out by an intelligent cook in the kitchen; in fact, it was practised long before the “germ” theory was promulgated. On the manufacturing scale, a steam steriliser is substituted for the water-bath. [Reply to PRESERVATIVE.—15/1.]

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

Distribution of Manganese. P. Pichard finds that the presence of manganese is almost universal in the ash of organised matter, whether of animal or of vegetable origin. The seeds of phanerogams and the tissues of rapidly growing cryptogams are specially rich in this metal. It is also found in various marine animals, such as molluscs and crustacea, in the bones, eggs, flesh, and hair of vertebrates, also in cow and horse dung. The accumulation of the metal in the seeds and actively vital parts of plants, as well as its occurrence in the two last-named manures, is confirmatory of the theory lately advanced as to its vital importance in the vegetable and animal economy.—*Comptes rendus*, cxxvi., 1882.

Acids of Geranium Oil. Flatau and Labbé contradict the statement of Messrs. Schimmel, that the chief acid constituents of Indian geranium oil are equal parts of acetic and caproic acids. They find that the chief ester is a compound of geraniol with an isomer of myristic acid, from which the acid differs only in having a lower melting point, $28^{\circ}2$ C., instead of $53^{\circ}8$ C. The analytical numbers obtained from silver, barium, and calcium salts are all in accordance with the formula $C_{14}H_{28}O_2$. Besides this, acetic acid and traces of valerianic acid were isolated. Bourbon geranium oil did not give this new body, but about one per cent. of another acid having the formula $C_{10}H_{18}O_2$, half of which exists in the free state, and the rest as a geranyl ester.—*Comptes rendus*, cxxvi., 1876.

Calcium Hydride. By passing pure hydrogen over pure crystalline calcium heated to dull redness under pressure, H. Moissan has obtained calcium hydride CaH_2 . At ordinary temperatures calcium is unaffected by hydrogen, but as soon as a dull red heat is attained, it combines with that gas, with incandescence. The hydride thus obtained is a white melted mass which has a crystalline fracture, and a micro-crystalline structure. Heated to bright redness, freely exposed to the air, it does not alter, but if the temperature be increased by the blow pipe it burns with a bright flame, leaving a residue of fused lime. It burns in oxygen below red heat. When it comes in contact with water, violent decomposition takes place, both bodies giving up hydrogen thus, $CaH_2 + 2H_2O = Ca(OH)_2 + H_4$ —*Comptes rendus*, cxxvii., 29.

Compound Carbonic Esters. P. Cazencuve and A. Moul have succeeded in producing many hitherto unobtained double carbonic esters of the aromatic and fatty series by heating certain neutral phenolic carbonates in various alcoholic media, with certain organic bases. Thus, when phenyl carbonate is treated with urea in the various alcohols of the fatty series, a double carbonic ester of the phenol and the respective alcoholic radicles has been obtained. In this manner phenyl-methyl and phenyl-ethyl carbonates, and those of the higher members of the fatty series, have been isolated; by substituting other phenolic carbonates, such as those of guaiacol, thymol, and cresol, corresponding double carbonates resulted. Many of these bodies have not previously been isolated. The presence of the base is necessary for the reaction; probably this first combines with the alcohol radicle to form an alcoholate, which is subsequently decomposed; thus acting in the same way as sodium ethylate, which, when brought into a cooled alcohol-ether solution of phenyl carbonate gives double ethyl-phenyl carbonate. *Comptes rendus*, cxxvi., 1871, and cxxvii., 111.

[VOL. LXI, (FOURTH SERIES, VOL. VII.) No. 1469.

Influence of Borates upon Nutrition.

According to Chittenden and Gies (*Amer. Journ. Phys.*), moderate doses of borax and boric acid up to 5 grammes per diem, even when continued for some time, are without effect on the general nutrition. Large doses of borax, from 5 to 10 grammes per diem, lead to an increased excretion of urea. Boric acid is practically inert. Both the acid and the salt are so quickly eliminated through the kidneys that they are unable to exercise any cumulative toxic action. *Therap. Gaz.* [3], xiv., 393.

Hæmatozoon of Goitre.

E. Grasset has observed the presence of a parasite in the blood of eight persons recently developing goitre; in form this closely resembles the hæmatozoon of paludism described by Laveran, but differs from it in containing granules of brick red pigment. The symptoms observed in the first stages of goitre are similar to those in paludal diseases, where such bodies are found in the blood. Figures of the various stages of development of the organism are given.—*Comptes rendus*, cxxvii., 75.

Pectin in Gentian.

Bourquelot and Herissey find that the pectin of gentian root, similar to that of beetroot examined by Wohl and Nissen, when treated with warm nitric acid, gives crystals of mucic acid. When hydrolised with sulphuric acid it gives arabinose.—*Journ. de Pharm.* [6], ix., 49.

Dioscorine.

Plugge and Schütte have lately investigated (*Archiv. Intern. de Pharmacodyn.*) the crystalline alkaloid first isolated by Boorsma from *Dioscorea hirsuta*, one of the most poisonous of the Yam tribe, growing in Java. The pure alkaloid melts at $43^{\circ}5$, and is mono basic. The formula attributed to it is $C_{13}H_{19}NO_2$. Pharmacologically it belongs to the picrotoxin group of poisons.—*Pract.*, lxi., 73.

Anemonin in Anemone Pulsatilla.

Noel and Lambert (*Arch. Internat. de Pharmacodyn*) conclude that anemonin is not the sole active principle of *Anemone pulsatilla*, and that it does not pre-exist in the plant; by distillation, an acrid oil, anemonol, comes over, which probably by subsequent oxidation produces anemonin. The observed pharmacological results obtained with anemonin and with the tincture of the plant are quite different. It is concluded that anemonin does not represent the whole therapeutic value of the plant.—*Pract.*, lxi., 74.

Determination of the Ash of Fats.

Dr. A. Delecœuillerie suggests the following simple plan for burning off fats, previous to incineration, in the analytical determination of the ash. The weighed quantity of the sample is melted in the platinum dish, and then a small ash free filter paper folded in four is stood in the melted fat and lighted; this then serves as a wick, and the fat is quickly and completely burnt off.—*Rev. Pharm. de Flandres*, v., 65.

Toxic Ptomaines of Preserved Meat.

Van Ermenglin states that the toxic ptomaines sometimes found in preserved meats, hams, game pies, etc., are due to the presence of a specific organism *Bacillus botulinus*. The soluble toxine it secretes, called botuline by the author, is stated to be so intensely toxic that one thousandth part of a milligramme killed a rabbit in twenty-four hours. Fortunately this ptomaine is destroyed at a temperature of 60° — 70° C., and the bacillus which produces it at 85° C., so that thorough cooking will remove all dangers in the case of salted or smoked meats.—*Journ. de Pharm* [6], ix., 88.

PHOTO-MICROGRAPHY.—V.

BY EDMUND J. SPITTA, L.R.C.P. LOND., M.R.C.S. ENG., F.R.A.S.

On the Condenser and Substage Diaphragm.

The primary object of the substage condenser is to collect light from the illuminant and concentrate it upon the object. It consists of a system of lenses which form a cone of light, the apex impinging on the specimen, and when thus used, without any stop, the object is said to be illuminated by a "large solid cone of light." But if an iris or other diaphragm contract the aperture of the condenser, the base of the cone is reduced in diameter, and the object is declared to be illuminated by a "narrow solid cone." If a stop—say of a piece of cardboard, or preferably a piece of metal—be placed in the base of the cone so as to prevent all rays passing through its centre, the object has then a hollow cone of light impinging upon it, and is said to be illuminated by "annular light."

Condensers, like objectives, are capable of being made of different foci as well as of different numerical apertures, and also of being constructed chromatically, achromatically, or after the style of the apochromatic objective, when they are called chromatic, achromatic or apochromatic respectively. The ordinary so-called Abbe condenser is a chromatic one, and of no use in photo-micrography. It is a poor form of condenser at the best of times, and from a scientific point of view I have often wondered how its use has ever been adopted in this and other countries in the manner it has, but possibly the words of Dr. Dallinger sufficiently explain it when he says "The fact is that a large part of the admiration that has been expressed for this condenser has resulted, not from a comparison of its results with those of other high-class achromatic condensers, but of images obtained without any substage optical arrangements at all, placed in contrast with the results obtained by using this condenser against the same objective when used without its aid."

A microscope without a condenser is not a microscope at all in these days of perfection, and those who declare that with medium power photo-micrography no condenser at all is required are mistaken, that is, if they desire to obtain perfection of result.

Condensers theoretically should be of the same N. A. as the objective, even to 1.40, but practically it is not of so much service if they are, as no objective—excepting when employed on bacilli—that I am acquainted with will stand a solid cone of light from the condenser the same size as its own N. A.

If one should be so constructed we should look for much greater perfection of the final image, but at present even the Zeiss and Powell and Lealand apochromatic objectives will not bear more than about two-thirds of the illumination of the back lens, as seen down the tube of the microscope on removing the eyepiece, when employed on objects in general, such as diatoms. It will be thus understood if we could obtain a really perfect condenser of about 1.0 N. A., it would practically illuminate at its full solid cone aperture the amount required to about fill a 1.40 N. A. objective so far as necessary; and observers who have tried a condenser of higher N. A. than this, without prejudice have expressed their belief that inasmuch as the higher N. A. has to be cut down to fill only two-thirds of the objective, the advantage gained by the high angle condenser must be lost. And although some who read this may doubt the truth of these remarks, they seem to me to be based on careful observation, and after all are only rational deductions. Let two photographs of subjects other than bacilli, for example, be tried, as I have known, one with a 1.35 N. A. condenser cut down to the necessary

aperture, and the other when using a 1.0 N. A. condenser with its full aperture; the difference between the results, if using direct light and solid cones, have appeared to be indistinguishable.

But when employing the microscope on bacilli—by which is meant when photographing them at high magnification—a full cone of light must be employed, and here it may be found of service to employ a high N. A. condenser, because it shortens exposure and, in some cases, may sharpen the general aspect of the bacilli. If a small solid conc be employed, by closing the iris a white diffraction ring will be photographed around each little object, which will quite spoil the final result. Then again, when using what is called "oblique light"—that is to say, when a diaphragm is placed eccentrically in the base of the condenser, so as to limit the light entering it to one small edge of the back lens, thus passing obliquely on to the object—then, too, is the higher aperture of the condenser to which I have referred of definite use. It is obvious here why the extra aperture should be of service, as it necessarily permits a greater degree of obliquity of the rays passing to the object than would be permitted by one of smaller N. A. The application of oblique light as applied to photo-micrography will be given in a future place when dealing with objects which require its especial use, but mention is merely made to it here as connected with what we think is the real value of these condensers of high N. A.; that is, until objectives are made which will stand their use.

With respect to the hollow cones of light and their utility, much difference of opinion also exists. For testing and showing the inferiority of the outer zone of all objectives, even the very best of apochromatics, this annular light may be most advantageously employed by the optician, but I confess to agree with many who are more qualified to give an opinion than myself, that as to its increasing definition—except, perhaps, on the vexed question of how many lines can be resolved to the inch with a given aperture—is altogether a very doubtful and debatable matter. It is true those who are its advocates reply that it is only oblique light in all azimuths, and that is so; but to the use, except in special circumstances, of oblique light at all I must beg to demur, for it is not difficult to show that it is a most dangerous experiment, filling the image with optical phenomena perhaps in no way connected with the real details of the object itself. It is, moreover, evident from the studies of Professor Abbe in recent years that the final image of even the best of extremely high power objectives that are made is not to be regarded as an absolutely faithful representation of the minutest details of the object in their final form, unless indeed the objective has a N. A. of about 2.00, and is used in conjunction with an immersion fluid of sufficiently high a refractive index, both of which at present seem to be absolutely unattainable. Therefore, it is of very doubtful advantage I think to imperil the close approximation to the truth we already do possess in the performance of our highest power objectives by adding to the final image produced by them a series of the minutest details, which in all cases may, and in many positively are, due to optical phenomena of the highest order of complexity—false images rightly called, indeed, and which are only of interest to the optical student, and which can be varied at pleasure. If extreme oblique light be employed false images can actually be shown outside a diatom, and what can be more disturbing to the scientific mind than to see a photograph of an object with a well-marked additional image of one of its own edges—perhaps covered with dots—lying actually outside the real image of the object itself. There are several who have given as much attention and more to the use of both annular and oblique light than myself, and have abandoned the use of both

unless they can make themselves absolutely confident that what they see with its use is nothing more than an emphasised and better defined expression of what less perfectly can be seen without it.

If anyone is desirous of studying the effects of the use of annular light, whether visually or photographically, he may find the following method of much service to enable him to ascertain the diameter of the central stop to be placed in his condenser for each objective. Having centred the light, look down the tube after removing the eye-piece, and close the iris until it just equals the aperture of the objective, which is known by seeing the iris commencing to narrow the aperture of the posterior lens. Measure this aperture of the iris directly with compasses and make the stop for the lens under consideration $7/10$ of that diameter. If this little stop be suitably supported on thin arms and placed just above, or resting on the edge of the iris itself, it will be found to leave an outside ring of annular light about enough to fill the outer zone of the objective.

For convenience, I may mention an arrangement has been made at my suggestion by Mr. Mason, of Clapham, an optician of much constructive skill. It consists of a ring, as the ordinary stops are made, but where the three arms unite in the centre stop all the brass is filed away, save a sufficient amount to support a little projecting pin. Upon this pin any of the accompanying discs of brass can be dropped—and several sizes are supplied. This is shown in Fig. 1.

FIG. 1.

When condensers were first introduced, and before theoretical considerations were complete, they were racked up or down—that is to say, within or without the focus—so that the image of the edge of the flame was avoided. An even illumination was then thought to be of far more consequence. The Carpenter school used to say the better effect was always produced by racking without the focus, whilst the Quekett disciple stoutly maintained it was just the reverse. Now-a-days we know that for critical definition Sir David Brewster was correct when he pointed out that “the source of light should be focussed by the condenser on the object.” Great authorities like Mr. Nelson and others in the present day have proved this assertion beyond all possibility of doubt.

The Critical Image.

To obtain a “critical image” we must have “critical light,” and this is obtained easily enough with a very limited amount of practice. Having focussed the object with the objective in the ordinary manner the condenser is racked up or down until the image of the edge of the lamp-flame is seen lying across the field; as now the condenser and the objective are both focussed on the object, critical light is said to be obtained. There are those who strongly object to this critical “flame-image,” as it is sometimes called, and will lower their condenser just enough to avoid it, but if this be done with high powers the resulting gain in even illumination must only be obtained at the expense of critical definition. When searching for objects with low powers, say, with an inch or half inch, it may be at times more convenient to sacrifice the ideal image to obtain an evenly illuminated field; for when the correct position of the object is found, it is simple enough to obtain the critical image for purposes of study. If equal critical illumination, however, is required absolutely over the whole field when visually employing the microscope, it can be obtained, if the condenser is really aplanatic, by turning the wick broadways after it has been focussed on the object; but if the condenser be not so aplanatic as could be desired, or when taking a photograph, a second quasi-

aplanatic condenser (the best I know being called a Nelson’s “Bull’s-Eye”) can be interposed between the light and the mirror of the microscope, which, when properly placed, will have the desired effect.

The best position for the auxiliary condenser is such that it will throw parallel rays on the mirror, or if the mirror has been removed, on to the substage condenser. This is obtained by pushing it quite near the illuminant—the round side towards the light—so that the rays issuing from it are practically the same width at a distance of a few feet. A puff of smoke will make their path very apparent and show them up admirably. If they widen, the condenser is too near the illuminant; if they come to a focus, too far away.

In some cases of high magnification I have found definition suffer decidedly from the use of this second condenser, whilst with other objects it was exactly the reverse. There are those better versed in mathematical optics than myself who declare that the final definition must suffer unless this condenser is corrected as well as any other part of the optical apparatus, and that the occasions in which we have found benefit were in reality due to the fact that the parallelism of the rays falling on the substage condenser suited the specimen better than convergent ones.

I shall describe the arrangement I have designed in due course, but there are several points about a condenser to be stated and explained first before passing any further. Tabulated they are:—

1. The focus.
2. The numerical aperture.
3. The size of the aplanatic cone.
4. The definition.

1. With respect to the length of focus, this is usually given by the makers, but may be roughly obtained by allowing parallel rays, say from the sun, to fall upon the back lens of the combination, and having focussed the sun’s image on a piece of paper, by ascertaining the distance this point of focus is from a plane midway between the front and back lens. The method is rough but accurate enough for the purpose.

2. To ascertain the N. A. it is only necessary to employ the Abbe apertometer in the manner already described.

3. To gather the amount or rather the size of the aplanatic cone is quite another matter. First, what is meant by an aplanatic cone? It is a term often used but rarely explained on account of

FIG. 2.—APLANATIC.

the somewhat involved nature of the reply. The word itself derived from the Greek means, in point of fact, “free from wandering,” by which the optician understands (as he uses the

FIG. 3.—UNCORRECTED LENS.

word) that all rays, whether from the periphery of the lens or nearer its axis, shall meet in one point in a given plane, as shown in Fig. 2. This is the ideal perfection of the optician’s art. An ordinary uncorrected lens will always suffer from what is called spherical aberration, by which is meant the marginal rays come to a focus in a point on the axis closer to the lens than those situated

nearer to its axis or centre, as seen exaggerated in Fig. 3. The art referred to of the optician is to try and unite these planes of

FIG. 4.—OVER CORRECTED.

focus by combining glasses having different properties. If he overdoes it, producing what is technically called

FIG. 5.—UNDER CORRECTED.

“over-correction,” he brings the peripheral rays too far along the axis, as shown in Fig. 4, and if he does not correct enough—“under correction” as it is termed—he leaves the combination with the same error outstanding, although to a less degree, as that possessed by an uncorrected lens, as shown (greatly exaggerated) in Fig. 5.

Now in a condenser it is evident spherical aberration should be as perfectly corrected as possible, and the ideal form should transmit a cone of rays of uniform light equal to its full aperture. In other words, its spherical aberration should be *nil*. Few condensers indeed will approximately do this. Even those by Zeiss are greatly faulty in this respect, but the last dry apochromatic by Powell and Lealand is a decided advance. The best series I have ever seen, I feel bound to admit, are those recently introduced by Mr. Conrady, to whom I have already referred. Whether this be due to the same thought in their construction, which he holds to so strongly in the manufacture of his lenses already mentioned, it is difficult to say; but anyhow they transmit a solid aplanatic cone of great purity, nearly—if not exactly—of the same diameter as their aperture, and how this can best be ascertained and proved must be the next subject.

Let us consider the following. It is desired to ascertain the size of the largest aplanatic cone of a given condenser, whose N. A., we will say, is stated to be 1.0. Fix it in the usual position on the substage, and place on the nose-piece of the microscope first an objective of N. A. .6, and on the stage a diatom. Focus it with the objective, using as an illuminant the edge of the flame, and rack the condenser up and down until this image of the flame is seen across the field with the diatom lying in its centre. This is obtaining critical light. Shift the diatom just out of the field of view, still leaving a portion of the slip and its cover-glass *in situ*. Remove now the eye-piece, and look down the tube of the microscope. One ought to see the back lens of the objective full of light, because the aplanatic cone of the condenser should be greater than that of an objective 0.6, such as we are using. Return now the eye-piece and remove the objective, substituting one of 0.95 N. A.; again focus the diatom, and again obtain critical light by focussing the condenser on the diatom until the edge of the flame is seen across the field. Once more shift the diatom out of the field, and look down the tube as before. The back lens should be quite evenly filled if the aplanatic cone equals the numerical aperture. Then close the iris diaphragm until its edge is just seen, and carefully note the exact size of the opening with a pair of compasses. Now remove the 0.95 and place in its stead an objective of 1.40 N. A. Treat as before with respect to focussing and obtaining critical

light and look down the tube. Only the centre two-thirds of the back lens is now seen full of light, and the slightest touch of the condenser upwards so as to try and fill the lens to a greater amount will cause two dots of black to appear on each side of the lamp flame, which then becomes immediately recognisable. The last point before the appearance of these black dots (really due to spherical aberration) indicates the largest aplanatic cone of the condenser. Slowly and cautiously close the iris diaphragm until it is just visible and measure the size of the aperture with compasses as before. If the diameter is slightly greater than the previous measure for 0.95, the aplanatic cone is just above 0.95. A little experience will soon render these operations quite easy, and the microscopist will be able to readily compare the largest aplanatic cone of the condenser he is testing with its advertised N. A., and the performance of one condenser with another.

The difference which so often exists in these two measures is very striking, and is said to be mostly due to errors in spherical aberration, most condensers being more or less under-corrected, and consequently focus their central rays at a greater distance than their peripheral ones. If a condenser be well corrected the lamp-flame image, as seen on looking down the microscope with the eye-piece *in situ*, should be, when accurately focussed, intensely bright, whilst the field is commensurately dark; but very frequently this darkness is conspicuous by its absence.

It may be here asked what does it matter even if the condenser should be badly corrected and possess a small aplanatic cone? It is this. The object of a condenser is to bring as much of the light of the illuminant as possible to a focus on the object. If now all the rays do not come to the same focus all of those which come to another are so much lost, and only serve to scatter light into the field, and besides this, when using a broad illuminant (such as is produced after obtaining critical light with the edge of the flame, by turning the lamp flame broad side on), not only is there an unequal illumination of the field which is immediately apparent, but no critical light is obtainable at the margins of the field without losing it at the centre, and *vice versa*. As the best of definition will only lie over the area where critical light exists, so a critical image cannot be obtained over the whole field at one and the same time, and appearances may thus be produced in that part where it is absent which do not in reality exist. Again in using oblique light the loss at the margins of field is a serious matter. Two pictures I hope will be shown, one giving the effect of the condenser out of focus over the whole field, and the other with true critical light. When we come to the photography of bacilli and diatoms and other minute objects it will be seen that neglecting to obtain this actual critical light over the whole field may be a source of positive evil.

The definition given by a condenser is important so far as it goes in one respect only. If a good sound image of the flame edge is not well shown, it is very obvious it is more difficult to obtain critical light with the same ease as if it was good, but condensers never give fine images like objectives, it would make them too costly. To test for definition the condenser may be placed on the microscope, and its performance compared with that of an objective of the same N. A., always remembering that the slide should be turned round the opposite way, *i.e.*, with the cover-glass towards the mirror and the plane glass of the slip towards the condenser when fixed on the nose-piece. This, of course, is necessary because the correction has been made, or should have been made, by the optician with respect to the thickness of the slip just as he makes the correction for objective with respect to the thickness of the cover-glass. Another point here comes before our notice. Slips, unfortunately, are of great difference in thick-

ness, some being much thinner than others, just as cover-glass vary, and it is with pleasure I note that Mr. Conrady has allowed for this variation within a certain limit in his new condenser of 0.95 by giving the mount what may be called a corrective collar, just after the fashion that dry objectives of high power are made.

Condensers are manufactured, as before stated, of different N. A., and that of 1.0 is the highest that can be made dry, and all condensers of higher N. A. have to be oiled to the slip with cedar oil, just as the immersion objectives are oiled to the cover glass. The reason of this is the same as that given in the previous article upon dry and immersion lenses, viz., to make one homogeneous system to lose no rays, at least, not more than possible.

Lastly, in using all condensers the distance of the lamp from the mirror, plus the distance of the mirror from the substage condenser, is important, and it would be well if makers marked this conspicuously on the mount. With some opticians it is greater than others, and can mostly only be found by direct experiment. Mr. Conrady has fixed a total distance of six inches, which I regard as a subject of regret, as it seems too small.

All condensers should be mounted so that they can be centred with the optical axis of the microscope to enable them to perform at their best. This is very important, especially with those which are badly corrected for spherical aberration, thus forming another objection to the use of those with small aplanatic cones—they are so extremely sensitive to slight differences in centring.

THE MANUFACTURE OF TOBACCO IN IRELAND.

Not the least interesting incident during the Belfast Conference last week was the visit of inspection by a large party of members of the Conference and their friends to the tobacco factory of Messrs. Gallaher and Co. The new buildings of this factory cover a space of four acres, and form an immense structure. The bonded store occupies a considerable portion of the building, although kept quite unconnected with it so far as entrance is concerned, the door being so locked that it can only be opened if the manager and the Customs official are present at the same time.

In the bonded warehouse or store the tobacco is kept in large cylindrical casks containing about 2 cwt. of the dried leaf. The casks are opened and their contents weighed and the duty paid upon them before they are taken to the factory, the duty varying according to the dryness of the tobacco or the moisture that it may have attracted in the warehouse; the drier it is the less duty being payable. To give some idea of the extent of the business it may be mentioned that the duty paid sometimes exceeds £12,000 a month, and that in the room alone where the tobacco roll is pressed there is as much as £80,000 worth of tobacco at one time. The first operation when the tobacco enters the factory is to moisten the leaf so as to render it pliable. The excess of moisture is removed by passing the leaves between two rollers. The leaves are then flattened out by hand as much as possible, and are then placed in a machine, where a revolving fan drives them up through a wide tube, like a stove chimney, to the top of the warehouse.

