EARLY SYMPTOMS AND DIAGNOSIS OF TUBERCULAR JOINT DISEASE.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY EMMET RIXFORD, M.D.

SAN FRANCISCO, CAL.

In view of the fact that there are to read two papers, besides the present, on the symptoms and diagnosis of tubercular joint disease, it has seemed best to me to confine my remarks to a limited portion of the subject rather than to attempt to cover a larger field. I have chosen as a fitting introduction to the study of tubercular joint disease to say a few words on the value of early diagnosis in these conditions, and the relations between diagnosis and the therapeutic measures at our command.

In most medical matters it is best on general principles to make the diagnosis when the case is first seen, but this means that it is best largely as a matter of convenience and to enable the attendant through early prognosis the better to control his patient, for a little delay in instituting treatment would make almost no difference with the patient's welfare. The cases are few where therapeutics are so perfected as to permit of the disease being aborted, or much modified by treatment, even if seen in the very beginning.

In tubercular joint diseases, however, it is quite otherwise. Here we are dealing with a disease which begins insidiously and progresses so slowly as to require observation for a considerable period of time to make that progress evident. Changes in symptoms are to be noted not day by day, but week by week, or perhaps only month by month. The time element here holds a prominent place.

When we consider that the chief factor in the extension of the disease is traumatism more or less frequently repeated, we at once see the value of an early diagnosis, for orthopedic surgeons taking the hint have worked out the mechanical problem of how to avoid such traumatism. By this, the so-called conservative method of treatment, the real cure is left to the innate resistant and reparative forces of the organism, stimulated by intelligent support of the general system. If such treatment can be instituted at a time when the disease is limited to a small collection of granulation tissue, say in the articular extremity of a bone, the joint can be put in the best possible condition as regards probable cure.

Experience has abundantly shown that this method of treatment when begun early gives excellent results, but it requires the constant attention of the surgeon for from two to six years, a hardship on the medical attendant, and on the parents, and most of all on the child. To initiate such a course of treat-

ment in a delicate sensitive child is like passing sentence of imprisonment for a like period of time—it would be justified only by the extreme conditions of the case. It were almost criminal to pass such sentence on circumstantial evidence or in fact on anything short of almost absolute certainty in diagnosis.

Then again these children are mostly offspring of the poor who can not have the means to procure properly healthful surroundings and who all too often, their patience exhausted in the long siege, willfully or ignorantly neglect those measures within their reach.

Were some more direct method of treatment shown to give equally good results in regard to function it would be more than welcome. Of such methods there are a number which, though still in the experimental stage, bid fair to be of value.

Early excision of tuberculous foci at a time when the disease is confined to small areas outside the joint proper has been long practiced and is theoretically, where it can safely and thoroughly be carried out, an ideal treatment. To drill out the neck of the femur through the trochanter in coxitis, enucleating the tubercular foci in the head of the bone may be a rational procedure under certain conditions and may be carried out by those who have the requisite skill, but to be justified it must be done early and at a time when the diagnosis is most difficult. Not only must the diagnosis of tubercular coxitis be certain but the lesion must be accurately located in the head of the femur. The procedure is by no means an innocent one nor is it certain that in a given case there might not be left a portion of the diseased tissue. Further, there may be more than one focus of disease, and of this we have no means whatever of determining the existence. After all, granting that the technique of the operation can be perfected the whole matter hinges on the diagnosis. Senn says that with the exception of circumscribed points of tenderness outside of the joint, that indicate the existence of primary osteo-tuberculosis during its early stages, we have no symptoms which enable us to make a positive differential diagnosis between a primary osseous and a primary synovial tuberculosis of a joint. In the superficial joints such points of tenderness can be located, but that is quite out of the question when the focus of disease is in the hip or in the deeper parts of the other large joints. However, those cases in which the muscular atrophy is rapidly progressive are quite certainly of osseous origin, or at least involve the bone.

Another method of treatment and one which bids fair to be more generally applicable than early excision is puncture and injection of iodoform directly into the foci of disease. This requires, with the latter, the most perfect aseptic technique, fairly accurate localization, though there is little or no harm done by injecting sterile iodoform emulsion into the

tissues about a joint and if the emulsion is not known to be sterile it should not be used at all.

A number of other methods have been suggested, some of more or less value, the latest of which is that advocated by Bier in the Twenty-first German Surgical Congress. In a second paper in 1893 he reported forty-three cases of surgical tuberculosis treated by this method, which consists in causing a continuous hyperemia of the extremity for a number of weeks. Many of the cases were cured within three months. The method has been taken up by Mikulicz who has seen from it sufficiently good results to think it of considerable value. If this simple procedure proves to justify the hopes of its originator it can be tried as soon as the diagnosis is made and as it is thoroughly innocent the diagnosis need not be absolute.

The study of diagnosis and treatment should go hand in hand. Important as it is to make the diagnosis in tubercular joint disease at the earliest possible time, the diagnosis should be made certain before such severe measures as long continued immobilization or operative procedures are instituted. In most cases, if immobilizing apparatus be applied early, the symptoms of muscular spasm, pain and even tenderness will soon subside and unless the diagnosis is certain in the beginning, there will be a lurking suspicion that an error has been committed and the child is being badly punished. In other departments of medicine in case of doubt it is generally advisable to settle upon the more severe of the diagnostic possibilities, but here a little delay sufficient to clear up the doubt is the lesser of the two evils as long as there remain to be devised methods of treatment entailing less hardship on the patient. Unfortunately, too, there is no symptom or group of symptoms which determines with certainty when a tubercular joint is permanently cured. The case is not unlike that of syphilis. In many instances it is impossible to make the diagnosis, no matter what the probabilities, before the appearance of secondary symptoms and it is a very severe thing to initiate a long course of mercury and iodid of potash in a case of doubt. So in tuberculosis of the joints, the diagnosis is not to be made in the very beginning of the disease; we must wait for certain symptoms and sometimes, be it said, characteristic symptoms are late in making their appearance.

I do not wish to be understood as really advocating delay, but rather as emphasizing the necessity of making the diagnosis certain beyond reasonable doubt and then the earlier the better.

We have still too many cases of rheumatism developing into hip joint disease and too many cases of hip joint disease with cautery marks and blister stains about the knee joint.

In view of the previous considerations let us consider at what stage of the disease the diagnosis is to be made with certainty. Taking tubercular coxitis as the type, in general the first symptom to be noted is almost invariably the limp, an evidence of more or less conscious pain. There is nothing characteristic about this limp—it may be simulated by a number of other conditions. Its real value is to direct the attention of the physician to the child's hip, that he may the more carefully observe the case and watch for more definite symptoms. Actual pain about the hip, or pain reflected to the knee, makes the diagnosis of coxitis probable, but in many

cases pain severe enough to attract attention is entirely wanting. It seems to bear no definite relation to the extent or character of the lesion. Of most value in making the diagnosis are symptoms ascribable to inflammatory irritation, chief of which is spasm of the muscles controlling motion of the joint. No single symptom is characteristic of tubercular joint disease but the nearest approach to it is this muscular spasm, especially if it varies in intensity and intermits. A case in point deserves mention:

A boy of 5 years in whose family there was a case of pulmonary tuberculosis was noticed to limp for several days. The right leg was held somewhat everted, slightly flexed and abducted, though the boy would stand perfectly straight when his attention was directed to his position. Considerable joint pressure made in various directions failed to elicit pain; movements of the leg were normal in extent and painless, save adduction which was slightly limited, as was also rotation of the thigh in the flexed position. The child was kept under observation without treatment and the limp entirely subsided in a week or two. He was seen from time to time for several months but no further evidence of hip joint disease appeared.

Another case in a boy of 14 whose brother came to me nearly a year ago in the so-called third stage of hip joint disease with a large abscess, has had a hip-joint limp for many months. It varies in degree, subsiding almost entirely at times. He has occasionally had a little pain in the region of the joint. The leg is habitually held in slight flexion but abduction is more marked. Adduction is somewhat limited. There is no shortening. There is a slight fullness to be made out about the hip. Vigorous movement up to the limits of range failed to bring out expression of pain as did also severe joint pressure in various directions. It was thought to be a low grade of inflammation in a bursa in the region of the lesser trochanter. The boy is kept under observation and without treatment the condition has materially improved though there is still a considerable limp at times. His general health is excellent and he is a lively growing boy.

EARLY SYMPTOMS AND DIAGNOSIS OF TUBERCULAR JOINT DISEASES.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY A. B. JUDSON, M.D.
NEW YORK.

In writing on the subject proposed by our honored chairman I have limited my paper to the consideration of Pott's disease of the spine and hip disease. These affections present many difficulties, especially in the early diagnosis. In diseases of the other joints the same principles and methods of examination hold good and diagnosis is easier because the bones lie nearer the surface.

POTT'S DISEASE OF THE SPINE.

The most important symptom of Pott's disease of the spine is pain in the stomach. Two lines which should find a place in the *vade mecum* of every physician are: "The pain of spine disease is in the stomach," and "the pain of hip disease is in the knee." No prescription for recurring colic should be written, unless it is preceded or presently followed by a careful questioning of the health of the spinal column. The inspection thus prompted may reveal a projection in the median line which should be located by counting the spinous processes downward from the vertebra prominens (seventh cervical), or upward from the fifth lumbar, which is in the line connecting the posterior superior spinous processes, or the result of one method may be verified by the other. The rounded back of rickets or spastic con-

traction should not be mistaken for the deformity caused by vertebral caries. In the lower dorsal region, from the sixth to the ninth inclusive, it is also well to avoid a peculiar source of error. The spinous processes of these vertebræ have a great inclination downward, overlapping like the shingles on a roof, and when a thin patient stoops they approach the horizontal, and pushing against the skin make a projection which has often led to error or unnecessary apprehension. This mistake may be avoided by noticing whether the projection is angular or not.

The expression, *angular curvature*, has been criticised because an angle and a curve are essentially different. But in practice the term is admissible and convenient, because the long natural curve of the spine is broken in Pott's disease into two short curves which are united and make an angle at the point of union, as shown in the figure. This point may not make a marked projection, but if it marks the union of two curves even in the slightest degree, as shown in the figure, it means that caries is present and has proceeded to very serious destruction of the bone. A moderate lateral curvature is also sometimes present. An angular curvature then is usually an absolute demonstration of the presence of Pott's disease.

Stephen K., 4 years old. Pott's disease. Duration of symptoms, four months. Normal curve broken into two curves united at an angle.

But it is sometimes desirable to make or approximate a positive diagnosis before angular curvature occurs, and to do this several things are to be borne in mind. The first and most important has already been mentioned; the pain in the stomach, or gastralgia. Next in importance is the peculiar gait. The child in walking avoids stamping with his heels and puts more of his weight on the toes than is customary; or he walks as if he were stepping on a surface which he fears will break if he is not careful; or the line made by the top of his head as he moves across the room is noticed to be rather a straight line than the undulating line made by the rising and falling of the head in the buoyant gait of a well child. And then the deportment of the patient is to be considered. He will play quietly by himself perhaps, or, easily tired, he will frequently lean across the mother's lap, or, if the caries is at a high level he will often support his head with his hand, the elbow resting on a chair or table. He is disturbed by the jolting of a carriage or street-car. He will sometimes be stopped in the course of a rough game by a seizure of pain in the stomach, the laughter ending in cry-

ing. A common sign is a frequent or habitual grunt accompanying each expiration. By following these lines of observation a conjectural or rational, and sometimes a positive diagnosis may be made before angular curvature appears.

In making a diagnosis but little attention may be paid to the general condition. Many cases are seen in which the health remains good in the early stage, as is shown by the normal appetite and digestion, abundant fat, and good facial color and expression. While these signs of health are present and persistent the disease in question may be in quiet pursuit, and this insidious quality should not be forgotten.

In two points, thus far, we have seen that the unexpected has claimed our attention. The pain is in the stomach and not in the back, and the general health shows, as a rule, no reaction. But there is another surprising thing to be noticed in the fact that, although the patient's back is virtually broken, local disability, which is usually found in parts which have lost their bony integrity, is almost entirely absent. So true is this that when we hear of spinal pain and disability we at once think that there is no Pott's disease. If these alarming symptoms are present, together with a comparatively frank onset, it is necessary to think of cancerous disease of the vertebræ, or paraplegia dolorosa. I have seen two or three verified cases of this disease which were believed at first to be Pott's disease and other cases are in my memory which, with a fatal termination unexplained in the absence of autopsies, may have been instances of the rarer and more intractable affection

HIP DISEASE.

Two precepts which should be deeply inscribed in the memory are: "The pain of hip disease is in the knee," and "the pain of spine disease is in the stomach." Recurring pain in the knee, in the absence of physical evidence of disease in this joint, should call early attention to the condition of the hip. But the pain of hip disease, except as an alarm, is not often an important element in diagnosis. It belongs to the group of subjective symptoms and may be almost disregarded in favor of objective signs in an affection which displays so many physical evidences of its presence. Among the first signs is lameness which, in the early stage, may disappear entirely to return after an interval of days or weeks; it is present sometimes in the morning when the patient leaves his bed, and "wears off" after a brief period of activity; it breaks up the natural rhythm of walking, in which equal time is given to the two feet, leaving the well foot on the ground longer than the affected foot and leading the former to give a more accented stroke as it hastens to relieve the latter from the weight of the body. Akin to lameness is the attitude "at rest" in which the patient stands favoring the affected limb, which is abducted and advanced while the weight of the body is principally thrown on the well limb.

Next to lameness in the order of obviousness is the muscular atrophy, seen in the flattening of the nates, as the patient stands with his clothes removed, and in the characteristics of the gluteal fold, which is shorter and more shallow than that of the unaffected side, and recognized by the tape measure which shows that the thigh and leg are less in circumference than those of the well side.

Then comes the most valuable, and yet most fre-

quently neglected, sign of the early stage, the checking of passive motion by reflex muscular action. This is found earliest perhaps in rotation. Let the patient sit on a table with the legs hanging over the edge and then impart a lateral pendulum like motion to the foot and leg and note whether the arc of motion is less on the suspected side. Or let the patient lie supine on a hard bed or table and impel the limbs, giving them a rolling motion in inward and outward rotation. On the well side the inner and outer borders of the foot will in turn strike the table, or nearly so, while on the suspected side rotation may be obviously limited. Limited abduction, adduction and flexion may be sought manually by testing the passive motion of the two sides alternately. The patient may be induced to give himself a test for limited passive flexion by grasping the shin and kissing the knee. On the suspected side he may not be able to bring the knee to the mouth. These examinations should be made with deliberation and the utmost gentleness, for our object is to detect very slight differences in muscular action or even to recognize the reluctance of the muscles to relax in certain directions, although they may not yet by their spasmodic action prevent wide motion.

Aside from this reflex interference with passive motion, it is instructive to note the deportment of the adductor muscles as revealed by the hand placed on them. They may be entirely relaxed, but when passive motion is begun they may suddenly contract and remain in spasm till the attempt at passive motion ceases and the limb is allowed to remain quiet. Or the abdominal muscles, as well as the adductors, may make a single reflex spasm the moment passive motion is begun.

In this, the early stage, all these reflex signs should be sought for in both limbs for the sake of comparison. By comparison, too, the inguinal fold (as well as the gluteal) may be seen to be short and shallow, or the surface over the capsule of the joint may be slightly elevated, or the soft parts about the trochanter may, from being infiltrated, have a brawny feeling which makes it difficult to include a small portion of the skin and cellular tissue in a pinch between the thumb and finger.

When a later stage is reached some of these points may be dismissed from consideration because overshadowed by three unmistakable and easily read signs, and a comparison may not be strictly necessary between the two sides, although a careful comparison is useful at any stage as throwing light on the progress or severity of the case. 1, the patient's lameness is then constant; 2, the muscular disparity is marked, being due in part to over-work on one side and disuse on the other; and 3, there is no motion or almost no motion in the joint. These three features combined make a picture of hip disease which is not easily mistaken for anything else. In regard to the first and second, nothing need be said, but the absence of motion in the joint may readily escape detection. The amount of motion, or its absence, can be recognized only by noticing the deportment of the pelvis while attempts at passive motion are made. To test for lateral motion, arrange the pelvis so that the line of the two iliac spinous processes is at right angles with the edge of the table or the wall of the room, then if there is no motion in the joint the slightest attempt at passive motion in abduction

or adduction, will be accompanied by a disturbance of this line and, if there is some motion, its extent may be observed by noting the point at which the line is disturbed by either abduction or adduction. To test for antero-posterior motion arrange the pelvis by raising the limb till the lumbar spines rest on the table and then as flexion or extension is attempted, in passive motion, the disturbance of the pre-arranged relation between the lumbar spines and the table will indicate the absence or the extent of antero-posterior motion in the joint.

THE EARLY SYMPTOMS AND DIAGNOSIS OF TUBERCULAR JOINT DISEASE.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY A. J. STEELE, M.D.

PROFESSOR OF ORTHOPEDIC SURGERY, MISSOURI MEDICAL COLLEGE, ST. LOUIS, MO.

No more important division of our subject could have been given me for consideration than this; for while the aim of our calling is to cure disease, yet preceding the therapeutics comes the definite recognition—the diagnosis. And it is just here the physician most frequently errs. Four-fifths of the cases of joint and spinal disease that come under my observation have previously been wrongly diagnosed by medical men. It is in the matter of diagnosis that we need to more thoroughly enlighten the profession—how to early and unerringly recognize these joint troubles. To those of us who have given years of study to this subject, it seems simple and trite, and so while to some I may be amenable to the charge of being commonplace, yet in accordance with the duty assigned me, I will briefly outline the symptoms of the tubercular joint affections.

The earliest symptom, and one ever present, is limitation of the normal motions of the joint. It may be semi-voluntary from apprehension of pain, but as a rule it is caused by the reflex contraction of the muscles controlling the joint. We assume it granted that there is an inflammation in some or all of the tissues composing the joint, and as the nerves supplying these tissues also have filaments from their main root distributed to the muscles, so reflexly the latter contract when the former are irritated. Within a limited radius motion is permissible—beyond that, both in flexion and extension, hindrance is met. A stiffness more or less pronounced is had, observable not only in the freely movable joints, but even in the spine, as is so pronouncedly observed in Potts' disease. This muscular contraction with limitation of motion continues so long as joint irritation or inflammation exists. If it is a joint of the inferior extremity that is affected, limping or lameness is produced and is the symptom first observed, and which calls attention to the afflicted child.

The position in which the limb finds itself as a result of the joint inflammation next deserves attention. Ordinarily, yes, universally, it is flexion. The position of the foot in ankle joint disease would seem to be an exception, as it is always carried downward—but what is that but palmar flexion? Is this flexion of the diseased joint due to the patient voluntarily placing it in the position of greatest ease? Is it because the flexor muscles are more powerful than the extensors, and as all are goaded to contraction they overcome their antagonists and thus

flex the joint? Or is it because that portion or tissue of the joint which is diseased is supplied with the same nerve or nerves which are distributed to the flexor muscles, and thus the latter by reflex irritation contract? Or rather may it not be that the joint in its dilemma simply assumes the position which is most natural to it; that is if it is a question simply of flexion and extension? We always find the fetus with marked and the young child with decided joint flexion.

Scarcely a case will go through its course without pain, most marked when the initial lesion is in the bone, and too, when the progress of the case is acute; usually confined to the joint, occasionally, as in coxitis, remote. The night cry is characteristic of these affections, being most marked during the early hours of slumber.

Swelling of the joint is a decided symptom, more especially so as the case progresses, exceptionally so, however, in *caries sicca*. The joint enlargement is more pronounced when the synovial membrane is the seat of the inflammation than when the initial lesion is in the bone. The superficial joints evidence the swelling more promptly than the deep-seated articulations, such as the hip. The thickening of the capsule and of the periarticular structures, with exudation in the latter, and also effusion within the capsule cause the swelling.

Nineteen-twentieths of the cases occur in children; the growing epiphysis being especially vulnerable to the bacillus. In the adult the synovial membrane is more prone to be the seat of the disease.

Dislocations and marked deformities occurring during the progress of the disease do not concern us here, as we are speaking only of the early symptoms.

The tubercular troubles need not be confounded with other articular affections when we consider their frequency, their proneness to attack children, their insidiousness and their slight influence on the general health in the early stage. Ordinarily unarticular, *i. e.*, two or more joints, being rarely or never attacked at the same time. A tubercular history, inherited or acquired, would assist in the diagnosis. A suspicion of syphilitic joint disease could be cleared up by a course of specific treatment. Abscesses do not occur early, but a rheumatic or gonorrhoeal synovitis would be attended with more pain and more acute symptoms than a tubercular abscess. Doubt as to whether there was fluid in the joint and also as regards its character could be determined by the tapping needle. Rheumatism may attack children but likely as a polyarticular affection and with fever. The spine and joint affections following typhoid fever are ephemeral and quite amenable to treatment by rest, and thus the differential diagnosis of tubercular joint troubles is readily made out.

THE CONSERVATIVE TREATMENT OF TUBERCULAR JOINTS.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY REGINALD H. SAYRE, M.D.
NEW YORK.

The chairman of this Section has asked me to prepare a paper on the conservative treatment of tubercular joints, and this brings us to the question of what is conservatism. According to the views held a few years ago in Europe and even now

upheld by some, conservatism consisted in the immediate eradication of all foci of tuberculosis as soon as detected, on the ground that each focus was so dangerous a menace to life that it should be treated with the same kind of conservatism we would use in dealing with carcinoma. According to the observation of many men of vast experience in this country, however, this view is entirely too radical and the etiology of tubercle, both in joints and in other parts of the body, shows us that better results are to be obtained by less radical modes of procedure. For instance, let us suppose we have a bone infected with tuberculosis in the neighborhood of a joint, for it has been shown that tuberculosis of joints in the great majority of cases commences in the bone although, in a certain number of instances, it may primarily affect the synovial membrane; let us suppose, I say, that we have a tubercular focus; in order that this tubercular disease shall spread, it not only must have its germ, but it must have the proper soil in which the germ can grow and the proper conditions favoring its development, and conservative treatment in my opinion consists in so regulating the conditions of life of the patient, and the conditions of the affected joint that they are not favorable to the growth and development of disease, and if we can so regulate the conditions which surround a patient's life, that the elements necessary for the growth of tubercular bacilli are not present, the patient will recover. We see numberless instances of patients who have been practically left to nature, and who have gotten well; gotten well, however, as a usual result with deformity and disability. But if the vitality of the patient was sufficient to enable him unaided to recover with deformity, properly applied surgery should have enabled him to recover without deformity in most instances, if his vitality was sufficient to enable him to recover at all.

What are the elements necessary to the preservation of a joint that has become the seat of tuberculosis?

1. The prompt recognition of the disease in its earliest stages. This is the most important consideration in securing a good result, and one which can not be under-estimated.
2. To give the joint physiologic rest as soon as the slightest symptom of disease is detected.
3. The protection of the joint from traumatism.
4. The continuance of this protection for many months until all symptoms of disease shall have passed.
5. Building up the general health of the patient to the highest possible degree.

These general principles would, I presume, be accepted by most of us, although there might be some differences of opinion in the practical application of methods to secure these results.

The first thing that should be done when a patient comes under observation with a tubercular joint is to put that joint, as nearly as possible, in a condition of physiologic rest and to do this at once. A slight delay at the onset of treatment may mean months and years of subsequent suffering to the patient, which might have been avoided by the prompt application of measures cutting short the inflammation at the start. It is not sufficient, as a rule, to tell a patient with an inflamed joint to go to bed and keep quiet. If it is a child, it will not have intelligence enough to keep quiet, and even if it had

the intelligence, if the joint should be badly inflamed there will be sufficient reflex muscular spasm present to injure the joint in spite of the patient's will, and therefore the joint must be kept quiet by mechanical means.

The first thing to do is to adopt some way of keeping this joint free from motion, and that is the best thing to use in these cases which is most easily to be procured, and later on this can be modified as occasion may direct. If, for instance, you are called to attend a case of knee-joint disease, which requires for its proper treatment, apparatus made by an instrument-maker, do not leave the case at the mercy of the patient's will while the instrument is being made, but protect the joint as well as possible for the time being with some kind of a splint,—with a wooden or pasteboard posterior splint bandaged to the leg, or by encasing the limb in plaster-of-paris from the toes up to the hip, and if there is so much muscular spasm present that the simple application of a retentive splint does not ease the pain in the joint, apply traction by means of a weight and pulley fastened to the foot.

One of the most important causes of trauma is the weight of the body and the concussion of walking, and one of the vital elements of success is the removal of this cause. If the disease is in a lower extremity, never allow your patient to put the weight of the body on it from the time you first see the case until you think it is well and, if possible, so adjust your apparatus that the patient is *obliged* to keep his weight off of the diseased member and do not allow this to be left to his discretion.

In order to secure physiologic rest in an inflamed joint, several things are necessary,—the avoidance of traumatism in movement of the body, and the avoidance of traumatism produced by involuntary muscular spasm and in order to secure the latter, in the vast majority of instances, it is necessary to employ not only a simple retentive apparatus, but one which shall make slight traction upon the joint. The question whether or not traction is of any use in diseases of various joints has been discussed at great length, and different opinions have been held by different observers, but in my personal experience I have found that a large number of cases do not get freedom from pain until traction is applied and *properly* applied. I am accustomed to judge of the success of my methods in protecting the joint by the amount of relief which they give the patient, and I am sure that if I fail to make the patient comfortable by my treatment, I have failed to give the joint the protection which it ought to have in order to arrest the progress of disease. The mere application of a plaster-of-paris splint to the diseased ankle, knee or hip is very good, as far as it goes, and is a very great aid to the joint, but freedom from pain in many instances can not be secured in this way, and traction must be employed in order to make the patient comfortable.

It is not always necessary to employ a cumbersome apparatus to use traction. I remember a case of inflamed ankle joint, which was sent to me a couple of years ago from Texas, the doctor having employed plaster-of-paris boots for nearly a year to secure rest of the joint, without giving the patient relief from pain. She was a hospital patient, and while she was making arrangements to buy an apparatus for the protection of her ankle, I put on a

plaster-of-paris boot to protect her joint temporarily, with the result of giving her partial relief, as had been done in Texas, but not complete freedom from pain. I, therefore removed this dressing, and applied adhesive plaster strips, running from the ankle towards the knee, and long enough to be reversed back to the ankle again, and bandaged these firmly to the leg. I then applied another plaster-of-paris boot from the toes to the knee, and when it had become hard, reversed the adhesive plaster over the top of the boot and bandage and held them firmly in position by a roller bandage thus making traction on the ankle joint by the grip which the plaster-of-paris boot had on the foot, while the adhesive plaster exerted counter-traction on the leg. As soon as traction was applied in this way the patient was free from discomfort and continued to wear this apparatus, it being changed at intervals for a number of months, and eventually recovered without the necessity of resorting to the more expensive appliances constructed by the instrument-maker. In the same way, in treatment of inflammation of the wrist, traction can be applied in a very simple manner by covering a palmar splint, properly adapted to the contour of the hand and forearm, with adhesive plaster, the sticky side being outwards. This should be first bandaged to the hand and then traction should be made upon the hand by an assistant until the patient is comfortable, and the splint fastened to the patient's forearm in this position, the adhesive plaster preventing it from sliding up, thus securing such traction as is requisite to give the joint rest.

You will find that some patients are made comfortable by splints applied in this way, who are not comfortable after the simple application of antero-posterior splint bandaged to the arm and forearm before traction has been made upon the wrist.

Counter-irritation, in many instances, is a most useful addition to rest and traction, and in many cases severe pain does not subside until after the application of blisters or the actual cautery over the point of disease, and in those cases that get almost well and still have a tender spot which persists for months and months, in spite of the careful application of apparatus and sedulous protection of the joint, I have found great benefit from running the fine point of Paquelin's cautery deep into the bone. This can be done with cocain as a local anesthetic, but if the patient is nervous, care should be taken that an assistant holds the joint with great steadiness while you apply the cautery, in order that the application may be made where you desire it.

Now the question arises, How long are we to continue protection to this joint? and I would answer that there is very little danger of your protecting the joint too carefully or too long. I have seen many cases which relapsed on account of over-anxiety on the part of parents or physician to arrive at the end of treatment, but I have seen very few that had been encumbered with apparatus longer than was necessary. I think it is safe to say that as long as any symptoms are present which would suggest to you the use of protection if you were seeing the case for the first time, just so long is it necessary for you to continue protection, irrespective of the number of months or years which the case has been under treatment.

I think the length of time, which is usually laid down as the average duration for tubercular disease

is too short, and I believe that if instead of two years the patient were told in the beginning to expect three years of treatment, it would be nearer the truth. There are cases of tubercular joint disease which get well inside of a twelvemonth, but they are largely in the minority, and so exceptional that the patient should not be led to expect anything of the kind when an opinion is asked as to the length of time during which treatment will be necessary. I think that the severity of pain in the beginning or the rapidity of the onset of the disease can be used as a very accurate guide in estimating the duration of the process, for those cases which seem the simplest when they first come under observation very often are the most tedious to manage.

The question of effusion into joints is a very important one, and the wonderful benefit to be derived from rest and compression is something very surprising to those who witness it for the first time. In cases of acute synovitis, aspiration is often indicated, but in the chronic tubercular joint, compression, with a large compress sponge wrung out in cold water, and bandaged very snugly with a cheese-cloth bandage, is to be preferred.

The question of abscesses is one which comes within the scope of one of the other papers, but I would say that there is also a conservative side to the treatment of abscesses. If the abscess is simply a collection of tubercular material, I believe that it is safer to let it alone and treat it by compression, unless it is in a position where the focus of inflamed bone which gave rise to the abscess can be removed with safety without sacrificing too much healthy bone in the operation. If, however, the tubercular mass becomes infected with pyogenic organisms, the case is altogether different and demands prompt surgical interference.

The time limit which has been set by your chairman is so short that it will be impossible for me to enter into details in regard to the practical application of the principles I have just mentioned, in their relation to the different joints of the body except in the most cursory way, but I will crave your indulgence for a few moments while I rapidly mention a few points which have seemed to me to have been overlooked quite frequently by the general practitioner.

In treatment of the spine, for instance, in the case of children under 3 years of age, as a rule it is impossible to apply any apparatus which will allow the child to run about, and secure for its inflamed spine the rest which scientific treatment demands, and yet I have frequently seen children between 1 and 2 years of age to whom plaster jackets and various other kinds of apparatus had been applied while the child was allowed to run about. These children should always be treated in the recumbent position, the weight of that part of the body which lies above the point of disease being in this way removed and at the same time gentle traction should be made upon the head, while counter-traction is made upon the feet or pelvis, for the purpose of counteracting the reflex muscular spasm which is always present in inflammation of any joint. These principles can be carried out if the child is placed upon a hard bed and securely bandaged to it. But it is extremely difficult to keep the child in a proper condition of quiet on a bed of this kind, and it also has the great disadvantage that the child can not be carried up

and down stairs, and given the benefit of fresh air and outdoor life without being removed from its bed, which proceeding is necessarily attended by more or less traumatism, and I therefore prefer to put the child in a wire cuirass or fasten it to a board, like an Indian pappoose, if it is too poor to buy anything better. In fact, you practically have a portable bed made but a little larger than the child and the child and bed can be carried downstairs, placed in a rubber-wheeled baby carriage and transported wherever its health demands. In many cases of older persons this recumbent position is far better treatment for the spine than any other, but it is so difficult to carry a child about when it is 5 or 6 years of age, that it is almost always treated with some kind of an appliance which allows it to run about. In the vast majority of cases I think that the best appliance for children of this kind is the plaster-of-paris jacket combined with the jury-mast, but it is not the simply wrapping a plaster bandage around a child which does it good, but the correct application of the principle which I have sketched and having a child's spine at rest, whether it be by a plaster bandage or an iron splint, or any other material that the surgeon chooses to adopt which benefits the patient; and to simply envelope it in a loose plaster bandage which slides up and down and does not protect its spine, but is merely an additional weight, hanging upon its already enfeebled form (in some cases actually held up by shoulder straps instead of resting on the ilia) this is the treatment which I wish most strongly to condemn. In order to support the spine a plaster jacket must have a basis of support; it can not be applied to small children with undeveloped hips, and in applying it the child must first be stretched to the point at which it feels comfortable, and plaster bandages fitted so accurately that the child is retained in that position twenty-four hours a day, the jury-mast being added if the disease is above the tenth dorsal vertebra, in order to effect this object. As long as a child has a grunting respiration, a tender careful gait, and desire to support itself against any object which comes within its reach, just so long is its back imperfectly guarded by the apparatus which it carries, and those children should be taken off their feet, put to bed, and absolute rest of the inflamed bones maintained for a long period of time.

In the hip joint also, I frequently see efforts at treatment of no avail, because the gentleman who has had charge of the case has thought that the application of this, that, or the other splint was all that was needful to effect a cure, whereas it is the proper application of the principle of rest of the inflamed joint which is essential, let the principle be carried out in whatever way best suits the surgeon.

I have seen traction applied to inflamed hips, flexed, and strongly adducted, with the result of causing intense pain to the patient, simply because the traction was not applied in the proper direction, and because the patient's body was not held firmly fixed in bed, in order that the traction might have some point from which to pull. I have seen splints put on patients' limbs in this crooked position, which were only meant to be applied to the body when the legs were straight and parallel, and which under these circumstances produced great pain and suffering.

In these distorted and inflamed joints, the first thing to do is to immobilize the body and sound leg in the straight position, and allow the diseased limb

to assume such attitude as it will while the spine is flat, and a line joining the anterior superior spines of the ilia is at right angles to a line passing from the center of the sternum to the symphysis pubis. Now, make slight traction on the diseased limb, in the direction which it assumes while the trunk retains the position I have just mentioned, and make the traction just sufficiently strong to give ease and comfort, the leg being placed meantime on an inclined plane to give it support. If you have fastened the patient securely in bed, and applied traction as I have indicated, you will make him comfortable and can gradually change the direction of this traction little by little, day by day, until both legs are flat in the bed and parallel, without tilting of the pelvis or arching of the lumbar spine. If you find that traction in the line of the deformity does not give the patient absolute comfort, pass a bandage around the thigh, and make a slight lateral traction outwards. In some cases this will give ease to the joint which the longitudinal traction fails to give, but is not necessary in all cases. When the legs are parallel apply your hip splint, and not before, the object being to again allow the patient to take outdoor exercise while the inflamed joint is kept at rest, but if you find that the patient begins to have pains in his joint when you allow him to get up on his splint, or splint and crutches, it shows that you have not applied the splint in such a manner as to protect the joint from the traumatism of locomotion, and if you can not succeed in so adjusting it that the child can go in the open air without increase of tenderness in its joint and without being disturbed by cries at night, put it back in bed, and have it trundled out in the air in a baby carriage until you are capable of so applying the splint as to protect the inflamed joint and, at the same time, leave the rest of the body free for locomotion.

In passing to the knee I would draw attention to the fact that the knee is not simply a hinge-joint, and that efforts to straighten a knee which has taken on the characteristic deformity of chronic tubercular inflammation of the knee-joint, by simply pulling on the leg are apt to increase the pain, because the front of the knee-joint is strongly compressed by force applied in this manner. There is always a sliding backward of the head of the tibia upon the condyles of the femur in cases of chronic knee-joint disease, and to counteract this posterior displacement of the tibia, pressure must be exerted on the head of the tibia from behind forward, at the same time that traction is made in the long axis of the shaft of the tibia, if we wish to relieve the spasm of the joint, and correct the deformity of the knee. The tight ham-string muscles, brought into fierce spasms as they are by irritation within the joint, form a fulcrum, and when the knee is straightened as if it were a simple hinge the joint surfaces are pressed together with a lever of enormous strength acting upon these firm ham-string muscles as a fulcrum, which increased with articular pressure results in pain and damage to the joint. On the contrary, by applying traction for the purpose of reducing the deformity along the line of the articular surface of the condyles of the femur, the deformity is corrected gradually, almost imperceptibly, and the joint can then be put up in a splint which embodies the same principles of treatment—traction in the long axis of the tibia, and pressure from behind forward against the head of the tibia, while at the same time the patient is prevented

from bearing weight upon the inflamed joint, and able to get the benefits of fresh air and outdoor life during the months or years of treatment which will be necessary before the joint is well.

Your chairman has warned me that ten minutes is to be the limit of our papers, so all that I can hope to do is to draw your attention to the principles of treatment and leave the practical application of them to some future occasion.

THE CONSERVATIVE TREATMENT OF TUBERCULAR JOINT DISEASE,

OR, MORE EXPLICITLY, THE PURELY CONSERVATIVE TREATMENT OF TUBERCULOSIS OF THE JOINT STRUCTURES.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY HARRY M. SHERMAN, M.D.

SAN FRANCISCO, CALIF.

For the purpose of the present paper it does not especially concern us which or how many of the different tissues which together constitute a joint are affected, and I shall not attempt to discuss methods of treatment based on anatomic differentiation of the location of the lesion. It may, however, be stated that in the great majority of cases the initial lesion, so far as the joint is concerned, is in the bone; but in the purely conservative treatment the management of these cases differs hardly any from that of those which are primarily synovial.

Underlying the treatment of all forms of chronic tuberculosis, of whatever tissue or wherever situated, is the gospel of rest and food. This is founded upon the fact, learned in the first place by experience, and confirmed later by the results of biologic investigations, that there is in living tissues an inherent antagonism to all forms of infection, and that this antagonism is best exerted by tissues that are not functioning and are at the same time well nourished. In the infection of no tissue has this been better shown than in the infection of bone. This is due, in part, to the very chronic course these cases follow, which permits careful and extended study of them, and in part to their large number—for tuberculosis of the joints or bones constitutes more than 80 per cent. of all cases of tuberculosis in patients under 17 years of age; and I have calculated on reliable data that in San Francisco, for instance one child out of every 286 of the child population has tuberculosis.

Work, for a bone, is resistance to pressure and strain,—pressure being produced by the weight of carried structures, and strain caused by the use of the bone as a lever. As bone is a living tissue, work must physiologically be followed by a loss of energy and the need of rest. Rest for a sound bone necessitates that it shall be subjected to neither pressure nor strain beyond that which properly exists between the different parts of the skeleton with the individual quiet. Perfect rest for a diseased bone contemplates that it shall be subjected to absolutely no pressure or strain, whether that be developed in the doing of work, or be the natural result of its position in the skeleton. Practically, it is impossible to wholly eliminate the latter factor, and the aim of treatment on conservative lines is to secure, in the first place, the complete cessation of active work and

then to lessen, as much as possible, the physiologic and unavoidable pressure between bones so that a rest of therapeutic value may be had. During the period of this rest careful attention is given to the general health of the patient, and every effort is made to secure a gain in body weight. This is a brief statement of the principles of conservative treatment.

There are two major plans, in accordance with one of which these principles are applied: One aims to secure rest by fixation alone of the joint, claiming that with fixation is absence of inter-osseous friction and of pressure. This is considered to be true, no matter what may be the relative position of the bones, but the plan arranges first for the gradual correction of any faulty position and then fixation in the proper position. So long as a pathologic process is present the fixation must be maintained, and never must the joint be released until the reparative process is complete. In this method no account is taken of pressure developed by the muscular spasm which is the most common and prominent accompaniment of joint lesions.

The other plan endeavors to secure rest by traction below and counter-traction above the diseased joint, thus addressing itself primarily to the spasmodically counteracted muscles, by antagonizing their spasm, relieving the pressure on the bone and consequently the cause of the spasm itself; the rest from the spasm and the spasm-pressure removes the tendency to early deformity, and the immobilization is then an easy matter,—for in a diseased joint there is no tendency to ordinary motion, but rather the avoidance of it. In regard to arranging for the gradual correction of any faulty position and to the continuance of treatment until the disease has ceased and repair is accomplished, this second plan does not differ from the first.

Of these two distinct methods of attaining the same end, the latter apparently complies more nearly with the requirements of the proposition.

Under conservative treatment, cases of joint disease follow one of three courses: Either they entirely and wholly recover, with a joint so little damaged that its function is in no ways impaired, and its disability must be looked for to be found; or they recover after a certain amount of permanent damage has been inflicted, are functionally more or less incompetent, and their disability is evident; or they do not recover but go on for long periods of time, their condition constantly bad or going from bad to worse; they can perform no function; their disability is complete.

In its results, then, tuberculosis of the joint structures differs in no particular from tubercular or other forms of not necessarily fatal infection of any other part of the organism. That is, the conservative treatment is a method of treatment but it is not a means of cure.

It is important, for its proper use, to know in what cases it will succeed and in what cases fail.

At the Twenty-third Congress of the German Chirurgical Society held in Berlin on April 18 of this year Bruns, of Tübingen, reported 600 cases of tuberculosis of the hip joint; of these but 200 were available for statistical use. They covered a long period of years, had been treated by various methods all conservative, as by revulsives, vesications, cauterizations, immobilization, traction and iodoform. On

their results he declared himself, with very slight qualification, in favor of conservative treatment. He summed up practically, as follows:

1. Of all cases, 48 per cent. begin in the first ten years of life, 37 per cent. in the second ten years, and but 6 per cent. in the third ten years.

2. In 66 per cent. of all cases there is suppuration, abscess and fistula.

3. Recovery is attained by conservative methods in 55 per cent. of all cases, and in an average time of four years.

4. Death occurs usually of a visceral tuberculosis, or amyloid degeneration, or sepsis, in 40 per cent. of all cases; and in an average time of three years.

5. Prognosis depends chiefly, in each particular case, on the presence or absence of suppuration—of non-suppurative cases 77 per cent. recover; of suppurative cases 42 per cent. only.

6. Prognosis in general depends on the age of the patient when attacked. In the first ten years of life the recoveries are 65 per cent.; in the second ten years, 56 per cent.; in the second twenty years of life, 28 per cent. only. No case recovers which is over 40 years old when attacked. Suppurative cases are especially serious in patients over 20 years.

7. Most of the recovered cases die later of tuberculosis of other organs. Of those who recover in the first ten years of life, 6 per cent. die later of tuberculosis of the lungs; in the second ten years, 9 per cent.; of those who have passed 20 years, 7 per cent.

The functional results, in spite of atrophy, shortening, ankylosis, and vicious position, he considered good. In all cases motion was limited. Ankylosis was a frequent result of suppuration. In every case the limb was in a vicious position of flexion, and usually adduction, rarely abduction—the flexion sometimes being 90 per cent. Flexion, rather than shortening, was the cause of the functional disability. The shortening was due to three factors. Atrophy of disuse, absorption of the femoral head, and extension of the acetabulum in an upward and backward direction due to absorption of bone. Without giving any statistics of resection cases he claims that their results, in view of life and limb, are no better than these. His qualification to his advocacy of conservatism was his desire to await modern methods of wound treatment in resection cases. At the same time, Schede, of Hamburg, Helferich of Griefswald, Gussenbauer, of Prague, and von Bergmann, of Berlin, advocated conservatism as against operation.

There are several points in these statistics which would bear careful discussion, but I must not, in my allotted time, attempt more than a brief mention of one or two. His total percentage of deaths, 40 per cent. is a higher mortality than is usually credited this particular form of joint tuberculosis; but this is explainable, partly, on the fact that many of his cases occurred in the time before systematic treatment by traction and immobilization was instituted. The mortality of the suppurative cases, 58 per cent., is of the whole report the part that most holds attention. According to it the chances of a given case's dying are more than doubled by the occurrence of abscess. There can be no doubt in this world but that it is proper to persevere in conservative treatment in cases where there is no abscess for the ultimate chances of recovery with a useful limb are good. But if abscess comes it is a symptom that the organism is not able to absorb and eliminate the

detritus of the infected tissue—tissue that is potentially or actually dead and must be removed; the disease is gaining on the patient; conservative treatment is not conserving. At this point of any particular case what sign or symptom will tell us the patient's chances: whether he will, after being more or less ill, ultimately recover or whether he will die. We know he has forty-two chances of recovering to fifty-eight of dying, but what is this particular patient going to do? How long should conservative treatment be persevered in under these circumstances? That is, how long should the patient be left to the surgical efforts of the staphylococcus to rid him of his diseased bone when the original infection, the bacillus of tuberculosis, may be extending its operations on the bone *pari passu*, or migrating to and attacking other organs?

These statistics are the latest I know of that cover any considerable number of cases. They have been compiled under strict stipulations as to what cases were proper ones to be included. In spite of the consensus of opinions in favor of conservatism, I can not see but that the statistics themselves force us to ask these questions, questions which Bruns himself suggested when he stated that he waited to know the results of later methods of wound treatment before finally committing himself. It is not my duty, in the present instance, to attempt to formulate the answer.

CONSERVATISM IN THE TREATMENT OF TUBERCULAR JOINT DISEASE.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1904.

BY JAMES E. THOMPSON, M.B., B.S., LOND., F.R.C.S., ENG.
PROFESSOR OF SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF TEXAS, ETC.
GALVESTON, TEXAS.

The days of conservatism, to judge from a perusal of our medical journals, seem almost to have passed; for no sooner does a student gain the magical cognomen of M.D. than he seeks fields and pastures new where he may acquire local if not world-wide fame. He seeks this, not in the direction of honest, hard, painstaking clinical work but only too often sees his chance in some major operation, requiring not alone judgment in its planning but experience in perceiving its necessity. Too often in his endeavors to count his majors by the tens or hundreds he loses sight of the main object of his art, which is to save nature's organs intact as far as is compatible with health and life, and errs in his enthusiasm wilfully if not criminally in producing mutilations that cause older and more conservative surgeons to shudder in dismay. Thus it is that our journals are flooded with records of hip-joint amputations, heroic operations on the spine and such like, to the exclusion of records, which happily are being collected, where the limb still remains as a monument of the patient efforts of some obstinately conscientious practitioner, who, following nature's dictates and methods succeeds in saving life and limb in spite of the sneers and innuendoes of his fellow practitioners. However, it is possible for us in our admiration of conservatism to let the pendulum swing too far and to lose sight of the fact that mutilation is not naturally the antithesis of conservatism, but, that between the two there lies a field where bold, active surgical

measures may be of paramount benefit to the patient and absolutely indicated in the various stages of the disease. It is this boundary line between conservatism and active treatment of a tubercular joint that I wish to discuss in some detail, and to make as far as possible a clear distinction between cases that require operation and those which will be decidedly the better for absolute unhindered rest.

There are so many considerations that enter into a calculation of this nature and which influence one's opinion in coming to a just conclusion that it is impossible to lay down definite rules which will hold in every case. Diathesis, present health, social condition particularly the power to gratify certain requirements, such as climate, food, apparatus, etc., influence so materially the conduct of cases, that each patient must be judged on his or her own special condition and environments.

Given a patient in the first stages of hip-disease, a patient whose social condition is such that every luxury can be obtained, that change of climate, fresh air, conveyances, the best of food cooked in the best way, are all procurable; a patient whose common sense or the moral control of whose friends would help in carrying out instructions as to rest in bed, the use of apparatus and the like, I should have little hesitation in giving a very favorable prognosis. In the great majority of such cases cure would follow and, with care in after treatment, the cure would be permanent.

On the other hand, a case of this sort denied all care, all necessities and all luxuries, and, especially denied intelligent supervision and nursing would sooner or later progress from bad to worse and would end, as most of these unfortunate cases do end, in total destruction of the joint and perhaps in death from exhaustion. This is the course with only too many patients seen in our crowded cities; everything is ordered but nothing procured, with disaster as the result. In the face of this, can one wonder at the surgeons in crowded manufacturing centers advocating and carrying out excisions at the very earliest period, even before the joint cavity is involved, under the perfectly legitimate idea that it will only be a question of a short time before the process will go on apace and destroy the articulation?

These advocates of early excision undoubtedly go too far in their views, and often a joint which could be saved with the limited means at their disposal is sacrificed ruthlessly as a holocaust on the altar of their faith. I have among my collection of hip joints one which was removed by one of my old teachers which shows two caseous foci close to the epiphysial line, the joint otherwise being healthy. Knowing as I do both the operator and the squalid surroundings of most of his patients, I am fully prepared to accept this specimen as an evidence of skilled diagnosis and appropriate treatment. However, I think that if the social conditions had been otherwise that it is just in such cases, viz., those where the disease commences primarily in bone that conservative treatment will show the most brilliant results.

Diagnosis is everything and an error committed in the early stages may result in a disaster to the patient. It has been my luck to see cases of commencing hip disease in children diagnosed as intracapsular fracture of the femur and subjected to rough passive movements under chloroform. Most of these

cases ended in excision, and in one a subacute osteomyelitis set in, which necessitated removal of two or three inches of the shaft and scraping out the medullary cavity. So then, I would lay it down as a dictum, that where the disease can be diagnosed as confined to bone, conservative treatment should be relied on as giving the best results.

This is seen to a remarkable degree in tuberculosis of the vertebræ where perforce, in the majority of cases, conservatism is the only available treatment. One sees daily, numerous living examples of healed spinal caries where we have deformity but no other trouble. Here the disease is primarily in bone and is surprisingly curable when allowed to have a chance. Sometimes, in spite of maltreatment, it will clear up in a marvelous manner.

The relation between symptomatology and conservatism is a close one, as it is only in cases where the diagnosis is made early before the joint is extensively involved, that we can hope for a good result. Everything, then, hinges on an early recognition of the joint disease and this, in skilled hands, is usually an easy matter, although cases occasionally occur which for a time defy a positive opinion. I would here be dogmatic and lay it down as an absolute rule, that, in cases of doubt, the patient should be treated as if the suspected joint were the seat of a veritable tuberculosis.

The slightest stiffness of or unwillingness to move the joint in a patient of a tubercular diathesis should be viewed with suspicion, and these symptoms accompanied by pain should at once be a signal for absolute enforced rest. We should be just as much on the alert to diagnose our joint cases at their curable stage as we are to diagnose malignant disease when it is essentially local and amenable to treatment. One could cite cases innumerable where patients who had suffered from the early stages of hip disease during infancy had by careful treatment recovered full movement of the limb, and were in adult life to all appearance free from tubercular foci. It is impossible to say whether the bacilli or their spores are merely latent and awaiting a suitable opportunity to blossom into life; and knowing as we do the tendency of a once actively tuberculous focus to awaken, we are very careful to advise moderation in using a joint once diseased.

The cases that are the most troublesome are those where it is difficult to come to a decision as to the employment of operative procedures. In other words, when should we advise rest and when operation?

The answer to this depends mainly on two considerations: 1, on the joint affected; 2, on the situation and extent of the disease in the particular joint. 1, considering all things the joints of the upper extremity are more amenable to conservative treatment than those of the lower, because they can be more easily rendered immovable and are less liable to be injured during locomotion; added to which the patient can obtain exercise and fresh air without risk. The joints of the spine occupy a peculiar position in being almost beyond the reach of accurate surgical treatment, in the early stages at least.

2. In considering this section, with due regard to what I have previously said as to the views of the advocates of early excision, I should be very much inclined to doubt the efficacy of rest and conservative measures generally in joints where the symptoms pointed to the destruction of the articular surfaces

and pus formation. In these cases I should feel it my duty to advise something more than the expectant treatment.

The particular joint affected and the anatomic region involved would also modify my attitude towards conservatism in any given case; thus in cases of tuberculosis affecting, and appearing to be confined to, the synovial membrane of the knee joint, while recognizing the fact that here rest is a powerful aid towards cure, I should have less compunction than formerly in the face of brilliant results, such as I have seen from arthrectomy, in advising this procedure. It is in these cases, however, that treatment by rest associated with pressure or passive congestion (Bier's treatment) has shown its best results; and consequently the greater one's experience the less dogmatic would one become in favor of or in opposition to any particular method. Occasionally one may be shaken somewhat in one's power of judging as to whether operation is necessary or not. A colored girl aged 7 was under my care some two years ago suffering from spinal caries affecting the fourth, fifth and sixth dorsal vertebræ associated with absolute paralysis of the lower limbs; no anesthesia and no implication of the bladder and rectum. There was marked angular deformity but no evidence of pus formation. The temperature varied and occasionally rose as high as 101 degrees F. in the evening. Absolute rest was enjoined and during six months the child was encased in a well fitting Sayre's plaster jacket, but with no effect. In despair, I had made up my mind to operate and the jacket was removed for that purpose, but for some reason the operation was postponed for two weeks, during which time the child was allowed to roll about the ward floor. To my surprise, I found she was regaining the use of her limbs, and I postponed the operation indefinitely and had the satisfaction of seeing her recover the use of the lower members entirely. Had I operated, I should have attributed the improvement to the operation and not to nature's own processes.

Having made up our minds to put any particular joint at rest, the method of carrying out our plans deserves some description. The forms of apparatus for each joint are legion and most are good. However, as a rule it is not the particular apparatus which is going to cure our case, but the individual care expended on it by the surgeon and his assistants. Wherever practicable the joint should be fixed immovably and shielded from traumatism; and usually plaster-of-paris is the best material to use. In the case of children afflicted with hip disease, the limb is fixed firmly in a plaster case from foot to pelvis, and the same bandage is carried over the sound joint as far as the lower part of the thigh. I have, however, found it impracticable to use plaster-of-paris during the hot weather of our summer and have been forced to be content with rest in bed with extension, using sand bags to steady the body and limbs. The enforced rest is absolute and is kept up for one year, the patients not even being allowed to sit upright during the early part of this time. Each day the patients are wheeled out on the gallery and allowed to bask in the sun, as I find a remarkably good effect from sunlight and fresh air.

Is it possible that a limb can deteriorate by rest too prolonged? The answer to this reveals some curious facts by a perusal of the rather scanty literature of the subject.

Teissier¹ showed by dissection that long continued immobility in a joint might produce a series of important changes including synovial effusion, permanent shortening and thickening of the ligaments, swelling, softening and erosions of cartilage, and even true fibrous ankylosis.

Volkman² reported a number of cases of transient effusion which appeared in joints which had been immobilized in the treatment of fractures and other diseases.

Menzel³ experimented on animals by confining their limbs in plaster-of-paris and found well marked degenerative changes at the points subjected to the greatest pressure. Further information and researches will be found in papers published by Reyher,⁴ Paget⁵ and Butlin,⁶ and all go to prove that certain changes may and do occur in healthy joints kept at rest for any appreciable length of time. Notwithstanding this, the good effects of rest on diseased joints are too well recognized to lessen the value of this procedure.

In many cases, especially those where starting pains at night form a prominent symptom, it may be advisable to put extension on the limb, the object of which is to separate the joint surface and to prevent destruction by pressure. The method of application deserves some care, as it may be possible in some cases to increase the symptoms which it is intended to allay. Thus, in some instances of extreme flexion of the hip associated with shortening of the psoas muscle, if extension be put on and the line of force be perfectly horizontal, the head of the femur is forced deeper into the acetabulum and more pressure is brought to bear on the articulating surfaces; the mechanism being a lever of first kind, the power being applied at the lower end of the femur, the fulcrum at the psoas insertion. Therefore extension should at first always be applied in a direction parallel to the shaft of the displaced bone; in cases of hip disease parallel to the flexed femur, in knee joint disease parallel to the flexed leg. Otherwise extension not only increases the suffering of the patient, but is positively harmful. Later on, when one has overcome the resistance of the contracted structures, it is possible to change the direction of the extension and gradually to bring the limb into the desired position.

The value of extension depends on the power of separating the diseased surfaces from one another and so preventing undue injury by friction. The relief that a patient experiences from starting pains at night is too marked to doubt the efficacy of this procedure.

When we ask ourselves what are the limits of the treatment by rest, we are unable to fix any arbitrary boundary line. As long as there is any evidence of inflammation present, such as pain and tenderness, and especially if there be suppuration, rest must be continued. It is advisable in all cases of early tuberculosis to err on the side of too prolonged rest rather than to allow movements in a joint where there is the least chance of the disease being active. But the question naturally forces itself on us, Are we to use passive motion in a previously diseased joint when, from the absence of pain and tenderness, we have reason to believe that the tubercular process is in

abeyance? This is always a very difficult question to answer. At times, especially where the tubercular disease is confined to the synovial membrane, massage combined with moderate passive motion may be of benefit; but I am not inclined to view this procedure with approval. Yet when one compares the treatment which is advised in pulmonary tuberculosis with that usually followed out in joints, it seems at least curious that in the lungs exercise should be found beneficial and, in fact, in moderation absolutely necessary for a favorable termination, whereas, in joints one condemns exercise as deleterious. Is it possible that full inflation of the lungs increases the vascular supply and helps the connective tissue cells to fight the bacilli without deleterious consequences to the intrinsic lung tissue, whereas movement in joint surfaces injures the intrinsic tissues without in any way bettering their nutrition and placing them in a more resistant attitude? I am not prepared to believe this difference, but am rather inclined to think that the processes are identical and that, if we could only interpret aright the conditions favorable to passive motion, there are many joints that would be decidedly benefited. But the difficulties in the way of a correct knowledge of the pathologic condition of a joint are so great that any attempt to move a joint is attended with more risk than is justifiable.

As adjuncts to rest we have such means as compression, counter-irritations and massage. All these means have a limited application and considered alone a very doubtful value. Compression is particularly useful in cases of tubercle confined to the synovial membrane and where we have no evidence of a central tubercular osteitis. It may be applied with a rubber bandage or by strips of adhesive plaster over a cushion of cotton.

Cold may be applied during the non-inflammatory stage by means of an ice bag or a Leiter's coil. One should, however, guard carefully against its abuse as it may interfere with the proper circulation of the part.

Heat has a more extended field of application. It is best used in the form of antiseptic fomentations, medicated if thought necessary with iodine, corrosive sublimate or boric acid. We may also surround the joint with a Leiter's coil and keep up a continuous stream of hot water running through the tubes.

Blisters, actual cautery, setons, moxas have no place in the modern treatment of the disease. They only incommode the patient and have no beneficial effect on the diseased joint.

Bier,⁷ of Kiel, has advocated the treatment of tubercular joints by a method which he calls "*passive congestion*." The procedure, which is simple, consists in placing a broad elastic band around the limb a few inches above the diseased joint, firm enough to produce congestion but no edema, and loose enough to run no chance of rendering the limb anemic. This congestion is kept up continuously and the movements of the part encouraged, the elastic band being changed occasionally to prevent chafing and abrasion. The congestion is confined to the immediate neighborhood of the joint by carefully bandaging the distal portion of the limb.

The idea was suggested to him by an old dictum of Rokitsky's, that all cyanosis is incompatible with tuberculosis, a remark which however true in its

main features is not absolute, for one occasionally sees phthisis associated with congenital heart disease.

I have had no experience in this method, but will quote the conclusions arrived at by Miller⁸ who has put this method to a fair test. He says that his experience has not equalled that of Bier, as most of his cases were afterwards treated by other means and could not under the rules of the hospital be allowed to remain a sufficient length of time in the wards. In summing up he comes to the conclusion that the new method can not in the majority of cases take the place of amputation, excision, scraping nor of immobilization, but that combined with immobilization it is undoubtedly an aid in the treatment of these affections.

A limb with a tubercular joint has smaller arteries and is in consequence inadequately supplied with nutriment. May it not be that the diseased part is on account of its malnutrition unfavorably situated as regards its contest with the tubercle bacilli, and that the congestion of the neighborhood assists in the destruction of the bacilli and the throwing off of the disease by bringing more blood and serum (pabulum) to the fighting tissue?

THE OPERATIVE TREATMENT OF TUBERCULOSIS OF JOINTS—(EXCISION).

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY ROBERT W. LOVETT, M.D.

BOSTON, MASS.

OUT-PATIENT SURGEON TO THE BOSTON CITY HOSPITAL; ASSISTANT SURGEON TO THE CHILDREN'S HOSPITAL; SURGEON TO THE INFANTS' HOSPITAL.

The question of the operative treatment of joint disease should involve the discussion of several procedures; excision, arthroctomy, incision and ignipuncture. The limits of this paper, however, compel the writer to confine his attention to the consideration of the place of excision in the treatment of tuberculous joint disease. On this subject there is a wide range of opinion in the surgical world. Some surgeons advocate early excision as a routine treatment in tuberculous joint disease; others would never excise at all, because they consider the operation as rarely necessary, and as dangerous; and a third faction believes that excision is to be kept in the background until conservative measures (*i. e.*, mechanical treatment) have had a faithful trial.

Mechanical treatment is a term which has been often applied to the loosest and most incomplete imitations of proper conservative measures. Consequently, when one attempts to define the sphere of operative measures, contrasted with mechanical ones in joint tuberculosis, it must be understood that by mechanical treatment is meant here the intelligent and systematic application of suitable apparatus by surgeons of special training; not the reference of a patient to an instrument-maker with the order for a "hip splint." This is not the mechanical treatment which yields good functional results.

There are two dangers from excision of joints: 1, loss of life; 2, generalization of the tuberculosis.

1. Excision of even the larger joints is not an operation which is accredited with a high death rate. Of late years the mortality has become much less, but the immediate mortality is of little significance compared with the remote, of which we know very

little; for few figures deal with the latter. Immediate results in these cases show very little, because relapse and generalization of tuberculosis occur later, and are the really significant factors. Just as any statistics of operation for cancer of the breast, which only dealt with the three months after operation, would be of little or no value in determining the value of the operation as a cure of cancer. As an example of the very favorable aspect of operative treatment considered (as usually is the case) in the light of immediate results, the following figures are of interest, taking a group of the latest results in excision of the knee for instance:

Lücke¹ reports 101 excisions of the knee with 85 per cent. of good results; Lucas-Championniere² 44 excisions without a death; Thompson³ reports 50 knee excisions without a death; in 287 cases in adults, reported by Schüller⁴ 12.5 per cent. died, and in 274 cases under 20, 10.9 per cent. died. In 129 excisions, reported by Bothe, there was no death⁵; Zeuge-Mauteuffell⁶ had 11 per cent. of deaths in 55 cases done at the Dorpat clinic.

In Lücke's cases there were 60 per cent. of cures; in a series of 48 excisions in children, reported by Angerer⁷, below the age of puberty, there were 70 per cent. of total recovery; in the series of 561 cases, reported by Schüller, which have been already alluded to, 63.8 per cent. were cured. In the last 61 operations, of the 131 reported by Boeckel⁸, union without fistulæ occurred in 82 per cent. In the fifty-five cases operated on at the Dorpat clinic, union by first intention occurred in 71 per cent. As was said by Verneuil, at the Congress for Tuberculosis: "We have reason to be optimistic when it concerns immediate results."

Turning to remote results there are fewer figures. Korff⁹ reports the final results in 104 cases of general resections, with a mortality of 37.5 per cent.; Boeckel relates 127 resections of joints in general. There were sixteen deaths soon after operation (nine from tuberculosis), and fourteen late deaths (eleven from tuberculosis); a mortality of 24 per cent. at least.

The class of cases from which these statistics are drawn is not one from which the remote results can be well estimated, so easily do they escape from observation. In the more inaccessible joints, such as the hip, the results are not as favorable as to recovery rates. In 2,461 cases of hip excision, collected by G. A. Wright¹⁰, the mortality was 34 per cent.

2. Generalization of tuberculosis. This danger demands serious consideration, because it is a danger which the improvement of antiseptics has not tended to diminish. Wartmann¹¹ analyzed 837 resections and found that 10 per cent. of all deaths were the result of rapid miliary tuberculosis. And Mr. Barker, a radical advocate of excision, stated in a lecture before the Royal College of Surgeons in 1888, that in 10 per cent. of all deaths following excision, "rapid miliary tuberculosis came on in such a way as to suggest strongly, if not to prove, that the surgical interference was the cause of the generalization

of the disease." In thirty deaths occurring in 151 resections, reported by Boeckel, 20 were from generalized tuberculosis. In 39 deaths occurring in 104 resections, reported by Korff, 34 were from tuberculosis. Sherman¹² reported 106 cases of hip disease, of which 42 were treated conservatively, and 64 were excised. Of the sixty-four cases excised, the present condition is known in fifty-six, thirteen died—ten of tuberculosis, a mortality of 23 per cent.

In a series of cases of hip disease at the Alexandra Hospital¹³ in London (occurring from 1867-1879), which were treated conservatively, there were 384 cases of hip disease treated, and only 23 deaths (6 per cent.) from tubercular meningitis. König¹⁴ reported that of twenty-one hip excisions, 47.6 per cent. died of tuberculosis inside of four years.¹⁵ Caumont treated twenty-six cases of bad hip disease by conservative measures, and found that 20 per cent. died of tuberculosis, while in twenty-two similar cases which were resected, 33 per cent. died of generalized tuberculosis. These are only some of the writers who believe that operative measures in tuberculous joint disease cause tubercular generalization. This question was discussed at the Société de Chirurgie as early as 1883 by Verneuil, Trelat, Berger and others, who agreed that tubercular meningitis could develop after the slightest intervention in the treatment of these affections. Metaxas and Vêrchère¹⁶ claim that more than one-half of the cases of tubercular meningitis are caused by operation for tubercular bone disease.

FUNCTIONAL RESULTS.

The successful results after resection of the joints must needs be inferior, in most instances, to the successful ones brought about by mechanical treatment in a similar grade of cases. Resection implies some destruction of sound tissue. No surgeon attempts to remove only diseased bone; he must go further and remove a layer of sound tissue with it. Nature cures by the absorption or elimination of the diseased products alone. On general principles a joint mutilated by surgical interference is not likely to be as useful as a joint cured by assisting nature. In the hip, resection means the removal of the head of the bone, and often the neck and trochanter major, perhaps part of the shaft also. Shortening is a necessity; important muscular connections are severed, and an unstable and flail-like joint may result. Wright reported 100 cases of excision of the hip. There were,

| | |
|----------------------------|-----|
| Soundly healed | 17 |
| Unhealed | 57 |
| Dead or dying | 18 |
| In bad condition | 3 |
| Amputated | 4 |
| Recent case | 1 |
| | — |
| | 100 |

In short, about 20 per cent. were satisfactory cases, and of the whole 100, in 30 the excision was done within nine months of the beginning of the disease, representing the most favorable condition for its performance. In Sherman's very favorable group of thirty-four recoveries out of sixty-four excisions, sixteen were reported in two years or less after operation,

so that they are hardly remote results. Of the twelve cases where three years or more had elapsed since operation, two walked with a crutch five and seven years after operation; in two more, Dr. Sherman noted the limp as bad; in two as medium and in five as slight. Yet these are, so far as the writer knows, the best statistics yet presented in favor of hip excision.

Excision of the knee leaves a stiff joint, no matter how successful the case. After mechanical treatment successful cases have motion. A foot which has successfully recovered from ankle joint disease without operation is manifestly a better one than when bone has been removed.

No attempt will be made here to define or defend mechanical treatment. Considering briefly what is expected from mechanical treatment in its best aspect, the group of results in hip disease referred to¹⁷ are a sufficient warrant for the statement that in skilful hands, modern conservative treatment yields, as a rule, good results in the case of children before puberty. All surgeons agree that unnecessary operating is to be avoided; all surgeons would agree that, other things being equal, non-operative measures should precede operative ones where there was a chance of their success. Here comes the struggle, however, that advocates of excision decry persistence in conservative measures as useless.

In this connection the experience of the Children's Hospital, Boston, may be of interest in the matter of hip disease. From 1878 to 1892, inclusive, there have been some seven hundred and fifty admissions to the wards for hip disease, many of the cases having been admitted twice, so that the number of patients is not quite so large. Of these cases only thirty-seven have been excised. It may be added that the surgeons of the Hospital have not been specialists, but general surgeons, holding appointments in general hospitals. To show more accurately the number of cases under treatment it may be stated that in the last nine years of this period (from 1884 to 1892 inclusive) 718 new cases of hip disease have applied at the out-patient department for treatment. Some of these were admitted afterward to the wards, while others were treated as out-patients. All were treated by conservative measures except in very severe cases. Briefly, in several hundred hip cases, many of which were severe at the time of application, only thirty-seven have required excision.

These figures will serve to show the practice of those surgeons who believe in mechanical treatment, namely that excision should be regarded in children as a measure to be reserved until mechanical treatment has failed. This is done on the ground that operation is in most cases unnecessary; that it is attended by certain risks which have been pointed out, and lastly that it yields, on the whole, inferior results to conservative measures. Excision is therefore necessary in children when efficient mechanical treatment is not obtainable, and when mechanical treatment has failed.

The evidences of the failure of mechanical treat-

ment are these: When in spite of good care, joint swelling increases, dense induration comes on with discharging sinuses, the granulations become flabby and inactive, and when, most important of all, the general condition of the child has begun to fail, the time for operation has manifestly come. Certain painful cases, which are rare, demand excision as soon as it has been demonstrated that mechanical measures have failed to control the pain.

The chief index, however, in the care of children is failure of the general condition along with a bad condition of the joint. Either alone is incomplete. This states only the view of those surgeons who are familiar with and believe in mechanical treatment. The loud advocates of operation are, as a rule, those surgeons at home and abroad who know little or nothing of the best conservative measures. In adults, tuberculous joint disease is from the beginning a more serious matter than in children. The process is more acute; it is not so amenable to mechanical measures; the systemic infection is more, and in cases of even moderate severity, excision is, as a rule, the best treatment. The results of mechanical treatment are not satisfactory except in mild cases, nor should mechanical treatment be persisted in for more than a brief time if progress is unfavorable. Nor are the results of excision so successful as in children, although the perfection of operative methods have tended to improve the death rate and the results.

The writer has avoided burdening this paper with masses of comparative statistics bearing upon the results to be obtained by mechanical and operative measures. A list of recent and important references is appended.

SECTION ON SURGERY AND ANATOMY.

SECOND DAY, JUNE 6.

Papers on "Early Symptoms and Diagnosis of Tubercular Joint Disease" were read by Drs. EMMET RIXFORD, San Francisco, and A. J. STEELE, St. Louis, Mo. A paper by Dr. A. B. JUDSON, New York on the same subject, owing to his absence, was read by the Secretary.

"Conservative Treatment of Tubercular Joints," papers by Drs. R. H. SAYRE, New York, and HARRY M. SHERMAN, San Francisco, were read by the authors, and one by Dr. JAMES E. THOMPSON, Galveston, Texas, in the absence of its author, was read by the Secretary.

Dr. ROBERT W. LOVETT's paper on "Operative Treatment of Tubercular Joints" was also read by the Secretary, its author being absent.

"Treatment of Tubercular Joints by Injections of Iodo-

form," was a paper presented and read by Dr. STANLEY STILLMAN, San Francisco.

"Treatment of Tubercular Joints by Injections of Corrosive Sublimate," by Dr. R. H. PLUMMER, San Francisco, was read by title and referred for publication, as was also a paper by Dr. A. E. HOADLEY, Chicago, on "Common Errors in Prescribing and Applying Mechanical Apparatus."

DISCUSSION.

DR. MEYER, of San Francisco—I take the pleasure of introducing a patient with tuberculosis of the elbow joint, treated by combining operative (incision and scraping) with Bier's method of constriction. The wound apparently healed quicker; while it has quite dangerous symptoms as to discoloration, it is noticed that a line of demarkation forms, a slough is thrown off, and the wound apparently heals quicker than by other treatment. This case is only put on exhibition as a suggestion to those members present who have an opportunity to try this new method and report at subsequent sittings, or at some future association as to the value of this treatment. While with the regular incision for resection of the elbow joint there may be considerable of the humerus scraped out, the wound here cicatrized in less time than usual, taking in this case only five weeks. And for that reason I would recommend to surgeons, who have an opportunity, to try and see whether by this method we make more headway than by iodoform and other treatment with operative interference.

DR. H. M. SHERMAN, San Francisco (introducing three patients)—I wanted to give as nearly as I could an example of a later result of hip resection, to show what the work is. This child has been operated on now, I think it is something like four years. For the last two years she has used no support in the way of a crutch or a stick, for her limp; the shortening is accurately corrected by the shoe. Her limp is the lateral list, the unavoidable mechanical result of removal of the neck of the femur. She has perfect support and a very good functional result in being able to move the limb around in almost any way she wishes. The lateral list is practically the only thing she has and there is very little of that. In making a table of cases, she would be put down as a child having a very slight limp; and technically it is not so—her limp is a list.

It is seven years since this boy's hip was removed. He had also at that time a dorsal spinal tuberculosis, and was wearing a leather appendage, and a little apparatus to carry his head. His limp is less than the other, but that is because he can not make the lateral sway; his spine is too rigid.

I think it is nearly three years since this young gentleman's hip was removed. He ordinarily uses simply this cane. The shortening is made up by one of those patent boots, in the position of extension, so that nothing shows. Now that is a bad limp, but this gentleman was older than the children when he was operated upon. And with his stick on the other side that limp becomes insignificant. His hip had become ankylosed so that there was abscess; the bone was really in a very bad condition, and he elected himself to have the operation done so that he could go hunting, and riding on horseback, which he could not do very well with an ankylosed hip. He spends a good part of his time on horseback, and does everything that anybody else could want to do.

As regards what Dr. Rixford said about the diagnosis, and postponing the beginning of treatment until he is sure of his diagnosis, I must object to that. If a child comes to me and I suspect there is tuberculosis of the bone, I begin treatment at once. Afterward if I find out that I was mistaken I have done no harm, and am very glad, indeed, under the circumstances to be mistaken and to have made an error in diagnosis; but I do not want to wait, to be absolutely sure that there is tuberculosis of the bone, before beginning my treatment, and let the disease get ahead of me. I took a splint off of a child the other day for hip joint disease, where she had worn it only a year, and where she had apparently no remnant of the disease at all, and I told the mother I doubted very much if the child had had tuberculosis of the bone; she had gotten well too quick.

Then, as regards the iodoform injections. In the first place, it is as well perhaps for us to remember that it is not an emulsion, it is a suspension of iodoform in whatever vehicle you choose, but it is not an emulsion. I am disappointed in the treatment. I have had a series of cases at the Children's Hospital which have been watched very carefully, the injections have been made, and I have failed to see that they in any way affected the progress of the cases. In no instance

did it do the child any harm, but I do not think that it has made the recovery any more rapid, or that there has been any effect from it.

A tissue that has been infected by the bacillus tuberculosis is destroyed; it has to be removed, and the injection of iodoform will not postpone the removal of it. Nature will do that in those cases that do not suppurate, by the absorption of the infectious tissues and their replacement by cicatrix. When suppuration takes place the staphylococcus thrives on the infected tissue, and it is broken down and runs out through the sinus. I do not see how, when once it is firmly established, the injection of iodoform, even into the tissue itself can in any way facilitate that process. It might perhaps kill the bacillus tuberculosis, but then its effects are still there in the shape of tissue that was infected, and that, either potentially or actually is dead tissue.