In the top room the midrib of the leaf is removed from top to bottom by folding the leaf and catching the midrib against a small iron point like the point of a packing needle, placed in a block in front of each worker. (For all the light operations throughout the factory, women and girls are employed.) The movement is so dexterously performed that it is hardly possible for the eye to follow it. The midribs are placed in a heap at the side of each worker, and are subsequently used for grinding into snuff. The leaves are then conveyed to the floors below, where various machines are at work. The finely cut tobacco, such as shag or

birdseye, is cut up by a machine, something like that used for cutting paper, but the blades are like wide chisels, and are removable for grinding when necessary. The appearance of the birdseye is due to the presence of the smaller or upper portion of the midrib of the leaf, this not being present in the more uniform tobaccos, such as shag. The flake tobacco is made in a similar machine, but hand pressure is exerted against the tobacco as it issues in the cut form, by a flat piece of iron, which is pressed against it. It is then cut into pieces to fit the boxes of various sizes in which it is packed, this operation being performed by the deft fingers of women, who weigh the tobacco for each box, so that the contents may be uniform.

On a lower floor the twist or roll tobacco is made by a machine which twists the tobacco into a roll of a definite size, whence it passes to another machine that makes it into a coil. As it passes from the one machine to the other, a large and a small leaf of tobacco are placed under the roll, the smaller forming an inner, and the larger an outer coat to the roll, the leaves overlapping each other as they are placed under the roll, and thus forming a continuous covering. To render the roll black it has to be submitted to hydraulic pressure in a hot room, being previously treated with olive oil and supported by a coil of rope so as to prevent its being pressed flat in the hydraulic press. On being removed to a cold room it turns black. The coil of rope is placed around it in a machine by the operator who makes the roll of tobacco into a coil. The above comprise the principal forms of tobacco manufactured, but there are several varieties of each form, differing chiefly in size and colour. The leaves used are imported from North Carolina, Kentucky, Turkey, China, and Japan. The Carolina and China leaf is pale coloured, the Kentucky darker. The Carolina is used for fine tobacco and cigarettes, the Kentucky for Irish roll and shag, the Japanese for mixing with other tobacco, the Chinese for colouring smoking tobaccos, the Turkey for making smoking mixture mellow. The Latakia (which consists chiefly of flowering tops) is used for flavouring smoking tobacco, and the Havana seed leaf for cigars. For the above information we are indebted to the kindness of Mr. Gallaher, who has kindly presented to the Museum of the Pharmaceutical Society specimens of the different commercial leaves used in tobacco manufacture.

OPIUM SMOKING IN INDIA.

In the return of recent correspondence between the Government of India and the Secretary of State in Council (including the reports of the Local Governments in India) as to the measures adopted to give effect to the recommendation of the Royal Commission on the subject of the evils connected with opium smoking in India, and the use of rooms as opium smoking saloons, the Government states that steps have been, or are being taken, in all those provinces in India proper in which shops had formerly been licensed for the sale of opium smoking preparations, for the discontinuance of this practice, it being left to the smokers to manufacture their own preparations, subject to strict limits as to the amount of such preparations they may possess at any one time.

In Burma alone, where opium smoking, and not eating, is the common habit, the sale of these preparations to non-Burmans and registered Burmans under prescribed regulations and restrictions will not be interfered with.

With regard to the question of suppressing opium smoking saloons, the majority of the Local Governments agree in the opinion that it is undesirable at present to undertake penal legislation against opium smoking in saloons and clubs. It is hoped, however, that the recent measures taken by the Government of India

against the sale of preparations of opium used for smoking, supplementary as these were to the previous prohibition of smoking on shop premises, will cause so much inconvenience to be attached to the practice of opium smoking that it will gradually fall off.

REVIEWS AND NOTICES OF BOOKS.

ALKALOIDAL ESTIMATION: A Bibliographical Index of Chemical Research Prepared from Original Literature for the Committee of Revision and Publication of the Pharmacopœia of the United States, 1890-1900. By PAUL I. MURRILL, under the direction of ALBERT B. PRESCOTT. Pp. 58.

The object of this book is to furnish a descriptive index of the work that has been done on this subject, that is to say, it contains the names of the authors and the titles of the papers dealing with some of the alkaloids. It cannot be said that the book has much value; it is a collection of a few names and papers without any discrimination as to the value of the papers written on the subject, and of what use such a list of ancient memoirs can be to the Committee of Revision it would be difficult to say. It commences with papers written in 1861, and purports to include work done to 1898. It has, however, no reference to pilocarpine, except that of Poel in 1881, to Maclagan's test for the purity of cocaine, or to the latest work on ipecacuanha in 1894 and since. It contains a list of thirty-seven papers on caffeine from 1876 downwards, some of them very ancient history and now obsolete. A bibliographical index of approved methods of alkaloidal determination would no doubt be useful to compilers of pharmacopœias, but it cannot be said that this index answers such a purpose. Objection may be taken, by the way, to the use of the word "estimation" in the title of the book. "Assay" or "determination" would much better express the idea it is intended to convey.

THE DIAGNOSIS OF DISEASE. By J. PORTER PARKINSON, M.D., M.R.C.P., F.R.C.S. Eng. Crown 8vo. Pp. 178. Twenty-one illustrations. Price 4s. London: Baillière, Tindall and Cox.

In the author's preface it is stated that this small work is meant to meet the requirements of students preparing for examination and junior practitioners of medicine. The first chapter deals with certain general observations to be made; *e.g.*, a survey of the patient's general appearance, posture in bed, etc. The acute specific fevers are then dealt with clearly, if tersely. The third chapter deals with the diseases of the respiratory organs; the succeeding chapters with the circulatory, digestive, urinary and nervous systems. Finally, short sections are devoted to the bones and joints, the blood and the skin. The illustrations are good, but a disproportionate number of them deal with intestinal parasites. Only two anatomical diagrams are given. In a work of this kind such diagrams are usually abundant and most helpful to the student. Works of this class have a certain sphere of utility, but that sphere is a limited one: they are only to be used as companions to clinical work. If that clinical work is thorough the data for diagnosis must be fully investigated. From this point of view it is perhaps to be regretted that the author in the section that deals with the examination of the blood has not found room for illustrations of the microscopic appearance of the blood in leucæmia, pernicious anæmia, malaria, etc. In other purely clinical matters of observation the work would bear amplification. For instance with regard to rheumatic nodules, the student would, in a work on diagnosis, expect more help than is given in the sentence: "Rheumatic nodules, or small masses of fibrous tissue over subcutaneous bones or tendons, are often seen in young patients."

JOHN RADCLIFFE, M.D.

FOUNDER OF THE RADCLIFFE LIBRARY, OXFORD.

Among the famous English physicians of the closing decades of the seventeenth century and of those with which the eighteenth opened, there is no more striking figure than John Radcliffe. He owes this distinction partly to his character, which was original, and indeed in some respects unique, partly to a professional success, unrivalled before or since, and not a little to the splendid munificence of which his founding the Radcliffe Library at Oxford is only one, though the most conspicuous illustration. He was a rough, blunt, independent man, and nevertheless achieved superlative success in a profession in which qualities exactly the opposite of those are generally supposed to lead, with or without conspicuous medical skill, to popularity and reputation in the worlds of rank and fashion. His independence never showed itself more laudably than when he domineered over patients of the highest rank, and told them the truth with disagreeable, and sometimes unnecessary, bluntness, while denouncing as incompetent all of his brethren who had been consulted before recourse was had to himself. It is to his credit that in an age of time-serving he adhered to his principles in Church and State through thick and thin, and when consistency seemed most damaging to his professional prospects. He did not write satires in prose like Arbuthnot or in verse like Garth, but he was a humourist and a wit, and of few physicians of any age and country have so many racy sayings been recorded. As regards his professional skill, it may be said of Radcliffe that he was a born physician who owed little or nothing to books or to the precepts and example either of his predecessors or of his contemporary professional brethren, who often reproached him with an ignorance of medical theory and a divergence from established medical practice. It was to a sort of intuition that he seemed to owe what according to every one but his professional rivals was the almost magical skill with which he discovered the nature of a disease and decided on the proper remedies to be applied to it. At the last extremity, when all other physicians and their remedies had failed, to "call in Radcliffe" was the final resource of patients and their friends, however much they might dislike his plain-speaking and rough manner or view with repugnance his frankly-expressed political opinion. How good a use he made of the large fortune which his medical reputation brought him will be told hereafter.

He was born in 1650, the year after the execution of Charles I. His father was Governor of the Wakefield House of Correction, and a staunch Commonwealth's man, a political creed which the son either did not inherit, or in course of time exchanged for one very different. The youngster received most of his early education from the Wakefield Grammar School, and at fifteen was sent to University College, Oxford. He became senior scholar of his college, "gaining much honour in the Logic school," took in due course his B.A. and M.A. degrees, and was made a fellow of Lincoln, there being no fellowship vacant at University. Such an academic career disposes sufficiently of the charge of ignorance, and even of illiteracy, which was sometimes brought against him in after-life. He turned his attention to medicine, and after taking his M.B. degree, resigned his fellowship at Lincoln, rather than enter holy orders, but retained rooms there while practising medicine in the university, city and county. His unconventional style of treatment procured him the enmity of the local practitioners and the leading apothecaries, but Radcliffe's proved skill, aided perhaps by a little good fortune, overbore all opposition. A hit which he made by curing a lady of "quality" who was suffering from small-pox crowned his success, and the apothecaries were glad to rally to him. In university circles, his racy talk made his company be sought by dons. To one of them, no less a person than the Master of Trinity, we owe an anecdote which throws light on Radcliffe's medical procedure then and afterwards. The Master on one of his visits to Radcliffe's rooms, fancying that such skill as he had displayed must be the result of study, but seeing no books about, asked where his library was. Pointing to a few phials, the inevitable herbal and a skeleton, "There is my library," was the reply.

The chief other anecdote of Radcliffe at Oxford is a little broad, but we do not write for that young lady of fifteen whom Mr. W. S. Gilbert laments he has to keep in view when inditing his librettos. It is too characteristic of Radcliffe to be omitted. Among the quasi-medical knaves at Oxford who practised on the ignorant and credulous were the so-called urine-casters—they seem to have belonged to the lower grade of apothecaries—who pretended that

they could diagnose any and every disease by a simple inspection of the sufferer's urine. They found many dupes, and drove a thriving trade, especially among the rustic population. An old woman who was more ambitious than her neighbours, and was attracted by Radcliffe's fame, came to him with a fee in one hand and a urinal in the other. She made so bold, she said, as to consult him about her sick husband. "Where is he?" said the doctor. "Sick in bed four miles off," was the reply. "And that's his water, no doubt," rejoined Radcliffe. "Yes, an' it please your worship," said the applicant. "What's his trade?" "A shoemaker." Thereupon Radcliffe, taking the urinal from the woman's hand, empties it into his own chamber-utensil, fills hers with his own urine, hands it to her and dismisses her, saying: "Very well, Mistress, take this with you home to your husband, and if he will undertake to fit me with a pair of boots by the sight of my water, I'll make no question of prescribing for his distemper by a sight of his!"

A squabble with the rector of his college, who was much given to antiquarianism, and whom on that account Radcliffe ridiculed in his rough and ready way, led him to give up his rooms at Lincoln—and having taken rather tardily in 1682 his M.D. degree at Oxford—to turn his face Londonwards. The squabble was an unfortunate one for the college, since it alienated Radcliffe from Lincoln; and when he was both able and willing to be a benefactor to his alma mater, it was his first college, University, which profited by his munificence. His stay at Oxford was one of great importance to him in several ways. It strengthened his inborn confidence in himself and in his methods of cure, which his local brethren of the faculty denounced as eccentric and unprofessional. It might be so, but his patients recovered whilst theirs languished or died; and he learned that skill, or a reputation for skill, could easily triumph over the opposition of rivals if its possessor, instead of allowing himself to be browbeaten, repaid his enemies in their own coin, and treated them with a contempt quite equal to that which they professed for him, and with a vigorous insolence in the display of which none of them could approach Radcliffe. In another way his fortunes were powerfully served by an influence, quite unconnected with his profession, which life at Oxford and the society of its dons doubtless exerted on him. His father, it has been seen, was a staunch republican; but the Commonwealth had fallen, never to rise again. Oxford was the headquarters of Toryism, and Radcliffe left it a high-flying Tory, ripe for Jacobitism when the time for Jacobitism should arrive.

Radcliffe came to London in 1684, and his first known domicile was in Bow Street, then a somewhat fashionable locality, in which stood Wills's Coffee House, a favourite resort of wits and beaux. The witty Earl of Dorset, Wycherly, and Sir Godfrey Kneller were among Radcliffe's neighbours. The year after Radcliffe arrived in London James I. became King, and the political creed which Radcliffe had learnt at Oxford was more than ever in the ascendant at Court and in society. Physicians have not ceased, since Radcliffe's day, to hold opinions of their own on politics and religion, but these are seldom paraded, and neither mar nor promote their professional prospects. No one in any class in our day prefers to call in Dr. A rather than Dr. B because Dr. A is a Liberal and Dr. B a Conservative, or Dr. B rather than Dr. C because Dr. B is a High Churchman and Dr. C a Broad Churchman. It would puzzle nine out of every ten patients to say what were the views of their medical advisers on Home Rule or Ritualism, or on the comparative merits of the late Mr. Gladstone and Lord Salisbury as statesmen. It was different in the days in which Radcliffe's lot was cast. There was Dr. Robert Lower, for instance, who, for a considerable period before Radcliffe's arrival in London, was at the head of the profession, and much favoured at the court of Charles II. But with the excitement produced by Titus Oates' huge imposture of a Popish plot, Lower fancied that there was about to be a triumphant Whig reaction, and he trimmed his sails accordingly to profit by the coming gale. The consequence was that he lost favour at Court and with the Tory nobility and gentry, while his general practice fell off considerably. It had been partly snapped up, especially when a Roman Catholic king came to the throne, by Dr. Thomas Short, who was of the same communion as James. As it happened, both Lower and Short died soon after Radcliffe came to London, and the Tory physician from Oxford inherited a large share in the practice of both. Radcliffe's first and best biographer, Pittis, assures his readers that he had frequently heard Radcliffe's apothecary represent him as not having been a year in practice in London when he was making twenty guineas a day, equivalent to three or four times the sum in our time. Such a

success, such gains for a London physician in the first year of his practice, are without a parallel in these or any other days.

What was the secret of this both sudden and splendid success? Several causes contributed to it. First and foremost, undoubtedly, was a belief in the accuracy of his diagnosis and also of his prognosis. His admiring biographer, Pittis, who was, like himself, an Oxford man, and who knew him personally, gives some marvellous illustrations of what seems to have been his intuitive skill in both these respects. When physicians, his rivals, with Hippocrates and Galen, Sydenham and Willis on their lips, pronounced the patient to be suffering from this, that, and the other malady, Radcliffe pronounced it to be something quite different, and turned out to be in the right. Sometimes it happened that the patient's malady was aggravated by the application of remedies little suited to his complaint. Then Radcliffe protested that he had been called in too late, and declared that the case was hopeless, proceeding to ban in the plainest and strongest language the physicians who had treated it as ignorant pretenders to medicine. If the patient in these circumstances did die, great was the general faith in Radcliffe's prognosis. Even in the depreciatory criticism heaped upon him by his enemies it is admitted that he had made lucky hits both in diagnosis and prognosis, and in those days, when the art of medicine was in its infancy, a few hits would make a great noise and create a reputation or wonderfully strengthen one already made. It has been said that Radcliffe was distinguished from his rivals by the simplicity of his treatment; which lay more in monitions respecting regimen than in giving doses of medicine. Doubtless he avoided the administration of such remedies as found favour with his predecessor, the once celebrated Dr. Willis, who though actually credited with a simplification and improvement of the materia medica of his time, recommended in certain cases the "exhibition" of salt of vipers, water of snails, and even the dung of a foal! But that Radcliffe did not leave everything to nature and regimen is proved by the fact that his apothecary died worth £50,000. However, of the solitary record which has reached us of his detailed treatment, and of one specific known to us to have been of his invention, more hereafter. Sometimes he had recourse to daringly eccentric and even ludicrous expedients, of which one instance gravely given by his biographers may be cited with the preliminary caution that a good deal possessing a legendary look seems to have crept into the chronicle of his medical doings. Here is a ludicrous story told by the serious and dignified Dr. Munk himself in his agreeable little volume "The Gold-Headed Cane," which in a fanciful autobiography is made to tell the story of Radcliffe as its owner.

"He was once sent for into the country to visit a gentleman ill of a quinsy. Finding that no external nor internal application would be of service, he desired the lady of the house to order a hasty pudding to be made. When it was done, his own servants were to bring it up, and while the pudding was preparing, he gave them his private instructions. In a short time it was set on the table in full view of the patient. 'Come, Jack and Dick,' said Radcliffe, 'Eat as quickly as possibly, you have had no breakfast this morning.' Both began with their spoons, but on Jack's dipping once only for Dick's twice, a quarrel arose. Spoonfuls of hot pudding were discharged on both sides, and at last handfuls were pelted at each other. The patient was seized with a hearty fit of laughter, the quinsy burst and discharged its contents, and my master soon completed the cure."

The authority of Dr. Munk is needed to make this story believable.

What also contributed to Radcliffe's success—though without a reputation for professional skill it might have availed him little—was the delight taken by both sexes in his conversation. It was witty, racy, and if on occasion coarse, that may have rather enhanced its attraction in those free and easy days. Even at a later time, when Addison endeavoured to refine both the language and manners of "the town," there were passages in the *Spectator* which could not and would not now be read aloud in any family-circle with average notions of decency. No printed prose of Radcliffe, apart from his profession, survives, with the exception of a few familiar letters. But there does survive a copy of verses by him in reply to a singularly indelicate query addressed to him by a married lady. They were not only printed by Pittis, but were reprinted in the memoir of Radcliffe in the dry and solemn pages of the 'Biographia Britannica,' and form a startling illustration of the extraordinary licence of the age. They are quite unfit for republication in our own by no means prudish pages. It is to be hoped that it was not by conversation in a similar strain that

Radcliffe gained the favour of the fair sex, which it would be more benevolent to ascribe to his more innocent wit and handsome person. That he was a great favourite with the ladies and that many of them among his patients tried hard to allure him to the altar is sufficiently vouched for. We are even asked to believe that some of them feigned illness in order to receive professional visits from him and enjoy his society and conversation. Of his adventures, when years later he did think of matrimony, more hereafter.

It is interesting to contrast Radcliffe's legitimate success on starting as a London physician with the shifts and devices to gain a practice to which one of his brethren stooped under similar circumstances. The story would be worth telling were it only for the light which it throws on the procedure of the London physician of those days, and also a little for its connection with one of Radcliffe's best known witticisms. Among the Oxford physicians who were attracted to London, perhaps by hearing of Radcliffe's success, was a certain Edward Hannes, who became in time Sir Edward, and a Court physician, though partly at least by methods which Radcliffe never needed to use, and which, even if he had needed them, he would have disdained to use. Hannes, on coming to town, set up a very spruce equipage to attract attention, and so far succeeded, but he was not satisfied with this. The rest of the story is thus told in his lively way by Mr. J. C. Jeafferson in his 'Book About Doctors,' a work to which we are occasionally indebted.

"To make his name known Hannes used to send his liveried footmen running about the streets, with directions to put their heads into every coach they met and inquire, with accents of alarm, if Dr. Hannes was in it, as if he were pressingly required by a patient. Acting on these orders, one of his fellows, after looking in every carriage between Whitehall and the Royal Exchange, of course without finding his employer, ran up Exchange Alley into Garraway's Coffee House, which was one of the great places of meeting for the members of the medical profession." (Apothecaries used regularly to come to it and consult the physicians, while the latter were over their wine, paying only half-fees for the advice so given, without the patients being personally examined.) "'Gentlemen, can your honours tell me if Dr. Hannes is here?' 'Who wants Dr. Hannes, fellow?' said Radcliffe, for he, according to Pittis, 'was usually there about Exchange time and planted at a table with several apothecaries and surgeons that flocked about him.' 'Lord A and Lord B, your honour,' answered the man. 'No, no, friend,' responded the doctor slowly, and with pleasant (?) irony, 'you are mistaken; these lords don't want your master, 'tis he who wants them.'"

So signal and so rapid was the growth of Radcliffe's reputation that only two years after his arrival in London the Princess (afterwards Queen) Anne chose him for her principal physician; of the rupture of their connection more hereafter. In the following year (1687) he was elected a Fellow of the Royal College of Physicians. To the same year, with his increasing wealth, belongs the first of a series of munificent gifts to his alma mater, an east window in the chapel of University College. James I. thought it worth while to take steps for bringing over to his own communion a physician of Radcliffe's professional eminence and social popularity. One of the royal chaplains was commissioned to make the attempt, and when it failed, seemingly another more promising was made by the head of Radcliffe's earliest Oxford College, which his generosity had already adorned. The Master of University was that Obadiah Walker who figures in Macaulay's 'History' as a renegade from Protestantism to Romanism soon after the accession of James, and as labouring during his short reign to Romanise his college. He failed completely in his strenuous efforts to convert Radcliffe, who may not have been a very religious man, but was far too honest and self-reliant to apostatise in order to secure the favour of the king and what it might bring with it. Some of the letters which passed between Walker and Radcliffe on this matter have been preserved. "As I never flattered a man myself," Radcliffe writes to Walker, "so it is my firm resolution never to be wheedled out of my real sentiments, which are that since it has been my good fortune to be educated according to the usage of the Church of England, established by law, I shall never make myself so unhappy as to shame my teachers and instructors by departing from what I have imbibed from them." But he bore Walker no ill-will. On the contrary, Radcliffe showed him practical sympathy when, fallen from his high academic estate and deprived of his mastership, he was impoverished and sent to prison. Radcliffe stepped forward, gave Walker a handsome

allowance during life, and when he died contributed largely to his funeral expenses.

This was not the way to court the favour of William the Deliverer. But Radcliffe was a man of thorough independence, political and personal, and so far his character, however faulty in some directions, commands respect. And it seems to have commanded the respect of those whose respect was best worth having. When the Revolution of 1688 seated William III. pretty firmly on the throne, Radcliffe adhered to the fallen cause, declared himself a Jacobite and remained one to the end of his days. Yet this "professed Jacobite," as the Whig Bishop Burnet reproachfully called him, was the physician whom William and William's favourites trusted most, and both William and Mary were very liberal in their dealings with him. William wished to make him one of his physicians, and though Radcliffe declined the honour, for eleven years he pocketed more than six hundred guineas annually by attending medically on the King. For medical services rendered to two of William's favourites, Portland and Rochford, the King made him a gift of five hundred guineas from the Privy Purse, and having sent for him to attend Albemarle when in camp on the Continent, 1200 guineas was the sum which he presented to Radcliffe, for having come so far and cured his especial favourite. Another 1000 guineas was given him by Queen Mary for his successful treatment on one occasion of her nephew, the boy Duke of Gloucester, the Princess Anne's one surviving son and heir-presumptive to the crown. When Queen Mary herself was seized by the malady which ended in her death, to the unutterable grief of her husband and amid general lamentation, the Privy Council itself called in the "professed Jacobite," but too late. "Sir Thomas Millington," says Lord Macaulay, "who was physician-in-ordinary to the King, thought that she had the measles. But Radcliffe, who with coarse manners and little book-learning had raised himself to the first practice in London, chiefly by his rare skill in diagnosis, uttered the more alarming words, small-pox." Further on Macaulay adds in a suggestive passage well worth quoting.

"During two or three days there were many alternations of hope and fear. The physicians contradicted each other and themselves in a way which sufficiently indicated the state of medical science in that age. The disease was measles, it was scarlet fever, it was spotted fever; it was erysipelas. At one moment some symptoms, which in truth showed that the case was almost hopeless, were hailed as indications of returning health. At length all doubt was over; Radcliffe's opinion proved to be right. It was plain that the Queen was sinking under small-pox of the most malignant type."

(To be continued.)

TRIFLES IN PHOTOGRAPHY.

When one is away from home enjoying a well-earned holiday, one is apt to overlook some one or more of those little trifles which just make all the difference between a "might-have-been" and a success. For example, to quote a personal experience, some time ago, when starting from home with a new camera, we loaded up the slides the day before starting, and did not make any exposures until the day after arriving at our destination. The plates were carefully dusted before inserting in the holders, but a long and shaky railway journey had somehow raised a dust, and those plates were almost spoiled by dust spots. The moral obviously is, dust the plates just before exposure, after a journey. Another dust trouble may be mentioned. The camera and slides are sometimes carried along a dusty road for a mile or two, and, although all are shut up in the usual waterproof canvas case, yet experience shows that this by no means prevents dust finding its way into slides and camera. The camera can easily be dusted out by extending to its full length, removing the lens and focussing screen, and blowing through it a few times.

The lens and shutter are both worthy of attention in the matter of protecting from dust. How many splendid pictures have been spoiled by a grain of sand getting into the working parts of the shutter, and making it stick just at the critical moment? It is a good plan to wipe out the camera bellows with a bit of rag, with just a suspicion (no more) of glycerin, or, failing that, olive oil.

The lens should be kept in a soft, clean, chamois leather bag, large enough to pull tight with a string and slot, and then tied round the neck. The shutter may also, if detachable from the camera, be packed in a similar bag. The feathery end of a good stiff quill pen is a capital thing for clearing dust away from the working parts of a shutter. The focussing cloth wrapped round

the camera and slides is generally sufficient to keep out dust. The plates should be dusted after they are in the holders, and again just before development. Should, by chance, the plate dusting brush be forgotten, a very fair substitute may be made out of a bit of wide velvet ribbon. Take half-a-dozen pieces of stout paper, say the size of a postcard, and bend (not fold) over so as to bring their narrow edges together. Then over this fasten by a few stitches the bit of velvet, and there is at once a springy pad which will serve fairly well as a substitute for the ordinary camel-hair brush. Whatever plate duster is used, the user should be careful to see that it is dry, clean, and free from grit, otherwise a trifle of this kind may add another to the list of "might-have-beens."

Another group of trifles which at times are just enough to turn a possible success into a "might-have-been" are those immediately connected with the actual manipulation of the camera at the moment of taking the negative. For instance, carelessness in lifting off the cap and giving the whole apparatus just enough of a shake to spoil the picture. Or, again, a want of due care in seeing that the camera is level, and the swing-back vertical. These two points are, perhaps, most frequently brought home to us in dealing with architecture, but the effect of their neglect is by no means limited to that class of work.

The hand camera man will be wise to employ a level at any rate until he has acquired the instinct of holding the camera level without this aid. This point leads one to think of the failures due to faulty judgment of distance, and the consequent result of getting the important parts of the picture markedly out of focus. Quickly and correctly judging distance with sufficient accuracy to see the focus right is almost an instinct with some, but it is one of those things that anyone with a little practice may learn.

It is, however, when one finds one's self at the seaside, and in lightness of heart begins snapping away at the water craft, and estimating the distance of some boat to be ten feet, when, perhaps, twenty yards would be nearer the mark, that attention to such trifles becomes a serious matter. Everyone knows by experience or hearsay that objects on the water are apt to look nearer than they are, but few are careful to bear this in mind when the distances are small. Yet one may easily convince oneself of this by picking up a couple of similar sized pebbles from the shingle, and throwing one along the shore and the other out to sea. One is generally surprised to find what a short distance the latter stone seems to go.

Supposing the plate safely exposed, there are yet several trifles which may stand in the way of its becoming a perfect negative. We may assume that the majority of practical men are of the opinion that the exposure and development of a plate should be harmonised to each other—in other words, that most workers would not attempt to use the same strength and relative constituents of the developer for one plate very fully exposed and another with the exposure cut down to a minimum. Hence, it becomes highly desirable to know the details of exposure of a plate before commencing development.

Not a few of us, when on a holiday, take the precaution of numbering our exposed plates in some way, so that they can easily be identified before development begins. A neglect of this little trifle may spoil a good thing. In connection with this point, one may take this opportunity of urging upon the younger members of the craft the desirability of always using an exposure pocket book, where is entered details of the month, hour, light, lens stop, and subject. It is well not to trust to memory to put these things down by and by; it should be done at once, and less mistakes are likely to be made. Each plate must be lettered or numbered, of course, so that it may correspond and be recognised before development takes place.

In the matter of changing plates, one is apt, when away from home, to be a little careless about excluding actinic light. One is, perhaps, tired after a long day's excursion, and apt to hope it will not matter—when, alas! the issue of a fogged plate makes one afterwards vainly wish a little more care had been taken to see that all dangerous light had been kept well away from the plate. It is, of course, not always possible to secure a really dark room, but a little forethought may go a long way towards mitigating the possible evil consequences—keeping as far as possible away from a window where light is sneaking in, or getting partly behind a chest of drawers, or utilising a cupboard or wardrobe, and also protecting the plate by turning one's back to the light, and letting the body act as a screen. Then, again, by getting everything ready before the slides or plate boxes are

open, and being expeditious in one's movements, much may be done. Neglect of such trifling matters may prove serious.

Again a warning in time—*experientia docet*, do not leave slides or plate boxes about in the bedroom, where inquisitive domestics may innocently wonder what there is in that little funny box. It is not a pleasant thing to find that a boxful of carefully-made exposures have all been hopelessly fogged in this way. N.B.—Turn the key on all plates exposed or not exposed. It is a trifling precaution that can do no harm, and may save one much annoyance and disappointment.

The foregoing suggestions as to the neglect of some trifles, which may in the issue prove serious, are for the most part drawn either from painful personal experience, or have been learned through the warning example of others. At any rate, they are all practical points, which may by the unthinking or inexperienced be easily overlooked until their due consequences are realised, and when remedy is beyond the court. Therefore the proverbial wise man, *i.e.*, "one who profits by the errors of others," will here exemplify his wisdom by putting into practice the old adage, "forewarned is forearmed."—*Photography*.

FEDERATION OF LOCAL PHARMACEUTICAL ASSOCIATIONS.

A meeting of delegates of various local associations was held at the Grand Central Hotel, Belfast, on Wednesday, August 10, the President, Mr. W. L. Currie, of Glasgow, in the chair. Delegates representative of the following local associations were present:—

- Edinburgh and District Chemists' Trade Association.
- North-East Lancashire Chemists' Association.
- Liverpool Chemists' Association.
- Manchester Pharmaceutical Association.
- Newcastle-on-Tyne and District Chemists' Association.
- Plymouth, Devonport, Stonehouse and District Chemists' Association.
- Glasgow and West of Scotland Pharmaceutical Association.
- Forfarshire and District Chemists' Association.
- Burnley and District Chemists' Association.
- Midland Pharmaceutical Association.
- Midland Chemists' Assistants' Association.
- Cambridge Pharmaceutical Association.

The following resolutions were approved:—

- (a) That it is desirable in the interest of pharmacy that firms trading under ancient titles should also use the names of the present proprietors in conjunction therewith.
- (b) In view of the passing of the Pharmacy Acts Amendment Act, 1898, the Federation suggests that local associations use their best efforts to induce all registered chemists to become members of the Pharmaceutical Society.
- (c) The Federation invites local associations to elicit the opinion of their members as to whether the recommendations issued by the Pharmaceutical Society regarding the keeping and storing of poisons should become bye-laws of the Society.
- (d) That the Secretary be instructed to send a communication to all local associations suggesting that during the ensuing winter session each association should consider, in committee, the whole question of company trading, as it affects the legitimate interests of registered chemists and the protection of the public safety aimed at in the Pharmacy Acts; and that an effort should be made to formulate some definite line of policy on which all registered chemists should agree to act.
- (e) That the Secretary be instructed to send a communication to the Council of the Pharmaceutical Society, congratulating it on the successful passing of the Pharmacy Acts Amendment Act, and urging it to press forward the question of company trading as affecting the legitimate interests of registered chemists.

It was the general opinion of the meeting that local associations could do more towards furthering the aims of the Federation by bringing trade questions forward for discussion and sending the opinions elicited to the Secretary to be brought forward at the next Annual Meeting of the Federation.

Mr. R. C. Cowley, Liverpool, was elected Hon. Secretary of the Federation, in succession to Mr. R. Darton Gibbs, Birmingham.

THIOL is the potassium salt of guaiacol-sulphonic acid, and contains 60 per cent. of guaiacol. It forms a white powder of bitter and subsequently sweetish taste. It is readily soluble in water, does not irritate, is readily absorbed, and is employed as a remedy in tuberculosis. Doses of 1 to 1.5 gramme in twenty-four hours have been prescribed in aqueous solution sweetened with syrup of orange.—*Zeit. d. Allg. oest. Apoth. Ver.*, lii., 306.

FORMULÆ FOR TEST PAPERS.*

POTASSIUM FERRICYANIDE AND CITRIC ACID.—The papers have likewise the property of precipitating albumin from urine.

WURSTER'S DIMETHYL-PARAPHENYLDIAMINE PAPER. (Wurster's red ozone paper).—Filter paper impregnated with a solution of paraphenyldiamine. Indicator of ozone, sulphuretted hydrogen, etc.

WURSTER'S TETRAMETHYL PARAPHENYLDIAMINE PAPER.—Filter paper impregnated with tetramethyl-paraphenyl-diamine. Assumes an intense bluish-violet colour in the presence of traces of active oxygen in neutral or acetic acid solution. Reagent for ozone and peroxide of hydrogen.

REAGENT PAPER (AFTER GEISSLER AND OLIVER) FOR DETECTING ALBUMIN.—(a) *Picric and Citric Acids.*—A precipitate results if a strip of the paper is dipped into urine containing albumin. (b) *Sodium Tungstate and Citric Acid.*—The presence of albumin, mucin, uric acid, peptones, and creatinine is revealed by a precipitate resulting after strips of the above paper have been dipped into the urine.

DETECTION OF SUGAR IN URINE—INDIGO, CARMINE AND CARBONATE OF SODIUM PAPERS.—These papers furnish the Mulder reaction (a successive green, red, and yellow coloration) in the presence of sugar in urine.

GRIESS TEST PAPER.—Filter paper saturated with an alcoholic solution of metaphenylene-diamine. Gives a yellow to brown colour reaction in the presence of nitrous acid and nitrites.

GRIESS RED TEST PAPER.—Filter paper saturated with an alcoholic solution of sulphanic acid and alpha-naphthylamine hydrochloride. The presence of nitrous acid and nitrites produces a dirty red coloration of the paper.

PALLADIUM CHLORIDE PAPER.—Swedish filter paper saturated with a solution of palladium chloride. Reagent for coal gas, carburetted hydrogen, carbonic acid, etc., shows liberation of metallic palladium.

PHENOL PHTHALEIN PAPER.—Filter paper impregnated with an alcoholic phenol phtalein solution employed as indicator in alkalimetry.

PHLOROGLUCIN VANILLIN PAPERS.—Filter paper saturated with alcoholic solution of phloroglucin-vanillin, employed as a reagent for detecting the free hydrochloric acid of gastric juice.—*Deutsch. Amerik. Apoth. Ztg.*, xviii., 100.

AZOLITMINE PAPER.—A reddish-violet bibulous paper impregnated with azolitmine. It is coloured red by acids, blue by alkalis.

LEAD ACETATE PAPER.—Filter paper saturated with a solution of neutral lead acetate, for detecting the presence of sulphuretted hydrogen.

LEAD GLAZED PAPER.—Glazed paper impregnated with carbonate of lead, for detecting the presence of sulphuretted hydrogen.

BRASILINE PAPERS.—Filter paper impregnated with a solution of brasiline; serves as an indicator for acids.

BLUE CARMINE PAPER.—Filter paper impregnated with a solution of indigo carmine, for detecting oxygen.

RED CARMINE PAPER.—Paper saturated with a solution of ammonia-carmine, an indicator of acids, giving a yellowish-red colour reaction.

CURCUMA PAPER.—Filter paper saturated with an alcoholic tincture of turmeric. Indicator of caustic alkalis and alkaline earths, giving a reddish-brown colour reaction. It is coloured brown by boric acid, sulphur-yellow by acids. Sensibility for KHO about 1:180,000, for NH₃ 1:35,000.

FUCHSINE PAPER.—Paper saturated with an alcoholic fuchsine solution, employed for detecting sulphuric acid.

DAHLIA PAPER.—Filter paper impregnated with an alcoholic solution of the colouring matter of *Dahlia variabilis*. Indicator of acids and alkalis.

HÆMATOXYLIN PAPER.—Filter paper saturated with aqueous solution of hæmatoxylin. Extremely sensitive indicator for ammonia, alkali, alkaline earths, and certain metals.

BILBERRY PAPER.—Paper saturated with an alcoholic or aqueous extract of bilberries. Employed as an indicator of ammonia and fixed alkalis.

BLUE AND RED LITMUS PAPER.—Very sensitive indicators obtained by immersing filter paper with a neutral alcoholic litmus tincture. Sensibility of red paper for KOH 1:20,000 of blue paper, for HCl 1:50,000.

COBALT PAPER.—Filter paper impregnated with cobalt chloride and methyl blue solution. Indicator of zinc, copper, and nickel.

CONGO PAPER.—Prepared by impregnating filter paper with a solution of Congo red. Turned blue by acids. Indicator of free acids.

ALBUMIN PAPER.—Paper impregnated with an aqueous solution of albumin. Principally employed in photography.

LACMOID PAPER.—Filter paper saturated with an aqueous solution of lacmoid. Obtainable in red and blue, and used in the same way as litmus paper. The red lacmoid paper is greatly superior to red litmus paper as an indicator for alkalis. It should be kept in a well-stoppered bottle, as it is very apt to spoil.

METHYL ORANGE PAPER.—Filter paper saturated with an aqueous solution of methyl orange. Employed as an indicator of acids and alkalis. The methyl orange paper is coloured deep brownish-yellow by mineral acids.

OZONE PAPER.—Potassium iodide starch paper. (Schonbein's ozone paper.) Filter paper saturated with starch paste which has previously been mixed with potassium iodide. Gives a blue reaction when ozone is present.

THALLIUM PAPER.—Filter paper saturated with thallos hydrate. Gives a brown reaction when ozone is present.

BOETTGER'S TEST PAPER.—Filter paper saturated with neutral gold chloride, coloured violet in the presence of ozone.

POLE TEST PAPER.—Unsize paper saturated with an alcoholic solution of phloroglucin-vanillin. The paper, when moistened, turns red when applied to the negative pole of an electric current.

SILVER PAPER.—Filter paper impregnated with an aqueous solution of silver nitrate. Indicator of chromic acid, arsenious acid, etc. Delicate reagent for arsenic, specially suited for toxicological examinations.

TROPEOLIN PAPER.—Filter paper impregnated with a saturated alcoholic solution of tropeolin. Gives a lilac reaction in the presence of free hydrochloric acid in gastric juice.

POTASSIUM MERCURIC IODIDE AND CITRIC ACID PAPER.—Albuminous urine shaken with this paper gives a voluminous precipitate.

EXTRACTS FROM CONSULAR REPORTS.

THE CHINESE NAME FOR STAR ANISEED is Pa-Chioh, signifying "eight horns or corners," from the shape of the fruit, which consists of eight seed-capsules, arranged to form a star. The tree (*Illicium verum*, Hook. f.) which produces this fruit, Mr. Alexander Hosie reports, occupies a comparatively small area, being confined, as far as is yet known, to Tonquin and the south-west of Kwangsi. The bulk of the aniseed trade has hitherto passed through the port of Pakhoi, and in 1896 Pakhoi exported 6691 piculs, of the value of 113,817 Haikwan taels. This, as well as aniseed oil extracted from the amber-coloured seeds (2053 piculs, valued at 410,692 Haikwan taels), was sent to Hong Kong, while 69 piculs of oil, of the value of 15,552 Haikwan taels, passed Lungchow for Tonquin. It is stated that, owing to the destructive method of collecting the fruit, there is a good crop only once in three years. Complaints have been made that the oil is frequently adulterated with kerosene.

THE OVOID CARDAMOM, the fruit of *Amomum medicine*, Low, like aniseed, is a native of South-western Kwangsi as well as of Tonquin. The centres of export by the West River are Nan-ning and Po-sê.

THE DYE-PLANTS OF KWANGSI are indigo, probably from *Indigofera tinctoria*, L., and the dye-yarn (Shu-liang), the so-called "false gambier," the tuberous root of *Dioscorea rhipogonoides*, Oliver. The former is exported in a liquid state in wooden tubs mostly by junk to the Canton province. Dye-yarns are also largely exported, and are used in the Canton and other provinces for tanning and for dyeing native and foreign cottons, grass-cloth, and silk. The natural dye is brown, if a darker shade is required alum or nutgalls are added, and in Canton the juice of green or unripe persimmons is frequently applied as a varnish to the outside of the cloth. This possesses a waterproofing quality, and to remove dirt only superficial washing is necessary, as the cloth does not absorb the water.

THE MOST IMPORTANT FIBRE-YIELDING PLANT grown in Kwangsi (China) is *Boehmeria nivea*, L., from which rhea, ramie, or China-grass is derived. The chief centre of cultivation lies between Wuchow and Kuei-lin, the capital of the province.

* From the *Pharmaceutische Post*.

SULPHIDE OF ANTIMONY is abundant in the Nan-ning, Ssu-ch'eng, Chên-an, and T'ai-p'ing prefectures of Wuchow, where it is stated there are whole mountains full of the ore.

ENGLISH COPPER SULPHATE finds the readiest market, and is most preferred by the viticulturists of Algeria, according to the report of Consul-General Hay-Newton, it being slightly cheaper and also purer than that from other countries. About 1000 tons are annually imported into the French colony, of which some 478 tons arrive via Marseilles from Great Britain. Sulphate of Copper is used in large quantities in the composition of "Bouillie Borde-laise," as well as for sprinkling on the vines. The price is from 22 to 24 fr. per 100 kilos., and the duty 2 fr. 75 c. to 3 fr., accord- ing to purity.

THE WINE EXPORT OF ALGERIA during 1897 was 80,871,632 gallons, an increase of 9,765,828 gallons over 1896.

PHYLLOXERA has so far caused very little trouble to the vine growers of the province of Algiers, which is entirely exempt from the disease, but the same cannot be said of Oran, where, in the spring of 1897, it gave great cause for anxiety. In the department of Constantine the phylloxera is gaining ground, and notwithstand- ing all precautions taken to check it, the disease seems to increase every year. In the region of Jemmapes the fight against it has been abandoned and the proprietors have been authorised to replant with American vines, but this cannot be done without expense, and they have not the money to expend. The Conseil-Général voted the sum of £4000 to be given to growers who replant in the Philippeville district if the Government gave a like sum. This was decided on, and hopes were entertained that the sum would be forthcoming at once. The growers were disappointed, however, for the Government decided that the amount in question was to be divided, not as first agreed, between the growers of the com- munes of Philippeville and St. Charles, but between all the growers in the arrondissement of Philippeville, which comprises thirteen communes and an area of 406,833 hectares (1,005,184 acres), of which 4822 hectares (11,915 acres) are planted with vines.

PHOSPHATES have recently been discovered at several places in Algiers, viz., Tocqueville, Bordj Rediz (near Setif), and Rio Salado. At Tocqueville 212 tons have been extracted, and at Rio Salado 100 workmen produced 738 tons during five months. The bulk of this was sold, the lowest price realising 40 fr. per ton.

THE ALGERIAN TOBACCO CROP of 1896 amounted to 10,288,408 lbs. and in 1897 to 6,862,376 lbs., the greater part of which was bought by the French Regie; the remainder was manufactured in Algeria and consumed or exported to the French colonies blended with a small portion of American and Havana tobacco. Vice-Consul Drummond-Hay reports that since last year the French Regie have authorised the introduction into France, with a special duty, of two or three Algerian firms' produce.

SULPHURIC ACID is to be manufactured at Bôna (Algeria) if the project of a French firm is carried out. According to Vice-Consul Scratchley, the sea-shore at Philippeville was the site originally chosen for the factory, but this project was abandoned and Bôna decided upon.

THE CASSIA-PRODUCING DISTRICTS OF CHINA are situated in the southern borderlands of Kwangtung and Kwangsi provinces, in the south of the West River. The market town of Ta-wu, in the P'ing-nan district, is the great centre of the cassia trade, where 50,000 to 60,000 piculs are annually disposed of. It is exported, packed in matting, by junk to Canton, where there is a powerful cassia ring, which has an arrangement with the native custom house and likin offices and virtually controls the whole trade of Kwangtung and Kwangsi. The former province is reported to produce three times the export from the latter. The total export of cassia, including cassia lignea, buds, twigs, twig-bark, and broken cassia from the two provinces through Canton in 1896 amounted to 102,810 piculs, valued at 590,798 H. taels. Of so-called cinnamon 99 piculs valued at 4801 H. taels were also exported, as well as 398 piculs of leaf-oil of the value of 56,484 H. taels, making a total value of cassia and cassia products of 653,083 H. taels. China is reported to consume very much more than she exports, so that the total value of the cassia trade must be very considerable.

SELECTED FORMULÆ.

PALATABLE LAXATIVES.

Oil of cinnamon, 2 minims; oil of coriander, 2 minims; oil of caraway, 2 minims; oil of fennel, 2 minims; oil of orange, 10 minims; oil of anise, 10 minims; tincture of ginger, $\frac{1}{2}$ fl. oz.; tincture of podophyllum, $\frac{1}{2}$ fl. oz.; water, $2\frac{1}{2}$ fl. ozs.; fluid extract of senna, 12 fl. ozs.; tartaric acid, 1 oz.; syrup, to make 4 pints. Dissolve the oils in the tincture of ginger, add the tincture of podophyllum, then the senna, then the acid dissolved in the water. Set aside for seven days, and filter. Add sufficient syrup to the filtrate to make up to 4 pints. Rhubarb, 1 oz.; Alexandria senna, 1 oz.; pumpkin seed, $\frac{1}{2}$ oz.; anise seed, $\frac{1}{2}$ oz.; wormseed, $\frac{1}{2}$ oz.; hydrastis, $\frac{1}{2}$ oz.; potassium bicarbonate, 1 oz.; sugar, 32 ozs.; oil of peppermint, 10 minims; glycerin water, alcohol, and treacle, of each *q.s.* Reduce the drugs to No. 40 powder, moisten with a menstruum of glycerin, 1 part; rectified spirit, 2 parts; and water, 3 parts. Macerate forty-eight hours, then percolate up to 2 pints. Dissolve the potassium bicarbonate, sugar, and oil of peppermint in the percolate; lastly, add enough treacle to produce 4 pints. Dose: 1 to 2 teaspoonfuls for children.—*Pediatrics*, iv., 380.

OXYTUBERCULIN.

Hirschfelder gives this name to tuberculin altered by oxidation. After numerous tests he concludes that oxytuberculin is able to heal local and general tuberculosis. The culture medium employed for cultivating the tubercle bacillus consists of veal bouillon, with 4 per cent. of glycerin, 1 per cent. Witte's pepton, $\frac{1}{2}$ per cent. sodium chloride, and $\frac{3}{10}$ per cent. normal carbonate of sodium. After the bacillus is completely grown the culture is sterilised for an hour and filtered. The filtrate is mixed with an eighth part of a 10 per cent. solution of peroxide of hydrogen, put into a bottle plugged with wool, and sterilised thoroughly. The same quantity of the above solution is added every 12 hours, in eight successive portions; free peroxide of hydrogen is removed by alkalisation, before the lymph is used. The advantage of oxytuberculin is said to be that it can be used in proportionally larger doses (20 C.c. per diem) than similar preparations, without producing any ill effects.—*Pharm. Zeitg.*, xlii., 326.

KOLA TABLETS.

The following formulæ for the preparation of kola in a convenient form are due to L. Bernegau:—KOLA TABLETS.—Dried extract of kola, 50 grammes; vanillin sugar, 35 grammes; chocolate powder, 15 grammes; mix intimately with sufficient starch and divide into 100 tablets. An aromatic mixture may be added, such as powdered cinnamon, 10 grammes; powdered cardamoms, 20 grammes; powdered cloves, 0.5 gramme; powdered mace, 0.1 gramme. KOLA PEPPERMINT TABLETS:—Dried extract of kola, 50 grammes; white sugar, 49 grammes; peppermint oil, 1 gramme. Mix intimately with sufficient starch and divide into 100 tablets. KOLA CITRIC ACID TABLETS:—Dried extract of kola, 50 grammes; vanillin sugar, 45 grammes; citric acid, 5 grammes; lemon oil, 2 drops. To be mixed intimately with sufficient starch and divided into 100 tablets. For lozenges the mass is mixed with mucilage of acacia or of tragacanth. Vanillin sugar is composed of sugar, 500, and vanillin, 1. KOLA PEPSIN TABLETS FOR INDIGESTION:—Pepsin, 10; pure hydrochloric acid, 2; milk sugar, 38; dried extract of kola, 50. To be mixed intimately with sufficient starch divided into 100 tablets.—*Pharm. Centralh.*, xxxix., 92, after *Pharm. Ztg.*, 1897, 781.

A GENERAL DISINFECTANT.

Tichborne recommends the following mixture for general disinfecting purposes:—Crystallised phenol, 2; camphor, 6; naphthalene, 1; coloured with rosaniline carbolate. For use on the large scale terebene may be substituted for the camphor, and crude carbolic acid or light tar oils for the crystallised phenol. When sewers have to be disinfected light tar oils are preferable to phenol, since the former, by reason of their low gravity, float on the surface of the sewage, and all gases evolved are bound to pass through the disinfecting layer, whereas when phenol is used its greater gravity causes it to sink, and so the gases do not come in contact with it.—*Dublin Journ. Med. Science* [3], cccvii., 6.

STARCH GLOSS TABLETS.

Starch gloss tablets may be made by mixing stearin, 5 parts, with Japan wax, 2 parts.