DR. L. SCHOOLER, Iowa—The general tendency of Dr. Sherman's paper was in favor of conservative treatment. In the treatment of hospital cases, and where the patients can be kept constantly under the observation of the attending surgeon, I grant that the statistics are better under that class of treatment than under the operative. In private practice, and in consultation work, both in your cities and country towns such as many surgeons are engaged in, I conceive that the difficulties of conservative treatment are in many cases insurmountable, and I am of the opinion that in the great majority of cases under these circumstances the operative system will give better results, and will save long suffering to the patient. Operative treatment, if effectual at all, effects a rapid amelioration and cure of the disease. Tentative treatment, conservative treatment, by injection of different substances and by the application of mechanical apparatus, is in a great majority of cases tedious, and in the class of cases to which I refer extremely unsatisfactory in my estimation.

DR. J. B. EAGLESON, Washington—The gentleman has said exactly what I wished to say. I will simply add one word to what he has already said; that the ability of the average practitioner, scattered about the country in isolated places, to try the conservative methods of treatment must certainly be limited always. I care not how thorough the discipline the person has been subjected to, if he is placed where he will see one of these cases once a year, or twice a year, or half a dozen times in a lifetime, his ability to handle them, from the conservative standpoint must be minimized, to say the least. Hence I say that the dealing with this class of cases must be looked at from the standpoint of the operation done under those circumstances, and if dealt with from that standpoint, then I say that the necessity for early interference is all-important. It is little less than criminal, it is cruel to watch the progress of a case for months and months, and perhaps for years, with the promise that at some time you will interfere to give possible relief by operation. I believe that an early operation in these cases is the resort of such persons under such circumstances. I believe that can not be emphasized too strongly.

DR. KURTZ, California—It is too late to enter into any close discussion on this subject. I simply want to direct your attention to two points. In the first place it seemed to me that there was a discrepancy in the papers in regard to early diagnosis. Perhaps it is trifling, but I think it is of considerable importance. The first reader, I believe Dr. Judson, of New York, pointed out that we have, as a first symptom, pain. I think that is certainly incorrect, according to my experience and according to my study. It is not the pain that first appears, but it is lameness, and that should be well remembered, for it is of very great importance. A child will drag his leg, it will slightly limp and that limp of the patient with hip disease is very characteristic; he drags the whole leg, not one part as in other diseases, and if you examine that, you will find neither pain nor limited motion, but you have that peculiar dragging limp, probably for a month or two months before the subsequent symptoms, the pain sets in. The same reader also made the remark that we should be perfectly satisfied in preliminary diagnosis before instituting treatment. Really, if we want to wait for the pain that he points out as being the first symptom, I think it will be too late. We should rather make a mistake on the safe side and put our patient in bed with his lameness for a week, or a month, or six weeks, or even more, and see if we can not overcome that condition. If we put a child unnecessarily in bed for a month or two months what does it matter? He will not suffer from it. So I say, begin the treatment as soon as you notice his dragging limp. Dr. Sayre in his very able paper seemed to lay great emphasis on the absolute rest cure in

cases of spinal disease; he lays great stress, I say, on the absolute rest cure. This would be the ideal means of treatment; to place your patient on a hard bed, as he says, or board, and keep him there, with or without a bed. I say if we once put a child on a hard bed, with extension, we need no apparatus at all. We all agree that it takes from two to four or six years to cure any of those cases of Pott's disease, or coccyxitis, or any tubercular disease of the joint, with the exception of the smaller joint. So I say it is rather a risky thing to lay a child on his back that long. Give that child a comfortable splint, give him a Bostwick splint, or some modification of it, and you will have fully as good results. That is my experience. I prefer a living slightly deformed child to a straight dead one.

DR. LYON, Conn.—It seems to me that this case, (referring to the case exhibited by Dr. Meyer) is proper to illustrate the subject before us, and I wish to make one remark in reference to it. He tells me that he was injured eleven years ago by the crushing of this elbow joint. He has now a well-nigh useless arm, but he has a valuable forearm and hand if he could make it available. Now if that elbow joint had been taken out, two to four inches of it, he would have had, not a useful forearm and hand, but he would have had a useful arm. That interference with the nutrition of the arm made it a proper site for the infection of other diseases. He has now a wasted arm, but if that had been taken out, I venture to say, from two to four inches, and allowed the bone to come together, this lad would have had a useful forearm and hand.

DR. MEYER.—I wish to say that this case was under my treatment only since June, 1890; that I had nothing to do with the primary injury, as eleven years ago I never thought of the study of medicine even. I only take this case to illustrate what can be done by combining the treatment by constriction in operative cases, and showing what can be done in a comparatively short time, in six weeks after the operation was closed. He was very much emaciated then, but is now better in that respect, and I intend to make a typical resection of the elbow joint, trying to get a movable elbow. Eleven years ago I did not have this case.

DR. THOMAS, Pa.—With regard to the statement that pain is not the first symptom of disease of the joint, I think that the child who is too small to let us know the fact that he has pain will limp; that very limp is an indubitable sign of pain; it can't be otherwise.

DR. GEORGE F. SHIELS, San Francisco—Apropos of this point concerning pain, I think that this word, pain, is merely a word to express an idea. No matter what we call it, a feeling of weakness in the bone, carrying to the individual the idea that it is not strong enough to support the body, will cause him to limp to save that bone. If the individual feels that there is a weakness in that joint and that he must protect it in such a way as to relieve it, and thereby causing a limp, I think it is a very small matter to argue about whether it is a limp or a pain. It is certainly something by which the patient is made aware of the fact there is a weakness in that joint and that it has to be protected by walking in a particular manner, which produces what we call a limp.

DR. R. H. SAYRE, New York—There are one or two points that have been made to-day which I would like to dwell on. I fully indorse the remarks of Dr. Shiels, and also in that connection I would like to say that when Dr. Rixford says he does not get pain in these cases it is probably because he does not cause sufficient pain in the child for the child to cry out and complain. The truth, however, is that it has a little spasm of the muscles, that there is a twitching of these muscles under his hand, as he moves his hand up and down; however the child may say it does not hurt. You will find sometimes these children say it does not hurt, while they cry. Very often they are too little to understand enough of your language to express their feelings properly, and you must be guided by their faces and see if they express sensitiveness in the eyes and mouth; then they have pain, although they very likely tell us they have no pain. And Dr. Shiels is perfectly right when he says that the involuntary protection to the joint which the child gives by its limp, by its little muscular spasm is a symptom that it has pain. I think that to avoid the beginning of treatment till the child has a marked limp, has deformity, a hump in its back which makes you positive that your diagnosis is correct, is a distinct mistake. If you wait until that time you will never get an absolutely good result in your treatment. You have passed the time. You might as well expect a man who has a little hacking cough in the morning, who has slightly elevated temperature, who gives a

little bronchial breathing in the upper part of his lung, to wait until he has a large hemorrhage in his pulmonary cavity, and expect to cure him of his consumption, as to wait until this child has a hump in his back and a limp, rather than confine him for a few weeks at the beginning, for fear it may prove ultimately to have been unnecessary. Sometimes pain is due to an involvement of the cartilage. In many cases we have a marked presence of the disease before there is acute pain. Unless there is an abscess forming or the cartilage is involved, very often there is a distinct disease before there is alarming pain. But a little pain is what we want to find. We want to be able to take this thing in its incipiency.

In regard to these statistics which Dr. Sherman read, that no case recovers which is over 40 years of age, that I know to be a distinct mistake. I have seen cases of tuberculosis over 40 years of age which have recovered. I know of a number of cases in my father's practice, and several in my own, where the patients were over 40 at the time of their first symptoms, and they have gotten well, or, at any rate, they have lived in a comparatively good state of health, well to all appearances for varying periods until they died of old age later on.

The mechanical list of which the Doctor speaks as a necessary consequence of removal of the head of the femur, I do not think is always present. It depends upon how much bone is regenerated after the removal of the head and neck of the femur. It does not always follow because you have removed a couple of inches of bone that you have a couple of inches of shortening. If the cavity is packed and the periosteum left open, there is very often a large amount of bone regenerated, and it may be sufficient in character and sufficient in size to prevent the limp. I think the cases Dr. Sherman showed here are remarkably good, but I think it is not always a fact that we have a limp after the removal of the neck of the femur. I have seen one or two cases where that limp was not present, and where there was a very little amount of shortening, although extensive bone removal had been practiced.

In regard to the gentleman who remarked that he preferred a living deformed child, crooked, to a straight dead one, I would also, but I do not think that to confine a child to a comfortable cuirass or keeping it in bed for even two years, or more is going to be necessarily followed by death. We see that the Indians carried their children around on a board in the way I have suggested when they are small, and there are a great many Indians in the world yet. And the fact that a child has an inflamed spine, and is six months or a year old, I think is a very good indication for putting that child in bed, in a little portable bed, and keeping it at rest. The point I made was that a little child who had an insufficient pelvis on which to get a basis of support, to put his spine at rest ought to be treated in a recumbent position. If they are big enough to run around, all right. But I see lots of children fastened up in apparatus which is simply hung on their shoulders, and they have to lug around that weight in addition to their body and bones. If these children were put in bed they could be transported by their parents, and when they get better they can be put in apparatus.

One gentleman has said that in country practice it is not practicable to practice conservative surgery. The object I had in my paper was to show that apparatus and the instrument-maker were not necessary always to the practice of conservative surgery in treatment of joint diseases. If you should put the joint at rest by your own intelligence and the work of a blacksmith, carrying out the principle which I treat and lay down in my paper, by such means as you may have in your bureau, plaster-of-paris and so on, and even resort to the blacksmith's shop for apparatus, I think that you can in any part of the country get a good result in these cases, if you will attend to the diagnosis and take the abscess before it has made vast strides. There is no doubt that in our large centers we have a great many opportunities which the men in the country towns do not have, but to say that these cases must be subjected to early treatment with the knife because they have tuberculosis is in my judgment a great mistake.

The papers of Dr. James T. Jelks, of Hot Springs, Arkansas, on "The Causation and Prevention of Hernia;" of Dr. L. Emory Lanphear, Kansas City, Mo., of Dr. C. M. Fenn, San Diego, Cal., on the "Management of Reducible Hernia"; of Dr. James D. Eagleson, Seattle, Wash., on "The Treatment of Irreducible Hernia," were read by title and referred for publication.

REDUCIBLE HERNIA.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY C. M. FENN, M.D.

SAN DIEGO, CAL.

In response to the courteous invitation of our Chairman, I have recently been endeavoring to recall the number of times the errant gut has yielded to my manipulations, and the *modus in quo*. The record enumerates thirty-five reductions since 1865, most of them implicating the inguinal region, and apparently confirming the statement that 80 per cent. of hernias affect that site. It appears further, in comparison with Dr. Dallas' estimate of 3,500,000 cases of hernia in this country alone, that the writer has measurably exceeded the ratio to each practicing physician. So large a number of successful replacements, some of them following the failure of other measures, may seem to warrant a brief consideration of the method of procedure; and as I may not rightfully invade the domain of those who have been delegated to speak to you of the etiology, pathology and surgery of ruptures, my remarks will be confined to the technique of reducible hernia. Not a few of the intestinal aberrations noted, occurred in the person of the same individual who, though for more than forty years a victim to those serious types of hernia known as left, oblique, incomplete, inguinal and right scrotal, attained the ripe old age of 79 years. We shall refer to his interesting case further on.

At the inception of this discussion, I venture the assertion that hernias are not merely mechanical displacements of the intestine, but often simulate neuroses, which strangely enough are not limited to the ruptured patient. The latter, if a novice in hernial accidents, or if his unaided efforts have failed to placate his ancient enemy, is frequently overwhelmed with fear of strangulation and impending death. His dyspeptic, flatulent and neurotic habit, added to the emotional excitement of such occasions, causes a rapid accumulation of flatus, which in local excess arrests normal peristalsis, and with the concomitant paralysis of the gut, presents one of the obstacles to its restoration. Hence, also, constipation due to paralyzing effects upon the visceral nerves. This, you are aware, may often follow incarceration of the omentum alone, of the appendix, or of a small knuckle of the bowel, and in the entire absence of any contraction of caliber or impediment within the canal. Furthermore, as showing the assistance during taxis to be derived from intestinal motion, to which we shall refer further on, a recent writer¹ suggests utilizing the cough, which sometimes produces the rupture—an application possibly of the Latin aphorism, "*Capilla ejusdem canis*"—the hair of the dog cures the bite. The enterocele, also, is often typical of the condition within the abdominal cavity, becoming "smaller after fasting and the use of purgatives, and larger when the tube is distended with food, gas or fecal matter," and hence presents one of the indications for treatment.

And how shall I describe the anomalous symptoms of the medical attendant who, at the outset of his career, if not always, seems to approach such cases with illy-disguised trepidation, his brain filled with phantasms of adherent and necrotic tissues, of abnormal epigastric arteries, and other pathologic phe-

¹ Geo. Wherry, F.R.C.S., England.

nomena. Twixt hope and fear that the knife may be required, and scarcely permitting his client to disrobe, much less assume a proper attitude for taxis, he seizes the rupture with both hands and attempts to reduce it *en masse*. Or later, summoning counsel and with the aid of chloroform or opium narcosis, he renews the ineffectual contest, unmindful of the fact that ruptures, like swine, never yield to force.

Protesting, therefore, against undue haste as unnecessary, in view of any immediate or serious pathologic changes, and ignoring all forms of narcosis because of its paralyzing effect on the bowel, I advise, first, removal of all apparel except the shirts. To lay aside the coat merely, or drop the trousers is not sufficient. The patient, now so far free from restraint and on his back, is ready for the examination of hernia and abdomen, and this, by the way, should be accompanied with words of encouragement and instructions as to respiration, no degree of anesthesia during taxis being an adequate substitute therefor. If constipation is present and the intestine is still distended with feces and flatus, a laxative enema with carminatives is indicated. Should none of these things be found to complicate the situation, invert a chair, as the most convenient substitute for an inclined plane, cover it with a quilt and elevate the patient's hips as high upon its back as possible, resting his flexed limbs and inverted extremities on one of the rounds or better still in the hands of an assistant. If there is much tenderness at the hernial site, or other evidences of congestion or constriction, it may be advisable to employ, topically, sulphuric ether or iced or hot flannels. The latter are to be preferred especially for elderly persons, and are best prepared in a colander placed over boiling water. When the abdominal viscera manifest a disposition to gravitate toward the thorax, which may be learned from sound, sight, etc., the opportune moment for the taxis has arrived. I need not dwell on this latter procedure further than to enjoin the utmost gentleness, and to remark that while one hand exerts a compressive *vis-a-tergo* force upon the head of the hernia, the other is engaged in urging the gut piecemeal, so to speak, through the ring. The entire manipulation is a species of *tactus eruditus* which should be cultivated with every opportunity.

Though this attention to details is not always required and may seem unimportant, it undoubtedly contributes to success.

With a few cases from my note-book, I submit the subject for your discussion:

Case 1, having an inguinal weakness of long standing, had taken temporary possession of a hotel bed, hoping to reduce his rupture and withdraw unseen. He was, however, discovered in a helpless condition by the landlady and medical assistance summoned. Failing to accomplish the object, the latter called in one consultant after another, until four were in attendance. After many delays, owing partly to the patient's forced change of lodgings, the hernia was pronounced strangulated and a surgical operation determined upon. At this juncture, the evening of the fourth day, the sufferer was transferred to the hospital under my service, some three miles from the city. I went out on the following morning, the fifth day after the accident, expecting to operate under difficulties, but finding his condition somewhat ameliorated it was decided to make one attempt by taxis. During my temporary absence he was to have a light breakfast, followed by a clyster containing turpentine and assafoetida; then to be placed upon the back of an inverted chair and have ether applied to the rupture. Upon my return the hernial tumor, though larger than the closed hand, promptly responded to the procedure described. Patient was discharged on the following day

Case 2.—The octogenarian's case, already briefly referred to, on one occasion assumed a medico-legal phase, which I venture to narrate. Advancing years had now added loss of vision to other infirmities. While on the street one day, the hernia came out, necessitating his removal into the nearest house. Messengers were dispatched for his regular medical attendant, but in my protracted absence two other medical gentlemen were summoned, with a result which the patient's own words may in part describe. Upon my arrival later, I found him alone and on the floor, his tear-filled eyes and voice betokening great suffering. The hernia was larger than a cocoa-nut and more sensitive than at any previous period, yet it readily yielded to the position, and taxis already described. As he arose from the chair he exclaimed: "I'm glad you came at last, for those fellows, after sticking a needle into me, tried to push my rupture back with both hands, and couldn't do it." At the same time he handed me a note, left by my predecessors, and reading: "We would advise the family physician to apply ether when he comes."

The somewhat remarkable legal sequence came two months later, in the guise of an \$80 law-suit—for services in operating upon a strangulated hernia! The issue was joined, and a number of expert witnesses promptly responded to the hypothetical question, How much is it worth to operate upon a strangulated hernia? "From \$50 to \$200." The plaintiffs, who had pooled their claims, were awarded \$60 and costs, the jury evidently congratulating the defendant that the maximum fee had not been demanded. The history of the case, besides illustrating the faulty methods referred to, recalls the student's definition of a crab, viz: "An animal that always walks backwards." "Correct," quoth the Professor; "with the trifling exception that the *Crustacea* are not animals and never walk backwards."

Evidently the hernia was at this time neither strangulated nor had an operation (?) been performed.

TREATMENT OF IRREDUCIBLE HERNIA.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1904.

BY J. B. EAGLESON, M.D.

SEATTLE, WASHINGTON.

On looking up the literature at my command on the subject assigned me by the Chairman of our Section, I find that nearly all authors of surgical works have been content to pass it by with very few words.

A hernia is said to be irreducible when, while the circulation of the contained parts is not impaired or the passage of the feces obstructed, the contents of the sac can not be returned into the abdominal cavity. This form of hernia is usually of long standing and of quite large size. It may have one or more of several causes, which have been divided into the following general classes, viz., those depending on the shape of the contents of the sac; those depending on the existence of adhesions; and those depending on the condition of the sac itself.

There is nearly always more or less omentum in the sac, in addition to the intestine which, from neglect in allowing it to go unreduced for a long time, assumes a pedunculated form with the enlarged portion occupying the sac in such manner that it can not be pushed back through the neck of the sac into the abdominal cavity. The intestine can frequently be reduced while the omental contents remain. Occasionally the intestine itself, or its mesentery, may become thickened in the sac while the portion surrounded by the neck may become contracted, thereby preventing its reduction.

The presence of other abdominal organs, such as

the cecum, bladder, ovaries, uterus, liver or spleen in the sac usually make reduction impossible.

Adhesions may form between the omentum and the intestine, or between either of them and the wall of the sac, thus preventing the return of the tumor.

There may be a thickening or a folding of the neck of the sac, or the surrounding tissues may compress the neck in such manner as to interfere with reduction. In old cases, especially where a large portion of the bowel or some of the large solid organs have remained in the sac for a long time, the abdominal cavity may be found in such a contracted state as to preclude their return to their former positions.

An irreducible hernia, if neglected, usually has a tendency to keep on increasing until such an enormous size is sometimes reached as to make the patient totally unfit for any manual labor. Irreducible herniæ of either the inguinal, femoral, umbilical or ventral type are, from their exposed condition, very liable to injury from external violence, and may very easily become incarcerated or strangulated. Inflammation of the sac may extend upward and set up a general peritonitis.

Those affected with this form of hernia are usually subject to some derangement of the digestive organs, such as indigestion, eructations, nausea, flatulence, colicky pains and constipation; besides they suffer from the great inconvenience of its bulk and weight as it gradually increases, causing an unpleasant sensation of dragging pains.

TREATMENT.

In the treatment of irreducible hernia, Prof. Gross presented three prominent indications which must be met: "1, to render the affection, if possible, reducible; 2, where this can not be done, to prevent its increase; and, 3, to palliate the suffering caused by the confined and compressed condition of the displaced parts." To these must be added the modern radical cure operation. In all cases the treatment should be guided by the age and condition of the patient, and also the size and nature of the hernia.

In fulfilling the first indication, all the circumstances of the case must be taken into consideration. The probability of the hernia being changed into a reducible one will depend principally on the size and age of the tumor. All other conditions being equal, a small tumor will be more easily reduced than a large one, and one of recent date than one of long standing, in which adhesions have had time to form, and the tissues to become altered in character and the normal relation of the organs changed. Mr. Bransby Cooper recommended a method which has also been successful in some cases in the hands of many other surgeons. His plan is to keep the patient on his back in bed for several weeks—from six to ten—on a low diet, devoid of all fatty and starchy articles of food, with total abstinence from all alcoholic drinks. The bowels should be moved by an active purgative once in six or eight days with a view to aid in the absorption of the thickened omentum and also to increase the peristalsis in the protruded bowel. Iodid of potash and mercurial preparations should be administered for their absorbent effect. Ice is kept constantly on the tumor. Taxis should be employed at frequent intervals. The late Prof. Agnew recommended constant compression by the application of a bag of small shot over the tumor. Repeated venesection has been recommended by some authors.

This plan of treatment is so tedious and annoying that many patients will not submit to it, as success very seldom follows its trial. Maisonneuve and others have been successful in some cases by elastic pressure applied by the means of an india rubber bandage or bag. In cases where the obstruction to the reduction was caused by a contraction of the neck of the sac, or a small band, the subcutaneous division of the constricting part by a small puncture in the skin, through which was inserted a grooved director and a small bistoury, has been done by Velpeau, Bouchut, Guerin, Pancoast and R. W. Johnson, of Baltimore. The latter devised an ingenious probe-knife with a concealed blade for this purpose. This is a dangerous procedure and can not be successful, except in cases where there are no adhesions of any kind to retain the contents of the sac.

When it is impossible to reduce the hernia by any of these methods, or it is not considered advisable to attempt a reduction, the tumor must be supported in such manner as to prevent its increase and, at the same time, protect it from external violence. In cases where the tumor is small, the best appliance will be an ordinary spring or elastic truss fitted with a concave pad to fit the tumor. This may be made of metal, gutta-percha, wood or heavy sole-leather, so long as the hollow is lined with chamois or soft leather, and properly padded to prevent too firm pressure on the tumor. When the tumor presents a peculiar shape or outline, Mr. Bryant has constructed a successful pad of metal molded on a cast taken from the tumor when at its smallest size. When the hernia becomes too large to be supported by a hollow truss, the best device will probably be a strong elastic suspensory bag, especially in the scrotal variety. A form of bag-truss made to lace up on the sides, and a cup made of soft leather supported by a metal rim have also been used.

In the present day of aseptic surgery, the reduction of an irreducible hernia can be most successfully accomplished by performing the operation for a radical cure. Under strictly aseptic conditions and surroundings, open up the hernial sac and carefully dissect loose all existing adhesions, tie off all the superabundant omentum contained in the sac, which may be so changed as to render it unfit to again occupy the abdominal cavity, with sterilized catgut, and after checking all hemorrhage resulting from the freeing of adhesions, return the protruded bowel, enlarging the neck of the sac or the abdominal ring if necessary to accomplish this easily. The operation for closing the internal ring and restoring the inguinal canal, or making a new one can now be performed by any of the popular methods which will be fully described by the papers on the radical cure of hernia.

In cases where the hernia is very large, and the patient is quite fleshy, it is advisable to keep him in bed on a low non-fat producing diet for two or three weeks, preparatory to the operation. Where the abdominal ring is very large, some authorities advise the removal of the testicle and cord on the affected side, in order to make the radical cure more certain. In old and fleshy or very much debilitated persons the operation should not be undertaken rashly, for there is always great danger in operating on such cases.

Where the operation is not considered advisable on account of the age or condition of the patient,

or is refused by him, the tumor must be sustained by means of a hollow truss, elastic suspensory or other appliance for its support.

In these cases where for some reason the hernia can not be reduced, a course of treatment should be instituted to relieve the derangement of the alimentary canal resulting therefrom. This will be best accomplished by strict attention to the diet and bowels. The food should be plain, simple, concentrated and easily digested. Articles of diet likely to produce acidity or flatulence should be avoided. The bowels should be kept in a soluble condition by mild laxatives. The general health of the patient should be sustained to the highest degree possible, and he should be made to realize that he carries with him a constant source of danger, and that any indiscretion in eating, or external violence, may lead to obstruction or strangulation.

TREATMENT OF STRANGULATED HERNIA.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOSEPH RANSOHOFF, M.D., F.R.C.S.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, MEDICAL COLLEGE OF OHIO CINCINNATI.

"If you see a strangulated hernia in the day, reduce it before the fall of night; if in the night, let not the rising sun witness its presence."—*Stromeyer*.

It is almost a truism that a strangulated hernia, if unrelieved, means death. In an experience of seventeen years, I have seen, with Dr. Richards, one case of umbilical hernia recover without operation after the formation of an artificial anus. It is almost equally true that if the strangulation is relieved early, recovery is the rule that ought to admit of few if any exceptions. The fatal cases of to-day are those of septic peritonitis, of gangrene, of contusion, paresis, and in the aged, pneumonia. With the possible exception of the last named, these fatal conditions are directly ascribable to delay in interference. Fortunately this must be oftenest charged to the neglect of the patient, but the cases are not a few in which, from insufficient examination or a doubtful diagnosis, the limit of safety is permitted to pass. The salient feature in the treatment of strangulation is the diagnosis. With that established the course is reasonably clear. I may be pardoned, therefore, for briefly touching on some of the points which seem of special importance. Given the following complex of symptoms, an irreducible tumor, hard and free of impulse in the side of the hernial apertures, accompanied by abdominal pain, obstipation, nausea and continuous vomiting, the diagnosis is indisputable. It is in the absence of or ill-pronounced development of one or many of these phenomena that the cause for doubt must be sought. The physical evidences of the hernia are often defective. The tumor may be small, too small to make a perceptible tumor, and palpable only in the depth of its canal. In the presence of a loose or irreducible hernia on the opposite side, the real seat of the strangulation is easily overlooked. Where a large and a small tumor are present, the probabilities of strangulation are *ceteris paribus*, greater in the smaller one. Furthermore it may be said that, inversely to the size of the hernia, are the acuteness of development and the severity of the symptoms.

The absence of communication between hernial sac

and peritoneal cavity, as shown by the suppression of impulse and irreducibility, is an infallible evidence of strangulation if the constriction is at the neck of the sac. In large hernias, strangulation by hands within the sac is common, in which cases there will be an impulse and the hernia may be partly reducible. In a specimen presented to the Association two years ago—which I was enabled to present—through misinterpretation of these data, perforation within the sac had taken place by pressure from a Meckel's diverticulum.

Torsion of a loop within the sac, occlusion within a diverticulum, of the sac, acute inflammation as of the appendix may occur without the suppression of abdominal impulse, and without increase of tension in the totality of the hernial protrusion. To an experienced surgeon, increased tension is a most important evidence of strangulation. Through gaseous distension of the intestine and serous transudation within the sac, a hernia after two days' strangulation may resemble a cystic tumor in its hardness and elasticity. The detection of a pedicle deep in an abdominal orifice, may avert an error. A subperitoneal lipoma or a cyst may conceal the hernia and complicate the diagnosis. Inflamed and retained testicles, and deep-seated lymphatic glands have been mistaken for strangulated hernia. The error is trivial. To err in the other direction has often proved fatal.

The symptom which in my judgment is most calculated to deceive is that of pain. Until adhesions form about the neck of the sac or within it, or unless manual efforts at reduction have been made, a strangulated hernia produces little or no pain at the site of the tumor. If present, it is overshadowed by the colicky pains of obstruction and the dragging pain of a fixed omentum or intestinal loop. It is felt chiefly in the umbilical region. Until the extra-peritoneal soft parts are involved in the inflammatory processes, a strangulated hernia is not very tender, except over the line of constriction. Within a year I have seen a patient treated for intestinal colic for three days. A small femoral hernia was overlooked. Three days later, an operation revealed a gangrenous hernia and septic peritonitis.

Nearly every strangulated hernia is obstructed. Therefore vomiting and obstipation are capital symptoms. They are not pathognomonic. In acute cases, vomiting is an initial symptom. It is copious, recurs at short intervals, and may in *foudroyante* cases, within twenty-four hours change to regurgitation of feculoid or fecal matter, with persistent hiccough. Such vomiting can not be mistaken. But even in acute cases the vomiting may be limited to one or two seizures in the twenty-four hours. Such vomiting, associated with diminished renal secretion and albuminuria, may readily be mistaken for that of uremia. Quite recently I saw a case of this nature with Dr. Hoppe. The diagnosis was further obscured by pregnancy. Vomiting did not supervene until the fourth day. The operation revealed a small knuckle of intestine concealed behind an adherent omentum. Opposite Gimbernat's ligament it had become gangrenous.

Obstipation is the rule in strangulated hernia. Lavage may remove the contents of the lower bowel. After that the intestine is impervious. The cases are very rare in which strangulation involves the omentum alone. Such a case I reported two years

ago. In the beginning the intestinal current may not be interfered with. With continued fixation of the gut, it soon becomes impermeable. This applies to strangulation of the appendix caught in a hernia, of which a number of cases have been recently reported, and to that form of hernia in which only a part of the circumference of the gut is involved.

There are yet other cases of hernial obstruction in which the diagnosis can not be made in one or two days. They occur in the large irreducible scrotal hernias of the aged. There are present retardation only of the onflow of the intestinal contents, slight colicky pain, little or no vomiting, recurrent constipation. Gradually the bowel is distended to a point beyond which the rings can not be made to yield. Then ensues strangulation as in the acute cases. One or two weeks may pass before the latter makes itself manifest.

Notwithstanding all that has preceded, cases will occur in which doubt can not be dissipated. The prudent and wise surgeon will deal with all these as cases of strangulation.

In a brief paper on the treatment of strangulated hernia, only two methods can claim consideration: 1, taxis; 2, operative interference.

TAXIS.

As surgery has progressively sought the light for its manipulations, and learned the value of larger open wounds, the usefulness of taxis has become restricted. The indications for taxis are few; the contra-indications many. I have long believed that the future of hernia patients would be bettered, if taxis could be altogether stricken from surgical technique. This statement is made with the full understanding that the mortality of reduction by taxis has been placed at from 4 to 8 per cent. (Bryant, Tscherning.) No statistics can be obtained of cases in which an unsuccessful taxis was followed by kelotomy. Taxis should be restricted to the subacute obstructions of old hernias. The smaller the hernia and the acuter the symptoms, the less is taxis indicated; never in these cases after the first twenty-four hours of strangulation.

The bowel may be irreparably damaged before this, but not often. Gangrene may be present without the usual evidences thereof, such as local edema and redness, great tympanites, rapid and feeble pulse, albuminuria. To consider the absence of any or all of these symptoms as indication for taxis, means enlarging the mortality from strangulated hernia.

Should the effort at taxis be successful which, perhaps fortunately, in the class of cases under consideration it rarely can be, it is so at the risk of returning to the abdominal cavity a loop of intestine doubtful as to viability, or with adherent limbs, and a hernial fluid ready to infect the peritoneum. Every effort at taxis is a contusion of the strangulated intestine. The blood-tinged hernial fluid is an evidence thereof. In intra-abdominal strangulation it is never encountered. Rents of the peritoneal coat of the distended intestine, the dread of the surgeon in laparotomy for obstruction, are none the less likely to occur because the bowel is manipulated under the soft parts and through the medium of a water-pad.

When reduction by taxis is indicated, it should be done under full anesthesia. The absolute relaxation thereby obtained is doubtless responsible for many of the successes of taxis. A time limit to the man-

ipulation has been given by many. Two unskilled hands can do more harm with taxis in twenty seconds than a careful operator will do in twenty minutes. Forced taxis is an abomination which has been expunged from surgical practice. It has been my fortune to see but one case of reduction *en masse*. The efforts of taxis should be gentle, continuous, and gradually increasing in force. Lateral pressure and gentle traction upon the neck of the sac may, by straightening the bend of the gut at the point of constriction, open a passage for the escape of its contents and thus be the immediate precursor of a reduction.

Taxis should be resorted to but once. When it fails, herniotomy can not be too soon performed.

KELOTOMY.

An operation for strangulation is, *per se*, not dangerous. The measure of its gravity is formulated by the condition of the parts and of the patient at the time of operation. I have had thirty-seven operations for strangulated hernia, in every case but one. Of these, six ended in death, two from gangrene and peritonitis, one from pneumonia in a man of 70, one from heart failure in a woman with aortic regurgitation, and one through an error in judgment in adding the radical to the relief operation in a large scrotal hernia. In the sixth case, laparotomy was performed for reduction *en masse*. The intestine, which seemed viable at the time of operation by lamplight, gave way on the fifth day. With my present knowledge the deaths from heart failure and pneumonia might have been averted, by substituting cocain for general anesthesia, since in neither patient could it have been a question of radical operation. In a case recently seen with Dr. Topmiller, I made the relief operation, removing a mass of omentum the size of a walnut, and returned the intestine without inflicting enough suffering to elicit a moan. The patient was 68 years of age and the subject of cardiac asthma.

From the foregoing limited experience, the conclusion is justified that in an otherwise healthy individual, death does not follow herniotomy, except as a consequence of grave changes in the hernial contents or within the abdominal cavity. The full statistics of Hagedorn of 170 operations fully bears out this view. It includes cases treated between 1883 and 1890. The general mortality was 14 per cent. The death rate was *nil* in cases in which the large intestine was involved; 48 per cent. in cases where the small intestine and omentum were unchanged; from 22 to 38 per cent. in cases where it was ecchymotic or suspected of gangrene. These results are a vast improvement on those given by Benno Schmidt, Rose and authorities of Great Britain a few years before, according to which the mortality varied from 25 to 48 per cent. Thus is negated the view that the modern methods of wound treatment have not influenced the mortality of operations for strangulated hernia. As operations are performed earlier, and larger experience improves the methods of dealing with the grave complications, the mortality will be doubtless still further reduced.

OPERATION.

Except in the hernias of infants and in the large hernias of the aged, and then only when the constriction is known to be at the neck of the sac, the incision should be ample. An utter disregard of the anatomic tunics will facilitate procedures. There

must be no enucleation until the sac proper has been reached. To recognize this will sometimes embarrass an experienced operator. When thickened and covered by pendulous masses of fat it may greatly resemble a part of the colon. In acute hernias containing considerable sanguinolent fluid, the resemblance to a discolored intestine is very great. The presence of ramifying vessels in the sac is distinguishing. So long as there is a doubt, it is quite certain that it is *not* the bowel which is exposed. In very rare cases there may be no sac under the line of incision, an uncovered portion of the large bowel or of the bladder presenting. An exploratory opening such as would naturally be made into the sac as ordinarily found, would while elucidating the relations, be far from being a serious mishap, if it involved the bowel.

Is the sac to be opened? This question has been affirmatively settled for all times, if not for all cases. In every case in which the radical operation is to be performed, in which there is the least doubt as to the site of the constriction or the condition of the hernial contents, and always before the constriction is relieved, the sac must be opened; the constricting ring to be divided from within. In the hernias of very young children, where the surroundings might make the aseptic course uncertain, and in the large obstructed hernias of subacute course as seen in the aged in whom a confinement of two weeks might be serious, an external herniotomy is doubtless justifiable. Although I have seen a number of cases in which it seemed applicable, I have never performed one, nor is it probable that I shall. An irrepressible anxiety to see the condition of the hernial contents impels me to what was known as the greater procedure of internal herniotomy. The division of the stricture is always a most delicate operation, in which the hernia knife of Cooper is almost indispensable, the finger serving as a guide. Save in the very tightest strangulations, the intestines are readily displaced to permit the nicking at one or several points of the constricting band. To avert the danger of wounding the intestine, the constriction can be divided from without. In inguinal hernia it is feasible. In femoral hernia it ought not to be practiced, since it entails the division of the crural arch.

The constriction relieved, the hernial contents often have a tendency at once to slip into the abdominal cavity. This is to be prevented, for no intestine is to be returned until it has been thoroughly inspected below, at, and for some distance beyond the line of constriction. In hernias which have been irreducible from adherent omentum, it may be difficult to find the strangulated intestine. Often it is small. In a case seen with Dr. Marcus, only a part of the circumference of the gut was found beneath the constriction. In not a few cases the intestine can not be properly exposed until the adherent and thickened omentum has been excised. Since, as a rule, it can not be returned, it might as well be radically treated first as last. In dealing with the omentum, too much tissue should not be included in the ligature; this should be tightly drawn, care being taken that in the necessary manipulation the thin-walled veins are not torn. After thorough disinfection, the omental stump should always be returned into the abdominal cavity and not be permitted to remain near or within the hernial ring. I have seen, with Dr. Forchheimer, one internal strangulation consequent on the fixation of an omentum to the inter-

nal ring, after a radical cure had been effected by truss. Personal experiences I have not had with complications produced by the omental pedicle returned to the abdomen. Those interested in the subject will find them ably set forth in a recent paper by Dr. Bull.

Hernias in which there is obstruction without strangulation are generally dry. The coils of intestine are reddened, covered often with fibrinous flakes, and often adherent to each other and to the sac wall. Such adhesions should always be severed, lest after reduction the obstruction continue. The greatest care is necessary in severing the adhesions which have formed within the neck of the sac. They must be looked upon as the barrier to peritoneal invasion from an ulcerated bowel. Even with the greatest care, a rent may be made here as the bowel is drawn into the wound. This accident happened to me during the winter, before my class.

There are few things more beautiful to the surgical eye than the fast changing colors of a tightly strangulated intestine, relieved of its constriction. Within a few minutes, dark brown or even black, in turn becomes chocolate, purple, dark red, and pink before the intestine is normal. The contained gases pass on, the constriction groove becomes shallower and while you observe, peristalsis may be reestablished. Such an intestine can be returned with safety. Here two things are to be remembered: 1, it is as unsafe to return a distended gut to the abdomen after herniotomy as after abdominal section; and 2, that false reductions can be made after an operation quite as easily as after taxis. The absence of the gut from diverticula of the sac, which may be present between the musculo-fascial planes or in front of the peritoneum, must be established by the finger within the belly cavity before the reduction of the hernia can be said to be assured. With a free severance of adhesions about the neck of the sac, a mass reduction is not possible after herniotomy. When complications such as these follow herniotomy or taxis, the opening of the abdomen is justifiable. In no ordinary strangulated hernia, however, is hernioplasty a proper procedure.

Introduced as early as 1590 by Rosset and in 1723 by Cheselden, this chimera was almost forgotten until Mr. Tait made an effort to revive it in a paper before the British Medical Association, in 1891. Possibly of service for the radical relief, for reasons almost obvious it can have no place among procedures for strangulated hernia.

The most important question entering into the treatment of this subject is what to do with gangrenous hernia. Shall the constricting ring be divided? The theory was long advocated, and recently again promoted by Banks, that the constriction ring should ordinarily not be divided in gangrenous hernia, on the ground that it bars the development of general peritonitis. By the constriction the septic products of a hernia may be isolated for a time. But the peritonitis develops from within, and that without the direct implication of the intestine. In a case of gangrenous hernia which contained only omentum, seen with Dr. Tilton, of Kentucky, death resulted from general peritonitis. Just beyond the neck of the sac was the colon fixed by the adherent omentum, and its wall rendered paretic through traction, was unable to resist the passage through it of organisms fatal to the peritoneum.

Gangrene of the omentum is rare. Its safety is found in the ease with which it forms adhesions to the sac wall, through which it then receives its nutrition. The case alluded to is the only one I have seen. Benno Schmidt questions altogether the existence of primary strangulation of the omentum. Of Hagedorn's 170 cases, gangrenous omentum was only once the sole occupant of the sac. I have found reports of two other cases: One from Heidelberg; the other of W. H. Bennett, of St. George's Hospital. There is but one opinion as to the management of gangrenous omentum. Excision after ligation in healthy tissue, and return to the abdomen, generally ends in recovery unless peritonitis already exists. The three cases quoted all recovered, although in each the radical operation followed that for strangulation.

When gangrene involves the intestine, the solution of the problem is far less easy. Since Ramdohr first successfully resected the gut for hernia in 1727, the possible success of primary excision has been conceded.

Of recoveries there have been many. But the measure, however ideal, has never gained firm footing among surgical procedures. This in face of the fact that the results from the alternative measure, that of the formation of an artificial anus, have been most deplorable. Recently Poulsen reports twenty-nine cases, with but four recoveries. Of thirty-five cases as treated at St. Bartholomew's, four were saved (*British Medical Journal*, June, 1891, i., p. 701). Certain is it that all cases should not be treated alike, and that every case ought to be considered with reference, first to the condition of the intestine and its environments, and second to the probability of the patient to bear the shock of a prolonged operation.

A strangulation affects the gut either along the line of constriction, or at some or all points of the coil involved, or in the course of the intestine for a varying distance above the point of constriction. Where the constricting band binds the gut, a well-marked groove is made by direct pressure. The constriction, tight enough to occlude the caliber of the bowel, may not interfere with its vascular supply. If gangrene results it will be from pressure at the bottom of the groove and limited in extent. Except for the usually small ulcer in the constriction groove, the gut above and below may be normal in appearance. In the fruitless effort of nature to protect the general peritoneum, adhesions are quickly formed between bowel and neck of sac. In the attempt to sever these, the fragile wall of the bowel tears along the line of constriction. Doubtless many cases of this kind occur, the fecal outpour taking place at the time of the operation. To avoid this it might be wise to follow the practice of Mikulicz, who in every case of suspected gangrene opens the rings from within the belly cavity, thus making a laparocolotomy which permits, as he thinks, thorough isolation by gauze of the infected area. The difficulty appears in the fact that pressure gangrene limited to the furrow and made by the constricting band is not always easily recognized. Fortunately the tissues about it, whether torn by manipulation or not, are in a fair condition for partial excision and lateral suture, by which the patient may be saved the perils and annoyance of an artificial anus. Krumm reports such a case successfully treated, and Barette

three, of pressure gangrene successfully managed in the same manner. In such a case the gangrenous area may profitably be inverted and the contiguous parts sutured in a horizontal fold. In the case of rupture appended, the aperture was treated as a gunshot wound, sutured, and the coil returned to the abdomen, but anchored for forty-eight hours to the wound by a catgut suture through its mesentery.

In some cases the force of strangulation, although influencing the circulation of the whole knuckle, appears to affect most seriously its central part and at a point farthest removed from the mesentery. It is clear that if in such a case excision were to be done, it could only be beyond the limits of constriction. The cyanotic gut about the really gangrenous center would ill support a suture. Let alone, it will recover. The handling incident to suture might easily prevent it. Furthermore, in cases of this nature the gangrene is often more extensive than is apparent. Beginning generally in the mucosa, the serous tissue is the last, and therefore least affected. The fixation of the gangrenous area in the bottom of the wound, relying on nature to make the anus preternaturalis, appears to me sound judgment. The data on which this view is based differ from those which militate against the formation of a fecal fistula when the gut is gangrenous in its entirety.

First and foremost, the caliber of the gut remains patent, and death from inanition is rendered impossible. Again, the fistula which results will probably be small, and close in a few weeks or months without operative interference.

When gangrene involves the entire strangulated knuckle the appearances are sufficiently characteristic. Chocolate or dark slate-colored, denuded in patches of its peritoneum, covered with flakes of lymph and in a collapsed condition, it fails to react to mechanical or chemical irritation. The odor is fetid before perforation has taken place. When the strangulation has been very acute, the changes in and about the hernial sac need not be very marked. After the escape of a varying amount of turbid bloody fluid from the sac, the latter appears of a bright or dusky red, minus the glistening appearance of the normal serosa. When it is of older date, one after another of the hernial coverings are involved in the inflammation. They are welded together, in turn to break down. A fecal abscess is the result.

The most serious and far-reaching changes in gangrenous hernia are often found in the afferent portion. They may be said to involve its caliber, its nutrition, its contents and the peritoneum singly or together. Although long recognized, the dangers inherent in this part of the intestine have recently been strongly brought forward by Beneke. Above the constriction there is always some dilatation with more or less paresis and congestion of the intestinal wall. It may be dark in color and edematous from venous stasis. Possibly from the same cause its mucous lining secretes abnormally, and as a result, at times, enormous accumulations of fluid are found—according to Mikulicz from one to three quarts. This forms an excellent culture medium for bacteria and in the process of putrescence, toxins are formed, the absorption of which doubtless accounts for many deaths under the mask of acute sepsis from strangulated hernia before peritonitis has developed. The disintegration of this fluid gives rise to a fecal odor irrespective of the site of the constriction, and it is

this fluid forced into the stomach and thence regurgitated that is so often mistaken for fecal vomit.—(Mikulicz.) Furthermore the wall of a paretic and congested gut has no power to resist the pathogenic organisms which it incloses. Far above the constriction, hemorrhagic infiltrations, diphtheritic-like deposits on, or ulceration of the mucous membrane may ensue. This is far more liable to such necrotic changes than the outer tunics and there is no way of knowing how far the process has extended. In one of Kocher's cases the gangrene extended four inches, and in one of Taendler's six inches above the suture line. In a case not submitted to operation, the diphtheritic deposits were found six feet above the constriction.

When death follows hernia, the symptoms of peritonitis are rarely absent. In the majority of cases, even of gangrene, there is no perforation within the abdomen, and the course of the peritoneal infection must have been through the microscopically intact gut. That it may occur where the gut does not enter into the hernia has already been seen. It has long been known through Nepveu's investigations that the fluid transudate in a hernial sac is rich in pathogenic organisms before gangrene has developed. Benneke has recently shown that the bacteria readily pass through the wall of the paretic bowel and produce diffuse peritoneal infection. On microscopic sections he was enabled to trace their progress through the intestinal wall. (Before the French Surgical Congress, Clado has recently made similar demonstrations.) From these sources metastatic infection in remote organs may ensue. The process is like that seen in other morbid conditions of the intestine; notably in typhoid fever and appendicitis, where peritonitis develops without actual perforation.

Equally important with the local, is the general condition of the subject of a strangulated hernia in determining the plan of procedure. When delay has brought the patient to the verge of collapse, when even the shock from prolonged anesthesia can not be ventured, that must be done which most readily gives relief to the strangulation. It may be the opening of a fecal abscess, the division of the stricture, or the rapid fixation of the gut in the wound. Whatever the procedure adopted in the condition indicated, the result will probably be the same—death within a few hours or days.

In most cases, however, the condition is less deplorable and evidently tolerant of a somewhat prolonged operation. It is in this class that choice must be made between the establishment of an artificial anus, and resection of the bowel with immediate suture of the divided ends.

Authorities are at variance as to the value of the two procedures. In England, Baker, MacCormac, Banks and Treves decidedly oppose the greater operation of resection. In this country the same opinions have been held, unless they have been recently influenced by the reports of successful cases of excision by McCosh, Richardson, Dawbarn and others. In Germany, Kocher's and Czerny's first successes were followed by many failures which frustrated the natural desire of surgeons to make primary excision the normal procedure in gangrenous hernia. Finally Reichel's critical review of the statistics in 1883 made it appear that the preferable primary operation was enterostomy, to be followed by a second operation for the closure of the preternatural open-

ing. From the first, Kocher has remained steadfast to the ideal operation, and in Mikulicz he has recently found a most able supporter.

The advantages and disadvantages of the two procedures are almost apparent. If primary resection is successful, the patient is well in from four to six weeks. If an artificial anus is successfully established, a second operation of a very serious nature must follow. The artificial orifice is as large as the bowel, and the mucous membrane is prone to prolapse. Such an opening never closes spontaneously.

While in a considerable number of cases the enterotome of Dupuytren might be successfully applied with the low mortality of 5 per cent. (Korte), it will fail in many cases and be absolutely inapplicable in others. Again, according to Dupuytren, it should not be used for two or three months after the primary operation. It is during this interval that the greatest danger from artificial anus is encountered, that from progressive inanition. Recently Poulsen has used it twelve and even nine days after the first operation.

It has not yet been established how much of the intestinal canal is essential to the maintenance of nutrition, but where the fistula is above the mid-part of the ileum, rapid emaciation and death follow before any secondary procedure for closing it can be practiced. McCosh does not overrate the argument of statistics in the statement that the death rate of all cases in which an artificial anus is made, including the operations for its relief, is 50 per cent. The danger from secondary resection and enterorrhaphy is very considerable. Haelnel mentions forty-three cases, with sixteen deaths and two failures.

To be successful, the artificial anus must be established in healthy bowel, else the dangers inherent in the afferent portion will not be removed nor will a free outflow from the intestine be secured. The only advantages therefore which can be claimed for this method are the rapidity with which it can be performed and the slight technical skill required in its performance. A further advantage is supposed to exist in the lesser danger connected with this, as compared with the major procedure of immediate resection.

There is hardly a subject in surgery concerning which statistics are so much at variance as are those relating to gangrenous hernia. According to Korte, of 111 cases treated by enterostomy, eleven ended fatally. Herman (quoted by Haelnel) mentions eighty-three cases with seven deaths. On the other hand, Weil reports fifteen cases with thirteen deaths. Benno Schmidt places the mortality at 85.5 per cent. for the formation of an artificial anus, as against 71.1 per cent. for primary resection.

F. A. Southern, Surgeon to the Manchester Royal Infirmary, recently reports eighty-five cases of herniotomy with nine cases of gangrene. All of the latter died. In six, an artificial anus was made; in three, primary excision.

If statistics are of any value in solving the relative merits of enterostomy and primary excision, it is evident that the reports of scattered cases are far less weighty than such from a few and skilled operators, and from hospital records where nothing is concealed. Such a tabulation has recently been made by Mikulicz from seven large clinics of Germany and Switzerland. Of 168 cases of gangrenous hernia, 109 died. Of ninety-four in which an artifi-

cial anus was made, seventy-two died; mortality, 76 per cent. Of sixty-eight primary excisions, thirty-two, or 47.1 per cent. died. Of six intermediary resections, five died. It would appear from this that the mortality of primary excision is very much less than that of the lesser operation. But this can be accounted for by the certainty that the latter was often used as a last measure in conditions approaching collapse, and therefore precluding the major operation.

These statistics practically coincide with the very extensive and recent tabulation of H. P. Zeidler, of St. Petersburg. Of 289 cases in which primary excision was performed, 142, or 49.13 per cent. died. Of 287 cases in which an artificial anus was established, 213, or 74.22 per cent. died. This is an increase in the mortality, of 25 per cent. In the group of cases of artificial anus, there were 5.55 per cent. more of cases hopeless from the beginning than in the group of primary resections. This still leaves 17 per cent of cases which might probably have been saved by primary excision.—(*Cent. f. Chir.* 1893. p. 62).

The advantages of primary resection are patent. Its disadvantages are, the time required for its performance and the danger of peritonitis from imperfect technique. In a measure both can be overcome. The first of these is probably grossly exaggerated. With separation of the mesentery and its closure by suture, to be followed by the continuous Lembert-Czerny suture by lateral anastomosis, or by the use of button or potato plates, not more than half an hour at most should be required for the enterorrhaphy. Complicated clamps, a separate row of stitches for mucous and serous tunics, interrupted sutures unnecessarily waste time. When the continuous suture is used and appears weak at points, a few supplementary stitches can easily be taken. Suturing the mesentery brings the intestinal ends naturally together and gives assurance that the most treacherous part of the suture, that near the mesentery, can be properly applied. The second danger is from injudicious selection of the lines for suture. As elsewhere in gangrenous processes, the danger lies rather in removing too little than too much. If Kocher excised five and Koeberle six feet of intestine, a few inches more or less can not be important. In acute cases, where the caliber of the gut has not been long occluded, and koproöstasis is little, if at all developed, an inch or two on each side of the constriction groove will probably bring the suture line in healthy tissue. Where the mesentery has not been included in the strangulation, the same favorable conditions may be expected. Where, however, much dilatation of the afferent gut exists, its thorough evacuation should precede the enterorrhaphy. After hernia, as after laparotomy for obstruction, it is fatal to return a distended gut to the abdomen. The further danger, that of septic infection of the peritoneum, can in a large measure be reduced by thorough irrigation of the sac before suturing; by careful handling of the gangrenous gut without the wound, meanwhile protecting the peritoneum by gauze packing. Finally, the sutured intestine should be left just within the abdominal cavity and a radical cure should not be attempted. Mikulicz, whose success surpasses that of any other operator—twenty-one cases with fourteen recoveries—insists on the open treatment of these cases. Should fecal extrav-

asation ensue from defective suture or other cause, it would naturally turn towards the wound, whereby the danger of general peritonitis would be largely averted. For from two to five days after the operation the sutured intestine remains where it is placed within the abdomen, and after that length of time the development of peritonitis is not probable. To hasten the process of wound repair, deep and superficial sutures might be drawn through the wound margins and kept over the gauze packing, to be tightened without anesthesia after the danger line has been passed.

Between the extreme measures considered, others looking toward a compromise have recently been brought forward by a number of surgeons. Among these are the intermediary, excision and suture of Riedel. The artificial anus is established in the usual way. After twenty-four or forty-eight hours the edges of the intestine are vivified and united by suture. In 1882 Bouilly suggested excision and suture, the latter being purposely made imperfect at one point to guide the fecal extravasation. To avert the danger from imperfect suture, Hahn follows the kelo-tomy with a median laparotomy. Through this wound he brings the divided ends of the bowel, thoroughly protecting the abdomen against infection by packing them in gauze. When the suture is completed, the closed knuckle is kept in the wound between gauze splints until union is assured. The competency of the suture is certain after twenty-four hours, when the bowel is returned to the abdomen and the external wound closed. It is difficult to understand why the same procedure should not be carried out in the inguinal herniotomy wound. Nevertheless, Hahn has had two successes with it; and in a third, reported by Kutschera, the result was equally satisfactory.

To overcome the danger from death from inanition, Helferich has recently combined enterostomy with an intestinal anastomosis above the constriction furrows. By this method two courses are open to the intestinal circulation, and the closure of the artificial anus is greatly facilitated. The operation was done in two cases, one of which was successful, the fecal fistula closing spontaneously.

There is yet another class of cases in which the condition of the bowel is such that whereas gangrene is not yet present, it might through subsequent necrosis cause death if returned to the abdomen. Such a knuckle is a menace. Who has not seen it? Especially if operating by light, both artificial and bad. A bowel that is not at all doubtful in appearance will at times repay the trust placed in it by a perforation. Among ninety-six deaths after herniotomy, it was in twenty-six cases the result of returning to the abdomen intestine which subsequently perforated. In Hagedorn's clinic three deaths out of fifteen resulted in the same way. To return doubtful intestine is unnecessarily jeopardizing life. To treat such intestine as radically as bowel already gangrenous is an extreme measure, not to be advocated. Fortunately the intestine can be retained in the wound for a number of days in gauze packing or by sutures. When its viability has been established, it is an easy matter to return it to the abdomen. Graefe recently reported a successful case in which the intestine was so retained for five days before replacing it. Should the dread of adhesions be feared, the intestine might be retained just within the abdo-

men by fixation sutures or by gauze. In the event of gangrene, the fecal extravasation would course toward the external wound.

When in 1880 Czerny reported his first case of primary excision for gangrene, he believed that the operation would not displace the older operation of enterostomy. Although the last four years have brought forward success after success from primary resection, the dictum of Czerny still holds good. Each operation has its proper field. The boundary lines are becoming more clearly defined. Nevertheless, it must always remain for the judgment and tact of the surgeon, as individual cases arise, to determine the proper procedure to be adopted. In operative surgery, as elsewhere, the ideal should be sought. This would make primary excision the normal procedure in gangrenous hernia, and only cogent reasons should cause the operator to refrain from striving for the ideal.

CASES OF GANGRENOUS HERNIA.

Case 1.—Male, aged 60 years; Germantown, Ohio; left inguinal hernia; reduction by taxis; obstruction unrelieved. Two days later, laparotomy by lamplight. Bowel apparently viable. Perforation peritonitis on fifth day. Death.

Case 2.—W. P., male, aged 29 years; Carlisle, Ky. Rupture of several years standing. Taxis attempted on second day. Operation in the night of the fifth; one-half pint of foul smelling bloody serum in the sac. Omental mass large as a fist, gangrenous; no intestine in sac. Death in twenty-four hours from peritonitis.

Case 3.—Miss D., aged 30 years; seen with Dr. Jenkins, of Newport. Recent rupture of four days; strangulation. Sac contained several ounces of bloody serum; coil of small intestine four inches long; in its center, opposite mesenteric pudic, gangrenous patch large as a silver quarter. Constriction divided; intestine anchored by catgut suture through mesentery; gauze packing; perforation on the fourth day; profuse discharge during two weeks. Gradual contraction of fistula and permanent closure in one month.

Case 4.—Mrs. K., age 56 years, seen with Dr. Harff. Large intestinal inguino-labial hernia. Strangulation by band; operation twenty-four hours after inception; gangrene of intestine; excision of fourteen inches and end-to-end suture by Czerny-Lembert method. Recovery.

Case 5.—Mrs. P., age 58 years; seen with Dr. Potter, Carthage, Ohio. Small femoral hernia right side; strangulated six days; refused earlier operation. Great abdominal distension; vomiting fecal. Pulse 110, temperature 101. Fetid and bloody fluid in sac; loop of small intestine six inches long, gangrenous, afferent gut normal. Relief of constriction, excision of gut several inches. End-to-end suture by Czerny-Lembert method. Fixation of gut near wound, gauze drainage, death in twenty-four hours from peritonitis.

Case 6.—I. F., male, age 54 years; Good Samaritan Hospital. Irreducible femoral hernia; right side; strangulated four days; fecal regurgitation; general condition good. Few ounces of purplish fluid in sac. Knuckle of intestine and adherent omentum in sac. Constriction at Gimbernaut's ligament divided. Intestine gives. When brought into wound there is a perforation in the constriction groove one-third inch wide and one-half inch long. Edges normal. Inversion and closure by suture as in gun-shot wound. Slight anchoring of intestine; gauze packing; uneventful recovery.

Case 7.—Mrs. H., age 35 years; seen with Dr. Hoppe; four months pregnant. Right irreducible femoral hernia of many years standing. Absolute constipation, five days; vomiting twenty-four hours; sac contained several ounces of bloody fluid and adherent omentum and a knuckle of small intestine, eight inches long. Gangrenous in constriction groove but not perforated. Anchored to wound. Fistula established on fourth day; closed permanently in a month. Recovery.

HOSPITAL CAR.—A hospital car, recently adopted by the Central of New Jersey, is the latest departure in railroad engineering. It is supplied with every known medical and surgical device for prompt aid in case of wrecks or other accidents. While on the line it is given the right of way.

THE SURGICAL TREATMENT OF HERNIA.

Read in the Section on Surgery and Anatomy, at the Forty fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY HENRY O. MARCY, M.D.

BOSTON, MASS.

One of the most brilliant triumphs of modern aseptic surgery is the undoubted demonstration that hernia, in all its common varieties, may be permanently cured. This occasion offers little more than the possibility of somewhat dogmatically emphasizing certain fundamental factors and conditions which enter into the problem, and which must be understood in order to make possible the permanent cure of hernia.

Since inguinal hernia in the male is by far the most common of all varieties, and much the more difficult of cure, it is proper that the limited time at our disposal should be devoted to the consideration of this variety. The normal anatomic relationships of the important structures which form the anterior lower portion of the abdominal wall are invested with an entirely new interest when considered from the standpoint of their physiologic function in connection with the reproductive organs.

For many reasons it would have been of great advantage to the male, if the testicle had been held in suspension within the abdominal cavity, somewhat after the general disposition of the ovary in woman. The dislocation of the testicle into an external pouch necessitates long and tortuous blood vessels, with a corresponding increase in length of the spermatic tube, and these component parts of the cord must traverse an opening in the muscular abdominal wall, which is ever varying in functional activity and motion. We can but admire the adjustment of these entirely diverse relationships, so as to render possible the functional equilibrium of such diverse structures.

In a large degree this is rendered possible only by the obliquity of the inguinal canal, which traverses the abdominal wall in a direction that is normally maintained at or near to a right angle with the intra-abdominal pressure—a condition analogous to the penetration of the ureter through the urinary bladder, which is the only other important illustration of this principle of mechanics found in the human body. It is not a valve which acts only at the exit of the canal to prevent the reflow from backward pressure, but it is exerted upon the whole length of the canal equally, so that, when the normal conditions are maintained, the greater the intra-abdominal pressure, the more firmly in juxtaposition are the walls of the inguinal canal, effecting its complete closure.

Whatever may be the causes which produce a departure from this normal anatomic relationship and result in hernia, certain conditions invariably pertain. The first of these is an enlargement, almost always from above downward, of the internal inguinal ring. When this has taken place, the thin elastic peritoneum easily yields to the intra-abdominal pressure, and the fluid contents of the intestinal canal soon form a hydrostatic wedge, operating more or less constantly in its further enlargement, until at last the obliquity of the inguinal canal is lost and only a large direct opening through the abdominal wall exists. Although these conditions were more or less recognized and described by the earlier mas-

ters of surgery, as well as their functional importance hinted at, the reconstruction of the deformed structures, so as to restore the parts to their normal condition, was not made possible until surgical methods were perfected, based upon the knowledge of the rôle of the bacterial ferments in wounds, and the adoption of methods which should render their exclusion a practical certainty. This having been demonstrated as possible, free dissections, involving structures hitherto considered beyond the domain of surgery, were ventured upon, and thus it became possible to open with safety the peritoneal cavity, dissect away and remove its redundant pocket which served as a receptacle for the hernial contents. The technique of the wound treatment became the next important factor for consideration. Had the testicle been dissected away and removed as was advocated in the sixteenth and seventeenth centuries, the problem would have been simple, not unlike any abdominal wound, to be closed by a considerable variety of methods. On the contrary, however, the maintenance of the cord gave a wound which presented troublesome conditions, and the closure of the abdominal incision in the usual way left the internal ring open, and the canal no longer oblique, but more or less in direct line with the intra-abdominal pressure. It is owing to this faulty technique that hernia after operation, as still too commonly performed for cure, is so likely to be recurrent, and it has caused such severe criticisms, indiscriminately applied to all operative measures for the cure of hernia.

In order to obviate these difficulties and reconstruct the inguinal canal after its normal oblique pattern, it became necessary to employ some method of closure which should permit the permanent retention of the suture material in the posterior wall of the reconstructed canal. To fulfill this demand, it occurred to me that the structures could be coaptated and permanently held in place by the use of buried catgut sutures, a deduction derived from the well-known but then recent experiments of Mr. Lister upon the ligation of arteries in continuity by catgut, and the permanent retention of the ligature.

Important and interesting experimental studies now destined to bear fruit, were carefully made and published by Dr. Jamieson, of Baltimore, in the early part of the present century. This valuable contribution should have given great honor to American surgery, but unfortunately it was prematurely advanced and forgotten.

In order to close the internal ring from below upward, quite upon the exit of the cord from the abdominal cavity, it is necessary to lift the cord, holding it toward the median line. If, as is too often the case, the abdominal wall has been thinned from the long wearing of a truss, the muscular aponeurosis of Poupart's ligament and the conjoined tendon should be incorporated with the transversalis fascia in order to reinforce the posterior wall of the internal inguinal canal. This having been effected, the cord is replaced and the tissues which enter into the formation of the external wall of the canal are sutured. It is important to remember that in doing this, the usually thinned abdominal wall on a level with the internal ring should be reinforced by a stitch or two, carried above the line of the incision through the muscular aponeurosis. Otherwise, a bulging of the weakened abdominal wall may occur, giving discomfort, though not causing a return of the hernia.

The soft parts above the muscular structures are closed with light running buried sutures, the skin is easily coaptated in the same way, and the wound is sealed with collodion *without drainage*. If the wound has been maintained and closed in an aseptic condition it will so remain and primary union will supervene, without suppuration. The patient is rarely a sufferer from pain, is of necessity confined absolutely to the bed only a day or two, any posture of the body being assumed which will give surgical rest to the parts involved. The danger attendant upon the operation for the cure of hernia is so slight that it is scarcely worthy of consideration. In my entire experience I do not recall a case where the life issues seemed to be involved. I have elsewhere¹ collated and reported over three thousand cases, in which the death rate was only the fraction of 1 per cent., and this attributed by the surgeon to some other cause than the operative measures.

Rather more care is requisite with children, but the little invalids are not sufferers and may be made happy with their toys and playthings. After six weeks, light occupation can be resumed and I can not help feeling that it is a serious mistake to apply a support of any character. I believe a truss to be positively injurious and abdominal supporters, rubber bandages, etc., are as a rule harmful. At the best they fail to support the part upon the integrity of which the permanency of the cure largely depends, to-wit: The reconstruction of the posterior wall of the inguinal canal, and undue pressure upon wounds of every description interferes with their circulation and nutrition.

The experience of the year only emphasizes the conclusions which I had the honor of presenting to this Section at its last meeting. From the very large number of hernial operations which I have performed during the last twenty years, I then tabulated 135 cases in which I had followed up the conditions to date. During the year I have re-operated upon two cases where I thought further surgical procedure advisable. In both, there was no return of the hernia, the cord lay obliquely in its reformed canal, surrounded by a dense loose-meshed connective-tissue stroma. In both cases, by ill-judged advice a strong truss had been adjusted soon after operation, and the thinned abdominal wall above the line of the internal inguinal ring was weak and bulging. In one case, over thirteen months after the primal operation, I dissected out well-defined sutures, and I take pleasure in presenting sections of the unmistakable, vitalized connective tissue of the tendon suture, incorporated with the surrounding parts.

I have been recently criticised by a writer upon hernia who evidently fails to appreciate the value and force of the anatomic considerations which, elsewhere as in this paper, I have emphasized as fundamental and primal. He writes:² "In the infantile type of inguinal hernia, as there is practically but one ring, and hence no canal, other tissues must be utilized as a tampon." . . . "When the radical operation is essayed in this considerable class, we are not concerned with the physiologic inguinal canal for there is none."

There is little doubt but that the common cause of hernia, although it may appear after adult life,

¹ The Anatomy and Surgical Treatment of Hernia, H. O. Marcy. D. Appleton & Co.

² Manley, Hernia, p. 134.

originates in an improper development of the inguinal canal, pertaining of necessity to the infantile period. From my standpoint of observation, the "infantile type of inguinal hernia" is by no means an "undesirable class" for operation, since here we are primarily concerned in constructing a physiologic inguinal canal, and not in looking about for material which we may utilize as a tampon. Again my critic, when discussing the chronic or senile hernia, dismisses the possibility of the reconstruction of the obliquity of the inguinal canal as follows: "It is obvious that with these chronic or senile herniæ, pathologic changes have wrought such a radical alteration in the position, consistence, and the relation of the gross structures, and the minute histologic elements, that we need hold out no hope for a cure by radical operation; as the most which we may expect to accomplish is the comfortable reposition of the parts, in such a manner, that they may be painlessly and securely retained by a prothetic support after operation." Quite the contrary, these large old direct herniæ are the cases of the greatest interest and are as susceptible of cure as the smaller or less developed ones. They are the very class of herniæ which I select by preference, when operating in public, for the purpose of teaching the method above outlined. Interesting as is the subject, time forbids a review and analysis of a very considerable number of modifications in the surgical procedures which have within a very recent period been advocated.

There is a general consensus of opinion that the operative field should be sufficiently ample to permit a full inspection of the structures involved, that the hernial sac should be opened in order to ascertain its exact condition, contents and relationship. As a rule this should be sutured, or ligatured to its very base, and the redundant peritoneum resected and removed. A considerable number of very distinguished surgeons in Europe and America advocate the closure of the wound by buried animal sutures, varying, however, in their method of application, without a clear definition of their purpose or manner of reconstruction of the parts. Doubtless such excellent anatomists as Championniere, of Paris, and Park, of Buffalo, have restored the cord to its normal oblique position without making special emphasis upon the importance of this procedure. Certainly their results are in the highest degree satisfactory.

Bassini, of Padua, has somewhat recently published his method, which, in its essentials, incorporates the principles I have so long advocated as fundamental and basic. He emphasizes the necessity of producing a buttress or reinforcement of structures posterior to the cord. Moreover, he describes the closure of the tissues in a way which must certainly narrow the internal ring and increase the obliquity of the reconstructed canal, the importance of which I believe can not be over-estimated. More recently Potempshi, of Europe, Halstead and Fowler, of America, have gone one step farther by firmly closing the muscular aponeurosis of the abdominal wall beneath the cord, protecting it only by the fatty structures, superficial to the muscular layer. Time alone will determine if the nutrition and function of the testicle are impaired by this external implantation of the cord. Most surgeons agree that the wound must be made and maintained aseptic with the most scrupulous care, and closed without drainage.

RECAPITULATION.

The operation for the cure of hernia must be performed with the most careful aseptic detail. The wound must be sufficiently large for free inspection, the cord is lifted from its position, slight tension being made upon it upward and inward, in order to expose its entrance into the abdominal cavity. If the hernial tumor is large, the sac is opened and its contents replaced. The peritoneal sac is then dissected to its base, held tense, sutured at its neck, resected and excised. The posterior wall of the inguinal canal is intra-folded and reinforced by a line of double continuous tendon sutures, until the internal ring is reconstructed closely about the cord. The cord is replaced, the external structures are sutured in like manner, commencing at the upper portion of the incision, closing the structures closely upon the cord quite to the reconstruction of the external ring. The superficial tissues are brought into coaptation also, by buried tendon sutures, and the wound sealed with collodion *without drainage*.

The essential factors of this method are the obliteration of the peritoneal pouch, the reconstruction of the internal inguinal ring, the reinforcement of the posterior wall of the canal which restores its obliquity, and the closure of the wound with buried animal sutures, aseptically applied without drainage. Personalities count for little, but this method for the cure of hernia and the general introduction of the buried animal suture which made it possible, are the result of more than twenty years of original study and investigation, and I claim the privilege of presenting them as my contribution to American surgery.

OBSERVATIONS ON THE RADICAL CURE OF HERNIA.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

A. E. ROCKEY, A.M., M.D.
PORTLAND, OREGON.

The individual opportunity of a surgeon practicing in the larger cities to recommend and perform operations for the radical cure of hernia, is certainly greater than that of a surgeon in general practice in the smaller cities and towns. It is consequently to the former class that we owe the evolution of the present operations, but as a whole by far the larger number of cases come under the observation of the latter class, and until recently and at the present time too frequently relegated by them to an indifferent palliative treatment, or worse, advised against operation and turned adrift, only to fall into the hands of some charlatan who "cures without detention from business."

As a representative of surgeons in general practice, I desire to speak in favor of reform. Instead of regarding only cases of strangulated hernia or those of exceedingly difficult retention as proper ones for operation, I unhesitatingly recommend it in all cases except retainable hernia in the aged, or inguinal hernia in young children where the prospect of truss cure is fair. This opinion is based on results of about forty operations without a death and with a few relapses. The experience is a moderate one, but if I had made use of the opportunities I have lost, between the failure of my first Wood's silver wire invagination operation fifteen years ago, and the final adoption of a

satisfactory method in recent years, it would be hundreds instead of tens. We are slow to learn, and the profession, as a whole, are yet losing thousands of opportunities because of lack of confidence in themselves or the methods before them.

My experience in open operations has been with those of Czerny, MacEwan, MacBurny, Halstead and Marcy. Hernia may be cured by either of these methods, but far superior to all others are those of Marcy and Halstead. In technique and theory and perhaps, too, in practice Marcy's operation is the most perfect. There are points in the performance of either of these operations where beginners should have special caution.

In Marcy's operation the cobbler's stitch is so perfect in its support of the parts, and the kangaroo tendon so enduring that too much tension must not be used or the tissues will be strangulated. This is particularly liable to occur in the suture of the more muscular outer wall of the canal. Marcy describes the occurrence of liquefaction and shreddy discharge in two cases evidently without suppuration. In the second case in which I performed his operation exactly this result followed, and I believe that it was due to strangulation by over tension and the peculiar manner in which the tissues are surrounded by his stitch. After this I tried various modifications using the tendon as silk is used in Bassini's operation, and in another case using interrupted tendon sutures in the lower side and a mattress suture above the cord. More extended experience, however, has brought me to believe that the best way to perform Marcy's operation is to follow his description without any variation whatever. It should be remembered, though, that in using the cobbler's stitch in closing a hernia, it is not being used in leather, and the tension must merely be sufficient to hold the surfaces in light apposition. The great importance of the animal suture and the intervening blood clot as a framework, over and through which the young connective tissue cells may proliferate in closing a wound of this kind has not been sufficiently emphasized. It is this new tissue that prevents recurrence. Were we to depend on simple edge-to-edge adhesion, we would have a vastly greater number of failures.

In the week following the publication of Halstead's method, I performed his operation twice. The first was a right inguinal in a man 50 years of age, and the second an enormous congenital hernia, irreducible for seventeen years in a man of 40. The performance was typical in both cases. A part of the veins were excised and the reduced cord brought out between the two outer stitches. In both cases there was great swelling of the testicle and in the elder man a considerable degree of atrophy has followed; both, however, made good recoveries and are perfect cures. Since that time I have performed Halstead's operation without removing the veins from the cord, and the results have been most satisfactory. I believe that this feature of the operation is unnecessary to success, and that an otherwise quickly performed and simple operation is needlessly complicated by it. As Halstead, himself, says in his report of fifty-eight cases published in the *Bulletin* a year ago, that "essentially this procedure with or without modification was followed," I surmised that he has practiced this modification himself and that we may also use it and yet give the operation his name. In operating on both sides of double hernia, I have recently

chosen this method in two cases, for the reason that the single row of mattress catgut sutures is more quickly introduced than the double row of tendon. The comparative merits of tendon and catgut can only be referred to here; so far as my own experience is concerned I can see no difference. The method of closing central abdominal incisions by suturing the peritoneum and muscles with interrupted sutures of heavy catgut, and then stitching the skin over them with fine silk is the one I have used to the exclusion of all others in the last three years, and I have had but one ventral hernia, and that a very small one, at the site where a drainage tube had been worn, the hernia appearing six months after the operation during a violent attack of influenza accompanied by severe cough.