PARLIAMENTARY NOTES.

THE LAST WORKING DAY of the House of Lords presented a very interesting exhibition of the Lord Chancellor in a fighting mood. A member of the late Government in a stump speech had hinted that the Select Committee on the Companies Bill had not been working with that assiduity which the country had a right to expect. He had even gone so far as to wickedly suggest that the functions of the Lord Chancellor were confined to making magistrates and drawing magnificent emoluments. This naturally somewhat ruffled Lord Halsbury and led him to submit to the House an elaborate defence of the Select Committee, and an explanation of the circumstances which have contributed to the two years' delay in reporting on the Companies' Bill. In the first place, the Committee has on its strength several of the great Law Lords, and they cannot devote their exclusive energies to the consideration of Committee work without neglecting their more important judicial duties. Then, again, as the Lord Chancellor explained, he has other duties besides sitting on the woolsack, which render it impossible to have a meeting of the Committee every day. Hence the Committee has been obliged to move very slowly. A third reason is to be found in the undisputed fact that the company problem is not an easy one to solve. So far we may sympathise with the Lord Chancellor. But is it the wisest thing to do, if the Government be really in earnest, to remit such a difficult matter to a body which is already overburdened with other duties? And why should it be necessary to have a three years' Select Committee after the Departmental Committee of the Board of Trade have exhaustively investigated the whole question of the inadequacy of company law, has collected evidence, reported conclusions, and even drafted a Bill with a view to giving legislative effect to the amendments thought essential in the interests of commerce and of equity? These be mysteries which no speech from the woolsack is likely to clear up.

THE MIND OF THE LORD CHANCELLOR respecting joint-stock companies was pretty well revealed by two items in his speech. He stated as his conviction that no attempt should be made to retard the development of joint-stock companies carrying on industrial enterprises. And, secondly, he felt that the proportion of fraudulent or bogus companies was ridiculously small when one considered the mass of *bonâ-fide* concerns in this country. Perhaps this may be so, but after the decisions of the House of Lords *in re* Wragge and Salomon, it is rather difficult for an ordinary person to agree to the legal definition of a "*bonâ-fide*" company. The obvious deduction to be made from Lord Halsbury's remarks is that no very sweeping alteration of the law need be expected. The Committee expects to be reappointed next Session, and hopes to complete its labours, but the outcome of those deliberate exertions will probably not be of a very startling nature.

A GOOD WIND-UP to the Session in the House of Commons was the announcement that an Imperial Penny Postage will on December 25 be established between the United Kingdom, Canada, Newfoundland, the Cape of Good Hope, and Natal. Since the opening of Parliament an unprecedented number of postal reforms have been inaugurated, and though the indefatigable Henniker Heaton may have been the exciting cause of many of them, the Postmaster-General and his permanent officers are to be congratulated on the enterprise they have shown and their growing willingness to consider the public convenience.

THE PRIVY COUNCIL OFFICE has just experienced a somewhat violent change. Sir Charles Peel, who has been Clerk to the Council for many years, has retired owing to ill-health and, contrary to expectation, his place has not been taken by the Deputy Clerk, Mr. J. H. Harrison, son of a former Clerk to the Council. The new head of the department is Mr. Almeric W. Fitzroy, a private secretary to the Lord President, and formerly on the staff of the Committee of Council on Education. The post is worth £1700 a year. We may expect to find some of the Scotch Members of Parliament asking questions about this appointment next Session. Mr. Caldwell and Dr. Clarke are specially desirous of effecting economies in the Privy Council Office.

BACTERIOLOGICAL INSTITUTE FOR INDIA.—Replying to Mr. H. Roberts (Denbighshire, W.), Lord George Hamilton stated on the 12th inst. that the Indian Government has been considering the desirability of establishing an institution for the bacteriological investigation of certain diseases specially prevalent in tropical climates. He had no information, however, as to the possible outcome of the proposal.

THE GERMAN MONOPOLY in aniline patents so long upheld by the Patent Law of England has, according to the *Times*, been overthrown by the Board of Trade, which has granted Messrs. Levinstein, Ltd., of Manchester, an order calling upon the patentees to issue a licence to the petitioners to "make, use, exercise, and vend" in the United Kingdom the inventions which the patentees have hitherto refused to exercise here, or allow anyone else to exercise. A minimum royalty of £250 a year is specified. Messrs. W. P. Thompson and Co., of High Holborn, Patent Agents, point out that this is the first time the Board of Trade has exercised its powers under the Patents, Designs, and Trade Marks Act, 1883. No doubt the procedure has involved Messrs. Levinstein in heavy cost, but a severe blow has been struck at the tactics of the foreigner, who thinks to take advantage of British red-tapeism. It is felt that the Board of Trade has been considerably influenced in its action by the speeches and questions in the House of Commons, of Mr. Cawley (Prestwich), and Sir J. Leng (Dundee).

PROCEEDINGS UNDER THE PHARMACY ACTS.

THE PHARMACEUTICAL SOCIETY *v.* THE ACME CHEMICAL CO., LTD.

The Acme Chemical Company, Ltd., was sued at the Tonbridge Petty Sessions, on Tuesday, for selling poison otherwise than as provided in section 17 of the Pharmacy Act, 1868.

Mr. H. A. Darbishire presided over the Bench, and the other Justices sitting were Viscount Hardinge, Col. Stanley Williams, Mr. J. Stanford, Mr. H. J. Wood, and Captain Down, R.A.

Mr. C. Langley Flux, of the firm of Messrs. Flux, Thompson and Flux, solicitors, of London, appeared to support the prosecution, and Mr. A. H. Neve, jun., solicitor, Tonbridge, defended.

Mr. Flux said the proceedings were taken on behalf of the Pharmaceutical Society, under section 17 of the Pharmacy Act of 1868, 31 and 32 Victoria, Chapter 121. The Act provided that no poison should be sold by wholesale or retail unless the box, etc., was distinctly labelled with the name of the article and the word "Poison," and that an entry should be made in a book giving the name and address of the purchaser, and the name and quantity of the article sold, to which entry the signature of the purchaser and that of the person (if any) introducing him, should be affixed. Any breach of this Act rendered the seller liable to a penalty not exceeding £5 for the first offence. In this case, said Mr. Flux, Mr. Harry Moon wrote to the company from his private address, asking them for a tin of their weed killer.

Mr. Neve objected to the contents of the letter being stated as evidence. He had not the faintest idea what the letter contained, and had had no notice from the prosecution to produce a letter. The learned Clerk would inform the Bench that the contents of any letter could not be given in evidence unless the other side had received notice to produce the letter. The letter might be on the file of his clients' correspondence, and he asked them the previous night if they had had notice to produce the correspondence. He might say that he could not prepare his defence until he had some definite knowledge as to what were the intentions of the prosecution in regard to that matter. He objected to the case proceeding that day.

Mr. Harry Moon, a clerk in the employ of the Pharmaceutical Society, was sworn, and stated that he addressed a letter to the Acme Chemical Company.

Mr. Neve here again objected to the contents of the letter being given in evidence, whereupon

The Chairman remarked that the whole case at present seemed to hang upon the letter, and the Bench decided to adjourn it for a fortnight, the prosecution to bear the costs of the adjournment.

It was understood that the Pharmaceutical Society will be represented by counsel at the next hearing.

CRITICISM OF THE NEW PHARMACOPEIA.

THOUGH the general discussion on the new Pharmacopœia, at Belfast, was very unwisely deferred until so little time remained that it was impossible to do the subject justice, the matter was taken up with so much earnestness that the one hundred minutes which the honorary secretaries thought worth devoting to it were utilised to the best advantage. For above all else, an opportunity was afforded for ascertaining what the average pharmacist thinks of the new "standard and guide." Not unnaturally perhaps, he seemed inclined to attribute all that is objectionable in the book to the wholesale druggist, after making due allowance for the numerous unnecessary modifications introduced for the sake of securing simplification in the classification of doses, and it can only be described as unfortunate, if not unfair, that representatives of the wholesale drug trade should not have had a proper opportunity of defending their position and putting the actual facts of the case clearly before the meeting. A work that has absorbed the united energies of so many prominent pharmacists and medical practitioners for scores of months should be worthy of consideration for a longer period of time than one hundred minutes, at the first representative meeting of the pharmacists of the United Kingdom held after its publication, and it is no excuse to urge the prior claims of a social meeting, however attractive, for there was no good reason whatever why the discussion should have been permitted to clash with a garden party. However, the depths of the official mind are unfathomable, and somewhere in those depths, beyond the ken of ordinary mortals, a reason of some kind may possibly be found for deciding that the British Pharmacopœia, 1898, is worth discussing in a public assembly for one hundred minutes at the outside. The contributors of papers may feel aggrieved at being deprived of the right of reply, and it would not be surprising if the representatives of wholesale houses felt sore that no time was allowed them to defend themselves against what they regard as baseless attacks, but all that counts as nothing if the chief officers of the Conference decline to allow more than one hundred minutes for discussing the main item in their programme, even though six papers have been read which bear directly and exclusively on that subject.

The chief purpose served by the discussion was to emphasise the points mentioned by Dr. SYMES in his presidential address—that it is a grave mistake to exclude pharmacists from the body which is responsible for the work of revision, and that it would be vastly preferable to have all new and altered processes and formulæ criticised before rather than after a new Pharmacopœia had been published. Even with the plan adopted in Germany, opinions doubtless differ to some extent regarding the official monographs, but no such widely differing views could possibly prevail as were manifested in the discussion reported at p. 232 *et seq.* If all the workers who expressed opinions on the results of Pharmacopœia processes on Wednesday week could have exchanged views on the same points in advance of publication of the much-criticised book, the result ought to have been a more generally satisfactory work than at present—good as that undoubtedly is from a pharmaceutical point of view. The plan suggested by Mr. MACLEWAN for compelling recognition has much to be said in its favour, and it is not surprising to find that the ideas expressed in his paper were generally approved of. But it is a question for consideration whether, before resorting to such extreme measures, the Formulary Committee of the B.P.C. would not do well to wake up and do something to justify its existence, especially in the direction of so extending the 'Unofficial Formulary' as to make it a matter of necessity for every chemist in business to possess a copy of the book. Such a work, to be complete, ought to contain, not only improved formulæ for official preparations, but also a formula for every medicinal preparation not official in the British Pharmacopœia but in general demand, together with characters and tests for all non-official crude drugs and chemicals in common use. The 'Unofficial Formulary' would then become worthy of its name, and rival the Pharmacopœia in size and importance.

But, in any case, discussions on the Pharmacopœia processes whether at Conference meetings or elsewhere, should not be allowed to degenerate into squabbles between the retail and wholesale sections in pharmacy. So far as pharmacists have been consulted at all in the compilation of the new Pharmacopœia both sections have been equally consulted, and prominent representatives of each have equally been ignored. What is required is that every one competent to take part in the work of revision should be allowed an opportunity of expressing his opinion before the book is published and before the official formulæ and processes are rendered unalterable for the time being. Until some such plan is resorted to, it cannot be expected that any pharmacopœia will meet with general acceptance as a work embodying the best that is known concerning all official medicaments. Nor can such a plan be a success without the cordial co-operation of pharmacists as a body. The General Medical Council will be wise, therefore, to vary its method of procedure in future, and, if necessary, to obtain fresh legal powers enabling that body to accord to pharmacists the full recognition they are entitled to. There appears to be a growing feeling amongst pharmacists that unless such recognition is forthcoming they ought to decline to have anything to do with future revisions of the Pharmacopœia, and if in addition they proceed to prove, by deeds rather than words, that they alone are competent to deal with a certain section of the work, it may be that long before another new Pharmacopœia is called for pharmacy will have attained its proper position in the matter.

ANNOTATIONS.

MR. R. J. DOWNES, of Dublin, has recently been informed, in a somewhat unamiable note published in the official organ of the Society of which he is President, that no Society in Ireland "is rich enough to buy the editorial opinions" of that journal. One gathers by inference from this pharisaical announcement that the editorial opinions of the journal in question have their price and—judging from those expressed on the Parliamentary work of the past session and on Dr. Symes' presidential address—that price ought not to be excessively high. It seems all the more unkind, therefore, for the gentleman in charge of the Irish official organ thus to twit his official chiefs with the assumed poverty of their organisation. That he should have accused Mr. Walter Hills of being a party to the betrayal of trade interests was to be expected, and it is no more surprising to find him calling Dr. Symes "the *enfant terrible* of the Bloomsbury family party," but why, oh why! need he be so rude to the head of the Society which has purchased the privilege to expound its policy in the pages he controls. Of course, everyone is entitled to hold an independent opinion, but it is not always wise to publish such, and it certainly does appear indiscreet, to say the least, for the editorial opinion of the official organ of the Pharmaceutical Society of Ireland to appear to support the principle of company pharmacy. Let the supporter of such a principle invest his surplus cash in joint-stock drug stores, by all means, if he wishes to do so, but really, for his own sake, he ought not to break out with expensive editorial opinions on the subject. He, at least, is not expected to be consistent.

THE GLAMOUR OF BELFAST still persists with many of us, and no Conference of recent years is likely to leave more permanent recollections than the meeting just concluded. Hospitality and goodwill were rampant in the commercial capital of Ireland from the beginning to the end of the week, and the charms of the ladies who helped to make the proceedings such a success were such as to cause even the most experienced and normally sedate members of the central executive wax sentimental. The highest praise was showered upon Miss Watson, the Hon. Secretary of the Ladies' Committee, and rightly so, for no mere male creature ever went about the business of organisation so systematically. It was even rumoured that one of the honorary secretaries of the B.P.C. had expressed a desire to vacate his position in her favour, so impressed was he with the business-like manner in which she went about her self-imposed task and made everything she touched a success. But all the social arrangements were carried out as successfully as the conditions would permit, and the garden party given by the Lord Mayor and Lady Mayoress was one of the most brilliant affairs recorded in the annals of the B.P.C. Such slight drawbacks as were experienced during the week were entirely due to the thoughtlessness of those persons who had not previously intimated their intention of being present, and as usual in such cases the comfort of the large majority who had taken their tickets in advance was interfered with by the unexpected accession of a number of laggards at the last minute. Great sympathy was expressed on that account with the local Executive Committee, and it is only due to the members of that Committee to say that they overcame all these difficulties in an extremely creditable manner.

THE PLYMOUTH EXECUTIVE COMMITTEE should take the lesson of the Belfast meeting to heart and refuse to supply tickets for any of the social gatherings after the Monday of the Conference week.

It is distinctly unfair to visitors from a distance who have secured tickets in advance for persons living near at hand to wait until they feel sure about the weather and then crowd in and usurp the places that have been bespoken by others. Another point that will require consideration next year is the question of reserving a specified amount of time for purely business purposes. Having definitely arranged that certain hours shall be devoted to the Sessions of Conference, that time should be regarded as inviolable and not curtailed for the sake of taking photographs, attending garden parties, or for any other purpose. It may be that, seeing the days of the Conference are now virtually four, the Sessions of Conference might with advantage be spread over three days and end at an earlier hour each day. Thus, it has been suggested that the business hours should extend from 10 or 10.30 a.m. to 2 p.m. on the Tuesday, Wednesday, and Thursday, leaving Friday for the excursion and three long afternoons for other social functions. There is much to be said in favour of such an arrangement, and we commend it to the consideration of our Plymouth friends. All the papers submitted might be read on the first and second days, whilst a general discussion on some selected topic might take place, and all more or less formal business be transacted, on the third day. There should also, of course, be a smaller number of papers than was the case this year, and none of those accepted should be left out in the cold, whatever might happen.

THE STUDENTS' NUMBER of the *Pharmaceutical Journal* will be published on September 10 next, and the Editor will be pleased to receive as early as possible particulars of courses of study suitable for pharmaceutical students, or any other information that may prove useful in that issue. Preferably, particulars regarding the courses of instruction should be summarised on the lines of what was published last year, as the time involved in searching for what is essential in prospectuses will thus be saved to a considerable extent.

ANOTHER CORONER has been displaying his ignorance and going out of his way to blame a chemist who had done nothing wrong. It appears that an Exmouth medical man had written a prescription for an eyewash containing atropine and cocaine, and that was duly dispensed by Mr. J. T. Bickford, chemist and druggist, who copied the prescription in his prescription book as usual and labelled the bottle containing the eyewash "Not to be taken." The bottle was left within reach of a young child, who drank part of the contents and died shortly afterwards. At the inquest all the facts were properly laid before the jury, but the Coroner, in defiance of both law and fact, told the chemist that he had broken the law by not labelling the bottle "Poison," and had laid himself open to a charge of manslaughter. The chemist protested against that wrong view of the matter, the Pharmacy Act was read, and the medical man who prescribed the eyewash did his best to clear the air. But the Coroner refused to listen to reason, ignored the expressed opinion of several of the jurymen, who thought that the bottle was properly labelled, persisting in his erroneous view of the case, and even going so far as to suggest that the jury would be justified in returning a verdict of manslaughter against the non-offending chemist. This so far worked upon the feelings of the apparently susceptible foreman of the jury, that he added a rider to the verdict on his own account, embodying the Coroner's idea that all medicines containing scheduled poisons should be labelled "Poison," and that naturally served as the text of another uncalled-for sermon. Mr. Bickford is greatly sympathised with in this matter, and we hope the chemists of the district will not let the matter drop until the

unduly officious Coroner has been taught not to exceed his duty or exaggerate facts.

THE CHEMISTS OF ARBROATH are to be congratulated upon their action in protesting to the directors of the local infirmary because the lady superintendent of the infirmary, to whom is at present assigned the duty of dispensing the medicines used in that institution and the medicines supplied to the outdoor patients, neither possesses such qualifications as are by Statute required by a practising dispensing chemist, nor a competent practical knowledge of potent drugs and chemicals. They have also pointed out that under the present arrangement preparations containing as their ingredients some of the most virulent poisons, of which no proper record is kept in the books of the institution, are freely distributed, and that in view of the great danger to which patients in the infirmary and poor persons supplied through the dispensary are thus exposed, a serious responsibility rests on the directors of the infirmary, in respect that under the stringent conditions imposed by the Pharmacy Act on practising chemists whose professional training involves a long and arduous course of study, persons not duly qualified and registered as chemists are debarred under severe penalties from selling poisons, which really means distributing them. It was further urged that in such an institution precautionary measures for the safety of the public are of paramount importance, and that it is a duty specially incumbent on the board responsible for its administration to ensure that in a matter which so vitally concerns the health and the lives of the indoor and outdoor patients alike the arrangements should be such as to command the unqualified confidence of the public. After a prolonged discussion, the directors decided to ascertain whether they could arrange for the employment of a nurse legally qualified to dispense medicines, as an addition to the infirmary staff.

KITCHEN BACTERIOLOGY is now a distinct subject, in Königsburg at least, for according to the *British Medical Journal*, Dr. Jäger of that place has recently given a course of hygiene and bacteriology for ladies, which included practical exercises in the preparation and preservation of food by methods used in bacteriological work. The method of procedure was simplicity itself. In the first place, the vessels employed had well-fitting, overlapping lids, instead of the inside lids used in kitchens all the world over, which allow stray bits of matter that may adhere to their rims to fall into the food. Then, care was taken to avoid opening the vessels in which the food was kept, except such precautions were taken as are common in bacteriological work, and cotton-wool was freely used as a covering material. Special cotton-wool lids had been constructed, which consisted of circular discs of cotton-wool, tightly held between two metal rings, the outer of which formed the overlapping rim of the lid. At the close of the lectures raw and cooked food-stuffs were exhibited, which had been kept in a warm room for five to sixteen days; all were perfectly fresh, and quite unchanged in appearance and taste.

THE VACCINATION ACT, 1898, will not come into operation in its entirety until January 1, 1899, but the provisions of Section 2—the so-called Conscience Clause—came into force on the date of the passing of the Act, and the Local Government Board desires, therefore, at once to draw attention to those provisions. The section states that no parent or other person shall be liable to any penalty under Section 29 or Section 31 of the Vaccination Act of 1867 if within four months from the birth of the child he satisfies two justices or a stipendiary or metropolitan police magistrate in petty sessions that he conscientiously believes that vaccination would be prejudicial to the health of the child, and within seven

days thereafter delivers to the vaccination officer for the district a certificate by such justices or magistrate of such conscientious objection. Though the section comes into operation at once, in its application to a child born before the passing of the Act a period of four months from the passing of the Act is substituted for the period of four months from the birth of the child.

A NEW OPENING FOR WOMEN is suggested by the Countess of Warwick, who is about to conduct an interesting experiment, which is likely, if it meets with success, to have an appreciable effect upon agriculture in England. Lady Warwick's idea is that it would be useful to form settlements of women in different parts of the country for the cultivation of the land, and thus enable them to add to their incomes by the sale of fruit, flowers, vegetables, poultry, eggs, honey, etc., the produce of their gardens and poultry runs. There is little doubt, observes the *Times*, that a moderate means of livelihood can be obtained in this way, but in the present state of keen competition success falls chiefly, if not entirely, to the "trained capacity" and organised worker. Those women, therefore, who propose to embark seriously in such an enterprise must first qualify themselves for the work. The hostel, which Lady Warwick hopes to open in October in connection with Reading College, will be an institution where such qualifications may be obtained, and the grounds of the hostel will afford room for practical work. The institution will be founded for the definite purpose of enabling women over the age of sixteen to obtain a thorough training (theoretical and practical) in the lighter branches of agriculture, viz. :—Flower and fruit growing, and packing for market, especially bush fruit, tomatoes, mushrooms, etc., bee and poultry keeping, dairy work. The Council of Reading College has consented to provide the necessary courses of instruction, and to recognise the Countess of Warwick's Hostel as a place of residence for women students. The full course of instruction will extend over two years, but students who wish to do so may join short courses and special classes, and it is hoped that the inclusive fees for instruction and board will not exceed £50 a year.

THE DISTORTION OF FACTS and misrepresentation of action has nowhere lately been more marked than in a short paragraph in the *Grocer*, which appeals specially to grocers who deal in proprietary articles. The readers of that paper are told that a crusade was opened a few years ago by the Pharmaceutical Society against unregistered persons—especially grocers—who were selling proprietary medicines containing poison. Since then the Poisonous Substances Bill, which the Privy Council introduced, provided for the regulation of the sale of certain poisons. "It did not, however, give the members of the Pharmaceutical Society the monopoly they wanted, and so for some time past they have been working themselves into a kind of frenzy of indignation against the Bill, which the Duke of Devonshire has dropped for the present session." This impartial chronicler then proceeds, "But perhaps the worst feature of the Bill, from the point of view of the chemists, was that, as one of them said at a meeting, 'it would involve inspection, and that was an outrage on the chemists of the country.'" "Why?" he asks. "Surely chemists need to be looked after as much as grocers! They paid their own inspectors to look after grocers who sold poisonous proprietary medicines, and then discovered that many chemists were selling the same preparations without any of the precautions provided by the Pharmacy Act." This is as pretty a version of a cock-and-bull tale as we have met with of late, and chemists who hope to work hand-in-hand with grocers, in regard to the protection of prices, would do well to take note of the manner in which the chief organ of their would-be allies slanders their craft.

The British Pharmacopœia, 1898.

DISCUSSION AT BELFAST.

AS previously announced, it had been arranged in connection with the Belfast Conference to hold a general discussion on the new British Pharmacopœia, but the discussion, unfortunately, was not permitted to take place until the final Session of Conference, on Wednesday afternoon, and the subject was, therefore, most inadequately dealt with, owing to the time then available being so limited. In addition, no opportunity was offered for the authors of papers dealing with the Pharmacopœia to reply to the various criticisms offered, and due allowance must be made for that fact in considering the statements and arguments reported below.

Mr. S. R. ATKINS wished to lead the van of the discussion by saying that of course it must be admitted that any defects that there might be in the new Pharmacopœia must arise from the fact that no Irishman had been engaged on its production. Without saying anything controversial, he wished to say that he did think it was quite time that they as pharmacists demanded respectfully a very different position to that which they had in the production of the Pharmacopœia. It was not enough for them to be brought in simply as experts—and the most important of the experts engaged in its production—but they should ask for a statutory position in its production; that it should not be a position accorded to them as a mere compliment by the body now entrusted legally with its production, but that they should say that, being the body who by their training and their experience were most qualified to furnish the best processes and the best results, they should not simply be invited to co-operate, but that they should ask for something more. Having said this much, he wished to express his difference of opinion from the argument put forward by Mr. MacEwan, who said, in the very valuable paper that he had read, that it would be well if the position of advising on the compilation of the Pharmacopœia were relegated to the British Pharmaceutical Conference. He agreed with him to the extent of thinking that the work which had been done in the past by the Formulary Committee should be continued by them as leading up to the main thing. Speaking for the moment as a member of the Council of the Pharmaceutical Society, he wished to say that that Society was the body to whom that work ought to be entrusted. The Conference could do a good deal of the guerilla warfare leading up to the campaign, but it was the function and the duty of the Society to be represented. This was no new doctrine of his. In the early days when he proposed to read a paper on pharmaceutical ethics, so absolutely conservative were they that there was a very solemn conclave of the elders of that day to decide whether the paper contained any dangerous or explosive matter; but they had advanced since those days. One of the advantages of their meeting at those Conferences was that as free-lances they could stand up and say what in another place it would not be expedient to say. Although they had made great progress, he still thought it was their duty to say that they believed that in future Pharmacopœias the pharmacists should have legal recognition.