The cases in which I have performed Halstead's operation, both as he describes it and without removing the veins from the cord are perfect cures. Notwithstanding this it must be admitted that the theory of longer support for the new tissue during its strengthening by maturity is distinctly in favor of the tendon suture, which undoubtedly remains three times as long as the catgut. It is my belief that an extended experience, especially in cases that were to bear strain early would support the statement that while catgut cures, the kangaroo tendon suture is better. As to double operations, I see no reason why the patient should be inconvenienced by an additional operation and detention in bed. In five double hernias operated at the same time, the result has been good in all, with the exception of a possible recurrence in one side of one case. One of these was complicated with tuberculosis of the left testicle and tubercular enlargement of the glands in both groins; the testicle and glands were removed and the wound dressed by MacBurney's method, on account of the soiling of the surfaces by the breaking of a softened lymphatic. The man has worked at the lathe in a machine shop for two years in good health and without recurrence. In the last double hernia the operation was done at the patient's house, and though every possible care was taken, one side suppurated. Recovery was but little delayed, however, and the patient walked about in three weeks, and now after two months the cure seems perfect. This patient had been operated for stone in the bladder five years ago. It was the straining, incident to stone, that caused the hernia. Patients like this, and the young woman who coughed out the ventral hernia have strong abdominal muscles, and permanence in cure would be much enhanced by a well impressed caution to avoid all severe strain in coughing, evacuation or lifting. The fact that there is a weak spot in the abdominal wall should ever be present in the mind of the patient, and then when severe strain is necessary the groin may be protected with the hand or by flexing the thigh on the abdomen. To advise care does not necessarily argue that the result of the operation is a weak cure. The inconsiderate strain to which some persons subject themselves would force the abdominal contents through anything with which nature or art might surround them. In the one recurrence after double operation, I have no doubt but that it was produced in this way. The patient was a muscular young man who had produced double direct hernias in a tussle with a bull. He was apparently well cured by direct catgut suture of both sides, and remained so for six months when

he was confined for some time in an insane asylum; after his release and more than a year after the operation, he wrote me that he had recurrence on one side, although I have not seen him.

In regard to drainage, I believe that where oozing is completely controlled it is unnecessary, but where multiple operations are performed and perfect technique must be somewhat sacrificed to time, or for any other reasons there may be even slight bleeding, there can be no objection to drainage by a folded strand of catgut in the upper angle of the wound, but in such cases safety would be much enhanced by it.

As to the subcutaneous suture, it requires more time and in my experience the apposition is less perfect than with an ordinary continuous suture of fine silk. I am inclined to believe its advantages in avoiding infection as somewhat problematical. When, however, I set out to perform a typical Marcy or Halstead operation I always use it.

The conclusion to which my experience leads me is that in the radical cure of all hernia, direct suture with tendon or catgut offers a safe and satisfactory means of cure, and that in oblique inguinal the method of raising the cord and closing the canal under it will give better results than any other now at our command.

DISCUSSION.

DR. GEORGE F. SHIELS—I think we have had the opportunity of a lifetime here to-day. You have heard some very interesting remarks upon the subject of hernia, but I would like to refer particularly to the remarks made by the first reader, Dr. Ransohoff, who gave us a paper as full of information as a nut is full of meat.

In reference to the time that strangulated hernia should be reduced, he gave a quotation here, saying that if you see it during the day it should be reduced by the night, and if you see it at night it should be reduced by the morning. I will go a little further and say that a man should see that it was reduced within fifteen or twenty minutes after he became convinced that it was strangulated. And I say this for the reason that if the hernia is strangulated, I wish to draw your attention to the fact that the taxis tends to lower the vitality of the hernia to such an extent that it always becomes a danger. I have had some little experience in operating for strangulated hernia, and I have had several cases where efforts were made to reduce the hernia through several hours, first without and then with an anesthetic; and then when the time came, that an operation was decided to be finally necessary, it was only to discover that the bowel had been so bruised that it had lost its vitality and could not be returned. Hence, I would beg to say firmly, that you should make the time short. I do not believe that you should try taxis very long; if you try it all, and then it should be done very delicately and for two or three minutes without an anesthetic to see if it will return, and then two or three minutes with an anesthetic and then, if you do not succeed, decide to operate carefully.

In regard to vomiting not being a point of particular interest or import, that you should not look for too much vomiting as a symptom, I have had cases, and one I recall in particular, where a girl had return of the tumor or femoral hernia; she did not suffer very violent vomiting or of a fecal nature, but occasionally would have almost a mechanical regurgitation. This would recur for a day or two. The vomiting is not necessarily present, and it is a mistake to expect it always. Neither is the pain invariable. In fact, this girl had gone out and did not think there was much the matter with her. And yet she had a strangulated hernia which required operation, and which was operated upon.

Concerning whether it is wise to return the bowel. It becomes a subject of very great interest when you get down to the bowel, to know whether it is in a good condition enough to return it or not. And that will only be gained by experience, I believe. Still, at the same time, I think that a bowel that is viable will usually, if slightly scratched, just gently scratched, bleed pretty freely, and I find that a pretty good test to know whether the bowel is in a condition to return or not. I give it a very gentle scratch, and if it bleeds pretty

freely it is a fairly good sign that you can return it. Sometimes even a bowel which has lost its glossiness will be in a condition in which you can return it. The idea of returning the hernia after opening the sac is one which I think had better be condemned, in so far that if you do it you are liable to reduce the hernia in block and have it in as bad a condition after as before.

Concerning the operation for the radical cure of hernia, I have very little to say on that subject. We have had a great authority who has read a paper to us to-day, and I would bow in differing from him. I do not believe that the radical cure for hernia is always an operation which should be performed. There are certain cases of hernia which have existed for many years in an individual, which become very large, and become practically irreducible, even by operation. It seems that the long existence of the condition has led to an alteration in the capacity of the abdominal cavity to contain its contents and the hernia becomes larger, an increased abdominal cavity for annex, and that annex becomes sometimes nearly as large as the abdominal cavity itself. Woe be to that man who thinks that he can return that to the abdominal cavity and cover it up, because if he does, I fancy he will find that he can not get it back again; simply because the structures by having been long used to the present condition have so adapted themselves that you may operate as much as you like, but you can not return the contents of that sac into the abdominal cavity; it is not large enough.

DR. ANDREW SMITH, Oregon—I wish to add my indorsement to the suggestion by Dr. Ransohoff of the importance of acting early for the relief of strangulated hernia. He expressed it very aptly and beautifully when he said, Let the sun not go down upon a strangulated hernia, or if it is in the night let it not rise again upon it, but operate at once and use taxis with caution. I wish also to say that I do not believe the results we are getting these days from hernia are due to the particular modification that Dr. Marcy or Dr. Bassini, or Dr. McEwen has made to the old processes of the masters, such as Banks and Turney, so much as the success is due to improvement in technique. While we are judging now of these operations, we are judging of them in the past. The future only will tell whether we can judge as well of the operations that we are now championing, such as those of Bassini and Halstead and others. We all know that hernia operation can not be pronounced a success definitely until time has proved it so. I maintain that it is not a fair proposition to compare those results in the light of but a year or two, with the results of the old masters, whom we are now holding scarcely worthy of mention.

DR. HORRAN, Texas—I want to suggest one thing with reference to the treatment of hernia. We have heard the discussion in reference to operative procedures, but they do not tell us how to avoid such procedures. Now I want to suggest on this line that it is our business, not so much to operate on cases that have hernia as to prevent operations. I think every surgeon will justify that idea. I have operated along this line when I have been forced to do it, as these other gentlemen I presume have done, but I want to ask these gentlemen before they condemn a case of strangulated hernia to operative procedure, even under the methods of technique suggested here by the last reader, that they do one thing, and that is to take the patient out of bed and incline him in a position about like that, (indicating an incline of about 45 degrees) with head against the wall and the feet as high as the head and shoulders of a couple of men or a little more than that, and placing the patient before this position is assumed under the anesthetic—under chloroform—to its fullest relaxation, and then see the results. You do not want taxis. These gentlemen are condemning taxis, and yet, I believe it has its place. But it should not go too far. Under this method I have seen a hernia of three days and a half duration, subside without any taxis. I ask you to accept the suggestion and give it a trial.

DR. T. W. HUNTINGTON, Sacramento, Cal.—I only wish to allude for a moment to a matter which has been under discussion, in regard to the reduction of strangulated hernia. I have had some little experience in this matter. It is a class of cases which have come under my observation frequently. I am aware that a strangulated hernia has been reduced by putting a man in a wagon in an uncomfortable position and traveling him for eight or ten miles to a doctor, and finding the hernia reduced after he has arrived there. I believe it would have been better practice to operate upon that patient before he was put into the wagon. I believe that when ordinary efforts at taxis, such efforts as the ordinary person will ordinarily pursue have failed, then we are

entitled to operate. I do not think we have any right to jeopardize the patient's life by unnecessary delay, because it is in the delay that the danger lies. That is all I wish to say in regard to that.

I have something to say on the subject of the radical cure of hernia *per se*. It is a measure which I have advocated for ten years, and it is a method which I have pursued for five or six years quite frequently. Since my earliest efforts in this direction I have been impressed with one fact, and it is this, that hernia, the ordinary oblique inguinal hernia which I believe to be the most frequent, is a congenital condition. We may not have during the earlier years of life, during the years of infant life, or during the earlier years of adult life, hernia, but when it occurs it occurs as a congenital condition. Now in pursuance of that thought I have gone further and have alleged that when you have corrected the congenital condition you have cured the hernia practically. I care not what steps you may adopt subsequent to that. But you cure the hernia by simply tying off the sac. I do not know any one who has taught this, but I think that when you have caught up the sac, and tied so much off, and pushed the pedicle back into the abdominal cavity you have cured at least that hernia. With regard to dealing with the pillars of the ring subsequently, I have no great choice. Personally I do but one thing; draw the pillars of the sac together, and close them with kangaroo tendon. I believe that the natural channel for the cord and vessels is the better channel. So far as I am concerned, I prefer to put the cord and membranes untouched back into their natural channel and close the pillars of the ring over it, trusting to nature for a result.

DR. E. GRISWOLD, Pennsylvania—There is one condition which we encounter sometimes, especially those of us who go into the country to do surgical work and do hernia operations, that has not been discussed. As it is one of the most important conditions with which we can meet, and one which I met with, unfortunately, not a great while ago, I am anxious to have the sentiment of those who are accustomed to operate, and especially such men as Dr. Marcy in regard to the matter, and that is in cases where gangrene is really present, or so apparently likely to come as to make it doubtful whether it is proper to return the gut, or create an artificial anus. About a year ago last month I was called a distance of fifteen miles one evening to a lady, 68 years of age, who was very thin and who had a recognized femoral hernia on the left side which had not been recognized or even been diagnosed. You all know, who have been accustomed to deal with femoral hernia, how difficult it is sometimes to be certain what you have got. The tumescence is so very small, and sometimes the pain is trifling and the nausea and vomiting so long postponed, that there is a sort of hope entertained by the medical attendant and friends that there is nothing serious the matter, and that dallying along as we did in that case, from Sunday until Thursday evening is allowed. When I got there I made the diagnosis. It happened I had two or three very skilful men with me to help me. I made the diagnosis of strangulated femoral hernia on the right side. The case was an old lady with thin muscles, feeble constitution, rapid pulse and she was vomiting considerably and suffering some pain. I operated by lamplight the best I could. When I got down to the gut, you know how small it is in a case of femoral hernia, but there it was, a little knuckle about the size of my finger nail, and it was so discolored and apparently defective in circulation that I hesitated about returning it. I really thought we ought to make an artificial anus. However, it was concluded to take the risk and return it. The stricture was not very hard to overcome but I made use of considerable force in returning it. I returned it and she did very well for between two and three weeks. I went away to Omaha to attend the National Association of Railroad Surgeons, and when I got back to Pennsylvania afterwards when I called I learned that there was a little opening which had formed in the lower end only a day or so, and had an escape of gas now and then. Finally it closed up and remained closed for three or four weeks, but in the meantime, before it closed there were times when it was extremely difficult to get the bowels to act. It seemed as if there was contraction and constriction going on, and I was prepared to make interectomy, although I was afraid that the woman would not be able to withstand it. So it was postponed, and as I stated, it closed up and remained closed for three or four weeks, and then it opened again, when I got her bowels so that they could be moved without a great deal of difficulty, and from that on she has been able to live although she has still a sinus. Now the question is with me, What shall a surgeon do in a case such as that? Shall he do as I did, or shall he take the risks of operating

at once? As for excising a portion of the intestines in that case I do not think it would have done, but in other cases perhaps it might do. The woman was too weak, too feeble, and had suffered too long to stand it; she had not enough vitality left to stand the operation of interectomy.

DR. REYNOLDS, Wisconsin—I merely want to speak for a moment, since this discussion has taken a wide range, about the way of operating. I have seen in the course of a long practice quite a good many hernias. I used to operate two or three times a year, perhaps. In the last fifteen years I have not had occasion to operate on a hernia, although I have been in active practice and had many hernias to treat. My way of treating hernias, if I got there early, is to put them profoundly under the influence of opium, and give them this position that this doctor has spoken of here. He raised their heads; I lower their heads very much, and put them profoundly under the influence of opium, and if there is much inflammation put on a bag of ice, and let them go to sleep and have some one to keep up the ice bag on the hernia. In the last fifteen years I have had twenty-five cases, to say the least, and every one of them reduced at first, except five; five with gentle taxis, when they got so they were snoring with opium, they would go back; five I had to push back, and the rest all subsided of themselves. That is my experience. My treatment of hernia is similar to that spoken of, the radical cure, where it is strangulated, if it had been very long. You can have that experience for what it is worth.

DR. KURTZ, of California—I hope I may be excused if I talk a little too much here, but we should not pass this subject without mentioning the name of Kölliker, and his operation in connection with radical cure, or in connection with the operation for radical cure of hernia. All the other authors have been named, but Kölliker has not. His operation is very simple, and I think it is just as efficient as any other. It simply displaces the sac and disposes of the sac in such an excellent manner that it will be a protection to the ring. The incision is made right down upon the sac; the sac is then thoroughly dissected from the cord; it is pulled out away beyond its constriction, and thoroughly dissected off from the cord. Then the finger is entered in the hole, into the canal, the same as in the ordinary herniotomy, right to the internal ring, a button-hole is made to the remaining structure, a little incision sufficient for the use of a pair of forceps. With these forceps you get hold of the sac and pull that through this little button-hole and twist it thoroughly. Upon the structure you place the sac and now close up the hole, from the pillars down to the very end. You may use either subcutaneous sutures, or deep sutures; I prefer the deep sutures, whether catgut or kangaroo tendons, or any other superficial sutures; the deep suture should take everything, the sac included, except the superficial fascia and skin. Then the superficial fascia and skin is sutured over with silk. This may also be closed with collodium, and no drainage is, as a rule, needed.

DR. JOSEPH RANSONOFF, Cincinnati, Ohio—I think the return of a hernia that is in the least doubtful, is one of the gravest mistakes that a surgeon can possibly make. Furthermore, in such a case as one of the gentlemen mentioned where the area of gangrene is very small, not larger than a finger nail, the whole thing can be turned in and treated as a bullet wound is treated.

DR. A. E. ROCKEY, Portland, Oregon—I have nothing to add, except in answer to the gentleman in reference to large hernias and the improbability of reducing them. I have operated a few very large hernias and have known that in the majority of these the principal mass was omentum which was ligated, and no considerable difficulty was found in reducing the hernia. One of these was that large, irreducible hernia I have spoken of. That was congenital, and had existed for seventeen years and extended clear down almost to the knee. I think that one who operates much on hernia would not hesitate because the hernia was large and because it was irreducible.

DR. H. O. MARCY, Boston, closed the discussion by exhibiting some drawings he had made on the blackboard during the debate, and explaining the same to illustrate his position in regard to the treatment of these cases. He believed kangaroo tendon to be the best suture that could be used, and said he could not too strongly emphasize the importance of hermetically sealing the wound and the use of aseptics.

On motion, the session was continued for half an hour, which was used by DR. GEORGE F. SNIELS, San Francisco, in the reading of a paper prepared by him entitled, "A Plea for the better Teaching of Anatomy."

A Bill to Regulate the Practice of Medicine and Surgery in the District of Columbia.

The Medical Society of the District of Columbia, at its last meeting entered upon a discussion of the bill to regulate the practice of medicine and surgery in the District of Columbia, to license physicians and surgeons and to punish persons violating the provisions thereof in the District. The bill is as follows:

WHEREAS, Because of the absence of a law to ascertain the qualification of individuals desiring to practice medicine and surgery in the District of Columbia, it is made a resort of persons who are excluded from the practice of medicine and surgery in other States by laws in said States requiring evidence of such qualification.

Be it enacted, etc., That the Commissioners of the District of Columbia shall appoint a board of examiners which shall be known as the board of medical examiners of the District of Columbia; said board shall consist of nine members, five to be selected from a list of not less than ten names submitted by a majority vote, at some regular meeting of the Medical Society of the District of Columbia, three homeopaths to be selected from a list of not less than six names submitted by a majority vote at some regular meeting of the Washington Homeopathic Medical Society, and one eclectic to be selected from a list of not less than two names submitted by a majority vote at some regular meeting of the Eclectic Medical Society of the District of Columbia; of the members of the board first appointed three shall be appointed for one year, three shall be appointed for two years and three shall be appointed for three years, and thereafter each member of said board shall be appointed for a term of three years, or until his successor is appointed; provided that no member of said board shall serve more than two terms in succession; that no member of said board shall have been engaged in the practice of medicine and surgery in the District of Columbia for less than ten years at the time of his appointment, and that no member of said board shall be connected with any college or university having a medical department; and provided further, that the Commissioners of the District of Columbia may at any time remove any member of said board, upon petition by the medical society by which such member was first nominated, and that in case of the death, resignation or removal of any member, the vacancy for the unexpired term of said member shall be filled in the same manner as other appointments are made.

DUTIES OF MEDICAL EXAMINERS.

That each member of said board of medical examiners of the District of Columbia shall, before entering upon the discharge of his duties, take an oath to fairly and impartially administer the provisions of this act; said board shall elect a president, a vice-president, a secretary and a treasurer; it shall have a common seal, and the secretary shall be empowered to administer oaths in taking testimony upon any matter pertaining to the duties of said board; said board shall hold meetings for examination in the city of Washington on the second Thursday in January, April, July, and October of each year and continuing so long as may be necessary to examine all applicants, and at such other times as a majority of the board may deem expedient; said board shall keep an official record of all its meetings, also an official register of all applicants for examination for a license to practice medicine and surgery in the District of Columbia; said register shall show the name, age and place, and duration of residence of each candidate, the time he or she has spent in medical study in or out of medical school, and the names and locations of all medical schools which have granted said applicant any degree or certificate of attendance upon lectures in medicine and shall show the school of medicine which the applicant desires to practice; said register shall also show whether such applicant was rejected or licensed under this act; said register shall be *prima facie* evidence of all matters contained therein; it shall be the duty of the secretary of said board to mail to the address of each applicant a notice of the time and place of examination; said notice shall be mailed not less than seven days before the examination and at a longer period if requested by the applicant at the time of making application; said board shall make such rules and regulations as they may deem necessary to carry into effect the provisions of this act; said rules and regulations, when approved by the Commissioners of the District of Columbia, shall have the full force and effect of law; provided that

said board may elect a secretary from other than its own members, and when so elected said secretary may be removed at any time by a majority vote of said board.

That from and after the passage of this act all persons desiring to practice medicine and surgery in any of their branches in the District of Columbia shall apply to the said board of medical examiners for a license so to do; applicants shall submit to examination upon the following named branches, to-wit: Anatomy, physiology, chemistry, pathology, materia medica and therapeutics, hygiene, histology, practice of medicine, surgery, obstetrics and gynecology, diseases of the eye and the ear, medical jurisprudence and such other branches as the board may deem advisable; said board shall not examine any applicant until satisfactory proof is furnished that he is of good moral character and over 21 years of age; nor until he has presented a diploma conferring upon him the degree of doctor of medicine issued by some medical college authorized by law to confer such degree, provided that said diploma if issued prior to July 1, 1897, shall be accompanied by satisfactory evidence that said applicant has studied medicine and surgery for not less than three years prior to the issue thereof, and if issued subsequent to June 30, 1897, shall be accompanied by satisfactory evidence that the applicant has studied medicine and surgery for not less than four years prior to the issue of said diploma. All examinations shall be both scientific and practical, but of sufficient severity to test a candidate's fitness to practice medicine and surgery.

ISSUE OF LICENSES.

That each application for a license shall be made to the secretary of said board of medical examiners upon a form prescribed by said board and approved by the Commissioners of the District of Columbia, and shall be accompanied by a fee of \$20; each application shall be in the hands of the secretary of said board not less than two weeks before the day set for examination; each application shall state the full name and address of each applicant, his or her age, the place and duration of residence of said applicant, the time he or she has spent in the study and practice of medicine in or out of medical schools and hospitals, the names and locations of all medical schools which have granted said applicant any degree or certificate of attendance upon lectures in medicine and surgery, the school of medicine which the applicant desires to practice, and such other information as the board may require; said information shall be furnished under oath; any application may be rejected for refusal to furnish any of the information called for or for other irregularity; each application shall be kept on file by the secretary of the board.

That examination shall be in writing; in all examinations the questions must be, except in practice of medicine and in materia medica and therapeutics, such as can be answered in common by all schools of practice; and if the applicant intends to practice homeopathy or eclecticism, the member or members of said board of the schools selected by him shall examine said applicant in practice of medicine and in materia medica and therapeutics; the votes of all examiners shall be "Yes" or "No" for the respective branches and written with their signatures upon the backs of the examination papers of each candidate; said examination papers shall be kept on file by the secretary of said board for five years and shall be *prima facie* evidence of all matters contained therein.

That if any applicant shall pass such examination as is hereinbefore provided for in a manner satisfactory to seven members of said board of medical examiners of the District of Columbia, said board shall issue a license, signed by the president and secretary thereof, and attested by its seal, which shall entitle said applicant, after it has been registered as hereinafter provided, to practice medicine and surgery in the District of Columbia; any applicant refused a license by said board for failure on examination may, by depositing \$15 with the treasurer of said board, to cover the cost thereof, appeal from the decision of said board to the appointing power thereof, who may thereupon appoint a medical committee of review, consisting of three members, one from each school of medicine, none of whom shall have been engaged in the practice of medicine in the District of Columbia for less than ten years, nor be connected with any college or university having a medical department, who shall examine the examination papers of said applicant and from them determine whether a license should issue, and their decision shall be final; each member of said committee shall receive for the examination of the papers of each candidate the sum of \$5; if said committee by a unanimous

vote reverse the finding of said board, the board shall thereupon issue a license to the applicant, and the treasurer of said board shall return to said applicant all money deposited by him to cover the cost of said appeal and shall pay the cost of said appeal out of the funds belonging to the said board; if, however, the finding of said board is not reversed by said committee of review, the cost of said appeal shall be paid by the treasurer of said board out of such funds as may be in his possession as a deposit made by appellee to cover the cost of said appeal; all licenses issued by said board shall be numbered consecutively and a register shall be kept by the secretary showing the number of each license, the date of issue and to whom issued.

REVOKING A LICENSE.

That the board of medical examiners of the District of Columbia may, by a vote of seven members, refuse to grant or may revoke, a license, or may cause the name of any person to be removed from the record of the Supreme Court of the District of Columbia or from the register of the health office, or from both, for the following causes, to-wit: Chronic and persistent inebriety, the practice of criminal abortion, conviction of crime involving moral turpitude, or for publicly advertising ability to treat or cure diseases. In complaints under this section the accused shall be furnished with a copy of the complaint and be given a hearing before said board in person or by attorney. Said board may at any time within two years from the refusal or revocation of a license or the cancellation of registration under this section, by a unanimous vote, issue, without examination, a new license to the physician so affected, restoring to him all the rights and privileges of other physicians licensed under this act.

That any person receiving a license as hereinbefore provided shall have it recorded in the office of the clerk of the Supreme Court of the District of Columbia within three months from the date of said license, and the date of record shall be indorsed thereon by said clerk; and the holder of the license shall pay to the recording clerk a fee of 50 cents for making the record; the holder of said license shall, after the same has been recorded, exhibit the same at the health office, and register, in a book provided for that purpose, his name and address. Whenever a license is revoked by said board, the secretary thereof shall report that fact in writing to the clerk of record and to the health officer of the District of Columbia, who shall thereupon cancel such registration.

That this act shall not apply to commissioned surgeons of the United States Army, Navy or Marine-Hospital Service, nor to regularly licensed physicians and surgeons in actual consultation from other States or Territories, nor to regularly licensed physicians and surgeons actually called from other States or Territories to attend specific cases in the District of Columbia, nor to any physician now registered at the health office of the District of Columbia, nor to dentists in the legitimate exercise of their profession, nor to midwives registered at the health office of the said District in the management of uncomplicated cases of obstetrics, nor to the treatment of any case of actual emergency, nor to the use of ordinary domestic remedies without any fee, gift or consideration of any kind being given in return therefor.

WHO IS A PHYSICIAN.

That any person shall be regarded as practicing medicine and surgery within the meaning of this act who shall append the letters M.D. or M.B. to his or her name, or who shall prescribe, advise or apply for the use of any person or persons, any drug or medicine or other agency, or who shall perform any operation, for the treatment, cure, or relief of any bodily injury, infirmity or disease, or who shall publicly profess to do any of these things.

That from and after the passage of this act any person practicing medicine and surgery in the District of Columbia without having first obtained a license to so do and registered the same as herein provided, or in violation of any of the provisions of this act, or of any of the rules or regulations made by authority conferred by section 2 thereof, or after his license, or registration, or both, has been canceled by order of the board of medical examiners of the District of Columbia, shall be deemed guilty of a misdemeanor and, upon conviction thereof, shall be punished for each offense by a fine of not less than fifty nor more than five hundred dollars, or by imprisonment in the District jail for a period of not less than ten nor more than ninety days, or by both such fine and imprisonment. It shall be the duty of the United States district attorney for the District of Columbia to prosecute all violations of the provisions of this act.

That the secretary of the board of examiners shall be paid for taking testimony the same fee that is allowed to an examiner in chancery for the same service; the expense of the said board and of the examinations shall be paid from the license fees herein provided for, and if any surplus remain on the 30th day of June of each year, the same may be divided among the members of said board, *pro rata* to the number of examinations at which they have been present during the preceding year. That all acts or parts of acts, general or special, now existing not in accordance with the provisions of this act, or inconsistent herewith, be and are hereby repealed.

BOOK NOTICES.

Biography of Eminent American Physicians and Surgeons. Illustrated with fine Photo-Engraved Portraits. Edited by R. FRENCH STONE, M.D. Published by Carlton & Hollenbeck, Indianapolis. Pp. 729. 1894.

Since the publication of the remarkable work of James Thatcher, (Boston, 1828) on American Medical Biography, works on this subject have not been numerous, but three important works having appeared in three score years, Williams, Gross and Atkinson. There have been many smaller works, such as Toner's "Medical Men of the Revolution," and medical men of certain States and circumscribed localities by various authors, but the fact remains that a systematic work on American medical biography has appeared once in twenty years. None of them have passed to a second edition and it is more than likely than none of them have been profitable either to the author or the publisher. A curious coincidence is noticed; in the work of Dr. Stone, on page vi. of the preface it is stated that:

"When at length, in the spring of 1893, a sufficiency of material was gathered to form a large volume, the financial panic suddenly occurred, prostrating all branches of business, and this also for a time operated against its more rapid completion. This statement it is considered necessary to make in order to show that the unlooked for delay in the appearance of the work was not occasioned by any fault, neglect or mismanagement of the editor who never for a moment despaired of the enterprise, and who has been unceasing in his efforts to urge it on to final completion."

Dr. Gross in the preface to his "Lives of Eminent American Physicians and Surgeons of the Nineteenth Century," (Philadelphia, 1861), says:

"When at length, in 1857, a sufficiency of material was secured to form a large volume, the monetary crisis suddenly occurred, prostrating all branches of business, and thus effectually preventing, for a time, the publication of the work. This statement it is considered necessary to make in order to show that the delay in the appearance of the work was not occasioned by any fault, neglect or mismanagement of the editor, who never for a moment despaired of the enterprise, but did all he could to urge it on to final completion."

It is thus that history repeats itself—even medical history.

The introductory by Dr. Stone is admirable in style, interesting, and highly instructive. It consists of a "general review of the progress and present condition of medical science and medical practice in the United States of America," and the subject is exhaustively treated. The author concludes the introductory by a plea for the creation of a Department of Public Health as a fitting conclusion of the work of the present century of American medicine.

Like all works on biography which include an account of the living, the material has been very largely compiled, but the vast store of material has been carefully edited by Dr. Stone, and leaves no just ground of criticism; while there are a few names included that may be of questionable "eminence," yet it is doubtful if any work including living men has been more carefully expurgated.

We congratulate Dr. Stone on the completion of this truly great work, and as "history is philosophy teaching by examples,"¹ and "biography the heart of history," so this heart of the medical history of our time should be read and studied by every progressive American physician. Books of this kind as a rule do not pay, and the author of a work

¹ Bolingbroke, On the Study and Use of History.

of this character, a volume devoted to the story of the achievements of the profession itself, should receive at the hands of his brethren that financial encouragement which only a subscription to the work can give.

An International System of Electro-Therapeutics for Students, General Practitioners, and Specialists. By HORATIO R. BLOELOW, M.D., and Thirty-eight Associate Editors. Illustrated. Philadelphia: The F. A. Davis Company. London: T. J. Rebman. Cloth. 1894.

This bulky volume is the result of an attempt to bring up to date the knowledge of medical electricity. The well-known men who have contributed to it, are recognized as advanced workers on the subject, and as a general rule their statements may be admitted as correct. If there are over-claims made by enthusiasts for the uses and advantages of electricity in therapeutics, it must be laid to the fact that electricity, like many other branches of medicine, is far from being an exact science.

The book consists of a series of essays; the first is by Prof. Wm. J. Herdman, of the University of Michigan, and it furnishes an excellent introduction. Prof. Herdman says:

"It is useless for an instructor to attempt the inculcation of therapeutic rules in the use of electricity to a class not familiar with the physical differences between frictional, voltaic and induced currents; and it is worse than useless for the members of that class to attempt the application of such instruction to the patient if they are unfamiliar with the management of the machinery by which such different forms of electric energy are applied. Such attempts are but doomed to ignominious failure, discouraging the physician and disgusting the patient, while the abused agent bears the blame until better methods prevail."

The author then follows with a well considered and powerful plea for special instruction in electro-therapeutics in our medical colleges. This instruction to be preceded by a well grounded knowledge in the physics of electricity and magnetism. There is no doubt that ignorant application of electricity has not only done harm to the innocent patient, but has brought much discredit on electro-therapeutics.

The careful reading of these essays will be very useful to nearly every practitioner of medicine and surgery. There are some statements, like those concerning the treatment of stricture of urethra for example, that are not yet accepted. To establish the truth of a given proposition, the experiments on which the proposition is based must be corroborated by some one, beside the original experimenter, and from identical experiments, the same results should be obtained. Surgeons generally have not been able to duplicate the excellent results in urethral surgery reported by Newman, and there is therefore much skepticism as to the absolute accuracy of his statistics. Medical statistics, like the soundness of an egg, should be above suspicion.

The volume as a whole (a disjointed collection of essays), will be found very useful to practitioners; bristling with electric flashes and sparkling with new thoughts, but it is not at all adapted for use as a text-book by medical students. Its form would preclude its use as a text-book, if there were no other reason. Its curious style of paging (modeled on that of Sajous' Annual), is rather unpleasant, although the copious index makes up for the deficiency to a considerable extent. The illustrations are fairly executed, and are sufficient to elucidate the text.

Materia Medica, Pharmacology and Therapeutics.—Inorganic Substances. By CHARLES D. F. PHILLIPS, M.D., LL.D., F.R.S. (Edin.). Second edition. London: J. & A. Churchill. Pp. 898. Cloth. 1894.

It is a pleasure to examine a book written with such care, and so well printed that each page looks like a work of art. The art of printing from types has advanced but little in the past three centuries, and in examining some of the books that come to our table, we feel sure that the mechanical part of bookmaking has upon the whole materially degenerated since the days of Peter Guttenberg and John Aldus.

Dr. Phillips who is personally well known in America through his attendance upon the International Medical Congress of 1877, has produced a highly creditable work. The present edition has taken account of the many changes in the knowledge of the subject since the issue of the former edition in 1882. Due credit is given American investigations.

From a London standpoint, and writing for a British constituency, it is perhaps hardly necessary to mention American mineral waters, natural baths, and thermæ, and one may look in vain for a single reference to an American water—we are of opinion that our own countrymen are largely to blame, for not reporting the therapeutic results of our own waters, and with the exception of the *Sanitarian*, few of our medical journals have given any attention to the subject. Much space is given to continental waters, and medicated baths by Dr. Phillips. We commend the work as one of the most clearly written, and satisfactory works on the materia medica, pharmacology and therapeutics of the inorganic substances with which we are acquainted. The addition in their proper place of some of the well established American waters, would add much to the value of the book for American readers.

A Compend of the Practice of Medicine. By DANIEL E. HUGHES, M.D. Fifth Physicians' Edition. Thoroughly revised and enlarged, including a very complete section on skin diseases and a new section on mental diseases. Philadelphia: P. Blakiston & Co. Chicago: The W. T. Keener Co. 1894. Pp. 568. Full morocco, gilt, \$2.50.

This book is one of the best of its class, indeed, it is now so complete as scarcely to be classed with the compends. We notice, however, that the author fails to make use of modern bacteriology to any great extent in his pathology, and antiseptic therapeutics finds no place. The author also uses the old system of weights and measures in his prescription writing, although he occasionally gives parts by weight. We trust that with the next revision these blemishes on an otherwise excellent book, will be corrected.

The publishers have left nothing to be desired; good paper, clear type, handsome binding, and gilt finish have made a volume as pleasing to the eye as its contents are instructive.

Healthful Womanhood and Childhood. Plain talks to Non-professional Readers Relative to Healthy and Diseased Conditions Peculiar to Women and Concerning the Care of Young Children. By HENRY BIXBY HEMENWAY, A.M., M.D. Pp. 290. Cloth. Evanston, Ill.: V. T. Hemenway & Co. Sold by subscription. Price \$2.

This is an extremely outspoken little book, so much so that we doubt the expediency of having it read by "all classes of society." It contains much valuable information, but a book which contains such chapters as that on the "Hygiene of the Marriage Bed," and on the "prevention of conception," et cetera, is scarcely one to be chosen for the parlor library. For mothers whether old or young the book will be found very useful and instructive, but it would be out of place in the hands of youths of either sex.

As a work on popular hygiene, within its limits, its precepts are founded on common sense, and sound medical theory. We feel sure that the public would be benefited if it could be placed in the hands of all parents capable of reading it understandingly.

Practical Lectures in Dermatology Comprising a Course of Fifteen Lectures Delivered at the University of Vermont Medical Department during the Session of 1892 and 1893. By CONNICK W. CUTLER, M.S., M.D. 8vo., cloth. New York and London: Published by G. P. Putnam's Sons. 1894.

This little work contains in convenient form the outlines of the subject of dermatology. It is elementary, but on that account will be found useful to students, and to those practitioners away from great libraries, whose text-books are a little the worse for the lapse of time since they were published. The author is a little short-sighted it seems to us, in omitting to translate the antique British weights and measures in his prescriptions, into the decimal system—now made official by the last Pharmacopœia. With that exception the student may safely study the book.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

SATURDAY, JULY 7, 1894.

MEDICAL PRACTICE IN THE DISTRICT OF
COLUMBIA.

Although it is not strictly accurate to assert, as is done in the preamble to the act to regulate the practice of medicine in the District of Columbia—the text of which will be found in this issue of the JOURNAL—that there has been hitherto no “law to ascertain the qualifications of individuals desiring to practice medicine and surgery in the District,” it is unquestionably true that the District has become “a resort of persons who are excluded from practice in other States by laws in said States requiring evidence of such qualifications.” As a matter of fact and of history the Medical Society of the District has been, for over half a century, charged with a duty in this respect. By an act of Congress, approved July 7, 1838, the Society was authorized to elect a board of examiners who were empowered “to grant licenses to such medical and chirurgical gentlemen as they may, upon a full examination, judge qualified to practice the medical and chirurgical arts;” and it was forbidden, after the appointment of such board, to practice in the District without said license. The act was vague and inoperative in many respects; those already in practice in the District were exempted from its operation; newcomers who could produce “a diploma from a respectable medical college or a board of examiners established by law” were also exempt; while the sole penalty for others who entered upon practice without the license was a prohibition against the collection of “any fees or reward for the same by any process of law”—a prohibition which was seldom, if ever, enforced, although a majority of those engaged in practice obtained licenses *pro forma*.

While the new law is by no means perfect it is a step in the right direction, and, if judiciously and vigorously enforced, its operation should serve to exclude unqualified practitioners from the District in

the future. Some of its provisions are admirable, as, for example, that by which the diploma is made merely the passport to an examination, carrying with it no higher claim to recognition—the applied test of qualification being examinations in the entire curriculum of medical study, which “examinations shall be both scientific and practical, but of sufficient severity to test a candidate’s fitness to practice medicine and surgery.” So, too, the provision by which the diploma, if issued prior to June 30, 1897, must be accompanied by satisfactory evidence that its issue was preceded by not less than three years’ study of medicine and surgery; and, if after that date, by such evidence of not less than four years’ such study. Section 7, in which are defined the causes for which a license to practice may be refused or revoked, will relieve the Board of an embarrassment which besets similar Boards operating under laws which are less specific on this point. The District Board may refuse or revoke license and otherwise disqualify for practice for any of the following causes: Chronic and persistent inebriety; the practice of criminal abortion; conviction of crime involving moral turpitude; publicly advertising ability to treat or cure disease. This is, probably, as far as it is necessary to go and the authority thus clearly conferred upon the Board should result in excluding the notoriously unfit and unworthy from practice in the District.

The obvious defects in the act fall within the category of those commented upon in the editorial entitled “Schools of Practice,” in the JOURNAL of last week. Three different “schools of medicine” are recognized, both in the composition of the Board of Examiners and in the examinations; and connection with a medical teaching and graduating institution is no bar to membership. The objections to these two points were urged in the editorial referred to, and there need be nothing further said on the subject, except to call attention to the fact that in the original draft of the act it was provided “that no member of said Board shall be connected with any college or university having a medical department.” This provision was stricken from the act before its passage—probably because its retention would have excluded so many of the profession in the District. Some compensation is made, however, in Section 6, which provides for the creation of a “Medical Committee of Review,” none of whose members shall be “connected with any college or university having a medical department”—and to which reviewing body appeal may be taken by any applicant refused license by the Board of Examiners.

On the whole, the act is a distinct gain both for the profession and for the public of the District of Columbia.

THE SANITY OF PRENDERGAST.

The second trial of the assassin PRENDERGAST who foully murdered the Mayor of Chicago, MR. CARTER H. HARRISON, last autumn, resulted in a verdict by the jury that the prisoner had not become insane since his conviction and sentence.

On the part of the public there is apparently not only no desire to "go behind the returns," but a demand for speedy justice by the application of the *lex talionis*.

At the first trial, the plea of insanity was set forth with great ability by the counsel for the prisoner, and "experts were put upon the stand to give testimony for and against the lunacy of the assassin. The jury then decided that the prisoner was sane and fully responsible for his acts, and thereupon, in due course the judge pronounced sentence upon him.

The relatives of the assassin were not idle. His counsel in due time served notice on the Court that the prisoner had become insane since the trial, and after much discussion, the question of his alleged insanity again came to the front with the usual tedious torturing of the testimony of the hapless medical expert.

There will be a sense of relief that there is a fair prospect of ridding the world of such a monstrosity as PRENDERGAST, and whether these wretches are sane or insane, it can not be denied that the world will be better off when its PRENDERGASTS and SANTOS shall have taken leave of it. We can well spare assassins from our midst, and sympathy might much better be expressed with the State, and the families of the victims, than with the murderer.

It is impossible to entirely lose sight of the magnitude of the crime committed in the examination of this question, and it is an evident truth that if the peace of society is to be maintained, laws respected, and the State preserved, we must not obtrude a defense of technical insanity to shield the perpetrator from the consequences of his crime. The insanity, when valid as a defense, should be clear and distinct. There are worse perils for a country than the execution of a criminal whose brain may be technically aberrant, and while one view of the humanities would naturally prevent the execution of a maniac, there is no excuse for preserving the worthless lives of those assassins who are simply eccentric.

THE DEATH RATE OF ST. LOUIS.

The following editorial article appears in the *Medical Brief* of St. Louis:

We have just finished reading, with surprise and indignation, an editorial in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION (May 26, page 813) giving a comparative list, in point of healthfulness, of the most prominent cities in the United States.

Great stress is laid upon the salubrity of Chicago, the death rate being given at 17.8 per one thousand; while the

other cities mentioned range from 20.54 per thousand for Baltimore to 24.48 for Philadelphia. St. Louis is *conspicuous* by her absence. The reason for this omission will be found in the following letter from Dr. George Homan, City Health Commissioner:

St. Louis, May 31, 1894.

DR. J. J. LAWRENCE, Editor *Medical Brief*, City:

Dear Sir:—In answer to yours of 29th instant I have the honor to state that the annual death rate in this city, as calculated by the Health Department, is based on the last census enumeration (460,000) plus 4 per cent. annual increase, which would make the total population in 1893 about 520,000.

As thus reckoned the death rate per thousand for the municipal year ending March 31 last was 17.9.

It is very easy for city officials to assume any convenient population figures that would suit their purpose and thus, on paper, minimize the death rate; and it was because of this custom or liability that this department adopted the basis and ratio above mentioned, and publishes them in the monthly bulletin in order that those concerned may know on what the given percentages rest.

Very respectfully yours,

GEO. HOMAN, Health Commissioner.

St. Louis is unquestionably one of the healthiest of American cities, her system of sewerage has no superior, she is blessed with pure water, the climate is unexcelled, and her death rate, calculated upon a *known* population, is only 17.9.

In the JOURNAL article, which has called forth the above, the second paragraph, first column of page 814, begins: "Of other large American cities *whose bills of mortality for 1893 are at hand*," etc. The bills of mortality for the city of St. Louis for 1893 were not at hand when the article was written, and there is a distinct disclaimer, in the phrase above italicized, of any attempt to deal with the death rate of all large American cities and an equally distinct avowal that the comparison was limited to those "whose bills of mortality for 1893 are at hand."

As a matter of fact there were before the writer, at the time of writing, the St. Louis mortality returns for the months of June, July, August, September and October only. These gave a total of 4,235 deaths for the five months, or an annual death rate for the period of 19.54 per thousand. This rate, as is shown by Dr. HOMAN's letter, would have been much too high, and, therefore, St. Louis was omitted from the comparison, as were several other large cities whose returns were also incomplete.

It is unnecessary to say that the JOURNAL has no intention and no motive for discriminating against or in favor of any city.

THE JUDICIAL COUNCIL.

Our esteemed contemporary, the *Philadelphia Medical News*, states that the question of the "conduct of the JOURNAL," was referred to the Judicial Council and has not yet been decided by them.

At the last meeting of the ASSOCIATION, the question of the action of the management of the JOURNAL in publishing certain advertisements was considered by the Judicial Council, and after a full hearing in the matter, the Council decided to leave it as heretofore in the hands of the Trustees.

MALICIOUS JOURNALISM.

We observe the following in our usually carefully edited contemporary, the *New York Medical Record* of June 30:

The JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION publishes this fortuitous combination of items:

"The American Academy of Medicine will meet in Jefferson, N. Y., August 29 and 30."

"R. In debility from seminal losses, elixir nutrans, ℥viii. Sig. Dessertspoonful four times a day, after meals and at bed-time."

As this journal never published any such item, we at first concluded it a silly attempt at a joke by some compiler, but searching through our file of exchanges we found the following in the *St. Louis Medical Review* of June 16:

The American Academy of Medicine will meet in Jefferson, N. H., August 29 and 30.

R In debility from
Seminal Losses
Elix nutrans ℥viii
Sig - Dessertspoonful
four times a day
after meals and
at bed-time

No man in his senses, having the page before him, could have mistaken the type for that of this journal, and we are rather reluctantly forced to conclude that the *Record* man deliberately published this statement and purposely gave a wrong credit.

The *Record* owes not only the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, but its own readers, a prompt correction.

CONSTRUCTION OF RELIEF DEPARTMENT CONTRACT.

The growth and multiplication of railroad and other corporations employing large numbers of persons in more or less dangerous occupations, has led to the formation, in many instances, among, or for such employes, of aid associations or relief departments. The Burlington Voluntary Relief Department is such an organization, of a very peculiar constitution. Its scheme is that the employes of the Chicago, Burlington & Quincy Railroad Company and certain other associated companies shall contribute certain amounts from their wages to constitute a species of insurance fund to be paid out to the employe in case of injury, or to the beneficiary named by him in his application for membership, in case of his death. The railroad company furnishes the clerical force for the management of the department, keeps the custody of the funds, pays to the association interest upon monthly balances, and also guarantees the payment of losses. A member of this

association agreed that, in consideration of the amounts paid by the company, the acceptance of benefits for injury or death should operate as a release and satisfaction of all claims for damages against the Company, arising from such injury or death, which could be made by him or his legal representatives. He was killed in an accident upon the railroad. The beneficiary named was his widow, who accepted the benefit, and by instrument in writing, received it "in full satisfaction and discharge of all claims or demands on account of, or arising from, the death of said deceased, which I now have, or can hereafter have," against either the relief fund or the railroad company. Subsequently, as administratrix, she brought suit for damages against the railroad company on behalf of herself and children. Under these circumstances, the Supreme Court of Nebraska holds, in the case of *Chicago, Burlington & Quincy Railroad Company v. Wymore*, decided May 15, 1894: 1, that the deceased's contract did not, of itself, waive a right of action; 2, that neither that contract, nor the acceptance of the money or release of liability by the widow, operated to bar a right of action by the administratrix on behalf of the children; 3, that her voluntary acceptance of the benefit, and release of the Company, did not operate to bar any action for her own benefit. The membership contract was, in effect, only that the beneficiary named therein might waive her right of action by accepting the benefit; but this action was not for the benefit of his estate, but for that of his widow and next of kin, and the measure of damages was not what he might have recovered, had he lived, but their pecuniary loss by reason of his death. Whether or not he could, by a compromise after the accident, before his death, deprive them of their right of action, he could not contract away their right before the injury, and without their consent. Nor could he contract that the widow might, after his death, deprive the next of kin of their remedy. She had a right to compromise with the Company after her husband's death, so far as her own rights were concerned, but that was all.

SECTION REPRINTS.

Gentlemen desiring copies of section reprints of particular sections will please send their names to the JOURNAL at once, unless they subscribed at the meeting. No section book will be published unless there are at least fifty subscribers for the volume.

CORRESPONDENCE.

Address of a Sanitarium in Adirondacks.

To the Editor:—Will you be so good as to send to me the location and name of that sanitarium for phthisis in the Catskills or the Adirondacks? The man in charge has a French name, I believe. Very respectfully,

N. H. P.

ASSOCIATION NEWS.

American Medical Association.

SECTION ON SURGERY AND ANATOMY.

Minutes of Meeting, 1894.

The Section was called to order Tuesday afternoon, June 5, 1894, at 2:10 P.M., Dr. John B. Roberts, of Philadelphia in the chair. In the absence of Dr. Floyd McRae, of Atlanta, Ga., Dr. Reginald H. Sayre, of New York, N. Y., was appointed Secretary.

The chairman then delivered his address entitled, "Some Surgical Sins."

The following scientific papers were then read:

"The Pathology of Malignant Growths," E. Laplace, Philadelphia, Pa.; read by title.

"A Critique of the Sporozoan Theory of Malignant Neoplasms from a Micro-technical Standpoint," A. P. Ohlmacher, Chicago, Ill.

"The Clinical Recognition of Malignancy in Tumors," C. A. Wheaton, St. Paul, Minn., Henry W. Coe, Portland, Oregon; read by title.

"The Necessity of Early Surgical Interference in Malignant Tumors," R. A. McLean, San Francisco, Cal.

"The Value of Caustics in Malignant Growths," John Parmenter, Buffalo, N. Y.; read by H. O. Marcy, of Boston. L. Duncan Bulkley, New York, N. Y.; read by Secretary.

"The Radical Cure of Malignant Tumors by Operation," J. H. Wythe, Oakland, Cal.

"The Value of Inoculations with Septic or Toxic Agents in the Treatment of Malignant Neoplasms," John A. Wyeth, New York, N. Y.; read by title.

Discussed by Marcy, Boston; Shiels, San Francisco; Griswold, Pennsylvania; McLean, Detroit; Quimby, Kansas City; Copeman, Iowa; Bulkley, New York; Ransohoff, Cincinnati; Rosenstirn, California.

"Non-Malignant Stenosis of the Pylorus and Duodenum," X. C. Scott, Cleveland, Ohio; read by title.

The Chairman then appointed as a nominating committee to nominate officers for the ensuing year, Drs. D. W. Graham, of Chicago and H. M. Sherman, of San Francisco, and as alternates on the executive committee to take the place of Drs. J. M. Matthews, Louisville, Ky., and W. E. B. Davis, Birmingham, Ala., Drs. Joseph Ransohoff, Cincinnati, Ohio, and Reginald H. Sayre, New York, N. Y. The Section at 5 P.M. adjourned. When called to order at 9:10 A.M., June 6, the discussion on "Tubercular Disease of the Joints," took place. Papers on the "Early Symptoms and Diagnosis of Tubercular Joint Disease," were read by Emmet Rixford, San Francisco, Cal., and A. J. Steele, St. Louis, Mo., while that of A. B. Judson, New York, N. Y., was read by the Secretary. "The Conservative Treatment of Tubercular Joints," was set forth by H. M. Sherman, San Francisco, Cal., Reginald H. Sayre, New York, N. Y., and a paper on the same subject by J. E. Thompson, Galveston, Texas, was read by title.

The paper by R. W. Lovett, Boston, Mass., on the "Operative Treatment of Tubercular Joints" was read by the Secretary.

"The Treatment of Tubercular Joints by Injections of Iodoform" was considered by Stanley Stillman, San Francisco, Cal., and a paper on the same subject by Nicholas Senn, Chicago, Ill., and one on "Injection of Corrosive Sublimate," by R. H. Plummer, San Francisco, Cal., were read by title. The subject was then discussed by Drs. Sherman, California; Schoaler, Iowa; Eagleson, Washington; Kurz, Colorado; Shiels, California; Sayre, New York, and Huntington, California.

A paper on "Common Errors in Prescribing and Applying Mechanical Apparatus," by A. E. Hoadley, Chicago, Ill., was then read by title.

The Section was called to order at 2 P.M., and on motion adjourned till 2:30 P.M. When called to order again the

Nominating Committee presented the names of Dr. Joseph Ransohoff, Cincinnati, Ohio for Chairman and Reginald H. Sayre, New York, N. Y., for Secretary for the ensuing year and on a vote being taken they were declared elected. The following scientific work was then transacted, it having been moved that papers of those not present be read by title:

Papers on "The Causation and Prevention of Hernia," by James T. Jelks, Hot Springs, Ark., "The Management of Reducible Hernia," by Emory Lanphear, Kansas City, Mo., and C. M. Fenn, San Diego, Cal., and "The Treatment of Irreducible Hernia," by James B. Eagleson, Seattle, Wash., were read by title.

"The Treatment of Strangulated Hernia," by Joseph Ransohoff, Cincinnati, Ohio, was considered.

"The Radical Cure of Hernia," by W. E. B. Davis, Birmingham, Ala., and H. O. Marcy, Boston, Mass., read by title.

A. E. Rockey, Portland, Oregon, read a paper on "Some Observations on the Radical Cure of Inguinal Hernia."

These papers were discussed by Drs. Shiels, California; Rockey, Iowa; Horton, Tex.; Huntington, California; Griswold, Pennsylvania; Reynolds, Wisconsin; Ransohoff, Ohio, and Marcy, Massachusetts.

A paper on "Concussion of the Brain," by L. C. Lane, San Francisco, Cal., was then read, and then a paper on the "Treatment of Fractures of the Lower End of the Humerus,"

by Oscar H. Allis, Philadelphia, Pa., was read by the chairman. The following papers were read by title:

"Treatment of Fractures of the Lower End of the Radius," by P. S. Connor, Cincinnati, Ohio.

"Treatment of Fractures of the Neck of the Femur," by Bedford Brown, Alexandria, Va.

"Treatment of Fractures of the Shaft of the Femur," by Llewellyn Eliot, Washington, D. C.

"Treatment of Open or Compound Fractures," by H. H. Mudd, St. Louis, Mo.

The question of fractures was discussed by Drs. Lane, California; Sayre, New York; Birkstein, California; Kent, California; Wheaton, Minnesota; Horton, Texas; and Thomas, Pa.

After a paper by G. F. Shiels, San Francisco, Cal., entitled "A Plea for the Better Teaching of Anatomy," and one on "Tendon Grafting for the Deformities following Infantile Paralysis," by S. E. Milliken, New York, N. Y., the Section adjourned.

On being called to order Thursday morning, June 7, at 9 o'clock, the subject of "Obstruction to Urination in the Male," was considered.

Papers on the "Effects of Obstruction in Urination upon the Bladder and Kidneys," by J. William White, Philadelphia, Pa.; the "Diagnosis and Treatment of Enlargement of the Prostate Gland," by Hunter McGuire, Richmond, Va., and William T. Belfield, Chicago, Ill.; the "Symptoms and Treatment of Stone in the Bladder," by Wm. T. Briggs, Nashville, Tenn.; and the "Symptoms and Treatment of Tumors of the Bladder," by John B. Deaver, Philadelphia, Pa., were read by title.

C. F. Buckley, of San Francisco, read a paper on this last subject and presented pencil removed from the bladder.

The subject was discussed by Thomas, Pennsylvania; Huntington, California; Thompson, Washington; Dodge, Michigan; Griffith, Missouri; and Ransohoff, Ohio.

In the afternoon the following papers were read by title: "Stricture of the Male Urethra," by W. H. Crawford, U. S. A.; "Carcinoma of the Urethra, with a Report of Two Cases," by H. O. Walker, Detroit, Mich., by title; and the following read by the author. J. Rosenstirn, San Francisco, Cal., "Treatment of Stricture of the Urethra."

"The Pathology and Symptomatology of Hemorrhoids, Anal Fistulae and Anal Fissure," by J. M. Matthews, Louisville, Ky., and David Powell, Marysville, Cal., read by title.

"The Treatment of Hemorrhoids," by Charles B. Kelsey, New York City; "The Treatment of Anal Fistulae," J. McF.

Gaston, Atlanta, Ga., read by title. One on the same subject, by G. B. Somers, San Francisco, Cal.

"The Treatment of Anal Fissure," by T. W. Huntington, San Francisco, Cal., and one on the same subject, by Lewis H. Adler, Jr., Philadelphia, read by title.

On Friday morning, June 8, the Section was called to order at 9:15 o'clock, and the following papers were read by title:

"A Plea for the Early and Systematic Removal of the Inguinal Lymphatic Glands in Cases of Malignant Growths in Regions from which these Glands receive Lymphatics," by H. Reineking, Sheboygan, Wis.

"Shall it be Catgut, Silk, or Both?" by A. Morgan Cartledge, Louisville, Ky.

"Electrolysis in the Treatment of Aneurism of the Aorta," by C. M. Richter, San Francisco, Cal.

"Spinal Surgery; with Report of Two Cases of Laminectomy for Paraplegia caused by Potts' Disease," by F. C. Schaefer, Chicago, Ill.

A paper on "Bloodless Vaginal Myomectomy" was read by O. J. Mayer, San Francisco, Cal., who also showed a patient on whom he had operated for varicocele by removal of the enlarged veins of the cord through a longitudinal incision and then sewing up the incision by approximating the ends, thus transforming the cicatrix into a transverse one.

A paper on the "Surgical Uses of Acetanilid" was then read by G. W. Woods, U. S. N., and discussed by Dr. Grand, Oregon.

Dr. J. D. Thomas, Pittsburg, Pa., read a paper entitled, "How long is Syphilis Contagious?" and the following papers were read by title:

"Clinical Recognition of Malignancy in Tumors," by Dr. Wheaton, Texas.

"Treatment of Phlegmonous Erysipelas and other Forms of Suppurative Inflammation by Ice Water," by H. Bergstein, Minnesota.

Dr. Haughton, of Texas, then read a paper entitled, "How Best shall we Treat Wounds To-day?"

Dr. Shiels, of San Francisco, Cal., showed a case of multiple bilateral lipomata.

Dr. Bonnewell, of Philadelphia, Pa., exhibited a surgical engine, and the Section was declared adjourned.

REGINALD H. SAYRE, Acting Secretary.

SOCIETY NEWS.

Des Moines Valley Medical Society.—The Des Moines Valley Medical Society held its twenty-fourth annual meeting at Ottumwa, Iowa, June 23. Dr. H. C. Eschback, of Albia, presided, and Dr. A. O. Williams, of Ottumwa, Secretary. This Society comprises the physicians residing in some twenty counties.

Dodge County, Iowa, Medical Association.—Drs. McDonald and Sears, of Beaver Dam; Owen, of Fox Lake; Scoen, of Mayville; Clason, of Neosho; White and Feld, of Watertown, and Hallock and Lueck, of Juneau, met in Juneau and organized a Dodge County Medical Association. Dr. Hallock was elected President and Dr. Sears Secretary and Treasurer. The next meeting of the Association will be held at Beaver Dam, July 9, 1894.

Colorado State Medical Society.—At the recent meeting of the Colorado State Medical Society, held in Denver, the following officers were elected for the ensuing year:

President, Dr. Hubert Work, Pueblo.

First Vice-President, Dr. J. R. Robinson, Colorado Springs.

Second Vice-President, Dr. E. Stuver, Rawlins, Wyo.

Third Vice-President, Dr. Laura Liebhardt, Denver.

Treasurer, Dr. W. F. McClelland, Denver.

Corresponding Secretary, Dr. C. K. Fleming, Denver.

Reporting Secretary, Dr. E. R. Axtell, Denver.

Assistant Secretary, Dr. Chas. Manly, Denver.

South Dakota State Medical Society.—The thirteenth annual session of the South Dakota State Medical Society was held at Huron, June 22. The following were elected officers for the ensuing year:

R. T. Dott, of Alexandria, President; G. E. Martin, of Carthage, first Vice-President; Wm. Edwards, of Bowdle, second Vice-President; W. J. Mayturn, of Alexandria, first Secretary; Earl Rice, of DeSmet, second Secretary; C. B. Alford and G. W. Moody, of Huron, and J. C. Morgan, of Sioux Falls, Trustees. The Legislative Committee consists of Drs. Peterman, of Parker, Martin, of Carthage, and Moody, of Huron.

The officers will name the time and place for holding the next meeting. The banquet was provided by local members of the Society and served by ladies of Grace Episcopal Church. Dr. Alford, of Huron, was toastmaster.

The St. Louis Medical Society met June 23. Dr. Fry described an interesting case of bulbar paralysis in a woman 50 years of age, dwelling minutely upon the symptoms of the patient, and giving a complete history of the case. Dr. Funkhauser explained a case of a lesion of paralysis in a female child aged 1 year, caused by a fall from bed. Both cases having been discussed, Dr. Smith took the floor to introduce a new trephine invented by him, to be used with either a dental engine or an electric motor. He read a brief paper on trephining, when a recess was taken in order that the doctors might examine the trephine at work. In the discussion which followed, the new trephine was somewhat adversely criticised by Dr. Meisenbach and others. Dr. Fairbrother's paper on "Simulated Diseases," read on the 16th ult., was then discussed in detail, many of the participants reporting cases in point that had come under their notice.

North Texas Medical Society.—The meeting was held at Sherman, Tex., June 19.

Mayor Edmonds welcomed the Association to Sherman, and Capt. J. S. Porter then welcomed the Association in behalf of the citizens. The addresses were replied to by President Chilton, who delivered his annual address.

Dr. Ford also delivered an address.

The following papers were read:

"Operative Treatment of Prolapsus and Retro-displacements of Uterus—Report of Cases," by F. B. Fite, of Muscogee, I. T.

"Face Presentation with Report of Case," I. P. Gunby, of Sherman.

"Uterine Fungosities," by W. R. Hoord, Whitewright, Texas.

To-day's session opened promptly at 9 o'clock.

Hon. John H. Reagan was a visitor at the morning session and by request delivered a short address to the Association in which he avoided any mention of politics. He dwelt principally upon his experience with surgeons and physicians in the service of the Confederate States.

The Section on Practice was then resumed.

"Purpura Rheumatica," by S. D. Thurston, of Dallas.

"Caricature of my Experience with Dengue and La Grippe," by J. M. Foot, of Paris.

The afternoon session was devoted to obstetrics and gynecology.

"Septic Endometritis," by R. R. Walker, of Paris.

"Some of the Dangers and Their Proper Treatment of the Third Stage of Labor," by W. R. Wilson, of Dallas.

There were about seventy-five members in attendance.

Minnesota State Medical Association.—At the last session the following officers were elected: President, Dr. J. Ohage of St. Paul; First Vice-President, Dr. W. A. Hall, of Minneapolis; Second Vice-President, Dr. F. S. Bissell, of Litchfield; Third Vice-President, Dr. John B. Dunn, of St. Cloud; Secretary, Dr. C. B. Witherle, of St. Paul; Treasurer, Dr. R. J. Hill, of Minneapolis. A committee composed of Drs. Beard of Minneapolis, Hewitt of Red Wing, Hoog of Minneapolis, William Davis of St. Paul and McGaughey of Winona,

was appointed to take steps toward securing legislation tending to prevent the spread of tuberculosis. An appropriation of \$300 was made from the treasury to pay for the printing of the State medical directory.

In the afternoon the Section of Surgery, presided over by Dr. Thomas McDavitt of St. Paul, held a four hours' session. Thirteen papers were read and discussed. Operations on the Middle Ear and Mastoid was Chairman McDavitt's subject. He was followed by Dr. C. A. Wheaton, of St. Paul, who made an excellent address upon general surgery. Parasitic Origin of Carcinoma was the subject of a paper by Dr. W. T. English, of Winona. One of the most interesting papers of the afternoon was that by Dr. L. C. Bacon, of St. Paul, upon The Advisability of Opening the Medullary Canal in all Cases of Acute Infectious Bone Disease of Children. Dr. Burnside Foster, of St. Paul, gave some Notes on a Few Clinical Experiences of Inherited Syphilis, and Dr. F. A. Dodge, of Le Sueur, presented a paper upon Vesical Calculus with specimens. The first paper discussed at any length was that of Dr. Archibald McLaren upon Enterorhaphy—Report of one Successful Case of End-to-End Anastomosis of the Large Intestine with the Murphy Button. Dr. J. H. Dunn's paper upon Appendicitis, with a Summary of Thirty-three Consecutive Cases, was also given considerable attention. Dr. C. H. Mayo, of Rochester, read a paper upon Brain Cysts, which was followed by a talk upon Fractures of Orbital Wall and Margin by Dr. H. McI. Morton, of Minneapolis. The discussion which it provoked was led by Dr. C. H. Hunter, of Minneapolis. The other papers read were as follows: Some Remarks on the Treatment of Suppurating Wounds, by Dr. Harold Graff, of St. Paul; Diagnosis and Surgical Treatment of Cancer of the Stomach, by J. W. Macdonald, M.D., L. R. C. S. E., of Minneapolis; Non-Tuberculosis Diseases of the Joints, by Dr. A. J. Gillette, of St. Paul.

The Association was entertained at a banquet by the Ramsey County Medical Society. Dr. Park Ritchie was toastmaster. The next meeting will be held in Duluth.

The Association of American Medical Colleges.—Resolutions adopted at a meeting held in San Francisco, Cal., June 7, 1894:

Resolved, That colleges, members of this Association, shall require of all matriculates an examination as follows:

1. An English composition in the handwriting of the applicant of not less than two hundred words; said composition to include construction, punctuation and spelling.
2. Arithmetic, fundamental rules, common and decimal fractions and ratio and proportion.
3. Algebra—through quadratics.
4. Physics—elementary—Gage.
5. Latin—an amount equal to one year's study, as indicated in Harkness Latin Reader.

(The above resolution does not apply to students exempt from the entrance examination, as per Sec. 2, Art. III.)

Resolved, That the following classes of students be recognized as entitled to apply for advanced standing in colleges members of this body:

- a, Such graduates of recognized colleges and universities as have completed the prescribed courses in chemistry and biology therein.
- b, Graduates and matriculates of colleges of homeopathy.
- c, Graduates and matriculates of colleges of eclectic medicine.
- d, Graduates and matriculates of colleges of dentistry requiring two or more courses of lectures before conferring the degree of D.D.S.
- e, Graduates and matriculates of colleges of pharmacy.
- f, Graduates and matriculates of colleges of veterinary medicine.

It is provided, however, that the above class of students be required to comply with the provisions of the entrance examination and to prove their fitness to advanced standing by an individual examination upon each branch below the class he or she may desire to enter.

Resolved, That students graduating in 1899 or subsequent classes be required to pursue the study of medicine four years, and to have attended four annual courses of lectures of not less than six months' duration each.

PUBLIC HEALTH.

Aniline Colored Candles.—Two deaths occurred last week in New York City as the result of eating candies, known as "jelly beans" and "strawberry balls," which were ascertained on analysis to be colored with aniline dyes. The City Health Department is pursuing an investigation into the extent of this dangerous manufacture.

Wisconsin Sanitary Organization.—The State and local health authorities of Wisconsin are to be organized under the name of the Wisconsin Association of State and Local Boards of Health, for the purpose of popularizing sanitary work and knowledge in the State and to secure uniform and effective sanitary legislation.

Canadian Quarantine Station.—The Canadian quarantine station on Grosse Isle in the St. Lawrence below Quebec, is reported as being in perfect order and one of the most extensive of modern quarantine plants. There are forty buildings with a capacity of housing three thousand persons and the effects of one thousand immigrants can be thoroughly disinfected in twenty-four hours. Dr. Montzambert is in charge of the station and has been appointed Superintendent of the Canadian Quarantine System by the Dominion Government.

Restriction of Phthisis in Texas.—Dr. R. M. Swearingen, State Health Officer of Texas, has issued a circular letter to every county physician and local health officer in the State, urging the enforcement of recognized measures for the restriction of the spread of consumption, with especial reference to the hotels of Southwest Texas—Austin, San Antonio, El Paso and other cities, which have induced many consumptives to leave their less favorable Northern surroundings by "glowing advertisements of pure water and balmy airs that could magically restore flesh to wasted frames, and have kindled hopes that reason had extinguished."

Making Vaccination Safe.—In making vaccination compulsory within twelve months after birth, the State of Maryland wisely provides for a supply of pure and efficient vaccine. Section 3, sub-title, "Infectious Diseases," title, "Health," of the Code of Public General Laws of Maryland, recites that: "The State Vaccine Agent is required to take all the steps necessary to reproduce from the cow true vaccine virus, for the use of physicians residing and practicing medicine in the State, and shall furnish none more than four removes from the cow, and none that has not been produced under his own supervision and direction; provided that he may take, use and furnish such virus furnished to him by any physician intrusted by him to procure the same, such virus not to be taken from the arm of a child less than three months old."

Smallpox in Michigan.—Dr. Henry B. Baker, Secretary of the Michigan State Board of Health, has compiled a tabular statement of smallpox in that State since Jan. 1, 1894. From this it is learned that there have been fifteen outbreaks in thirteen cities and towns and twelve counties—the first January 9, the last June 11. In all there were forty cases, with fifteen deaths, in twenty-one infected houses. Dr. Baker desires to congratulate the health officers in Michigan, and especially the people who have been protected by their efforts, on the success of their work for the restriction of smallpox. In the fifteen outbreaks there have been on the average to each outbreak only 2.7 cases and one death; in eleven of the fifteen outbreaks the infection was restricted to the one house in which it first occurred. Dr. Baker adds: "The fifteen deaths out of forty cases are a powerful argument for vaccination and re-vaccination, be-

cause they show that among persons unprotected by vaccination smallpox is still the same deadly and dreadful disease that it has been—the mortality thus far having been 37.5 per cent."

Notification of Contagious Diseases.—A determined effort is being made by Dr. N. G. Tucker, Health Officer of Nashville, to enforce the law passed at the last session of the Tennessee Legislature, requiring physicians to notify the health authorities of every case of a communicable disease they may be called upon to treat. The penalty for neglect or refusal to notify is a fine of not less than ten nor more than one hundred dollars, or the county jail for not more than three months, or both fine and imprisonment. Every communicable disease, except venereal, is comprehended in the law; but the State Board of Health limits the list, "for the present," to smallpox, cholera, yellow fever, scarlet fever, diphtheria, measles, whooping cough, chickenpox and typhoid fever.

A Factor of the New York Death Rate.—Out of a total population of 1,856,695, New York has—according to Dr. Roger S. Tracy, Deputy Registrar of Vital Statistics, who has just completed the semi-annual census of the tenement-house population of that city—a total of 1,332,773 souls living in 39,138 tenement houses. Of this number there are 2,346 rear houses with a population of 56,130. In the ward which contains the largest tenement-house population there are 7,702 houses, with a population of 252,331; and in the ward which contains the smallest number there are 8 tenements with a population of 175. The total number of children under 5 years of age living in tenement houses is 180,359. This enormous aggregate of human beings, living under the conditions of the tenement house, is the chief factor in New York's excessive death rate.

Vital Statistics of Rhode Island.—An act prepared by Dr. Gardner T. Swarts, Secretary of the Rhode Island State Board of Health and State Registrar, has been passed by the Legislature, which seeks to remedy a defect in the system of registration of births, deaths and marriages heretofore in vogue. It is now made the duty of the clerk or registrar of each town and city to transmit certified copies of births, marriages and deaths, by him recorded, whenever the child born, or the bride or groom, or the person deceased were resident of any other town or city (in or out of the State) at the time of the birth, marriage or death, to the clerk or registrar of the town or city concerned. This will often greatly facilitate the legal establishment of the fact of birth, marriage or death—a use of vital statistics not to be overlooked. The fee for recording births was increased by the Legislature to 20 cents for each birth, instead of 10 cents for the first fifty entries and 10 cents for each subsequent one. It is through such measures as these that the vital statistics of Rhode Island have acquired exceptional value.

The Bubonic Plague.—Latest advices from Hong Kong are by the Pacific mail steamer *Peru*, arrived at San Francisco, July 1. She is the first vessel that has arrived at a United States port from the plague-smitten district since the disease broke out in Hong Kong last May. Four days out from the latter port a Chinese wiper in the engine room developed a case of the disease and died in four hours. On arrival at Nagasaki the *Peru* was put in quarantine and detained for seven days. She brings news that the plague has become worse and that the disease has broken out in new districts. From June 7 to 14, 701 persons died from the pest in Hong Kong and fully 75,000 Chinese had fled from the city. It is reported that a Chinese junk, with about 400 passengers from Hong Kong, escaping from the plague, capsized and sank in Cop Siu Moon Pass. Five British

soldiers who were engaged in the enforcement of sanitary laws in Hong Kong have fallen victims to the plague. Advices from the United States Legation at Tokio, June 30, confirm the reports of the existence of the disease at Canton and announce that the Japanese Imperial Government has proclaimed quarantine against vessels from several Chinese ports to Japan. Arrivals from Yokohama at Victoria, B. C., are subjected to rigid sanitary inspection and treatment and all effects of Oriental passengers are thoroughly disinfected.

Rarity of Phthisis.—At the recent meeting of the American Climatological Association, Dr. Guy Hinsdale, of Philadelphia, called attention to the low mortality from consumption in a district falling partly within New York and partly within Pennsylvania and embracing an area of 12,000 square miles. Throughout this region there is, according to the best available information, a population of over one thousand persons living, to each annual death from phthisis. The maritime district of New York, including Westchester County and Long Island, has one annual death from phthisis to every 400 persons living, while the southern tier of counties, from Broom to Chataqua on Lake Erie, has an average of only one death to 1,091 persons living. Co-terminous, on the south, with these counties of New York are the Highlands of Pennsylvania—the northern and western uplands behind the escarpment of the Alleghenies, with an elevation of 1,200 to over 2,000 feet, characterized by extensive forests, a dryer air and lower temperature than prevails at the seaboard or lake shore, and, by reason of its distance from the storm tracks of the St. Lawrence Valley and the changing temperature of the seaboard, eminently suited for consumptives. In this region, Kane, in the southwestern part of McKean County, has acquired a considerable reputation for consumptives and hay fever victims. The surrounding country is an elevated table land of 2,000 feet elevation; the water courses are small and fogs, which are common in the valleys, are not observed on this high plateau or "Big Level" as it is called. Pneumonia, pleurisy and diphtheria are rare in this locality.

Public Health at Home and Abroad.—A congress of sanitarians and medical men will be held in London, Eng., during the latter part of the present month to consider "many topics of immediate and vital interest." In connection with the call for this congress it is announced that "cholera now rages in many parts of Asia, and that strange disease, indefinitely termed the plague, has gained a foothold in the seaboard cities of China. Smallpox is more or less prevalent on the continent of Europe, and it is to deal with these various epidemics that threaten Great Britain that the congress has been called. It is recognized that sanitary precautions of the most rigorous sort must be imposed, but it is thought that timely action will preserve the health of these islands as completely and effectually during the present season of danger as during last year's cholera scare. There is no actual fear expressed, but it is recognized that early measures must be taken in order to conserve the health of the Kingdom." Meanwhile, it may be noted that the freedom from alarm in the United States with regard to the foreign epidemic diseases continues undisturbed. Smallpox is abating and has ceased to furnish the press with sensational head-lines; our sanitary officers abroad fail to discover ground for alarm in the cholera situation—notwithstanding the detection of the cholera vibrio in some cases in Paris, the extent of the outbreak in Belgium and its continuance in Eastern Europe; fewer yellow fever ships have arrived than usual and these have been promptly cared for at the quarantine stations; due vigilance is being exercised with respect to the Chinese plague; and, except for an increased mortality in some localities, due to the phenom-

enally high temperature of June, the public health conditions of the country, up to date, are most gratifying. To the wide-spread labor troubles we are at least spared the addition of the horrors of a cholera or yellow fever epidemic.