Mr. J. C. UMNEY said there were two or three points he should like to refer to. Mr. Bird said it was not usual to be able to obtain ext. ipecac. liq. 1 in 1, with 2.25 per cent. total alkaloids, as recognised in the Pharmacopœia, he did not think there was any difficulty in obtaining 16 fl. ozs. from 1 lb. if really good ipecacuanha was used practically free from stems—the root only. That was his experience on comparatively a large scale. With regard to ext. bellad. liq., Mr. Bird had referred to a paper by Mr. Bryant, calling attention to the fact that belladonna was not exhausted by the official process which he confirmed. The Pharmacopœia made no mention of the time of collection of belladonna roots, which had an important bearing in the future on the belladonna preparations made from the root. The time of collection now practically was in the autumn, which probably was the wrong time for getting the best alkaloidal strength. As long as they used green extract

perhaps this was unavoidable, as they could not have both, but if they did away with the green extract they would be able to get the root at the proper time. With regard to liq. thyroidei, his observation was that half per cent. phenol solution with glycerin did not keep it satisfactorily, and that they would have to make some alteration in the preservative. He (Mr. Bird) also referred in glowing terms to the abolition of proof spirit. This was all very well from a pharmaceutical point of view, but so long as the chemists and Revenue authorities recognised proof spirit for export work, and in everything connected with the buying and selling of spirit, it had to be reduced to the standard of proof. They paid duty as proof spirit. If a spirit was 58 over-proof it was exported as 158. For the present, therefore, they would still have to make their calculations at percentage by volume, and also degrees over-proof. With regard to ung. conii going mouldy through leaving out the boric acid, he quite concurred in that. Then Mr. Bird referred to ung. hyd. nit. He (Mr. Umney) had recorded his experience that this ointment did not keep satisfactorily made with a base heated to the high temperature now prescribed compared to what it did before. Mr. Bird then referred to the difficulty of making tincture of orange. There might be some difficulty, but it would only happen this year in consequence of the Pharmacopœia being issued in April, two or three months after the latest time when the peel could be got. In future, any prudent pharmacist would look forward and make his year's supply in January. Mr. Gadd stated in referring to the process for concentrated liquors, that they did not exhaust the drugs. In the case of the percolated liquors that was not the case, provided the percolation were conducted slowly and in accordance with the terms of the Pharmacopœia. It was the case even with rhubarb, which one would suppose to be the worst of all. He also said that the official formula for Easton's syrup was not satisfactory. His observation was that it was one of the most satisfactory in the Pharmacopœia—at any rate, it appeared so after three or four months' experience. He understood Mr. Gadd to say that the strength of the present preparation of tincture of strophanthus was half what it was before, and more than that with a 1 in 20 preparation the drug was not exhausted. That did not accord with his experience. With reference to the statement about lavender oil corresponding to the characteristics of the Pharmacopœia not being obtainable, he had no knowledge of such difficulty. Then Mr. Kelly referred to the necessity for the test for tartaric acid in citric acid. Under certain conditions and at the time of publication there was no necessity for the test. Of course their relative values to one another were by no means constant, and even at the present time there was a sufficient difference in price to make it necessary to have a test. With regard to the relative proportion of citric and tartaric acid in effervescing preparations, they were adjusted on a manufacturing scale in accordance with the ingredients to be used, there being a necessity in some cases to add more of the citric acid with its molecule of water of crystallisation, according to the nature of the active substance to be exhibited in granular form. If they were to frame some particular test, such as Mr. Dyer suggested, he did not know what wholesale druggists would do. They had enough effervescent preparations returned to them now after being kept for two or three years on the retail druggist's shelves, and if there were to be some particular test proposed, to which they should be required to correspond, even after being kept he did not know how long, they would be still worse off.

Mr. D. LLOYD HOWARD wished to offer a few remarks from a point of view which had not been touched upon in the papers, viz., that of a manufacturer who was not a pharmacist, but a chemist. He thought the chemical manufacturer ought to be considered in framing a Pharmacopœia, because there were many substances, like Rochelle salt, Epsom salts, quinine and camphor, which few practical pharmacists manufactured themselves. The Pharmacopœia, therefore, ought to be a guide to them as well as to the pharmacist. He, therefore, cordially endorsed Mr. MacEwan's

remarks as to the great excellence of the method on which the U.S. Pharmacopœia was compiled. He knew of no other publication which was so concise and clear to the manufacturer, and if the B.P. Committee had taken that as a basis, and given a U.S. Pharmacopœia, the result would have been superior to that now produced. He would only speak of the substances with which he was acquainted. He could not speak of the galenical preparations, which he hoped were all that Mr. Bird claimed for them. That speaker remarked very truly that it was necessary to look both to excellence of product and economy of production. It was very desirable that all products should be of very high quality, but there was a proverb not always borne in mind—that the best is often the enemy of the good, and sometimes he thought they might be tempted by insisting on an unreasonable degree of purity to lead to extravagant expense for which no adequate advantage was obtained. This was especially the case with two articles which were very largely used for domestic purposes as well as pharmacy—citric and tartaric acid. Some years ago there were several prosecutions for selling citric acid containing lead. Undoubtedly some citric acid on the market at that time did contain an amount of lead for which there was no excuse. It was looked into carefully by members of the Drug Club and manufacturers, and it was found that the 1895 B.P. test, if suitably applied, would detect something like 1 part of lead to a million. Now it was difficult to visualise one million, but you might reckon it as 1 grain in about 1½ cwt., so that an acid that contained that degree of impurity cannot do very much harm. In the 1898 Pharmacopœia, instead of the acid being dissolved in water and treated with sulphuretted hydrogen it was directed to be neutralised. That introduced a very serious element of error. It was a very difficult thing to neutralise citric acid or tartaric acid exactly. The public analyst would be very likely, in order to make sure of complete neutralisation, to slightly over-neutralise, and in that case not only was the lead shown by sulphuretted hydrogen in a minute trace, but iron was also shown. It was obvious that in making lemonade or anything of that sort in using natural water, however good, there was almost always a trace of iron in it. Now, was it to the public advantage that the manufacturer of aerated water should be compelled to buy citric acid at an enormous expense containing no trace of iron when he would inevitably put a much greater amount of iron in when he used natural water? With regard to proof spirit he quite agreed with Mr. Umney that it was a great pity that the number of degrees proof were not officially stated, because it was on the proof strength that one had to buy spirit. He could not agree with Mr. Bird, who approved of the 90 per cent. by volume as against a definite strength by weight, because although it might not be the rule to weigh liquids in this country, it was in many other civilised countries, and in the case of such a liquid as alcohol, which behaved very irregularly when mixed with water, the more scientific plan would be to have it of definite strength by weight. Mr. Doran referred to the removal of the tests to the Appendix, but from a chemical point of view he could not help thinking that taking the tests out of the text was a retrograde step of a disastrous nature. It seemed to be thought if you said a thing must not contain a long string of things, beginning with alumina and ending with zinc, any man of reasonable brains was competent to perform the characteristic tests. Of course he was if it were a question of identifying the substances naturally; but if you had to detect a very minute trace, or if you had to fix a limit to the trace that might be permitted, it was a matter of the highest importance to have the exact details of manipulation given in every case. To take one instance, oxide of zinc should not contain more than a trace of sulphate. How were they to estimate that? The answer would be, by dissolving in acid and adding barium chloride. But which acid? It made a material difference, however carefully you avoided an undue excess of acid, whether you used nitric acid or hydrochloric acid. There were scores of other instances in the Pharmacopœia. To revert once more to a comparison of the B.P. with the U.S. Pharmacopœia, in the latter you did not find any such indefinite expression as “shall not show more than the slightest characteristic reaction with” so and so, but you found a definite direction given—“take a certain amount, dissolve it, add a certain amount of barium chloride, filter it off, and it ought not to show a precipitate with” another amount of barium chloride. There you had a limit, and the manufacturer who wished to be well up with his work would take care to be within the limit, but when it came to showing a characteristic reaction, who was to say what was a characteristic reaction? He

looked at the Appendix, and he found “this chloride gives a curdy white precipitate with nitrate of silver.” He should be ashamed to certify some things as free from chloride unless they were a great deal better than that. He should confine himself there to the faint blue which was shown when the test was carefully applied. He earnestly hoped that at some future time they might have not merely the tests inserted in the text, but that careful details should be given in each case varying with the necessities of the case, and that in cases where an impurity was innocuous, and likely to occur in manufacture, that a limit—as fine as you liked, but that some limit should be fixed, and that that should be the standard. Because, although the B.P. occupied a somewhat anomalous position, it was the only guide which a bench of magistrates in the country had. They were placed in a very difficult position. Very likely, although they were all fairly well educated gentlemen, not one of them would have any knowledge of chemistry or physiology. They went by the report of the public analyst, who might be a very good chemist, but was almost certainly not a physiologist, and they fell back on the only authoritative work, the B.P. He could not help thinking that the test for bismuth salicylate was defective. They were working on it now at Stratford, but he had not got the latest results. Some weeks ago they had an inquiry—could they supply bismuth salicylate which would answer the new Pharmacopœia test? They then looked at what they had in stock and found that on shaking up with alcohol at the ordinary temperature it gave a coloration. They looked at one of the other Pharmacopœias, he thought the French, and found it stated there that bismuth salicylate would yield the whole of its salicylic acid on continual boiling with alcohol. It naturally occurred to them that if that were the case it would be very likely that there was some, if only a slight action, with alcohol at the ordinary temperature of the air. They divided a sample into 2 parts; and, shaking one part with a considerable amount of alcohol, carefully cooled down to the temperature of melting ice. When he left they had not tried a lower temperature. That quantity of alcohol was quite sufficient to dissolve out very much more free acid than was at all likely to be present in the sample. They also shook up an equal amount of bismuth salicylate with an equal amount of alcohol at the ordinary temperature. The difference in the colour produced was most marked, and that was to a certain extent *prima facie* evidence that the test was defective, because alcohol had some action at the ordinary temperature of the air on bismuth salicylate.

Mr. WARDLEWORTH thought there was one point which arose out of Mr. Howard's remarks which was very pertinent—that with the increase of the percentage of bitartrate of potassium in cream of tartar there was an alteration in the synonym. He had looked back to two or three Pharmacopœias, and in the last the synonym was “cream of tartar,” but in the 1898 edition it had been altered to “purified cream of tartar.” Now the question to his mind was this, What was the position of the chemist who was asked for cream of tartar, say for domestic purposes such as had been indicated by Mr. Howard, or when asked for cream of tartar for pharmaceutical purposes? It seemed to him a distinct issue was brought about there, for the simple reason that cream of tartar was largely imported with the percentage of bitartrate of potassium varying from 90 up to 98 per cent. If the B.P. was accepted as the standard, what was the position of the man who sold cream of tartar that was not purified? Was the customer to ask for “purified cream of tartar” when he wanted 97½ per cent. bitartrate of potassium, or was the retail chemist to run the risk of selling 92½ per cent., which was a very common percentage, and be caught by the public analyst for selling cream of tartar which was deficient in bitartrate of potassium?

Mr. WELLS rose as an Irishman to ventilate one more Irish grievance which he could assure the Conference was a real one. He alluded to their not having any part as pharmacists in the compilation of the Pharmacopœia. In 1883 they were asked to assist in an informal way with suggestions for the Pharmacopœia then being prepared, but declined on principle, as they thought they ought, as pharmacists, to have a right to take part in it. In 1890 they were again requested to assist, and did send some suggestions, but they were rather busy with a parliamentary campaign, and had very little time to give to it. Of course they had to go by the B.P., but they thought there was too much of the London Pharmacopœia about it. Take mist. ferri aromat., that was a preparation which was very largely used in Dublin, and he knew one retail house where they prepared as much as fifty

gallons at a time, that was left out altogether, but they left in *mist. ferri co.*, a preparation seldom ordered in that city; *dec. chinchonæ* was also largely prescribed in Dublin, but there is now no official standard for these and other old and much used preparations. If they in Ireland had had some little part in the drafting of the book it was probable that each place would have left in the things which were most in use, whilst a great many things might be left out which were perfectly useless. There was another point of general interest to pharmacists all over the kingdom which he feared would cause some trouble, viz., the change in the strengths. Most chemists in Dublin, when the Pharmacopœia became official, began to use it, but with regard to tincture of *nux vomica* and some other potent medicines, they did not know what was intended in the prescriptions of the present time. This was very important. The compilers ought to bear in mind that these unnecessary changes caused an immense amount of trouble. There might be some good reasons for them, but he had not heard of them. He had had four Pharmacopœias and a few Addenda pass through his hands, and he must say he got rather mixed up between them. It was all very well to improve the Pharmacopœia, but unnecessary changes should not be introduced. The only way to arrive at that would be to put it into the hands of the pharmacists, and then they would have a book which the British nation might be proud of.

Mr. T. MALTBY CLAGUE concurred in the view that pharmacists ought to have a statutory right to the making of the Pharmacopœia, or, at all events, a large share in it. He was surprised to hear on Irish soil Mr. Atkins, who was always noted for the graceful way in which he did things, say that the Pharmaceutical Society, which only ruled in the Sister Isle, should be the body to whom this work should be entrusted. He thought the Conference was *par excellence* the body which should have the duty, because it represented Great Britain and Ireland, and so the catastrophe of having a Pharmacopœia compiled without the aid of Irishmen would be avoided. Mr. Atkins began on right lines, but he got sadly astray. He was glad to hear it come as a confession that day that this last Pharmacopœia was a wholesaler's Pharmacopœia. He maintained that the retailers ought to have a great deal more to do with any future Pharmacopœia, and he thought they intended to. The wholesale people had had a little too much their own way this time, but the retailer ought to be represented, because he paid for it more than anyone else. Not one doctor in twenty was in possession of a copy of the 1898 Pharmacopœia; the wholesale druggist absorbed a fair number, but the great bulk of the purchasers came from the men behind the counter. They had a right to criticise the wholesalers' treatment on the subject. They were glad of the generous way in which they set to work, carried out researches, gave samples and read proofs, but he noted in one or two particulars they had not been quite so generous as a retail pharmacist would have been. Where was the generous wholesale house to be found which said when it came to a question of concentrated liquors, they are all quite easy except gentian, we have a good formula for gentian, here it is? but they did not rise to that magnanimity. There were hundreds of retail pharmacists who would gladly have given them a good formula, and one that would keep. There was another point which the wholesalers would have to explain away, either there or when they got into the witness-box, viz., why they put glycerin into tincture of *rhubarb*. He thought it was so that no one could make a reliable analysis of it.

Mr. FARR said he should like to endorse Mr. Bird's remarks that repercolation could be with advantage extended to a number of other preparations. Judging by his own experience, it might have been adapted to a number of drugs where it is not now official. There was no doubt whatever that the use of heat as now official was deleterious in the case of many preparations. Mr. Gadd spoke of the non-exhaustion of belladonna root in making the liquid extract, and working with very small quantities no doubt that would be the case, but with any reasonable quantity a fair degree of exhaustion was obtained. Further, it was questionable how far it was desirable to carry exhaustion in the case of some of these drugs. Taking into consideration the cost of the drug, the process could not be profitably extended beyond a certain degree. It either meant an undue waste of spirit or else the application of heat in recovering spirit that was not rewarded by any extra quantity of active matter. As a rule, the active portion of drugs came away in the earlier fraction, which had a less relative proportion of extractive. Mr. Gadd also spoke of the assay for strychnine in the *nux vomica* preparations, and seemed to be in favour of the reprecipitation process, but personally he could not endorse that

view, though he had used it on a number of occasions. There was no doubt whatever that it contained a small proportion of brucine, which was precipitated with the ferrocyanide of strychnine, but that proportion was very slight, and the extra trouble in the assay was not compensated for, as the actual amount of impurity remaining was almost infinitesimal. The reaction for brucine was very delicate, and also the bitterness could be easily detected. Mr. Bird said, with reference to the concentrated calumba preparation, that the liquid should be 18 ozs. instead of 16 ozs., but he did not think that was permissible, because it would alter the proportion of spirit present in the resultant product. If a definite volume was required it should be made up by adding a mixture of spirit and water on to the filter. He also suggested that the present tincture of *strophanthus*, although only made from half the proportion of drug, was considerably more than half the strength, but he did not think he had any warrant for making that statement. Some two or three years ago Mr. Wright and himself examined into this question, working on the *strophanthus* which had been extracted with ether, and also on that which had not been so extracted. They made preparations for the whole series of different strengths of spirit, and afterwards found that the amount of extractive present in these preparations which was soluble both in absolute alcohol and distilled water, i.e., the amount of extractive less the mucilaginous, resinous, and oily matters present in the seeds which would correspond very fairly with Fraser's impure *strophanthin*, was practically the same, whether the menstruum used were 40 per cent. or 90 per cent., or where the seeds had previously been extracted by means of ether.

Mr. RUTHERFORD HILL said there was one point in Mr. Kelly's paper which he thought deserved notice. He referred to many changes which had taken place in the Pharmacopœia, and particularly to the change in the atomic weights of the elements. Mr. Bird paid a compliment to the Pharmacopœia Committee that in the book now produced they had something thoroughly up to date. He supposed it must be accepted that this change in the atomic weights was with the view of being up to date, but at the same time he did not think there was any justification whatever for these changes. It seemed to him it was almost reducing the question to an absurdity to introduce these atomic weights in the case, for instance, of the volumetric solutions. Take for example sodium hydrate, the equivalent for which was now given as 39.76 in place of 40. Admittedly in volumetric estimations the results were only approximate, and it seemed absurd in arriving at approximate results to trouble with such minute differences. Mr. Kelly remarked that of course they could not change the atomic weight of hydrogen "which remained 1, of course," he said. That was a very common remark, but it seemed to him entirely beside the point. It was not the case at all. Taking hydrogen as unity was perfectly arbitrary, and it seemed to him the mistake that had been made had been in taking hydrogen as unity instead of taking oxygen as 16. It did not matter where you began; if you took oxygen as 16, and made that the central point, you could arrange all the other weights around oxygen, and in that case the hydrogen would come out about 1.007. For most purposes they would not take it as 1.007, but as 1; but if you did wish to be particularly exact in some original research, you might take the 1.007. If instead of taking hydrogen as unity, you began with oxygen as 16, and worked out every single one of the volumetric solutions, and the operations involved in using them, you had round numbers in an immensely greater number of instances than you had when you took hydrogen as unity and oxygen as 15.88. He thought the modern tendency to begin with hydrogen as unity, and give all these minute fractions for the other elements, was an entirely erroneous one, and that it would be much better and make the working out of all these calculations much simpler to take oxygen as 16, and range the other elements around it. He had tried it in many instances, and found in the majority of cases it worked out at practically round numbers for all the calculations.

Mr. COWLEY said with regard to the extraction of belladonna root, working with small quantities he had been able to obtain nearly $1\frac{1}{2}$ times the volume that the Pharmacopœia ordered in the first percolate, and even then it required slightly letting down. With regard to syrup of *rhubarb*, he was at a loss to understand the reason why the coriander was put in to commence with, because in the evaporation almost all trace of the oil of coriander was lost. It would appear to be much better if the oil were put in at the last, or to take, for instance, a small part of the distillate, and add it to the product. He agreed with Mr. Hill with regard to the

atomic weights, and he believed a great number of chemists were adopting the plan he suggested, for it certainly made it much easier to make most of the calculations with which pharmacists had to do.

Mr. MARTINDALE said he must, as one who had assisted the Pharmaceutical Society's Committee in the production of the Pharmacopœia, acknowledge that the book had been fairly criticised, and he was glad that it had come out as well as it had. At the same time he was sorry Dr. Attfield was not present, as they hoped he would be. At the outset he must disclaim holding any brief in favour of the Medical Council. He stood there simply as a member of the Council of the Pharmaceutical Society, and to express his individual opinions. He might say that, whatever claims might be made by pharmacists to be entitled to produce the Pharmacopœia, they had no legal foundation for the claim. The Medical Act of 1858 clearly gave the Medical Council the right to produce the British Pharmacopœia, which should displace the Pharmacopœias of London, Edinburgh, and Dublin, and that had been so far done by the introduction of the Pharmacopœias of 1864, 1867, 1885, and now of 1898. The Pharmaceutical Society Committee gave advice and assistance as far as possible as experts, but they had no voting power with regard to the preparations to be contained in the book. They sat in committee and gave the best attention to the subject, and their reports went to the Medical Council, and more especially to the committee appointed by that Council to deal with the matter. He could not say the position was always agreeable—sometimes there was a little clashing, but at the same time he thought they were in a better position, and that pharmacists and the public were in a better position with regard to it than the pharmacists of the United States were with regard to their Pharmacopœia. As Mr. MacEwan had said the United States Pharmacopœia was really a private speculation. It was undertaken by a committee of revision which produced the first United States Pharmacopœia. It had gone through eleven or twelve revisions, a new edition being produced every ten years, but it was entirely in the hands of a self-elected Committee, just as the Unofficial Formulary was produced by the Conference. In fact, the U.S. Pharmacopœia was more of a private speculation than the Unofficial Formulary, because there was no legal status for the Pharmacopœia of the United States, though it was a legal authority. He granted they took every care possible, and it was a work well worthy of imitation in many respects, but in others he should say the British Pharmacopœia was better. The U.S.P. contained much matter which was irrelevant to a Pharmacopœia. With regard to the British Pharmacopœia, a good many of the chemical tests had been transferred from the text to the Appendix, which he thought was an advantage, though he did not wish to dwell upon that point, and would pass on to some of the criticisms which had been made. First of all, liq. ext. cascara, which had been noticed by Mr. Bird; it was Mr. Moss's formula slightly modified. It was believed by a good many to be a good preparation, although he differed from that, and had expressed himself so on many occasions. He thought a drug which depended a good deal for its activity on its resinous matter should have a better solvent than distilled water as a vehicle for exhausting it; he should have preferred 20 per cent. of alcohol. It had been complained that in making liq. ext. bellad. the root was not fully exhausted. He did not know that it was necessary that any drug, vegetable especially, should be fully exhausted. What was the use of so doing, when the game was not worth the candle? If you had very little left in the marc it was better to throw it away, and save time, labour, and spirit.

Mr. NAYLOR suggested that it was said there was a loss of 20 per cent. total alkaloids.

Mr. J. C. UMNEY added that his experience, working with percolators each containing 100, was equally unfavourable.