NECROLOGY.

HOWARD G. ATKINSON, M.D., of St. Joseph, Mo., June 28.—Joseph Potts Thomas, M.D., of Louisville, Ky., ex-President State Medical Society, June 24, aged 64.—Perry Tipton, M.D., at Washington, D. C., June 25.—Geo. T. Wiseman, M.D., of Bainbridge, Pa., June 26, aged 73.—F. M. Eckford, M.D., at Los Angeles, Cal., June 18, aged 76.—James Loar, M.D., of Bloomington, Ill., June 14. He was aged 64 years and had practiced medicine in that city nearly thirty years.

MISCELLANY.

S. S. Kahn, has been appointed City Physician of San Francisco.

Mr. George S. Cox, State chemist, of Madison, Wis., has been recently appointed Professor of Chemistry and Dr. F. T. Nye of Beloit, Wis., Professor of Rhinology and Laryngology in the Wisconsin College of Physicians and Surgeons.

Georgia Medical Practice Act.—Notwithstanding the best efforts of the best elements of the profession in Georgia, the bill to regulate the practice of medicine in that State has been defeated, and she still continues to be an asylum for the rejected of her sister States that have some legal protection against incompetency and charlatanism.

Lactophenin.—In the *Lancet*, April 21, a new analgesic and hypnotic product finds favorable mention. Dr. Landowski has given it a trial in the wards of Prof. Pronst. This substance is an analogue of phenacetin, with a difference, namely, that lactic acid is a constituent instead of acetic acid. It is in the form of a white powder, tasteless and soluble in 330 parts of water. The initial dose is .50 given thrice daily. The maximum dose is placed at 1 gram. In small doses the drug is valuable as a calmative of neuralgia; in large doses it is hypnotic. It is well borne by some patients who are antipathetic to antipyrin. In some cases diaphoresis was produced.

Recognition of Dr. Rauch.—Speaking of the effect of the laws intended to regulate the practice of medicine in the improvement of the standard of medical education, Dr. R. H. Fitz, in his annual address before the Massachusetts Medical Society, said: "There is not only a prolongation of the period of study as the effect of these laws, but there is also an increased demand for a preliminary education, the establishment of new professorships, and more exacting examinations for the degree. Of all agents distinctly bringing about this change, the Illinois State Board of Health, and especially its Secretary, the late Dr. John H. Rauch, deserve the highest consideration."

Zola's Bacteriology.—One of Emile Zola's characters in his new novel, "Lourdes," is evidently a student of bacteriology and has witnessed demonstrations of the increased morbific potency obtained by mixing cultures of the toxigenic bacteria. Standing at the pool in the miraculous grotto and watching the increasing nastiness of the water, in which so many persons suffering from cancerous and tubercular affections, purulent sores, ophthalmia and offensive cutaneous diseases, are bathed, he exclaims: "What a home for microbes! The present mania for antiseptic precautions receives a fearful blow from such a spectacle. How does it happen that one common nasty disease does not kill all the invalids?"

Masonic Home for Consumptives.—With the consent of the Grand Master of the Grand Jurisdiction, A. F. and A. M. of New Mexico, the Montezuma Lodge of Santa Fe has adopted a resolution setting forth "that the death rate from consumption is increasing at an alarming rate all over the world; that the benefits of climatic cure are now universally recognized by physicians; that the most perfect climate is found at Santa Fe," and inviting the Masons of the United States and Canada to coöperate with Montezuma Lodge in the erection there of a national home for consumptives, to be governed and maintained by Masons for benevolent and charitable purposes.

Where They Move To.—Commenting upon the destination of a recent applicant to the Texas State Board of Medical Examiners—who defined histology as "the history of medicine," and when asked what system he practiced replied, "The Vanderbilt and St. Louis systems and sometimes the homeopath system," further explaining that this latter system consisted in "sweatin' the patient"—the *Atlanta Medical and Surgical Journal* sadly remarks: "In Texas and most other States such applicants are promptly declined and told to move on. They do move on to Georgia, Ohio, etc., where their ignorance is safely guarded by the absence of any law that may interfere with them."

Sequardine—a Glycerio-Phosphate.—Dr. Albert Robin has enunciated before the Paris Academy some original views regarding the replacement of Dr. Brown Séquard's elixir by a less sensational preparation. Starting with the working thesis that the late Professor's orchitic remedy was important in a certain range of cases, and that the good effects wrought through it were due to phosphorus elements, and also taking into consideration the fact that phosphorus is present in nearly all the reliable brain foods, or restoratives of nerve waste, Dr. Robin has made a series of trials with a glycerio-phosphate of his own invention. These trials have advanced sufficiently far and favorably to warrant him in addressing the Academy. The new remedy will doubtless be thoroughly investigated by the *confrères* of the late Dr. Brown-Séquard. There are many admirers of his who will be gratified to see the name of the enthusiast and physiologist embalmed in a monument of this kind—a neurologic remedy of permanent use and value.

The Young Doctor's Opportunity.—Dr. Hugh Blake Williams tells the *Chicago Herald* a doleful story of the experience of a young physician: "You have no idea, my dear boy," he said, "of the difficulties which environ the young man when he first starts out in the practice of medicine and surgery. When I first started out I was trying to do both, and considered myself competent to do either, but somehow the balance of the community where I started down in old Virginia, did not seem to agree with me. I used all the arts usually employed by young practitioners. I had my horse brought round every morning, and I used to gallop around as though there was a pestilence in every section of the county and nobody could get well until I got there. I had a boy regularly employed to call me out of church in the middle of the services, and I used to go with a rush that would break up a camp meeting. None of these things seemed to work worth a cent. To add to my discomfiture, the balance of the doctors in town seemed to have leagued against me and to be working against my interests.

"Finally, however, my chance came. There was a medical convention one day in the next county, and all the doctors of my own town except myself went over to attend it. That afternoon an Irishman named Rafferty fell in a sewer and broke his leg. I was the only doctor left in town, and I got the case. I fixed that Irishman up in the best shape you ever saw. I put more splints on him than would be needed for the fractured leg of an elephant. I gave him a big drink to settle his nerves, and when I left him I had the neighborhood covered with tanbark for several squares to stop any noise that might disturb the patient. I went

around in the morning expecting to find him calm and composed, and I found him hot and clamorous for my blood. What was the matter? Well, I don't want anything more than is necessary said about it, but to tell the whole truth to you, I found that I had set the wrong leg."

Medicine Among the Aztecs.—In a review of Flores' "History of Medicine in Mexico," Dr. David Cerna, of the Medical Department of the University of Texas, furnishes (*University Medical Magazine*, July, August, 1892, *Tri-State Medical Journal*, May, June, 1894) some interesting information concerning medical education and the regulations of medical practice among the Aztecs during the earliest period of ancient Mexican history, *i. e.*, that prior to 1521. The scientific professions were considered sacred; the privilege of following them was tendered only to the higher classes of society, and such professions were studied under the guidance and immediate supervision of the priests, who, among the Aztecs, were the most learned. The teaching of medical science, however, was both sacerdotal and hereditary, and father-physicians usually made physicians of their children and guided these afterwards in the practice of the healing art. For the proper study of the more or less rudimentary medical science among the Aztecs, the branches required to be mastered were medical and surgical pathology, therapeutics, botany, pharmacy and lastly clinical medicine and surgery. The studies of the pharmacist were more simple, but he was required to possess a knowledge of botany and pharmacy. Obstetrics remained always in the hands of women, and of those females especially who had already borne children and had, therefore, some practical knowledge. These, stated in a few words, were the principal branches of the healing art taught to those who intended to follow the professions of physician, surgeon, midwife and pharmacist. The candidates, however, who had satisfactorily finished their respective studies, were not allowed to go into practice without legal authorization. Physicians, surgeons, obstetricians and pharmacists, even after graduation, were obliged to obtain licenses before they were permitted to practice, and, notwithstanding the prevalence of superstitious ideas, quackery and witchcraft in connection with medicine, were severely punished by a special court or tribunal. Transgressors of the law, in this respect, frequently fell victims to human sacrifice so common among the Aztecs. Physicians were not idle in regard to medical studies; they had their societies which provoked reunions especially at the capital of the Empire, and in them the most interesting medical topics were brought forward and discussed. There were diffused throughout the land, especially at the two great cities of Texcoco and Tenochtitlan, civil and military hospitals for the reception of the sick among the poor and destitute, and of those who had been injured in the service of the country. The hospitals were superintended by the ablest physicians and surgeons, although always under governmental control. Five hundred years before the American Public Health Association met beneath the shadow of the great bust of the last Emperor of the Aztecs, that picturesque and interesting people had already attained a remarkable degree of development in the most complex of the learned professions—that of medicine.

Medical College Notes.

HARVARD MEDICAL ALUMNI'S FOURTH BANQUET—The fourth annual dinner of the Harvard Medical Alumni Association was held June 26.

There were present about 200 members of the Association. The retiring President, Dr. James R. Chadwick, sat at the head of the table. The guests of the occasion were Dr. William W. Keen, Professor of the Principles of Surgery and of Clinical Surgery in Jefferson Medical College, Philadelphia; Dr. William Osler, of Montreal, Professor of the Principles and Practice of Medicine at Johns Hopkins University, Baltimore; Dr. William M. Polk, Professor of Obstetrics and Diseases of Women and Children in the University of the City of New York, and Dr. John S. Billings, Deputy Surgeon-General of the U. S. Army, of Washington-

The other distinguished medical men at the guests' table were Drs. Francis H. Brown, Henry W. Williams, Dr. Reginald H. Fitz, Professor of Theory and Practice of Medicine at the Harvard Medical School; Dr. George B. Shattuck, editor of the *Boston Medical and Surgical Journal*; Dr. David W. Cheever, Professor of Surgery, Emeritus in the Harvard Medical School; Dr. Henry P. Bowditch, Professor of Physiology at the Harvard Medical School; Drs. Samuel W. Langmaid and William K. Wilcox.

Scattered about the other tables were Drs. George W. Gay, Frederick C. Shattuck, Thomas M. Rotch, Maurice H. Richardson, Theodore W. Fisher, Edward Cowles, H. A. A. Beach, John H. McCullom, Francis H. Williams, Charles N. Green, Francis H. Davenport, E. W. Mackie, Arthur B. Duel, Joseph H. Cunningham, R. F. Chase, A. K. Page, Charles F. Sweet, Leander M. Farrington, C. G. Page and John E. McGrath.

Dr. Chadwick opened the post-prandial exercises. In reviewing the work of the Association during the past year he said that the most important bit of legislation, from a medical standpoint, was the passage of the medical practice act. The law, in the speaker's opinion, did not go far, but a little advancement was encouraging. Its passage was due solely to the medical profession, which, said Dr. Chadwick, when confronted by problems regarding the public health, shows a singular and unselfish disinterestedness.

Dr. Chadwick pictured the contrast, as he viewed it, between the selfish political legislators at Washington and the unselfish medical congress which recently met at the capital. He said he was glad to record another successful year for the medical school, all classes except the entering showing an increase. This exception was due, he thought to the business depression rather than the four years' course. He announced that two new scholarships had been given during the past year, making twelve in all, whereas for this number there were forty-two applicants. The medical school during the past twenty-five years has received in bequests \$491,469.

Dr. Samuel W. Langmaid, Chairman of the Committee to report upon the work of the school, referred to the changes in the Faculty, and congratulated the Alumni upon the death of the three years' course. The Committee looks forward to the time when the degree of Bachelor of Arts will be necessary for admission to the school, and reported that after July, 1896, a step will be taken pointing in that direction. After that date six subjects will be made compulsory in the entrance examination, and the standard made in every way higher. The committee spoke of the work of the school at great length. Harvard ought to teach other schools how to teach, said the Chairman, and it ought to supply the constantly increasing demand for higher medical education formerly secured abroad.

Dr. Keen opened the talk on "Medical Education." Colleges, he said, are taking cognizance of the fact that medical education is advancing rapidly, and are preparing for it. He hoped the time would come when professors should give up their private practice, and confine themselves to the school and hospital. He believed in taking care of the soul but thought the proportion of money given to divinity and medical schools was rather too one-sided in favor of the former. He hoped the time was not far distant when foreigners would come to our shores as students.

Dr. Osler, of Johns Hopkins, made a witty address, in which he spoke of the requirements of the degree in sciences before admission could be secured to Johns Hopkins, and also, as he termed it, the delicate question of medical co-education. To this he is opposed on principle, and from his standpoint believes it to be non-successful. At the end of one session 33½ per cent. of the female students get married, he said.

Dr. Polk's address was most interesting. If, he said, the lengthened medical courses were to be conducted upon the old lines of study the advanced system would prove a dismal failure.

Dr. Billings spoke on the subject from the standpoint of his own experience, and attached great value to his college course, his medical school training being limited. The Doctor believed that Harvard was at a disadvantage without its own hospital.

The newly elected President, Dr. Geo. B. Shattuck, was introduced to the Alumni, and he made a few remarks, thanking the Association for the honor conferred. He promised to have some foreign speakers at the dinner next year.

The annual meeting of the Association was held before the dinner at the medical school building on Boylston Street.

Dr. Augustus Thorndike, the Secretary, read his report of the last meeting and of the Councilors' meeting. The report showed that, with twenty-seven members of the graduating class of the medical school who will join the Association tomorrow, the strength of membership is 1,159. Fifty-four members joined during the year and eighteen died.

The report of the Treasurer, Dr. Walter Ela, showed a balance in the treasury of \$1,536.83.

Dr. William T. Porter, Assistant Professor of Physiology in the Harvard Medical School; Dr. William D. Howells, of Johns Hopkins University, and Dr. James K. Paddock, of Pittsfield, President of the Massachusetts Medical School, were elected to honorary membership.

The following officers were elected for the ensuing year: Dr. George B. Shattuck, of Boston, President; Dr. Walter Ela, of Cambridge, Treasurer; Drs. J. B. Adams, of Framingham, I. T. Dana, of Portland, Me., Richard H. Derby, of New York, Samuel A. Fiske, of Denver, Col., John Green, of St. Louis, Mo., Henry Hun, of Albany, N. Y., Horace G. Miller, Providence, R. I., John L. Robinson, Manchester, N. H., John Brooks Wheeler, Burlington, Vt., W. S. Whitwell, San Francisco, Vice-Presidents; Drs. T. F. Breck, of Springfield, James R. Chadwick, of Boston, Charles E. Stedman, of Dorchester, Councilors for three years.

UNIVERSITY OF NASHVILLE.—Dr. Charles S. Briggs has been elected Professor of Surgery in the medical departments of the University of Nashville and Vanderbilt University to succeed his father, the late Dr. W. T. Briggs. Dr. S. S. Crockett has also been elected Professor of Anatomy, to fill the vacancy caused by the transfer of Dr. C. S. Briggs.

KENTUCKY SCHOOL OF MEDICINE.—The thirty-eighth annual commencement of the Kentucky School of Medicine was held at Louisville, June 21. There were 200 graduates.

MEDICO-CHIRURGICAL COLLEGE.—Prof. William H. Pancoast has resigned from the presidency of the board of trustees of the Medico-Chirurgical Society of Philadelphia.

Hospital Notes.

NEW HOSPITAL FOR THE IOWA INSANE.—The site for the new Iowa State hospital for the insane has been located, joining the western limits of the city of Cherokee.

EMERGENCY HOSPITAL MILWAUKEE.—The new \$60,000 Emergency hospital on Sycamore Street, opposite the Union depot, will be ready for occupancy July 4. Only two stories will be finished, but the doors will be opened. There will be accommodations for at least 100 patients in case of necessity. The common council has appropriated \$7,500 for furnishing the building.

OHIO EPILEPTIC HOSPITAL.—The trustees of the Ohio Epileptic hospital at Gallipolis held a session June 22. The Board will open bids on July 19 for the erection of three or four buildings. One of the buildings will be a dining room, two cottages and possibly a hospital. The cottages for females will probably be ready for occupancy some time in August or early in September, but the date can not be definitely fixed upon at this time. The institution now has about 200 male inmates.

The Lying-in Hospital at New York City.—This institution is nearly a century old, but has never yet had a building worthy of the name of hospital. The Society, caring for the institution, has recently determined upon a new and radical departure. It has obtained possession of an exceedingly valuable and handsome property, the Fish mansion at the corner of Seventeenth Street and Second Avenue. The cost of the property is over \$200,000, of which \$90,000 is a cash payment. Money from the original fund has been expended, year after year, under the direction of a board of managers, in supplying physicians to poor women who were in need of attention at their homes. Rented rooms in the building at 314 Broome Street, have been occupied by the Society for office purposes for a number of years. The old Fish mansion is to undergo alterations, and will be used as an administration building for the Society, and in the near future they expect to erect a large hospital on the adjoining grounds.

The Society was organized expressly for charitable purposes, and the hospital which they will build will be a place to which poor women can be sent for treatment. It is not connected with any church or creed, but it has a number of wealthy friends who would give of their money in aid of the charity. Heretofore the work of the Society has been mainly among the poor women in the Hebrew quarter of the city.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from June 23, 1894, to June 29, 1894.

Capt. GUY L. EDIE, Asst. Surgeon, is granted leave of absence for one month, to take effect on or about July 1, 1894.
First Lieut. WILLIAM F. LIPPITT, JR., Asst. Surgeon, is granted leave of absence for two months, to take effect upon the return of Major CALVIN DE WITT, Surgeon, to Ft. Leavenworth, Kan.
Major GEORGE H. TORNEY, Surgeon, is relieved from duty as attending surgeon and examiner of recruits at Philadelphia, Pa., and will report in person to the Superintendent U. S. Military Academy, West Point, N. Y., for duty, relieving Major PHILIP F. HARVEY, Surgeon, who, after being thus relieved, will report to the commanding officer, Plattsburg Bks., N. Y., for duty at that post.
Lieut.-Col. JOHNSON V. D. MIDDLETON, Deputy Surgeon-General, is relieved from duty at the Presidio of San Francisco, Cal., and will report to the commanding General, Dept. of California, for duty as Medical Director of that Department, relieving Lieut.-Col. ALBERT HARTSUFF, Deputy Surgeon-General. Lieut.-Col. HARTSUFF, on being thus relieved, will report in person to the commanding General, Dept. of the Missouri, for duty as Medical Director of that Department.
First Lieut. CHARLES WILCOX, Asst. Surgeon, relieved from duty at Angel Island, Cal., and ordered to Presidio of San Francisco, Cal., for duty, relieving First Lieut. HARLAN E. MCVAY, Asst. Surgeon.
First Lieut. MCVAY, on being thus relieved, ordered to Alcatraz Island, Cal., for duty, relieving Capt. OGDEN RAFFERTY, Asst. Surgeon.
Capt. RAFFERTY, on being thus relieved, ordered to Benicia Bks., Cal., for duty, relieving Major JOSEPH B. GIRARD, Surgeon.
Major GIRARD, on being thus relieved, ordered to duty at Presidio of San Francisco, Cal.

PROMOTIONS.

Lieut.-Col. JOSEPH P. WRIGHT, Deputy Surgeon-General, to be Asst. Surgeon-General with the rank of Colonel, May 16, 1894.
Major ALFRED A. WOODHULL, Surgeon, to be Deputy Surgeon-General with the rank of Lieut.-Colonel, May 16, 1894.
Major JOHN S. BILLINGS, Surgeon, to be Deputy Surgeon-General with the rank of Lieut.-Colonel, June 6, 1894.
Capt. WILLIAM R. HALL, Asst. Surgeon, to be Surgeon with the rank of Major, May 16, 1894.
Capt. GEORGE H. TORNEY, Asst. Surgeon, to be Surgeon with the rank of Major, June 6, 1894.

Marine-Hospital Changes. Official list of changes of stations and duties of medical officers of the U. S. Marine-Hospital Service, for the four weeks ended June 23, 1894.

P. A. Surgeon A. H. GLENNAN, granted leave of absence for five days, June 18, 1894.
P. A. Surgeon R. M. WOODWARD, to proceed to Cleveland, Ohio, for duty, June 11, 1894.
P. A. Surgeon C. P. WERTENRAKER, to proceed to Reedy Island Quarantine for special temporary duty, June 12, 1894.
Asst. Surgeon W. J. S. STEWARD, granted leave of absence for thirteen days, May 29, 1894.
Asst. Surgeon EMIL PBOCHAZKA, to proceed to New York City for duty, June 11, 1894.
Asst. Surgeon A. R. THOMAS, to proceed to St. Louis, Mo., for duty.

ORIGINAL ARTICLES

AMBROSE PARÉ, THE FATHER OF FRENCH SURGERY. 1509-1590.

Read before the Des Moines Valley Medical Society, at Ottumwa, Iowa, June 21, 1894.

BY JAMES MOORES BALL, M.D.

PROFESSOR OF OPHTHALMOLOGY AND OTOLGY IN THE ST. LOUIS COLLEGE OF PHYSICIANS AND SURGEONS.

ST. LOUIS, MO.

Great good sense, wonderful industry, remarkable opportunities, and an untiring and unconquerable ambition, have combined to render the name of Ambrose Paré celebrated in the annals of surgery. Born of humble parents, amid unfavorable surroundings, under circumstances which would have crushed a spirit less ambitious, Ambrose Paré, by his unaided efforts, made himself master of the surgical science of his day, commanded the confidence of emperors and peasants, of statesmen and soldiers, and left posterity the record of a life well spent. He marks the dividing line between the servile surgery of the ancients and the original, independent and progress-

FIG. 1.—Initial from Paré's book, A. D., 1594.

ive art of the moderns. Just as Vesalius, Eustachius and Fallopius dared to contradict the errors of thirteen hundred years, and correct the anatomic mistakes of Galen, so Paré brought about a new order of things in surgery. Firm in his convictions, honest in his statements, and accurate in his observations, this great man was far in advance of his age. The story of his life reads like a romance.

Paré was born at Laval, a small town in the province of Mayenne, in France, in the year 1509. His life was spent during a period of great and stirring scenes—a time remarkable in the history of the world. At the time of his birth the art of printing had been invented less than sixty years; the existence of a new

continent had been proclaimed by Columbus seventeen years; Martin Luther was delivering Biblical lectures in the University of Wittenberg, and preparing to shake the foundations of the theological world; Ariosto, of Italy, was writing immortal verse; Erasmus, residing in the same sunny clime, was delighting the world with his matchless scholarship and educating the young son of James IV. of Scotland; and Copernicus, while studying the revolutions of the heavenly bodies, had not dared to proclaim his views. Louis XII., of France, was engaged in war with Italy. Henry VIII. had just succeeded to the English throne. Maximilian I. ruled the land from the Danube to the Zuyder Zee.

The same year that Paré first saw the light of day, there was ushered into the world, one Michael Servetus, destined to discover the lesser circulation and die by slow torturing fires; and John Calvin, the theological bigot of Geneva. Paracelsus, that compound of science, eccentricity and charlatanism, was in his sixteenth year. Realdus Columbus, celebrated as an anatomist, was 15 years of age.

The early education of Paré was obtained from a priest. While yet in his teens he was apprenticed to a barber-surgeon who instructed him in minor surgery. While thus engaged, Laurent Colot, the celebrated lithotomist, chanced to visit the town for

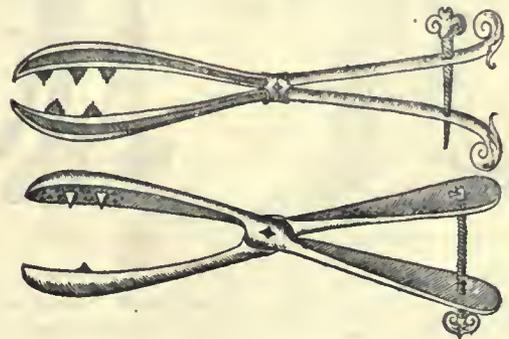

FIG. 2.—Stone crushers used by Paré.

the purpose of operating for stone. Paré was present, and was so struck with admiration at the result of the operation that he resolved to devote himself to the higher branches of surgery, an art which was then almost exclusively in the hands of the barbers. With this object he set off for Paris where Jacques Goupil, one of the professors in the College of France, acted as his preceptor. Here the masters explained to him the works of Lanfranc, Albucasis, Guido de Chauliac, and John de Vigo, the only surgical textbooks of the times. Soon Paré became interne to that famous hospital, the Hotel Dieu, where he remained for three years. During this time Paré was engaged in teaching anatomy. In 1536, in his twenty-seventh year, he received the appointment of military surgeon and was directed to accompany

René de Montjean to Italy. After the surrender of Turin, and the death of Montjean, Paré returned to Paris and began the practice of surgery.

The three years spent in campaigning were of great value to Paré and during this time he made some important observations. In the treatment of gun-shot wounds, the teachings of John de Vigo, physician to Pope Julius II. had been followed implicitly. Such injuries were regarded as poisoned wounds and the practice was to cauterize them with boiling oil, or the hot iron, while alexipharmics were administered internally. John de Vigo assures us that the danger of these wounds results from the round form of the balls, their degree of heat, and the poisonous qualities that the powder communicates to them. This theory, so destructive in its effect, received universal credence until Paré arose to combat it. After the battle of Pas-de-Suze, the supply of boiling oil having given out, it was observed on the following morning by Paré that those wounds looked best which had not been dressed with hot oil; and he also noticed that such patients showed less

French surgery, was published, with the following title: "The Manner of Treating Wounds made by Arquebuses and other Fire Arms, and those made by Arrows, Darts, and the like; and also of Burns, made especially by Gunpowder: Composed by Ambrose Paré, Master Barber-Surgeon, Paris."

In a few months a second edition was issued. In both editions the use of the actual cautery was advised to check hemorrhage. Paré, however, was thinking, day by day, of a plan by which hemorrhage could be controlled without the frightful torture of the hot iron. He resolved to test his theory and finally, at the siege of Dampvillier, in the year 1552, an amputation was made upon the person of M. de Rohan, and, for the first time in the history of surgical science, Ambrose Paré ligated the bleeding vessels. Fortunately the patient recovered and, full of joy at having escaped the red-hot iron, said that he had parted with his leg on very good terms.

The young surgeon had made two great discoveries: By the first he saved from cauterization all who had simple gun-shot wounds; by the second all who suffered an amputation were spared the tortures of the actual cautery. And, in the language of Malgaigne, "Military surgery, which till that time had been a torture, became a blessed art, and it was a barber-surgeon who produced the double marvel."

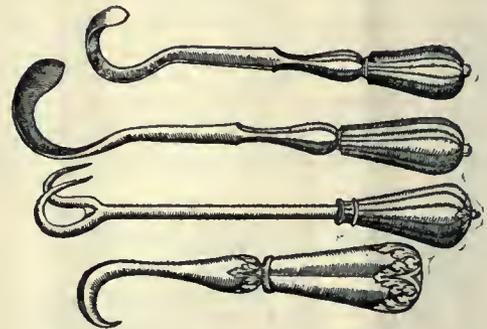

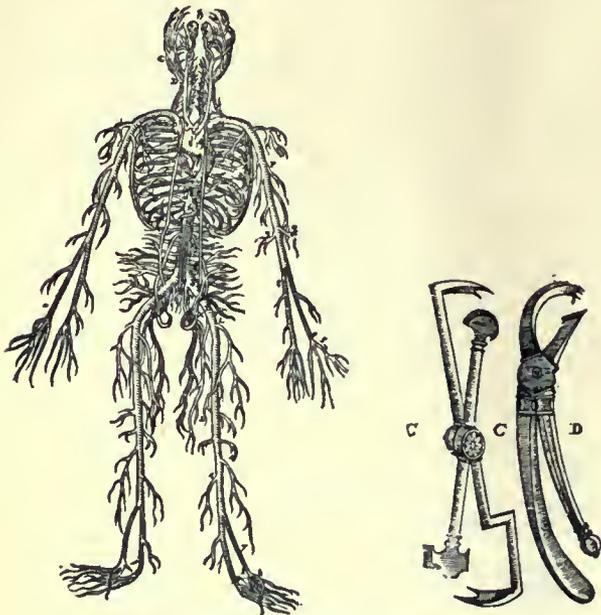

FIG. 5.—Obstetrical instruments, (Paré.)

febrile reaction than the others. It required great courage for him, a young man without name or authority, to combat a doctrine so universally accepted; but Ambrose Paré was not the man to be overawed by weight of authority when his own sober judgment taught him differently.

In Paris, Paré was interviewed by Sylvius de la Bœe. Malgaigne says: "This interview was honorable in all respects to both." Sylvius, whose teachings attracted more auditors than those of Fernel, even invited the young surgeon to dinner, and heard with great attention, the observations and experiments on which Paré had established his doctrines on gun-shot wounds, and was so much struck with them that he besought him with great warmth, to write them out and make them public. Paré felt sensibly this encouragement, coming from so high a source, and prepared his text, drew the figures, and in the year 1545, at Virant Gaulterot's, sworn bookseller in the University of Paris, that little work which marked in a manner so glorious the revival of

The practice of ligating an artery was entirely new, but the idea was old. Galen, Celsus, Avicenna and Albucasis had all spoken of the tying of arteries and veins, but there is no evidence to show that they practiced it. For centuries the actual cautery had been the principal means of checking traumatic hemorrhage. Sometimes, by way of variety, hot oil or boiling pitch were applied to the bleeding surface. The discovery of Paré revolutionized the practice of surgery and brought on his devoted head a torrent of abuse. Like Harvey at a later date, Paré suffered in his practice for a time. Of all his enemies, Gourmelen, President of the College of France, was the most clamorous. At the present day he is remembered only for his opposition to the great surgeon. "It was then," said Gourmelen, "very forward, rash and presumptuous in a certain individual, to venture upon condemning the cauterization of bleeding vessels after cutting off a mortified limb, a method so highly and continually commended and approved by all the ancients, teaching in opposition to that, without any authority, without good sense, some new method of his own, of tying arteries and veins." He called Paré a bloodthirsty cruel rascal, while Paré, stung to the quick, sometimes lost his temper but generally conducted his defense with admirable coolness, as the following will show:

"You boast, M. Gourmelen, that you will teach me

my lessons in surgery, and my operations; but in that, I believe, you are a little mistaken, for my education has been quite after another fashion. I have learned my art, not in my closet; no, nor by hearing the discourses of physicians, though that also I have not despised; but in the Hotel Dieu, where I lived for three years, seeing many diseases, and practicing many operations upon the living body, and learning also much anatomy from the dissection of the dead. But," he continued, "I have yet more to boast of, for, being in the service of the King of France, I have, in my time, served four successive Kings, having followed them in battles, skirmishes, and assaults;

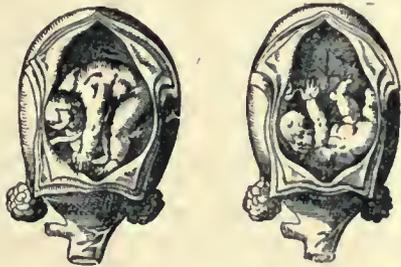

FIG. 6.—"De situ infantis in utero." (Paré.)

sometimes I have been in sieges, and sometimes shut up with the besieged, curing their wounds." "And last of all, I have lived in this great renowned city of Paris many long years, where, thank God, I have been held in some repute, and ranked at least equal to my peers, insomuch that there have been few difficult or celebrated cures in which my head and hand have not been employed. How, seeing these things, dare such a man as you, who has made surgery no part of your study, talk of teaching me?"

Paré, although proud of his discovery, arrogated nothing to himself, but with true piety ascribed it all to God. He says: "I think it was taught me

FIG. 7.—Reduction of a dislocation of the humerus. (Paré.)

by the special favor of the sacred Deitie; for I learnt it not of my masters, nor of any other, neither have I at any time found it used by any. Only I have read it in Galen, that there was no speedier remedy for staunching of blood than to bind the vessels through which it flowed towards their roots, to-wit, the liver and the heart."—(Johnson's translation, London, 1634.)

Nor was the use of the ligature the only discovery made by Paré. He was the first to employ the twisted suture in the operation for hare-lip; to extract cartilaginous bodies from the knee joint; and to perform podalic version in difficult labor. He was a man of great mechanical genius, as is evidenced by the large number of new instruments and appliances

found in his book. He gave the first account of what is now incorrectly described as Hey's saw, and the club-foot boot, claimed to have been devised by Mr. Syme, of Edinburgh. Among the many wood cuts of curios, one sees artificial eyes, ears, noses, teeth, arms, legs and hands.

Surgeon successively to Henry II., Francis II., Charles IX., and Henry III., it was said of Paré that "the Kings of France transmitted him to their suc-

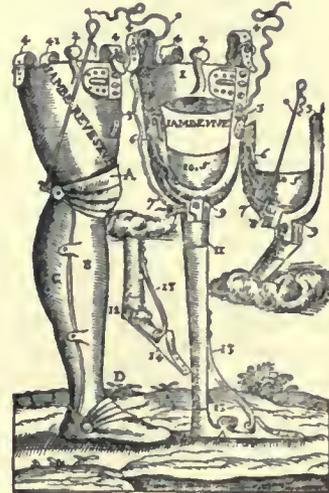

FIG. 8.—Artificial limbs. (Paré.)

cessors as a legacy of the crown." These monarchs were all warmly attached to Paré; he was at once their privy-councilor and trusted surgeon, and his influence over them was by no means small. Let it be said in his honor that this influence was never exerted in an unjust cause. So great was the power of this good man over Charles IX., that he was enabled to put a stop to the massacre of St. Bartholomew, (Aug. 24, 1572), when 70,000 Huguenots were murdered in Paris and various parts of France. The

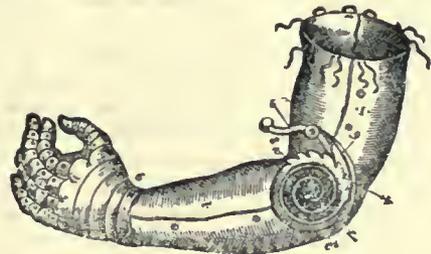

FIG. 9.—Artificial arm. (Paré.)

details of that horrible event are well known. For years, Huguenots and Catholics had been at enmity; and affairs had at last reached such a crisis that the bloodthirsty mother of Charles deemed it necessary to kill all the Huguenots. For three days and nights these unfortunates were hunted like the beasts of the field. Helpless infants, old men and women were slain by hired assassins. The streets of Paris were blocked by the bodies of the dead. How long the slaughter would have continued is impossible to say, had not one man, and he a Huguenot, done his duty. That man was Ambrose Paré. "It was not long," says the Duke of Sully, who has so graphically described the scene, "before Charles felt the most violent remorse for the barbarous action to which they had forced him to give the sanction of his name and authority. From the evening of the 24th of

August, he was observed to groan involuntarily at the recitation of a thousand acts of cruelty, which every one boasted of in his presence. Of all those who were about the person of this prince, none possessed so great a share of his confidence as Ambrose Paré, his surgeon. This man, although a Huguenot, lived with him in so great a degree of familiarity that, on the day of the massacre, Charles telling him the time was now come for him to turn a Catholic, he replied, without being alarmed: 'By the light of God, sire, you can not have forgotten your promise, never to command me to do four things, namely, to enter into my mother's womb, to be present in the day of battle, to quit your service, or to go to mass.' The king soon after took him aside, and disclosed to him freely the trouble of his soul. 'Ambrose,' said he, 'I know not what has happened these two or three days past, but I feel my mind and body as much at enmity with each other as if I were seized with a fever; sleeping or waking, the murdered Huguenots seem ever present to my eyes, with ghastly faces, and sweltering in blood. I wish the innocent and helpless at least had been spared.' The order which was published the following day, forbidding the continuance of the massacre, was the consequence of this conversation. At the time, Paré was 62 years of age, and of all his good deeds this was the greatest.

Nor was the influence of Paré over the populace less potent. Among the soldiers his presence was sufficient to inspire new courage. At the siege of Metz, when Charles V. had surrounded the town with an immense army, and the garrison, comprising the flower of French nobility, were reduced by hunger and sickness to the utmost extremity, Paré was introduced into the city by stealth, much to the joy of the besieged, who exclaimed: "We have no longer any fear of dying, even if we should be wounded; Paré, our friend, is among us." At this period Paré had already passed sixteen years as an army surgeon and was known to all the officers and many of the rank and file. In his "Chirurgia," our subject tells how the Duke de Guise commanded that he "should be weel used, and bid mee I should not faile to be the next day upon the Breache, where I should meete with all the Princes and divers Captaines, which I did; who receaved mee with great joy, and did me the honor to imbrace me, and tell me I was very welcome, adding withall that they did not feare to dye if they should chance to bee hurt." (Johnson's translation). The next day after his arrival, Paré successfully trephined M. de Bugend, who had been struck on the head by a piece of stone, and had remained insensible for fourteen days.

Paré became a member of the College of Surgeons in 1554, submitted to the examinations and received successively the degrees of Bachelor, Licentiate, and Master in Surgery. Although ignorant of Latin, Paré was received regardless of a statute which required that the candidate should know that language. He never wore the professor's cap and gown. He was tall in stature, with slender figure and a grave and dignified countenance. All his portraits represent him in his court dress, with the frilled collar characteristic of the age. No one can examine that grand old folio, "Opera Chirurgia," of Paré, without being overwhelmed with the thought that this work was penned by the intellect of a giant. Here we have nearly one thousand closely printed pages, over 300

illustrations—many of which contain numerous figures—which cost the author an almost fabulous sum. We find complete treatises on many subjects; on human anatomy; beasts, birds and fishes; monsters and prodigies; fractures and dislocations; tumors and wounds; artificial arms, legs and hands; amputations and ulcers; cauteries and ligatures; trephines and dental forceps, etc., etc.

So long as surgeons practice their beneficent art, the name of Ambrose Paré will be mentioned with reverence.

2600 Gamble Street.

CONCUSSION OF THE BRAIN.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY L. C. LANE, M.D.

PROFESSOR OF SURGERY OF COOPER MEDICAL COLLEGE, SAN FRANCISCO.

During the last forty years the subject of concussion or commotion, as the Germans and derivative Latin writers term it, has been a matter of careful study, observation and experimental research. It is caused by some external violence which communicates vibration, oscillation or minute movement to the anatomic elements of the parts acted upon. In the causation all observers agree; but what occurs in the constituent elements of the parts affected can not be said to be as yet satisfactorily settled. All the parts of the body may be the subject of such action: Bones, muscles, nerves, viscera; and some assert that the blood itself may be the subject of concussion. The study of the effects of concussion has been devoted chiefly to the brain; yet it seems certain that the same cause would be followed by like effects, no difference what part of the body might be the site; and hence that one common definition might be given of concussion, founded on physical and physiologic laws. In a classic article on this subject by Verneuil, the able French surgeon and writer, after revealing to the reader the difficulties which perplex him in his task, he offers us the following definition of concussion: It is a series of phenomena, occurring more or less suddenly, which result from a mechanical shaking or jarring movement of the anatomic elements, tissues and organs, characterized by temporary excitation or depression of the properties, offices or uses of the parts which are shaken; and as a result there are caused anatomic changes similar to those which are normally seen in the successive phases of functional excitation or functional repose. This definition is the embodiment of what its author has derived from his own observations and that of others, and especially from results which others have obtained in experiment on animals.

In the milder grades of concussion in the animal, the question has been whether there is any appreciable lesion to be discovered in the part subjected to experiment. The most admit that such lesion can not be discovered, and since in man, in case of concussion of the brain, the subject soon recovers, hence there is no opportunity of searching for the evidence of such lesion; for as Verneuil says, we derive our elements of the diagnosis of any disease from three sources, to-wit: The causation, the symptoms arising, and the direct inspection of the parts affected. But in the case of cerebral concussion one or more of these sources of information is often wanting.

The inspection of the injured part is wholly denied to the surgeon; the extent of the violence done can only be vaguely and imperfectly estimated; and not infrequently it is wholly unknown; as where the patient is found unconscious or unable to explain how he was injured; and finally the remaining source of knowledge, viz., the symptoms, are often far from being clear and well defined.

Concussion as will presently be more fully detailed, may be said to present itself in three grades which we will designate the mild, severe and fatal; the second of which offers symptoms sufficiently durable to admit of deliberate consideration, and presents as a marked condition a depression of the cardio-pulmonary functions, in which pulse and breathing are slow and feeble; temperature is lowered as a result of these changes and the functions of the sensory and motor nerves are temporarily abolished. The patient neither moves nor feels; the mental faculty is, for a time, reduced to nullity; the patient is not conscious of existence; and in all this the animal, for a time, has lost his distinguishing characteristics, and lies at the verge of plant life.

Many explanations of these conditions have been offered, as will be seen by a brief review of the literature which, during the last forty years, has been written on the matter.

In 1842 Haworth wrote on concussion of the brain, and claimed that the violence impinging on one side of the skull carried the brain against the opposite wall, and thence rebounding a vacuum remained, in which blood and gas collected, as it were, by *contrecoup*. Haworth thinks that a vacuum is also formed in the brain in those who ascend great heights, and thus he would explain the cerebral trouble more or less present in such cases. This explanation of the phenomena arising from concussion could only be applicable in those cases which have arisen from great violence, in which the patient dies at once from the violence to the brain; the organ being lessened in its volume, and into the empty spaces thence arising, blood escapes from lacerated vessels. The filling of the space with blood is a secondary effect of the injury.

In 1852 there were reports on concussion of the brain by Fano, Chassaignac and Haas; the former two find that where death has immediately followed the blow on the head, then there will be found an effusion of blood around the pons-varolii; but if death occurs later, then in the cerebral structure there will be found disseminated small clots of blood, which these writers attribute to cerebral contusion. They deny that concussion can injure without leaving some signs of violence; one always can find ecchymosis or marks of cerebral injury. Haas thinks that there can be concussion with or without ecchymosis; in which there is sopor, and unconsciousness; if it be simple concussion then these conditions may soon disappear; but if blood be effused then these symptoms may continue and even increase in intensity.

Continuing his studies, in 1853 Fano discredits the notion that in concussion there is perceptible material change in the cerebral structure, but he claims that there will be effusion of blood near the base of the brain. Fano, Chassaignac and Sanson have found in the brain small points of effused blood, not larger than millet seeds. In milder cases, Eisenmann thinks there is a shock which acts reflexly through

the vasomotor filaments on the capillaries, and produces a stasis of blood in the latter; and in more severe cases the stasis may be carried to the extent of rupturing the vessels. The order of the phenomena is as follows: The shock is first propagated from the vibrating bones to the nerves, and thence a recurrent reflex action on and through the nerves, next stasis, and sometimes rupture of the vessels, and occasional structural softening.

Paget, writing on cerebral concussion in 1863, made three stages of it: In the first stage an unconsciousness occurs, and this may vanish and the patient recover; in the third stage the violence is greater, and the condition may be sthenic, or asthenic in character. The sthenic symptoms occur early, viz., within a day or two; the asthenic symptoms occur after a longer period, viz., after ten or eleven days. Between the first and the third, or inflammatory stage, Paget places a second one in which there is almost a total absence of morbid signs. After surgical operations, for example an amputation, Paget finds that similar conditions may arise, viz., an asthenic stage, or that of depression, or a sthenic stage, or one of reaction may appear. As here, different plans of treatment are demanded in the opposite conditions, so in concussion of the brain, the stage of depression demands stimulants, while that of reaction requires sedatives and depressants.

Paget estimates the chances of recovery to be very slight after severe concussion of the brain; in such cases not more than one in twenty get well.

Alquié, in Paris, made some experiments in 1865 on concussion and determined from them, that through the injury caused, the functions of the brain were more or less interfered with; and further, he decides that concussion and contusion do not differ much from each other in their respective actions. The lesion produced by slight concussion is so slight that it eludes the closest search with the eye. Its mechanism is not that of vibration, but of a blow that came and went at once. The causal violence carries the brain forward in one direction, viz., that of the causal violence. Alquié concludes that concussion and contusion are convertible terms. Local and diffused concussion can not be distinguished from each other in their action. The phenomena resulting from severe concussion, are vertigo, fainting, weakness, drowsiness and coma. The cerebral trouble caused may appear in remissions and exacerbations. From concussion, one or many functions of the head, or the parts dependent on it, may be impaired or annulled, and this disturbance may be brief or lasting. Concussion in its action resembles grave mental disease.

In his treatment, Alquié is in accord with Paget. Collapse and depression demand stimulants; active reaction demands an opposite course.

Beck, of Freiburg, in 1865, referred the effects of cerebral concussion to violence transmitted to the medulla oblongata, and to lesion of the centers which preside over the functions of the heart and lungs. He finds as common causal agency, a blow with a blunt instrument.

Witkowski, in 1877, made some experiments on animals, in which the head was struck with a hammer, and the pressure of the blood in the carotid arteries was noted in the meantime. The immediate effect was increased blood pressure in these vessels; the increase commenced immediately after the injury,

and reached its highest degree in from twenty to fifty seconds, and continued for from one to two minutes. This increased pressure followed both slight and more severe concussion. It was afterward succeeded by a slight descent of pressure below the normal standard. The pulse, as a rule, was not changed.

In the cases in which the skull has been trephined, so that the brain could be seen after removing sections of the dura mater, it was found that the strokes caused a perceptible contraction of the vessels of the dura mater; this continued for a minute or two, and then a slight reaction followed. Witkowski decided that these alterations in the blood pressure were not due to the oscillations from concussion, but were the consequence of direct action on the nerve matter. Though he offers this explanation, it is probable that few readers can recognize or comprehend it.

Duret, of Paris, in 1877, made experiments on animals, in which he studied the effects of concussion on the brain. The violence done to heads of animals was produced by blows on the skull, and also by violently injecting fluid into the cranial cavity, through a trephined opening. He finds the leading results of concussion to be slowness of the pulse and respiration; and, finding an absence of all lesions in the cerebral hemisphere, he sought for injury in the medulla oblongata. In the experiment in which water was violently injected into the skull, the fluid in the lateral ventricles was caused to pass downward through the middle ventricle, and the canal of Sylvius, from the third to the fourth ventricle. In its passage through the canal, the fluid caused lacerations of the walls of the narrow passage. In another experiment the skull was trephined above, and the posterior ligament connecting the axis and the atlas was exposed. Now when pressure was made through the trephined opening above, then an impulse could be perceived below, from the descent of the fluid into the spinal canal.

Duret's experiments were done chiefly by the injection of water into the cranial cavity. This fluid was forcibly thrown against the surface of the brain beneath the dura mater. It is evident that the action of such violence differs from that caused by a blow. It is not so instantaneous, the violence progressing from a slight grade to the higher one; and only when the fluid reaches a certain amount could it displace the intra-ventricular fluid. Such action must differ from that in which the violence impinges on the outside of the skull and thus travels upward to the less resistant cerebral matter; hence the results of Duret's experiments may be deemed an approximation to, rather than an actual reproduction of, the action of concussion from direct violence.

In 1878 Duret continued his researches on this subject, and divides the shock of concussion into three classes, viz., central, bulbar and medullary, according as one of these structures is most involved. In the case of a blow the passage of the fluid downward acts most severely on the bulb.

Duret divides the action of concussion into two periods: In the first period there is a spasmodic and a paralytic stage, in which there is coma with depression. In the second period there is a congestion and inflammation. The site of the blow has an influence on the morbid phenomena; for when the forehead receives the blow, the pons and bulb are the

most affected, but when the side of the head is the site of the violence, then the other hemisphere is the more affected.

After the review of the subject of concussion, if the facts which have been drawn from so many quarters be condensed, and conclusions be drawn from them, the following may be offered as an epitomized summary of the changes which are induced, temporarily or continuously, in the brain, from concussion. In the mildest grade there is a brief diminution of the blood pressure in the part; its tension is temporarily lowered. As the result of this there is mental disturbance. The cells in the cortex of the brain, on whose normal condition the evolution of thought in some unknown way depends, are deprived for a few moments of their accustomed supply of nutrient material; the result is a brief perversion of intellect; memory is lost; the power to recognize surrounding objects is weakened or lost. As a personal illustration of this, from a fall from a carriage the writer once suffered temporary concussion of the brain; though he arose at once to his feet on a street with which he was very familiar, yet for a moment all appeared to him as if he was in a strange city. That picture registered in the memory, yet remains as an enduring scene of mental imagery; and though there was knowledge of what had occurred, and thought enough to search the head for fracture, yet the subject of the injury possessed no accurate knowledge of his surroundings. The writer would attribute the conditions to the temporary disturbance of the circulation in the surface of the brain.

If the violence be somewhat greater than that here supposed, then to the disturbance of blood pressure there is superadded a disturbance of the cellular constituents composing the surface of the brain. A jostling or displacement of the molecular elements of these cells, even though it be microscopically minute, must suffice to induce functional derangement. In such condition the patient lies unconscious to all that is around him; he breathes naturally; the pulse is commonly somewhat weakened and irregular; the temperature is not increased, and sometimes is less than normal; the pupil is neither dilated nor contracted, and reacts somewhat to light. The patient may remain for hours, a day, or even a week in this condition in which he is neither awake nor asleep; he is so nearly asleep that his condition is often mistaken for sleep; but it differs from sleep in this: That the eye-balls do not occupy the position they have in healthy sleep; they are often in motion beneath the closed eye-lids. There is an absence of snoring in the breathing. In fact, the patient breathes as one who is partly asleep, rather than as one who is really so. For the lack of a name we will designate it the sleep of concussion.

In the grades of concussion just mentioned, its action is chiefly manifested in obtunding or temporarily depressing the functions of the mind; but if the intensity of the causal violence be still greater, then besides the abolition of the thinking faculty, the cardio-pulmonary functions are disturbed, depending doubtless on the lesion of the centers at the base of the brain, which preside over these functions; the lesions which were represented by the lacerations in that region observed by Duret. The pulse is soft and often irregularly hastened; the breathing is similarly affected; regular, alternating with irregular breathing; slowness with accelera-

tions; and these disturbances of the action of the heart and lungs, conjoined to unconsciousness may remain for days or weeks, and then consciousness may reappear suddenly, the patient arising, as from a sleep, with a gradual disappearance of other abnormal conditions. Such an injury of the head as here described often results from a fall from a carriage or a horse, also to the boy from an accident in climbing. In such accident the weight of the body multiplied by the velocity acquired at the final moment of striking the ground, represents a high degree of violence, especially where the surface fallen on is a hard one. In such cases, when severe, there is a contusion of a limited surface of the brain; and thence results a localized or isolated palsy of some part of the body. Or, as the writer has observed, there may be a partial hemiplegia in the arm or leg; and not infrequently one limb is more affected than the other; and at the same time there may be restlessness of the limbs on the non-paralyzed side.

In the still higher grade of concussion, the functions of life are permanently suspended, either at once or death ensues in a few minutes after the receipt of the violence. Such fatal result gives the opportunity of necropsy, in which the condition of the brain could be inspected; yet singularly enough there is far from agreement among observers in respect to these conditions; some asserting that the brain did not fill the skull; others have found to the contrary. Of the first condition there is a notable instance on record; an observation made and reported by Littré over a century ago. This case, cited by nearly all writers on concussion, was that of a criminal who, to escape punishment, ran and struck his head so violently against the wall of his prison that he fell dead. The desperate energy displayed in the fatal act has had no small share in retaining the account in history.

In the necropsy of the case reported by Littré, the cerebral matter was found broken down, and to lack much of filling the cranial cavity; that is, a vacuum was found in the upper part of the skull. There have been reported a few other cases, in which there was found a slight open space above the brain in those who had died from cerebral concussion. There has been reported an effacement of the natural irregularities of the cortex of the brain. Other observers contend, however, that both the empty space as well as the alleged leveling of the surface is not present in the unopened cranium, but is caused by the escape of blood from vessels which are divided in the opening of the cranial cavity. Notwithstanding these discordant utterances, the predominant weight of observation is on the side of those who assert that there is some lessening of volume, as well as an effacement of the cortical irregularities of the brain. Besides these evidences of violence, the cerebral matter, on being cut, presents minute ecchymoses of blood, due to ruptured minute vessels, and it is probable that such rupture, in less extent, occurs in concussion of a mild degree.

DIAGNOSIS.

The diagnosis of cerebral concussion is an easy matter in cases in which there is history of violence acting on the head. Yet in the absence of such history the problem of diagnosis becomes sometimes difficult, since it must be wholly solved by the symptoms present; then the pulse, the breathing,

the pupil and the color of the face give valuable information; stertor and contracted pupil point to poison with opium. The fumes of spirits in the breath point to alcoholic excess. An instance of this kind came within the knowledge of the writer: A man who was found prostrate by the side of the street was the object of puzzling study to some physicians, when the coachman of one of the doctors solved the matter by saying that he would give half a dollar to be as sick as the man was.

There are cases in which the work of diagnosis is much embarrassed by the lesion not being a simple one of concussion: since there may be joined to it contusion and compression; especially compression, which would greatly modify or change the usual symptoms of a case of concussion; in fact, concussion and compression present in a case would mutually interact, and influence the symptoms of each other; and in such case the surgeon would find it extremely difficult, perhaps impossible, to determine all the conditions present; in such embarrassment the most prominent symptom should claim attention and treatment.

PROGNOSIS.

From what has preceded, it is clear that the prognosis of concussion of the brain must depend on the grade of the injury. In the grades of slight severity a recovery may be certainly anticipated at an early period; but in the severer forms the prospect is more unfavorable. The patient may remain in an unconscious and half dead state for weeks, and afterward slowly recover, or from his half dead condition he may lapse into actual death. Also it is to be observed that after severe concussion, though the patient may live, yet not infrequently there remains some vestige or memento of the injury in the form of perverted motion, sensation or impaired mentality. From the observations of Griesinger and other alienists it has been seen that the mental character often undergoes some change in those who have been the subject of severe cerebral concussion. The memory may be weakened or altered in some way; the recollection of proper names, of specific nouns and adjectives may be partly or wholly lost; from the framework of language may be plucked the most of its exuberant appendages, and the whole be reduced to a meager skeleton of generic headings and categories. Besides this, the character of the individual may be slightly or greatly modified; the hitherto well-controlled temper may become vehement and rash; he has outbursts of anger, and may become the actor of lawless deeds. He becomes distrustful of those around him. These changes may be plainly manifest, or they may be so slight as only to be perceptible to the subject's intimate friends; and whatever character these changes assume they will probably remain permanent, inasmuch as they depend on structural change which will continue unchanged. In modern times, when crime seeks for its defense that its subject can not control his actions, and consequently that he is not responsible for his offenses, the matter of concussion has assumed a special importance in forensic medicine. As the concussion of the spinal column from railway accident seeks, for real or assumed injury, reparation from the pockets of the corporation, so the transgressor of law often claims immunity on the ground that at some time previously he has been injured in his head, and as concussion

leaves no tangible or visible mark, hence it conveniently serves the purpose of such subterfuge.

TREATMENT OF CONCUSSION OF THE BRAIN.

Since there are two totally different states in which the patient of concussion may be, viz., depression or excitation, so the treatment must be shaped as one or the other condition exists or predominates. As a rule, the first effect of concussion is to induce depression and exhaustion of the vital forces; and this condition must be met and counteracted by stimulants and excitants. The patient is often so prostrated that the reflex action of swallowing can be only imperfectly performed; a condition, in fact, which renders it extremely difficult to administer remedies by the mouth. If, while the muscles of deglutition are in a partly palsied state, liquid medicine be given by the mouth, the most of it will probably pass into the trachea and add to the patient's perilous condition by partially asphyxiating him. In fact, the same precaution is required here as must be exercised in administering medicines to a person moribund or near death. The wine or other thing then given, as the writer has witnessed, can strangle and immediately end life. Hence, when the patient is greatly prostrated by depression and can not readily swallow, fumes of ammonia should be applied to the nose; also tickling of the nostrils will often rouse the patient. Stimulants, as brandy and warm water and black coffee, may be injected into the rectum. Hot applications should be placed over the præcordia, and the surface of the body should be well rubbed, so as to promote the movement of the blood. In case of extreme prostration, syncope may be avoided, or rather life awakened by lowering the head so that the heart may be aided by gravitation, in carrying the blood to the brain. After the patient has been sufficiently resuscitated to swallow, then remedies may be given by the mouth. The administration of stimulants must be limited to the period of depression; afterward the treatment must look to controlling the inflammatory symptoms which usually present themselves after a few days. The stage of excitation is ushered in about the eighth, ninth or tenth day after the receipt of the injury. Should the patient be plethoric, then bleeding from the arm should be done; not less than a pint of blood should be drawn. The signal advantages of such depletion have been verified by the writer in several instances. If the subject be very robust, as much as thirty ounces can be safely withdrawn; thus inflammatory action, through the absence of material for its maintenance, is subdued and retained within tolerable limits. Depletion might be done by means of leeches; yet withdrawal of blood from an open vein is more effectual. A valuable adjuvant in this antiphlogistic treatment is ice, which should be applied to the patient's head as soon as he emerges from the primary stage of depression. The ice, well crushed, should be applied to the head in an India rubber bag, and this should not be heavy, lest it cause sloughing in the subjacent scalp. The head should be maintained in an elevated position, so as to favor the ascent of the blood through the veins, toward the heart. All constriction of the neck should be avoided. As a faithful ally in this work of derivation of the blood from the head, is warmth applied to the lower extremities; for this, hot water, contained in bottles or a rubber sack may be used. As

there is danger of freezing the scalp, so there is of burning the feet, unless the warmth be carefully used.

As to internal treatment, there should be given a purge; for this, none is better than calomel and jalop, 10 grains each. Besides this, to restrain or prevent the development of inflammation there should be administered iodid of potassium in doses of 10 grains, repeated every four hours for the adult. If the patient be a child of 4 or 5 years of age, the dose should amount to 3 grains, repeated three to four times daily; and should there be the usual restless somnolence, this must be controlled by bromid of potassium, of which an amount equal to that of the iodid of potassium should be given. By the use of this internal medication, the writer has frequently seen the subjects of severe concussion pass safely through the inflammatory stage; the temperature retained in low limits.

There should be mentioned a mode of treatment formerly much used in cases of cerebral concussion; this was vesication of the scalp. To do this, first let the hair be shaven off, and then the whole covered with emplastrum cantharidis. This does not act entirely as an ordinary blister; little serum is drawn out, but instead there will form a coating of fibro-albuminoid material over the scalp, tenacious and adherent. This vesication was a favorite of Dupuytren, and it is claimed that good results followed its use. Yet when one considers the slight anatomic connection between the scalp and the encephalon, it is difficult to conceive how this external blister can act on the parts within the cranium.

Frequently two or three months are required for entire recovery of the patient, so that he can resume some occupation; and for a yet longer period, limited exercise of the body and mind should be enjoined.

SHALL FRACTURE AT THE LOWER END OF THE HUMERUS BE TREATED IN THE FLEXED OR EXTENDED POSITION.

OSCAR H. ALLIS, M.D.

SURGEON TO THE PRESBYTERIAN HOSPITAL, PHILADELPHIA, PA.

As only ten minutes are allotted to this paper the author can not enter into any defense of the principles herein advocated. For a fuller discussion, the reader is referred to the *Annals of the Anatomical and Surgical Society, Brooklyn*, Vol. 11, No. 8, 1880. Reprints of the article therein contained will be cheerfully sent to any one interested in the subject, by addressing the author, 1604 Spruce Street. For alleged malpractice, with verdict for the defendant, see paper by Dr. C. E. Kurtz, *Trans. College of Physicians of Philadelphia*, Pa.

The advantages claimed for the rectangular position are:

1. That it is convenient. the patient can be up and about, enjoying his freedom.
2. That if ankylosis supervenes, the rectangular position furnishes the most useful stiff elbow.

In regard to the first point, viz., "that it is convenient," I have simply to say that the argument has far more consideration from the profession than it is entitled to. The vital question is, In what position can a fracture be treated that will yield the best and most perfect results? It was a wise remark of the late Dr. Levis that there was no good reason why a person should not as properly go to bed for a fractured clavicle as for a fractured femur. In the treatment of fractures of the extremities the recumbent posture is in the highest degree favorable to the

earliest attainable decline of inflammatory processes.

The chief, and as some say unanswerable argument, in defense of the flexed position is, that it is the most favorable if ankylosis takes place; this is true but it is also true that only a small percentage of fractures at the lower end of the humerus result in stiff joints, and of these the injuries are from direct crushes, in which the fragments are comminuted, or the injury compound. In my experience the majority of elbow fractures in childhood are due to indirect violence, as falls, and in this class no ankylosis is likely to follow.

Whatever advantages may be claimed for the rectangular treatment, these should be carefully weighed with the disadvantages, if such there be. One thing is certain that deformity and loss of full function is apt to attend injuries at the elbow. Is the deformity due to the mode of treatment?

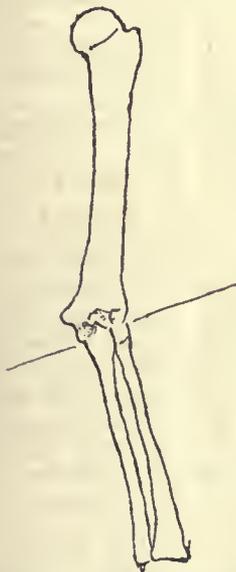

FIG. 1.—Note the length of the internal condyle, and contrast the axis of the shaft to the humerus with the axis of the articular surface.

FIG. 2.—Note the support obtained by resting the elbow against the side of the pelvis, especially serviceable in weight carrying.

Neither the upper nor lower extremity is straight. In the humerus and femur the inner condyle extends below the level of the outer condyle, hence the long axis of the humerus does not agree with the long axis of the ulna, nor the long axis of the femur with the long axis of the tibia. In the normal extended arm, the limb during supination appears most crooked.

This is best seen in the emaciated. This is nature's own mechanism and the laborer turns it to advantage. When carrying a heavy weight, as a pail of water, he brings the middle of his extended arm against the pelvis, and this throws the weight at a distance from his feet, and does not impede locomotion.

In the treatment of fractures at the lower end of

the humerus, by arbitrary manufactured splints, the tendency is to change the plane of the articular surface. As a single illustration of this I will take a fracture of the internal condyle. In this fracture the condyle is detached from the humerus, but remains attached to the ulna through the lateral ligament, while the outer condyle remains a firm part of the humerus. In the application of an anterior rectangular splint, the bandage that binds the arm to the splint has a tendency to displace upward the broken internal condyle. This is not observed dur-

FIG. 3.—Pathological specimen from Gurlt. Internal condyle displaced upward.

FIG. 4.—Gun-stock deformity seen in horizontal elevation of the limb.

ing the treatment while the arm is bent, but when the cure is effected and the arm extended, a typical gun-stock fracture is noticed.

This deformity is of comparatively trifling disadvantage for the lighter offices of the joint, but it is a very great loss when the carrying function of the limb is taken into consideration.

ADVANTAGES OF THE EXTENDED TREATMENT.

1. It permits of the best flow of circulation and is the position best suited to combat excessive inflammation.
2. It permits of inspection of the whole limb, and permits of comparison with its unbroken fellow.
3. It is a position in which the dressing can be applied with ease and simplicity.
4. In this position if either condyle is unbroken we have a natural splint, by means of which the natural articular surface can be preserved.
5. It is the position in which we dress fractures of the condyles of the femur, in which we get perfect joints with full range of motion.

TREATMENT IN THE EXTENDED POSITION.

In the treatment of fractures at the lower end of the humerus, no manufactured splints are ever required. Dr. Powers, of New York, has had excellent results in treating fractures of the elbow at right angles, but he never uses manufactured splints. He invariably uses plastic material, which he molds to the limbs.

FIG. 5.—Note the loss of support due to the altered articular axis of the lower end of the humerus. Elbow can not rest against the pelvis.

If I have a skilled assistant, I usually hold the limb extended and ask him to apply the dressing. Otherwise I place the limb in the care of attendants and apply the dressing myself. A first dressing should always make provision for swelling. Hence I either apply cotton or an elastic substance above and below the point of fracture, or lap about it pieces of flannel saturated in lead water and laudanum. The patient is then placed in bed and the limb made to rest comfortably upon a pillow. The renewal of the dressings for the first week must be left to circumstances. If dressed dry and the pain rapidly subsides, I often do not disturb the first dressing for a week.

As soon as the swelling subsides sufficiently, I apply a soft bandage directly to the limb. I prefer thin flannel, butter-cloth or the thinnest, coarse-woven cheapest muslin. In applying the bandage I make no reverses, except at the top and bottom when I wish to change the direction of the bandage. I only use the spiral and let the bandage take its own course. By degrees as the bandage runs up and down the limb, the whole is covered in. This mode of applying the bandage is immeasurably superior to the spiral-reverse, which latter creases the skin and slips. When the limb is properly dressed with the spiral, the bandage alone makes an excellent splint. On completing the bandage, a glutenous paste may be rubbed into the outer layer, or adhesive plaster may be made to cover in the bandage. Such a dressing will permit of easy motion without displacement.

Usually after the swelling subsides, the patient will be able to rise and walk about, but the arm must be left hanging and not bent and put in a sling. If the hanging arm is painful, the patient should again assume the recumbent or the semi-recumbent position.

As to passive motion I have only time to add that if begun too early or with too much spirit, the result will be to protract the cure. Only gentle passive motion in the latter half of the treatment will be conducive to early functional return. The complete range of motion is often delayed for months after the cure is effected.

FRACTURE OF THE LOWER END OF THE RADIUS.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY P. S. CONNER, M.D.
CINCINNATI, OHIO.

As ordinarily met with, fracture of the lower end of the radius, is the result of "cross-breaking strain" consequent upon over-extension of the hand upon the forearm. Force received upon the palm, carried up through the os magnum and the projecting line of junction of the scaphoid and semi-lunar, if sufficient to break the radius must do so in a more or less longitudinal direction, not transversely. Over-bending of the forearm bones may, and at times does, cause fracture of the radius, which is approximately transverse; but the level of the break is always higher than that of the common "wrist fractures."

Experimentally, by over-extension, every variety of the fracture under consideration can be produced; from the simple crack through the articulating extremity to a separation and displacement of the car-

pal fragment equal to that of the most severe injury coming under professional care. Whatever its degree, displacement is due to the secondary action of the anterior radio-carpal ligament upon the fragment already dragged off from the radius; and it is in the majority of cases largely maintained by the binding force of an untorn dorsal strip of periosteum, as originally shown by Pilcher. Much has been written, and more said, respecting impaction of the dorsal compact edge of the lower end of the upper fragment in the cancellous upper surface of the lower fragment; and proof of its existence has been found in inability to properly adjust the fragments by traction upon the hand in the direction of the long axis of the forearm. But, unless it may be under very unusual conditions, a force sufficient to pin the upper fragment in the lower would be sufficient to, and would split the lower fragment into two or more pieces and consequently prevent impaction. The resistance to replacement by direct extension is, in the great majority of cases, probably in all, not in any fixation of the upper in the lower fragment, but in the untorn periosteal band already mentioned. Only when such band is absent because of complete laceration at the time of injury, or it has been torn by the dragging force exerted through the hand, can proper apposition be secured by such manipulation. But, if instead of pulling upon the hand it be over-extended, brought, in other words, in the position in which the fracture occurred, any existing periosteal band is at once relaxed; and moderate pressure upon the upper end of the lower fragment is sufficient to carry this fragment into its proper place, at times with a very audible snap. Little or no pain is produced, no anesthetic is required; the securing of proper apposition of the fragments is the work of but a few seconds. Personally, I have never had any difficulty in thus adjusting a case coming under care within twenty-four hours after receipt of the injury. If there is, as there certainly is at times, a fixation of the ulnar styloid process under, or in the posterior annular ligament, such process will be set free either by simple over-extension, or by such combined with rotation. Once properly apposed, there is practically nothing other than outside violence to produce a secondary displacement. The weight of the dropped hand strongly tends to maintain apposition, and additional security is afforded through the action of the tendons crossing over the line of break on the palmar and dorsal surface. The supinator longus through its styloid attachment, does without doubt act upon the lower fragment, but such action is too feeble to cause displacement.

Proper adjustment (and the earlier it is effected the better) will prevent or greatly limit effusions, exudations and adhesions. The unfortunate result, at times observed, which has been attributed generally to age, to rheumatic or gouty habit, to too short or too long employment of splints, to improper conduct on the part of the patient, or carelessness on the part of the doctor, is commonly, very possibly always, due to imperfect adjustment at the time of the original dressing; the displaced lower end of the upper fragment making such pressure upon the soft parts upon the palmar surface near the wrist as to interfere with both arterial and venous circulation, especially the latter, and that not only directly but indirectly through the induced nervous disturbance. Under such circumstances the ordinary treatment by splint

and bandage only makes a bad matter worse, the vessels and nerves being compressed between bone and board. That which is absolutely essential to thoroughly satisfactory repair, is early and complete adjustment. This is one of the few fractures in which the chief difficulty lies in securing not maintaining apposition. Once secured, only the simplest after-treatment is really required; a band around the wrist perhaps, to lessen the after-spreading due to separation of and later somewhat misplaced attachment of the inter-articular cartilage.

In view of possible after-ligation, as professional opinion is now, it is wiser as a rule to employ some form of splint, plaster-of-paris or other, never extending below the wrist line and thus supporting the hand, which should be allowed to hang free. But the use of such splint is not necessary so far as the break is concerned, provided (and this proviso must be kept constantly in mind) complete apposition of the fragments is secured.

Its manner of production well understood, the difficulties in the way of primary adjustment duly recognized, and the first dressing properly made, this fracture becomes one of the simplest to treat, causes little inconvenience, comparatively, to the subject of it, and is very satisfactory in its end-result.

FRACTURES OF THE NECK OF THE FEMUR AND THEIR TREATMENT.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY BEDFORD BROWN, M.D.
ALEXANDRIA, VA.

My personal experience in fractures of the neck of the femur comprises fourteen cases. Of these about 10 per cent. died in less than twelve months from complications, as inflammation and suppuration at the seat of injury, and fever. Two per cent. were bed-ridden for the balance of life. The remainder recovered sufficiently to walk with the aid of a cane or crutch for the balance of life. All the bed-ridden cases were of the extracapsular variety while the cases that recovered the power of locomotion were of the intracapsular non-impacted variety.

All of these cases of fracture of the neck of the femur occurred in females varying in age from 60 to 85 years old. These fourteen subjects presented every variety of conformation of figure. In two there was great obesity. In some the figure was tall and spare, while in others it was quite petite, and very delicate and slight. In one the figure was that of a very robust woman a little over 60. In one, a woman of 85, the weight did not exceed eighty pounds and the person was very emaciated.

Causes of fracture of the cervix femoris.—The causes of this fracture may be classified as the direct or major and the indirect and minor.

The major form of cause is always from direct violence, as a sudden fall from a distance on the hip, or a violent blow or great pressure from mechanical causes on the same point. On the contrary, the minor causes are always of the indirect variety from unusual sudden pressure on the foot while walking, a slight misstep, a sudden twist of the foot while walking.

A knowledge of the major and minor, or direct and indirect character of the existing causes will aid us

materially in differentiating the variety and location of the fracture. The major or direct causes almost invariably cause the extracapsular variety of fracture with or without impaction, while the minor or indirect cause produces intracapsular fracture.

Symptoms.—In all cases of suspected fracture of the neck of the femur, the entire person, from the anterior superior spinous process of the ilium to the toes, with the exception of the external genital organs which can be protected from view by a napkin, should be exposed to inspection. After the clothing has been removed above the pelvis we are at once enabled to see the relationship of the two opposite trochanters to each other, their corresponding appearance, their relative prominence. We can also observe the relative positions of the two limbs throughout their entire length, and also we can better detect the slightest eversion of the foot in the least departure in its direction, and at the same time detect the least degree of shortening of the limb. Much of the information gained by this investigation is in these cases derived from comparative observation. The trochanter should first be examined. In the fractured bone, except in cases of impaction and non-displacement of the fractured ends, the trochanter is depressed and flattened compared with the sound side, and when moved from side to side the arc of the motion is considerably reduced. Extending our investigation downward, we observe the lower or tibial end of the patella does not correspond with that on the sound side. It is from a quarter to an inch above the line of that of the sound limb. Continuing our observations to the foot we find a shortening of the limb to the extent of from a quarter to an inch and a quarter in length. At the same time we find the foot of the injured limb everted. When by our own aid we correct this eversion it invariably returns spontaneously, and when the patient is requested to correct it, she is unable to comply with the request. Here we have a typical picture of a simple fracture of the cervix femoris,—first the depressed flattened trochanter, the difference in the line of the corresponding patellæ, the shortening of the limb and eversion of the foot. When the entire person is exposed without any movements of the patient, or manipulation on our part, the eye can detect these peculiarities at a glance.

Then again, in non-impacted fracture, if an assistant grasps the foot of the injured limb and alternately extends and relaxes the limb while the attendant grasps the trochanter and presses it firmly towards the pelvis, distinct crepitus may be detected.

Methods of Differentiation between Intracapsular and Extracapsular Fractures.—In determining the important question whether a fracture is intra or extracapsular, is non-uniting or uniting, the peculiar character of the cause assumes diagnostic importance. It may be said with much degree of certainty that shortening of the limb to the extent of a half or one inch, eversion of the foot, moderate pain in the hip, no indications externally of contusion, some crepitus on extension, flattening of the trochanter occurring after a slight indirect injury, as a very sudden misstep, striking the foot against the floor or steps forcibly, or a sudden twist or wrench of the foot from any slight cause in the aged, denote intracapsular fracture with no possible tendency to unite. On the contrary, shortening of the limb to the extent of from one to two inches with eversion of the foot, great

pain in the hip, flattening of the trochanter, effusion in the surrounding tissues in front and rear of trochanter, crepitus on extension in the comparatively young, much contusion of soft parts, from a major form of cause as a violent fall, blow or pressure directly on the trochanter denote extracapsular fracture with tendency to union of ligament.

Then again a slight shortening of the limb and eversion of foot, with much pain on attempted motion, absence of crepitus, slight ability to raise the limb or stand upon the foot, great effusion in front and rear of trochanter, from a violent direct injury to the trochanter with contusion of soft parts, indicates impacted fracture.

Diagnosis of Impacted Fracture of the Cervix Femori.

—The two cases of impacted fracture of the neck of the femur which came under my observation both resulted from indirect and violent causes. In one the patient was 70 years old, and had a violent fall directly on the trochanter of that side. The trochanter was found on comparison with the opposite side to be flattened and depressed, and very tender on pressure. There was considerable swelling back of the trochanters, and in front below Poupart's ligament there was great swelling and much pain and tenderness. There was entire loss of power over the limb and inability to stand on it.

Shortening of the limb was imperceptible and eversion was entirely absent. The injury occurred more than six years since, and the patient has never recovered the use of the limb and is still comparatively bed-ridden.

The second case occurred in a comparatively young person with identical symptoms as the former, and has never recovered a fair degree of locomotion in the limb since the injury.

Complications.—One of the most serious complications observed in my experience has been symptomatic fever following the injury. It is more apt to occur in the extra than the intracapsular variety, because the causes are of a more violent character, and the anatomic structures of the part are more extensively lacerated.

I never saw but one case of protracted fever following intracapsular fracture in an aged person recover, and that was in the case of a woman aged 85 years. She recovered and lived in comparative health and comfort to reach 90 years, and then died from hemiplegia.

A temperature ranging from 101 to 103 degrees, a quick pulse, pain and restlessness denote serious organic changes going on in the injured structures, that if permitted to progress will continue until extensive inflammation, effusion of exudates and suppuration intervene.

Treatment of Fractures of the Neck of the Femur.—

There is no class of fractures that require the exercise of more judgment in their treatment or more accuracy in diagnosis than fractures of this kind.

In one variety of fracture, the extracapsular, in those below middle life we can adopt means with safety to bring about union. To adopt the same means in intracapsular fracture in the aged would insure certain death. Hence the importance of an accurate differential diagnosis.

Treatment of Intracapsular Fractures.—In my own experience a good rule to work by in treating intracapsular fractures of the cervix femoris in the aged, is to so manage the case from the beginning as not to

expect union of the fractured bones, but on the contrary to so conduct the management of the case as will, if possible, insure a good, strong, false joint, by which after a time the patient can regain a fair degree of locomotion for the balance of life. To bring about this desirable object, the pelvis from the anterior superior spinous process is enveloped with a broad flannel roller four inches wide and fifteen feet long, applied down below the trochanters. This flannel bandage gives comfort by the support that it affords the fractured bones, and the prevention of too much motion, and gives opportunity to the soft parts involved to throw out adhesive exudations. This is the full extent of the apparatus to be applied. As for the balance of treatment, pillows long and short, small and large, are to be relied on for splints and supports. Comfort of position is to be the guiding rule in the management of this class of cases. The ingenuity of surgeon and nurse will be taxed to so arrange the pillow splints as to insure comfort, relieve pain and secure sleep. When these objects are accomplished all has been accomplished that judgment and experience can do until inflammatory action subsides, and the process of fibrinous exudation is completed, and then the false joint is ready for use. To attempt, on the contrary, to confine this class of patients in a stiff apparatus with the view of accomplishing that which no power can ever effect, a union of bone or ligament, is to condemn our patient not only to unnecessary suffering but to certain death.

In the treatment of extracapsular fracture from violent and direct causes in the comparatively young, we may calculate with a degree of certainty on ligamentous union, provided the method adopted will maintain perfect adaptation of the fragments and we can adopt such methods and apparatus as will insure this end, without fear of detriment to the patient as in the former case. After the pelvis has been firmly enveloped in the broad flannel roller, as in the former case, then Buck's extension apparatus is applied and the extension maintained until union takes place, which is usually about six weeks.

In impacted fracture my method of treatment has been to envelop and support the pelvis and fractured hip bones by means of the flannel bandage, which I consider better and more comfortable than a simple band, and for the purpose of supporting the limb and the prevention of motion, which might cause dislocation of the fractured bones. Two sand bags, the longer, external, reaching from above the pelvis below the foot; the other, shorter, reaching from a little below the external genitals on the inside of the limb below the foot. These arrangements appear to meet the desired ends better in my own experience than any other.

THE TREATMENT OF FRACTURES OF THE SHAFT OF THE FEMUR.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY LEWELLYN ELIOT, A.M., M.D.

SURGEON TO EASTERN DISPENSARY; CONSULTANT TO ST. ANNE'S INFANT ASYLUM, ETC., WASHINGTON, D. C.

Our chairman having paid the high compliment of assigning the subject of the "Treatment of Fractures of the Shaft of the Femur" to me, I shall, within the time allotted, place my views before the Section in the briefest possible manner.

The causes, the symptoms and the diagnoses of fracture of the femur being entirely foreign to my subject, no mention will be made of them. We shall likewise exclude from consideration all fractures of the femur not located between the lesser trochanter and the condyles. Although every variety of fracture is found in this bone, the transverse and the oblique are the most frequent; these fractures may be either simple, comminuted or compound.

Having made our diagnosis, we must have the patient's bed arranged so as to allow permanent and continuous traction to be employed. This traction, in the case of adults, may be effected, after the proper adjustment of the fractured ends of the bone, through the employment of the apparatus of either Liston, Desault, MacIntyre, Thomas, the Smith anterior, the Hodgén suspension, Buck, Boyer, Neill or the double inclined plane of Esmarch, Gross, or others, the foot of the bed being raised so as to insure counter extension. In infants, either Hamilton's apparatus or vertical extension will give satisfactory results. To enter into a description of the various devices employed in the treatment of fractures of the femur would be of no interest to you, since all are familiar with them. The employment of permanent dressings, plaster-of-paris, silicate of soda or others of a like nature, I do not think justifiable before the third week, when union is sufficiently strong to warrant their application, although many surgeons employ them from the start, and I would hesitate quite a while before I would use any of them previous to the establishment of union of the fragments. Objections will readily present themselves. Should a compound fracture present itself, I should be still slower in applying a permanent dressing.

The question of suturing or pegging fragments in cases of compound fracture, and of amputation, may be settled in a few words. Where the fragments can be properly and accurately adjusted and the blood supply to the limb remains good, the fragments should be sutured or pegged and the wound treated by the open method; where, however, the soft parts are lacerated and the vessels supplying the limb are divided, amputation should be resorted to early, before the patient's strength is wasted through secondary hemorrhage, gangrene or other causes.

The treatment of fractures of the shaft of the femur resolves itself into the following: A suitable bed, accurate apposition of the fragments, the proper application of the splint and extension, good nutritious food, and unless the case is one requiring amputation, the results will generally be satisfactory, although shortening occurs in very many cases.

There is one question in relation to extension in fractures of the femur to which I would like to call attention. This is the matter of the priority of the application of adhesive plaster in extension. The generally accepted opinion is that Dr. J. K. Swift is entitled to the credit of first using it and Prof. S. D. Gross, in his "The Anatomy, Physiology and Diseases of the Bones and Joints," page 50, published in 1830, puts forth his claim as follows: "In complicated fractures of the leg, it not unfrequently happens that the soft parts about the ankle are so much contused or otherwise injured as to render it impossible to employ the usual extending bands. When this is found to be the case, the difficulty may usually be remedied by applying along each side of

the leg, as high up as the seat of fracture will admit, a piece of strong muslin, about two feet and a half in length, two inches and a half in width, and spread at one of its ends with adhesive plaster. The part which is applied on the limb should be confined by three or four circular strips, so as to keep it firmly in its place, and equalize the extending power. The free extremities of the extending bands should then be tied under the sole of the foot and be secured to the block or bar which connects the lower ends of the splints. This mode of making extension, for which we are indebted to the ingenuity of my friend and preceptor, Dr. Swift, of Washington, will, I am fully persuaded, be found highly useful in practice and satisfactorily obviate the inconvenience to which I have just alluded."

Now, for more than twenty years, I have endeavored to adduce evidence so as to accord the credit to Dr. Alexander McWilliams, of Washington, and to that end have searched books and journals and papers. At the time when success seemed to crown this research I find published evidence which dissipates all contention.

The following appears in "Medical and Chirurgical Observations," as an appendix to a former publication, by Benjamin Gooch, Surgeon, London, published about 1771: "To answer the same purpose I have confined one end of a strong strip of sticking plaster of a suitable length and breadth under a circular piece of the same, about the middle of the side of the foot, carrying it over the heel, up the leg and confining the other end above the calf with another circular plaster. First gradually bring down the muscle gastrocnemius as far as they will readily yield, giving the limb at the same time the position described in my treatise on wounds. On the like occasion I have also fixed one strap by the circular piece about the foot and another by that above the calf of the leg, passing the one through a slit in the other, and using them as the uniting bandages; but then two more circulars are requisite to confine the other ends of the longitudinal strips securely."

That the studies and this publication of Gooch did not receive attention from surgeons and other writers is evident from the fact of so many others afterwards working in the same line of thought, each unconscious of the work of the other. Among those workers was Dr. Alexander McWilliams, who treated in 1827, a case of fracture of the femur by this method of extension, at the Washington Almshouse. Failing to establish the claim of Dr. McWilliams to priority in the application of the idea of extension by means of strips of adhesive plaster, I will present such evidence as I possess, all derived from letters in my possession, to establish his claim to the credit of being the first surgeon in the United States to put into practice this idea. At that time (1827) according to the letter of Dr. Hall, the recognized surgeons of this country knew nothing of this method, and indeed as late as 1836, M. Larray mentions the method only to condemn it, as will be seen in the extract taken from the Minutes of the Société Royale de Médecine of June 21, 1836.

In a letter under date of Jan. 9, 1875, Dr. Noble Young, of this city, writes: "In regard to the matter of the invention and application of adhesive strips for the purpose of extension in cases of fracture of the femur, by the late Dr. Alexander McWilliams, I have to state it is within the recollection of

his family that it occurred prior to 1829; they know this by circumstances impressing it indelibly upon the memory. He sent a model explaining the application to Paris by Dr. Hall, brother of the late David A. Hall, and received a letter from the French Academy of Medicine, congratulating him and thanking him for his valuable contribution. This letter has been mislaid only within the last few years. I may add that Dr. Jos. Barrows remembers its application at the almshouse in this city before 1828, when he was a student there."

Dr. James C. Hall, under date of Feb. 15, 1878, writes: "My evidence as to the application of adhesive strips as a means of extension in the treatment of fractures by Dr. McWilliams must be circumstantial. I came to Washington in October, 1828. After graduating (1827) I was for one year a resident physician and surgeon in the Philadelphia Almshouse, now Blockley Hospital. The visiting surgeons and clinical lecturers were Profs. Gibson, Horner, Rhea, Barton and Harlan. Very many and all kinds of fractures were treated in the House, and I am positive that I never heard McWilliams' mode either mentioned or practiced during my term of service. . . . My recollection is almost positive that my first knowledge of Dr. McWilliams' use of the strips as a means of extension was derived from an article which the Doctor published in a newspaper here, I thought it was the *National Intelligencer*, but Dr. Toner has searched for it and not found it there. This has not weakened my conviction that Dr. McWilliams published in some paper an account of his method of treating fractures of the femur. . . ."

Dr. Joseph Barrows, under date of June 6, 1878, writes: "Excuse my apparent neglect in not answering until now your letter in reference to the use of adhesive plaster in fractures of the lower extremities. In the year 1827, I was one of the resident students in the Washington Asylum or Almshouse, of which Dr. Alexander McWilliams was the attending physician. Dr. McWilliams at that time exhibited and used adhesive plaster for the purpose above indicated."

In the *Archives G n rales de M dicine*, Book ii, p. 247, 1836, I find: Soci t  Royale de M dicine, Paris, s ance du 21 Janv: "Rapport de M. Larray sur un appareil   extension continue pour les fractures des extr mit s inf rieures; par le Docteur Williams de Washington.—Cet appareil est une copie  peupr s enti re de l'appareil de Boyer. La seule diff rence consiste dans une attelle interne qui se fixe   la traverse sur laquelle la vis s'appuie. M. Larray bl me la m thode en g n ral et tous les appareils qui s'y rattachent. Il n'adopte pas d'avantage le double plan inclin , et pr f re toujours son appareil inamovible."

Dr. B. Troutman, of Philadelphia, Pa., at my request called upon Prof. Gross, asking him for some definite data of Dr. Swift's application of this method of extension and he writes under date of June 27, 1879: "I called on Dr. Gross several times, but he always happened to be out of town, but last week I called again and saw him. He told me that Dr. Swift employed adhesive plaster in complicated fractures first in 1829."

The record of the Almshouse shows in the morning report of July 18, 1827: "Admitted P. Boady, 40 years. Report of July 21, 1827: Fracture femur."

This is evidently one of the cases to which Dr. Joseph Barrows refers in his letter.

In no work on surgery of this date—1827 to 1836—have I found any reference to this method of extension, so it is very evident that there had been no published development of the idea until Dr. McWilliams sent his model, a doll baby with the apparatus applied, to Paris. Dr. J. F. May was present at the presentation and verbally testified to the favorable reception accorded it.

To my satisfaction, I have established the following facts: 1, Dr. Gooch was the first to employ adhesive plaster as a means of extension in fractures; 2, the idea was allowed to pass into oblivion; 3, Dr. Alexander McWilliams, of Washington City, was entirely ignorant of the work of Dr. Gooch; 4, Dr. McWilliams developed and put in practice the idea in 1827; 5, the claim of Dr. Swift is too vague to carry weight with it; and 6, the published report of the Soci t  Royale de M dicine is the first published account of the method after its revival by Dr. McWilliams.

TREATMENT OF OPEN OR COMPOUND FRACTURES.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY HENRY H. MUDD, M.D.

ST. LOUIS, MO.

An open wound communicating with a fractured bone is a serious complication. Every effort is directed to its closure by sound healing. Its importance and the difficulty of its management is determined largely by the amount of injury inflicted upon the soft tissues about the fracture, and by the extent of the comminution of the bone. This open wound is usually determined by the violence which inflicts the fracture, but may result from ulceration. An oblique fracture where the skin has been torn by the sharp angling of the bone, with or without impact against an external object, offers a good opportunity to convert a compound into a simple fracture.

Fractures by direct violence which is not crushing, even if the bone is comminuted, present often good opportunity for the immediate closure of the wound. The soft parts are not necessarily much injured by such a fracture. This is especially true where the bone is superficial.

Extensive lacerations and contusions of the soft parts with a small or a large wound of the skin preclude an effort at immediate closure of the skin wound. They demand drainage. Even in such conditions a compound fracture may occasionally be promptly converted into a simple one by the agglutination of structures contiguous to the fracture, though the skin opening may remain free for drainage.

Absolute cleanliness is the first requisite in an attempt to convert a compound into a simple fracture. A razor, soap and water, are essentials, and must be well used in order to cleanse the skin. The purity of the water used in washing the wound is of first importance. The removal of extraneous matter from the wound may be accomplished by a wash of hot water, but where grease, cloth, and dirt of various kinds are adherent to the raw surfaces, the fingers, forceps, etherial soap, turpentine, and sublimated washes may fail to accomplish perfect cleanliness,

though the wound may be rendered aseptic and heal readily. A fairly perfect adjustment of the fragments is a requisite of early healing. Maintenance of the adjustment by a well adapted splint which does not provoke engorgement and pain by undue pressure, is a most important item in the treatment. Many compound fractures where the local conditions would permit primary union of the wound, fail to progress favorably on account of the injudicious application of an apparatus, which is good in itself but is imperfectly applied.

The external wound may be hermetically sealed by suture and collodion, if it is small and the soft parts are not extensively bruised. Where the skin wound is extensive, that portion of it which overlies the fractured bone should be closed by suture, if a point favorably situated for drainage can be found somewhat removed from immediate contact with the bone.

If bone is protruding and has been contaminated by clothing, by a dirty skin, or by external objects, it must be thoroughly cleansed by careful picking and sponging, and then washed with an antiseptic solution, in order that aseptic conditions may be obtained. If the protruding fragment is not essential to solid union, the difficulty of cleansing its surface and the doubtful vitality of sharp long points of bone, which are denuded of periosteum and bruised by violence, justify its removal by bone nippers or saw. In the more extensive injuries, where direct violence has crushed the soft tissues, comminuted bone, and driven foreign matter into the wound, the cleansing of the parts and the removal of dead tissue will very often require an enlargement of the wound, or an incision to give free access to the injured parts. Fascia and muscle if irretrievably damaged must be cut away with the scissors. Loose fragments of bone are to be removed, and a complete knowledge of the extent of the injury to the bone and to contiguous parts, including joints must be obtained. Blood clots should be washed out, and after thorough cleanliness has been obtained, efficient drainage must be provided. The original skin wound may be closed and drainage be secured by special incision, or through an opening made for the inspection and cleansing of the wound. Every effort is to be made to avoid suppuration, as it will destroy still more tissue. It should be remembered that it is difficult to maintain a perfect asepsis about a wound which is slow in healing, hence even where the skin opening can not be closed, it is important to so arrange bone and soft tissues as to favor the agglutination of soft tissues about the line of fracture, in order that it may be shut off from the external wound at the earliest possible moment.

Fragments of bone, or the sharp ends of the fractured surface must not be permitted by malposition, to exercise undue pressure upon the soft parts. Angling at site of fracture must be corrected; and if the tendency to shortening is marked and not easily controlled, as it is not infrequently, where the ankle joint is involved in the fracture, the shortening of the limb by excision of the fractured end is proper and is a conservative measure. The adjustment of the compound and comminuted bone may not be perfect, but it must be practically so good that undue pressure on the soft parts will not produce ulceration, and must be such as to give a good outline and a useful extremity.

Extension and lateral support are the two chief

agencies in maintaining apposition of fragments. Wiring of bone and the use of ivory pegs are occasionally necessary and can be used to advantage in isolated cases. They are, however, rarely necessary, and are an obstacle to rapid and solid union, except where they overcome the greater danger of persistent and obstinate displacement.

A solid union will often result without serious constitutional disturbance, even where the fracture remains an open one. The exposed bone will develop granulations, and if a part of it is necrosed, separation by granulation along the line of junction of the dead and living bone will occur, even while new bone is forming at other areas in the line of fracture.

Cleanliness, an easy and comfortable position for the fractured member, free drainage, and a good constitutional condition will generally insure solid union, though it may be long delayed. Union of bone in a compound fracture is much slower than in simple fractures, or than it is in the compound fractures which are promptly converted into simple ones.

Delayed union should be tolerantly dealt with; a persistent maintenance of the conditions which favor the nutrition of the injured leg will very generally be rewarded by a good recovery.

A thorough appreciation of the extent of the injury to the different structures of the extremity, must be obtained in cases where the judgment wavers between an effort to save the limb and an amputation. Amputation should be immediate,—that is it should be promptly enforced, as soon as the shock has passed, or postponed until the acute inflammation has subsided. A so-called secondary operation is safer than an immediate one.

The perfected technique of aseptic surgery enables us to save many extremities, where suppuration with its attendant damages must have supervened and destroyed the limb, before the details of antiseptic and aseptic methods were well understood. No less important is the selection of a splint which permits cleanliness, and at the same time insures the rest and the undisturbed position of the fracture, which is so essential to the rapid repair of the soft parts, and the union of the broken bone. The suspension splint of Dr. John T. Hodgen with its extension and free motion is a most important adjuvant in the treatment of compound fractures of the leg and thigh.

AFTERNOON SESSION, JUNE 6.

Dr. Graham, Chairman of the Nominating Committee, presented a verbal report, recommending for Chairman Dr. Joseph Ransohoff, of Ohio, and for Secretary, Dr. R. H. Sayre, of New York. The gentlemen nominated were elected by a unanimous vote.

Dr. LEVI C. LANE, San Francisco, read a paper on "Concussion of the Brain."

A paper by Dr. OSCAR H. ALLIS, Philadelphia, on "Treatment of Fractures of the Lower End of the Humerus," was read by the Chairman, Dr. Roberts, its author being absent.

Dr. P. S. CONNER's paper on "Treatment of Fractures of the Lower End of the Radius" was read by title.

Dr. BEDFORD BROWN's paper on "Treatment of Fractures of the Neck of the Femur" was read by title; also the paper of Dr. LLEWELLYN ELIOT, Washington, D. C., on "Treatment of Fractures of the Shaft of the Femur;" also the papers of Drs. H. H. MUDD, St. Louis, Mo., and JOHN B. HAMILTON, of Chicago.

DISCUSSION.

The discussion was opened by Dr. R. H. SAYRE, who said—I would just like to put myself on record as differing in some particulars with that paper which has just been read, and which, unless some remarks are made about it, would

probably go down as the unanimous consensus of opinion of the Section. It seems to me that there were a good many cases in which fractures of the lower end of the humerus are better treated in a flexed than in an extended position, and I think that the reason possibly that we get the various bad results which Dr. Allis has mentioned, of loss of function on account of the destruction of the normal angle between the humerus and the ulna, is on account of their using, as he says, arbitrarily manufactured splints. I think you must adapt your splint to the patient, and if you take an arbitrary rectangular splint and tie a broken arm to it, you will probably get a worse result than if you let the arm hang in a straight position and put a board on the front of it. But it seems to me that neither of those methods is as rational or scientific as placing the arm in a position of right angles, and then adapting the splint to the particular shaped arm that you have to deal with; and not only that you should come down to the wrist, but that you should come down and include the wrist in the splint. I turn the hand with the palm upward, and as the splint is being applied for this purpose I prefer plaster-of-paris rubbed into the meshes when it is put on, rather than to put on a bandage and pepper it over the surface with a plastic substance, as Dr. Allis suggests. And while you are putting on this you put the arm in a position so that the forearm is in a normal position, and then when you get a final recovery you will not have lost the carrying power, you will not have destroyed the relation of the external and internal condyles to one another, and you will have an arm which if you should have the mischance to get ankylosis, which is very improbable unless it is a very bad case, is in a more useful condition than if the arm is straight. I think that except in cases of exceptional severity, fractures of this kind should be so treated that the man is able to go about his business, and if he is a professional man he can attend to a good deal of work and not suffer this loss.

DR. L. C. LANE, San Francisco—As Dr. Sayre has said he wishes to put himself on record, not entirely upon the side of Dr. Allis, that is in favor of the flexed position, I wish, on the contrary to be on record as in favor, wholly, unconditionally, and forever in favor, of treating in the straight position. I have treated over one hundred cases of fracture of the elbow of different kinds, and have never had a bad result when I treated in the straight position; we have a great deal more muscularity in the front than behind. In the fracture at the elbow, the joint is usually torn, or some of its muscles are torn, and if you put the arm in this position (illustrating) these torn muscles here about the blood vessels, here about the nerves, heal, and with the cicatricial contraction of the vicinity, fix and hold those blood vessels so that there is danger. When the arm is kept in the straight position the several irregular surfaces or hollows, that is, the concavities or convexities one fills the other; but when you bend it in this way (illustrating) you leave hollow spaces, into which cicatricial or neoplastic growth will come in and interfere greatly with your passive motion. The only point on which I disagree with Dr. Allis is in regard to passive motion. He would defer it for some three or four weeks. I would have it a great deal earlier. I would say in regard to Dr. Allis, he is really the author of this method of treating in the straight position. That credit is given to him in some of the foreign authorities, you will find it in Billroth's "Surgery." He has the credit of recommending that position, and he has fought for it. When he began he was almost the only man in the United States in favor of it. As I say, I agree wholly with the plan of Allis, except I would commence passive motion earlier than he does.

DR. BERGSTEIN, Nevada—It is almost unnecessary for me to add anything now that Prof. Lane has robbed me of my thunder. And it is not surprising, considering that he taught me. But I can add this, that while dressing the arm in a flexed position may be more scientific, the proof of the pudding is in the eating thereof, and for twenty odd years I have treated a large number of cases of fracture, extending into the elbow joint, in the straight position without a single failure or a loss of a particle of the usefulness of the member. I have generally made my splints from that magnificent material known as a shingle, and have padded it with cotton. I have begun passive motion in three weeks, and have never seen bad results follow it.

DR. KURTZ, California—I only add a few words to what has been said already, and that is this: Whether we get ankylosis, or partial ankylosis from the extended position, or from the flexed position, it is immaterial; if you get that far, you will have great difficulty to remedy the evil by

simple passive motion. It has been my practice for many years to add to passive motion, massage. I think that no fracture should be treated without massage. But fracture in the neighborhood of the joint, and fractures of the elbow most particularly, leading so often not only to ankylosis but to suits for malpractice, I would suggest to you never to omit to practice massage, say from two weeks after the occurrence. It can be just as easily practiced as the passive motions themselves.

DR. C. A. WHEATON, St. Paul, Minn.—I would like to occupy the attention of the Section for only a moment to express my gratification at the position taken by Dr. Sayre. The title of the paper, it seems to me, is decidedly ambiguous. It speaks of fractures at the lower end of the humerus. The gun-stock deformities of fracture at the elbow joint, as a rule, result from fracture of the internal condyle. If we have a fracture of the lower part of the humerus, involving the elbow joint and we attempt to put that fracture in position it seems to me that there is a very strong liability of the overriding of those fragments and the impairment of the ultimate usefulness of that joint. I do not know Dr. Sayre's position exactly, but it seems to me that the anterior angular splint, such as I was taught to use, applied to the anterior surface of the forearm, bringing the fulcrum of the lever at the apex of this splint at the elbow joint, tends to mold these fragments into bad position. Such a fracture can not be molded into position and held there, with the expectation of getting a useful joint, unless it is put in an anterior angular splint, such as we were taught to use in our earlier days; consequently it is my belief that these fractures ought to be treated in the rectangular position.

DR. HORTON, Texas—I have but one or two remarks to make with reference to the discussion and the position of the gentlemen on the two sides of this question. In the first place we should recall the principles laid down in all questions of fracture; first muscular relaxation, afterward the position of the broken fragments. I understand that that underlies all questions of treatment. So far as we can judge of the questions which have been presented to us in the management of practice, it would be about this: That they rely upon the splint, whatever may be used, a straight one or an angular one, for the accomplishment of the entire cure. I do not so comprehend it. This is a principle which I want to impress upon our minds; that unless there is relaxation of the muscle and adjustment of broken surfaces, I care not what the treatment may be, you will certainly not secure a good result. And I ask you to think of that proposition a moment. After that has been accomplished I care not, so far as I am concerned what principle you may use; you may use a straight splint, and I have also used the angular splint as well. I have had a reasonable experience of forty-five years, and I have never had a bad result on the lines of that practice when I secured the principles laid down.

DR. THOMAS, Pennsylvania—If the fracture is above the condyle, a transverse fracture, I think a right angle splint is probably as good a splint as we can use, but if there is a fracture of one or the other condyle, as Dr. Allis says in his paper, and we put on the right angle splint, by removing the bandage and attaching the arm to that splint and the forearm, and pulling up the forearm, you take up the fractured condyle with it, and so long as you keep the forearm in the rectangular position it looks very pretty, but when you change it you find it can not be pulled up. Now you may talk about the relaxing process of the muscles, but in a fracture of one or the other condyles by placing it in such a position the condyle, itself, keeps the fragments in position. My experience is that my cures are almost perfect in that manner, while in the rectangular cases they are not.

The paper of Dr. S. E. MILLIKEN, New York, on "Tendon Grafting for the Deformities following Infantile Paralysis" was read by title, the author being absent.

Evidence of Appearances will not Discredit a Post-Mortem.—The fact of a number of persons meeting another from time to time, and observing nothing in his appearance to indicate ill health, the Supreme Court of Indiana holds, in the case of Sharpe v. Commercial Travelers' Mutual Accident Association, decided April 25, 1894, raises no conflict upon the evidence of a post-mortem examination, for example, as to the existence of fatty degeneration of the heart and brain.

DIAGNOSIS AND TREATMENT OF PROSTATIC ENLARGEMENT.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY WM. T. BELFIELD, M.D.
CHICAGO.

The prostate of mammals in general is a purely sexual gland, often separated by a considerable space from the bladder, and entirely independent of this organ; in some animals (*e.g.*, the ram) the prostate is lacking; in others (the squirrel) it is entirely suburethral. In some mammals, notably man, the prostate presents an intimate anatomic relation with the bladder; its muscular fibers completely encircle the urethro-vesical orifice, and perform the function of a vesical sphincter. The human prostate lies at the junction of the genital and urinary channels, and it is intimately associated in function with both; it, moreover, almost includes that vestige of the Müllerian duct, the prostatic utricle; through it and around it courses the blood to and from the bladder.

While the etiology of prostatic enlargement still remains a matter of speculation, it is certain that the earliest clinical symptoms are due to vascular engorgement of the prostate and by consequence of the bladder. The actual increase in the size of the gland should not obscure the other factors in producing the symptoms, which may be out of all proportion to the perceptible enlargement. The factors contributing to the familiar symptoms associated with prostatic enlargement are:

1. Venous congestion and edema of prostate and bladder.
2. Fibroid thickening of the vesical (prostatic) sphincter, often extending to the detrusor and to the prostate.
3. Suppuration in the prostatic urethra (glands and utricle).
4. Hypertrophy of the prostatic elements (glandular or muscular or both).
5. Chronic retention of urine, due to any one or all of these four antecedent conditions.

The most important as well as the most difficult task in diagnosis, is the differentiation among these various morbid states; for the prognosis as well as the treatment is determined by the predominance of one or another of them. For example a prostatic patient complains of frequent and painful urination; the chief trouble may be an aggravation of the usual venous congestion, in which case a brisk laxative, suppositories of ichthyol and ergotin and strychnin internally will secure speedy relief. Again, the symptoms may be due to prostatic suppuration, in which event irrigation of the deep urethra with hot water containing hydrastin or silver nitrate is needed; or the frequent urination may be simply the overflow of a distended bladder, which is relieved by the cautious daily use of a clean catheter.

It would far transcend the allotted limits of this paper to discuss the differential diagnosis; I can only emphasize the statement that the symptoms clinically associated with prostatic hypertrophy depend upon several distinct morbid conditions, of which the mechanical impediment to the exit of urine may be the least; and that no routine treatment can be prescribed—the requirements varying with the case.

Our resources for meeting the needs of different patients may be thus summarized:

1. *Medical*—*a.* Improvement in the circulation through prostate and bladder is favored by proper diet and exercise, avoidance of constipation, massage of prostate between a sound in the bladder and finger in rectum, and by the daily use of a clean catheter; internally, ergotin and strychnin are certainly useful.

b. Suppuration in the bladder neck requires irrigation of the prostatic urethra with hot water, solutions of hydrastin, silver nitrate, etc., in addition to the measures already mentioned.

c. Induration and distortion of the bladder neck may be improved by dilatation with large sounds or a special dilator.

In a certain percentage of cases the time arrives, sooner or later, when these measures fail to relieve, and more efficient and immediate aid must be rendered.

2. *Surgical Methods*.—*a.* The simplest is a puncture of membranous urethra from the perineum, and introduction of a drain which is permitted to remain for a couple of weeks. The subsidence of congestion and edema, the cleansing of the bladder thus induced, sometimes makes an apparent cure for many months. Puncture with a trocar through the prostate (Harrison)¹ or drainage of the bas fund behind the organ (Belfield)² is even more desirable.

b. By a perineal urethrotomy the surgeon can secure not merely drainage but also thorough digital stretching of the prostate, and the incision or excision of obstructions at the orifice of the bladder.

c. More satisfactory excision of prostatic obstructions has been accomplished by a combination of suprapubic cystotomy with perineal urethrotomy—now a standard operation.

Within the past year there have been reported attempts to relieve the sufferings of the prostatic by securing atrophy of the enlarged prostate; by Bier,³ through ligation of the internal iliacs, and by Ramm,⁴ through castration. Bier reports three cases; in one, death from septic peritonitis occurred; in the remaining two, marked reduction in the size of the gland and decided improvement in symptoms are reported. Castration alone is said to have caused the same results in Ramm's two cases.

It would seem that, however efficient either of these dubious operations might be as a preventive of prostatic hypertrophy, their success as curative measures must be limited; for while they may be expected to induce atrophy of the gland proper, it seems questionable whether they would cause absorption of the new growths, arrest of suppuration, removal of the fibroid degeneration, and complete evacuation of the diseased bladder—any or all of which may be essential to a cure. However, clinical experience rather than speculation may decide these questions.

Two new operations upon the enlarged prostate itself have been recorded—one by Nicoll,⁵ who made a submucous removal of the entire prostate from the perineum in two cases with good result. The other, by the present writer,⁶ combines the removal of any part or all of the prostate with perfect drainage of the bladder and deep urethra. By incision into the ischio-rectal fossa, the prostate and trigone are laid bare and incised in the median line; each half of

the prostate can be enucleated to any desired extent. A suprapubic incision—robbed of its danger by the perfect drainage secured through the posterior wound—can be made if required for freedom of manipulation. This operation seems to meet all the indications of all cases—perfect drainage, excision and enucleation not only of prostatic outgrowths but also of the entire gland if required.⁷ It is undoubtedly too severe for feeble patients to endure; but so, unfortunately, are most operative procedures. Like the measures of Bier, Ramm and Nicoll, its clinical value must be determined by extended experience.

Such are our resources, medical and surgical, for relieving the distress and preventing the fatal consequences of prostatic enlargement; and probably no other disease of the genito-urinary organs tests to an equal degree the knowledge, judgment and art of the surgeon. The day has long passed when the sole treatment for prostatics was the routine, sometimes careless and bungling, use of the catheter. While these patients commonly exhibit the impaired vitality of age and often the added effects of renal insufficiency, yet as a class they are far more amenable to treatment than our standard literature leads us to suppose.

SYMPTOMS AND TREATMENT OF TUMORS OF THE BLADDER.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOHN B. DEEVER, M.D.

PHILADELPHIA, PA.

The earliest and most constant symptom of tumor of the bladder is hemorrhage; this usually appears before irritation of the bladder.

When vesical tenesmus and frequency of micturition precede hemorrhage, malignancy should be suspected.

Hemorrhage from the bladder occurs towards the end of micturition. The first urine passed is clear and as the bladder empties itself it becomes blood stained, while the last urine passed is of a bright red color due to the presence of fresh blood. Following exploration of the bladder, the first urine passed is uniformly blood stained. Confusion may arise in cases of hematuria as to the source of the hemorrhage.

When the hemorrhage is from the kidney and of idiopathic origin, the blood is intimately mixed with the urine giving it a reddish brown color, while if traumatic in origin the blood is passed as clots which assume the shape of the ureters, being passed in whole or in parts. Clots from the bladder are irregular in size and shape. The hemorrhage is usually intermittent and irregular, and particularly so in the more solid tumors.

Pain, as a rule, is an unimportant symptom except in the advanced stages of the malignant forms of growths, and then usually accompanies the increased micturition. In some cases, however, there is pain referred to the loins and hips.

Characteristics of the Urine.—The urine in vesical hematuria shows the presence of red and white blood corpuscles. Shreds and cells of the growth may be found in the normally voided urine. By forcibly

⁷ I have since modified this as follows: supra-pubic incision, perineal urethrotomy, division of prostate in median line from capsule upwards to urethra; large drain and tamponade of iodoform gauze in lower wound, suture of upper.

washing out the bladder, particles of the growth are more likely to be found. The evacuator which is used in the crushing operation for stone is a more reliable means of securing a specimen of a growth. The lithotrite may be used to confirm the diagnosis. The stream of urine, as a usual thing, is not altered, yet in the pedunculated forms of tumors, especially when situated near the mouth of the bladder, it may be interrupted, thus simulating stone. The sensation communicated to the fingers upon the introduction of the sound frequently gives valuable information, also a digital examination per rectum or vaginam; by these means the growth may both be located and its approximate size made out. The most valuable instrument in the diagnosis of tumors of the bladder is unquestionably the cystoscope. I have repeatedly been able to diagnose the situation, size and character of bladder growths by means of this instrument, and afterwards confirmed it by operation. Digital exploration through a median perineal cystotomy, formerly a common practice, has been displaced by the cystoscope. In the female, digital exploration through the urethra will usually suffice to establish a diagnosis, but does not offer the same advantages as the cystoscope.

Treatment.—The treatment resolves itself simply into the choice of operation. Suprapubic cystotomy offers the greatest advantages in the majority of cases. By the suprapubic route more room is gained for manipulation, the interior of the bladder can be illuminated by the electric head light, thus permitting the growth to be dealt with to the best advantage, and the hemorrhage can be more readily controlled. In sessile growths, curettement is the method or removal. The pedunculated growths are best removed by the wire *serre-nœud* or the cautery scissors. In the latter variety of growths, if situated near the mouth of the bladder, in the absence of great prostatic enlargement, median perineal cystotomy is the preferable operation.

I report the two following cases which illustrate the different operations:

Case 1.—Papilloma of the Bladder (Perineal Cystotomy).—C. L., age 45 years. For some months prior to admission to the German Hospital, he suffered from painful urination. The urine had frequently been charged with blood. There was present a constant dull pain in the hypogastrium. Cystoscopic examination demonstrated the existence of a sessile lobulated growth on the antero-lateral surface of the bladder. Median perineal cystotomy was decided upon as the most suitable operation. The bladder being filled with a boracic acid solution, the staff was introduced into the urethra and a median incision made from the central point of the perineum down to the staff, and thence along its groove into the bladder. A growth about the size of a small egg was revealed and thoroughly curetted from the mucous membrane. A soft catheter was passed into the bladder through the perineal wound and stitched in position. To the end of the catheter was attached a long rubber tube serving to carry off the urine into a vessel under the bed. Convalescence was uninterrupted. The perineal wound closed rapidly. The patient was discharged two weeks after the operation.

Examination of the growth showed it to be a simple papilloma. It weighed scant two ounces.

Case 2.—Suprapubic Cystotomy for Papilloma.—Perineal Cystotomy for Recurrence.—Death from Exhaustion.—G. W., age 45 years. was admitted to the German Hospital, April 15, 1893. Personal and family history good. Six months before, he suddenly developed an attack of hematuria, with dysuria. All symptoms then subsided. About a month before his admission to the hospital, the patient noticed a return of the original trouble; his condition became steadily worse, the hematuria and dysuria being alarmingly severe. The act

of voluntary micturition became very difficult and finally impossible, and repeated catheterization had to be resorted to. The urethra finally became so sensitive that the passage of the catheter occasioned much suffering. The urine was always rich in blood and small clots. He was admitted with the diagnosis of a probable papilloma with blood clots in the bladder. Suprapubic cystotomy was performed. The surface being thoroughly prepared, the abdominal incision was made and the bladder exposed. The bladder was picked up with tissue forceps and a silk thread passed through its wall for the purpose of making traction thus facilitating the next step in the operation—the incision into the bladder. This was now opened by a longitudinal incision. Examination revealed the condition suspected; the bladder was practically filled with blood in a more or less advanced stage of coagulation. Fully two handfuls of clotted blood, part of which was quite firmly organized and closely adherent to the mucous membrane were removed. After it was thoroughly emptied of its contents, a close inspection of the lining membrane of the bladder revealed the existence of a small papilloma on the posterior wall.

The little growth was cut away and the bladder thoroughly irrigated with boracic acid solution. A rubber drainage tube was introduced into the bladder through the abdominal opening, and the latter closed. The patient reacted well, and convalescence was uninterrupted. At the time of his discharge, May 17, the suprapubic fistula had entirely closed, and the urine was passed without difficulty through the normal channel.

On June 30, the patient returned, giving a history of several attacks of hemorrhage since his discharge from the hospital. He now sought relief from an existing attack that had baffled all attempts made to check it. The usual stypitic methods failing, it was decided to perform a perineal cystotomy. Thorough drainage was effected by the reestablishment of the original suprapubic opening and the newly made perineal incision. One week afterwards, a violent hemorrhage took place, but was easily controlled. A growth gradually developed involving the whole bladder wall, and ulcerating through the abdominal wall.

At the autopsy, August 11, the growth, a carcinoma fully as large in size as a fetal head was removed.

SYMPTOMS AND TREATMENT OF TUMORS OF THE BLADDER.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1894.

C. F. BUCKLEY, M.D.

SAN FRANCISCO, CAL.

The original intention which I entertained relative to this paper had to be abandoned, owing to the vastness of the subject. I considered it must involve too much of the Society's time, and lead in the main to rather inhospitable results, as the question of tumors of the bladder in their extensive bearings and differentiations is one affording more than the ordinary amount of learned and unlearned expressions of opinion to the gentlemen who devote their attention to this branch of medicine. Take, for example, the small matter of the cystoscope alone, and the opinions as to its value in diagnosis are certainly as diverse as the colors of the spectroscope, while such careful observers as Guyon of Paris, and Thompson of London, represent the extremes of divergence.

There is one very conspicuous fact, however, in relation to this whole subject, and that is a complete absence, among all the most prominent observers, of anything like a consistent or intelligible effort at an explanation of the etiology of tumors of the bladder. Hence I have decided to term this paper, "Papillomata of the Bladder," arising from external injury, and while I do not claim that such is always or even commonly the cause of such tumors, I offer a few cases which appear to me very significant and worthy of consideration in this, that they may lead to a line of inquiry in a direction hitherto unnoticed. In one

of the three cases which I shall report, the relation of cause and effect is very definite, and almost unmistakable, while in the other two, there may be room for some doubt though a strong presumptive evidence in favor of my views:

Case 1.—In the summer of 1875, while on a visit to Europe, a gentleman friend of mine thought proper to consult me regarding his health. He was a fine healthy specimen of manhood, about 45 years old, stout and robust of frame and general constitution. A generous liver but not a glutton; accustomed to spend most of his time in the open air, a great deal of it on horseback; and for nearly twenty years prior to this time he followed hounds quite frequently. He married early in life; had a large and healthy family. He never had any form of venereal disease. He never knew anything about ill health until about November, 1873, when he had a partial fall—so to speak—from his horse in hunting. The horse stumbled over a fence, and, to use his own expression his "crotch came heavily down on the pommel of the saddle." For a little while he felt faint and had some disturbance of the stomach. In about half an hour after the fall, however, he was able to ride home, and for ten days afterward was confined to bed, complaining of considerable pain in the pelvic region, and passing urine very frequently, which at intervals had some blood mixed in it. His bowels were also kept quite free during this time, but this he considered due to the medicines prescribed by his attendant. After two weeks he was able to move around again, but from the time of that injury he had more or less discomfort from the frequent passage of water, but not very much pain. The necessity of passing it had grown to become very urgent, and as a consequence a great source of annoyance, owing to its indelicacy. His medical adviser told him he passed some blood in the water but he never observed anything of that kind himself. On passing a No. 7 English sound into the bladder I found a rough gritty sort of substance, which felt very like a stone, but did not give the clear ring which a calculus usually does when the metal strikes against it. This was in the inferior or posterior portion of the bladder, not far from the neck. I then advised that he should go up to London and have an operation performed, as it was the only method of effectually removing the difficulty. There were some doubts as to the nature of the difficulty, but these would be speedily decided by an operation, and at the same time the disease could be readily removed. My advice—like most gratuitous ones—was temporarily ignored, but a year or more later it was followed, and my friend then wrote in a cheerful way—"I have at length done as you advised; a tumor nearly as large as a pigeon egg has been removed from my bladder and I feel almost as well as ever I did." This improvement has remained, and writing not long ago he remarked: "I never since had any trouble with the bladder, but of course I do not enjoy the saddle as I used."

Case 2.—In February, 1888, a young gentleman 19 years old was brought to my office in a perfect state of collapse, unable to raise his head or talk, though evidently not unconscious. He was reported to have fallen from a buggy. While examining him with some care he revived sufficiently to inform me that he was employed by a real estate firm, that he was out posting bills on various premises, and on one occasion, having to reach high, he stood on one of the buggy wheels to achieve his purpose. While in this position, unfortunately, his horse moved, and he fell heavily—for his legs were rather long—astride of the wheel, his perineum thereby receiving the whole brunt of the fall. Around this region there was general diffused ecchymosis and on passing as ound per urethram, there seemed to be much difficulty in reaching the bladder. The sound more easily got around the organ than into it. After withdrawal of the sound which had been used without any force, a copious hemorrhage followed. Recognizing that I had to deal with an intra-cystic hemorrhage from some source, I determined on an operation to control it as soon as possible. I had the youth removed to his home as quickly and safely as possible, and shortly after, by the median operation for lithotomy, discovered the offending ruptured bladder.

I was amazed at the extensive injury beneath the surface without any laceration of the skin, and this fact may have a very extensive application in a medico-legal direction. I ligated six good-sized blood vessels—three on each side—and brought the sundered edges of the bladder together with fine sutures of catgut, placed a gum elastic catheter in the bladder, and subsequently treated the injury as if the

median operation for calculus had been performed. The patient made an excellent recovery, though his nursing had never been characterized by the highest efficiency; the ligatures and sutures were all carefully counted at the time of the operation, and subsequently correctly accounted for. This young man never had any form of venereal disease.

About three months after he left his room, he consulted me about an irregular difficulty of passing water which seemed to grow worse. "At one time he could pass water quite freely, but lately it seemed to grow worse and it acted strangely. Sometimes he noticed no difficulty whatever, but on other occasions it seemed to be suddenly obstructed, and this occurred most commonly as the last portion of the water was about to leave the bladder. Something seemed suddenly to close the passage." In passing a sound I noticed a distinct contraction of the membranous urethra, and considered I had to deal with a common spasm due to stricture. I proceeded to dilate this with the daily use of sounds and, after ten days of treatment, on passing a No. 12 English sound with a sharp curve into the bladder, I noticed a rough but yielding mass that reminded me very forcibly of the prior experience. In this case, however, I considered that the sensation yielded by the sound may be due to a neglected suture or ligature, for, as I remarked, the nursing was not of the most efficient character. I felt that some foreign body had entered his body, and at once the lithotrite suggested itself to me as a judicious means of removing it.

These three cases contain many points of interest. In the two former, of the lobulated variety of papilloma, I think the evidence is quite clear that they were directly due to injury of the perineum; and furthermore, they were both unaccompanied by any hemorrhage at any stage of their development except, probably, at the outset, and both were covered by a calculous deposit. In the third case, there was no history of venereal disease—a complete immunity from all bladder symptoms, up to a short time prior to death, and no hemorrhage, though the disease was evidently of long standing.

The lithotrite suggested itself as the proper appliance to remove this foreign body, as I regarded it. I accordingly used it, and after careful manipulation succeeded in grasping a substance that was rough and quite gritty, offered little or no resistance to crushing, but when withdrawing the instrument an unpleasant resistance was offered, so much so that I was obliged to separate the blades, change their direction and withdraw the lithotrite without any substance in its grasp. An unpleasant hemorrhage followed and kept up for three days with such persistency that I determined again upon a median operation in the old cicatrix to the offending vessel. To be brief, I discovered in the bladder near the line of the incision a tumor larger than a good sized pea and covered over with an incrustation of calculous deposit. I removed it without difficulty, by a fine wire *Crasenur*. I experienced little or no trouble from hemorrhage, again treated the patient as one who had undergone a median lithotomy. Recovery was speedy and natural, and since then, a period of over six years, I have not heard any complaints touching his urino-genital system from this young gentleman who at the present time seems in splendid health.

A gentleman of 55 years old, plethoric and fleshy in appearance, consulted me in April, 1889. He complained of all the general symptoms of cardiac degeneration, of the presence of which the lithoscope immediately left no doubt. Of late he also "suffered a good deal from frequent desire to pass water, and quite often had passed little particles like flesh from the bladder, which he did not understand." He had never passed blood from the bladder. Had practiced law in Nevada in earlier life; had frequently long rides in the saddle; did not remember any one particular hurt or injury while riding, but had frequently some "hard knocks," and hurt a testicle badly more than once. Nephritis and cystitis, both in an advanced degree, forbade any instrumentation, and so with general tonics I recommended a sojourn in a warm country place. This advice was adopted. In the middle of May the patient died suddenly and to subserve a great many purposes a careful autopsy was made. The heart was fully the size of the ordinary ox heart; the kidneys were both large and waxy, and the bladder was one mass of papillomata of the fimbriated type.

TREATMENT OF URETHRAL STRICTURE IN THE MALE.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held in San Francisco, June 5-8, 1894.

BY JULIUS ROSENSTIRN, M.D.
SAN FRANCISCO, CAL.

To give you an elaborate description of all the different devices to relieve suffering man from strictures of his urethral canal would be very tiresome indeed. Fortunately, the ten minute limit precludes any such wild desire on my part, and I shall give you simply a brief aphoristical record of my personal views and conclusions, drawn from a rather ample experience. Urethral strictures are attacked either by gradual dilatation, rapid dilatation, divulsion, electrolysis, internal or external urethrotomy or both combined, either the perineal or high section or urethrectomy with or without urethroplasty. The treatment of strictures varies according to their size. Strictures of large caliber as over No. 14 or 15 French, (a French measure that is the only rational one and should be universally adopted) should nearly always be treated by gradual dilatation. Metallic sounds are the best for the purpose. Use antiseptic precautions. Clean the glans and prepuce well with soapsuds, then with ether and alcohol, finally with solution of 1 to 1,000 bichlorid or 5 per cent. carbolic acid. Wash out the urethra through soft catheter with solution of Condy's fluid 1 to 50, then cocainize urethra with 5 per cent. solution. Sterilize your sound, lubricate with 10 per cent. borated glycerin, and you are ready for introduction. Never push the sound into the bladder but stop at the membranous part.

I had a good many troublesome cases of cystitis come to me where the patients dated the commencement of their suffering back to the first introduction of an urethral sound. I leave the instrument in ten to fifteen minutes, to stimulate absorption of products of inflammation in the urethral wall by pressure massage. After two or three days' rest during which time, in irritable cases, salol, salicylate of soda, boric acid or quinin can be given in full doses, night and morning, you introduce the same size again and will be able in most instances to use immediately afterwards the next size. For some strictures of large caliber in the pendulous portion of the urethra of older date and unyielding in character, internal urethrotomy is recommended. I have not often in my own experience found it necessary, and believe it is well to remember that a vast majority of these so-called large calibered strictures are physiologic narrowings and ought to be left severely alone. Another exception must be made for true stricture of the meatus and fossa navicularis, which can be quickly and safely cut at the floor by a short convex blunt pointed tenotome. I underline here true strictures, for as Keyes says, meatotomy and anterior urethrotomy have run riot in the profession and have led to much unnecessary surgery and some positive injury. Strictures of small caliber, that allow the passage of a sound, should also be treated with gradual dilatation. I rarely try the introduction of metal sounds below No. 7 or 8. Injuries to the urethral walls and false passages are in the majority of cases traceable to such attempts. Flexible bulb-tipped bougies should be used. If even the smallest size does not pass readily, a prolonged pressure can be exercised by fixing and holding it against the stricture for several hours.

If that does not succeed, the filiform whalebone bougies should be tried, either the straight, angular or screw-tipped. Sometimes by introducing successively several filiform bougies, side by side, one is made to pass. If one should only enter the stricture and not pass it, the bougie can be tied there and left twenty-four hours *in situ*, after which time it often passes. Should no pressing symptoms exist at the time, you can leave the filiform bougie for one or two days, after Lefort's method of "dilatation—immediate progressive," with the certainty almost, that other bougies can be passed alongside and may be used as a guide for a tunneled catheter or for soft and metal bougies. If expediency is necessary the introduction of a tunneled catheter can be tried over the guiding filiform at once, or the whalebone bougie may be used for a guide to perform external urethrotomy. Every careful and persevering effort should be employed to succeed in gradually dilating even these refractory strictures. Internal urethrotomy of the posterior urethra with the *Maisonneuve* or *Teevan's* instrument from before backward, or from behind forward with the old *Civiale*, or *Sir Henry Thompson's* modification, or *Roser's* urethrotome and our own *Otis's* instrument is an operation I most heartily dislike. I consider it dangerous and unsurgical and believe it will be abandoned like the dissection of the cervix uteri by the *nterotome*. I used it formerly, also, in the few strictures of the anterior urethra that resisted dilatation, where I now leave a bougie *a-demure* for about twenty-four hours with antiseptic washings and obtain excellent results; and in the exceptional cases where in spite of the most careful asepsis, rigors and urethral fever followed each and every introduction of a dilating instrument, the patient refusing external urethrotomy; or in cases with multiple strictures where I performed external urethrotomy on the most central one, cut the others internally and plugged the urethra in front of the opened part for several days with iodoform gauze. Fortunately, I never met with a serious accident from internal urethrotomy, but the possibility of infecting the deeper strata of the wounded urethra, the danger of uncontrollable hemorrhage always gives me a feeling of uncomfortable insecurity when I am forced to undertake it.

External urethrotomy with *Symes's* staff and *Teale's* probe gorget as described by *Treves* in his admirable book, should be the operation of choice in all strictures of the deeper urethra where gradual dilatation is impossible. Perineal section takes its place where no instrument, however small, can pass the stricture. I performed it twice after *Wheelhouse's* method, the urethra being divided over the end of his staff, the urethral walls held apart by long threads drawn through it, the central opening found either by the eye or probing, and cut into on the probe gorget. I prefer this method to *Cook's* operation, where "you go it blind," having as a guide only your index finger in the rectum pressed against the apex of the prostate gland. With all these manipulations and operations the strictest asepsis and antiseptics must be exercised, together with internal administration of drugs for rendering the urine sterile or even give it some antiseptic properties. For external and internal urethrotomy, as well as perineal section, the introduction of a full-sized metal bougie immediately after the operation and at regular intervals of a few days afterward, till dismissal, must not be neglected.

It insures better than anything else the healing and closing of the wounds. I was forced on one occasion to apply retrograde catheterization. Four years ago the son of a dear friend and colleague, out hunting, dragging his gun after him, received its entire load of shot into the perineum and adjoining parts, lacerating the scrotum and penis in a frightful manner. The boy remained on the ground six or eight hours before he was found; there was retention of urine relieved only by puncture of the bladder and aspiration, until I arrived about two days after the accident. It was impossible to see anything in the swollen and lacerated parts. I opened the enormously distended bladder and drew a soft rubber catheter from behind forward carefully through the remnants of the urethra and united the lacerated parts over it. It was done easily and should be practiced in all cases where after a thorough search the posterior opening of the urethra can not be found. Urethrectomy, excision of parts of the urethra on account of very callous and fibrous indurated urethral and peri-urethral tissue has been successfully practiced after *Guyon* by quite a number of European and American operators. In cases of traumatic stricture, *Guyon* excises the hardened peri-urethral tissue, and insists upon the removal of the entire circumference of the indurated part of urethra, in opposition to others who leave the upper wall. He deems it unnecessary to unite the cut ends of the urethra, but sews the surrounding parts with a double row of buried continuous catgut sutures and adds an external row of deep and superficial silkworm-gut sutures. He leaves a permanent catheter for three or four days; the results are excellent.

Urethrectomy has been combined with urethroplasty; the substitution of the removed part of the urethra by transplantation of some other piece of mucous membrane. Pieces from the inner layer of the prepuce, after *Meusel*, have been used most frequently, but various other sources are made to serve, from the prolapsed uterus of lovely woman down to the esophagus and bladder of the guinea pig. The methods of divulsion or forced catheterization are most reprehensible and unsurgical. They possess all the faults of internal urethrotomy with the additional ones that the wounds made by the operation are rough and lacerated and unknown in their extent.

No general definite conclusions have been arrived at as to the therapeutic value of electrolysis. My own experience would not justify as great an enthusiasm as most of its advocates demonstrate, or as severe a condemnation as comes from the members of the opposing faction. In a few cases a very careful employment of this method seemed to ease and hasten the progress of gradual dilatation; in a great many others no effect could be attributed to its application. I have not as yet used *Deno's* water electrode for this purpose, an instrument that is reported to permit the application of forty to sixty milliamperes without pain and with great success.

The surgeon called upon to treat stricture of the male urethra will be impressed with the fact that the great therapeutic maxim of our craft, *nil nocere*, should be foremost in his mind.

Gradual dilatation is always a safe method and should be employed whenever feasible, although it lacks the great desideratum of permanency in its curative effects. I doubt very much that internal urethrotomy is any more lasting. I have seen a

great many relapses after this treatment which, together with its many objectionable features, gives external urethrotomy or one of its allied modifications the decided preference in all instances unsuitable for gradual dilatation.

THIRD DAY, JUNE 7.

The following papers were read by title, their authors being absent: "Effects of Obstruction in Urination upon the Bladder and Kidneys," Dr. J. William White, Philadelphia, Pa.; "Diagnosis and Treatment of Enlargement of the Prostate Gland," by Drs. Hunter McGuire, Richmond, Va., and William T. Belfield, Chicago, Ill.; "Symptoms and Treatment of Stone in the Bladder," Dr. William T. Biggs, Nashville, Tenn.; "Symptoms and Treatment of Tumors of the Bladder," Dr. John B. Deaver, Philadelphia, Pa.; "Treatment of Stricture of the Urethra," Dr. Julius Rosenstirn, San Francisco, Cal.; and "Carcinoma of the Urethra, with a Report of Two Cases," by Dr. H. O. Walker, Detroit, Mich.

DR. C. F. BUCKLEY, San Francisco, Cal., read a paper on "Symptoms and Treatment of Tumors of the Bladder."

DR. HAUGHTON, Texas, read a volunteer paper of "How Best to Treat Wounds To-day."

DISCUSSION.

DR. R. H. SAYRE, New York, opened the discussion of the topic of the session, saying: It seems to me very unjust at this stage of medical science to attempt to detract from the immense progress which has been made in consequence of the views advanced by Prof. Lister. Carbolic acid, creosote, balsam of Peru, and various anti-bacterial agents have been used for a long time, but they were used simply because the people found out that the wounds did well when they were employed; but the great underlying principle of infection was not understood generally before that time. And certainly to James Lister belongs the credit of forcibly impressing it upon the minds of the profession to-day. And the reason that we had suppuration was because the wound was contaminated by substances introduced from the outside, and although in the beginning he made statements which very likely he was afterward very willing to retract, further investigations since his first experiments have shown that many appliances which were first thought necessary are by no means so. The principle which underlies the whole subject is still the same, and it is simply by increased experience that we have learned to arrive at the same results by means of simpler processes, because our knowledge of the subject is greater than it was when he first opened the door to us, and showed us how practically to put into execution the great principle of antifermentative surgery.

DR. HAUGHTON, Texas—It is not my intention to detract from anybody, but simply to give a historical *résumé* of this whole question so as to bring it fairly to our view. I think if the gentleman had heard the balance of the paper he would find out exactly where it leads.

DR. C. F. BUCKLEY, San Francisco, Cal., exhibited to the Section some specimens obtained in his own practice, including a slate pencil five and one-half inches long removed from the male bladder, and a series of gall-stones perfectly white, removed from the gall-bladder in life, by surgical operation.

DR. J. D. GRIFFITH, Kansas City, Mo.—I think that it is very little use to make rules with reference to the particular position in stricture of the urethra, divulsion, for cutting for rapid dilatation and for gradual dilatation; we make positive rules as to where these things should be done. Van Buren and Boulay (?) taught these things years ago, Guion is teaching them now, that is: It is easy to so dilate that cutting can be done internally in the urethra under the pendulous portion. Divulsion can be done on the deeper portion. Rapid dilatation can be done on the deep portion of the urethra, and gradual dilatation can be done on the pendulous portion. Those rules are safe. But if you divulge in the pendulous portion of the urethra, or rapidly dilate, either one, which almost amounts to divulsion, then you are very apt to either kill your patient—I have seen one death in eight hours from it—or to inflict a very severe shock. You can cut in the pendulous portion of the urethra, but if you go deep and cut then you are apt to have dangerous hemorrhage. I must say that I have not experienced the same amount of trouble in introducing the sound into the bladder, as some of these gentlemen speak of. If your sound is clean and if your

urethra is clean back of the cut off muscle as well as in front of it, then I think you can safely introduce your sound. But this thing of a guide that the doctor was speaking of in his paper, the whalebone guide, I think is a dangerous instrument if it is not carefully watched. I know of but one way to find out whether my guide along the canal is too deep. That is after searching the urethra thoroughly with guides, say eight or ten or fifteen, you have got in each a lot of false passages, one of them slips through somewhere; how do you know it is in the bladder? That is the point I wanted to speak of particularly. I think it is very easy to determine that question. If the guide is in a false passage anywhere from the cut off muscle back and not in the bladder—because you want to be certain before introducing the instrument that it is in the bladder—holding the guide with your right, pass the forefinger of your left hand high up into the rectum and behind the point around the prostate, above it, and then if your guide is in the center line, in the bladder, you will be able to retract it easily. If it is in a false passage it will slip just as easy as it did before.

As to the cutting instrument, the gentleman has spoken of Bodice's (?) instrument, and mentioned Bank's most estimable instrument. There is no instrument to-day I know of that is equal to W. F. Fleure's instrument for large caliber strictures. It is the most complete and thorough that I have ever seen for this purpose.

DR. JOSEPH RANSOHOFF, Cincinnati—With regard to the danger of internal urethrotomy, in the olden days when Maissoneuve's instrument alone was used, when we could not with it get the instrument to hold a urethrotome larger than the 18 or 22 French, it was not uncommon to find that the operation, in the first place, was not permanently successful, nor was it rare to find a death following from septic fever. But with the dilating urethrotome those dangers have been practically removed, and I think that one of the safest operations we perform is internal urethrotomy as done with the dilating urethrotome. I do not advise what has been recommended by the essayist here, the use of the catheter. The reason I do not like to let the catheter remain more than three or four hours, or at the very furthest a day or two, is that I have seen some disastrous results from the use of catheters for a long time in the bladder. I know that in cases of enlargement of the prostate, catheters, soft in character, have been introduced into the bladder, and on account of the difficulty in finding the bladder the catheters have been allowed to remain. But the most violent and dangerous results will sometimes occur from the use of the catheter, allowing it to remain six or eight hours, even, and it is absolutely dangerous to let it remain more than twenty-four hours; whereas, internal urethrotomy is an operation which can be quickly performed. It has not the advantages that external urethrotomy has. It is an easy matter enough to make an internal urethrotomy. It is an easy enough matter to make external urethrotomy if you can get anything through. And here comes, to my judgment, the important point, and that is to get something through the channel. I confess that I lack the patience which belongs, I think, or ought to belong to the man who does a good deal of urethral work. Most of my friends, as well as myself, lack that patience which is so essential to pass things through the urethra. For that reason I dare say there is scarcely a year passes but that I have three or four or five catheteral operations that have to be done without a guide. In the hands of those who have great patience the practice of external urethrotomy without a guide would be materially increased. It is without question as has long been stated, the most difficult operation in surgery, and I am glad to see that the essayist spoke very kindly of an operation which has been practiced quite extensively on the continent of Europe, but has not yet found a footing on this continent that I think it is entitled to. I refer to catheterization from behind. Just before I came here I saw a patient who had been on the table two hours and a half and the surgeon was trying to find the deep urethra through an external examination. The region looked as if it had been passed through a sausage machine. I helped the gentleman out, and I had no difficulty in getting my finger under the arch of the pubes; I could get around behind the bladder and around the prostate, and between the prostate and the rectum. The man had lost his bearings and had simply looked around blindly for the urethra. That may happen to any one, for there is scarcely a surgeon of experience who has not failed to find the urethra. If I fail to find the urethra after what I think sufficient search, or if I have failed to make a Cox operation, which has given good results sometimes, I open the bladder and get at the difficulty from behind. There is no question

among those who have tried it with the introduction of the finger into the bladder, to introduce an instrument into the bladder from behind. It is an operation that I think will come into favor here, as it has on the other side of the Atlantic. I am glad to see that there has not been a man on the floor, in the discussion of this subject, who has spoken of urethral stricture who has referred to permanent cure of strictures. After all, it is a pretty sad lot that falls to the patient after the operation. Ordinarily a man will have to use an instrument at times all the rest of his life. All strictures are not alike; some will yield readily to simple dilatation; if we have this form of hard strictures that are tougher than any cartilage we can conceive of, no simple dilatation is going to effect a permanent cure.

DR. JULIUS ROSENSTIAN, San Francisco, Cal.—Although I have been attacked on all sides, still I am very glad that my paper, at least, has given foundation to so many able remarks on the subject. I have not been convinced altogether that I have made an error. That there can be urethrotomies made, internal ones, in the deeper part of the urethra, without danger or with success to the patient I do not doubt. I believe it is our great statistician, Harris, who has shown that Cesarean operation has been done by Bull, who has opened by accident the uterus of a woman; most of those so opened do recover; still I do not believe anybody would recommend that as a safe and proper way to perform that operation. I do not believe that urethrotomy in the deeper portion is a safe method, because we can not guard against very dangerous hemorrhages; there is danger in this method, in spite of the assertions of the very able gentlemen here on the floor. I must say that if in such hands as those of De Aul (?) the mortality from urethrotomy is 8 per cent. I believe nobody can say that it is an indifferent operation. Such are the records of his hospital and his clinics. It is all very well to say, perfect asepticism protects against the immediate results of the operation. It may be for the time, but who will guarantee us that the deeper parts of the urethra opened may not be infected, and if there is infection on that urethral tissue, general infection may follow? I believe wounds that can be laid open with safety, can be accurately watched, should be treated in that way, and we should not rely on chance, as we have to in most cases of internal urethrotomy. In the pendulous portion, in cases, as was said here, of recurrent and hard and calloused strictures I have been perhaps more fortunate. I have not found very often the necessity, except when urged by patients where they are very anxious to get rid of it, to use the internal urethreter. I have gotten on very well with gradual dilatation, and I must say I have had no desire to try a method or apply what I consider a dangerous practice where I can get around it with absolutely safe methods.

As to electrolysis, that has been mentioned here by one gentleman; he seems to misunderstand my statement. I have not recommended it; I have said that I believe that in some cases it seemed to do some good; that in a great many cases I had no effects whatever. But certainly, although I have tried it a few times lately, I have not made it a practice to give it a trial in every circumstance from the result of my experience, and I do not believe I have expressed in the paper any great enthusiasm for it.

As to the catheter of A'Demeure, I have also mentioned in my paper that Guion uses it, but I myself do not use it. I have used a drainage tube in external urethrotomy cases for twenty-four hours, as long as I found it necessary, but I have rarely used the catheter of A'Demeure, except in those cases where the entire urethra was torn and the urethra united over the body of the catheter that was introduced through the open bladder.

I was asked to explain my idea of absorption in introducing a catheter and leaving it lie there for ten to fifteen minutes. I believe that just as we can by pressure and massage remove some exudations in the exterior parts, so we can by the same means do something similar in the interior organs. We think that by exciting the lymphatic glands and the vascularity of the parts, that absorption is stimulated by the taking up of inflammatory products in the surrounding tissues; that they are made more amenable to absorption. And it certainly seemed in the cases I treated that by thorough continuous introduction of a sound and leaving it to lie there for some time, that hard strictures cure swifter under the treatment by stretching and by absorption, and that is the explanation and the idea I had, by saying that, leaving the catheter or leaving the bougie for some time in the strictured parts stimulated absorption of the inflammatory products in the urethral canal.

THE PATHOLOGY AND SYMPTOMATOLOGY OF HEMORRHOIDS, ANAL FISTULA, AND ANAL FISSURE.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1904.

BY DAVID POWELL, M.D.

MARYSVILLE, CAL.

HEMORRHOIDS.

Although anatomically divided into external and internal, and presenting some pathologic features peculiar to their situation, hemorrhoidal tumors are essentially similar in structure, whether located in the rectum within the sphincter muscles, or about the margin of the anus. Pathologically considered they are identical, and composed primarily of the same morbid elements—enlargement or varicosity of the venous hemorrhoidal plexuses, and infiltrated connective tissue.

Within the dense areolar membrane which enters into the structure of the lower part of the rectum and verge of the anus, is a network of tortuous veins, the inferior or external, and the superior or internal hemorrhoidal plexuses. From the former, the blood finds its way into the general venous circulation through the middle and inferior hemorrhoidal veins which communicate with the internal iliacs; from the latter, through the superior hemorrhoidal vein into the portal system. The absence of valves in the hemorrhoidal veins; the dependent position of the parts; man's erect position; distension of the rectal ampulla from fecal accumulation; obstruction of the portal circulation; pressure by the gravid uterus or any abnormal tumor upon the inferior vena cava or iliac veins, tend to produce the pathologic conditions which favor the development of hemorrhoidal tumors, viz: The varicosity of the veins, and the extravasation of their contents into the surrounding peri-vascular tissues.

In their incipiency, hemorrhoids, both external and internal, are merely a dilated or varicose condition of the veins of the submucous areolar tissue in the region affected, without intumescence or any appreciable tumor. But as the disease progresses a constantly recurring congestion and inflammation, from various irritating causes, produce very characteristic changes and modifications in the vessels and tissues involved. The veins become more and more expanded; their coats become thickened; the surrounding cellular tissue is infiltrated and indurated; the investing tissues hypertrophied by plastic deposit, and sooner or later a well defined swelling or tumor is developed. If external to the sphincter it appears as a rounded venous-looking tumor, purplish in color with an ill-defined base, just at the verge of the anus, running up into the bowel and covered with the thin sensitive skin of the part. During the straining accompanying forced defecation the veins become greatly distended, finally give way and the blood is extravasated into the surrounding connective tissue, forming a large, tense, globular, painful hemorrhoidal tumor. Upon section an external pile is found to be composed of hypertrophied integument, infiltrated areolar tissue, and one or several dilated veins containing coagulated blood. The presence of coagulum in the distended veins and surrounding cellular tissue is an important pathologic feature of an external hemorrhoidal tumor, and is of much prac-

tical moment when considering the application of remedial measures.

Internal hemorrhoids differ in form, situation and structure, and are accordingly divided into venous, arterio-venous, and capillary. The venous internal pile differs from the external in being covered with mucous membrane instead of integument and having a tendency, from slight irritating causes, to bleed. The arterio-venous pile as described by Hamilton "consists essentially of hypertrophy of folds of mucous membrane surrounding the anal opening, the so-called pillars of Glisson. They have a red, almost vermilion color, elongated form, and contain within them one of the descending parallel branches of the superior hemorrhoidal artery."

Capillary hemorrhoids are small sessile tumors usually situated high in the rectum, exceedingly vascular and in structure consist chiefly of small arterial ramifications and hypertrophied connective tissue.

Symptoms.—The symptoms of hemorrhoids vary with the location, progress of the disease, and size of the tumors. A non-inflamed external pile does not cause much distress—merely a sense of fullness after defecation, with local heat and slight itching. But as the disease increases and the tumor becomes enlarged and inflamed the suffering is often intense. A deep seated, dull, aching, throbbing pain is experienced, radiating from the anus through the perineum into the nates, which is much increased by walking or standing. The spasmodic contraction of the irritated sphincter and levator ani muscles increase the patient's suffering and often produce general systemic disturbances, manifested by malaise, rise in temperature and anorexia. Pain, sensation of foreign body in the rectum, an uneasy feeling and smarting about the anus, increased during defecation and accompanied with or preceded by more or less hemorrhage, are among the first symptoms of internal hemorrhoids. Later the bleeding becomes a more urgent symptom, is more frequent and profuse, sometimes leading to extreme anemia and exhaustion. The pile-tumor protrudes during the expulsion of feces, is caught by the sphincter, becomes inflamed, sometimes strangulated, and the pain is excruciating. Constitutional and sympathetic disturbances ensue, evinced by fever, weak rapid pulse, languor and extreme restlessness. In many instances, too, irritation of the genito-urinary organs, producing frequent desire to void urine and difficulty in micturition with the accompanying tenesmus, add greatly to the patient's sufferings.

ANAL FISTULA.

Quite opposite opinions have been advanced regarding the exact pathology of fistula in ano. It has by some been contended that the fistule originates in an ulcer of the mucous membrane of the rectum, and that the "suppuration in the neighboring textures was subsequent to, and dependent upon this ulceration." In support of this view it has been suggested that the semilunar lacunæ, small valves or pouches, found in the mucous coat of the rectum, in which seeds and other foreign substances might readily find lodgment, may be frequent factors in the causation of ulceration resulting in fistulæ. While, furthermore, it can not be doubted that ulceration of a tubercular focus and traumatism may cause perforation of the rectal wall from within, through which

fecal matter may escape, and thus excite suppuration in the surrounding loose areolar tissue, yet the frequency with which fistulæ follow ischio-rectal and other abscesses about the rectum, indicates that the first pathologic manifestation of the disease, in a very large majority of cases, is an "inflammation and suppuration of the cellular tissue external to the bowel, and that the abscess subsequently opens into the gut" (or through the integument or both) "and thus constitutes the fistula." There is perhaps no surgical disease a clear appreciation of the pathology of which is of more importance than is that of fistula in ano. If therefore, periproctical suppuration is, in most instances, the cause and not the effect of the disease, the fact is of much practical significance; for successful preventive measures must rest upon a correct theory of the steps in its formation.

Symptoms.—Anal fistule is not usually accompanied by severe or urgent symptoms. Among the weak, debilitated and strumous who are the most frequent sufferers, other symptoms and conditions often divert attention from the local trouble. During the inflammatory stage, however, there is often much pain and considerable general systemic disturbance. But where the suppurating tension is relieved by free sinuous openings the symptoms subside, and the only inconvenience resulting may be slight tenesmus and pain in defecation, the passage of flatus and pus, if the fistula is complete, and the annoyance of soiled linen from the constant escape of a purulent, fetid, sanguineous discharge.

ANAL FISSURE.

Anal fissure is an affection of much practical importance and interest, not so much on account of its pathologic relations, but because it is often attended with extreme local pain, and frequently gives rise to grave constitutional disturbances. Beginning in an excoriation of the skin and mucous membrane to the extent of exposing some of the nerve filaments of the anus, the reflex irritation and spasm of the sphincter muscles thereby induced, lead to the formation of painful and oftentimes very obstinate ulcers. Fissures are usually of traumatic origin and in the great majority of cases are situated at the posterior commissure of the anal opening. They form suppurating grooves with inflamed indurated edges running parallel with the axis of the bowel, and may extend into the rectum above the sphincter. They are often associated with hemorrhoids, and the external termination of the fissure is frequently found concealed under a small external pile or fold of integument.

Symptoms.—The symptoms of anal fissure and ulcer, both local and constitutional, are characteristic. Among the former are a dull aching pain extending into the loins and thighs, aggravated by an evacuation of the bowel, and continuing with increased severity for several hours after each visit to the closet; morning diarrhea; spasm of the sphincter muscles from irritation of the peripheral nerves causing excruciating pain; and more or less loss of blood or muco-purulent discharge at stool. Continued and annoying irritation of the genito-urinary organs is also a common symptom, sometimes inducing spasmodic stricture of the urethra, frequent micturition, a sense of fullness and tenderness about the prostate, loss of sexual power, and seminal emissions.