Mr. MARTINDALE said he had not any facts before him to show there was such a loss, though he was open to be corrected. From the Pharmacopœia process now given, he got the preparation yielding the amount required by volumetric test, and, therefore, he was satisfied with it. He might have got more, but he hardly thought it was worth the trouble, especially as belladonna root was not very expensive. If it did not cost more than 6*z.* per pound, the labour used in exhausting it was worth more than the root. Coming to the solid extract of belladonna, his experiment produced a sort of moist powder. Mr. Bird's two preparations were shown, one was a very firm extract, but hardly a powder, and the other was somewhat soft. He thought the preparation in most cases would be a coarse, moist pow-

der rather than a solid extract. With regard to ergotine, now called *extractum ergotæ*, he thought this was a very great improvement on the last Pharmacopœia. It was a preparation somewhat similar to that in the Swiss Pharmacopœia, with an improvement suggested by himself and others who had worked at it. They found the Swiss preparation, originated by a Swiss professor, made a much better preparation than that in general use. The ergot was extracted by 60 per cent. alcohol, this was added to water which precipitated the resinous matter. The clear liquor, when concentrated, was acidulated with hydrochloric acid, which threw out the sclererehrin; on neutralising with soda and evaporating you got a preparation perfectly soluble in water when finished. The albuminous and mucilaginous matter in the preparation was not taken up if you used 60 per cent. alcohol at first to exhaust the ergot. About alcohol there had been a good many disputes, and, in fact, a terrible struggle in the Committees. The modification to produce the percentages now introduced, which he thought very much better than the old proof and rectified spirit, which really had no scientific standard at all, was certainly an improvement. Mr. Bird observed liquids were weighed for the formation of ointments, and looking to the probability of contaminating measures, although he was in favour of measuring liquid for most purposes, in this case they were more accurately and satisfactorily weighed. Mr. Bird complained of there being no formula for Parrish's syrup or the compound syrup of hypophosphites, but he did not think it was dignified to try and imitate every nostrum that got into use. It was degrading to pharmacy, and he was very glad they were not put in the Pharmacopœia. If they attempted to put in such preparations as the compound syrup of hypophosphites, look what it meant to introduce quinine, hypophosphites of manganese and iron, etc., and they would have to fill up the book by monographs on half a dozen preparations to insert imitations of these nostrums, which was certainly not worth doing. Syrup of iodide of iron was now very much improved; it was now virtually 10 per cent. It made the preparation a little stronger than the last, and was improved in another way by a test which really would be a check on the wholesale manufacturer, if the retailer did not choose to manufacture this himself. There was great competition nowadays with regard to supplying hospitals and others, and if it were sent in at 6*d.* or 1*s.* a lb., they could see whether it could be done at the price, and if the quantity of iodine was present. Passing to syrup of rhubarb, he was not a wholesale druggist, and wanted his preparation good, and in regard to this syrup he thought that was as good a preparation as could well be introduced. It was exhausted by means of weak alcohol, which exhausted the coriander as well. Percolated in that way you exhausted a drug as well as could be, and with syrup it was made palatable and efficacious. With regard to the loss of oil of coriander it was a very minute trace, it still retained a good deal of the flavour, which was sufficient to disguise the rhubarb. In the case of syrup of senna it was thought almost that it might be made by using the concentrated infusion as a basis, or the concentrated liquor that was made by repercolation. This concentrated liquor would have to stand the test of time, and he rather questioned whether it would stand it. He knew it would not with, perhaps, 30 per cent. of the senna in the market; it would be decomposed before it was finished making, unless you used chlorotonic water rather than plain distilled water as a menstruum. It was suggested they should use that as the liquor to convert into syrup by merely adding sugar, but that was at last discarded, and the syrup of senna made by repeated pressing, as our President once suggested, he thought, at Aberdeen, was adopted. If you added the smallest quantity of liquor necessary to moisten the senna, pressed it out and then put on the second quantity, setting aside the first, and even setting aside the second, and then at last added a little greater excess of menstruum, you got a third liquid, which could be concentrated down to a small volume, and the heat necessary to concentrate that preparation down to a small bulk was expended on the weakest part of the liquid obtained. If that were added to the previous liquors set aside you got a preparation of senna that had not been injured by the prolonged action of heat. A curious point then presented itself; it required Pasteurising, because it did not keep well unless heated up to 190°, or else when the sugar was added it decomposed. It differed from making syrup of senna or extract of senna with water in this sense, that if you employed water you took out a lot more than you needed; you took out a lot of mucilaginous and useless matter which you did not want. If you used 20 per cent. alcohol you only took what was the medicinal matter rejected, the mucilaginous

matter, which was inert, and was better not exhausted. Therefore, he held you got a good syrup of senna although it had been criticised as not being suitable for Ireland, where it was to be contracted for for unions. He held they ought to make preparations good, and if the pharmacists in Ireland, either Dublin or Belfast, could not make their prices meet the preparations, he was sorry for them. If they supplied a good preparation they would get credit for it. Passing on to tincture of rhubarb, he could not defend that altogether; he did not know why glycerin was added to the tincture after the rhubarb was exhausted by alcohol. He had nothing to do with it.

Mr. UMNEY said that suggestion appeared in the 'Year-Book,' but he could not at the moment recall the name of the worker.

Mr. MARTINDALE said, as a pharmacist, he doubted the efficacy of that preparation. Then, coming to the nitrate of mercury ointment, that process came from the formula of a celebrated house, and would make a good preparation if it were carefully done, but it required great experience to make it well. You could get the same results if you used the two solutions of nitrate of mercury and of lard and oil, both at 190° F., before mixing. In the present formula they had the oil and lard at about 300° F., and the mercury solution as cold as possible. He had made the preparation and it would make a good preparation, notwithstanding what had been said. He had made it exactly by the Pharmacopœia, taking the quantities named. With regard to liquid extract of nux vomica, the testing of that was only for the amount of strychnine it contained. There came to the knowledge of the Committee the pretty well authenticated fact that brucia is almost inert, and to volumetrically estimate the amount of combined alkaloids in the preparation which would give probably half strychnine and half brucia, this without verifying the amount of strychnine present, might give a preparation of very uncertain strength and doubtful utility, so that now it was to be tested for the amount of strychnine only. Compound extract of colocynth was a wholesale preparation. He did not like the preparation in the B.P., and should have much preferred to exhaust the colocynth by means of alcohol and evaporate that down to dryness, and added this to the other powdered drugs present. Why should they continue the evaporation with all the drugs which were dried merely to make a preparation which in powder had a nicer appearance? When this was suggested to be continued he said that his drugs were made to act and not to look at. The extract of strophanthus was exhausted by means of ether and alcohol and evaporated down to such a condition that it had to be diluted in a certain amount of sugar of milk. When you got the result it was a white powder; it was hardly in the nature of an extract. Extract of Calabar beans was a pasty extract, not a hard, stiff paste. He agreed with Mr. Umney and another speaker with regard to Easton's syrup; that of the Pharmacopœia had stood the test of keeping better than various others which had been prepared under his own supervision, not exactly according to the formula. The formula in the Pharmacopœia was to use sulphate of quinine rather than phosphate, it was suggested that the precipitated preparation of quinine should be used dissolved with phosphoric acid; you washed the quinine away by such a method. The small quantity of sulphuric acid which would be left in the preparation was not worth notice. He had proved that it would keep well for twelve months if carefully prepared without being much coloured. The alteration in the strength of the tinctures was not a pharmacist's alteration; it was introduced by the medical authorities. They wanted the doses of the tinctures to be 5 to 15 minims if active, or if weak half a drachm to 1 drachm. The alteration in the tinctures of aconite, nux vomica, and strophanthus was made to please the medical authorities. He held that it was a mistake, as it meant administering a larger quantity of alcohol than was necessary, and it was retrograding to alter their doses merely to please medical students. It would have been much better to have made them of decimal strengths, 1 in 5 and 1 in 10—1 in 5 if possible, but if not 1 in 10—then if the student knew the dose of a drug he would know the dose of the preparation. It would be 5 times, and in some cases 10 times, the quantity of the crude drug itself. He thought to make preparations of the present variable strengths was a mistake. Ung. staphisagriæ, Mr. Gadd said, would be much better made with the oil, but he did not think the oil contained all the properties of the drug, and that the maceration of the stavesacre seed in the melted fat gave a better preparation than if it were made from the oil. Unfortunately they left out the boracic acid from the ung. conii, with the result, as two of the speakers had corroborated, that it became fungoid. However, in this case it was not their choice,

but that of the Medical Council; they merely advised the formula. With regard to salicylate of bismuth, he agreed with Mr. Kelly and Mr. Howard that no salicylate of bismuth would stand the test of the B.P. You could wash out from even basic salicylate of bismuth salicylic acid by treatment with cold alcohol. You would get no preparation up to a present standard. He had not much sympathy with Mr. Howard as a chemical manufacturer in other respects. He held that they must keep manufacturers up to the mark. They wanted to produce a good article, and it was the business of the chemist to see that they did it. Then with regard to the U.S. Pharmacopœia limit of adulteration, he did not believe in limits of adulteration. Suppose they applied the same to milk. If they had a limit the milkman would adulterate up to the standard. It was a great mistake to set limits, it was very much better to have it indefinite and to get the manufacturers to produce as good an article as they could, and keep them up to a very high standard if necessary. With regard to Mr. Druce's remarks, he wished Mr. Holmes had been present to deal with them, but he agreed with Mr. Druce that the botanical part of the work had been thoroughly well revised, and had been brought up to date as well as any part of the book. With regard to Mr. Wells' remarks on mist. fer. aromat., it was not thrown out by pharmacists, but by the Medical Council themselves. The same remark applied to compound tincture of cinchona. The changes in strength were made entirely on the responsibility of the medical authorities. With regard to purified cream of tartar, he held that unless they sold it as purified it need not be up to the standard. Ordinarily, cream of tartar could not be up to the standard of the Pharmacopœia if it be natural cream of tartar. He was pleased to see that the Pharmacopœia had been accepted so well as it had. He thought it was a great advance on the last one, and when it got into full working order it would turn out very satisfactory. There were not above a dozen preparations which need to interfere greatly with the doses. Medical men need be under no alarm that they were getting a weaker or stronger preparation than the last if they would only learn the details of about ten preparations.

The PRESIDENT said they had had an extremely interesting discussion on the Pharmacopœia, and he should like to have said a good deal about it himself had time allowed. He should be sorry if there were the least idea that any of the remarks made there with reference to the B.P. were regarded as showing that pharmacists were in any way antagonistic to the medical profession. Several years ago, when the Society attempted to obtain recognition of pharmacists on the Pharmacopœia Committee, and sent out a form of petition for the purpose, to be signed by medical men, he, as the Local Secretary of Liverpool at that time, took it round to all the leading medical men in Liverpool, and did not get one refusal. Every medical man signed it, and he was very much complimented on the effort that was being made. It was, therefore, not a question of antagonism to the medical profession. Those who had been accustomed to take the volume and read the words "by authority" on the cover would be a little shocked when they heard Mr. MacEwan put the question "Why should British pharmacists trouble about the Pharmacopœia?" He, however, went on to explain his reasons, and he (Dr. Symes) might confirm his statement, because he had read the short Act of Parliament which authorised the Medical Council to prepare a Pharmacopœia, and there was not one word in that Act which prevented them from appointing a committee partly of pharmacists. He was afraid it was rather an unorthodox view, but he believed that if they had stood up for their position, and refused to act at all unless they had a proper status, they would before now have had the position they desired. It might be interesting to those Irish gentlemen who felt hurt that they were not properly represented to say that when three Pharmacopœias existed, one for Dublin, one for London, and one for Edinburgh, the Dublin Pharmacopœia was the only one which had the authority of an Act of Parliament. The London one was authoritative by an Order in Council; but that of Edinburgh had no authority whatever. Such was the statement in the preamble to the Act he had referred to. Referring to the present work he might say that there were difficulties in the way of reducing all kinds of tinctures to two uniform series of doses; if he were a medical man it would certainly puzzle him far more to remember whether such and such a tincture belonged to this class or that than to remember the actual dose. It seemed absurd that in drugs of all sorts of potentialities there should be an attempt to reduce those to two particular standard doses, whilst at the same time recognising the fact that these drugs must be dealt with differently

in the process of preparation and could not all be exhausted by any particular strength of spirit, so that they had wisely introduced four strengths of alcohol for exhausting various drugs. If they recognised the diversity with regard to the alcoholic extraction why try to reduce them to two levels in the matter of dose? As a matter of percentage certainly it would be very convenient if they had definite substances to deal with to have, say, 5 and 10 per cent. solutions, and so on. Whilst they had altered some preparations with this object in view, hydrocyanic acid, one of the most potent drugs in the Pharmacopœia, which would have borne making 1 per cent. had been left at 2 per cent. He thought it would have been a great advantage to have had hydrocyanic acid in a 1 per cent. solution, it would have been a very definite thing, affording greater accuracy in dispensing, and probably possessing better keeping qualities. If they were to have these alterations they should be at least consistent. He did not know whether time would allow of all the gentlemen who had read papers making replies, but if there were any vital point on which any remarks had to be made he should like to hear them.

Mr. BIRD said he should like to remove one or two little misapprehensions which appeared to have occurred from some of the statements he had heard. With regard to tincture of orange, he did not mention anything about the difficulty of making it. He simply alluded to the alleged objection to the use of fresh orange peel; but with regard to what Mr. Howard said respecting the strength of the alcohol in the Pharmacopœia, he found no fault with that whatever, and did not suggest that the strength should be expressed by weight. If you had to make a dilute alcohol in summer or in winter it was certainly better to weigh the spirit than to mix by volume. In the first place you had to reduce both liquids to 15°·5 C., then mix them, and then cool them down again to the required temperature. With regard to Mr. Wells' observations, the change of strength in the tinctures had affected Englishmen quite as much as Irishmen. The imitation of proprietaries referred to by Mr. Maitindale had a precedent in the Pharmacopœia, and there really was a great disappointment that those two syrups, the chemical food and the hypophosphites were not included. The new Pharmacopœia was essentially a physicians' Pharmacopœia, and perhaps their convenience had been primarily studied, but he did not think pharmacists had lost by the new formulæ. A man bought, say, 1 lb. of liquid extract of belladonna. He had several preparations which could be made extemporaneously, and was able to make those preparations with a minimum of trouble, and with an advantage formerly afforded only by non-official liquors. It was a great pleasure to him that this discussion had come before the Conference, because it really reflected so many interests, the interests of pharmacists not only of Great Britain, but of Ireland as well, and very wide and desirable publicity was given by the reports of what took place at those meetings.

Mr. MACEWAN asked if the Executive Committee in the course of the next year would definitely consider the proposals which had been made with regard to the recognition of pharmacists in compiling the Pharmacopœia. Several members had asked him if no definite resolution would be put, but he thought if the Committee took it up as a point of honour in association with the Formulary Committee, and made some inquiries, and put something definite before them next year, they would come to a conclusion once for all. This was the only Imperial British pharmaceutical body, the only body which could properly act, and for that reason the British Pharmaceutical Conference Executive ought to put into itself a little backbone, and give them something definite to guide them in the future.

The PRESIDENT said he felt sure that the authors of these Pharmacopœia papers would have replied more fully to the interesting criticisms had time permitted.

METHYLENE BLUE IN AFFECTIONS OF THE URINARY ORGANS.—D'Aulnay has employed methylene blue, both internally and as an injection, in various affections of the urinary organs. He finds that it is useful in epithelial nephritis, causing increased diuresis and complete disappearance of the albumin. In cystitis, the internal administration was accompanied by injections of the dilute aqueous solution with marked benefit. In gonorrhœal urethritis the effect was very variable. It is, however, found to be a good germicide and analgesic, and is likely to be useful in the treatment of those cases of urinary trouble where these properties will be valuable.—*Bull. Gén. de Thérap.*, cxxxiii., 353.

NEW REMEDIES.

GLYCEROL OF TEREbene AS AN ANTISEPTIC DRESSING.—A Russian doctor has employed a glycerol of terebene, prepared as described below, with much success as an antiseptic dressing. Doubtless the efficacy of the preparation is due to the hydrogen peroxide which it contains. Into a stoppered separator of a capacity of 5 or 6 litres, a mixture of glycerin, 7, water, 1, and terebene, 4, is added and left for a fortnight, with frequent agitation, at ordinary temperatures. The mouth of the bottle is fitted with a cork carrying two tubes, one of which passes to the bottom of the liquid; with this arrangement air is occasionally drawn through the fluid. Gradually the lower stratum, which originally consisted of glycerin and water, changes to an opaque, viscous mass, having the aromatic odour of terebene. This is the glycerol used. Compresses of tarlatan impregnated with this substance are placed directly on the parts, which are then covered with absorbent cotton. It is an energetic disinfectant, and promotes the rapid healing of wounds.—*Bullet. Commerc.*, xv, 466.

PROTARGOL—THE NEW SILVER COMPOUND.—As prepared by Eichengrun, this is a light yellow powder readily soluble in water, especially if it is first moistened with a little water previous to adding the bulk of the liquid. The solution is quite clear and light brown, and may be prepared up to 50 per cent. Its reaction is neutral, and it does not decompose on warming, but becomes brown after continual heating. The proportion of silver is 8·3 per cent. Protargol is, in this respect, richer than argonin, which contains 4·2 per cent., and argentamine containing 6·3 per cent., while it surpasses both these preparations in bactericidal action. The solutions of protargol are not decomposed by alkalis, alkaline sulphides, albumin, sodium chloride, or acids. Concentrated hydrochloric acid produces a precipitate, but this does not consist of silver chloride, but of unchanged protargol, which is dissolved again on dilution. This peculiar property of protargol has a favourable influence on its physiological action. In consequence of the extremely stable combination of the silver, no irritation or pain results when it is applied as an antiseptic; nevertheless it possesses marked bactericidal properties, especially on unhealthy wounds. Excellent results have been obtained in the treatment of acute gonorrhœa with dilute solutions of $\frac{1}{4}$ per cent. which may be rapidly increased to 1 to 1½ per cent. Stronger solutions of 5 to 10 per cent. used for urethritis of females were borne without any irritation resulting. Neisser states that he obtained better and more prompt results with protargol than with any other remedy.—*Pharm. Centr.*, xxxviii., 639.

TINCTURE OF MYRRH IN MIXED INFECTION.—The internal administration of myrrh, which is stated to bring about a marked increase in the number of leucocytes, continues to find favour in continental practice in cases of mixed infection. Stoll, of Munich, reports on eighty cases with only one death treated by this method. He prescribes tincture of myrrh, 4; glycerin, 8; distilled water to 200.—*Pediat.*, v., 365, after *Therap. Gaz.*

BIRCH LEAVES AS A DIURETIC.—Huchard confirms the statement of Winternitz that a decoction of birch leaves acts as a useful diuretic. In order to render the resinous matter soluble Moreau recommends the use of a little sodium bicarbonate. The decoction is made thus: From 10 to 50 grms. of the leaves are boiled in 1000 C.c. of water, then cooled to 30 to 40° C., and 1 gm. sodium bicarbonate is added. Instead of this decoction, an extract, made by percolation with alcohol from the leaves gathered from the flowering tree, is given in pills in a daily dose of 1·6 to 2·4 grammes.—*Répertoire* [3], x., 24, after *Journ. des Pract.*

QUINORAL.—This is a neutral quinine preparation, an oily syrup-like liquid, having a very bitter taste. It is soluble in every proportion in water and spirituous fluids. It is said to be free from the irritating effects on the heart caused by quinine or chloral. Quinoral is said to be principally an antiseptic and a valuable substitute for dangerous metallic compounds and phenol preparations. Bacteriological experiments with solutions of quinoral showed that bacteria were killed more rapidly with them than with sublimate. Quinoral is prescribed for internal use in doses of 0·05 to 1·0 gramme. Larger doses act as a hypnotic, especially in delirium tremens.—*Zeit. d. allg. oest. Apoth. Ver.*, li., 754.

ANALYTICAL NOTES.

DETERMINATION OF OIL IN DISTILLED AROMATIC WATERS.—Ranwez' method has been tested by Beckurts and Fierichs, who, while approving of the process in general, recommend the following modification:—Sixty grammes of sodium chloride are dissolved in 200 C.c. of the water in a separator, and the ethereal oil is washed out with ether by repeated shaking with successive quantities. The united ethereal solutions are dried over calcium chloride, and the solvent evaporated as follows:—The ether is distilled off on the water-bath until only 10 to 15 C.c. remain, and this is removed with the aid of a filter pump thus: the distillation flask is closed with a cork with two perforations, one of which is fitted with a short tube reaching only into the neck of the flask, and bent at right angles at the other end. This end is connected by indiarubber tubing to the air pump. The second perforation is fitted with a tube reaching almost to the surface of the ethereal layer contained in the flask, the arrangement resembling that of a wash bottle. The longer tube is connected to a drying tube about 40 Cm. long, 1.5 Cm. in diameter, filled with three-fourths of calcium chloride and one-fourth of caustic potash. The air pump being set now in motion, the remainder of the ether is rapidly evaporated, and the temperature of the flask sinks to freezing point, thus preventing the escape of any of the ethereal oil. As soon as the ice on the sides of the flask has disappeared, the vacuum is broken and the flask dried and weighed. Fresh distilled fennel and peppermint water will be found to contain 0.6 gramme of ethereal oil per litre, or 0.06 per cent. Concentrated aromatic waters cannot be tested in this manner, as they all contain more or less alcohol.—*Apoth. Zeit.*, 1897, 563.

ASSAY OF RED LEAD.—Baucher recommends the following process for testing commercial red lead:—*Foreign Impurities.*—Ten grammes of the sample are treated with 10 per cent. nitric acid until all the monoxide is dissolved. Invert sugar is then added to reduce the dioxide formed and render it soluble in the acid. The residue is allowed to subside, the liquid is decanted, and the insoluble matter again treated with nitric acid. The insoluble residue is washed first by decantation, then on a tared filter, and finally dried at 105° C. before weighing. The amount of insoluble matter should not exceed 1.5 per cent. *Determination of Dioxide.*—Ten grammes of the sample are heated on a sand bath for four hours with 500 C.c. of 10 per cent. nitric acid. After standing, the deposited dioxide is washed by decantation, collected and dried. The amount found should lie between 22 and 24 per cent. *Determination of Free Litharge.*—Ten grammes of the sample are digested on the water-bath with 20 grammes of neutral lead acetate, and 200 C.c. of water; after the insoluble portion has deposited the clear liquid is decanted, the residue washed, collected, and dried as above, the loss of weight giving the amount of free litharge. Theoretically, red lead should contain no litharge, but in actual practice commercial samples are found to give from 56 to 40 per cent. A red lead which contains a large proportion of litharge attacks zinc with great rapidity in the presence of sea water or fresh water rich in ammoniacal salts. This has an important bearing on certain technical applications of red lead. *Combined monoxide.*—This is determined by difference from the previously obtained figures. *Barium sulphate* is often used to adulterate red lead; it will be found in the insoluble residuum. Lime and the salts of other metals will be detected in the usual way in the nitric acid solution.—*Petit Moniteur de la Pharm.*, xlvii., 2651.

TESTING MILK SUGAR.—The following method is recommended by C. Beutner:—1.2 gramme of milk sugar are treated with 12 C.c. of alcohol, 60 per cent.; 10 C.c. of the resulting filtrate, representing 1 gramme of the sample, are evaporated on the water bath, and should leave only 0.03 gramme of residue. The average weight with pure milk sugar is 0.027. Milk sugar adulterated with 5 per cent. of cane sugar tested in this way furnished 0.076 gramme of residue. Deducting 0.027 for milk sugar, 0.049 or 4.9 per cent. is obtained for the cane sugar. Adulterations with 5 per cent. of glucose furnished a result of 4.7 and 4.8 per cent.; a mixture of 5 per cent. glucose and 5 per cent. cane sugar furnished a result of 9.6 and 9.7 per cent.; and an adulteration with 20 per cent. of glucose a result of 18.7 per cent. This test not only detects any adulterations, but also furnishes a good indication of their amount.—*Zeit. d. Allg. Oest. Apoth. Ver.*, lii., 6, after *Schweiz. Woch. f. Chem. Pharm.*, 1897, 589.

LETTERS TO THE EDITOR.

All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London, W.C., and not in any case to individuals supposed to be connected with the Editorial Staff no responsibility can be accepted unless this rule be observed. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ADVERTISEMENTS AND ORDERS for copies of the 'PHARMACEUTICAL JOURNAL' must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C. Cheques and money orders should be made payable to "Street Brothers."

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course no necessarily for publication. No notice can be taken of anonymous communications

LIQUORES CONCENTRATI.

Sir,—Your correspondent "Fluid Drachm" would wish us to think that he holds a brief on behalf of the poor dispenser. If I were the latter individual I would not have him for my advocate. For the sooner the dispenser sets himself with earnestness to think and work in terms of the metric system the better for him as to brains, pocket, and prospects. Again, let not dispenser think that the liquores concentrati are introduced into the Pharmacopœia for his convenience; as I read in the preface, page xvii., it is partly for that of the prescriber, but as to the dispenser, he, like one's good wife, should have his humour most when he obeys. Again, "Fluid Drachm" slides by the main issue and makes great importance of the merest trifles. "Alas" for my argument, says he (or she), "the liquors are uniformly 1 to 9. Yes; and there are only nine of them, which, with one representative of a well-known decoction, brings up the number to the fatal ten. How is this? In one list of a wholesale druggist before me I see enumerated no less than thirty-two so-called concentrated infusions, all of them 1 to 7; and in another seventy liquid extracts, all of them 1 to 1, with a note to the effect that these are they which have been most approved in medical practice, but they will be glad to prepare any others on request. Now this is a specimen of what I call unnatural uniformity. Orders—money—will do anything, but the responsible compilers of the Pharmacopœia, doubtless with plenty of money to spend, and plenty of scientific talent to boot, can find ten only of the one, and eighteen only of the other fit for inclusion in its pages. "Some of these compounds underwent deterioration on keeping, or were wanting in flavour and aroma, and were accordingly rejected"; and this being in accord with the experience of all who are competent to speak on the subject—except the traders themselves—could I not with justice have used a much stronger word than "Nonsense" to expose such absurdities? On the subject of doses "Fluid Drachm" would imply that the compilers were not sufficiently versed in arithmetic, that fragment at least of it which deals with the recurrent decimal, which, of course, is absurd. What we, as dispensers, are mostly concerned with is the fact that we have an official statement of doses—within wide boundaries—to fall back upon in case of need. All the minutiae concerning doses belongs to the prescriber; here, again, our wisdom consists in simple obedience.

Marylebone, N. W., August 16, 1898.

J. C. HYSLOP.

CHEMISTS AND THE SALE OF FOOD AND DRUGS ACT.

Sir,—Your correspondent H. C. Standage, in his haste to condemn, has fallen into several errors. Statistics show Erdington to be a healthy place; adulteration far below the average; and samples taken under the Food and Drugs Act to be well over the required two per 1000. I can also assure him that the Sanitary Committee of the Warwickshire County Council, which has the administration of the Act, is by no means harsh on the chemist, as a few weeks ago, when I brought forward the question of prosecutions under the new B.P., I was assured that the County Analyst, Dr. Bostock Hill, would pass any drug which corresponded to the standard of either the new or old B.P. until such time as the chemists and physicians had ample opportunities to familiarise themselves with the changes, and by special motion of the chair.

man I was elected to serve on that Committee so as to safeguard the interests of the trade. It may also interest your correspondent to know that the whole of the samples of drugs taken in the district last quarter were satisfactory, and that the inspector, whilst not ever in evidence, is by no means idle.