The constitutional disturbance, too, is often greater than the pathologic conditions would seem capable of producing. There is a marked perturbation of the nervous system which is seemingly in intimate sympathy with the local affection; and if the disease continues unrelieved, "the countenance becomes pale, anxious and careworn, and the patient's expression is indicative of constant suffering."

TREATMENT OF ANAL FISTULA.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. McFADDEN GASTON, M.D.

ATLANTA, GA.

PART I.

For a proper understanding of the principles underlying the management of anal fistule, it is requisite to present some data connected with the rectum.

Morton and Witherill state that the rectum in its upper and middle portion is derived from the internal and middle layers of the blastodermic membrane, while its lower third with the anus, like the buccal cavity, is formed by the external and middle layers. The rectal veins like the rectal arteries are divided into three sets; superior, middle and inferior. They form two distinct venous systems, the rectal emptying into the portal system, and the anal terminating in the internal iliac.

The throat and rectum have many points of correspondence in their structure, being supplied with circular fibers, which make them the counterparts of each other, by opening and closing their respective orifices. There are two sets of muscular fibers encircling the lower part of the rectum, known as the outer and inner sphincter, by which it is automatically closed except when dilated voluntarily for the release of flatus or the discharge of fecal matter. There is also another distribution of circular contractile muscular fibers at the upper limit of the rectum, which constitutes the division between it and the sigmoid flexure of the colon. This may be appropriately designated the recto-colic sphincter, and forms an effective barrier ordinarily to the descent of the excrement into the rectum. This annular muscle has not received from anatomists or physiologists the consideration which its rôle in the intestinal functions warrants. It is a veritable constriction from muscular contraction by which the colon is normally closed against the descent of the fecal mass into the rectum. When the excrementitious matter reaches the sigmoid flexure of the colon it is deprived of all nutritious properties and after this desiccated mass passes the muscular division between the colon and rectum, and is deposited in the lower reservoir it contains only effete matters.

The fecal deposit acts then as a foreign body, and stimulates this canal to expel the *débris* by the anal orifice, or by remaining there becomes a source of trouble and even of disease. If the indurated mass remains in the rectum for an undue period, it induces more or less local disturbance and extends an erethism to the general system, through the nerve supply to this portion of the organism.

The rectum is a pouch or depository consisting of contractile tissue and capable of great distension under the accumulation of fecal matter within it. While its proper function is that of a temporary res-

ervoir with the property of contraction for the expulsion of its contents, it may fail to perform the office of a waste pipe and become shut off as it were by the sphincters above and below. These annular muscles are provided with somewhat similar means of opening and closing at each extremity of the rectal canal; and being composed of tissues in their walls, which are alike subject to induration and thickening, with constriction of the passage.

Zeigler qualifies proctitis as an inflammation of the rectum, resembling in many points inflammation of the vermiform appendage. The exciting agents are frequently foreign matters and stagnating feces; but disturbance of the circulation in the hemorrhoidal veins may likewise end by inducing inflammatory change in the bowel. When the inflammation and ulceration extend deeply into the tissues of the wall of the bowel, the surrounding connective tissue becomes infiltrated and hypoplastic or breaks down into abscesses containing fetid pus.

Thus it occurs that the rectum becomes a seat of disease and among its disorders fistulas are not uncommon, either as sequelæ of peri-rectal abscesses or resulting from abrasions and ulceration of the inner coat.

Apart from fecal concretions and enteroliths lodged in the rectum and becoming sources of irritation and inflammation to its mucous coat, there are foreign bodies which pass through the alimentary canal and find their way into the rectum to cause trouble in the surrounding structures. Fish bones, spiculæ of chicken bones and other bony fragments have frequently been found in peri-rectal abscesses after having perforated the rectal wall. Very recently I removed a spicula of bone over an inch in length which had become lodged just within the external sphincter, and one extremity had perforated into the mucous membrane of the rectum. This would have ultimately effected an opening through which the fecal matter could have penetrated the tissues and set up a suppuration process. The incautious introduction of a syringe pipe or other solid substances, may also induce abrasions of the mucous membrane of the rectum, which will terminate in ulceration and perforation of the rectal wall.

The attempt to remove hardened fecal matter with a scoop or with the fingers may lead to a like bad result. But there are sources of disorder from injuries inflicted in the parts immediately around the anus, which set up inflammation of the deeper seated structure. Violence of any kind, by a kick, sitting down upon a projection or being thrown upon the pommel of a saddle, may lead to a peri-rectal abscess, which calls for considerable skill in its treatment to abort its termination in a fistulous outlet. The early recognition of such a purulent collection and its discharge by a free incision, with the subsequent use of a drainage tube and light tamponage with antiseptic gauze, are usually attended with a radical cure of such traumatic abscesses. But there will occur cases which resist treatment or which fail to be properly managed that result in fistula.

There is a class of tuberculous abscesses in the peri-rectal tissues which are of strumous origin, and independent of any mechanical injury, that are accompanied by fistula of the most aggravated type. This form calls for constitutional as well as local treatment.

It is not a legitimate inference that the drain of a

fistula upon the adjacent rectal structures has a salutary influence upon tubercular diseases of the lungs. The evidence is conclusive to my mind that the general debility and constitutional irritability, resulting from the constant wear and tear of fistulas involving the tissues around the anus, are in most cases aggravating circumstances in the progress of other diseases and the more effectually they can be cured the better is the result. There was a period when the names of distinguished members of the medical profession were arrayed against operating for fistula in ano when it occurred in a tubercular subject. But the weight of authority is now favorable to operative interference for eliminating the local disorder and arresting the drain upon the system.

Instead of the chronic cure by a slow treatment for fistula in ano, with oft-repeated temporizing applications, in subjects of tubercular disease, it is decidedly preferable to secure the prompt effect of a speedy and radical operation in cutting short the evil.

The openings may occur at distances from the anus varying greatly, both internally and externally. Where there is a sulcus forming a semi-circle around the lower portion of the rectum it is recognized as a horseshoe fistula, and may have the opening in the skin on the opposite side from that in the wall of the bowel.

The usual division of complete and incomplete is based upon the existence of an external and internal opening in the former, and either one or the other in the latter. Those having but one opening are known as blind fistulas and we may have a blind external or a blind internal fistula, as the opening occurs in the skin outside of the anus or in the mucous coat within the anus.

The cases in which the two openings in close proximity to the anus are presented usually involve only the external sphincter, and have the internal orifice between this and the internal sphincter, in the depression which exists in the space between the two muscles. This is accounted for by Allingham in the following manner: "The abscess forming, in most cases just outside the anus, does not burrow deeply but passes close under the external sphincter; it then is prevented from ascending higher up the bowel by the thick band of the internal sphincter, and consequently is turned inward and makes its way through the lax areolar tissue." This explains those cases in which the primary abscess is outside of the rectum; but a large proportion of fistulas have their origin inside, and by perforation of the rectal wall admit the fecal matter which works its way by suppuration out through the skin beyond the border of the anus forming a complete fistula.

When the abscess commences in the ischio-rectal fossa it burrows deeply, according to Allingham, and then most usually passes beneath the internal sphincter and opens, if at all, high up in the rectum. There may be more than one aperture in the rectal wall communicating with different fistulous tracts, leading out through the skin at varying distances from the anus. When the openings occur high up in the wall of the rectum, and the suppurating process extends from these into the surrounding tissue of the buttock, several external orifices may be found in the skin of the hip even at a distance of six or eight inches from the anus. Comparatively few of these cases have been noted in this country, but

quite a number of them came under my observation during my sojourn in South America. Some of these extensive fistulas will be referred to in connection with the surgical measures adopted for their relief.

The foregoing pathologic indications have not included a distinct recognition of what constitutes a fistula, and it may be defined as the ulcerated outlet of a suppurating tract through the subcutaneous tissues. This irregular and often tortuous channel is surrounded by a pyogenic membrane, bounded by a fibrinous deposit, which imparts a sense of induration to the touch by palpation. The object of treatment in any form should be the obliteration of this canal and the apertures connected with it, whether internal or external.

PART II.

As a preliminary step toward any measure of treatment for fistula in ano, whatever may be its form, it would be desirable to have the bowels freely evacuated for two successive days and to use an enema of warm soap water during the morning of the day fixed for an operation. After this procedure the patient should be placed upon the side, with the hips projecting over the edge of the bed so that the fistulous opening shall be uppermost, and a speculum introduced into the rectum with a view to open moderately the anus. A syringe with a small beak may now be employed to pass a 50 per cent. solution of the peroxid of hydrogen from the external aperture through the fistulous canal and out at the inner aperture, leaving it to escape through the dilated anus. This should be followed with an injection into the fistula of a mixture of one drachm of the concentrated Lugol's solution with four ounces of warm water, letting it escape by the anus, as in using the other wash. Lastly a stream of sterilized warm water should be passed through the fistulous tract and the patient is ready for whatever operation may be indicated.

Various processes have been employed for the cure of anal fistule, some of which look to the correction of the conditions involving the use of injections into the tract, while others by mechanical devices procure its obliteration, and again the more radical measure of a cutting operation is held to be the most effective treatment. It is evident that different modes of procedure are requisite, according to the nature of the case, and that which is applicable to the superficial complete anal fistule can not be adopted in the deep-seated anal fistule with one or more apertures in the bowel communicating by fistulous tracts with several outlets in the skin at varying distances from the anus.

When there is an external orifice within an inch or less of the margin of the anus, and an internal opening within an inch or less of the aperture of the anus, the knife may be safely employed. A grooved directory being introduced at the external opening is carried gently along the tract of the fistule until it emerges from the internal opening into the lumen of the bowel, when the index finger of the left hand is passed into the anus and up to the end of the directory.

If from any cause the directory is not found protruding it should be guided by the finger into the aperture, and then passing the end of the finger beyond the point of the directory it should be brought outside of

the anus. The tissues lying between the external and internal openings of the fistule are now resting over the directory and entirely exposed to the view of the operator. At this point I have found a departure from the custom of using a curved bistoury to give satisfactory results, and would advise the broad straight bistoury to be placed with its back in the groove of the directory and thrust through this intervening structure, which includes the external sphincter muscle. If the fistulous tract is not located at a right angle to the border of the sphincter, the directory should be forced into a position to make the cut transverse to the fibers of the sphincter muscle.

The next step is scraping out or curetting thoroughly the fistulous tract so as to remove the pyogenic membrane, and thus place the bottom of the wound in a favorable condition for the process of granulation. Packing the line of the fistule from the external to the internal opening with iodoform gauze, and filling up the incision with loose gauze over this, a compress may be secured with a T bandage to keep the dressing in position.

There is usually so much sero-sanguinolent oozing after this operation as to soak the dressing and require re-dressing within twenty-four hours. When fresh dressing with iodoform gauze is thus applied no further change is requisite for three days. Unless a movement of the bowels should take place there can be no object in removing the dressing, but if a fecal evacuation occurs, the parts should be thoroughly washed with carbolyzed water from a syringe and the dressing re-applied as previously. So soon as the bottom of the incision along the fistulous tract is found to be studded with granulations the packing should be discontinued and the sides of the wound brought in contact to secure union of granulation in all parts.

The practice of former times, in keeping the sides of the incision separated by lint or gauze until the wound fills up with granulations from the bottom is a fruitful source of protracted suffering to the patient and conducive to that loathsome result of inability to retain the feces and intestinal gases. If the curetting is done efficiently at the outset and the packing applied properly in the bottom of the wound for one week the granulating process ought to be so developed in this time as to warrant the closure of the incision. By the use of firm compresses on either side, held in place by strips of adhesive plaster or bandages, an operation of this kind should not require the attention of the surgeon more than two weeks. The union secured in this way between the divided parts of the sphincter obviates all inconvenience afterwards from fecal incontinence.

The attempt to dissect out the tract, when a fistule is laid open, has not been attended with results which should encourage the immediate closure of the incision after an operation and hence need not be dwelt upon here.

In regard to those cases in which the internal opening of the fistule is found above the internal sphincter, but within two inches of the anal orifice, while the external opening is something over an inch from the margin of the anus, the knife may still be employed with safety. But in view of the difficulty or even impracticability of turning the point of a grooved directory out at the anus, the process may be modified by introducing a concavo-convex wooden guard into the rectum to receive and

support the point of the directory when it emerges from the internal opening of the fistule.

An assistant should hold the directory firmly while the operator secures the guard and makes the incision with the broad straight bistoury, by thrusting it along the groove of the directory until the guard is reached and then cutting inward so as to divide all the intervening tissues. The subsequent management of the case corresponds very much to that above described, except that the packing must be carried higher up in the rectum to reach the end of the incision.

In this class of cases the elastic ligature has been employed with satisfactory results by some operators. It certainly has at least the recommendation of lessening the liability to hemorrhage which attends a cutting operation that extends above the internal sphincter. There is a decided advantage in using the elastic ligature instead of silk or other material which only cuts through a limited portion of the inclosed tissue, as the latter must be tightened from time to time, whereas the former continues the constriction until all the tissue is divided. In either case, however, there must be considerable delay in the process of cutting through the structures involved; and there is suppuration continuously, not only along the original fistulous tract, but from the entire surface left behind the ligature as it cuts its way out. Under these unfavorable conditions it is very desirable to adopt another procedure which may accomplish the end in view more expeditiously, without hemorrhage and without suppuration. All these requirements are fulfilled completely by employing the chain *écraseur*. This is suited not alone to the fistules having an external and an internal opening within an inch to two inches from the anus, but to those opening high up in the rectum and at a distance of several inches outside of the anus, through one or a number of apertures in the skin of the buttock. Having treated some cases of deep-seated extensive fistule in ano by this process during my sojourn in South America, which were reported in the *American Journal of the Medical Sciences* of July, 1881, I will present a few of the points recorded in that paper, to which members are referred:

If the source of the fistula is high up in the rectum, the route of the discharge may be in the direction of the sacrum or through the muscular fibers of the gluteus, and there may be several lines of communication with the surface. When the tract penetrates to such a depth as to cause apprehension of hemorrhage by cutting with the knife, the tissues may be divided without any risk by the chain of the *écraseur* of Chassaignac. The essential conditions which indicated this operation have been observed in four cases of extensive fistula in ano.

The internal opening in each case was high up in the rectum, and the fistula extended from this aperture deeply into the surrounding tissues, so that the line of communication between the internal orifice and the external outlet of these fistules exceeded six inches in length, involving the structures on a large scale.

As the space allowed for this paper does not admit of details and the record of the treatment with two chains at the same time is given in the report of the last case, it may be quoted verbatim from the *Journal*. Chloroform anesthesia was used in all cases: "Case 4 had two deep fistulas, whose external outlets were

nearly equi-distant from the junction of the sacrum and coccyx on either side, having each a communication with an opening about midway up the rectum. The channels being tortuous could not be traversed by a metallic probe or director, yet they were explored by a flexible bougie, to which the chain of the écraseur was attached, and thus loops were thrown around the intervening parts. Two instruments were used so as to encircle the tissues on either side and divide them at the same time. As the chains included a portion of the buttock containing no vessels that could yield any considerable amount of blood, the tightening was done rather too fast, and as a consequence there was some sanguineous oozing from the divided surfaces of the muscles. This, however, ceased upon the application of a strong aqueous solution of phenic acid, which has proved in my hands an effective hemostatic, even when small arterial twigs are divided by the knife.

"The usual dressing of fine strips of old linen saturated with carbolized oil was kept up for some weeks, and the cure was completed within two months, so that the negress went about her duties on the farm."

The most remarkable feature in connection with these extensive divisions of the deep-seated fistulas, involving the cellular tissue with the muscular fibers surrounding the rectum, is the comparatively slight effect produced upon the general system. There has been little febrile excitement and the restorative process has progressed satisfactorily after all these heroic operations.

TREATMENT OF ANAL FISTULA.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY GEORGE B. SOMERS, M.D.
SAN FRANCISCO, CAL.

In a very interesting article, occurring in the *New York Medical Journal*, on the history of anal fistula, Bodenhamer shows that this disease was well known and well treated in very ancient times. He says, in fact, that the ancients "possessed all the indications in the treatment of this disease, as well as the numerous measures and methods of putting them into execution. They had incision and excision with the bistoury; they had the ligature: and they also had cauterization in all its many forms; indeed, we are indebted to them for almost all we know upon the subject of anal fistula."

In the absence then of any particularly new ideas concerning this subject, there would appear to be no sufficient reason for taking it up. But in the face of the frequent failures attending its treatment, we are often driven to examine the subject afresh, in order to reassure ourselves concerning the ground principles of treatment.

Simple anal fistula is generally considered one of the easiest things in surgery to deal with; but the fact is that the majority of fistulæ are not simple. There are two factors complicating nearly every case, which must be understood and borne in mind in the treatment of the disease. These are the cicatricial walls of the canal and the frequent existence of collateral sinuses.

Mathews gives it as his opinion, that fistula in ano is invariably preceded by or is the result of an abscess. The importance attached to this proposition is that

the character of the abscess influences the character of the fistula resulting from it. Every abscess whether due to pyogenic or tubercular microorganisms, is lined by a new-formed membrane; and every fistula resulting from an abscess is lined by a similar membrane. In the pyogenic abscess and fistula the wall consists, in the first stages, of simple granulation tissue; but if the abscess lasts any length of time, the granulations gradually organize into tough, resisting cicatricial tissue, which forms an impermeable lining and really acts as a protective to the healthy tissues behind. In tubercular abscess and fistula, the lining membrane consists of fibrin or cicatricial tissue, which has been softened by the infiltration of numerous degenerating tubercles. This tubercular membrane is of a grayish color and may be easily stripped off in fragments by the finger or curette.

With such membranes present within a fistula, all efforts at healing are retarded; for the membrane of the first kind, through its thick tough walls, effectually suppresses granulations, and the membrane of the second kind, through the presence of the bacilli and degenerating tubercles, constantly dissolves away the granulations that may form. Consequently, in order to cure a fistula, the necessity of getting rid of its lining membrane is obvious.

The second factor to be considered in reference to any mode of treatment, is the likelihood of a collateral sinus, diverticulum, or pocket being present. Such a sinus would present the same characteristics as the main canal and should receive the same treatment. Otherwise the lining membrane will, in the majority of cases, prevent healing.

In considering what course to pursue in treating a fistula, the above mentioned conditions must guide the choice. The methods commonly adopted are four in number. They are by injection, by ligature, by the fistulotome, and by the knife. The first three are obviously not radical modes of treatment, and probably would be resorted to by the surgeon but rarely, were his judgment influenced solely by the local indications.

The methods by injection and ligature are well known and need no special consideration.

Mathews' fistulotome is an ingenious instrument and has been used with success by its inventor in a number of appropriate cases. Dr. Mathews himself, however, distinctly states that the instrument can only be deemed an expedient to be used when the patient refuses to undergo a radical operation. The instrument contains two concealed blades which, after insertion into the bottom of the fistula, may be disclosed and caused to cut through the walls of the fistula while being withdrawn. As the cutting is subcutaneous there is little or no pain. Mathews precedes the device by enlarging the whole course of the canal with laminaria tents. The method cures by cutting through the opposite cicatricial walls of the fistula, which allows granulations to spring up and fill the canal.

It is generally acknowledged that the most rational method of treating fistula in ano is by the knife; the reason being that by laying open the canal completely, the whole of its surface may be treated and nothing overlooked. But the dangers of cutting through the sphincter, no matter how carefully done, are real and the procedure is often followed by bad results. Accordingly, any reasonable attempt to

avoid this danger by less radical means than the knife is justifiable. Tuttle believes that in the majority of cases the sphincter should not be severed. He formulates his ideas as follows: "Convert the fistula into a cone-shaped cavity with its external opening for a base; scrape it out thoroughly; cauterize the surface and paralyze temporarily the sphincters and gut as high up as the highest point of the fistula by stretching." He believes that there is no excuse for converting a blind external fistula into a complete fistula until after this method has been given a fair trial. In blind internal fistulæ, however, his practice is to convert them into complete, by making an external opening, and then converting the canal into a cone-shaped cavity. Where practicable Tuttle's operation should always receive a fair trial in order to avoid the dangers of causing incontinence.

In the operation by the knife the consensus of authority agrees that the main steps of the operation should be somewhat as follows: 1, the insertion of a grooved director to the bottom of the canal, and even pushing it through into the bowel if the inner opening be not readily found; 2, the end of the director protruding into the rectum is brought out through the anus; 3, the tissues lying on the director are incised; 4, the membranes lining the canal are scraped out or dissected away, and any pockets or collateral diverticula are treated in like manner.

It goes without saying that strict cleanliness and antiseptics are in order. In addition, however, there are several factors, collateral to the above mentioned steps which will bear discussion.

Manley states that the sphincter ani is the key to the treatment of all ano-rectal maladies, and shows that nearly all rectal affections are favorably influenced by dilatation. In fistula the sedative effect of dilating the sphincter is of special value, for as the contractile tissues are put at rest, healing is allowed to go on undisturbed. Accordingly, thorough dilatation of the sphincter should precede the incision. Again, the external sphincter, which controls the escape of gases from the rectum, is generally completely severed in the radical operations; for the internal opening of complete fistulæ is usually found between the external and internal sphincters. The importance, therefore, of insuring its union is obvious. Experience teaches two facts with reference to cutting the sphincter, namely: That the muscular fibers unite better if they are cut at right angles to their course, and secondly that if the sphincter be divided in more than one place, incontinence will very likely follow. So much for the sphincter.

In tuberculous fistulæ the lining wall can not as a rule be cut out owing to its soft nature. The curette must be thoroughly used. The question of operating at all in a tubercular subject depends entirely on the physical condition. If the patient can stand the operation he will be better for it.

In reference to the inner opening of a fistula Gerster says: "When the internal orifice can not be found, or a burrow extends upward beyond it, the grooved director should be inserted as high up as the cavity or sinus permits, and thence should be thrust through the mucous membrane into the gut." The procedure quoted is logical, and is the modern practice. Formerly, entirely too much stress was laid on finding the inner opening, under the superstition that a fistula could not be cured unless the bowel opening were found.

In fistulæ that have very little tissue intervening between the canal and the rectum, it will be found after the incision is made, that the edges of the wound are thin and have a tendency to become inverted. In order to prevent inversion these edges should be quite freely trimmed off.

As a final proposition with reference to completing the radical operation for fistula, the question of the use of sutures in appropriate cases comes up. Suturing the raw surfaces in order to procure primary union was probably first thoroughly tried by Lange. The method has the further approval of Gerster, Mathews and Jenks. In suitable cases it undoubtedly hastens the cure. Lange and Gerster unite the walls by buried catgut. The sutures do not include the mucous membrane, but are inserted close to the edge on one side and brought out in the same manner on the opposite side. The object of burying the sutures is to prevent infection from fecal contents. The edges of the mucous membrane may be further drawn together where necessary. The external or cutaneous part of the wound should be only loosely sutured to allow for drainage.

AFTERNOON SESSION, JUNE 7.

The following papers were read by title: "The Pathology and Symptomatology of Hemorrhoids, Anal Fistula and Anal Fissure," by Dr. J. M. Mathews, Louisville, Ky.; "Treatment of Hemorrhoids," Dr. Charles B. Kelsey, New York; "Treatment of Anal Fistulæ," Dr. J. McF. Gaston, Atlanta, Ga.; "Treatment of Anal Fissure," Dr. Lewis H. Adler, Jr., Philadelphia, Pa.

DR. DAVID POWELL, Marysville, Cal., read a paper on the "Pathology and Symptomatology of Hemorrhoids, Anal Fistula and Anal Fissure."

DR. G. B. SOMERS, San Francisco, Cal., read a paper on "Anal Fistula."

DR. THOMAS W. HUNTINGDON, Sacramento, Cal., read a paper on "Treatment of Anal Fissure."

DISCUSSION.

DR. GEORGE G. SHIELS, San Francisco, Cal.—I came in time to hear the paper of Dr. Somers, and I want to point out the fact that he uses the term membrane, pyogenic membrane, in connection with anal fistula. New the sooner we condemn the use of this term the better. There is no membrane in fistule; there is no such thing as a pyogenic membrane. It is not a membrane in any sense of the term. It does not secrete pus, and I think it is wrong to use it. It is simply going backward to use it, and no man should allow himself to drift into the use of the term, pyogenic membrane. I want individually to condemn that very strongly.

DR. SOMERS—What would you call it?

DR. SHIELS—A mass of unhealthy granulation due to either one or the other condition. The point that I want to make is this, that a membrane is a secreting structure, it is a physiologic structure. You do not find membranes in the physiologic condition like fistule. It is merely the result of a chronic unhealthy condition leading to the formation of unhealthy granulation tissue. The term, pyogenic membrane, has passed out of the vocabulary of the scientific surgeon and is only retained in some of the older descriptive books. And I think it very wrong to use it.

DR. JULIUS ROSENSTERN, San Francisco, Cal.—I would like to make a few remarks on the paper of Dr. Somers regarding the treatment of fistule. I believe that the underlying and emphasizing thought in connection with the treatment of fistula is that it ought to be complete and not left incomplete. As a fact the membrane, as Dr. Somers called it, or rather as I find with Dr. Shiels in condemning the word, the granulations of the tissue ought to be excised and the wound united with buried catgut sutures, and afterward silk-worm gut tissues to unite the mucous membrane in the rectum. I believe that that is the only surgical method of treating fistula in ano. And I do believe that modern surgeons can not do any better than make a radical method of dealing with long standing wounds of that character and long standing fistula in ano, and they should not be satisfied with palliative measures that certainly do

no credit to the operative surgeon and do not relieve his patient very much.

DR. G. B. SOMERS, San Francisco, Cal.—In reference to the term, pyogenic membrane, I do not think that any of us understand it in the old meaning of the term. The old meaning of pyogenic membrane was the secreting membrane that secreted pyogenic matter, the source of pus. In the absence of any better term, in the absence of a substitute for it, that is for the term describing the lining of the canal, it appears to me that this appellation may be retained. I notice that in condemning the use of the word, membrane, the same word was used by the party in describing the structure.

Now in reference to cutting through the sphincter, the statistics, if statistics may be brought into the discussion, show that more than half of the operations for anal fistule in hospital practice result in failure, and it is for this reason that such men as Tuttle have been very anxious about cutting through the external sphincter and have attempted to devise some means of getting around this part of the operation. And in appropriate cases where fistula—say an external fistula may be formed into a conical-shaped cavity it appears the best method to pursue is make the external opening as large as possible, to scrape out the canal, and allow the cavity to granulate from the body.

DR. PRATT, Oakland, Cal.—If Dr. Huntington is present I would like to ask him a question. I notice that he emphasized especially the necessity of thorough dilatation. He said that it would be necessary to dilate several times. I want to know if he meant exactly what he said, or if he meant to say that we would have to dilate several times at that time, or several times on several different occasions. I did not understand his meaning.

DR. HUNTINGDON—What I intended to say and what I think I did say was to this effect, that if the method by dilatation simply was the resort, that in the large majority of cases several attempts at dilatation will be required for the relief of anal fissure. However, it is well known that they have been cured by a single dilatation, and occasionally I believe by a simple dilatation of the anal fissure has a cure been effected. That has occurred in my own experience, and as a rule, with the deep-seated affairs which we deal with more ordinarily than others, I believe that if dilatation be the method of treatment we shall have to dilate more than once; that is, we shall have to make more than one dilatation, and perhaps half a dozen.

DR. KUTZ, California—The statement was made here a little while ago that the best method of treatment was the true surgical proceeding of suture, after laying a fistula open. I hope the gentleman has not reference to all cases. If he practiced in the country where I practice, I think he would let the majority of them alone. I think all tuberculous cases should not be sewed up, for they will not unite. I have tried that in earlier days, and I have corrected my measures. I sewed up none of the tuberculous cases. They never will unite. Other fistulas, non-tuberculous fistulas, if divided thoroughly, may be sewed up, and with excellent results, but tuberculous may be treated openly, by packing with iodoform gauze or some of the other antiseptic gauzes.

DR. JULIUS ROSENSTERN, San Francisco, Cal., read a paper, omitted at the morning session, on "Treatment of Stricture of the Urethra."

DR. THOMAS, Pennsylvania—There are some things in the paper with which I am well pleased, and there are some others to which I take exception. In regard to the numbers of the sounds used in the treatment of the urethra, I think the French numbers should always be used, because the American numbers, as well as the English, are arbitrary; they mean nothing, while the French numbers always mean exactly what they enumerate.

The gentleman spoke of the use of cocain on the urethra before the use of the sound. My experience shows that the use of cocain before the use of the sound in the urethra is of very little value. Where you wish to make an incision in the mucous membrane of the urethra, cocain is then a very serviceable and useful medicament, for this reason, that in excising the mucous membrane the cocain has benumbed the sensibility, and you can cut the mucous membrane without producing pain; but in the introduction of the sound, the sensation of the sound goes far beyond the mucous membrane, and you will derive no benefit from the use of cocain in the introduction of the sound. I have observed this time and time again, so that I have discontinued the use of cocain before the use of the sound, which is always used before incising.

The gentleman is not apparently in favor of internal

urethrotomy. I agree with him, however, in the view that you can attain this by continual dilatation, and more particularly so if the stricture is of small caliber. My experience is that you can gain space for a certain distance much better, that when you get up near the circumference of the urethra your sound does not have as much effect in reducing it as it does early in the structure, for this reason, that you simply press that tissue in the sphincter, and hence you do not get the absorbing effect of the sound in these strictures of smaller caliber that you do in the case of the larger strictures. And again there are strictures that will not absorb, that may pass a sound to-day, and in three days you may fail to pass the sound which you first passed. And we can keep that up for weeks, and if we so treat our patient we are doing him no good. Now in these cases internal urethrotomy is absolutely necessary, and I do not think you can cure the patient in any other way.

With regard to divulsion of strictures of the urethra, the general opinion of the profession is against divulsion in stricture of the urethra. I never use divulsion in the anterior urethra myself, but I do wish to express a favorable opinion with regard to divulsion in certain cases, and I do this from experience. If we can relieve a man of trouble of that kind as safely, as surely by divulsion as we can by cutting, then in those cases why not divulge? I am sure that the consensus of opinion of urethral surgeons to-day is that divulsion is not a safe operation. But it is a safe operation if carefully done, and we could do it just as satisfactorily as cutting.

With regard to electrolysis, some few years ago I wrote two or three articles upon that subject for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, because I had not entered into the subject of electrolysis with a good deal of enthusiasm, and I went into it by reading the articles of those who pretended to treat in that way. I experimented for one year upon the treatment of strictures by electrolysis. And as I have said I can not see the philosophy of treating the strictures in the deeper portions of the body and curing them, when you can not cure them on the surface, the same with fibroid tumors on the deep parts of the body, when you can not cure them on the surface. So I think that in treating strictures by electrolysis the effect is absolutely *nil*.

DR. THOMAS W. HUNTINGDON, Sacramento, Cal.—I have been accustomed for a long time to state to my patient and to his friends that I was thoroughly convinced no operation was trivial to the patient. I believe we surgeons should add to that, that no operation should be considered trivial to the surgeon. Following out this idea, and applying it to the subject which has been introduced to us this afternoon, I am just as certain that no procedure which involves a dealing with the male urethra is ever trivial. I care not what it be. We have records of deaths from the passage of the catheter. We have records of very serious trouble from the introduction of the ordinary steel sound. There is no operation which can be regarded as perfectly safe when you come to deal with the male urethra. I have been, and am yet an ardent advocate of internal urethrotomy under many conditions, not under all, and I certainly hope that it will not go out from this meeting and from this Section as its opinion, that internal urethrotomy has lost its function and has passed into oblivion. I believe that as long as any of us live, as long as surgeons operate at all, internal urethrotomy will be a resort of every surgeon, or many surgeons who are doing excellent and efficient service.

The question arises in dealing with a stricture, Why are we called upon to deal with it at all? And I think that the answer may be divided into two parts, or it may be dealt with under two heads: 1, to relieve the retention of the urine; 2, to relieve a nasty, persistent and almost incorrigible discharge. I think that covers the ground mainly of the necessity for dealing with the male urethra under those conditions. It goes without saying that where there is retention with a minimized stricture that something radical, something immediate is the requirement, and under those circumstances I should certainly have no particular choice as to the method of immediate relief from the patient. If it can be obtained by gradual dilatation, dilatation which is done in such a manner as to render efficient service within a comparatively short time, I should certainly have no objection to that method; but where we have a minimized stricture, a stricture of small caliber which has once caused retention of the urine in a patient of medium age, I believe that just so sure as we deal with it otherwise than by very radical methods we shall have a return. And I mean by very radical methods, either persistent, long-continued dila-

tation by sounds or internal urethrotomy. I say nothing of divulsion because I do not practice it, and I can not speak with any authority upon that subject. I should in these cases regard myself as subject to rules of gradual dilatation or immediate incision, and I chose the latter. I chose it for this reason, that the stricture once thoroughly incised, then placed upon stretch, watched for a period of from ten days to two or three months succeeding that operation, can be placed in a condition where it will probably never become a narrow stricture again. I do not wish to advance the doctrine that cutting a stricture is a cure absolutely, but it places it in better condition to be handled by the sound.

In regard to the second cause for the use of treatment in this diseased condition with continuous diseases, I have found repeatedly that where we have a stricture of comparatively large caliber, a stricture that may readily admit from 18 to 22 of the French sound will maintain obstinately a discharge when it has been dilated up to a 32 or 33 French measurement, and I find that it is in many cases absolutely essential to do something else than gradual dilating; that these cases are amenable to the cutting process. I have cured quite a number of cases; I believe I have a record of sixty odd cases of internal urethrotomy, and they have proved almost without exception exceedingly satisfactory.

DR. THOMAS, Washington—I was taught only a few years ago that it was never wise to pass the sound into the bladder when sounding the urethra, as Dr. Rosenstirn said in his article. About a year ago a young man consulted me with stricture in the anus and I used Post's (?) method, and followed it by dilatation until I could pass a French sound. I kept that up for several months, until I was sure I had made a permanent cure and told the young man so. Lately I was called to treat the same man for appendicitis, and I found that the stricture was there yet and in the shape that a No. 9 catheter will not pass through. I mention this to show, in deep strictures the necessity of being sure that your treatment is complete.

DR. W. T. DODGE, Mich.—I wish to say that my experience has been so satisfactory in internal dilating urethrotomy that for the past five years I have used no other methods. I have seen more severe reaction follow the passage of the sound than I have ever seen follow the use of internal urethrotomy. In the same patients I have on first examination passed a sound and had hard chills, fever and very severe symptoms follow in a few days. I have done internal urethrotomy, and no reaction has occurred. After urethrotomy the sound should be passed, the patient should be furnished with the sound, and he should be expected to use it. If the surgeon expects to effect a permanent cure by his operation of urethrotomy and does not give his patient proper instructions as to the passage of sounds thereafter he will meet with disappointments, for these strictures will return. But if the proper directions are given for the use of the sound and they are properly carried out it is impossible for a stricture to return. The sound should be passed at least once a week, and the patient to be instructed to pass it at intervals of a month for the first year, and always occasionally to pass a sound and be sure that the constriction is not returning. In strictures of the deep urethra I have used divulsion with considerable satisfaction. I have been so well satisfied that I hesitate to make use of any of the old methods of gradual dilatation, and I have never experimented with the electrical treatment.

ADDRESS.

THE ADDRESS OF WELCOME

AT THE GRADUATING EXERCISES OF THE FOURTEENTH
ANNIVERSARY OF THE COLLEGE OF PHYSICIANS
AND SURGEONS, BOSTON, MASS.,
JUNE 20, 1894.

BY AUGUSTUS P. CLARKE, A.M., M.D., DEAN.

It now becomes my pleasant duty to extend, in behalf of the College of Physicians and Surgeons of Boston, a hearty welcome to all who have come here to witness the graduating exercises of the class of 1894.

It is upward of fourteen years since this College was founded and took up the work of its noble mis-

sion in thus offering to men and to women, alike, opportunities of pursuing a regular and systematic course of practical training in the science and art of medicine and surgery which had gradually been developing, and which have come as a priceless heritage from the great masters of this beneficent profession adorning the ages and generations preceding us.

Our ever accumulating wealth and increasing population, our closer intimacy in the varied relations of life and our adoption or employment of so many inventions have tended to multiply in no small measure, dangers to life and limb and to scatter broadcast the seeds or germs of disease that are everywhere prolific in the earth, in the water, and in the air round about us.

That we should have at hand, to employ with the greatest dispatch, the means and remedies for overcoming these diverse factors adverse to our health and to our soundness of being must be obvious to all. So far as our own school is concerned, it gives me much pleasure to say that it is fulfilling its share of the work intrusted to its charge and that it is giving promise of a brilliant future.

Co-education in the profession of medicine is no longer in its elementary stage, but its trial has long since demonstrated the fact that its adoption can be of the greatest advantage to both sexes, and that the percentage of attainment by the female student, even in the most difficult branches to master, is often indicative of great industry and of original powers for observation.

The corporate capacity of our College is strong; the members of its Faculty are learned, able and earnest; they will compare favorably with those in schools of the best appointment. We are also fortunate in having on our list of active professors the names of lady physicians and surgeons of exceptional ability and reputation. Furnished with such equipments who will say that we shall not continue our service?

There is no more noble profession than ours; the student can be engaged in no higher mission than that of preparing himself for rendering relief to his fellow creatures. To whatever branch of the healing art he may turn his attention he will there find an abundance of evidence that the ground has already been pressed by the footsteps of the great and good.

There is always an innate satisfaction and exceeding joy, or I might rather add there is an immediate fullness of fruition that flows into one's whole being when a real attempt is made to scan the heights and depths of research and achievement accomplished by the men of genius who have gone before. The wise sayings of Socrates, as portrayed by his pupil the immortal Plato, are no more replete with life-giving principle than are the aphorisms of his contemporary, Hippocrates, the father of medicine. The rapturous perorations of Cicero when addressed to our understanding and common needs bespeak no more helpful strains than do the writings of the good physicians, Celsus and Galen. Newton's discovery relating to the celestial spheres and Bacon's philosophy by induction and the demonstrations of the whole galaxy of the lesser lights in their work in this direction, though most important as mile stones set to mark the onward progress of human thought, have not been more efficient in ministering to our necessities than has been the discovery of the circulation

of the blood by the celebrated Dr. Harvey, and have been by common consent of infinitely less moment in intrinsic value than has been the discovery of the anesthetic properties of ether as first demonstrated by Dr. Morton in this our metropolis of New England.

The medical student in advancing upon his professional studies, will have for contemplation the mighty achievements left as abiding witnesses of the zeal and industry of such savants as Eustachius, Vesalius, Malpighi, Boerhaave, Albinus, and Williams and John Hunter, and a host of others, to say nothing of the great workers who have given possibility to results not heretofore obtained in obstetrics, gynecology and abdominal surgery.

I refer to the invaluable contributions by McDowell, of Kentucky; by Sims, by Emmet, by Peaslee, by Dunlap, all in our own country, and to the deductions and demonstrations of M. Lemaire and of M. Pasteur, of Paris, and to those of the elder Simpson and of Lister, of Scotland, and to the long list of contributors who have worked on German soil and whose names will ever shine in more resplendent glory than will the names of the greatest European kings.

I should not detain you longer with such recital and with further remarks of my own; but my official position prompts me to extend to you again a most cordial welcome, and to add to this our warmest salutation the following German sentiment which I trust may not be deemed inappropriate:

"Möge jeder Tag mehr dazu beitragen, volles Verständniss und Wahre Freundschaft, unter uns allen zu fördern." (May each day be helpful in advancing us to a full understanding, and in establishing among us true friendship.)

SOCIETY PROCEEDINGS.

American Surgical Association.

Annual Meeting held in Columbian University Building, Washington, D. C.

FIRST DAY—TUESDAY.

The Association was called to order by the President, Dr. J. EWING MEARS, of Philadelphia, who delivered the President's Address. In this was considered only matters of interest to the Fellows of the Association, referring to the previous work of the Association, and the methods of best carrying on the work of the society.

The Secretary, Dr. J. R. WEIST, on behalf of the President presented the Association with a gavel which had been made from a portion of the office chair of Professor S. D. Gross, the founder of the Association. This was accepted with the thanks of the Association.

The first paper was entitled,

THE SURGICAL TREATMENT OF EMPYEMA,

by Dr. JOHN ASHURST, JR., of Philadelphia.

The following summary was presented:

1. No operation is justifiable unless the presence of pus is certain; unless thorough treatment by medicinal agents, blisters, etc., has failed; or unless the symptoms, dyspnea, etc., are so urgent as to demand immediate relief.

2. The first operation should consist of simple aspiration, with antiseptic precautions.

3. When the fluid has partially re-accumulated, as it almost certainly will do, if purulent, incision and drainage should be practiced.

4. Drainage is best effected by making two openings, one at the lowest point, and carrying a large drainage tube through the cavity from one opening to the other.

5. Drainage should be supplemented by washing out the cavity with mild antiseptic fluids; when the lung has expanded and the discharge has nearly ceased, the tube should be shortened, the upper opening being allowed to heal, and

the tube then being gradually withdrawn through the lower opening.

6. When the lung is so bound down by adhesions that it can not expand, resection of two or more ribs should be practiced (Estlander's operation, so-called) in order to allow collapse of the chest wall and to promote healing by bringing the costal and visceral layers of the pleura into contact.

7. The more extensive operations of Schede and Tillmans, while probably justifiable in exceptional cases, are not to be recommended for general employment.

Dr. CHAS. B. NANCREDE of Ann Arbor—did not see the advisability in cases where pus was shown to be present by aspiration, of limiting the treatment to this operation. It is held that in a few cases this will be followed by cure, but he had never seen such a case. Where pus is present he preferred to immediately provide for its permanent evacuation. He called attention to the danger of the drainage tube becoming occluded by the pressure of the ribs and he believed that in empyema of long standing some form of excision of the ribs should be employed.

In irrigation, if the pus is not too much contaminated, sterilized water is sufficient, but if necessary an efficient antiseptic solution may be used and if there is fear of absorption, the chest can afterwards be flushed with sterilized water.

If provision is made for the free escape of pus, he had seen no necessity for the removal of large segments of ribs.

Dr. T. F. PREWITT, St. Louis—thought that the rule that no operation is justifiable unless the presence of pus is certain, needed modification. As a rule, we can now determine only that fluid is present and can not be sure that it is pus. He thought it advisable to aspirate even when serous fluid is present. If thorough antiseptics is maintained this can do no harm. He had never seen it result in the formation of pus, and this method greatly shortens the duration of the disease. In empyema in children he had seen several recoveries follow aspiration but never in adults. In children the pus does not seem to possess that thick clotting character so common in adults, and which requires a free opening. In empyema in adults he invariably resects a rib, sometimes two ribs.

Attention was called to the great necessity of caution in the administration of anesthetics in cases of this affection.

As to washing out the cavity, he always does that, using a weak solution of bichlorid of mercury.

Dr. DEFOREST WILLARD, Philadelphia—It seemed to him that the whole question was one of thorough drainage of an abscess cavity. Whether or not the ribs should be excised is to be determined by the question of securing free drainage. In children the ribs are so close together that removal of a portion of ribs is usually required. In the early treatment he favored the use of a clean aspirator rather than to compel nature to cause the absorption of a large quantity of fluid. Such operation does no harm and saves several weeks in time. He believed that washing as a routine measure did more harm than good. If the pus is decomposing it indicates that freer drainage is needed. If strong antiseptic solutions are employed there is danger of renewed inflammation.

Dr. JOHN E. OWENS, Chicago—called attention to the necessity when evacuating pus from the chest, or washing out the pleural cavity, of changing the position of the patient during the process in order that all the pus may be removed.

Dr. CHRISTIAN FENGER, Chicago—considered that there were certain cases in which Schede's operation was required. Its place was after milder measures such as incision, drainage, and Estlander's operation. He reported a successful case where this operation was performed after other measures had been resorted to during seven years.

Dr. ROSWELL PARK, Buffalo, N. Y.—thought that the treatment of empyema should be based upon the same principles as are applicable to other abscesses. In acute cases where we have to deal with streptococcus and staphylococcus forms of suppuration, it may be sufficient in a few instances to simply aspirate. A large proportion of cases of empyema, however, are essentially cold abscesses—tubercular abscesses. In these cases free incision, free drainage and excision of a rib is required. In certain cases he had resorted to scraping with the sharp spoon, and in some had cauterized the diseased surface with 50 per cent. solution of chlorid of zinc. He reported several cases where death would have occurred had it not been for some such radical operation.

Dr. W. H. CARMALT, of New Haven, Conn.—asked how far it was justifiable to go in the way of resection of ribs in these cases? He reported a recent case in which he had

removed portions of five ribs, the longest piece excised being four and one-half inches. In these cases, it is necessary to remove enough of the chest wall to permit of obliteration of the cavity. He had also used the sharp spoon in order to secure a fresh surface.

DR. M. H. RICHARDSON, of Boston, Mass.—said that the questions that arose in the treatment of empyema were different from those in ordinary abscess, for in the former condition we have an abscess with rigid walls. With regard to drainage, he had used double tubes provided with valve, but considered them inapplicable and liable to cause increased trouble, for when air or pus is forced out through the tubes by coughing, a vacuum is established and the valve is held against the chest wall, preventing drainage. He believed that Estlander's operation was applicable only to certain forms of cavity and that there were certain cases where the cavity involves a large portion of the thorax, in which the operation of Schede is the only one applicable after a failure of Estlander's operation.

DR. STEPHEN F. WEEKS, of Portland, Me.—thought that the rule of Dr. Ashurst to aspirate, especially in children, was a good one. Sometimes that will result in cure. The tuberculous cavity is to be treated differently than the cavity where this condition does not exist. Thorough drainage is sufficient in many cases. He called especial attention to drainage by packing the cavity with sterilized gauze. In twenty-four hours he removes the gauze and washes out the cavity.

DR. L. McLANE TIFFANY, of Baltimore, Md.—considered that the treatment of acute empyema was of more importance than that of the chronic form, as it was the more common. The most important point as bearing upon treatment and prognosis is the character of the pus and its bacterial cause. The reason that the child's empyema often yields to aspiration is that in many of these cases the pus is simply a pure culture of the pneumococcus. In the adult we rarely have the pneumococcus form. Here we have a mixed infection. If the empyema is of the amœbic form the patient dies. If empyema is due to the streptococcus, the odor is offensive and the cavity needs to be carefully washed out. If empyema is due to the staphylococcus washing out is not required. When there is time he prefers to withdraw some of the fluid with the hypodermic syringe and have it submitted to bacteriologic examination.

While he uses ether in general work, in these cases he prefers the use of a few whiffs of chloroform, which appears in these cases to have a peculiarly happy effect. Only a very small quantity is employed.

The employment of respiratory gymnastics is of much benefit in favoring the expansion of the contracted lung.

DR. JAMES McFADDEN GASTON, of Atlanta, Ga.—referred to the natural tendency for the empyemic cavity to open spontaneously in the anterior part of the chest. He reported two cases in which this spontaneous opening had occurred, followed by recovery.

DR. W. W. KEEN, of Philadelphia, read a paper entitled:

AMPUTATION OF THE ENTIRE UPPER EXTREMITY (INCLUDING THE SCAPULA AND CLAVICLE) AND OF THE ARM AT THE SHOULDER-JOINT, WITH ESPECIAL REFERENCE TO METHODS OF CONTROLLING HEMORRHAGE; WITH THE REPORT OF ONE CASE OF THE FORMER AMPUTATION AND FOUR OF THE LATTER.

In this paper were considered: 1, those amputations which allow of simple disarticulation at the shoulder-joint itself; 2, those cases in which the axilla is invaded, yet to such an extent as to allow of its being thoroughly cleaned out, followed by amputation at the shoulder; and 3, those in which removal of the entire upper extremity including the scapula and clavicle is required.

Simple amputation at the shoulder-joint: Here the control of hemorrhage is the key to the situation. The methods for the prevention of hemorrhage are first, those applicable to the subclavian vessels, and second those applicable to the axillary. Most text-books recommend compression of the subclavian by the thumb or well-padded key. Dr. Aldis has modified this method by substituting a stick eighteen inches in length with a pad of sterilized gauze at its extremity. This obviates the danger of slipping and can be applied without fatigue on the part of the operator. The author had suggested compression by means of a solid pad held in position by an Esmarch bandage passing over the perineum, but on trial in the case of a child this had proven unsatisfactory. A third plan consists in ligation of the subclavian artery. This is objectionable on account of the necessity of

resecting the clavicle in order to ligate the vein, and if the vein is not ligated there is danger of the entrance of air.

Axillary methods: 1, those in use prior to the introduction of Esmarch's tubing; 2, different methods of using Esmarch's tubing. Under the first head we have: *a*, compression of the inferior flap by the fingers which seize the vessels before they are cut; *b*, Harvey's method by compression of the vessels by means of a padded ruler thrust into the axilla; *c*, ligation or seizure of the vessels with hemostatic forceps before they are cut; *d*, Gross' compressor, but practically this is never used; *e*, Furneaux Jordan's method by making a circular amputation at the surgical neck, securing the vessels as in a hip-joint amputation, the blood vessels having been compressed by an Esmarch band or other method, followed by disarticulation of the upper end of the humerus.

Under the second head are: *a*, after making the antero-external flap, a stout pin is passed through the postero-internal flap between the vessels and the bone and elastic tubing wound over the ends of the pin. In this method there is danger of the vessels retracting above the constricting band; *b*, Esmarch's method in which an elastic tube is placed in the axilla and drawn tight over the shoulder, where it is grasped by the hand of an assistant. This is open to the danger of slipping of the bandage after disarticulation of the bone; *c*, Morre's method. In this method the tubing is applied as in the Esmarch method, but is held in place by a bandage passing around the chest and under the tubing in front and behind; *d*, Wyeth's method by pins and elastic tubing. In this method the operation is performed as follows: The arm is held at a right angle to the body. The sharp-pointed cylindrical pins, eleven inches long and one-fourth of an inch in diameter, are used. The anterior pin is introduced through the middle of the anterior axillary fold at a point a little nearer the body than what may be called the center of the fold transversely. The point of emergence is of much greater importance than the point of insertion; this should be one inch within the tip of the acromion. The second pin is introduced at a corresponding point through the posterior axillary fold, emerging an inch within the tip of the acromion. The point of emergence is of importance, for if the pin emerges near or at the tip of the acromion, the moment the head of the humerus is removed, the tubing is apt to slip downward and compress the two flaps against each other, thus hiding the cavity and permitting the vessels to retract. The pins being in position a piece of rubber tubing is wound around the axilla and shoulder on the hither side of the pins. The disarticulation having been effected, the main vessels and all visible vessels are tied and the tubing removed, the vessels spurting being grasped with hemostatic forceps. The author considers this the most satisfactory method of controlling hemorrhage, and he felt confident that any one who adopted it would abandon all other methods in its favor except, possibly, in emergency cases.

Amputation at the shoulder joint in cases in which the axilla is invaded so high that Wyeth's pins can not be used. In 1812, Dalpech proposed to make "an oblique incision extending from the external third of the clavicle to an inch above the inferior border of the great pectoral muscle. We thus discover and can cut near to its origin on the coracoid process of the scapula, the lesser pectoral. The index finger is then carried through the cellular tissue along the serratus magnus, then the subscapular, and is used as a hook in order to draw outward the mass of vessels and nerves. The artery is found in the anterior portion of this mass. The artery and vein are then ligated. The advantages of this method are that it gives wide access to the axilla, that we can determine with ease how far and how great is the invasion of the axilla, and if thought advisable, the operation can be abandoned at this point, or if it is decided to proceed with the operation the incision already made serves as the inner part of the deltoid incision. The author had employed this method with great satisfaction in a case where a sarcoma of great size had invaded the axilla nearly to the clavicle.

As a rule, recovery from this operation follows in from two to three weeks. The mortality in the more recent operations has been extremely low,—one in fourteen. Again by this method we can often amputate wide of the disease in consequence of the relative smallness of the flaps required. In view of these facts the author urged that in all cases of malignant disease of the upper end of the humerus, or even of the lower end when it is already diffused, we should not content ourselves with mere amputation at the shoulder joint, but should at the same time extirpate the scapula and clavicle.

The author reported a case in which the arm, scapula and clavicle were removed for myeloid sarcoma, occurring in a woman aged 20 years. The operation was done Nov. 20, 1893. The patient recovered and is still perfectly well.

DR. ROSWELL PARK, of Buffalo, N. Y.—said that he had had two cases of total removal of the upper extremity both of which had been successful. One was for railroad injury and the other for extensive epitheliomatous ulcer. In the first case the clavicle was already broken and the subclavian vessels were secured at the point of fracture. In the second case the clavicle was divided and the vessels tied.

DR. CHAS. B. PORTER, of Boston, Mass.—as an illustration of the rapidity with which malignant disease may advance, reported the case of a patient with sarcoma of the radius where the arm was amputated above the elbow. The disease soon recurred and amputation at the shoulder-joint was made and again the disease (sarcoma) recurred so high up that no operation could be employed. The whole history of the case extended over only one year after the first operation. A case was also reported where the arm had been torn off in a railroad accident where he had subsequently removed the scapula and outer portion of the clavicle by an osteoplastic resection and the sound was closed by skin grafts. Three months later a hard plate of bone had formed very similar in shape to the scapula.

DR. JOHN ASHBURST, JR., of Philadelphia—said that he had once used the Wyeth pins satisfactorily in an amputation at the shoulder-joint. Another device to which he had resorted in several cases was to make the incision in the lower flap from without inward and secure the vessels in the wound.

SECOND DAY—WEDNESDAY.

The first paper read was that of DR. J. S. BILLINGS, Surgeon U. S. A., on

METHODS OF TEACHING SURGERY.

There are two classes of students: 1, the average medical student who is presumably to become a general practitioner; and 2, those who wish to specially fit themselves for surgical work. For the first class the work should be divided between the professors of pathology, of surgery, of clinical surgery and demonstrations. Such students should be taught diagnosis and the best methods of treatment of the injuries and surgical diseases which the general practitioner is most often called upon to treat.

Taking up the question, "How are these subjects to be taught?" we find that there are five principal methods: Didactic systematic lectures, recitations, demonstrations and practical instruction by means of manikins, cadavers and animals, theoretical clinical lectures in the amphitheater, and practical clinical instruction in ward classes.

In the old-fashioned type of medical school, the professor of surgery taught the principles of surgery, gave considerable attention to surgical anatomy and was as well the teacher of clinical surgery. At the present time in a large medical school, the subject of surgery is subdivided among a number of teachers, and under these circumstances the difficulty is to avoid useless repetitions and embarrassing contradictions, and at the same time cover the whole field of surgery. There should be a professor of pathology and the relations between him and the surgeon should be intimate and friendly, while each should be independent of the other. As regards the teaching of surgical anatomy by a teacher distinct from the professor of surgery and the professor of anatomy, there is considerable difference of opinion.

Clinical teaching is the most attractive to the average student and is often the most useful to him because he remembers it better, but as a rule clinical material is not available to cover the whole field and it is therefore necessary to add some systematic didactic teaching. This didactic teaching may cover the whole field, the clinical teaching illustrating the didactic lectures. In this way the student has the benefit of the repetition. Undoubtedly the more clinical instruction of the right kind that can be given, the better for the student and for the school. There is no doubt as to the great utility and popularity of teaching to small sections or ward classes. In employing this method care must be taken that the people do not get the idea that in a teaching hospital the interests of the patients are not as fully consulted as they should be.

Recitations and quizzes are excellent methods of teaching for the majority of students, but are only well adapted to small classes. It appears more desirable that these should be applied to the clinical teaching than to the didactic lectures.

In the clinical and didactic lectures too much of the history and literature of surgery should not be included, but every school should have a course of lectures on these subjects including bibliographical methods.

The man who intends to be a surgeon should not only make a special study of surgical anatomy but should do a considerable amount of practical laboratory work in bacteriology, pathologic histology and experimental pathology and physiology. Much of the operative technique can be learned on animals, but much of it requires work on the cadaver with frequent repetition. Of great importance is residence in a hospital.

The author suggested that perhaps too much time was devoted to embryology and morphology as a basis of the study of anatomy. The study of anatomy should be kept up throughout the course and made a part of the final examinations.

In concluding, the author asked: "Would it not be good policy for a first-class popular medical school to limit the number of pupils which it will accept to its capacity to give them proper instruction in laboratory work in practical anatomy and in clinical medicine and surgery?"

This was followed by a paper by DR. JOHN CHIENE, of Edinburgh, on

THE TEACHING OF SURGERY.

In discussing this subject one must begin with a warning: The personal equation relating to himself and the traditional equation relating to his school must be allowed for and discounted. The teaching of surgery resolves itself into two heads:

1. Systematic consideration of general principles illustrated by clinical examples.

2. A clinical—bedside—opportunity given to observe, to use and to educate all the faculties, physical and psychical.

Under either head the teacher must be a learner; the student must be a teacher. The teacher has constantly to warn the student against a blind belief and at the same time he has to speak most decidedly in giving his opinion. The practice of surgery to be successful must be dogmatic. It has been objected to systematic lectures that now that we have books there is need of a hundred lectures on every subject. Those who hold these views can never have known the stimulus of speech; can never have felt the electrical impulses passing between hearer and speaker.

The method of teaching surgery in Edinburgh was then described.

In conclusion, the writer wished to add a word with reference to the teacher of surgery. He believed in a fallow time, in a time of rest from mental activity. The best rest is change of scene. He suggested the advantages that would accrue from an interchange of chairs in the great English speaking educational centers. In this way once in seven years a teacher would for a session leave his alma mater and speak to the students of another school. Or the fallow might take another aspect; give a teacher a session off every seven years and let him do in it what seems to him good.

The discussion of these papers was participated in by Dr. J. Collins Warren, of Boston; Dr. W. W. Keen, of Philadelphia; Dr. Hunter McGuire, of Richmond, Va.; Dr. Chas. B. Nancrede, Ann Arbor, Mich.; Dr. P. S. Conner, Cincinnati, Ohio; Dr. W. S. Forbes, Philadelphia, Pa.; Dr. Robert F. Weir, New York, N. Y.; Dr. T. F. Prewitt, St. Louis, Mo.; Dr. John E. Owens, of Chicago, Ill.

SURGERY OF THE KIDNEY.

By DR. L. McLANE TIFFANY, of Baltimore. The subject was such a large one that the author considered only those points which offer opportunity for difference of opinion. In the human body, bilateral organs are more than sufficient for the carrying on of life; not only may one such organ be removed without impairing existence, but even the remaining organ may be more or less damaged and yet life be carried on. Any paper on surgery of the kidney at the present day must take into consideration the influence of disease of the kidney on various operations on general surgery. The influence of anesthesia on the healthy kidney should be considered. In 150 cases of operation where healthy kidneys were present, albumen was found only in 2 per cent. of the cases after operation. Every case of railway accident and in some other cases where the patient had been exposed for a certain time, showed albuminous urine on admission to the hospital. In these cases operation has not been deferred on this account. Cases of advanced diabetes have not been operated on. In cases with healthy kidneys the amount of urine passed in twenty-four hours following operation is

diminished in quantity, the specific gravity usually being a little higher.

In the early stages the difficulty of diagnosis is great; especially is it difficult to recognize whether the trouble affects one kidney or both. Here it is that the cystoscope offers great opportunity. A moderate amount of urine, with a low specific gravity and an habitual low temperature independent of the condition of the pulse are danger signals more important than any other. In the recognition of the kidney affected we have to rely on pain, pressure and the cystoscope. The treatment before operation consists in exciting the kidneys to secrete by means of infusion of digitalis, acetate of potassium and infusion of buchu. Acid urine and pus suggest pyelo-nephritis very strongly. It is the author's habit not to operate until the patient's kidneys are acting well. After operation strychnin hypodermically is a useful addition to the previous treatment. The hot air bath has proven unsatisfactory in chronic cases.

When an operation on the bladder is called for and there is evidence of disease of one kidney or decided pain in one kidney suggesting disease, that kidney should be operated on at the same time as the bladder. Twice the speaker had done lithotomy in stone in the bladder, the lithotomy being done and the kidney opened at one and the same sitting. All went well. In another stone case, within two weeks acute suppurative inflammation took place and was followed by death. In a second case there was a similar occurrence.

SURGICAL TREATMENT OF SURGICAL KIDNEY.

This paper was read by DR. ROBERT F. WEIR, of New York. Suppurative pyelo-nephritis, suppurative interstitial nephritis and surgical kidney are the ordinary names given to a disease which originating as a rule in the bladder generally affects both kidneys. In this affection the kidneys are congested and studded with foci of pus. Dr. Delafield states that: "So far as I know all cases die."

It is difficult to say how often the affection is limited to one kidney, but this may not be infrequent. Even where both organs are involved it may be that something may be done for the relief of tension and the egress of pus by means of free incision made into the kidney substance.

With the happy experience of this case, the reader considered it hereafter justifiable, if the patient's general condition would warrant it, in a case of acute septic invasion of the kidneys, to make on one or both sides an exploratory incision not only in the hope of relieving the acute interstitial invasion, but also of perhaps encountering a larger and well defined focus of pus—which pathologic condition can not always be readily discriminated from the more dangerous lesions of the veritable surgical kidney. Should the symptoms point, as in the case narrated, to one kidney only, or should a double exploratory incision show the same result, a nephrectomy may with some hope be resorted to.

SURGERY OF THE URETERS.

By DR. CHRISTIAN FENGER, of Chicago. Accidental wounds and subcutaneous ruptures of the ureter have not as yet been objects of direct surgical procedure, upon the ureter at the seat of lesion.

Catheterization of the ureters from the bladder for the purpose of diagnosis has given valuable information. The procedure is reasonably practicable in the female. In man catheterization is practicable only through epicystotomy.

Catheterization of the ureter from the bladder as a curative measure for the evacuation of hydro- or pyonephrosis, has occasionally been performed. This is more difficult and uncertain than nephrotomy and the attempt to find and remedy the stenosis of the ureter from the pelvis of the kidney.

Dilatation of strictures of the female ureter by elastic bougies has been tried from the bladder with temporary success, and from the pelvis of the kidney successfully.

Permanent catheterization of the ureter from the bladder, a fistula or an implanted ureter is often tolerated only for a limited time and must be employed with caution.

Uretero-lithotomy is a safe operation by the extra-peritoneal method.

Intra-peritoneal ureterotomy should be done only when access outside of the peritoneal cavity is impossible, and should be completed by careful suturing, covering with omental or peritoneal flap and drainage.

Opening of peritoneal cavity to locate the seat of stone may occasionally be necessary, but when the diagnosis is once made ureterotomy should be done by the extra-peritoneal method.

In valve formation or stricture of ureter causing pyo- or hydronephrosis or a permanent renal fistula, nephrotomy

should be followed by exploration of the ureter. This is to be done by a long flexible silver probe or an elastic bougie. The size of a bougie that will pass a healthy ureter is from No. 9 to No. 10, French scale.

Loss of substance of the ureter too extensive to permit of uretero-ureterostomy or too high up to permit of implantation into the bladder may be treated by implantation in the skin or into the bowel. Implantation into the bowel is objectionable. Implantation on the skin in the lumbar region may have to be followed by secondary nephrectomy, which, however, is much less dangerous than the primary operation.

The discussion of these papers was postponed until Thursday morning.

EXECUTIVE SESSIONS.

THIRD DAY—MAY 31.

Officers elected: President, Dr. F. S. Dennis, of New York. Vice-Presidents, Dr. J. R. Weist, of Richmond, Ind.; Dr. J. B. Roberts, of Philadelphia; Secretary, Dr. M. H. Richardson, of Boston; Treasurer, Dr. N. P. Dandridge, of Cincinnati, Ohio; Recorder, Dr. DeForest Willard, of Philadelphia; Member of Council, Dr. T. F. Prewitt, of St. Louis, Mo.

The next meeting will be held in New York City. Dr. Dudley P. Allen, of Cleveland, Ohio, was elected to membership.

The following were elected to honorary membership: Sir Spencer Wells, F. R. C. S., London, Eng.; Dr. William MacEwen, Glasgow, Scotland; Dr. M. H. E. W. Schede, Hamburg, Germany; Prof. Ernst v. Bergman, Berlin, Germany; Prof. Karl Thiersch, Leipzig, Germany; Prof. Theodor Kocher, Bern, Switzerland; Prof. Jules E. Péan, Paris, France.

DISCUSSION ON PAPERS ON RENAL AND URETERAL SURGERY.

DR. M. H. RICHARDSON, of Boston—emphasized the importance of examination of the urine prior to all operations. In regard to the method of performing nephrectomy, he dwelt upon the abdominal method, the incision being made in front laterally. This enables the operator to control bleeding which is the chief source of danger in the operation. In this method the surgeon is able to determine the presence or absence of the other kidney. He believed that by this method the mortality of nephrectomy would be greatly reduced by so providing for hemorrhage that it could not be an element in the mortality.

DR. H. H. MUND, of St. Louis, Mo.,—agreed with Dr. Tiffany that in traumatic lesions of the kidney, even gun-shot and stab wounds it is not always necessary to do nephrectomy. He had seen such cases recover. He had also met with a number of cases of extensive laceration of the kidney from contusion, in which there was no external evidence of such injury. In many of these cases recovery without operation. Where operation was needed he believed that partial nephrectomy was justifiable. If necessary a secondary operation can be done. The removal of kidneys so injured, as a primary operation is apt to be disastrous.

In pyelo-nephritis and renal lithotomy the first operation should be tentative, consisting of incision and evacuation, the kidney being allowed to remain; a secondary operation being performed if necessary. He did not favor the abdominal incision for the removal of the kidney on account of the risk of infecting the abdominal cavity in suppurative conditions of the kidney, and because the lumbar incision was usually sufficient and if necessary it could be extended and the abdomen opened.

DR. T. F. PREWITT of St. Louis—called attention to several cases of renal stone, laceration, etc., coming under his observation. One of these cases was that of a man who had passed scales of stone by the urethra and in whom operation showed a stone in the pelvis of the kidney, with several small detached particles. He was unable to offer an explanation of this separation. With regard to diagnosis, he held that a large amount of pus, with a small amount of mucus in the urine indicated that the trouble was in the kidney rather than in the bladder.

DR. STEPHEN H. WEEKS, of Portland, Me.—reported a case of a man who developed an abscess in the groin after having had symptoms of renal colic some months before. On opening this abscess, pus was discharged and subsequently a small calculus was passed. No urine was discharged through the abscess at any time. The sinus has since almost healed.

DR. WILLIAM H. CARMALT, of New Haven, Conn.—reported the case of a woman on whom it was thought nephrectomy might be required. On preliminary examination through an abdominal incision only one kidney could be discovered.

The patient died three years later and autopsy showed that the second kidney was located in the pelvis.

THE TREATMENT OF MALIGNANT DISEASE WITH THE
TOXINES OF ERYSIPELAS

was read by DR. WILLIAM B. COLEY, of New York—The author had in a previous paper reported ten cases treated by the injection of living cultures of erysipelas. The first case was one of an inoperable recurrent sarcoma of the tonsil. The injections were continued some time without causing an attack of erysipelas, but finally a culture from a virulent case of the disease was used and caused erysipelas. The tumor ceased to enlarge, the general condition improved and the patient is still living, three years after the beginning of the treatment. Six of these ten cases were sarcomata and four carcinomata. In only four of the cases was erysipelas produced. Those cases in which the disease was not induced seemed to be as much benefited as those in which it was, and this led to a trial of the toxic products instead of the living cultures. The effect also of a combination of the toxines of the bacillus prodigiosus with those of the streptococcus of erysipelas was also employed and found to be more satisfactory than that of the latter alone. Since December, 1892, thirty-five cases of inoperable malignant disease were treated by the injection of the toxines of these two organisms. Twenty-five were cases of sarcoma, seven of carcinoma and three either sarcoma or carcinoma. Among the cases reported were the following:

A case of sarcoma of the abdomen and pelvis followed by recovery.

A case of recurrent sarcoma of the back and groin with entire disappearance of the tumor and no recurrence four months after cessation of the treatment.

Sarcoma of the iliac fossa with partial disappearance of the tumor, the health of the patient being perfect.

Inoperable sarcoma of the abdominal wall; entire disappearance under treatment.

Sarcoma of the leg recurring after amputation with enlargement of the glands of the groin; marked improvement but still under treatment.

Enormous round-celled sarcoma of the neck and thyroid with marked improvement.

Large pulsating round-cell sarcoma of the ileum and buttock. Marked diminution in size.

In the eight cases of carcinoma treated there has been marked improvement in two, slight improvement in four and no effect in two. In no case has the tumor disappeared.

Of the total number of cases treated there is reason to hope for a permanent cure in five. Nine cases showed a marked improvement, eight showed only slight and temporary improvement, while in two there was no apparent effect. One of these latter was an osteo-sarcoma of the sternum in which only four injections were given. The other case was a sarcoma recurring after removal of the tertir and in which owing to the condition of the patient only small doses could be employed. The spindle-celled and mixed-cell sarcomata seem to be the most susceptible to the action of the toxines, and periosteal and osteo-sarcomata less susceptible.

An important element in the success is the character of the culture employed. Cultures from any but virulent cases have but little effect. With regard to the manner in which the treatment acts, the author was inclined to base the explanation on an acceptance of the micro-parasitic origin of malignant disease. It is only in this way that we can explain the effect of this mode of treatment.

The following conclusions were presented:

1. The curative action of erysipelas upon malignant tumors is an established fact.

2. Its action is much more powerful in sarcoma than in carcinoma.

3. It is chiefly due to the toxine of the erysipelas streptococcus which may be isolated and used with safety.

4. Its action is greatly increased by the addition of the toxine of the bacillus prodigiosus.

5. The toxine to be of value should come from virulent cultures and should be freshly prepared.

6. The results obtained from the use of toxines without danger are so nearly if not quite equal to those obtained from an attack of erysipelas that inoculation should never be resorted to.

VENOUS TUMOR OF THE DIPLÖE.

This paper was read by DR. LEWIS S. PILCHER, of Brooklyn. The case reported differed from others which had been described, in that the tumor did not communicate with the

longitudinal sinus, but was essentially a large venous cavity into which numerous diplöic veins opened. The patient was a girl aged 15 years. When 5 years of age she fell and struck the top of her head. Within a few days a small soft swelling was noticed at the site of injury without pain or tenderness. This gradually increased in size. At the end of five years, it was lanced and a small quantity of clotted blood extruded. It immediately refilled. It was repeatedly opened with the same result. She came under the observation of the author in 1894. At this time there was a prominent tumor over the site of the anterior fontanelle, about two and a half inches in its largest diameter. Over the convexity of the tumor the skin was thin without hair. In the right anterior quadrant of the base an elevated plate of bone could be felt. The tumor was soft and could be diminished very slightly in size. It was gradually enlarging. March 14, the author operated for the relief of this condition. The tumor was opened. In the anterior part of the base, the cranial bone was wanting and over a space of two and a half by one and a half centimeters the dura mater was exposed. Certain venous channels of the diplöe were seen to be opened and from these free bleeding took place. The overhanging bone edge was cut away with bone forceps, the base of the cavity was well curetted, and the cavity packed with iodoform gauze, and as far as possible the wound was sutured. No complication disturbed the after course of the case.

FOURTH DAY—FRIDAY.

Paper of DR. GASTON, of Atlanta, on

MOOTED POINTS AS TO FRACTURES OF THE ARM, WITH NOTICE
OF AN IMPROVED SPLINT.

The purpose of the paper was to ask attention to practical considerations touching the treatment of fractures near the articulations of the arm. In cases of fracture complicated with dislocation, the author saw no advantage in first setting the fracture, but preferred to reduce the dislocation before treating the fracture, and efficient means should be taken to prevent the recurrence of the dislocation.

With regard to fractures at the wrist, the only one in which there is any notable diversity of opinion is the Colles fracture, which occurs from half an inch to one inch from the carpal articulating surface. After considerable experience with the double pistol-handle shaped splint in the treatment of Colles fracture the author had never seen a case in which there has remained any permanent impairment of the use of the fingers or the wrist joint, nor has any material deformity followed the treatment.

Fractures above and below the elbow. Dislocation of the head of the radius or the upper part of the ulna is frequently observed in connection with fractures of the lower extremity of the humerus. These require correction before the fracture is treated. In considering whether the arm should be dressed in the extended or flexed position, we should investigate thoroughly the bearings of tending into the axilla with a crutch-like termination, and the lower branch reaching the wrist.

In the treatment of fractures near the elbow, the author applies a roller bandage from the fingers to above the seat of injury, and with the arm in a flexed position pasteboard splints are molded to its inner and outer surfaces. These splints extend from the wrist to the shoulder. An internal angular splint is applied to the outside of the dressing until the pasteboard has become thoroughly dry. This dressing has all the advantages of plaster-of-paris and can be removed daily if it is so desired. The results of this method have been entirely satisfactory.

Fractures near the head of the humerus. These may be intercapsular or may only implicate the tubercle outside of the capsule. The most frequent seat is through the surgical neck. It is for this class of cases that a special splint has been devised by the author, the object being to effect extension and counter extension and keep the fragments in place and at rest.

THE REMOVAL OF STONE IN THE BLADDER, WITH THE
PRESENTATION OF A NEW LITHOTRITE.

By DR. W. S. FORBES, of Philadelphia—The points considered were:

1. The measured crushing resistance of vesical calculi.
2. The lithotrite from a mechanical point of view.
3. The measured strength of the lithotrite.
4. A new lithotrite.

A table was given of the size, displacement, specific gravity and measured crushing resistance in pounds and ounces of 183 human vesical calculi. The strongest calculus in this group took on the testing machine 406 pounds to crack it.

Several took upward of 300 pounds to crack them. In testing the strength of the lithotrites on the testing machine, the strongest lithotrite, No. 33 F., made by Tiemann & Co., had the female blade bent at 650 pounds. A Thompson lithotrite, No. 29 F., made by Weiss, London, bent badly at 333 pounds, on the same testing machine. The practical bearing on these observations is that the strength of the lithotrite may be tested and stamped on it before it leaves the instrument maker's shop, thus enabling the surgeon to begin his operation knowing the strength of the lithotrite.

The testing apparatus for determining the force required to crush the stone and the strength of the lithotrite was exhibited and demonstrated. The apparatus was the invention of Mr. John S. Forbes, son of the author. Mr. Forbes had also devised a new lithotrite designed to furnish a stronger instrument and obviate some of the defects of former instruments.

EXTIRPATION OF THE LARYNX.

By DR. WM. H. CARMALT, of New Haven, Conn. In this case the operation was done in such a way as to permanently close the opening into the mouth so that there should be no communication with the lungs. He was induced to do this by his knowledge of a case in which the larynx was extirpated and the opening to the mouth subsequently closed. The operation was done two and one-half years ago by Dr. J. Solis-Cohen, of Philadelphia, and the man gained the power of speaking loud enough to be heard in a large room. This was preceded by swallowing or drawing air into the pharynx.

DR. JAAVIS S. WIGHT, of Brooklyn, exhibited a number of instruments including needle forceps, self-threading needle, aneurism needle forceps and a new form of knife provided with a beak, substituting the use of a grooved director.

The following papers were read by title: "The Effect of Erysipelatous Attacks on Tuberculosis," Dr. De Forest Willard, of Philadelphia; "Hernia," Dr. W. T. Bull, of New York; "Cases of Extra-uterine Pregnancy with Remarks," Dr. M. H. Richardson, Boston; "Treatment of Urethral Vegetations by a Circular Cutting Curette," Dr. John B. Deaver, Philadelphia; "Report of Surgical Cases," Dr. Chas. B. Porter, Boston.

Medical Society District of Columbia.
Report on Typhoid Fever.

The committee appointed by the Medical Society to report upon the subject of typhoid fever in the District of Columbia begs leave to make the following report:

The consideration of this subject by the Society is justified and demanded by the very great prevalence of typhoid fever and by the large number of deaths, which gives Washington a most unenviable position among American cities.

It is right that a disease which is known to be preventable, which has been almost abolished in some of the capitals of Europe, should receive here, in the capital of this country, the closest study and attention. If the causes of its persistence are known, if, above all, these causes can be removed, it is our part and duty to make the facts public and to arouse public attention to the necessity and urgency for action. Who is better fitted to speak authoritatively on this subject than the Medical Society of the District, whose members are in daily contact with the disease, and who have every opportunity to study the modes of its diffusion among our population?

The committee has endeavored to present, as briefly as possible, the data upon which an intelligent judgment can be formed. The magnitude of the task of making a complete study of typhoid fever in all of its aspects must be apparent to all, and the committee must ask an indulgence for the imperfection of the report in many of its details. Much could only be touched upon, much had to be omitted. The importance of the subject demands continued observation and study, and it is suggested that the work be continued from year to year in whatever way seems best to the Society.

The committee is indebted for much valuable assistance from the District Commissioners and their assistants, who have all shown great interest in the work of Society in this investigation.

The accompanying report will consider:

1. The prevalence and mortality of typhoid fever in the District.

2. The relations of the dissemination of the disease to the a, public water supply; b, to the pollution of the soil with the leakage from privies, from defective sewers and from the backing up of sewerage from tidal movements; c, to the drinking of well or pump water; d, to contaminated milk and to other causes.

3. The difference in mortality in different areas of the city, with a view to discover the causes.

4. Conclusions based upon the foregoing data, as to what measures should be taken to diminish the spread of the disease.

PREVALENCE AND MORTALITY OF TYPHOID FEVER IN THE DISTRICT OF COLUMBIA.

The following table gives the statistics of typhoid fever in the District of Columbia from 1881 to 1893, the ratio of deaths from all causes and the total deaths based upon the records of the health office of the District:

Typhoid fever in the District of Columbia, 1881 to 1893, inclusive.

| Years. | Popula- tion. | Deaths from ty- phoid fever. | Ratio of deaths from typhoid fever to 1,000 deaths from all causes. | Ratio of deaths from typhoid fever to each 10,000 population. | Total deaths. |
|------------|------------------|---------------------------------------|--|---|------------------|
| 1881 . . . | 188,000 | 67 | 16.2 | 3.6 | 4,186 |
| 1882 . . . | 188,653 | 120 | 26.2 | 6.3 | 4,571 |
| 1883 . . . | 194,980 | 92 | 21.4 | 4.8 | 4,286 |
| 1884 . . . | 200,000 | 76 | 16.0 | 3.8 | 4,814 |
| 1885 . . . | 200,000 | 124 | 25.0 | 6.2 | 4,998 |
| 1886 . . . | 205,000 | 125 | 27.2 | 6.2 | 4,674 |
| 1887 . . . | 210,000 | 116 | 25.0 | 5.5 | 4,685 |
| 1888 . . . | 225,000 | 168 | 38.6 | 7.4 | 5,040 |
| 1889 . . . | 250,000 | 170 | 33.3 | 6.8 | 5,152 |
| 1890 . . . | 250,000 | 208 | 37.7 | 8.3 | 5,564 |
| 1891 . . . | 250,000 | 208 | 36.6 | 8.3 | 5,720 |
| 1892 . . . | 260,000 | 183 | 30.4 | 7.0 | 6,098 |
| 1893 . . . | 285,000 | 186 | 28.6 | 6.5 | 6,452 |

From 1881 there has been an almost uninterrupted yearly increase of the death rate, the highest point being reached in 1890, with a ratio of 8.3 to 10,000 inhabitants. In 1891 the rate was 8.3; in 1892 it had dropped to 7.0, and in 1893 to 6.5. The lowest mortality, 3.6 and 3.8, was in 1881 and 1884. The past nine years show a greater number of deaths, representing a larger number of cases, than at any previous time. In the past two years the ratio has been less than in the previous seven years. An exception should be made to the percentage of 1893, as given in Table 1. It is based upon an assumed increase of 25,000 population in one year. This is not thought to be justified by the actual increase of previous years, and the percentage of 6.5 as the ratio of deaths in this year should be much higher, as high, certainly, as 1892, which is 7.0 to 10,000 population.

The actual number of annual deaths has increased from 67 in 1881 to 208 in 1890 and 1891, both years reaching the same number. In 1892 there were 183 and in 1893 186 deaths.

In Table 2 the ratios of deaths in the white and colored population is given, in the ten years from 1883 to 1893, inclusive. The whites had an average mortality of 5.8 and the blacks of 7.8 to 10,000 population. Here, as in the general mortality statistics, the high death rate is due largely to the greater fatality of typhoid fever among the colored race.

Typho-malarial fever is not included in these tables. If death from this cause were added to those from typhoid fever, as they should be done, the percentage of fatal typhoid cases would be much higher than here given. The present drift of opinion is to abandon this term altogether, as it leads to continued confusion and error. That it is being abandoned may be inferred from the decrease in the death returns from this cause *pari passu*, with increase in the returns of typhoid fever. (See chart.)

Table 3. Deaths from typho-malarial fever and malarial fevers in the District of Columbia from 1881 to 1893:

| Deaths from typho-malarial fever in District of Columbia. | Deaths from typho-malarial fever in Balti- more. | Mortality from malarial fevers in District of Columbia. | Mortality from malarial fevers in Baltimore. |
|--|---|--|--|
| 31 | 50 | 99 | 27 |
| 44 | 44 | 112 | 22 |
| 38 | 48 | 93 | 24 |
| 34 | 66 | 66 | 23 |
| 30 | 75 | 78 | 27 |
| 17 | 58 | 53 | 30 |
| 22 | 55 | 99 | 28 |
| 14 | 41 | 62 | 24 |
| 28 | 33 | 80 | 23 |
| 35 | 54 | 68 | 19 |
| 20 | 39 | 62 | 26 |
| 23 | 33 | 62 | 19 |
| 18 | 31 | 85 | 25 |

The mortality from malarial fevers, as seen in the above table, is still greater than seems possible; the progressive falling off in the number of fatal cases shows either that malarial diseases are on the decrease or that there is a change of opinion as to the nature of many cases of fever.

In order to represent more clearly the extent and fatality of typhoid fever in this city, maps have been prepared which accompany this report.

Map 1 is compiled from the maps of the health office, and is made up of an aggregation of the fatal cases occurring in residences in five years from 1888 to 1892, inclusive, and shows the number of deaths during that period.

There were in the whole city 626 deaths in residences.

The same map shows the number of deaths from the malarial fevers, including the deaths from typho-malarial fever. The actual number of deaths from typho-malarial fever in the five years was 120, an annual average of 24. There were 328 deaths from malarial fevers in the same period in residences, an annual rate of 66. No one can believe that malarial fevers have any such mortality in the District, and we are forced to the conclusion that many of the fatal cases of malarial fevers are also typhoid fevers. In public institutions and in the county the fatal cases of malarial fever numbered 130 in the five years, making a total of 458 deaths from this cause.

The map shows that there is a coincidence in locality of the deaths from typhoid fever, typho-malarial fever and malarial fevers.

Deaths in the public institutions, hospitals and in the county are not represented on this map; there were 201 in the hospitals and 90 in the county.

Map 3 shows the locality of deaths from diarrheal diseases. Here, too, the area of greatest mortality is the same as that of typhoid and the malarial fevers.

Table 4 gives a comparative statement of the mortality from typhoid fever here and in a few of the chief cities of this country and Europe. The average annual mortality in the District to 10,000 population was 6.2; in Philadelphia, 6.3; Chicago, 7.8; Boston, 4.1; Baltimore, 4.1; New York, 3.1; Paris, 6.1; Berlin, 2.0.

Comparative statement of the number of deaths per 10,000 inhabitants from typhoid fever in the cities named during the years 1881 to 1893, inclusive, and the general average therein:

| Years. | District of Columbia. | Boston. | New York. | Philadelphia. | Chicago. | Baltimore. | Berlin, Germany. | Paris, France. |
|----------|-----------------------|---------|-----------|---------------|----------|------------|------------------|----------------|
| 1881 . . | 3.6 | 5.2 | 4.8 | 7.4 | | 5.7 | 4.7 | 8.7 |
| 1882 . . | 6.3 | 5.1 | 4.0 | 7.7 | | 4.6 | 3.0 | 14.3 |
| 1883 . . | 4.8 | 4.6 | 4.7 | 6.3 | | 3.4 | 3.0 | 8.4 |
| 1884 . . | 3.8 | 5.0 | 3.5 | 6.1 | | 4.0 | 1.8 | 7.0 |
| 1885 . . | 6.2 | 3.8 | 2.9 | 6.4 | 7.4 | 4.0 | 1.9 | 6.0 |
| 1886 . . | 6.2 | 3.4 | 3.0 | 6.3 | 6.8 | 3.8 | 1.6 | 4.2 |
| 1887 . . | 5.5 | 4.6 | 2.9 | 6.2 | 5.0 | 3.4 | 1.3 | 6.1 |
| 1888 . . | 7.4 | 4.1 | 2.3 | 7.7 | 4.5 | 3.8 | 1.4 | 3.3 |
| 1889 . . | 6.8 | 4.1 | 2.5 | 7.0 | 4.1 | 4.5 | 1.3 | 4.4 |
| 1890 . . | 8.3 | 3.4 | 2.2 | 6.3 | 8.4 | 5.6 | 1.9 | 2.9 |
| 1891 . . | 8.3 | 3.3 | 2.3 | 6.4 | 16.0 | 3.3 | 0.9 | 2.2 |
| 1892 . . | 7.0 | 2.9 | 2.2 | 4.9 | 10.3 | 4.2 | | |
| 1893 . . | 6.5 | | | | | | | |
| Avg'e | 6.2 | 4.1 | 3.1 | 6.31 | 7.81 | 4.19 | 2.08 | 6.14 |

The large chart adopted from the valuable report of Erwin F. Smith, now of the Agricultural Department, on "The Influence of Sewerage and Water Supply on the Death Rate in Cities," shows the comparative mortality in different cities of this country and Europe. We will have occasion to refer to this chart later.

CAUSES OF THE PREVALENCE OF TYPHOID FEVER.

What interests us most is to trace the cause of the disease as it exists here, and in so doing it is assumed in this report that the question of its etiology is definitely settled, and that the conditions underlying its prevalence are: 1, an impure water supply; 2, the imperfect drainage of a polluted soil; 3, infected milk; 4, and other causes.

1. The water supply of our city and the District comes chiefly from two sources, the Potomac River and the wells which are scattered about the city and county.

By reference to the tabulated list of cities (Table 5) it will be seen that Washington, out of fifty of the largest

cities, stands second in the list, with a per capita and per diem supply of 177 gallons. Only Buffalo, with 196 gallons, is better supplied, while Philadelphia has 111 gallons, Baltimore 92, Boston 89, and New York 74.

Much of our public water supply is used in government buildings and in public fountains.

It is not possible to compare the extent of typhoid fever in cities with abundant water supply with those which have an imperfect supply, or none at all, for cities well supplied with water are at the same time furnished with a good sewerage system, and it is not possible in most cities to separate these conditions so as to discover the influence of water supply alone.

The example of Dantzig, however, shows that an abundant water-supply alone does not diminish the death rate. This city was supplied with water in 1869, and sewered in 1872. No marked diminution in the death rate of typhoid fever occurred until after the introduction of the sewers. Washington, with a daily individual supply of 177 gallons, has an average annual mortality of 6.2, while New York, with 74 gallons per capita, has 3.1 deaths yearly to 10,000 population. Abundance of water alone, as might well be supposed, does not limit the spread of typhoid fever.

There is evidence enough to show that the public water supply may be contaminated with typhoid bacilli, and thus propagate the disease. The epidemic at Providence, R. I., in November, 1888, which was traced to the pollution of the water of the river with fecal matter from typhoid cases, three and a quarter miles above the pumping station, is a case in point. The bacilli were found by Pruden and Ernst in the filters of the Providence houses. It is an admitted fact that the disease has often been originated in this way, but it is a question as to what value this mode of infection has as compared with others. Does the typhoid fever, which is the chief endemic fever of Washington, owe its continued existence to recurring or continued infection from this source? Would we eliminate the disease by purifying the Potomac supply and destroying all its organic life?

Von Pettenkofer and other authorities do not believe in this as a usual mode of infection; it is a popular belief, easily laid hold of, easily understood, but difficult to prove.

The Potomac water has been subject to very careful analyses, and "in general, the water may be said to be in excellent condition and to compare extremely favorably . . . with that of other cities. Its chief defect" is "the presence of suspended clay in the winter" and after heavy rains in any season.

The value of the so-called biologic analyses of drinking water is, as Theobald Smith says (*Medical News*, Philadelphia, April 9, 1887), still very unsettled. As the result of one year's observation made by him, a relation was found between turbidity and the presence of bacteria. Bacteria were most abundant in winter, January and February having the highest average; August, September and October, the months of the greatest prevalence of typhoid fever, having the lowest. Bacteria, most of which were harmless, were most abundant after heavy rains, and their presence in association with turbidity proved the then source from the washing of the surface of the soil.

In the latest bacteriologic report on Potomac water, Theobald Smith adheres to this statement, and says that fecal bacteria and turbidity were coincident—that is, that rainfall carries into the Potomac whatever may happen to be on the surface of the soil; clay, manure from the fields, inorganic or organic matter of any sort. The nature of the country through which the Potomac flows, much of it being mountainous, as well as the absence of large cities on its banks, diminish the risks of infection. As the country comes more and more under cultivation, turbidity and impurity from the washing of plowed and manure-covered land will be more common. The possibility of the introduction into the water of the microorganism of typhoid fever is dependent upon its presence in localities washed by the Potomac and its tributaries. The question, after all, is not whether typhoid fever can be propagated in this way, but whether, as a matter of fact, it is propagated in this way. Before this question can be determined other probable sources of origin must be considered.

It is an unjustifiable conclusion, that because fecal bacteria are found in Potomac water, therefore typhoid fever is usually propagated by the drinking of Potomac water. Bacteriology may lead us astray here, and data of a very different sort must receive due weight before a logical conclusion can be reached.

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS,
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

SATURDAY, JULY 14, 1894.

THE DOCTOR'S HOLIDAY.

The opinion was expressed by the late SIR HENRY HOLLAND, that every physician needs an annual holiday for the recreation and recuperation of his physical and intellectual powers. His own practice was to take a holiday of three months' duration which he would spend in a yachting trip to Norway or on the Mediterranean, or devote to some similar and equally agreeable diversion. He thought that if the profession generally would adopt his advice and follow his example, they would be better physicians and more useful to the community during the remaining portion of the year than if they had kept steadily at work. There is sound philosophy in this teaching. It is a convenient but selfish assumption by their patients, that physicians are superior to the ills that flesh is heir to. In fact, the physician is popularly regarded as the repository of all the secrets of hygienic and therapeutic art, whereby every one might be kept in good health, if, indeed, he might not even enjoy perpetual youth, if he only chose to live according to disciplinary rule and method, and swallow the prophylactic dose of disagreeable drugs in proper season. We know, however, that this is not exactly in accordance with fact. If doctors do as a general rule have better health than their neighbors, it is because their vocation makes them sober, earnest men, who are liable to be called upon at any time, and at briefest notice, and ready to promptly assume the responsibility of life and death, at the bedside of the sick or injured. Plain living and high thinking are probably exemplified more in the ranks of the medical profession of to-day, than in the followers of any other calling. Leading more temperate lives, they may have better health than some who are accustomed to require their services; still, they are but mortal, and they are sometimes unpleasantly reminded by infirmity, or failing health, of their

common humanity when, alas, it may be too late to remedy the evil.

If a holiday will increase the efficiency of the doctor by improving his health, it is a duty which he owes to his patients, as well as to himself and his family, to temporarily lay down his work and to seek, among novel surroundings and unaccustomed scenes, a new stock of impressions and a new store of health. In fact, physicians living at some altitude claim that it is only by descending to the ocean level for a few weeks or months, every year, that health can be permanently maintained, or that cerebral injury can be prevented. Others living upon the plains, find inspiration and health in mountain climbing, while all sedentary workers are benefited by occasionally taking a pedestrian or equestrian tour, or by outdoor sports, such as fishing and hunting. The ancient temples of ÆSCULAPIUS were not placed amid thickly populated scenes; but in localities where HYGEIA could be worshiped in her native home, among the woods and near mineral springs, whose healing waters too readily obtained the credit of therapeutic result. This is beautifully expressed in the following stanzas, which deserve a place in all of our text-books on medicine:

"The murmur of a waterfall
A mile away,
The rustle when a robin lights
Upon a spray,
The lapping of a lowland stream
On dipping boughs,
The sounds of grazing from a herd
Of gentle cows.
The echo from a wooded hill
Of cuckoo's call,
The quiver through the meadow grass
At evening fall,—
Too subtle are these harmonies,
For pen or rule,
Such music is not understood
By any school;
But when the brain is overwrought,
It hath a spell,
Beyond all human skill and power,
To make it well."

Certain it is that great truths seem to find their most fitting expression in metrical phrase or poetic language. The sanitary lesson thus pleasantly brought to our attention is worth pondering seriously on account of the important interests at stake. An ounce of prophylaxis is said to be worth a ship-load of Galenical therapeutics; and, if we take the former in time, it may be possible to fulfil the thought of HOLMES and allow the latter to sink into the sea with all its direful consequences to the fishes, and corresponding advantage to humanity.

A TYPICAL ANTI-VACCINATIONIST.

Time was when the outcry of the anti-vaccination paranoiac against JENNER and his discovery found ready vent through the columns of the daily press, to the disquiet of many a worthy soul. It is among the encouraging signs of an increasing spread of in-

telligence that he has met with so little of editorial favor during the recent smallpox excitement. But the crank still lives and gets an occasional hearing. His latest noteworthy appearance is in the *Boston Globe* of the 22d ult., and it is noteworthy solely on account of the individual—not at all on account of his utterances, which are of the usual stereotyped character. The individual in this instance is one "RUFUS KING NOYES, M.D.," a person who for some months occupied the attention of the medical college faculties, and of the courts of three States some ten or a dozen years ago.

The *Boston Globe* is one of the influential newspapers of New England and in order to enable it to antidote whatever of harm its quasi-indorsement by publication of NOYES' screed may have worked, the following facts in the history of that champion of anti-vaccination are placed at its service:

In 1880, RUFUS KING NOYES, an anti-vaccinationist of some local notoriety in Lynn, Mass., obtained a charter of incorporation for the "Bellevue Medical College of Massachusetts"—a colorable imitation of the title of the Bellevue Hospital Medical College of New York. Two years later a "diploma" of this concern, signed "Rufus King Noyes, M.D., *President*," was presented to DR. RAUCH, then Secretary of the Illinois State Board of Health, and a license to practice medicine was demanded thereon. An investigation of the Boston "Bellevue" was at once set on foot, during which letters written by a young journalist resulted in an agreement by NOYES to furnish for \$150 tickets showing attendance upon two courses of lectures, and a "diploma" of graduation from his "college" to a man whom he had never seen; who had never been in Boston in his life; who only claimed to "hav bin Redin medesin about a year;" but who, having "ben tending on Sick purty Near all (his) life," thought he had a "Purty Good Idee about the Bizness;" and who furnished a thesis on "Vaccination," in which he professed to be ready to make "a Strong kick on the Part of our noble Proffession against the Inseartion into the Pure Blood and Vitle fluid of our Inosent offspring of that Diseas of the animals cow-pox."

This correspondence was begun in October, 1882, and on Nov. 2, 1882, NOYES wrote:

DEAR SIR:—You, as a candidate for graduation, have been favorably considered by the faculty, and your thesis has been examined by the Professor and found to be acceptable. . . . You are correct on the Vaccination question, and I am confident you will meet with continued success. Your diploma will be sent C. O. D, one week from the date of this letter. It will be securely packed in a pasteboard box. Your bill for diploma and two tickets is \$150," etc.

On receipt of the "diploma" it was promptly turned over to the United States authorities, together with the correspondence, as the basis of a prosecution for illegal and fraudulent use of the United

States mails—that being, as it was advised, the only ground upon which a charge could be made. On the trial NOYES and his coparceners pleaded that they were legally incorporated and empowered by the laws of Massachusetts to issue diplomas and confer degrees without any restriction as to course of study or professional attainments. The United States Commissioner held the plea to be valid and dismissed the case, saying:

"The law makes the faculty of the college the sole judges of the eligibility of applicants for diplomas. There is no legal restriction, no legal requirements. If the faculty choose to issue degrees to incompetent persons, the laws of Massachusetts authorize it."

Whereupon the "American University of Boston," the "First Medical College of the American Health Society"—now the notorious "Vermont Medical College" at Rutland, Vt.,—the "Excelsior Medical College," *et al.*, were immediately incorporated and the Massachusetts diploma-selling industry developed into magnificent proportions for a time. But, as MR. KIPLING remarks, that is another story.

"RUFUS KING NOYES, M.D.," the diploma-mill manipulator of 1882 is the typical anti-vaccinationist of 1894, and his diatribes should find no place in the columns of a reputable newspaper.

NOT METHODS, BUT RESULTS.

In a recent issue of this JOURNAL¹ some comments were made upon the remarkable argument urged in an address on the subject of "cramming in our medical schools." The argument was against the higher standard of medical education now in vogue as compared with that of a few years ago, the result of which, it was claimed, has been "to increase the hardships of the medical student."

DR. BAYARD HOLMES has been moved to discuss the same subject and arrives at the conclusion that State control of medical education is the remedy for the defects, abuses and evils in the present system. "It would pay the State," he says, "even if it were not its duty as the only capable corporation and the one most interested, to support, direct and conduct all the medical education of the country. This will be done so soon as we, as a nation, value men above all other products of our clime; so soon as men believe that the Kingdom of Heaven may come here in this world as the *Pater Noster* indicates; so soon as selfish men cease to exploit for their own aggrandizement, the sacred labor of medical education; so soon as our universities apply the same ethical and pedagogic principles to their medical departments as they use in directing their other graduate schools."

Meanwhile it remains to suggest and again urge that the divorcement of the educational from the licensing agency will do much toward bringing about

¹ A Singular Plea for the Udfit. JOURNAL AMERICAN MEDICAL ASSOCIATION, June 23, 1894.

the medical millennium for which DR. HOLMES is so earnestly laboring. Let the consensus of the profession fix the standard of qualification for the practice of medicine and then let the State apply that standard regardless of where or how the applicant obtained the qualification. The welfare of the public and of the profession is not involved, primarily, in the methods of medical instruction, but in the results. In regard to an applicant for the right to practice, neither the profession nor the public is greatly concerned in the question, "Where did he study?"—but rather in the question, "Has he learned?" Not in "How long has he studied?"—but "What does he know?"

LIABILITY FOR PROMISE TO CURE.

The case of *Boscow v. State*, decided by the Court of Criminal Appeals of Texas, May 23, 1894, was an appeal from a conviction, in the Fayette County Court, of obtaining money under false pretenses. The party so convicted insisted that because the information charged, as a part of the false pretenses relied upon, that he was to perform certain acts in the future, to-wit, to cure the wife of the complaining witness, the same could not be made the basis of swindling. It is true, says the Court, that, if the witness had relied on the promise, it could not be swindling; but, it holds, that where the promise is connected with the false pretense of an existing fact, as that the pretender was a physician, and at that very time associated with other physicians known to the witness, and he thereby obtained a credit and influence with the latter that he could not otherwise have obtained, it would support the charge. A part of the false pretenses upon which the money was alleged to have been obtained in this instance was that the party in question was a member of a medical institute in San Antonio, in which there were twelve physicians. One of these, the Court holds, was competent to testify to the falsity of such statement.

SURVIVAL OF ACTIONS FOR MALPRACTICE.

At common law, rights of action for injuries to the person terminate with the death of the wrong-doer. In order to secure their survival, various statutes have been enacted in the different States providing for their maintenance against the personal representatives of the deceased. Michigan has a statute which provides that if any person professing or holding himself out to be a physician or surgeon, shall be guilty of any malpractice, an action may be maintained against such person so professing, whether licensed as a physician and surgeon or not, and another, which provides for the survival of actions "for negligent injuries to the person." The executors for a deceased physician sought, in the case of *Norris v. Grove*, decided May 18, 1894, by the

Supreme Court of Michigan, to secure the vacation of an order continuing an action for malpractice against them. They contended: 1, that by the latter act the Legislature did not intend to include actions for malpractice; and 2, that the amendment to the general statute, relative to the survival of actions, can not be held to be an implied amendment of the statute respecting actions for malpractice. The latter contention is, the Court thinks, without force. Provisions conferring a remedy, and those which limit the time within which such remedy may be employed, and those which relate to survival, are rarely found in the same statute. The statute provides for the survival of all actions for negligent injuries to the person. The word, "person," is evidently used in contra-distinction to the word, "property." It is true that the books speak of wilful malpractice, negligent malpractice, and ignorant malpractice; but the Court does not consider it necessary to determine, in this case, whether all actions for malpractice would survive under the statute in question. Yet it does hold, that unless the injury be a negligent injury, the action will not survive, and that it is the right of an injured party to elect to treat an act as negligent, although it was in fact wilful and malicious. It is no more difficult, it says, to determine the negligence of an injury in an action for malpractice than in any other action for injury to the person. After thus expounding the law, and for the reasons given the Court denies the relief prayed.

CORRESPONDENCE.

Intestinal Putrefaction (Auto-Infection).

It seems remarkable that with all the teliologic acumen of our profession, one of the principal causes of disease has been hitherto almost entirely overlooked—that of intestinal putrefaction, so palpable that it could not have been concealed; and it is more than probable that the largest proportion of fatalities have heretofore resulted, directly or indirectly, from that single cause. The idea is a simple cognition apart from any technical qualification; in other words, we have only to see and believe; for if we observe the natural process of digestion, assimilation and elimination we can not fail to perceive the inevitable morbid influence that must necessarily follow in the wake of delayed defecation. As soon as the mass of chyme emerges from the stomach, the elements of which it is composed begin to change their relations, and as it gradually passes down through the alimentary canal the nutritive combinations are absorbed into the circulation, leaving the remainder constantly tending to putrefaction by retrograde combinations and the addition of intestinal excretions of systemic waste; and when it finally reaches that great filtering reservoir, the colon, the greedy absorbents of that receptacle drink up indiscriminately all that remains in a fluid state, to pass into the circulation and poison the tissues wherever they go; thus crippling the vital functions and establishing disease. It is possible, however, that a part of these elements may be appropriated in some process of metabolism, while the remainder must fall on the kidneys and other emunctories to be cast out as waste. It is evident that these

excretory organs would be sufficient to eliminate the poison if the natural calls for evacuation were promptly obeyed, as happens with inferior animals that labor under no ethical restraint; for it is a fact that those animals, provided with suitable food, pass their lives exempt from disease until they are weakened and wasted by age, though exposed to all the vicissitudes of weather. And so probably might the human escape the pangs of disease by obedience to this law of Nature. During his life the writer has been curious to learn the habits of friends who seemed never to be sick, and as a general rule they have all been accustomed to free evacuations every day, usually in the morning. But we must be aware that a vast majority of our kind are guilty of procrastination, exposing them to all the blighting evils of constipation, more especially among sedentary persons, who compose the larger part of our valued population. On the contrary, those subject to constipation have never been free of some complaint, and many have succumbed to malignant diseases. These are stubborn facts and what do they indicate? They teach the absolute necessity of daily evacuations by the gentlest means and never by active purging, except in cases of extreme obstinacy; surely the great variety of laxative pills and preparations, in easy reach of every one, can supply that want.

As an excuse for this lucubration, it may be insinuated that the scribbler is a veteran of more than three score years of active service, and now claims only the rank of a medical student. "*Verbum sat sapienti.*"

ROBT. HUNTER DALTON, M.D.

Typhoid Fever.

WASHINGTON, D. C., July 2, 1894.

To the Editor:—In the report of the proceedings of the Medical Society of the District of Columbia, June 21, I am quoted as having claimed that many deaths laid at the door of typhoid fever were due to malarial fever. On the contrary, I stated that many of the deaths classed under malarial and typho-malarial fevers (especially in former years) were probably due to typhoid fever.

I did not declare that never had there been any authentic report of a case of typhoid fever resulting from well water, but I did declare that the report of the committee did not show that a single case of typhoid fever had been traced to a single well in this city.

For reasons which were given in the course of my remarks the report was characterized as sensational, contradictory and illogical; a generalization based on the barest possibilities, and fancies stated as facts.

Very respectfully,

B. G. POOL, M.D.

The Status of an Eclectic.

AUSTIN, TEXAS, July 6, 1894.

To the Editor:—If a physician be a graduate of an *Eclectic* Medical College, of the first class in standing, and said physician be, in all respects, an honorable, well-behaved practitioner of medicine, and should apply in the usual regular manner, for *membership* in a local (county) medical society of so-called *regular* physicians, can the physicians—members of said local society—elect said graduate from an *Eclectic* Medical College, a member of said local society, without violating the *Code* of the AMERICAN MEDICAL ASSOCIATION?

I am not able to find any literature giving a clear and plain answer to the foregoing question; hence, I apply to you. Please answer, as you may deem best, as to mode: either through the JOURNAL of the AMERICAN MEDICAL ASSOCIATION or privately.

Yours truly,

Q. C. SMITH, M.D.

BOOK NOTICES.

Manual of Treatment by Active Principles. Concentrations and New Remedies. By WILLIAM F. WAUGH, A.M., M.D. Pp. 248. Cloth. Philadelphia: The Medical Press Company. 1893.

This little volume is a natural outgrowth of the earlier "Outline of Dosimetric Practice" by the same author. The first third of the work contains an alphabetical list of most of our newer remedies as well as the active principles of many drugs long in use and salts of good therapeutic repute. The remaining portion comprises a list of diseases and prominent symptoms with remedies suggested and usually a special explanation regarding each one or each group. A large number of valuable hints, tersely stated, is thus ready for convenient reference, and they merit confidence because culled from standard authorities. No one can fail to realize the advantages to be derived from the wider use of active principles and this work is to be commended as a step in that direction.

NECROLOGY.

SOLOMON R. GORGAS, M.D., died June 30, at Harrisburg Pa., of appendicitis. Laparotomy was performed in Philadelphia, and the diseased appendix was removed, but he died on the third day, from exhaustion. Dr. Gorgas was a member of the Dauphin County Medical Society, also of the State Medical Association and the AMERICAN MEDICAL ASSOCIATION. He was one of the Examiners for the Pension Fund and also Surgeon to the Pennsylvania Railroad Company. He was a graduate of the Jefferson Medical College of the class of 1874.

EZRA M. HUNT, M.D., the distinguished sanitarian and President of the New Jersey State Board of Health, died July 1.—Joseph P. Thomas, M.D., President of the Kentucky Medical Association, at Hopkinsville.—Wallace A. Sackett, M.D., of Dallas, Texas, June 28, aged 25. He was a native of New Albany, Ind., and graduated in medicine at the University of Louisville, Ky., in the class of 1893.—C. B. Ranes, M.D., of Rusk, Texas, June 28. He was born in Virginia on Jan. 17, 1808, and practiced medicine for sixty-two years. In 1835 he settled in Nacogdoches County, Texas, and lived in that county until 1849, when he removed to Dallas. He served throughout the war as regimental surgeon on the staff of Gen. Winfield Scott.—W. H. Ridenhour, M.D., of Toledo, Ohio, June 6, aged 70.—W. G. Austin, M.D., of New Orleans, June 15, aged 80. He was educated at Kenyon College, Ohio, and graduated M.D. at the Washington University of Baltimore in 1836. He began practice in Yazoo County, Miss., and after three years located at Bayou Sara, La. He was married in 1839, and shortly before the war was appointed a member of the State Board of Health. He was Superintendent of the Charity Hospital of New Orleans in 1862 when the city was taken by the Union troops, and he served in the Confederate Army until the close of the war. He was again appointed to the State Board of Health, in 1877, and in 1888 was United States Examiner of Drugs. Governor Nichols appointed him quarantine physician during the presidency of Dr. C. P. Wilkinson. Dr. Austin was one of the best qualified yellow fever experts in the South.—Joseph P. Connelly, M.D., of Williamsport, Pa., died June 23, 1894, aged 35 years. He was President of the Lycoming County Medical Society at the time of his death. He was a member of the Pennsylvania State Medical Society and of the AMERICAN MEDICAL ASSOCIATION. Few men of Dr. Connelly's years have attained the position in their profession that he had. He was always active in all society work, and had the respect and esteem

of all who knew him, and his death was mourned by his professional associates.—Richard H. Isham, M.D., at Louisville, Ky., June 30, aged 62.—W. R. Smith, M.D., at Sioux City, Iowa, July 1, aged 65. He was one of the pioneers of Western Iowa, was a native of New Jersey and educated in New York city. During the war he served the Government in various capacities as examiner of recruits, physician to Indians and was one of the Pension Examining Board. He was very prominent in politics and railroad circles in the last years of his life, and was one of the Commissioners of the State of Iowa to the Paris Exposition.

SOCIETY NEWS.

The members of the Illinois State Medical Society are hereby notified that the Transactions of 1894 are now in type. The Treasurer requests that those in arrears send their checks immediately to him at Springfield.

American Electro-Therapeutic Association.—The fourth annual meeting of the American Electro-Therapeutic Association will be held in New York, September 25, 26 and 27, at the New York Academy of Medicine. Members of the medical profession are cordially invited to attend.

WILLIAM J. HERDMAN, M.D., President.

MARGARET A. CLEAVES, M.D., Secretary.

American Public Health Association.—The twenty-second annual meeting of the American Public Health Association will be held at Montreal, Canada, Sept. 25-28, 1894. The following topics have been selected for consideration at this meeting: The Pollution of Water Supplies; the Disposal of Garbage and Refuse; Animal Diseases and Animal Food; the Nomenclature of Diseases and Forms of Statistics; Protective Inoculations in Infectious Diseases; National Health Legislation; the Cause and Prevention of Diphtheria; Causes and Prevention of Infant Mortality; the Restriction and Prevention of Tuberculosis; Car Sanitation; the Prevention of the Spread of Yellow Fever. Upon all of these subjects special committees have been appointed; and all papers thereon should be presented to the appropriate committee in season to be incorporated as a part of the report of the committee, if deemed advisable. The Executive Committee announces the following additional subjects upon which papers are invited: On the Education of the Young in the Principles of Hygiene; Private Destruction of Household Garbage and Refuse; Disinfection of Dwellings after Infectious Diseases; Inspection of School Children with Reference to the Eyesight.

Indian Medical Congress.—The Indian Medical Congress will be held December 24 to 29, 1894.

The objects of the Congress are to bring together medical men from all parts of the Indian Empire, to discuss medical subjects connected with Indian diseases, and to place on permanent record some of the work which is now lost to science for want of proper publication. This Congress will afford an opportunity, never before presented, for medical men who are in isolated but important positions in the different Provinces of the Indian Empire, meeting and comparing notes with their fellow-workers in subjects of mutual interest; former friendships could be renewed, and men who might never otherwise meet would become acquainted. It is proposed that the work of the Congress should be divided into the following sections:

Medicine and Pathology; Surgery including Ophthalmology; Obstetrics, and Diseases of Women and Children; Public Health; Medico-Legal Medicine and Insanity; Pharmacology, specially Indigenous Drugs.

Although the Congress is primarily an Indian one, invitations have been sent to medical men in other countries, some of whom have already accepted, and it is believed that many more will come.

A special committee has been formed to arrange for the accommodation of visitors and to provide for their comfort. The local secretaries of this Committee are: Surg-Captain H. W. Pilgrim, General Hospital, Calcutta; Dr. Prandhan Bose, M. B., Calcutta Medical School, Calcutta, to whom, or to the honorary central secretaries, applications should be made for rooms. The price of accommodation in Calcutta may be taken from rs. 7 to rs. 14 a day for Europeans, and rs. 3 to rs. 5 for Indians. Tickets of membership may be obtained from either the honorary central secretaries in Calcutta, or from the local secretaries in the different parts of the Indian Empire. An entertainment and reception committee will arrange for visits to places of interest in Calcutta and neighborhood.

Members are requested to notify to the central secretaries, or to the local secretaries of their districts, their intention to read papers and the titles of the same, which should reach the central secretaries not later than Oct. 15, 1894.

The cost of members tickets is rs. 10. Members will be entitled to a copy of the Transactions on payment of an additional rs. 10. Non-members may obtain the Transactions of the Congress on payment of rs. 25. Orders for a copy of the Transactions should be registered early.

A guarantee fund has been started, and all cheques should be sent to the honorary treasurers, Dr. Mohendra Nath Gupta, and Dr. Bolye Chunder Sen, Campbell Medical School, Calcutta.

American Academy of Medicine.—The nineteenth annual meeting of the American Academy of Medicine will be held at the "Waumbek," Jefferson, N. H., on Wednesday and Thursday, August 29 and 30, 1894. The greater part of the time is to be devoted to the discussion of certain problems relating to the Medico-Social Relations of the Medical Profession to the "Dependent Classes." The following papers may be expected:

"The Retrogressives: What Produces Them; Classification." Bayard Holmes, Chicago, Ill.

"Importance of the Study of the Subject to the Profession." Charles McIntire, Easton, Pa.

"The Provident Dispensary in England." H. Webster Jones, London, England.

Title to be announced. J. A. Spalding, Portland, Me.

"Assistance and Care for the Blind." Charles A. Oliver, Philadelphia.

"Prevention of Blindness." Benjamin Lee, Philadelphia.

"Present Status of Legislation for the Prevention of Blindness from Infantile Ophthalmia." Lucien Howe, Buffalo.

"Senile Dementia and Testamentary Capacity." J. N. Whittaker, Cincinnati.

Title to be announced. Gershom H. Hill, Independence, Iowa.

"What Agencies Conspire to Check Development in the Minds of Children?" J. Madison Taylor, Philadelphia.

"The Medical Service of the U. S. Pension Bureau." P. S. Conner, Cincinnati.

"Physical Training for Delinquents." Helen C. Putnam, Providence, R. I.

"Government Commission instead of State License." J. D. Kelly, New Haven, Conn.

"The Relation of Food Adulterations to the Dependent Classes." Henry Leffmann, Philadelphia.

Title to be announced. G. M. Gould, Philadelphia. President's Address.

Title to be announced. F. H. Gerrish, Portland, Me.

Several additional papers have been provisionally promised; if they can be read they will appear in the completed program. Arrangements have been made for a special excursion from New York and Boston and return at reduced rates. A choice is offered of an eleven days excursion, including most of the expenses, or of returning immediately at the close of the meeting, and is open to any one desirous of attending the meeting, whether members of the Academy or not. Any additional information about the meeting or the excursion may be obtained from

CHARLES MCINTIRE, Sec'y, Easton, Pa.

PUBLIC HEALTH.

Boston Board of Health.—The City Board of Health of Boston reprints and indorses the recommendations of the Massachusetts State Board of Health concerning tuberculosis and earnestly recommends their enforcement by the physicians and inhabitants of the city.

The Cholera.—Asiatic cholera is reported to be spreading in Russia with a decided increase in the number of cases and in fatality in St. Petersburg. Elsewhere on the Continent the disease attracts little general attention although sanitary authorities are exceedingly vigilant. On the 6th inst. four more cases of the disease developed among the passengers on an infected steamer recently arrived from St. Petersburg at Stockholm, and nineteen passengers had been removed to quarantine from another steamer just arrived from the same port.

The Plague.—Writing from Peking, June 20, Mr. Frank G. Carpenter gives the first coherent account of the origin and spread of the bubonic plague in China. Previous reports have attributed its spread from Hong Kong to Canton, at which latter place it was said to have made its appearance about the end of April. Mr. Carpenter asserts that the disease came originally from the interior and reached Canton during the last week of February where it speedily caused an average of 200 deaths a day. "This average steadily increased until in March and April it was 500 a day and the mortality at the present time (June 20) is very large." The disease made its appearance in Hong Kong in April, carried thither presumably by the fleeing Cantonese.

Washington Sewage Disposal.—Mr. Richardson's (Tenn.) bill to provide for the sewage disposal of the District of Columbia was discussed at a recent meeting of the Washington Board of Trade and, together with the report of the District Medical Society on typhoid fever, was unanimously indorsed and the action ordered to be reported to Congress. The bill provides for a total expenditure of \$7,500,000, of which sum \$1,000,000 is for the extension of the system of trunk sewers, \$3,350,000 for the completion of the system of sewage disposal and protection against floods, and the remaining \$3,150,000 for the improvement of streets, roads, avenues and reservations.

Hygiene in Medical Education.—At a recent conjoint session of the North Carolina State Board of Health and State Medical Society it was unanimously resolved to request medical colleges to give not less than two lectures a week on the subject of hygiene, and the Board of Medical Examiners was requested to require of applicants for license the same preparation on this as on other branches of medicine specified in the Medical Practice Act. The Secretary of the Board, Dr. R. H. Lewis, says that, while similar action has been taken by the Ohio and other State Boards of Health: "So far as we know, this is the first instance in which the organized medical profession of a State has joined in such action. It is significant of the progressive spirit that animates the profession of North Carolina."

"Scare-Head" Journalism.—The temptation to sensationalizing in matters affecting the public health, is so generally yielded to by the average newspaper that the *JOURNAL* hastens to recognize the value of such an exceptionally level-headed editorial as that in a recent issue of the *Washington Post* under the caption, "Beware of Scare-Heads," in which it advises its readers not to be alarmed because of the plague in China, or the cholera in Europe, or the yellow fever in Cuba. It summarizes the situation substantially as it has been given in this department from time to time and

says, as to cholera: "The interests of the United States in this matter were never so vigilantly represented abroad as they are now and our Eastern seaboard was never so well fortified against the introduction of cholera from Europe." As to the plague in China: "It is gratifying to know that all along the Western coast, from British Columbia down, the authorities both of the Dominion and of the United States have taken every precaution that medical skill could suggest to prevent the introduction of plague germs by ship-board." And, finally: "The symptoms of an epidemic visitation of any sort from any country are too slight to warrant anxiety, still less anything like a panicky sensation. They are just enough pronounced to remind the sanitary authorities all along the line that they have their duty to perform, which admits of no relaxation, and this, we entertain no doubt, they fully realize. The people have also a duty to discharge on their own account in exercising all possible precautions as to their own immediate conditions and the importance of carefully regulating their habits of life and maintaining the cleanliness of their surroundings." Such timely advice, so intelligently given, is in sharp contrast to the startling head-lines, sensational exaggerations, denunciation of quarantine regulations and vilification of sanitary authorities which would follow the advent of the first case of Asiatic cholera or bubonic plague upon our shores.

Sanitary Legislation Urged.—The Louisiana State Board of Health, acting in conjunction with a board of medical experts, has memorialized the Legislature of that State for the enactment of two bills—one providing for the inspection of dairies, milk and milk products, the other for the thorough inspection of meat offered for human food in the State of Louisiana. After reciting some of the general considerations for the enactment of such measures, the memorialists say: "To be brief, we will limit ourselves to the consideration of that most fatal of all diseases, that scourge of humanity, tuberculosis, better known as consumption. This disease causes more deaths than all the epidemic diseases combined. Statistics show that one-sixth of all deaths throughout the civilized world are caused by consumption. It is estimated that there are never less than two hundred existing cases in New Orleans. During the fourteen years, 1880 to 1893 inclusive, there were over twelve thousand deaths from that cause alone. It prevails the whole year round, in every country and climate, respects neither age, sex, social condition nor race, and affects every species of animals. Consumption is now recognized by the medical world to be a germ disease, caused by a special micro-organism, and communicable from man to man, and likewise from the lower animals to man. Perhaps the most frequent and least suspected cause of this infectious and fatal disease is due to the use of meat and milk from animals affected with consumption, to which disease the bovine race is the most liable. We should here notice that those animals which furnish us with our daily food, the cow, the hog and the fowl are precisely the most subject to consumption. Out of 1,058 cattle examined in Germany by Kapp, 738 were found to be consumptive. Among the animals slaughtered at the abattoirs of Berlin during the years 1887 and 1888, 4,300 were consumptive. In the United States the proportion of consumptive cows is from 10 to 15 per cent; in particular parts of the country much higher. In our city there are seven thousand cows in round numbers, and at the lowest calculation three hundred and fifty of these are poisoning our milk supply." The memorial concludes with this note of warning to the Legislature: "The Board of Health of the State of Louisiana, conjointly with the Board of Medical Experts, with due respect to your wisdom and patriotism, being aware of and appreciating its responsibility toward the people of the State, in thus asking and praying for proper legislation in securing a sound meat and milk supply, feels and emphatically so states, that in presenting the foregoing considerations it has done its whole duty in the premises, leaving the responsibility for the passage or failure of the proposed measures to the legislators."

WHAT IS THE PRINCIPLE INVOLVED IN THE TREATMENT OF OPERATIVE WOUNDS— IS IT BIOPLASTIC AND CELLULAR, OR IS IT BACTERIOLOGIC?

SANITARY SCIENCE AND SURGERY FOR THE TWENTIETH CENTURY.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY R. E. HAUGHTON, M.D., A.D.
MIDLAND, TEXAS.

Have we any definite pathology, and if so, is it bioplastic and cellular or not? Dr. Hughes has told us in his paper, "it takes something more than a germ to excite disease." The President, Dr. Hibberd, said in his address: "The progress in medicine in the immediate future, must be along biologic lines, following the lead of Virchow, Beale, Ferrier, Pasteur, Kock, Sternberg and many others." I desire to accentuate this thought, and render more impressive what they have said.

Surgical pathology should be comprehended in the genesis of cells. Transition and relation to the tissue should not be forgotten. That surgical pathology is based upon a careful study of pathogenesis, is the line of progress which has been most successful in developing the rich stores of knowledge in the past, and must continue to do so in the future of conservative surgery. Have we forgotten the discussion of the histologic questions of bioplasm, cellular elements and tissue formation? Have we left behind us the doctrines biologic, views which were in some sense the foundation of the pathologic views of Rokitansky, McCartney, Paget and Virchow? Do we believe that there is such a thing as a generation of living cells from protoplasm or bioplasm, and that degeneration, failure and death of cells and tissues may have origin in causes remote from the influence or presence of bacteria? Do we now comprehend the laws of life force, so that we say all disease springs from their presence? Is it not true that cellular elements are born, live and die as men do, new ones taking their place? If so, do not the laws of life so indicate by succession?

This began to be more fully understood when surgeons began to comprehend the processes of inflammation, and resort to means for immediate union of cut surfaces. I will not go over this beginning of the doctrine involved in such processes. Let us remember, however, the old maxim: "That art is long, experience deceptive and judgment difficult." While we do this, let us gather up the experience of the past and present, so that we may look into the future with an increasing confidence in our art, and a growing reliance upon better and improving methods. Let us test as well as gather up the facts of

results as they come to us in the methods of surgery to-day. There are many factors which enter into this question and a rigid and just analysis of all of them will the better enable us to judge, no matter how intimately and variously may be blended the known and the unknown. Every clinical history carefully recorded is experience made alive and known, and presents to every reader the *dramatis personæ* all absorbing in interest to life and person. It is the great centralization of fact in experience, viz., *the truth*.

We go back to primeval history and with historic certainty record the history and progress of our art through the ages and with contented serenity regard the wonderful discoveries of our own age. We have arrived at the top of some table land, peak or mountain top of observation, from which we look out upon the march of time and progress, observing the advance and recession of the waves of opinion. Stretching away in front we scan the outlying surface of the progress of the future, take in the mountain ranges of difficulty passed and in prospect, and wonder what mountains of difficulty and labor shall loom up before us in the future.

Like Bonaparte, whose ambition took the world for conquest and whose genius was equal to almost all emergencies (save the field of Waterloo), when his army came to the Alps in mid-winter he said to one of his generals: "Is the ascent possible?" He was answered: "Barely possible." Said he in reply: "Let the ascent begin." In this spirit we go forward in actual achievement, in almost herculean labor amid defeat, disappointment and death, yet with evident progress and *esprit du corps*; and this spirit in Europe, Germany and France speaks to America, and America back to these and other nations; while a trans-Atlantic writer having caught the spirit of the age writes this sentiment, viz.: "The medicine of the twentieth century—sanitary science and surgery." It may be surgery with Listerism, but at any rate it will be sanitary science and preventive surgery. I mean less operation and more prevention. Whatever it may be, in the advance of our science and art, it has certainly been demonstrated that cleanliness and surgery is next to godliness in life, and we accept the inevitable and call it progress. Invested with the interest which the discussions, pro and con of the past and present, have given to us, there is no subject which can occupy our minds more profitably.

In fact, from the early history of medicine to the present, no one subject has been of more value than the one we desire briefly to present in the treatment of surgical wounds. The methods have always differed, but perhaps less widely now than ever before. One of the first things to be understood is this, viz.: That there is a vast difference between a sub-cutaneous wound and an open one. In what does this difference consist is a very important question to settle. Hence that method which gives results most nearly

like those following subcutaneous injury, and this means when reduced to its simplest terms (as in algebraic formula) that method best adapted to secure primary or immediate union. Let us stop here a moment to learn what led to this view which is now accepted by the adherents of Listerism. Thanks to the revelations of the microscope, including the investigations of Pasteur, Koch and others, the present generation of medical men were taught that fermentation and decomposition are due to myriads of organisms, and these are found everywhere pervading the air and water and are rapidly multiplied under conditions of heat and moisture, especially in albuminous and nitrogenous compounds. Pasteur also showed that fluids had undergone no change when such germs were excluded and could be so excluded by filtering the air in which they were exposed through layers of loose cotton fiber. What remarkable relation this bears to wound treatment, not known or understood at the time, but applied by the revelations of the microscope becomes applied science on the basis of deduction.

In an article in the London *Lancet*, Vol. 2, page 553, by Jos. Lister, in 1867, "On the Antiseptic Principle in Surgery," Mr. Gamgee says: "On none of my visits to the Hotel Dieu, in former years, had I seen wounds look so well, and there could be no doubt that the old antiseptic practice, with a comparatively new agent had been generalized by Maisonneuve with manifest advantage, in resisting the pernicious influences of an unhealthy hospital." He says further: "The sensational circumstances under which the antiseptic system was revived in London, excited an amount of interest which detracted professional attention from great surgical principles, viz.: Rest, position, pressure and exclusion of air in healthy houses or hospitals are conducive to the healing of the majority of wounds. Pyemia, erysipelas, sloughing phagedena, and their allies are directly produced by unhealthy surroundings in hospitals. In prevention of these, antiseptic agents are of great value, but it must be borne in mind, that their use is not necessary in surgery out of unhealthy hospitals and in the absence of other unhealthy conditions." Van Sweiten advised antiseptic applications in very bad compound fractures quoted in Percival Pott, (op. cit.) Vol. 1, page 451. Burgreave, "Le Genie de la Chirurgie," 1853, page 42, advises "the application of hydrochloric acid and honey as a topical preventive of purulent absorption and hospital gangrene."

Sedillot, "Infection Purulente et Pyemia," Paris, 1849, page 503, recommended the application to suppurating surfaces of aromatic wine, and decoction of bark, with or without the addition of sul. acid, sul. copper, or cor. sub." Boyer "advised the use of the chlorids to counteract the putridity of the blood." Gerdy, (Chirurgie Pract.) Paris, 1853, Vol. iv, page 146, urged that "the treatment of suppurations required amongst other means, disinfectants;" and surgical literature abounds in records to prove that the same principles have been carried out by a variety of means, among which are mentioned "benzoin or benzoic acid, clay, pitch, tar and chloralum. Hence a larger experience since has not yet fully convinced many eminent surgeons of the necessity at all times and places of the use of antiseptics.

"The fact is now, and has been clear that the disturbing influence of the carbolic acid controversy, as the disinfectant *par excellence* has been especially

marked in the treatment of wounds not made by the surgeon, viz., compound fractures; and in these carbolic oil, putty, gauze and spray have served to detract attention from the essentials, viz., air exclusion, rest, position, pressure. Fundamental principles have been lost sight of, while theories have had an ephemeral repute." While this has been true in some senses, and while Lister stands to this question in very much the same attitude as Sir J. Y. Simpson stood in relation to that of anesthetics, let us gather up the present facts and status of the question and see if it be a real progress or is it only seeming progress. We should also remember the history of the question so far as Lister's name is connected with it. It was in the old Edinburgh infirmary, where was ignored all notions of hygiene and healthy surroundings, when Lister began his experimental use of the treatment of wounds by carbolic spray, dressings of gauze, carbolic oil, etc. Since then, having risen into some notoriety he was called from the University of Edinburgh to London to teach surgery in the metropolis of Europe. Yet with his position and commanding influence he has not been able to enforce upon the professional mind the entire acceptance of his teachings. It is well it is so. Governed by traditions of experience and the dogmatism and conservatism which has been the result of our educational systems, the profession in both hemispheres has ever been slow to adopt new methods and new doctrines, and have usually applied with rigorous severity the reason and the facts. The history of surgery for the last decade in all the world shows better results, owing to something. The question is, What is that something? When in cases of fever we observe the temperature and pulse we now know that these are correlated to something, and we now know what that something is. We see the patient emaciating, wasting every day, and the problem is solved in the estimation of the excreta of the body by a quantitative analysis. So we now bring all questions to the *experimentum crucis* before accepting as proved any doctrine or theory. The opponents of antiseptic methods, of whom there are many, claim that the improvement is due to greater care, sanitary regulations, better dressing of wounds, the better comprehension of the nature of inflammation, the better comprehension of the vital forces in each case rather than to any special local dressing, including special antiseptic methods. One thing here, however, must now be conceded, viz.: That the dangers to be overcome in the treatment of wounds lies in those special reasons or conditions which cause a failure of primary union, and that these conditions are due in great measure to the changes, septic or otherwise, which take place in the wound, and these are believed now to be, if not absolutely proved to be, the presence of living germs. Here I am trenching upon the actual groundwork of the whole question, and for the sake of the presentation of the history of the question by observation drawn from the experience of men all over the world, we will admit that germs exist and through air and water and clothing and dressings come into contact with wounds.

All surgeons are acquainted by observation with the rapidity and safety of repair secured in the proper dressing of a simple fracture, and equally well with the dangers to limb and life in compound fractures. What constitutes the difference? It is not now believed to be in the greater severity of the lesion in

the latter above the former, but owing to some element introduced which produces a wide difference, and these are believed to be living germs which occasion septic inflammation and suppurative history. This engenders a poison which affects the entire organism. Pyemic conditions are induced, blood contaminated and poisoned and thus the danger is not so much from the nature of the wound as from the conditions which grow out of it. The demonstration is, I suppose, quite generally accepted that a large number of acute and specific forms of disease are dependent upon the development of various kinds of germs which may be specific to the form of disease produced, and modified by peculiar or special circumstances so as to give definite results.

Recent developments in the investigation of the special influence which seems to be exerted in the causation of disease shows a much more widely diffused agency by germs in the production of disease than had previously been supposed, and now the investigators are asserting that germs exist, only to be positively denied by others who are entitled to equal acceptance. The wide dissemination and existence of pathogenic bacteria at least gives an easy and more satisfactory explanation to rapidly spreading contagious and infectious disease, and that subtle factor which has been so much needed to explain the facts of contagion and infection is believed to be found in the doctrine of germs. "Pasteur's experiments, in which he cultivated the germs, show that certain forms of bacteria which were rapidly destructive and deadly may be so modified as to lose a large amount of virulence though reproduced in a similar manner, and this modification of power is shown to be only in a change of temperature to which they are subjected." The converse may also be true, and ordinarily bacteria which might develop serious difficulties in disease may be rendered harmless, or permitted by circumstances to be fearfully destructive of human life. Apply this thought to cholera and diphtheria, which are now classified in "Ziemssen's Encyclopædia of Practice" as germ diseases. Everybody knows the dangers accruing from the unhealthy wards of long used hospitals to the unfortunate sick or wounded, yet while this is so and while hygienic and sanitary law are constantly being thundered in our ears it is yet a fact that the sanitary condition of hospital and home, and city and town are such as to produce disease and death to many who ought not to die.

In the history of the ever-widening knowledge of our art the relationship of medicine and surgery become more and more intimate. The factors in the production of disease are proven in many cases to be due to germs, and (injuries) as wounds—whether surgical or otherwise—are shown to be more readily manageable in proportion as cleanliness and disinfectants are and have been tried. Processes are now known to be putrefactive and septic, hence the relation which the special causes of these conditions bear to wounds and other processes of disease are relations of primary importance. It has been claimed that the "exudation" material does not depend upon the presence of germs. That depends upon the fact whether inflammation is upon a free surface or entirely subcutaneous. "It is claimed that the germs are also found in subcutaneous injuries, while again others claim that septic organisms are primarily the source of all inflammatory and other troubles to which wounds are liable." To one acquainted with

the processes of cure in wounds in different individuals there can be no doubt that the processes of putrefaction differ very widely, and this is owing to various causes and conditions. In one case the vital state of the individual; 2, the immediate surroundings of the patient; 3, the cleanliness which is observed, all have much to do in the history.

Lawson Tait, one of the strongest and perhaps most uncompromising opponents of Listerism, while at the same time the most exquisite as to methods of cleanliness, yet shows most remarkable results without the aid of anything save excellent knowledge and clean hands. He draws a distinction and asserts a difference between germs upon the living and dead tissues, alleging that it is introduction of the latter—conveying germs and dead elements of tissue—which causes such serious consequences. In this, he is at least partly right and may be wholly so, as witness what occurs in the deep recesses of organs when dead elements are changed in form and become lodged in various structures as fibrin from the valves of the heart thrown into brain, lungs or liver followed by inflammation, abscess and consequences. Here there are no germs. Yet Stokes makes answer to this objection and argument thus, "That those who hold this view ignore the elementary fact that there never was a wound, and especially one in which vessels are tied or twisted, in which dead and living tissues are not at once brought into contact." "Also, if dead material is necessary for the growth of germs the abscesses which are found infested with myriads of bacteria in pyemia and in ulcerative endocarditis are difficult of explanation."

It must be true if we would comprehend the changes in the bioplastic material in health, that we must also understand the capacity of this material for living under greatly altered conditions and which varies greatly as we descend from higher to lower forms, the highest being destroyed by a slight alteration in the conditions, while lower forms of matter resist destruction and for long periods of time. The pus corpuscle and the particle of contagium, both of which are descendants of the germinal matter of the organism retain their vitality under conditions which would be fatal to the germinal matter from which they spring. Hence we can easily understand the statement of Mr. Tait, "That the bioplastic exudation from a wound in healthy tissues has a vitality of its own, often superior to the most active germs, and either fails to furnish them the necessary pabulum or walls them in from producing further damage and finally eliminates them from the body as is found in a localized abscess."

But mark the difference which is manifested in a devitalized patient in the processes of the growth and multiplication of these germs. Many blastema distinguished by their ready coagulability (dependent upon the fibrin contained) do not rise above the lowest grade of form development, and if germs of disease or any other kind find admission into such material or blastema it is easy enough to see that the development of cellular forms in harmony with the law of organization or development can not go on in order and harmony.

In the discussion of surgical questions in various parts of the world, we find developed marvelous improvements in English, German, French and American surgery during the last decade, and it becomes us carefully and patiently to investigate the causes of

such progress. If it be assumed that men are mistaken as to the merits of antiseptics in the surgical treatment of wounds throughout the world, to what then is to be attributed the great advance in success and the lessened mortality. When we take up the question of evidence we find Lister himself from 1876 to his British Association address presenting the doctrine and methods; and Mr. Savary in his British Association address on surgery at Worcester, hurling denunciations against Listerism while Tait and many others are arrayed as outspoken opponents, having tested it to their satisfaction. Savary, in this address, claimed from the statistics of St. Bartholomew's Hospital, as good or better results without the use of antiseptics. He also read another paper before the British Medical Congress of 1881, "On the Causes of Failure to Obtain Primary Union in Operative Wounds." He claims "that the remarkable improvement in the surgery of to-day is due to better sanitary arrangements, yet Mr. Savary admits two things: 1, the germ theory of putrefaction; 2, that his method is essentially antiseptic, embracing carbolic catgut ligatures, carbolic oil, drainage, washing the wound with a solution of permanganate of potash, or some other potent antiseptic.

Stokes, of Dublin, in his British address not only vindicates Listerism, but answers Savary by stripping his address of all its pretensions, and brings out the admissions which he makes and yet so beautifully covered up by his touches of eloquence. Keith, the ovariologist, a very competent witness, says: "For some time I have not found carbolic spray necessary, and have not used it in my twenty-seven last cases, all of which have recovered easily. With every possible care, the spray has not in my hands prevented the milder septicemia, and its effect upon the kidney was sometimes disastrous. I have seen hemorrhages from the kidney follow long operations, and two deaths in hospital patients were occasioned by carbolic acid poisoning. Though I had at one time a series of eighty recoveries under spray, I have reluctantly given it up, believing that on the whole it did more harm than good." Lister, in his discussion of the question, Is the spray really necessary? replies with candor thus: "In other words is there sufficient chance of the air of an operating theater or private room containing septic matter which can prove effective in blood serum to make it needful to regard the question of contamination from the air at all? If the answer must be given in the affirmative and the choice must lie between the spray and antiseptic irrigation during the operation at intervals, or with syringing the cavity of the wound after dressing and with every precaution, then I should give my voice decidedly in favor of the spray, as being more certain of attaining its object and involving less irritation of the wound, and also in the use of carbolic acid much less risk of carbolic poisoning." He says further: "I should not feel justified, except on perfectly established grounds, in omitting any part of the technique by which results so important to our fellow creatures have been arrived at. Finally, if further investigation should confirm the conclusion to which our recent facts seem to point and it should indeed be proved that all idea of atmospheric contamination of our wounds during operations may be thrown to the winds, then no one will say with more joy than myself: 'Fort mit dem spray.'"

Notwithstanding the earnest advocacy of careful

antiseptic surgery by such men as Esmarch, Volkmann of Germany, Spencer Wells, Thornton, McCormac, Gant, Prof. Humphrey of England, Dr. J. Marion-Sims, now dead, (all honor to his memory) with many others, the reports of the British Congress made out a verdict that antiseptic surgery had received its doom and Listerism was dead. And so the refrain has been gathered up and echoed across the continents, and the AMERICAN MEDICAL ASSOCIATION, at St. Paul, through its members proclaimed with added proof that "Listerism was dead."

Why this refusal of men in both hemispheres to accept the doctrine, if tested by sufficient experience; if not proved then wait the results of more patient and conservative testimony before reaching a final judgment. It must grow out of the impatient restraints of dogmatic teaching, or otherwise it grows out of hasty and imperfect conclusions by men who ought to be in such positions as would enable them to decide upon the value of antiseptic treatment. So late as Nov. 5, 1883, the discussion before the London Medical Society was protracted an hour beyond the usual time of adjournment to hear Prof. Lister answer the objections made to his doctrine and practice. Bryant, author of a work on surgery, made a strong case against Lister's teachings. The subject under discussion was Lister's address, and the special question was the management of recent fracture of the patella by wiring the fragments together. Besides Bryant, Adams, Bloxam, Gant, Morris, Rose, Turner and Baker concurred in the opposition to the doctrines of Lister, and Bryant contended that strict Listerism was not necessary in order to be perfectly in accord with the grand principles of antiseptic surgery, which in the minds of the opposition means strict cleanliness in everything pertaining to the dressing of wounds, as well as the most perfect hygienic conditions about the patient. "Bryant thought that any operation upon the patella was unjustifiable, because the results of the old-fashioned treatment were in his experience quite satisfactory."

So we find Listerism is not accepted in Lister's own home in London, yet we should expect that the fiercest fight of ideas will come from men who live in his own city, verifying the old aphorism, "That a prophet is not without honor, save in his own country." Coming directly to the facts of the subject, Do they sustain the extraordinary claims of antiseptic surgery, it would seem that the verdict of the two great medical associations, British and American, ought to be able to settle this question, yet we are of the opinion that the verdict will be made by a more universal congress than either; the matured judgment and opinion resting upon it of the surgical thought and experience of the world. When this verdict of judgment will be rendered is still in the future. It may be long after Lister has departed, when his works shall be freely weighed and estimated. In such a vast problem it is very difficult to obtain reliable data, as "facts seem to have a special aversion to registration." Statistics alone can in time show the bearings of this question; in the question of suturing the broken patella we have the results in forty-nine cases which show 16.3 per cent. of suppuration of knee joint, 6.12 per cent. of deaths, 4 per cent. of necrosis of fragments, 4 per cent. of amputation of thigh—and which results completely negative the dogmatic assertion of Lister in his address that "antiseptic treatment converts

serious evil into complete safety." In favor of the operation it must be said, "that a large majority recovered with bony union and excellent use of the joint." But let it also be remembered that in eight cases there was suppuration of the joint and other grave difficulties—as exhaustion, death, pyemia, amputation; and in others which recovered of the eight there were stiff joints and necrosis of fragments.

Ovariectomy is not now regarded as a very dangerous operation. Its dangers have been greatly diminished by the precautions which have been thrown around it by antiseptic methods, and yet it is believed by many, among whom are Keith and Tait, that the antiseptic method is not so valuable here, while Lister himself regards his method in this field as least successful. Spencer Wells in this field has the most remarkable experience and which sweeps over a wider range, giving it as his unqualified opinion that both in safety and rapidity of recovery it is the most efficient and protective of agencies. Keith has abandoned the use of the spray, but is not inclined to the use of the method so much as formerly.

We have not time to review the broad field of surgical endeavor and must close without attempting a statistical review of the various kinds of operations and wounds resulting, as the statistical evidence is not yet full enough, nor complete enough with all the conflicting evidence in the question to determine the full value. In the cases of compound fractures, and other open wounds affecting large joints, are found a class of cases which furnish the best proof of the value of antiseptics. Prof. Volkman reports seventy-five successive cases of compound fracture without a death, and does not hesitate to claim that without infection there is no suppuration, and that to obtain primary union, by which is meant immediate union, two factors are necessary; complete disinfection and absolute opposition, so that the parts have the chance of growing together. "While admitting," Volkman continues, "that a depraved constitution and a devitalized condition would render the patient less able to resist the influences of germs or poisons, he asserts as a demonstrated clinical fact "that such patients have a revivifying bioplastic power sufficient to afford immediate and complete repair if treated antiseptically." We doubt this, as stated, because it is as fully demonstrated that there is an organic dyscrasia, by which is meant some "unknown aberration of nutrition" in certain cases, which can not be remedied by any processes yet made known to us. This dyscrasic state of the blood is a factor in disease now recognized by the leading teachers of medicine in the world, among whom are Vogel, Libert, Rokitsansky and many others. Hence, while using disinfectants the general question of nutrition must be comprehended. We have said these organisms are found in this relation *post puerperium*; hence the question arises, What relation exists between these and septicemia?

The fact of existence under the circumstances indicates some present relation. No condition exists in such cases by which these could so readily find admission to the interior of the body as after a lying-in or confinement. These changes are believed to be septic changes in the uterus, and the modes of introduction. There are three modes of infection: 1, absorption by the lymphatics; 2, extension of septic changes along the mucous membrane of the Fallopian tubes into the abdominal cavity, as seen in

the ovaritis by the gonococcus, which is a typical case in gonorrhoeal inflammation. This affects the lymphatic system, as seen in the enlarged inguinal glands, but its most permanent effects in the female are due to extension of inflammation along the mucous surface to the peritoneal cavity; 3, *direct passage* of septic matter into the circulation, as by the two first methods the septic matter reaches the circulation and causes or may cause metastatic abscesses in various organs. The uterus, under the conditions after delivery, presents most favorable conditions for such development. The veins close by thrombosis, and the septic material containing the microorganisms are rapidly thrown into the circulation. The latter method is the most likely mode of infection in this case.

If we would understand the present state of our knowledge as to the relation of microorganisms to puerperal septicemia, we must study the literature of the subject. Here we shall no doubt find a solution of that much *questio vexata* of puerperal fever, and here we may find a firm basis of pathologic facts, instead of vague theories and changing views or notions, upon which to ground a successful treatment.

HISTORICAL RÉSUMÉ.

The literature of this subject is fully brought up to about 1880 or 1885 by Dolores and monographs by Lusk, a more recent one by Lomer, and a beautiful work by Woodward. Hare gives an exhaustive description of pyemia and allied conditions. Attention was first directed to the subject in 1869 by Coze, Feltz and Mayerhofer of microorganisms as a cause of puerperal fever. They have been found since by others. They have been traced from the diphtheritic lining of the endometrium through the lymphatics, into the peritoneal cavity, and also by the lymphatics through the diaphragm. Pasteur, the celebrated investigator of organisms, recently applied to the study of hydrophobia, has given his investigations in seven cases of puerperal fever, various forms of germs being found in the progress of this disease. The exact relation of germs to the development of this disease and septic poisoning generally has not yet been satisfactorily tested, but there have been established some very important facts, viz: That we have the same pathologic changes in puerperal as we have in surgical fever, and that these hold the same relation to the germ theory. In most cases we have to do with blood poisoning from wounds identical in pathology with the poisoning of the blood from an amputation wound.

The conclusion from all that is known is that the condition of the interior of the uterus occupies the same position as to the septic poisoning as the stump of an amputation wound. The lochia gives valuable information as to the state of the uterine surface, but we should remember that we may have septic absorption going on when there is no factor of the lochia. We must distinguish between putrefying matter and septic matter, as all putrefaction within the uterus after delivery will cause septic poisoning, but all septic poisoning does not imply that putrefaction must have occurred as to the fluids. This difference grows out of the difference in the microbes which mark each process.

Finally, the germ theory receives confirmation from the fact that those substances which are shown to be

the most effective in the destruction of germs have proved most useful in the treatment of septicemia. It is a fact well observed and established beyond question that washing out the uterus with antiseptics in cases of puerperal fever is followed by most remarkable results in the reduction of temperature and pulse. Carbolic acid was first the favorite remedy, but solutions of bichlorid of mercury seem to possess so many advantages that it is among the most popular remedies because it is more destructive to germs. Toxic effect has been charged to both remedies, but bad results only occur in improper use or strength. So I would use solutions which destroy germs and produce antiseptic results, and thus save cases from the development of those much to be dreaded forms of disease, pyemia, septicemia and puerperal fever. This answers the questions at the head of this paper, and shows us that prevention in surgery as in medicine takes the form of the trans-Atlantic writer: "The medicine of the twentieth century, viz: Sanitary science and surgery."

THE TREATMENT OF OPEN FRACTURES.

Read by title in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOHN B. HAMILTON, M.D., LL.D.

PROFESSOR PRINCIPLES OF SURGERY AND CLINICAL SURGERY RUSH MEDICAL COLLEGE; PROFESSOR OF SURGERY CHICAGO POLICLINIC; SURGEON TO U. S. MARINE AND PRESBYTERIAN HOSPITALS, CHICAGO.

If aseptic surgery had been practiced only in the treatment of open (compound) fractures, it would have accomplished much for humanity. It is safe to say that there are not one half as many amputations performed since the commencement of the present treatment as formerly. Lives have been saved that otherwise would have been sacrificed, and useful limbs are now seen where a few years ago, a wooden substitute was worn as a perpetual reminder of the shortcomings of the surgical art. The aseptic treatment of an open fracture requires first the thorough cleansing of the limb and the wound. The limb should be shaved and washed clean. Irrigation with boiled water is the best means of securing cleanliness of the wound. If there should be venous oozing, it should be stanchd with hot water, or irrigated with a bichlorid of mercury solution 1 to 4,000. The styptic effect of this solution is at once seen in the bleaching and drying effect produced. Any spurting vessel should be tied with carefully sterilized catgut. The next step is to secure accurate coaptation of the fragments, sharp splinters (*spiculæ*) should be removed, but broad fragments, even when considerably comminuted, should be readjusted. The elevator and the heavy bone forceps will be frequently needed to bring the fragments into position. It is well known that the principal causes of non-union, outside of constitutional causes, are: 1, want of apposition; 2, interposition of muscles; 3, excessive motion. Every care should be taken therefore to avoid these causes of non-union.

Direct fixation of the fragments is one of the most important indications. This may be accomplished by periosteal suture or bony suture. I have many times secured good union in bones of the foot, for example, by the periosteal suturing of the fragments. Chromicized catgut or whale tendon should be used, and a sufficient number of stitches taken to bring the fragments together. In case the obliquity is such

the fragments can not be brought together by periosteal suturing, then the osseous suture may be made; after trying many expedients, and experimenting with many kinds of suture, I have reverted to silver wire as being that best adapted to the work. These sutures in some soft bones may be passed obliquely through with a stout needle, but generally a small drill hole must be made to enable the passing of the wire. The wires must after twisting, be left long and project from the wound so as to facilitate easy removal.