Erdington, near Birmingham.
August 16, 1898.

RICHARD HOLLICK.

Sir,—In last week's issue of the Journal I notice a letter signed "H. C. Standage," which contains a mistake, which is, I fancy, more or less common, viz., that the public analyst selects the samples to be analysed. As a matter of fact, he has nothing whatever to do with either the selection or the number of samples submitted to him. It is no doubt true that in many districts the Food and Drugs Act is very inadequately carried out, and that in many it is almost a dead letter. But this is the fault of the local authorities, and not of the analyst. The analyst is generally paid a very small retaining fee and a fee of one guinea per sample analysed. I have no doubt, therefore, that the majority of analysts would be only too glad to receive ten times the number of samples that they do now, either of food or drugs. The number of drugs analysed by all the public analysts put together must be very small, and out of all proportion to the samples of food (milk, butter, etc.) examined. The chief reason of this is, I think, the fact that the inspectors do not know what to ask for, and it is, and rightly so, no part of the analyst's duty to make any suggestions in that direction. I have no doubt that the drugs sold by pharmaceutical chemists are seldom adulterated (at any rate intentionally); but other people also sell drugs. I am strongly of opinion that the retail sale of poisonous drugs should be confined to pharmacists.

August 16, 1898.

PUBLIC ANALYST (139/36).

COMPANY PHARMACY.

Sir,—A most useful and suggestive letter appears in the Journal for August 23 from Mr. Glass. If it should set sharpwitted chemists re-perusing the Pharmacy Act, 1868, it will have effected much good. Mr. Gladstone once noticed the conventional rebuke "Be not wise above what is written" by saying, "Are we quite sure we are wise up to what is written?" I wish to put forward a few points from the aforesaid Act, subject to correction from the better informed of course. The preamble does not use the singular at all, but says "persons," therefore all the persons of which a company consists should be qualified, even if they be "legion," not that one should cover a multitude. Clause 1 says any person, but read with the preamble must still mean any or all, keeping open shop. Clause 3 says all persons, before the passing of this Act; not subsequently, which shuts out all interests since acquired (supposed to be). Clause 16 reserves rights to certain persons, therefore, no other rights can exist. Clause 26: The Privy Council may direct, etc. Would the Privy Council cause to be erased from the Register those guilty of covering, which is generally admitted to be infamous conduct, that is, professionally? Is the Register so kept that the names of persons covering can be identified? Generally; all or any persons keeping open shop must be examined: a company cannot be examined, therefore a company cannot lawfully keep open shop.

London, August 12, 1898.

E. WARRELL.

ETHEREAL OR ETHERIAL?

Sir,—It is perhaps too much to expect that the British Pharmacopœia should pay the same attention to questions of literary correctness as to the department of scientific nomenclature and terminology, which we have all seen revived again in connection with the issue of another edition of the work. It is therefore with diffidence that I direct attention to the spelling of the word "etherial" in this and in all the other text-books to which I have access. Ever since I have had occasion to consider the matter, I have been impressed with the incongruity of employing the spelling "etherial," which is so intimately associated with the sublimer subjects of poetry and astronomy, to the base, material, even though volatile products, of the pharmacy and chemical laboratory. The best authorities recognise both spellings, and, with your permission, I submit to your readers that this is a point which, though comparatively trifling, seems to call for the exercise of so much discrimination as I am disposed to claim for it.

August 13, 1898.

LIBRA (139/31).

AQUA SPIRÆA ULMARIE.

Sir,—Your correspondent inquires if meadow-sweet has been used in the preparation of a distilled water? During my apprenticeship in 1830 we distilled it from flowers by the sackful. The water was considered by ladies a good cosmetic and more agreeable than elder-flower water. I sometimes noticed a substance that crystallised on the apex of the cone, but my employers did not think it of any importance. It may, however, prove worthy of investigation in these days of patient research. Perhaps your correspondent may look out for, "and when found," "make a note of it."

Kew, August 16, 1898.

R. GOODWIN MUMBAY.

Sir,—In reply to Mr. G. Woodman, respecting this water, I find the following mentioned in the 'British Flora Medica (1877),' "the distilled water is said to be a good vehicle for other medicines," and "the flowers themselves have been used to strew about the room where patients are lying with fever, etc.," also "that the flowers were reckoned sudorific and antispasmodic, and a warm infusion has been given with success to provoke the appearance of receding or languishing eruptive diseases."

Sheffield, August 17, 1898.

J. PRESTON.

THE PHARMACOPŒIA DISCUSSION AT BELFAST.

Sir,—The discussion on the new Pharmacopœia, having extended far beyond the hour fixed for the concluding business of the Conference, was prematurely closed by the President. As there was no opportunity at the meeting for a detailed reply, Dr. Symes has desired me to deal, through the pharmaceutical press, with the points on galenic pharmacy raised by the various speakers. Mr. J. C. Umney alluded to the bad keeping qualities of liquor thyroidei. According to the Pharmacopœia, it should be "freshly prepared," but further on in the same sentence we are told that it is to be "kept" in well-stoppered, sterilised bottles. So that the efficacy or otherwise of the preservative depends on the construction placed upon the expression "freshly prepared." A well-known authority on these animal extracts told me that liq. thyroidei prepared with chloroform water (B.P., 1885) in place of phenol solution will keep good for quite six months—certainly the official liquor does not remain "free from any odour of putrescence for this period." Mr. Umney regretted the abolition of proof spirit on the ground that this standard is recognised by chemists and the Inland Revenue for export work. Whilst agreeing with him that for this purpose the proof standard is useful, I still strongly maintain that from the standpoint of the pharmaceutical laboratory the system of the Pharmacopœia is the more advantageous in every way. The Pharmacopœia is a guide for the preparation of medicines, and naturally does not study the convenience of those who export tinctures, etc., in bond. After all, the inconvenience to the latter is more apparent than real, for the many published spirit tables show the relation between proof strength and percentage volume at a glance. With reference to tincture of orange, what I wished to point out was that for the reason mentioned by Mr. Umney, the objections raised against the use of fresh peel have little weight. I think it would be inconsistent to officially state the equivalent of 90 per cent. alcohol in proof degrees as desired by Mr. Howard. 58° o.p. is well known commercially as the approximate strength, and having obtained the standard alcohol, all other operations can be conducted according to the Pharmacopœia system. Mr. Howard preferred to express the strength of the standard alcohol by weight instead of by volume. The official plan appears the more suitable for pharmaceutical purposes, 90 per cent. by weight being much stronger than and consequently too far removed from the rectified spirit of the 1885 Pharmacopœia. On the other hand, in order to take advantage of simple relations in strength the diluted alcohols would have been mixed by weight, a method which, where alcohol is concerned, is quicker and more accurate than measurement. Mr. Wells spoke of the inconvenience caused by changes in the strength of potent preparations like tr. nucis vom. This has been felt by everyone, and only emphasises the fact that the convenience of physicians has been the chief consideration with the compilers, and that as far as possible their object has been to simplify matters for the medical practitioner. Mr. Clague concurred in the view that the Pharmacopœia is a wholesaler's Pharmacopœia, and that retailers have not had sufficient to do with its compilation. A glance, however, at the list of names constituting the Pharmacopœia Committee shows that the retail element far outweighs the wholesale on that committee. I cannot

admit that the wholesale pharmacist is favoured more than his retail *confrère* by the new Pharmacopœia. The latter now makes his tinctures, etc., as easily as before, in some instances even more easily. The standardised liquid extracts, perhaps, are more difficult for him, but these serve as liquors for the extemporaneous production of the tinctures, etc., into which they enter, and thus render the economy claimed for such preparations officially possible. Mr. Clague also reproaches the wholesale houses for their want of magnanimity in not coming forward with a good formula for liq. gent. co. conc. This was one of those infusions experimented with by the compilers (under the advice, presumably, of the Pharmacopœia Committee), which underwent deterioration on keeping, or were wanting in flavour or aroma, and as wholesalers knew nothing of the contents of the Pharmacopœia until several copies of the work had been printed, it is not easy to see how they could have come forward with a good formula for the liquor in question. The presence of glycerin in tincture of rhubarb, which Mr. Clague wished wholesalers to explain away, can hardly be placed to their credit, for its use was recommended in 1893 by W. Warrington in the *Western Druggist* "to prevent precipitation, and render the tincture more permanent." A reference to this, as mentioned by Mr. J. C. Umney, may be found in the 'Year-Book' for 1893, p. 196. Mr. Farr did not follow my meaning with regard to liq. calumbæ conc. The suggestion was to use sufficient water at the second maceration to yield a definite quantity of product. The quantity of water would, of course, depend on the amount of liquid obtained at the first pressing. As the formula stands it is possible for the product to vary both in proportion of alcohol and extractive. Mr. Martindale was of opinion that the ext. casc. sag. liq. is not so good as the 1885 preparation on account of the absence of spirit in the menstruum and consequent imperfect solution of the resinous constituents of the bark. Although at first sight this is apparently a defect in the formula, experience shows that the concentrated aqueous solution of certain principles of the bark forms a very good solvent for the resinous portion, the latter precipitating on the addition of much water. Certain it is that after treatment with water, as in the B.P. process, neither boiling water nor proof spirit removes any appreciable amount of extractive from the marc. Ext. belladon. alch. generally occurs as a pale granular non-coherent mass, bearing little resemblance to an extract, and I did not intend to convey the impression that it possesses any of the physical properties of an ordinary extract. The ground on which Mr. Martindale defends the omission of the phosphate and hypophosphite syrups appears hardly tenable when the inclusion of liquor picis carb. and liq. pancreatis is called to mind, for precisely the same argument as to the undignified practice of imitating nostrums is applicable in those cases also. Might not the second difficulty which he mentions have been overcome by inserting very short characters and tests for the manganese, quinine, and other hypophosphites, etc., required in the formula? I am pleased that this important subject has been discussed at a meeting of the British Pharmaceutical Conference, a body which represents such varied interests of pharmacists, not only in Great Britain and Ireland, but throughout the British Empire, and the publication of whose proceedings affords such wide and desirable publicity to all matters considered at its sessions.

London, August 16, 1898.

F. C. J. BIRD.

AMMONIATED ALCOHOL.

Sir,—This preparation, when procured from wholesale druggists, is but too often very deficient in anhydrous ammonia unless prepared according to the Ph. Borussica 1847, and even then it only contains 10 parts in 100. In some cases I have known liq. ammon. fort., s.g. 0.880, to be mixed with s.v.r. and sent out as ammoniated alcohol, with the result that the addition of essential oils renders the liquid of course turbid. Some time ago I became acquainted with the proprietor of an ice manufactory, where he used anhydrous ammonia, and I induced him to saturate a quart of 60 o.p. spirit. In a few minutes after the tap was turned on heat was generated, so that ice had to be used: the result was an ammoniated alcohol which was as powerful as liq. ammon. fort., and in which essential oils were freely soluble. This article I have now kept in a well-stoppered bottle for fully six years, and although converted into Godfrey's essence its strength is unimpaired.

North Kensington, W., August 12, 1898.

PERCY WELLS.

ANSWERS TO QUERIES.

Special Notice.—Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable, but he cannot undertake to reply by post. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of senders. Questions on different subjects should be written on separate slips of paper, each of which must bear the sender's initials or pseudonym. Replies will, in all cases, be referred to such initials or pseudonyms, and the registered number added in each instance should be quoted in any subsequent communication on the same subject.

OIL OF BIRCH.—The simplest way of answering your question will be to try the experiment. [Reply to APPRENTICE.—14/19.]

PETROLEUM HAIR WASH.—The most effectual petroleum hair wash is nothing but odourless petroleum oil, flavoured with a little lemon oil. [Reply to J. A. D.—15/5.]

COMPOSITION OF MIXTURE.—Whilst prepared to assist readers to any reasonable extent, we cannot undertake to perform analyses of complex mixtures free of cost. Your customer should be asked to pay an analyst's fee. [Reply to PHARMACIST.—15/8.]

COMING OF AGE.—The fact of your attaining the age of twenty-one years would not release you from any legal contract or agreement into which you had entered. The question as to whether your contract was a legal one is a matter for a lawyer. It will probably depend upon the manner in which your indentures have been drawn up. [Reply to MEDICAMENTUM.—14/31.]

ILLEGAL SALE OF POISON.—Communications regarding the illegal sale of scheduled poisons should in all cases be addressed to the Registrar under the Pharmacy Acts, 17, Bloomsbury Square, London, W.C. All such communications are regarded as confidential. [Reply to J. T.—139/17.]

WATERPROOFING MATERIAL.—Apply, first of all, a hot solution of copper sulphate, 1, in water, 20. Thoroughly moisten the material with this; before it is dry again apply a solution of yellow soap, 42, in hot water, 20, and go over the surface already saturated with the copper, then dry. Possibly a solution of alum instead of copper will answer; if so try it. Take care that the soap solution is in excess, so as to thoroughly decompose all the copper sulphate. [Reply to G. W. M.—14/13.]

SKELETON LEAVES.—Immerse the leaves in a 1 in 8 solution of nitric acid until, on brushing with an old tooth or shaving brush the cellular tissue readily separates and leaves the skeleton. When the soft tissue has thus been removed, wash thoroughly first in a little very dilute ammonia, then in plain water. Finally bleach by immersion in a solution of peroxide of hydrogen freely exposed to the sunlight. This is best done in a wide-mouth (pickle) bottle. The time required to soften the cellulose will depend on the delicacy of the tissues. [Reply to A. H. N.—15/2.]

STUDY OF THE B.P.—There is nothing contradictory in the two statements, as you will see if you do not dissociate the one first quoted from what immediately follows in the same sentence. Some things, of course, you must commit to memory, but to depend upon memory only, instead of bringing the reasoning faculty into play, would be to commit an unpardonable error. Above all things do not for a moment imagine that we are attempting to provide students with a "short cut" to the study of the B.P. As a matter of fact, most students who work conscientiously on the lines indicated in our notes will cover much more ground than they would otherwise. [Reply to ARO.—139/26.]

OBITUARY.

NEED.—On August 7, the wife of J. Need, Chemist, Malvern. Aged 40.

STUART.—On August 15, John Edward Stuart, Pharmaceutical Chemist, New Bond Street, London, W. Aged 88. Mr. Stuart had been a member of the Pharmaceutical Society since 1850.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

Chlorophyll Produced in Obscurity.

A. Etard and M. Bouilhac find that *Nostoc punctiforme*, cultivated in perfect darkness in a suitable solution of glucose, affords a bright green growth, the colour of which is due to chlorophyll. The fresh colouring matter gives precisely the same absorption bands as fresh chlorophyll grown under normal conditions. It is an interesting problem whether the chlorophyll thus produced is physiologically inert, or if it retains the function of converting the sugar, in the dark, into other organic materials.—*Comptes rendus*, cxxvii., 119.

Ovalbuminic Acid.

By the action of iodine on powdered egg albumin in the presence of amorphous phosphorus and water, J. M. Albahary has obtained a decomposition product free from iodine which acts as an acid and gives a crystalline sodium salt, which has been obtained in fine needles. When liberated from this combination the acid melts with decomposition at 260° to 270° C. It is practically insoluble in water, also in solutions of neutral alkaline carbonates, but dissolves in mineral acids. From solution in hydrochloric acid it gives precipitates with picric acid, phosphomolybdic acid, and also with gold and platinum salts. In certain reactions it resembles caseo-albumin of A. Gautier, but this latter does not give either a gold compound or a crystalline sodium salt.—*Comptes rendus*, cxxvii., 121.

Alkaline Secretions of Ants.

C. Janet finds that instead of giving, as was expected, an acid reaction, test papers exposed in the chambers and galleries of ants' nests gave indication of a marked alkalinity, as long as the inmates were undisturbed. When, however, they were excited, the alkaline reaction was replaced by a marked acidity. It was found that this alkalinity was more intense in these species—the *Formicinae*—which secrete the greatest amount of acid venom. The alkaline secretion is furnished by the tegumentary glands, especially those in the buccal region. It is supposed that its function is to serve as an antidote to the acid venom and to prevent auto-intoxication of the insects when large quantities of formic acid are discharged by them when defending their nests.—*Comptes rendus*, cxxvii., 130.

Oil of Melaleuca Viridiflora.

Dobousquet de Laborderies reports most favourably on the essential oil of *Melaleuca viridiflora*, a native of New Caledonia, where it grows in the neighbourhood of Gomen. The oil contains 66 per cent. of cineol, some terpineol, a trace of butyric, valerianic, and acetic esters, and a terpene. The author makes the erroneous statement that oils of eucalyptus and of cajuput contain considerable quantities of aldehydes, which are toxic; the oil of *Melaleuca viridiflora* is stated to be free from these bodies. The oil has given good results in the treatment of tuberculosis and other respiratory affections; it was given in capsules containing 25 centigrammes, 4 to 10 of which were taken daily. Good results were also obtained in various affections of the urinary system; in cystitis, a 2 per cent. solution was useful as an injection. As an application in rheumatism and in neuralgia, the oil was also an extremely valuable agent. When employed hypodermically, it was free from irritant action. In commerce the oil has been imported under the name of "gomenol" or of "oil of niouli."—*Bullet. Gén. de Thérap.*, cxxxvi., 1.

Hydrocyanic Acid in Plants.

Hebert communicates to *Revue Independente*, the results of a wide series of experiments made to determine what plants contain or yield hydrocyanic acid. No trace of prussic acid was found in any of the *Aroidae*. The young green buds of *Ribes rubrum* gave a few milligrammes per 100 grammes, but the fully developed growing parts contained none. Traces were also found under like conditions in *Ribes nigrum* and *R. aureum*. Many rosaceous plants contain the acid, but it is not present in the cultivated plants of the genus *Rosa*. The embryo of the seeds of the Japanese medlar, *Eryobothrya japonica*, gives 0.040 per cent.; *Aquilegia vulgaris*, when in the young state, contains it to some extent in the combined form, as a body analogous to amygdalin, and to a less degree in the free state, in the flowers. In these it is almost all found in the ovaries. In fact, as a result of the investigation, it would appear that the presence of prussic acid or of bodies resembling amygdalin is practically confined to those parts of the plant which contain chlorophyll.—*Les Nouv. Rem.*, xiv., 271.

Adulteration of Saffron.

J. Wauters has made analyses of commercial varieties of saffron and its adulterations. A coal-tar derivative made by a German firm closely imitates the colour of the genuine drug, and is largely used as an adulterant. Curious to relate, it is itself adulterated with 75 per cent. of sodium chloride. Féminelle, derived from a species of marigold, which has long been employed to sophisticate saffron, is also coloured with a similar compound. In the assay of saffron, the proportion of genuine drug may be estimated from the amount of crocetin present, a microscopical examination reveals the presence of feminel, whilst the added colouring matter may be estimated by noting the percentage of sodium chloride present. A good test consists in trying the tinctorial power of a sample on wool, silk, and cotton. These materials strike a citron-yellow colour with a solution of the true drug, containing tartaric acid, which is not altered by subsequently treating the materials with potassium hydroxide. Under treatment with a solution of the spurious article, the wool takes a deep brownish-red; the silk a deep orange-yellow, and the cotton a lighter yellow tint; in each case the addition of potassium hydroxide causes a deepening of colour.—*Bull. de l'Assoc. Belge des Chim.*, xii., 103.

Oil of Cade.

Paul Adam has further investigated the characters of this natural product with a view to determine whether it is possible for the pharmacist to procure the genuine article. He obtained five commercial samples, and determined the density, viscosity and various analytical data. Considerable differences were noted, among them the viscosity varying between 32 and 360, the specific gravity between 0.9874 (at 0° C.) and 1.031 (at 14° C.). From the lack of uniformity shown by these average samples the author concludes that this drug, which formerly was held in high repute, will be dispensed with in the future.—*Bull. de la Soc. Chim. de Paris*, xix., 580.

Organic Glycerophosphates.

Adrian and Trillat have prepared several of the organic glycerophosphates, including those of cocaine, quinine, and phenylhydrazine. They find that these compounds are better obtained by the interaction of an acid salt with the organic base than by using glycerophosphoric acid itself. Their paper gives some of the properties of these important substances which are now engaging considerable attention among the medical profession.—*Bull. de la Soc. Chim. de Paris*, xix., 684.

GLACIAL ACETIC ACID—A NICE POINT.

BY JOHN C. UMNEY.

The British Pharmacopœia (1898) describes glacial acetic acid as containing 99 per cent. by weight of hydrogen acetate. In the 1885 edition it was described as containing "nearly" 99 per cent. of real acid. The characters and tests of the new Pharmacopœia, notwithstanding this slight alteration in description, are practically identical with those of the 1885 Pharmacopœia, and require that the acid shall have a specific gravity of 1.058; that it shall remain crystalline until the temperature rises above 60° Fahr. (15.5 C.), and that it shall indicate by titration 98.9 per cent. of real acetic acid, when titrated with volumetric solution of sodium hydroxide.

Now, although the acid is described as containing 99 per cent. by weight of hydrogen acetate, the temperature of liquefaction after crystallisation is not in accordance with this percentage.

The strength of glacial acetic acid may be determined more accurately by its melting point than by titration, and the melting point after solidification of glacial acetic acid of various strengths was the subject of a communication to this Journal by Rüdorff (series 3, vol. ii., page 241). From the results there quoted it will be seen that the solidifying point of a glacial acetic acid containing 99 per cent. of real hydrogen acetate is 14.8 C. and one containing 99½ per cent. is 16.65 C.

The following table is abstracted from Rüdorff's communication:

100 parts of mixture	Solidifying point.
Containing 0.0 of water	+16.7 C.
" 0.497 "	+16.65 C.
" 0.99 "	+14.8 C.
" 1.477 "	+14.00 C.
" 1.961 "	+13.25 C.

It is evident from this, and I have been able to confirm the results by experiment, that glacial acetic acid containing actually 99 per cent. does not remain crystalline after the temperature rises to more than 14.8 C.

The United States Pharmacopœia describes the acid as containing 99 per cent. of absolute acid, and states that at a temperature somewhat below 15° C., the acid becomes a crystalline solid, becoming liquid again at about 15° C.

Although the point must necessarily appear a very small one to pharmacists and others here, still it has an important commercial bearing to export druggists, many of whom are called to ship this concentrated acid in thousands of pounds annually.

Glacial acetic acid is admitted into New Zealand at an *ad valorem* duty of 20 per cent., but if the strength falls below that of the British Pharmacopœia it is required that 5*d.* per lb. duty should be paid upon it, practically five times as much as the proper duty already referred to.

The method adopted by the New Zealand Customs for the determination of strength has hitherto been based upon the liquefying point after crystallisation, and an acid which melted at a lower temperature than 15.5 C. has been subjected to payment of the amount referred to (5*d.* per lb.), such impost being justified by the statement in the British Pharmacopœia, which is viewed by the Customs chemical official as absolutely accurate.

It seems desirable, therefore, to record the fact that glacial acetic acid having a melting point of 15.5 C., will have a real hydrogen acetate strength of over 99 per cent., whilst an acid containing 99 per cent. or 89.9 per cent., which is the amount indicated by the titration in the British Pharmacopœia, will have a melting point of 14.7 to 14.8 C.

This trivial point has given rise to much correspondence between exporters in the city of London and importers in New Zealand, the latter expecting of course to be reimbursed for any duties in which they have been mulcted, the inaccuracy referred to notwithstanding.

ON THE SYNTHESIS OF ALBUMIN.

BY ALFRED H. ALLEN.

The announcement that Dr. Leo Lilienfeld, at the recent International Congress of Applied Chemistry at Vienna, had claimed to have effected the synthesis of albumin, will be received by chemists with considerably more scepticism than it has met with at the hands of the professional paragraphists. The circumstances of the announcement are not such as to encourage implicit faith in the reality of the alleged discovery, but Dr. Lilienfeld may be the victim in this respect of excess of zeal on the part of the reporters.

From the accounts which have hitherto come to hand it appears that it is not true albumin of which Dr. Lilienfeld claims to have effected the synthesis, but "peptone," which is a very different thing. It is said to be produced by the condensation of glycocine (amido-acetic acid) with phenol, by means of phosphorus oxychloride. The reaction is stated to occur quantitatively and with great facility, allowing of the whole process being shown at the meeting. Further, Dr. Lilienfeld is said to have demonstrated by the most conclusive tests the absolute identity of his product with natural peptone, or, according to some accounts, with true albumin. Seeing how very ill-defined are the chemical tests for "peptone," and that more than one kind of peptone is recognised, this part of the account must be received with caution. Still more doubt attaches to the statement that Dr. Lilienfeld's product has the same elementary composition as natural peptone (or albumin). Seeing that natural albumin and peptone both contain sulphur as an essential constituent, and that Dr. Lilienfeld's process does not involve the employment of sulphur in any form, there seems to be a screw very loose somewhere.

Although the description of the mode of formation of Lilienfeld's body appears to negative the conclusion that he has effected the synthesis of either albumin or peptone, it by no means follows that he has not produced an albuminoid substance of great theoretical interest. He has undoubtedly been working in the right direction; in fact, his method may not improbably have been suggested by the interesting and ingenious suggestions of Dr. P. W. Latham (Croonian Lectures, 1886).

Commencing with the fact that by the reaction of hydrocyanic acid on aldehyde, cyan-ethylic alcohol, $\text{CH}_3 \cdot \text{CH}(\text{CN}) \cdot \text{OH}$, is formed, Latham points out that the cyan-alcohols are, as a class, very unstable bodies readily undergoing change, and when treated with ammonia form unstable cyan-amides, which easily undergo condensation with formation of imido nitriles and elimination of ammonia. Latham thinks these facts suggest the inquiry: "Have we not in these cyanogen compounds substances possessing some properties that belong to living tissue, namely, those of undergoing intra-molecular change and also condensation? And, further, if from these substances we can obtain the various products which result from the disintegration of albumin, may not albumin itself be simply a compound made up of these elements?"

In the laboratory, it is practicable to obtain from these cyan-alcohols the corresponding amido-acids, glycocine, leucine, etc., and all the acids of the acetic and lactic series.

Latham suggests that, if it were found possible to reverse the process, albumin might be built up theoretically from such constituents.

Latham further instances the well-known molecular transposition by which ammonium cyanate is converted into urea, and quotes Pflüger's remark that the great molecular energy of cyanogen compounds suggests that the functional metabolism of protoplasm by which energy is set free may be compared to the conversion of the energetic unstable cyanogen compounds into the less energetic and more stable amides. In other words, that ammonium cyanate is a type of living, and urea of dead, nitrogen, and that the conversion of the former into the latter is an image of the essential change which takes place when a living proteid dies.

In accordance with this view the group, CO·NH, is dead nitrogen, and would, on becoming part of a living tissue, be transformed into =C:N·OH.

Cyanic acid, CNOH, is itself readily susceptible of polymerisation, with formation of cyanelide, C₃H₃N₃O₃.

Latham points out that the glycines are capable of uniting with each other, glycocine being not improbably glycocine amidacetate, H₃N { O·CO·CH₂ } NH₂; and that by the dehydration of this and allied bodies, cyan-alcohols might be formed.

Thus, a double molecule of glycocine by dehydration would give a substance which might contain either a CO·NH group or a C:N·OH group, according to the arrangement of the atoms in the molecule.

Trysine is a member of the glycine group, and has the constitution of a para-hydroxyphenol-amidopropionic acid. Latham shows that by coalescence with glycocine and elimination of water it would yield a body of the following constitution:—

By similar ingenious reasoning Latham shows how such a body as taurine may be introduced into the molecule, and he finally builds up the formula given at the end of this article, as possibly representing the constitution of albumin.

This suggestive formula contains C₇₂H₁₁₈N₁₈O₂₂S, and differs only by H₆ from Lüberküln's formula for albumin, C₇₂H₁₁₂N₁₈O₂₂S.

The discovery of lysine, lysatine, and trysophan or protein-chromogen necessitates some modification of the formula, which, of course, cannot be regarded as more than an ingenious and highly suggestive arrangement which might be of service as a working hypothesis.

Pflüger has observed, and Loew and Bokorny have corroborated the fact, that living proteid matter in the cells of various algæ reduces silver from a dilute alkaline solution of the nitrate, but that dead protoplasm or proteid does not give the reaction. Hence it is suggested that a compound of aldehydic nature exists in living protoplasm. By the reaction of formic aldehyde with ammonia, aspartic aldehyde may be supposed to be formed, a body which, though unknown, has the same composition as leucine. By its repeated polymerisation in presence of hydrogen and a sulphur compound, with elimination of water, the following equation may be realised:—6C₁₂H₁₇N₃O₄ + H₂S + 6H₂ = C₇₂H₁₁₂N₁₈SO₂₂ + 2H₂O.

Grimaux (*Compt. rend.*, xciii., 771) has proposed to define

proteids as "nitrogenised colloids, which by hydrolysis split up into amidated acids, carbon dioxide, and ammonia." On heating aspartic anhydride to 130° with urea for two hours, Grimaux obtained a thick mass, completely soluble in boiling water to a gummy, highly colloid liquid, yielding highly gelatinous precipitates with acids, alkaline salts, magnesium and aluminium sulphates, solutions of iron, copper, and mercury, and with tannin. The jelly yielded by acetic acid dried up to a substance resembling dried albumin. It softened in boiling water without undergoing solution, but dissolved in caustic potash to a liquid giving a violet coloration with cupric sulphate.

Of course, it by no means follows, as Dr. Lilienfeld is reported to have said, that a synthetical product of the same ultimate composition as peptone will have the same food-value. This fact is familiar to the mere tyro; but it may be of interest to recall the case of quinine, the synthesis of which may any day be effected. Already two distinct basic substances isomeric with quinine have been prepared synthetically, but neither base has the physiological characters of true quinine.

LATHAM'S FORMULA FOR ALBUMIN.

Public Health Congress at Dublin.

At Dublin, on the 18th inst., the Congress of the Institute of Public Health was opened at Trinity College, and the same day the Health Exhibition was opened in the Royal University. The presidential address was delivered by Sir Charles A. Cameron, M.D., President of the Congress, in the Examination Hall, Trinity College, and this function was largely attended by representatives from almost every part of the world. Handsomely got-up guides were extensively circulated, giving details *in extenso* of the daily programme between the 18th and 27th inst., on which latter date the exhibition will be brought to a close. The business of the Congress began on the day of the opening, when, following the President's address, a move was made to the Royal University buildings, where at noon the "Healtheries" was formally opened by the Lord Lieutenant, after which the remainder of the day was devoted to pleasure-seeking, including garden parties, concerts, etc. On Friday the serious business of the Congress commenced at 10 o'clock, and the reading of papers on preventive medicine and vital statistics, chemistry and meteorology, engineering and building construction, and a number of kindred subjects was indulged in, the Congress being divided into four sections, each presided over by its own particular chairman. Close on one hundred papers and addresses were submitted, but many of the former were taken as read.

A noteworthy feature of the Congress was the conferring of honorary degrees by the Apothecaries' Hall of Ireland and other licensing bodies. An inspection was made of the principal buildings in connection with the Public Health Department of the Corporation, and their working explained to the delegates. Large public works and institutions throughout the city were also visited. Excursions to various beauty spots in Ireland were largely patronised.

On Saturday morning, August 20, PROFESSOR TICHBORNE read a paper on

The Adulteration of Food and Drugs.

It was, he said, probably well known to most of the members of the Congress that it was contemplated, he might say promised by the present Government, to bring in a Bill to amend the Food Adulteration Acts. This movement was the outcome of a general consensus of opinion that the Acts as they stood at present were unsatisfactory in their working. He thought he was justified in saying that the public analysts were not satisfied, further, that vendors, *i.e.*, retailers, wholesale merchants and manufacturers, were also dissatisfied, whilst Somerset House, which was constituted a court of appeal by these Acts, seemed to be anything but happy. It had resulted in a most contentious kind of struggle all round, which had not added one iota to the settlement of the numerous questions in dispute; no side had gained in kudos. The public at large, who were really the most concerned, understood very little about the question, and in addressing the Congress on the matter he hoped to draw attention thereto, but at the same time he wished to avoid becoming the partisan of any particular class.

A Committee of the House was appointed, and finally reported upon the Foods and Adulteration Acts in 1896. It was originally appointed by the previous Government and was continued by its successor. The Committee carried on its investigation for three years and examined 68 witnesses, and he, the essayist, had the honour of being summoned before that Committee in 1895, but circumstances prevented him giving evidence before March, 1896. The report of that Committee was in three large Blue Books, and dealt in a most exhaustive manner with the whole subject. The evidence was taken from every standpoint. It dealt with a lot of special recommendations, many of which were of great value and certainly should be provided for in the Bill. But there was one great principle inserted in the recommendations of the Committee which Mr. Chaplin, who was bringing in a Bill on the subject, seemed to ignore. It was the backbone of the whole question, and its omission made light of the labours of that important and expensive inquiry. What was asked was that a representative board should be constructed whose functions should be to determine and fix the standards of the limits of purity and other questions as to the methods to be adopted. That question of the Board had been placed by himself

before the Committee in 1895; but, as he had already explained, circumstances prevented him from going forward to give evidence in support of it until 1896. He was pleased to see that Professor Hehner, who had been examined a few days before him, also advocated a very similar Board, and as that gentleman was supposed to be the mouthpiece of the Society of Public Analysts his evidence came with great weight. They had had no communication with each other. The merchants who felt aggrieved by some prosecutions regarded such a board as the way out of the difficulty, and after such a general concurrence of opinion, the Committee ended their labours by reporting also that this was the way to make the Acts work smoothly. Imagine the surprise of all interested to find that the whole matter was ignored in the new Bill.

He would illustrate what was meant by fixing a standard of limit by one of the most familiar instances which might be considered as typical of many more, *viz.*, the standard of limit as regarded water in milk. Water occurred as one of the natural constituents of milk. The vendor spun the milk out by adding more. Now in the milk analyses the analyst primarily divided his analysis into three parts—butter fat, solids less fat, and water. He was not now dealing with odd ingredients, such as chalk, sheep's brains, glue, starch, *et hoc genus omne*. Some of these adulterations were too gross to withstand the modern analyst, and hence become extinct. Now the butter fat was estimated to determine the "richness" of the milk, or to see if it had been skimmed, but the analyst relied upon the solid less fat to determine the added water, if any, thus:—

$$\left. \begin{array}{l} \text{One pint of milk (con-} \\ \text{tains a minimum of} \\ \text{solids less fat, 8.5)} \end{array} \right\} + \left\{ \begin{array}{l} \text{One pint of} \\ \text{water con-} \\ \text{taining no} \\ \text{solids.} \end{array} \right\} = \left\{ \begin{array}{l} \text{Adulterated milk con-} \\ \text{tains 4.25 solids less fat} \\ \text{or 50 per cent. of added} \\ \text{water.} \end{array} \right.$$

This seemed very simple if the solids of the pure milk were always constant, but unfortunately they were not. Even leaving out extraordinary samples, pure samples ranged from 8 to 11¼ per cent. It was self-evident that some standard of limit to pure milk must be fixed, and thus the term standard of limit (not an average as some would wish to establish). This limit should be of such a nature that the vendor could sell all his milk as long as it was pure and within reasonable limits, but it should not be one which would allow him to stretch his milk by the aid of the pump. This was one of the few food products which by general consent and general necessity they had arrived at a standard of limit, and that was that the solids less fat in milk should never fall below 8.5 per cent. But this very one was an apt illustration of the importance of standard as regarded the subject of adulteration. If they took up the book on 'Milk,' published in 1883 by Dr. Bell, the late head of Somerset House Laboratory, they would find a most interesting illustration of the importance of fixing fair standards. They found that standard of limit of solids less fat had been fixed by the Court of Appeal, if he might use the term, as 9 per cent., but at the foot of the page in the same book they found a note that Dr., now Sir Charles, Cameron in 1881 conclusively showed that the majority of country cows would not respond to that high limit, and so it had been altered by general consent to 8.5 per cent., his view being endorsed by analysts in other countries. Assuming such to be correct, did it not show that hundreds of men for some years had been unjustly prosecuted, and in many cases heavily fined? As a rule the milk vendor deserved all he got in that, but let them be just, or the law would get into disrepute. In dwelling upon this part of his subject, the speaker said he only wished to emphasise the importance of fixing these standards, which must be placed in the hands of those who know what they are about, and that they were not questions which could be left to the individual caprice of any one who chose to adjudicate. As long as Somerset House was the court of appeal they must be represented upon the Board of Control; but so must the analysts and the vendors through their Chamber of Commerce, and as these Acts covered drugs, so must the medical profession, however constituted; but he was sure no special Government Department would ever settle these questions to satisfy contending interests. They had tried it and failed. What did it matter if the Board

were called the Board of Inland Revenue or the Board of Agriculture?

Preservatives.

The question of the use of preservatives in food products, such as boric acid, salicylic acid, formaldehyde, calcium bisulphide, etc., was a burning one at the present time. Some analysts were for prohibiting such preservatives altogether. Others said they might be used in limited and restricted quantities; but the manufacturers said it was right to use them without limit, so long as they produced wholesome products. Now, who was to determine whether the preservative used was wholesome, whether necessary at all, and if so, what should be the maximum quantity allowed? He found there was the greatest diversity of opinion upon these cases when they came into courts of law. He maintained that such questions should first be dealt with by a Board, who would approach the question from a judicial and unbiassed position, and no manufacturer should be allowed to use any substance for such purpose which was not permitted. If a preservative be allowed, the amount allowable should be specified and the food products named in which it was permissible, and they should never be allowed to be used in quantities for the purpose of weight making. Salt, alcohol, spices, hops and many other things had long been employed, and no one would think of objecting to their use, because of their properties being so well known. Why should one stand still and refuse to make use of the progress of science in that direction if they were equally harmless?

The New Pharmacopœia as a Standard.

He wished to make a few observations upon the important question of the new Pharmacopœia as a standard of adulteration of drugs. It would afford subject matter for a lengthened communication by itself, but time would only permit him to glance at it in the most superficial manner. As regarded drugs and their preparation, the old Pharmacopœia had always been accepted as the criterion, and its standards of purity used by the courts. The Pharmacopœia of 1898 would not be likely to lose ground in that respect. As one of the Committee who formed the new B.P., he could state at once that although it was not compiled from the point of view of being an analyst's book, the tests had been very much extended and made more crucial, besides which the standardising had had more attention paid to it. It was no longer a student's book, but was intended to be a work of reference, first for the medical man, and indirectly for the analyst. Thus processes of their *modus operandi* were ignored, but standards of purity and strength were minutely detailed. It was a book for the expert. Now, taking the new Pharmacopœia as a whole, they would find that with a view to making the medicines more efficacious the cost of production had been greatly enhanced. Thus the commercial value was very much increased, and a corresponding tendency to adulteration would be created, at least it would be so for the next few years, which might be called the transition period. An endeavour to substitute the old pharmacopœial preparations would be very common. There was a term which had become very familiar in Dublin, namely, "The housing of the very poor," but there was also a very important question, and that was the physicking of the very poor. He meant that they should see that the medicine which the medical officers prescribed should be pure and up to strength. This was a question of life and death, and the medical officer could not do his best if he were not backed up by a proper supply of medicine.

They could only trust to the Local Government Board to see to that important question; but the present orders were in direct variance to such a reform being carried out, and their order was that the lowest contract in money value for drugs to the Poor Law Union must be taken. How could the honest contractor work against such an order when some of the contractors openly said they were not bound to supply the new pharmacopœial preparations? What were the medical men to do? The Local Government Board say they must trust to the medical officers to keep up the quality. How could such a proposition be carried out? The strength of ninety-four articles in the Pharmacopœia had been changed. The medical officer prescribed that useful medicine hypodermic solution of morphine, an invaluable medicine, but at the same time a deadly one. He thought he was giving one-twentieth of a grain of morphine, but he was really giving double that quantity. Besides, why should the medical officers convert themselves into analysts, even if they possessed the very special training necessary for such work? They were not paid for it. They had no time to

hold two distinct and separate functions, and many complications might arise which would place them in a false position.

The New Adulteration Bill.

But the most extraordinary part of the new Bill was the fact that it was brought in under the misleading name of "Agricultural Products, etc. (Adulteration)." A Bill brought forward this Session, but which was, he believed, only a pulse-feeler of the contending parties, was introduced, to be at once dropped. It was, however, held suspended over their heads for the next Session. The "etc." was not his insertion, but really stood as the heading of the Bill. It had evidently been found necessary to explain the objects of the Bill by saying "Adulteration." Something on the principle of Artemus Ward's picture of a bovine, underneath which appeared the statement "This is a cow." He did not think there was another Act in existence with a title similar to that referred to, but, strange to say, it was endorsed by Mr. T. W. Russell, who was Chairman of the Adulteration Committee. Mr. Chaplain, in introducing the measure into the House on July 22, said it was alleged that the existing Acts would be perfectly adequate if they were efficiently administered. Now, the very existence of the three years' Committee was based on the assumption that they were not adequate, and the verdict of the Committee was that they were quite inoperative, and in many cases unjust in their working. It seemed to him to shift the responsibility very much on to the Board of Agriculture. That Board might have a great deal to do with the question of butter and milk and the contagious diseases of animals, but surely it was a very narrow view to whittle the question to such limits as these. What had the Board of Agriculture to do with the subject of adulteration of wines, medicines, and such-like questions? As regarded the Court of Reference Mr. Chaplain said that the Committee recommended a Court of Reference, as it was termed, to prescribe standards of quantity and purity for all kinds and descriptions of food, but in place of what he (Mr. Chaplain) thought would be rather cumbrous machinery for the purpose of this Bill, he would propose that the Board of Agriculture have power to make regulations, etc. Would not the Board of Agriculture be a very cumbrous machine for fixing the standards, and whom would it satisfy? It did not even satisfy the Chambers of Agriculture. It contained a few clauses which would be very useful in connection with the importing of adulterated products from other countries, but which would have to be greatly modified to make them practical, but save as regards this they found the whole Act was contrary to the recommendation of the Government Committee. Professor Tichborne concluded his paper by expressing his belief that they got too much centralisation of local departmental details executed in London. If they had a Court of Arbitration it would, perhaps, be said that it would be necessary to meet in London. Very well; but Ireland and Scotland must have their representatives thereon, and when experts had to do departmental work it should be done in Ireland and Scotland. The Court of Appeal for Ireland should be in Ireland, not in London. Every phase of work removed from Ireland helped to make it discontented, and not worth living in, and it became a returnless waste to the most intellectual of its inhabitants.

Mr. R. J. Downes, president of the Pharmaceutical Society of Ireland, said the Bill to which Professor Tichborne had drawn attention was one of those numerous kites which the present Government was fond of flying. The kite used to be a useful scientific instrument, and was employed to ascertain both the direction and force of the wind, and, with the aid of an attached thermometer, the temperature; and he believed when they saw these kites, if they were interested they should blow their strongest and their hottest. Flying a kite was useful to see if it was well balanced, but looking back to his school days, a very important part was the adjustment of the belly-band, and that was, he thought, just the part to which Professor Tichborne drew attention. The Bill itself, if they knew more of it, might be a very superior Bill, and one which they might approve of; but the Board of Control was the essential part which required to be adjusted to make it carry and to render it workable. A Board of Reference on which would be represented the persons to be chiefly affected, but that Board would sit in London and fix standards, but there should be local boards of administration, and it should not be necessary to send all disputes to Somerset House to be upset or confirmed there. Ireland and Scotland should have their public laboratories, and in Dublin they could be easily

established and worked. As instances of the need of a Board of Reference that would control those matters in things affecting one's own trading, one of the earliest troubles they had had in England was over milk of sulphur, a preparation which had been and was still in demand. In 1864 for the first time the pharmacopœial authorities inserted precipitated sulphur, a very proper article to have in the Pharmacopœia, but milk of sulphur was an impure precipitate containing lime, but still preferred by the public for various reasons, but the analyst insisted on having the pure precipitate when milk of sulphur was asked for. Another innocent preparation known as lime juice and glycerin, many years before the public as a toilet preparation, the analyst has discovered contains no glycerin. This article was first named, he believed, under the impression that whenever there was saponification glycerin was liberated. These were instances in which a Board of Reference would not, he believed, have sanctioned prosecutions. As regarded the Pharmacopœia, it was of course a standard for all medical prescriptive work, but otherwise it might be questioned. Previous to 1885 linseed meal was the ground linseed cake, but in the Pharmacopœia of that year it was misdescribed as ground linseed under the old name of *lini farina*, and prosecutions ran over England and came across to Belfast, and thence to Dublin. He maintained that the old article had not lost the right to its own name any more than that their own Sir Charles Cameron should lose his because another Sir Charles was created. At last the case came before the Queen's Bench in Dublin, with the result that the judges decided that linseed meal was a domestic remedy, and that cake meal might be sold for it by the grocer and general merchant, but that if bought of the druggist it was a medical article, and the Pharmacopœia article should be supplied by the druggist. In the present year the Pharmacopœial authorities have thrown out the tincture of orange peel, which was sold since the days of Christeson, and appropriated the name to a new article introduced in 1885 under the title of *tinctura ourantii recens*, but the old tincture had by no means lost favour, and if pharmacists sold it as asked for he had the food inspector hovering over him, and if the doctor wished to order it he must indicate it by affixing a date to it. These also, he thought, indicated a necessity for a Board of Control on which the various bodies interested and likely to suffer by the zeal of the analyst should be represented. At this juncture the time allowed for discussing the paper expired, and Mr. Downes was unable to add to his remarks. There was no other criticism on the paper.

On Tuesday, August 3, Mr. R. J. DOWNES, President of the Pharmaceutical Society of Ireland, read the following paper before the Congress, on

Legislation as Regards the Sale of Poisons.

It is of interest that the first attempt to regulate the sale of poison in the United Kingdom is an Act of the Irish Parliament in 1791, which incorporated the Society of Apothecaries, and known as the Irish Apothecaries Act (31 George, cap. 34).

Section 28 provided that "Arsenic is not to be kept with medicines. No apothecary within the Kingdom of Ireland shall grind, compound, sell, or keep arsenic, oils or colours for painters' use in the shop or room wherein he compounds medicines, under a penalty of five pounds." This would indicate that the art of an apothecary was very mixed at that date.

Section 30 provided that "Less than one pound of arsenic to be entered. Every apothecary, druggist, or other such person selling any quantity less than one pound weight of arsenic shall, at the time of such sale and before delivering, enter in a book to be kept for that purpose the quantity sold and the time when it was sold, to which entry the person buying shall sign his or her name, addition, and place of abode, or in case such person so purchasing cannot write, the name, addition, and place of abode of such person being written, such person shall set his or her name thereto, and the same shall be attested by such apothecary or druggist or some other person present; and in case such apothecary or druggist shall not know the person buying to be of such name or place of abode, then such apothecary or druggist shall not deliver such arsenic until it shall be certified to him by some person known to such apothecary or druggist that the person buying is the same as he or she describes himself or herself to be; and in case any apothecary or druggist selling arsenic shall fail herein, he or she shall forfeit the sum of twenty pounds to be recovered as hereinafter mentioned."

Section 31 provided that "If mischief shall arise by arsenic sold and the apothecary to die, such book to be received as evidence."

These sections appear to be the fountain head of subsequent legislation. It is interesting to note that there is no mention of a label of any sort; that the druggist is mentioned as distinct from the apothecary; that the book is to be received in case of the death of the apothecary, and the word "she" which occurs in the final clause of Section 30. The label is the only advance in the British Acts, the clause as to identification is more specific in the Irish than in the British Acts. From the expression on "other people selling" it would at first sight appear that others than the "apothecary and druggist" might sell, but if so, the word "such" is out of place. We know from experience that down to much later than the middle of this century the druggists' business was a very close one; no one was allowed into it without apprenticeship, the term of which varied according to the age of the apprentice, from seven to five years generally, ending by maturity at twenty-one years, at which age he obtained his "freedom," so that the druggist in Ireland was always an experienced man.

The druggist in England also probably existed from time immemorial and learned the business, as all businesses were learned in those days, by service. We find that they were so early as 1815 in organised opposition to the efforts of the London apothecaries, who had been from the time of their incorporation, in 1794, planning "heroic measures for their suppression."

The first British effort to regulate the sale of poisons was the Arsenic Act passed in 1885, and it is remarkable that even at this date there is no mention of a label. It extended to Ireland without repeating the clauses of the Irish Act, and required the arsenic to be coloured; it fixed 10 lbs. as a quantity which might be sold without colouring, except when sold by wholesale; it exempted medical prescriptions and "the sale of arsenic by wholesale and retail dealers upon orders in writing in the ordinary course of wholesale dealing." The penalty is "not exceeding £20."

In 1857 and 1859 attempts were made at legislation to regulate the sale of poisons which were not successful. In 1863 the "Act to prohibit the sale and use of poisoned grain and seed" was passed, which was followed in 1864 by "an Act to prohibit the placing of poisoned flesh and poisonous matters in plantations, fields, and open places, and to extend the Poisoned Grain Prohibition Act, 1863."

Between this and 1868 several attempts were made to compass the control of poisons in general, and to obtain the exclusive right to the compounding of medicines to the pharmaceutical body which had been incorporated by Royal Charter, date February 18, 1843. This Charter was confirmed by Act of Parliament in 1852, which "greatly strengthened the position of the Pharmaceutical Society, as it secured the protection of the title "Pharmaceutical Chemist," "Pharmacist," etc., and gave legislative authority to the examinations and other transactions of the Society, but it left the business and title of "Chemist and Druggist," including the sale of poisons, open to anyone without restriction, excepting that provided by the Arsenic Act.