I have had no experience with the use of bone dowel plug placed in the medullary canal to secure fixation. It has seemed to me so liable to be septic, and there must be so many practical difficulties in the way of final removal, as to make it a dangerous appliance.

In five cases I have used the bone ring introduced to the notice of the profession by Professor Senn. In every case there was suppuration, and I have abandoned it, until such time as we shall be enabled to sterilize the ring. It is yet so far from perfection in that regard, as to make it almost certain that the wound will become infected. The principle may be yet found useful by the invention of some different material. The bone ring (or thimble) has one advantage, that is the great amount of exudate (forming callus) which is excited by the presence of the ring. So pronounced is this effect, that in cases of ununited fracture where there is no attempt at the formation of callus, the ring may be used to advantage notwithstanding its general lack of sterilization.

The condition of the soft parts must next be looked to. Indeed it is a matter which is scarcely secondary to the proper treatment of the fractured bone. Wounded tendons, torn muscular structures and lacerated nerves should be sutured according to the rules laid down for the respective tissue involved. Stout chromicized catgut will be found useful for tendons, and fine flexible catgut for nerves. In case the distal and proximal ends of a nerve or tendon can not be brought together, they may be sewed to the nearest adjoining nerve or tendon. All this takes time, but it will be well spent. When the wound is cleaned the bones are brought together, and the soft structures thus attended to, then irrigation is again practiced and the external wound closed by sutures of silk-worm gut. Extension is usually not necessary if the fragments have been brought into perfect apposition, nor is there much difficulty in retaining them. External support should be secured by a plaster-of-paris bandage, and when necessary a fenester cut opposite the wound.

In complying with the wishes of our distinguished chairman, to keep within the ten minute line, it will be seen that I have chosen rather to support the existing practice, than to compile the literature of the subject, and if more attention shall be directed to methods of suture of the soft parts, in addition to bone fixation, the paper will have served its purpose.

FISSURE OF THE ANUS.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY THOMAS W. HUNTINGTON, M.D.

SACRAMENTO, CAL.

The lesion known as fissure of the anus is an elongated oval ulcer from one-fourth of an inch to an inch in extent and of variable depth. By many authors it is designated irritable ulcer or painful

ulcer of the anus. Bodenhamer classified fissures, according to location, into four varieties; but for the purpose of this paper the term will be applied to those having their seat in the skin and mucous membrane, external to the whiteline of Hilton, the line of demarkation between the external and internal sphincter muscles. The favorite location of anal fissure is upon the dorsal surface but this general rule has many exceptions. It may consist of a small linear abrasion, capable of detection only by careful inspection, but more often it will be observed as an indolent ulcer with indurated base and rigid walls varying in depth from one to three lines. Externally its existence is often marked by a superficial hemorrhoidal tumor, the "sentinel pile" of Ball. Upon exploration with a probe it is customary to find one or more excessively tender points within the boundaries of the ulcer. There is a tendency to hemorrhage in many cases but this condition is by no means constant.

Anal fissure has been observed occasionally as early as the first year of infant life, and is now and then met with in persons of advanced age. A very large proportion of cases, however, occur during the period of adult life between the ages of 30 and 55.

It is generally alleged that it is found oftener in women than in men but my own observation does not verify this statement. For obvious reasons, persons leading an inactive or sedentary life are more subject to anal fissure than are those whose employment demands active physical exercise. Among the various causes to which this lesion is ascribed, the chief and most apparent one is habitual constipation. Constipation in turn that may have been accidental and quite amenable to simple treatment, having resulted in the establishment of a small fissure is by the latter rendered incorrigible through the peculiar reflex influence of the ulcer upon the sphincters, the rectum and the digestive organs in general. As a result we find that the gravity of the structural lesion and the functional derangement correspond closely.

Anal fissure is a common and serious complication of all structural diseases of the rectum. Pain when an attendant circumstance of rectal ulcer, hemorrhoids, rectal stricture and syphilitic manifestations always suggests the possibility of the co-existence of anal fissure. In penal institutions the practice of sodomy is an alleged cause of this lesion, and violence done the parts by scratching in pruritis ani, and forcible distension during parturition are among the more infrequent causes of the same trouble.

Allingham alleges the earliest symptoms of anal fissure to be morning diarrhea. The patient is called to stool instantly upon arising, but usually with an unsatisfactory result, a small loose motion containing viscid mucus matter sometimes streaked with blood. This is succeeded by tenesmus and an uncomfortable burning sensation, and the experience may be repeated several times during the early hours of the day. As the disease progresses it is characterized by intense, agonizing, paroxysmal pain during and subsequent to an evacuation. This symptom is wholly out of proportion to the pathologic lesion which underlies it, and as often attends an apparently trifling erosion as a deeper more extensive ulceration. It undoubtedly depends upon the exposure of filaments of the pudic nerves, which are distributed over the area below and adjacent to the external sphincter. In pronounced cases this pain is

described as well nigh unbearable, and the act of defecation is regarded as an ordeal so terrible that the patient is often compelled to seek relief in the hypodermatic use of morphia. It usually persists for a protracted period, during which absolute quiet in the recumbent position is rendered imperative. Temporary relief ensues but the suffering recurs with each effort to unload the rectum.

Numerous reflex disturbances are also ascribable to this condition. Obscure and tantalizing bladder pains are common to both sexes. Prostatic irritability in the male, uterine colic and ovarian neuralgia in the female are frequently noted. The appetite is impaired, the digestive function badly sustained, nausea and vomiting ensue, and the resulting condition is that of emaciation and extreme nervous irritability and prostration.

An effort at digital examination is always stoutly resisted by the patient on account of the exaggerated sensibility of the part, and in a fair proportion of cases this step can only be taken after the production of profound anesthesia.

Since several small fissures frequently exist, some of which may be deeply concealed by anal folds, the use of a speculum is essential to a thorough knowledge of the situation. For this purpose I have found a heavy wire bivalve instrument exceedingly efficient, in that it permits an almost continuous view of the entire anal circumference.

There is a wonderful unanimity of sentiment regarding methods to be adopted for the relief of this most distressing malady. It is certain that the disease, save when it occurs coincidentally with malignant trouble is amenable to some form of treatment.

Cases which are a sequel of syphilitic infection are successfully met by the usual constitutional remedies, combined with the use of mercurial ointment locally.

In recent and comparatively mild cases scrupulous cleanliness, careful attention to the bowels, an abstemious diet, cessation from labor, and the application of a stimulating ointment will suffice to effect a permanent cure. I have found an ointment composed of a drachm of creolin and an ounce of lanolin a very efficient agent. To this may be added belladonna, cocain or opium as occasion may demand. I believe the use of nitrate of silver has been generally abandoned. In the more advanced and urgent cases, pure nitric acid, or acid-nitrate of mercury retain a few advocates. It is probable that they may be useful where a resort to more radical and seemingly rational measures is prohibited by the patient. Cooper and Edwards, however, in their work upon diseases of the rectum and anus unhesitatingly denounce the use of caustic applications of all kinds as "useless and mischievous."

Matthews, on the other hand, for those cases wherein radical measures are inadmissible, employs pure carbolic acid as a topical application and as supplemental to this he highly recommends a daily injection of an olive oil emulsion of iodoform, 5 grains to the ounce. The frequent occurrence of a persistent and annoying dermatitis in the anal region, as a result of the use of iodoform, has led me to abandon it entirely. We know that the skin of many patients is peculiarly susceptible to the irritant effect of this drug; and this fact has caused me to regard it always with distrust.

Under the head of radical treatment two plans are included; dilatation and incision. Owing to the ex-

treme sensitiveness of the anal region neither method should be attempted without the use of an anesthetic.

If simple dilatation is to be resorted to, it may be accomplished by inserting one or two fingers of both hands well into the rectum, and stretching the sphincters by drawing upon them in all directions; or the same end may be attained by the use of a powerful speculum. The process should be persisted in until the sphincters become perfectly relaxed, and must usually be repeated several times before perfect relief can be obtained. It is claimed, however, that a single introduction of a speculum for purposes of examination has now and then completely eradicated the difficulty.

The combined plan of treatment by dilatation and incision has been found so efficient and satisfactory that it has received the sanction of by far the larger number of operators. By no other method can we hope for so rapid and perfect relief from the main feature of the disease, the excruciating pain which attends and follows an evacuation. The details of the procedure are very simple. The rectum having been thoroughly washed out and the patient etherized, the fissure is exposed between the blades of a speculum. A free incision is then made through the floor of the ulcer extending at either end considerably beyond its limits. If the lesion be of long standing and deep seated, the knife should be carried into and across the border of the external sphincter muscle. Subsequently the process of dilatation should be fully completed as before described. After treatment consists in maintenance of cleanliness and attention to the bowels.

A PLEA FOR THE EARLY AND SYSTEMATIC REMOVAL OF THE INGUINAL LYMPHATIC GLANDS.

IN CASES OF MALIGNANT GROWTHS IN REGIONS FROM
WHICH THESE GLANDS RECEIVE LYMPHATICS.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY H. REINEKING, M.D.
SHEBOYGAN, WIS.

The rule that operations for the removal of malignant growths should include also the removal, not only of glands already perceptibly enlarged from secondary deposits, but also those which from their anatomic relations to the primary growth are likely to become the seat of secondary disease, as now quite generally followed in operations for mammary cancer, has been productive of much good. The fact that we can not determine by our examination whether a gland, though not perceptibly enlarged, may not after all be the seat of a secondary deposit, and the further fact that when those glands nearest the primary seat of disease have become enlarged, others more remote may in turn have become infected,—these facts form a sufficient argument for the general adoption of the above rule wherever practicable.

I was somewhat surprised therefore, on looking up the literature on malignant growths of the external genitals and the lower extremity, to find how little was said in our standard text-books concerning the management of the inguinal glands in such cases.

Two cases occurring in my practice during the last

half year, brought the importance of this subject to my attention so strongly that I concluded to use them as a text for this plea for early attention to the glands in such cases:

Case 1.—M. K., male, aged 48 years, single, farmer, German. Family history good, except that one brother died of cancer of the stomach when 27 years old. Phimosis since childhood. During the summer of 1892 noticed swelling at end of penis. This was followed by inability to void urine, use of catheter, purulent discharge from the swelling and hemorrhage. Penis amputated near its root, March 20, 1893. No glands extirpated at that time. Several weeks later some enlarged glands were extirpated in the left inguinal region, but others in the same locality, as well as in the right groin, began to enlarge almost immediately.

Present condition (July 4, 1893) appearance of cachexia, although general nutrition fair; stump of penis healed, except a small granulating surface around urethral opening. Testicles healthy. Both groins occupied by large masses of enlarged confluent glands, those on the left in a more advanced stage, and the skin covering them sloughing, the abdominal walls considerably involved, the masses very painful. Thorough removal being out of the question, parenchymatous injections of pyoktannin were tried, which was effective in so far as they prevented all odor; but the disease progressed rapidly and ended in death Oct. 3, 1893, less than seven months after the primary operation. There was no metastasis at the primary seat of disease nor any evidence of metastases in internal organs.

Case 2.—Mrs. D., aged 67 years, married, American. Family history shows no cases of malignant disease. Severe pruritus and eczema vulvæ for past fifteen or twenty years; lately severe burning and sharp pains. Examination shows a flat epithelioma, about an inch in diameter, involving the clitoris and upper portion of the left labium minus, which was excised Nov. 18, 1893. Careful examination at this time failed to detect any enlarged inguinal glands. Healing rapid, mostly by first intention. About five weeks later, several glands in left groin became rapidly enlarged and were extirpated Jan. 11, 1894. No infiltration outside of the gland capsules. Glands contained large cysts filled with grumous, semi-purulent matter. Every particle of gland that could be detected by the touch was removed. Healing again rapid, leaving a small fistulous track leading to the bottom of the wound, with slight grayish, liquid discharge. Recurrence in same locality within a month, the swelling increasing rapidly involving the skin and occupying the entire left inguinal region. The right side remained unaffected. Third operation Feb. 15, 1894. Removal of entire contents of left inguinal region, including skin, adipose tissue and glands down to the deep fascia, as well as the glands lying along the large vessels and belonging to the deep inguinal group. The removal of all the tissues mentioned was not difficult, the region of the vessels being left until the very last. Wound partly closed and packed with iodoform gauze; it remained in good condition, but showed no tendency to heal. The patient rallied well from the operation, but after a week began to fail from exhaustion, or possibly, secondary internal complications, and died March 4, two and one-half weeks after the last operation and less than four months after the extirpation of the primary disease. No return at primary seat of disease.

These cases show clearly that there must have been secondary deposits in the lymphatic glands at or before the time of removal of the primary disease, notwithstanding the fact that they were not perceptibly enlarged. They further show the great tendency of malignant disease of the external genitals to secondary location in these glands, and the great malignancy when once it has become thus located.

If malignant growths are of local origin, the early and thorough removal of the primary disease, as well as of those structures which are almost invariably the first foci of secondary invasion, can be reasonably expected to lead to a fair percentage of permanent cures, as has been sufficiently shown by the results of extirpation of the cancerous mamma, with simultaneous clearing out of the axillary space. On the other hand, if the glands are left until they have become enlarged, the results will as a rule be very

similar to those illustrated in the cases just outlined.

Why, then, not apply the rule which has long since been adopted in cases of mammary cancer, with equal force and regularity to the cases here under consideration? The difficulties and dangers of the operation for removal of the inguinal glands are certainly not greater than those attending the operation in the axilla, and the same may be said of the after treatment of the wound. After the skin has become involved, a large and disagreeable wound may indeed be left, just as in other regions, which fact is only another argument for adopting the extirpation of these glands as an essential part of the operation done for the removal of the primary disease.

I have limited my remarks to cases of malignant disease affecting the external genitals. All that has been said, however, pertains as well to the lower extremities, skin of lower portion of abdomen, and all structures sending lymphatics to the superficial or deep inguinal glands. For anatomic considerations and surgical technique I must refer to works on these subjects.

BLOODLESS VAGINAL MYOMECTOMY.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1894.

BY OSCAR J. MAYER, M.D.

SAN FRANCISCO, CAL.

Probably no question of abdominal surgery has given rise to more animated discussion and bitter controversy than the treatment of uterine fibroids in all their three varieties—submucous, interstitial and subserous. After electrolysis failed to realize the hopes that were held out to the profession by Apostoli, laparo-myotomy and abdominal hysterectomy were once more eagerly resorted to, and led to many modifications in treating the pedicle so as to avoid hemorrhage and infection. Present indications are that all these methods will soon be discarded for the more correct and ideal operation of removing the uterus *in toto*. Arrest of growth of the neoplasms was sought by bringing about artificial menopause following oöphorectomy. More recently, ligation of the uterine and ovarian arteries has been recommended to effect atrophy of the growths and uterus. Vaginal enucleation is only applicable to such tumors as either can be pulled through the cervix, or those that appear as fibroid polypi, having their seat in the body or cervix of the uterus. The removal by morcellation, as originated by Péan, of large submucous myomata or pediculated fibroids distending the cavity of the uterus, although favorably recommended by many eminent surgeons, has never found much favor with the profession at large. The reason of this is the excessive hemorrhage that endangers the life of the patient. Some authors supplemented Péan's morcellation by first splitting the cervix bilaterally as far as the vaginal junction, and extending these incisions even into the body of the uterus itself, if necessary, to have the required room for their operations, and then ligating the uterine arteries to control hemorrhage. These preliminary incisions into the cervix and uterus have been regarded as such severe preparatory measures that most surgeons prefer abdominal hysterectomy.

The preservation of the womb of a young woman is a matter of most vital importance, and our aim

should be a conservative plan of treatment that will remove the benign neoplasm, and will not carry in its wake sterility fraught with such momentous psychical and physical sequelæ. In the following case in my practice, I have successfully removed a fibroid tumor by morcellation, without any hemorrhage to speak of, by means of *temporary ligation* of the uterine arteries, having first caused obliteration of the cervix and dilatation of the os by vaginal packing, inducing contractions similar to the first stage of labor:

Mrs. H., age 28, of previous excellent health, gave birth five years ago to a living child, passing a normal puerperium. Since then her menses were regular until ten months ago, when about two weeks after menstruation, patient had a hemorrhage which lasted about two days, accompanied with pains in the back and groins. From then on, hemorrhage occurred at irregular intervals, with more or less pain. Four months ago, while constantly losing in weight and strength, patient noticed an increase of abdomen, which was very hard to the touch. Consulting a notorious quack, he pronounced the growth to be a cancer, and patient became alarmed about her condition. During the past eight months patient had lost forty pounds, and at the time of consultation weighed ninety-eight pounds. The lower abdomen protruded, the uterus was plain to the touch, enlarged and perfectly smooth, the fundus a finger's breadth below the umbilicus, corresponding in size to the fifth month of pregnancy. Auscultation revealed no sounds over site of uterus. The os was sufficiently dilated to permit the entrance of one finger, which felt a hard smooth mass. The digital examination caused quite a hemorrhage, so vaginal packing with iodoform gauze was employed to check it. Twenty-four hours after the packing was removed, the cervix was found obliterated, os dilated to the size of a silver dollar. Removal of the tumor, per vaginam, was proposed to the patient, and at the same time permission was obtained that if this should prove unsuccessful, abdominal hysterectomy should be resorted to, to remove the growth and uterus.

The idea suggested itself to me to try and prevent, or to reduce hemorrhage to a minimum by passing a temporary ligature *en masse* around the uterine artery. The vagina having been thoroughly irrigated with a 2 per cent solution of lysol and a Martin posterior speculum *in situ*, the field of operation was still further enlarged by retractors. With a strong volsellum forceps seizing the tumor, tumor and uterus were strongly pulled downward and to the right side in order to bring into view the vaginal junction of the cervix. With a large, strongly curved needle, threaded with a double thread of No. 12 braided silk, a ligature *en masse* was applied around the uterine vessels, by entering the needle well anteriorly to the transverse median line of the fornix, bringing it out equi-distant posteriorly to that line, and the two ends of the ligature were then securely tied. The uterus including the tumor being strongly pulled toward the left side of the patient, a temporary ligature *en masse* was applied to the uterine vessels on the right side. Morcellation of the fibroid was proceeded with by means of a pair of Sims' scissors, guided by the finger, which resulted in bringing forth forty-eight small pieces of the tumor until sufficient room was made to deliver the large remaining mass by traction. The weight of the tumor was nearly four pounds. Before the operation the tumor must have measured six and one-half inches in diameter. This was ascertained by enveloping the removed pieces in a towel and measuring the circumference of the enclosed mass. The uterine cavity was packed with iodoform gauze and the temporary ligatures were removed. Patient was given two hypodermic injections of ergotin. The time required for the operation was one hour, during which time the patient did not lose more than two or three tablepoonsful of blood. Twelve hours after the operation the intrauterine tampon was found forced out of place to more than half its extent, and showed very little bloody discoloration. The second day after the operation, the remainder of the tampon was removed, and as a precautionary measure the patient received a hypodermic injection of ergotin. Patient was kept in bed for twelve days, passing an uneventful time toward recovery, the temperature at no time rising above 99.2 on the evening of the operation. On the twelfth day patient left her bed, a convalescent, rapidly gaining in weight, until now she shows an increase of twenty-six pounds.

Despite the free anastomosis existing between the ovarian and uterine arteries, the circulation can temporarily be arrested for a sufficient time to allow of a bloodless operation being made on the cervix or in the uterine cavity, as was demonstrated in this case. While the anastomosis of the ovarian and uterine arteries is quite free, I do not believe that the collateral circulation is as easily and quickly established as it would appear from accepted drawings illustrating the vascular supply of the uterus and its appendages. Dr. J. H. Barbat, Demonstrator of Anatomy in the Medical Department of the University of California, who kindly assisted me in this operation, has carefully dissected out the vessels supplying the female organs of generation in a well injected subject, that he might ascertain the exact anastomoses and sizes of anastomosing vessels between the ovarian and uterine arteries. Further researches on this subject are necessary to substantiate my skepticism and will be published by Dr. J. H. Barbat as soon as his labors are completed.

The danger of including the ureter in the ligature can be avoided if the needle is not passed too close to the cervix. Even should this occur no apprehension need be felt, as temporary compression of the ureter for such a short time will not cause any evil consequences. Puncture of the uterine artery is avoided by selecting a strongly curved needle of large size, taking care that the needle traverses a large semicircle from its entrance in the anterior fornix to its point of exit in the posterior fornix vaginae. Injury to the intima of the uterine artery from compression is not to be feared any more than injury to the vessels by using Esmarch's constrictor for bloodless amputations.

Bloodless operations are one of the triumphs of modern surgery, and with the great discoveries of the last fifty years, which enable us to operate without pain to the patient, and which have reduced to a minimum the danger of infection, conservatism should guide us in all surgical procedures. The time is fast approaching when the surgeon who removes an organ, except as a last resort, will have sinned against nature, and will by his very act pass sentence upon himself in the forum of Medicine.

THE USE OF ACETANILID IN MEDICINE AND SURGERY,

WITH SPECIAL REFERENCE TO ITS SURGICAL APPLICATIONS, INCLUDING ILLUSTRATIONS OF ITS USE IN MINOR SURGERY, AND ITS ACTION IN TWO IMPORTANT CASES INVOLVING OTHER IMPORTANT FEATURES.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY G. W. WOODS, M.D.

MEDICAL INSPECTOR UNITED STATES NAVY, IN CHARGE OF HOSPITAL MARE ISLAND, CAL.

Acetanilid is a synthetical compound produced by the inter-action of anilin with glacial acetic acid at a high temperature, the distillate being collected at 295 per cent, and re-crystallized from boiling water.

It appears in shining crystalline plates, in powder colorless and odorless having a greasy feel, is neutral to test paper, and has a feeble acid taste. It is soluble in 31 parts of alcohol, in ether and chloroform, and its alcoholic solution permits of large dilution with water without precipitation. It melts at 113 Cent., forming a clear liquid, and is decomposed

by acids and alkalies. Exposure to moisture and mixture with water does not affect its integrity.

An easy test for acetanilid is heating it with liquor potassæ and a few drops of chloroform, when a distinctive odor is developed partaking of the nature of phenyl and ethyl compounds, said to be phenylisonitrile. Another is the boiling of 6 grains with 1 drachm of acid-hydrochloric until the mixture becomes clear, and then adding 3 drachms of water with 4 drops of acid-carbolic previously dissolved in a half drachm of liq. sod. chlorinat. This produces a turbid pink solution, becoming blue on the addition of excess of ammonia.

The use of acetanilid, or antifebrin, its copy-righted title, or chemically, phenyl-acetamid, dates from 1887, when it was first brought to notice as an antipyretic, and classed therapeutically from its analogous effects on the system with those other but recently introduced remedies, antipyrin, and phenacetin.

As an antipyretic, acetanilid has sustained all that it claimed for it, and where given in moderate doses has never indicated the slightest poisonous or depressing effects even in children. Where toxic symptoms have been manifested they have followed an administration of the drug in the same manner as antipyrin, while the dose should be graded to one-third of the latter drug. It is adapted to every form of fever, the continued, enteric or malarial, and eruptive, and to all inflammations associated with high temperatures, but should be carefully watched for fear of individual idiosyncrasy and, commencing with small doses of 2 to 3 grains, be increased, if necessary, not to exceed a half a drachm daily, save where indicated to combat the more intense forms of pain.

In spasmodic affections such as asthma, pertussis and epilepsy, as a nervine and analgesic in the worst forms of neuralgia and rheumatism and, in fact, to all affections characterized by spasms or pain it is especially applicable; and in cerebral congestions, the delirium of fever, and even in delirium tremens it acts as a most satisfactory sedative and hypnotic.

In its effects on the temperature its influence is manifested more slowly than antipyrin; it is diuretic and diaphoretic; and while antipyrin is a positive cerebral sedative and general depressant, acetanilid while hypnotic, is rather a moderate stimulant to the cerebral, muscular and vaso-motor systems.

I have thus epitomized the experience and observations of seven years in the world-wide use of this drug in medicine, deeming it unnecessary to present any clinical notes as evidence, the periodical literature of our country during this period having offered an abundance of detailed reports establishing the facts enumerated. These bear testimony of a convincing character to the usefulness of acetanilid, and demonstrate the propriety of making it a permanent addition to the drugs we should always wish to have within our reach, as necessary to us as opium and its alkaloids, and the derivations of cinchona bark.

Thus much for medicine! But acetanilid has surgical applications of even greater importance, although until recently its external use was derided, and yet its antiseptic powers were long ago recognized and it was recommended as especially applicable to the preservation of aqueous hypodermic solutions. The only surgical indorsement it had hitherto received had been from Dr. K. P. Wasilevitch, who had found

it an admirable substitute for iodoform as an application to primary venereal sores, which had healed with great rapidity under its local application.

This was the status of acetanilid in surgery until less than a year ago, when a modest communication to the *Medical News*, (Vol. lxiii, page 438,) from Dr. Francis W. Harrell, of Gilman, Washington, announced its remarkable adaptability to the dressing of lacerated wounds. He states that he was led to use acetanilid simply from its being non-hygroscopic, and he first applied it to an extensive lacerated wound of the skin and muscles of the lower arm and fore-arm. The surfaces were cleansed with warm water and the substance applied freely, the only sensation being described as a "peppery" one and of brief duration. Within twenty-four hours the wound was examined and no pus found. Again it was dressed as at first and not disturbed for a week, when the wound was found to be completely healed.

Dr. Harrell is the surgeon-in-chief of the Seattle Coal and Iron Company's mines, and the surgical cases coming within his cognizance are principally wounds grimed with dirt, coal, or mineral dust, and oil, which can not be completely cleansed save with great difficulty; but under acetanilid healing progresses perfectly without pain, the formation of pus or poisonous effects from absorption.

Dr. Alfred Hand of the Surgical Dispensary connected with the German Hospital, Philadelphia, Pa., reports in the *Medical News* of March 10, 1894, that in the wide experience of this establishment the results have been excellent, especially in the lacerated wounds of mechanics imbued with dirt, oil and foreign bodies; that acetanilid has completely displaced iodoform, and permits of immediate resumption of work and the saving of fingers and toes, where formerly amputated under similar conditions. Its use has been extended to all forms of ulcers, venereal sores and moist eczema.

Dr. Charles H. Castle, of Cincinnati, Ohio, Resident Physician of the Cincinnati Hospital, in the *Medical News* of March 31, 1894, records its use in over two hundred and fifty cases including all forms of lacerated wounds, especially those of the scalp, incised and gun-shot wounds, venereal ulcers and burns. He first flushes surfaces with 1 to 40 solution of acid. carbol, dusts with acetanilid, and covers with gauze and protective, the result being that no pus forms. With him, acetanilid has entirely superseded iodoform, and the only objectionable feature has been a burning pain when applied to any extended granulating surface.

Another record is that of Dr. M. E. Knowles, of Hamilton, Montana, who has used acetanilid extensively in surgical veterinary practice, and found it especially adapted to the closing of fistulæ, first cleansing with peroxid of hydrogen.

My personal surgical experience with acetanilid is confined to twenty cases of lacerated wounds and operations, and the list embraces some new experiences and applications of this remedy.

After the removal of a keloid tumor from the hand, I employed acetanilid as a dressing with the result of perfect immediate comfort and rapid healing, without the formation of pus; I have found it an admirable and curative application to internal hemorrhoids and a satisfactory dressing in the form of a suppository after their removal by the Paquelin cautery; I have also employed it in solutions of dilute alcohol

—acetanilid grammes 4; alcohol c.c. 2; aquæ ad c.c. 500—in blennorrhagia, and with most satisfactory results, salol being administered at the same time, however. In a long fistulous tract of the right side of the neck, connected with a deep cervical gland, dipping down to the region of the deeper blood vessels, I succeeded after curetting the accessible portions, in closing the sinus by means of the above injection.

I herewith offer a brief clinical history of two cases of importance illustrating the efficiency of acetanilid in aborting or controlling the formation of pus, and the manifestation of an alterative effect over a large granulating surface following an extensive burn, affected also with an intercurrent eczema—of which there was a previous history—and incidentally its toxic effects through absorption.

Case 1—was that of a Japanese mess attendant from the U. S. S. *Alert*, who received bruises of the left thigh during a typhoon near Yokohama, Japan, on August 19, 1893, while en route to San Francisco, which eventuated in plegmous erysipelas. He was admitted to the U. S. Naval Hospital, Mare Island, Cal., September 23, with multiple abscesses on the inner side of left thigh, and extensions from this region to the iliac crest and sacrum, with an opening of discharge in the first mentioned site; and on the inner aspect, near the groin, two sinuses leading deeply and upward to other accumulations of pus. Counter openings were made in both situations, at the most dependent portions, and on the following day another opening over the tuber ischii to relieve a posterior pocket of pus. The discharge was abundant from all these openings and the temperature, which has been as high as 103.6, fell to 100.4. The integument was widely separated, forming large cavities, and from the openings there was estimated to be discharged daily from 200 to 400 cubic centimeters of purulent matter, necessitating two dressings each day, and thick coverings of absorbent material. Three days later another large cavity was opened, burrowing around the femoral. From this time with thorough drainage and thorough cleansing with sol. hyd. bich. 1 to 2000, there was some improvement, a diminished discharge and contraction of cavities, with general improvement under the most careful administration of stimulants, concentrated nourishment, and appropriate anodynes to relieve the constant aching pains in the limb. The temperature fluctuated between 99 and 100.4. October 20, an increase of temperature was noted, gradually rising to 103, and October 25, an extension of suppuration was perceived towards the groin, and an incision was made in the inguino-scrotal angle but no pus was found; on October 20, however, it forced its way into the incision and 200 c.c. was discharged. Again, the high temperature maintaining itself, a new focus was searched for, and found in Scarpa's triangle on November 2, a large incision giving exit to 250 c.c., which exit was subsequently extended by another incision, just below Poupart's ligament, and a drainage tube passed through both openings. It will thus be seen that the thigh of patient was for one-half its circumference, and extending from Poupart's ligament and the cresta ilii, a series of subcutaneous abscesses penetrating the muscular septa, discharging more or less profusely, and from time to time making new extensions. At this juncture, with no signs of permanent abatement of the existing conditions, and patient greatly prostrated, the employment of acetanilid suggested itself, and on November 9 its use was commenced. At first the sinuses and cavities were washed out with either warm solutions hyd. bichlorid or carbolic acid, and afterward powdered acetanilid was forced through the openings. This was an awkward and unsatisfactory way of using the remedy and yet it soon showed evidences, of controlling the pus formation. On November 21, another pocket of pus was found in Scarpa's triangle and, on probing, was found to extend into the gluteal region, where a counter opening was made which was enlarged on the 28th, this being the last incision. On November 22, it being well demonstrated that the acetanilid was acting favorably, it was determined to find some way of testing it more thoroughly, and the alcoholic solution employed as a urethral injection was made use of. With this the cavities were thoroughly irrigated daily, and improvement commenced at once the discharge diminishing, the pain almost annihilated, sleep refreshing, appetite rav-

enous, digestion excellent and strength increasing rapidly. In a month the discharge was practically annihilated and on Jan. 18, 1894, the cavities were obliterated and the openings had healed without the formation of large cicatrices. There was some contraction of the skin, and slight ankylosis of the hip and knee joint, with the leg in a partially flexed position from the prolonged disuse of the limb and rest in bed, with the leg habitually drawn up; but this condition is being gradually overcome without tenotomy or other operation being demanded.

Case 2—was that of Mr. X., a native of Germany, for many years a citizen of California, and the proprietor of a brewery which he personally superintended. The interest of this case lies in the constitutional effects of acetanilid being manifested on its application to a large granulating surface, the apparent grave condition without any recognition of this fact by the patient, its alterative effect without repetition being demanded over the entire surface, and its apparent control over an inter-current eczema. The case was one in which I was called in consultation by Dr. W. D. Anderson, a prominent practitioner of Vallejo, Solano County, Cal., and during his illness was in sole attendance on the patient for a considerable period, Prof. A. M. Gardner, of the University of California, and Superintendent of the State Insane Asylum at Napo, being the primary consultant.

On May 23, 1893, Mr. X. was scalded by his left leg slipping into a tub containing a boiling infusion of hops, the scald extending from nine inches above the knee to the ankle, the foot being saved by a closely-fitting congress shoe of thick leather. Brewer's yeast was applied as soon as the clothing could be cut from the limb, and after medical assistance had been summoned, carron oil was substituted; morphia was administered, and patient kept under its influence for a prolonged period. The scald was beyond the second degree, and the result was a sloughing of the entire cutaneous surface within the area indicated, involving the entire substance of the true skin. Profuse suppuration followed, and it was variously treated with iodoform, aristol, hydrogen peroxid and hydro-naphthol, each application acting well for a time and then losing its efficacy.

On July 15, the surface being covered with healthy granulations, it was determined to employ skin grafting and, within a period of eight days, 2,280 grafts were inserted by Drs. Anderson and Gardner, 40 persons contributing the grafts, not one of them having a history of either venereal or eruptive disease. These grafts were obtained from the skin covering the biceps, which was cleansed with soap and afterward with peroxid of hydrogen. They were raised with mouse-tooth forceps, severed with curved scissors, averaged fifty mm. by sixteen mm. in size, and placed immediately upon the surface previously cleansed with hydrogen peroxid. They speedily attached themselves, vitally, and the leg soon demonstrated its new covering, especially on the calf, where the current of pus had swept, and crowded the grafts, but islands appeared everywhere. The progress of repair went on rapidly and on September 6, when Dr. Anderson, becoming seriously ill, had to absent himself from the case, the surface was so nearly healed that the patient was expected to be out in a week.

About this time eczema appeared, and just subsequent to this date developed rapidly, when the newly-formed tissue began to break down, and the patient's wife becoming greatly alarmed, treated the leg to a coating of hot mutton tallow, an old German remedy. It was evidently applied at too high a temperature, the result was the separation of nearly all the imperfectly vitalized new tissue, save on the central posterior aspect of the limb, but here the grafts had formed a firmer covering, and the islands more anteriorly, still persisted. The suppuration again became abundant, forcing up the thick coating of tallow in little craters, which were found to be the seat of eczematous pustules, and the whole tallowy coating being removed three-fourths of the surface was found to be apparently returned to its condition before the grafting, with the added complication of an extensive eczema.

It seemed as though the work had all to be done over again, for we did not then hope for the persistence of the grafts, and the development of the pus in such abundance with the eruptive complication was discouraging. Hydriodic acid had been prescribed at the earliest appearance of the eczema, by Dr. Anderson, who had observed on the other limb evidences of its former existence, and now specific, alterative and tonic remedies were prescribed with a view to influencing the eruption more decidedly. Locally the changes were rung for some time on the old applications,

embracing bismuth subnit., sodii bicarb., iodoform, aristol, peroxid of hydrogen, hydro-naphthol, and lastly pyoktannin, without any appreciable improvement. In the end I proposed the use of acetanilid, stating my experience in its use as aborting suppuration and in consultation, it was decided to give it a trial.

The suppurating and eruptive surface was carefully cleansed with carbolized boiled water, and the superfluous moisture being absorbed by borated cotton was freely coated with dry acetanilid and covered with antiseptic lint. It produced, at once a burning sensation which patient complained of bitterly, but this effect was transient and in half an hour had completely passed away, when at 3 P.M., patient was left in a state of complete comfort and tranquillity. Not long after midnight of this day, November 17, Dr. Anderson was called from his sick-bed to see Mr. X., the message being that he was in a most alarming condition. On reaching the patient he was found to be completely tranquil himself, and protesting against the excited state of his wife who was, naturally, greatly alarmed at the pronounced state of cyanosis he presented. The face, especially the nose and lips, as well as the extremities of the fingers and toes were blue.

The pulse had been, the wife thought, weak and slow when she had first noticed the blue color of his lips and nails, and later accelerated; but when the Doctor responded to the summons about 2 A.M., the patient's heart was tranquil and the pulse only exhibited a great fullness, as distinct from its ordinary character, while the temperature was normal and respiration natural. Beyond the fullness of the pulse there was absolutely no changed condition except the cyanosis, which gradually passed away in twenty-four hours. The appearance of the limb was peculiar, and persisted for several days. All the granulations had a shrunken desiccated look, like cutlets of beef long exposed to the atmosphere, the pustules were scarcely demonstrable, and there was absolutely no formation of pus for forty-eight hours. A consultation determined against the further use of acetanilid, in consequence of the poisonous effects manifested, and on the third day, aristol was substituted at my suggestion; but there is no doubt that a permanent effect was produced on the open granulating surfaces by this one application and the eczema influenced in an equal degree. We are warranted in this conclusion as from this day the healing process went on rapidly, the eczema disappeared and on March 9, the patient went abroad with a good covering of skin, save at the seat of two small ulcerated surfaces, where the original injury had affected the superficial muscular fiber, and with scarcely any cicatricial tissue, most of the original grafts having survived through the many months of profuse suppuration and eruptive irritation.

Not many cases of poisoning by the use of acetanilid have been recorded, and the one cited through its external use is unique. In all, cyanosis is noted with pale and haggard face, nose, lips, and extremities of fingers blue, pulse slow and weak, and a slightly subnormal temperature, in fact an apparent collapse; but in none did it seem to be a grave condition, the patients in no sense showing the anxiety of those around, slight stimulation soon overcoming the disturbance of the circulation. The essential toxic effect of acetanilid would seem to be an interference with the physiologic process of blood oxygenation, rather than a disturbance of the circulatory and respiratory functions, the cyanosis being persistent after the normal reestablishment; or, as Prof. O. L. Potter expresses it: "The toxic effect is to destroy the ozonizing function of the blood, decolorizing it, and forming methyl-hemoglobin." Poisonous effects have followed 30 grains taken in two doses within a period of two hours; yet 100 grains taken by Dr. Simpson, of New York, in seven doses within a period of two and one-half hours produced no toxic effect whatever.

As a summary of its surgical advantages, I beg leave to present the following enumeration. It is; cleanly, odorless, antiseptic, desiccant, hemostatic, stimulant, alterative, non-toxic practically, lasting in its effects, if intermitted, does not crust, easily

removed; and it acts in these ways, when perfect cleansing of a wound is impracticable; while it is a perfect substitute for iodoform at an insignificant cost; and is not injured or altered by moisture, as it may be saturated with water, and being drained and dried, is found to be unaltered.

With these advantages, acetanilid should be welcomed to the outfit of all surgeons, but especially to those of the Army and Navy, this simple enumeration of its excellencies seeming certainly to demonstrate its special adaptation to the field and campaign work of the former, and similar duty in connection with landing parties and shore duty of the latter; in time of war, its application to all wounds being soothing, beneficial, avoiding the necessity of immediate, careful, antiseptic cleansing, and permitting of delay in completing the final surgical attention in most cases a delay often as necessary as desirable on shipboard, on account of the rolling of the ship or stress of weather.

CHRONIC PROSTATITIS AFTER GONORRHEA.

I. ITS CLINICAL PATHOLOGY—II. ITS MICROSCOPIC AND BACTERIOLOGIC ASPECTS.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY M. KROTOSZYNER, M.D., AND JOHN C. SPENCER, M.D.
SAN FRANCISCO, CAL.

I.—CLINICAL PATHOLOGY.

We desire to call your attention to a new method of examination and treatment for a certain form of prostatitis, which is very often found as a sequela of a prolonged and severe posterior urethritis.

Our knowledge of the pathology of specific urethritis has increased more during the past ten or even five years than on any other subject in medical science. All our ideas upon the etiology, pathology and treatment of this affection have entirely changed through the successful bacteriologic researches of the last few years. Further, we have learned to diagnose all possible complications of gonorrhoea since rare culture methods of the specific microorganisms, the gonococcus Neisser have been made on modified blood serum by Brunner and Wertheim.

The difficulty connected with the study of this microorganism has always been and is at present to ascertain the presence of gonococci in all the organs secondarily affected by the specific malady. We are still in want of an easy method of demonstrating the gonococci and differentiating them from non-infectious diplococci. But the rapid progress made by continued bacteriologic investigations upon the features of this microorganism will in the near future surely solve this question. Every physician will then be able to give a decided opinion upon the possible danger of infection after gonorrhoea, just as easily as for instance in tuberculosis by finding the tubercle bacilli.

Comparing both constitutional affections—tuberculosis and gonorrhoea—we are fully justified in stating that as important as it is for the patient himself and his possible cure to find the specific microorganism in tuberculosis, it is just as important to demonstrate successfully the *diplöe* gonococcus Neisser after a prolonged chronic gonorrhoea, on account of the possible danger of infection an individual might have for others. It is evident that by our present methods

of examination it is often impossible to state whether a chronic posterior urethritis has entirely died out or not. Experienced gynecologists coincide in the statement that in cases of posterior urethritis where by objective examination nothing could be found and as subjective symptoms existed the female genital apparatus was very heavily infected. It is worthy of note, that Zweifel says in his latest work upon gynecology: "This disease (or chronic urethritis) has a strictly social danger and wives and families even were then syphilitic, for it produced zoöspemia and sterility in males, and sterility and general debility in females."

You will readily coincide with me that every contribution which throws more light upon the question, at what time a chronic posterior urethritis can be considered as cured or is no longer infectious, must be gratefully received by the medical profession.

While in Europe last year, Dr. Posner, of Berlin, told me that in his opinion the infection in cases of posterior urethritis apparently cured might be produced by the secretion of the diseased prostate gland, which is pressed out at the moment of ejaculation. In an important contribution upon this subject this same author first called our attention to the fact that by examining the prostatic secretion much benefit might be derived as regards an exact diagnosis in obscure cases of posterior urethritis. Where by digital palpation of the gland and microscopic examination of its secretion a chronic inflammatory condition of this organ could be ascertained, this chronic prostatitis was in his opinion in almost all cases complicated with an insufficient action of the ejaculatory ducts, or even with chronic spermato-cystitis. The anatomic basis for Posner's suggestions was given a few years later by Finger of Vienna. In a number of cadavers where the prostatic portion of the urethra showed chronic gonorrhoeal affections he found the glands of the prostate the seat of periglandular as well as endoglandular infiltration. Very interesting is the fact that in a considerable percentage of cases thus examined passive pathologic conditions of the ejaculatory ducts could be found, namely, an obstruction of the ducts by an invasion of round cells. To such conditions, apparently, ejaculation is difficult or prevented.

We therefore have sufficient reason to believe that the residue of chronic gonorrhoea lies here. It is evident that by the insufficient action of the ejaculatory ducts, as well as by the cardoglandular infiltration of the prostate, infectious material is retained in the deeper appendages of the posterior urethra.

Lately v. Schlen, almost simultaneously with myself⁴ has utilized the investigations of the authors above mentioned to devise a new method of examination, by which positive results may be obtained where our previous methods failed to furnish any infectious material. Let the patient urinate at first in two portions, keeping a portion of urine in his bladder. As a rule these first two portions appeared to be almost void of threads, pus, etc. Then the prostate gland is forced out from the rectum and immediately afterwards the fluid and last portion of urine is voided which was uniformly cloudy, containing abundant material of an infectious character.

In palpating the prostate of many cases suffering from chronic posterior urethritis for this purpose, I could ascertain the fact that in a large percentage this organ was rather enlarged, of unequal consist-

ence and often painful to the touch. None of these patients complained of any of those symptoms generally ascribed to a subacute or chronic form of prostatitis. I am inclined to think that this condition of the prostate must be considered as an extension of the gonorrhoeal infection from the posterior urethra to the prostate gland and the peri-prostatic tissue. The deeper the inflammation extends the more it loses its violent character. If these glandular organs are once infected those remedies which will readily remove the infection from the urethral canal will certainly not influence the morbid condition of these organs owing to their anatomic structure and the insufficient action of the ejaculatory ducts.

I therefore concluded, with the valuable aid of Dr. Spencer, to systematically examine our entire clinical material of cases of posterior urethritis to ascertain what rôle the prostate gland plays in the infectious process. In order to exclude possible errors in drawing conclusions from our investigations, we have at the same time examined a number of persons who never had suffered from gonorrhoea. In all cases the prostatic secretion was acquired by pressing open the gland from the rectum, the fluid was then examined microscopically and bacteriologically by Dr. Spencer, who will give you his report in addition to mine, and will illustrate the importance of our investigation through some excellent drawings.

As I proceeded in my investigations I began to utilize his method of pressing out the prostatic secretion for therapeutic purposes. At first in a number of cases the palpation of the prostate was quite painful. Later all tenderness gradually disappeared. I therefore combined with my diagnostic object in pressing out the prostatic secretion, a systematic massage of the gland and could very soon macroscopically as well (in the appearance of the fluid) as microscopically (in the gradual disappearance of pus cells) notice a decided improvement. At the same time in those cases which presented subjective symptoms the symptoms gradually disappeared under the beneficial influence of the massage.

One case will illustrate the satisfactory results obtained by this method:

Patient C., aged 29, consulted me early last winter. He had suffered from repeated attacks of gonorrhoea, a slight discharge having been present for the last two or three years. In the last eight months he had been under very able treatment in New York, as well as here, with the result that all discharge had disappeared and no other symptoms were present. As he intended to marry shortly he wished to satisfy his mind upon the possible danger of infecting his future wife. In this case the two-glass method gave a negative result, both portions being absolutely normal. In palpating the prostate from the rectum it was found slightly enlarged and the left lobe was very painful to the touch. The microscopic examination of the prostatic secretion showed an abundance of pus cells. The third urine portion, voided after the expression of the prostate was cloudy and contained several threads, in which there were found gonococci. I advised the patient to postpone the wedding, which he did. Meanwhile I treated him with systematic massage of the prostate with the very satisfactory result that after two months all threads had disappeared while the prostate appeared to be normal in every way. His wife is perfectly healthy up to date.

Since then I have treated several other cases similarly, and desire to mention particularly one case in which we both, Dr. Spencer and myself, after each expression of the prostate made a careful microscopic and bacteriologic examination of the prostatic secretion. Here the gradual decrease of pus cells was accompanied with the disappearance of subjective and

objective symptoms. In another case I have to report that the improvement is only very slight up to date. Undoubtedly this method will fail to give satisfactory results where the prostatitis is complicated with a severe chronic spermato-cystitis.

Our material has not been large enough at present from which to draw absolutely certain conclusions. Even in the limited number of normal cases we could obtain for our purposes we could occasionally notice an invasion of round cells, indicating a congestive condition of the prostate. This was in one case most decidedly due to a hyper-irritation of the genital apparatus by masturbation. The positive value of our investigations still lacks the presence of gonococci in the prostatic secretion of any of our cases. Dr. Spencer will give you his reasons why the absence of gonococci in the prostatic secretion does not prove the absence of an infectious condition of the gland. Still I am ready to confess that the positive proof of a gonorrhoeal prostatic can only be obtained by the presence of the gonococci.

From our preliminary investigations—we intend to publish the result of our future studies upon this subject at a later date—I am convinced that much harm to the female genital apparatus will be avoided if any man having suffered from chronic gonorrhoea is examined in regard to his prostatic secretion before marriage. No patient who has suffered from chronic posterior-urethritis can be pronounced as cured without an examination of his prostatic secretion. The best treatment—if no after symptoms of posterior urethritis are present—will be the systematic massage of the prostate. If symptoms of post-urethritis are still present the massage of the prostate might be combined with a local treatment of the posterior urethra.

II.—ITS MICROSCOPIC AND BACTERIOLOGIC ASPECTS.

As an indispensable adjunct to the rational therapeutics of chronic prostatitis, we must consider the microscopic phases of this affection. Owing to the limited time and material at our disposal, our observations are necessarily incomplete. Such as they are, however, they are of the greatest interest to the urologist, and importance to the patient. Owing to more or less imperfect diagnostic methods, the knowledge of the actual condition of the prostate gland has been left largely to chance. Reliance has been placed principally upon the subjective symptoms of the patient and the very meager objective symptoms which he presented. By the aid of the comparatively simple method of expression of the contents of the prostatic follicles, as outlined by my colleague, Dr. Krotoszyner, and by a microscopic examination of the expressed fluid, a great flood of light is thrown upon the actual conditions present.

The literature upon this important subject up to the present is exceedingly scanty. Fürbringer, of Berlin, may be regarded as the pioneer in the use of improved direct diagnostic methods of ascertaining the exact condition of the diseased prostate. A notable contribution is that by Finger, of Vienna, in the *Archives of Dermatology and Syphilis* in 1893, afterward incorporated in the last edition of his work on "Blenorrhoea of the Sexual Organs." As my colleague, Dr. Krotoszyner, also refers extensively to this work, I will confine myself solely to the microscopic features. He examined the prostates of patients known to have had posterior urethritis dur-

ing life, but who died of intercurrent diseases. He found a number of cases in which the gland follicles were filled with desquamated epithelial cells. In such, during life, the prostatic secretion had shown nothing beyond a striking increase in the number of epithelia. In another group of cases examined in a similar manner, beside the desquamated epithelia, he found numbers of polynuclear leucocytes completely filling the gland tubules. In these cases, during life, the expressed prostatic secretion showed large numbers of pus cells in addition to the epithelia. Neither set of cases presented any subjective symptoms as affecting the prostate.

The last article on this subject appeared in the *Berliner Klinische Wochenschrift*, May 21, 1894, by Dr. Tonton, of Wiesbaden, entitled, "The Gonococcus and its Relation to Blenorrhagic Processes." Among other matters he writes "that he believes in the possibility of a continuance of chronic inflammatory processes (in the genital tract), without the presence of gonococci." He further believes it reasonable to assume that the vascular lesion caused by the virus may outlast the virus itself and be the cause of continued exudation. An extension of the process is due to the presence of the virus itself.

In order to make comparisons which should be the more striking, we have expressed the prostatic secretions of a number of normal cases, who have never had a gonorrhoea or any known inflammatory lesion of the genital tract. For present purposes it will suffice to describe the microscopic findings in three cases:

Case 1.—Age 19 years. Fluid expressed shows immense numbers of lecithin granules. Of these the majority are very minute in size; many are larger, approximating in size a red blood cell. They are perfectly circular in shape and present a uniform hyaline appearance. The majority lie free in the fluid or may lie on an epithelium, or corpus amylaceum.

There were numbers of medium-sized cells, presenting for the most part a densely granular structure, and containing several glistening bodies which were undoubtedly oil globules from a beginning fatty degeneration. The majority of these were simply granular.

There were moderate numbers of cylindrical epithelial cells from the gland follicles of the prostate. These presented a characteristic appearance of a long spindle-shaped cell body terminating in a long stem-like process. In certain cases this process branched at its extremity and formed two rootlets, as it were. Each cell contained a large oval nucleus, and was granular. There were a very few cells with one nucleus, which we regard as lymphocytes and of no pathogenic significance.

There were a few motionless zoöperms scattered about.

Case 2. Normal Prostate.—H. S., age 19 years. Fluid appeared in rather unusual amount for one of his age, at the meatus. Upon microscopic examination, there appeared numerous lecithin bodies as described in the previous case. A moderate number of medium-sized cells, presenting the granular appearance before referred to and also evidences of beginning fatty degeneration; corp. amylacea; a very few scattering cells, with one nucleus, which we regarded as lymphocytes; a number of the characteristic cylindrical epithelia; a few zoöperms.

Case 3.—H. H., age 24 years. Never had gonorrhoea. Abundant lecithin bodies; abundant granular cells with a few showing fatty degeneration; lymphocytes; cylindrical epithelia, and corpora amylacea.

Case 4.—S., age 33 years. Although we have examined several cases of chronic prostatitis, this case will stand as a type in lieu of a detailed description of the others. The case has been under treatment for nearly six weeks. The fluid at first expressed contained an abundance of dense flocculent masses, which upon examination proved to be closely packed masses of pus cells. At the beginning the expressions were carried out about twice a week, and subsequently once a week. A striking feature of the fluid was the unusually large cells, which had undergone granular

and fatty degeneration. These occurred in groups. There were also the numerous lecithin granules, as in normal cases; cylindrical epithelia, and a few zoöperms. With each succeeding expression, the diminution in the number and arrangement of the pus cells was very marked. After the second or third expression and instillation of silver nitrate solution, the pus cells ceased to appear arranged in the dense groups as at first. They became progressively more scanty and scattered through each field of the microscope. Finally, they were so reduced in number as to give evidence that the process had come to a close. A similar course obtained in the behavior of the pus cells in the other cases examined.

The corpora amylacea showed the structure of concentric laminae, and more or less well-marked cleavage as one might be led to expect in crystalline structures. There were also a number of more or less cylindrical-shaped bodies, which consisted evidently of hyaline casts of the prostatic follicle, as described by Paget, Clark and Fürbringer. In this case there were large numbers of isolated pus cells. Many cylindrical epithelia as in the normal cases. Abundant lecithin granules. A few zoöperms.

Case 5.—S., age 43 years. Fluid contained an abundance of flocculent threads. Upon microscopic examination, these threads were found to consist exclusively of pus cells grouped in masses held together by a scanty amount of mucus. In this case there were numbers of corpora amylacea, fatty and granular cells, lecithin granules and epithelia, as in the previous case.

Case 6.—R., age 24 years. This case presented features resembling those of the previous case. The fluid expressed contained numerous shreddy floccules which consisted of densely grouped masses of pus cells, corpora amylacea, epithelia and zoöperms.

The importance of our diagnostic methods is well illustrated in Case 6. After apparent subsidence of all of the symptoms and physical signs of urethritis, an expression of the prostatic contents revealed the presence of an abundance of pus cells in the characteristic manner, thus necessitating still further treatment.

General Observations.—From our observation we have concluded that, in the normal cases, the large cells seemed uniformly smaller, and showed less of a tendency to fatty degeneration than in the cases of the maturer and infected cases. From this we are led to the deduction, that these bodies do not reach the large size, and show evidences of fatty degeneration, in young persons whose sexual functions are as yet in a more or less dormant state. In Case 2, in which the sexual function was already somewhat active, we observed an increase in the number of lymphocytes. While this increase may hardly be said to assume the importance of indicating some pathologic change in the prostate itself, yet we regarded it as evidence of a functional over-activity. It is interesting to observe that upon a subsequent attempt to obtain fluid from this case the fluid was distinctly sanguinolent and upon examination proved to contain large numbers of red blood cells. Upon questioning the patient we found that he had indulged freely in sexual pleasures on the day preceding our expression. Through this indulgence the prostate became undoubtedly hyperemic and, owing to the presence of round cells, showed a condition of irritability.

As regards the presence of the above mentioned hyaline casts, we agree with others that they seem to occur toward the close of a desquamative prostatitis, as verified by our own experience. In order to exclude all doubt as to the nature of those bodies which we have regarded as pus cells and lymphocytes, we treated them with a 20 per cent. solution of acetic acid. Upon clearing the pus cells were found to be uniformly polynuclear, and the lymphocytes mono-

nuclear. According to certain authors, there are mononuclear pus cells, but Ziegler's "Pathology" in the last German edition says: "Among the cells emigrating from the circulatory system, two forms may be distinguished, viz: mono- and polynuclear, and the term pus cell refers to the polynuclear forms."

Fürbringer, in his classical work, "Die Inneren Krankheiten der Harn u. Geschlechtsorgane," edition 1890, states, that pus cells may appear plentifully in prostatic secretion as a result of a catarrh confined to one gland follicle, and not of the entire organ. Under all circumstances the finding of the large and beautiful Böttcher crystals, determines the secretory involvement of the prostate. The addition of a drop of a 1 per cent. solution of ammonium phosphate to a drop of the expressed fluid on a slide, should show these crystals after the lapse of an hour. Further, he says: "It must be admitted, that these crystals may not be found in true prostatorrhoea, because of extensive chemic changes in the gland secretion, especially in those forms tending to form necrotic areas and abscesses, also because of the admixture of urine." But the failure of this reaction by no means weakens the proof in the positive results afforded by their presence.

We have endeavored to demonstrate the presence of these crystals in each of our cases, according to the method indicated, but as yet without success, perhaps owing to the obstacles mentioned. Likewise in each case we have searched through many specimens for gonococci in the pus cells of the expressed secretions, but without success. Undoubtedly, with the advantage to be derived from examination of greater clinical material, our efforts in this direction should be successful.

Our method of staining for gonococci is one which has given us beautifully clear pictures, and generally brilliant results. It is that recommended by Lanz in No. 9 of the *Deutsche Medicinische Wochenschrift*, of this year. Briefly it is as follows: Spread on the cover-glass, dry and fix in the usual manner, being particularly careful not to overheat in fixing. Immerse from one-half to one minute in a 25 per cent. solution of trichloroacetic acid. Wash, dry, and fix again. Then immerse for about five minutes in a solution of thirty cc. of distilled water, to which add enough of a saturated aqueous solution of methyl blue to give a deep blue tint, and one or two drops of a 5 per cent solution of caustic potash. The gonococci will appear deep blue, and the rest of the cells a lighter blue. A double stain may be produced by immersing the cover-glasses for a few minutes in a dilute solution of Bismarck brown. The cell protoplasm will take on a greenish or brownish hue, while the gonococci will remain unchanged. As a negative criterion in cases in which all other methods of determining the presence of gonococci fail, cultures may be made. They grow only on such media as blood-serum, serum-agar or blood-agar, in the form of minute dewdrop-like colonies. It is a distinguishing characteristic of gonococci, that they do not grow on plain nutrient gelatin or agar.

In conclusion, we must express our regret that our limited time and clinical material have not enabled us to give you more extensive results, but we trust that the little we have presented will serve as a stimulus to our colleagues to devote more time and painstaking methods to the examination and treatment of

this hitherto somewhat unsatisfactory class of cases. If by definitely excluding all possibility of infection after an attack of specific urethritis, we may lessen the misery entailed on young wives through innocent contact with husbands pronounced free from infectious possibilities by their medical advisers, we may feel some degree of satisfaction; if in no other way, at least by curtailing some of the work of the gynecologists.

ON THE TREATMENT OF PHLEGMONOUS ERYSIPELAS AND OTHER FORMS OF SUPPURATIVE INFLAMMATION BY IMMERSION IN ICE WATER.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY HENRY BERGSTEIN, M.D.

RENO, NEVADA.

Phlegmonous erysipelas, phlegmonous inflammation, or pseudo-erysipelas, as Billroth terms it, I, in my earlier experience, found an intractable and destructive affection materially interfering with the future usefulness of the hand, the part most commonly affected.

After having treated a number of cases by the old method of free incision, local applications, hot fomentations, etc., with the usual results, it occurred to me that the rapid destruction of tissue was due to excessive heat, and that if some method of reducing the temperature were adopted the effect would be prevented. Cold has always been used as a method of treatment, with the added caution that it was liable to produce gangrene, as in these cases there is a natural tendency to that result. Pressure, such as would be produced by the application of ice would increase that danger, so the thought occurred to me to use immersion in ice water, and I will now cite a couple of cases treated in this manner:

In December, 1875, J. M., a half-witted fellow, becoming alarmed at something in the night, thrust his hand through a pane of glass. He came to my office the following morning, and I found an incised wound extending along the back of the hand from between the second and third fingers to the wrist. I brought the parts together with four silk ligatures, and giving him a carbolized lotion, told him to return in a day or two. He returned on the second day and I found the hand enormously swollen. The skin, of a roseate hue, with the well-known doughy feeling of erysipelas. I at once removed the stitches, and quite a quantity of ichorous pus escaped. I painted the surface with iodine, gave him the tincture of the chlorid of iron internally and ordered the application of flaxseed poultices. He returned on the following day, and the quantity of pus had greatly increased; the hand having assumed the well-known feeling of a bag filled with loose bones. I directed him to go home, fill a basin with water, and after putting in a large lump of ice to keep his hand completely and constantly immersed, and when he was ready to sleep, to wrap a towel, which had been previously dipped in ice water, around his hand and to renew the application every time he awoke, and, as in his mental condition he slept but little, it was kept pretty constantly immersed. In addition to the iron I had previously ordered, I gave him liberal doses of quinin, together with wine and nourishing diet. For the first twenty-four hours, I was rather uneasy about the treatment, visiting him every few hours to watch its progress. To my delight, suppuration ceased almost immediately, and to my amazement on the following day I found granulations springing up in various portions of the wound, which continued to do well and I discharged him at the end of twenty-one days, the wound being completely healed and the hand unimpaired.

In the practice of the country physician, cases of this character are not of common occurrence, and it was not until the summer of 1893 that a second case presented itself:

E. U., residing near Reno, working in a saw-mill, in some way brought the palm of his right hand in contact with a circular saw. He was attended by a *confère* for eleven days, when the patient, finding his hand in a bad condition, and realizing that he was to be disabled for some time, and not being overburdened with this world's goods, concluded to go to the county hospital which was at that time in my charge. At that time his condition was as follows:

A large portion of the surface tissue of the palm of the hand had sloughed away, shreds of dead tissue hung from the denuded surface, also from a number of openings into the fingers, and pus in large quantities was being discharged from all the parts named, and from two openings at the wrist.

I first removed all shreds of dead tissue, then made a thorough application of pure carbolic acid, injecting it into all the sinuses, then carried out the same treatment as in Case 1, except that I substituted tartarized iron for the chlorid. For two or three days there was a slight discharge of pus, at the end of which time it ceased completely. Granulation springing up freely continued to complete healing of the wounds, which occupied seven weeks, when he was discharged with some slight impairment of the flexor muscles. After eight months of active exercise of the parts, he reported the impairment overcome.

I report these cases in the hope that this method may be given a trial and the results be reported, for if it proves as efficacious with others as it has in my hands, it must become an established method of treatment.

HOW LONG IS SYPHILIS CONTAGIOUS?

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. D. THOMAS, M.D.

PROFESSOR GENITO-URINARY AND VENEREAL DISEASES, WESTERN PENNSYLVANIA MEDICAL COLLEGE (MED. DEPT. WESTERN UNIVERSITY), AT PITTSBURG, PA.

Syphilis has as clear and well defined a clinical history as characterizes the other contagious or infectious diseases. That the disease is due to a microbe is partially established, and the analogy that exists between syphilis and other diseases where germs are demonstrated as causative is so marked that there is little room for doubt. Some of the zymotic diseases are acute in their invasion and rapid in their career, while others are chronic. We may cite as extremes of this comparison, roetheln and the disease under consideration. If roetheln runs its course in comparatively a few hours he who would diagnosticate an eruption of ten days' duration as roetheln would be a poor diagnostician indeed. All germ diseases run a certain period, and that period is individual or peculiar to each, after which convalescence takes place, or there follows certain sequelæ. These sequelæ are due to an alteration in nutrition or function or both. Original diseases are not reproduced from their sequelæ. After an acute disease is over there is no danger to others so far as the patient himself is concerned; the remaining danger lies in the fact that the germs may be lurking in drapery, walls, etc. The convalescent patient is not a factor. In diseases that are contagious only, or those that require inoculation for their reproduction, when the active stage has expired the patient and his surroundings are absolutely innocuous. Syphilis being purely an inoculable disease then when the zymotic period has exhausted itself the patient is no longer capable of conveying or transmitting the disease.

All zymotic diseases have a pretty uniform history of invasion, period of acme and period of decline. Syphilis is not an exception to this rule. Let us take, for instance, diphtheria. Six months after the disappearance of the active stage the patient may be suffering with paralysis. The paralysis is not diphtheria; the condition is not a contagious one; it is a sequel. No one has the temerity to assert that a person who has had scarlatina or smallpox continues to carry about, for months, in his system the germs of these diseases, although the one disease may cause, for an unlimited time, a suppurative otitis and the other a necrosed maxilla. Why should not the same reasoning hold good with regard to syphilis? Why should such a large number of the profession still hold to the idea that the sequelar lesions of syphilis are contagious? But recently I heard a gentleman make the statement to a medical society that he had treated a patient for syphilis ten years before the patient's marriage, and that after the marriage the patient infected his young wife. To me the statement was absurd—I did not deny the contagion but did the source. The belief by some that the contagious character of syphilis persists for decades is an error due to faulty observation or to a lack of observation. Without entering any further into polemics I make the assertion, in language more forcible than elegant, that patients may be rotten with the sequelar lesions of syphilis and at the same time indulge in intercourse and procreate offspring without conveying the disease to the one nor transmitting it to the other.

In corroboration of the above opinion I present for your consideration a few cases from my note-book—cases that have been carefully observed. Here are the facts:

Case 1.—In the summer of 1885 Mr. G. E. acquired a chancre on his lip through kissing a prostitute, and afterwards conveyed the disease to his wife. This couple have already several children. On March 3, 1886, to this couple a child is born which soon becomes cachectic and in a few months dies from specific marasmus. On May 30, 1887, at full term a macerated fetus is born. On August 31, 1888, a healthy looking child is born and does not develop the disease. On Feb. 17, 1890, another healthy child is born which has given no evidence of syphilis. On May 3, 1894, (the present year) an exceptionally fine boy, weighing twelve pounds, is born and remains well. During all this time this family has been under my exclusive care, so that my opportunities for observation have been unobstructed. The mother ceased to convey syphilis in less than three years.

Case 2.—Mrs. B., mother of three children, becomes infected through her husband. For three years after the infection she remained unimpregnated. During this time she was under my care, but in an irregular manner—presenting herself only when symptoms or lesions appeared. At the end of three years she became pregnant, went to full term, and was delivered, by me, ten months ago of twin boys. At the time the twins were born she had a serious tertiary lesion on her posterior fauces. On the tenth day the larger child died with eclampsia, but presented no signs of the disease. The smaller child has not been ill a day and is at present the picture of health. The period of contagion here lasted less than three years.

These two cases bear upon the heredity feature of syphilis.

Case 3.—Was called to see Mrs. C., who felt herself indisposed. On taking hold of the wrist to examine her pulse I noticed an eruption. On further investigation this eruption, which was macular, was found to exist over nearly the entire body. In addition to the eruption there was sore throat and an adenopathy. I saw the husband of this woman privately. On putting the question, "Did you ever have syphilis?" to him he replied that he had had syphilis four years ago; that three months ago he entered the matrimonial state on the strength of the advice given him by his physi-

cian. Although I did not say so to the man I was perfectly satisfied in my own mind that the advice given was orthodox. So firm was I in my belief that this new wife did not receive the disease from her husband that at my next visit I made bold to tell the patient the nature of the disease and asked frankly how she acquired it; stating at the same time that her husband had had the disease and that he was safe from further infection. She denied the possibility of any other source of infection, but took my statement in such a matter-of-course way and with so much *sangfroid* that I was satisfied that my premises were correct. This patient remained unimpregnated for two years and three months. At the end of the third year from her marriage I delivered her of a healthy looking child which, in a few days, developed a papular syphilide. After a prolonged treatment this child recovered. In another year after the birth of the first child this woman became again pregnant, was delivered by me at full term of a healthy child which is now $3\frac{1}{2}$ years old and which has never shown any symptoms of syphilis. Now, to come back to the woman herself. After having by many devices attempted to get a correct history of her infection, at the end of four years she admitted having had intercourse with a man other than her husband the week before marriage. I ascertained from the physician of this man that four years before he did treat the individual professionally and that he was then in the active stage of syphilis.

Case 4.—Mr. D. and his wife called at my office. Mr. D. explained, privately, to me that he had been married but a few months; that his wife had an eruption which he feared was syphilitic; that he himself had been infected four years ago and as a result he had given the disease to his innocent bride. I saw this "innocent bride" alone and found the eruption spoken of by her husband. It was syphilitic. I said to Mrs. D., You have syphilis, you are perfectly safe in the companionship of your husband for he has had the disease and can never acquire it again. He did not give it to you, for too long a period has intervened since his infection. Now, you can make a confidant of me. She then admitted having had intercourse with an old lover about the date of her marriage.

These two cases prove the clinical fact that they were not infected by their husbands but by fresher syphilitics.

Case 5.—Mrs. E. was treated by me for syphilis. At the end of three years after infection she formed a *liaison* with a patron of mine who had never experienced the disease. This relationship was kept up for an indefinite period; the male in the case remained uninfected.

Further recital of cases would be tedious, although they are numerous enough. I have quoted no authorities, for this brief paper is intended as a purely personal contribution, the aim of which is to help establish the fact that syphilis can only be conveyed during the primary and secondary stages, and that the secondary stage ends not later than the third or fourth year from date of infection. I am sure that the chaotic views held by many of the profession in regard to the contagious period of syphilis is due to the acceptance upon their part of the word of the patient. We should not, and can not afford to, base scientific axioms upon the statements made by members of the laity. These statements are often studied deceptions; at other times they are honestly given but from ignorant premises.

A CONTRIBUTION TO SURGERY FROM ITS YOUNGEST SPECIALTY, DENTAL SUR- GERY.—THE SURGICAL ENGINE.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY W. G. A. BOXWILL, D.D.S.

PHILADELPHIA, PA.

While every medical man has heard and read of this instrument for the past twenty years, but few have ever witnessed the application of it in the surgery of the bones and tissues. Outside of Philadelphia

—my home—it has been but little used, so slow are surgeons to take hold of new appliances, and particularly this engine, which, to so many, seems so formidable that, while they can not doubt its great efficacy yet they fear to handle an instrument driven at the high speed of from one to twenty thousand revolutions a minute.

The dental engine had been tried for minor operations and was better than nothing; yet it was not until this duplicature of the human arm and hand was developed, that it was possible to call it a truly surgical engine.

This I present you to-day, is the only type that is of any value and is based on the surest basal principles of mechanics. It is not necessary to describe it in detail. Suffice it to say that a look at its working parts will satisfy the most skeptical that it must do all that is claimed for it.

As a further guarantee of its value in surgery, I need but mention a few of those eminent in this line. Both the elder and younger Gross, Agnew, of Philadelphia, and Horsley, of London. These are enough.

Be it said to the credit of the conservatism of surgeons, it would have been more largely used had I not parted with it and sold to a manufacturing firm, hoping to have it more extensively made and better and cheaper. But I made a great mistake. It is not too late to have it remedied. As you see it here in operation there is every element about it calculated to perform any operation in surgery on soft or hard tissues, and it is so simple any one can take care of it, and so cheap that any surgeon of extensive practice can afford to have one. Beside, it is so made that it is used for a dental engine and wherever it is to be found, in any town or hamlet, in the possession of a dentist, it can be borrowed at any time and made available for surgical work by simply adding to it a crank to give it higher speed; so that an amicable arrangement can be made with the dentists for its use, and they would be too glad to be of service in assisting the surgeon anywhere.

In this way the first cost to the surgeon is nothing, further than having a few instruments adapted for its special work which would be but a trifle. Then, its universal presence could be relied upon at any moment and anywhere if it is in the possession of a dentist. This one item, of combining the dental with the surgical power, must militate largely in its favor and one's surroundings can be adapted to its use. This argument is no mean one. While not so good for the manufacturer, yet to the *user* of it a favor not to be resented.

Up to the time of the death of both of the Professors Gross, not an operation on the bones was performed but I did it for them.

As to Prof. Horsley, of London, he said before the Washington Congress: "Thanks to one of your fellow-countrymen—Dr. Bonwill. Without this engine I would not like to undertake the formidable operations I have to perform on the skull for removal of tumors and treatment of nervous affections."

Its range enables you to perform the most delicate as well as the most extensive operations, and can be confined to 100 revolutions or run up into the 1,000 revolutions.

It will remove in a few minutes the hardest osseous tumor, or with the diamond will cut a stone in the bladder into atoms.

In plastic surgery wherever tissues are to be united

there is no loss of substance and success is more certain. In the bones, whether taking away the whole shaft leaving nothing but the periosteum for renewal of the parts—there is no necessity for opening into the bone further than merely exposing for access, thereby saving the covering of important arteries or interfering with nerve tissue. In the reduction of ununited fractures and the absolute apposition with which they are afterwards held by special appliances, it is of great value.

It can be used in fractures of the patella without opening into the membranes. Removal of the whole of the superior or inferior maxilla without other access than by the mouth. Its aid with its special appliances enables you in fractures of the skull to elevate the parts without trephining.

Removal of the bones of the coccyx has been done in a few minutes and no injury done to the rectum or shock to the surroundings. With a special instrument I have, the vault of the cranium can be entered at any point without a trephine, and of any shape, without any danger of injury to the dura mater or much loss of bone.

In operations upon the cervix, the diamond wheels it carries at high speed chafe off the hardened tissues with but trifling loss, and enables the parts to the more certainly be brought in apposition, and left nearly the normal size of cervix.

It is unnecessary to speak further of its possibilities, as the ingenious surgeon would soon see that it would be his constant companion and when once he had learned to manipulate it, it would be as much of a *sine qua non* as it is to-day a part of modern dental surgery.

No one can estimate the value alone in time saved in all cases and, from its high speed and capability of reaching 20,000 revolutions a minute, *pain* itself can almost or quite be annihilated or prevented, and if nothing more the shock is comparatively light, the effort at healing by first intention is made certain in every case, and from the smoothness of the bone cut, drilled, burred or sawed, there are no spiculæ of bone left to induce the least inflammation or necrosis.

THE NON-OPERATIVE METHODS OF TREATING ANAL FISSURE OR IRRITABLE ULCER OF THE RECTUM.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY LEWIS H. ADLER, JR., M.D.
PHILADELPHIA, PA.

PROFESSOR OF DISEASES OF THE RECTUM, PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE; SURGEON TO THE CHARITY HOSPITAL, ETC.

When anal fissure is of recent origin and not associated with much spasm of the sphincter muscles there is a fair prospect of cure without operative procedure.

This statement is made advisedly and in the face of a criticism published in *Mathev's Medical Quarterly*, (January, 1894, Vol. i, No. 1, p. 185) of the writer's brochure: "Fissure of the Anus and Fistula in Ano," (Physicians' Leisure Library Series, 1892. Geo. S. Davis, Publisher, Detroit, Mich.) in which the following statement is made: "It is a pity that this admirable little work wastes so much time in discussing the palliative (?) treatment of the disease," (fissure).

"In an affection so simple in its etiology and pathol-

ogy and that can be so quickly and radically cured by divulsion of the sphincters, it seems a great loss of time to talk about applying ointments, when it is a recognized fact that not one case in ten is ever benefited by their use."

I do not doubt but that the reviewer quoted, honestly expressed himself in the statements made; and furthermore, that the opinion given,—that not one case in ten is ever benefited by other means than operative measures,—is based upon personal experience. But I must be pardoned for dissenting from the same views as my experience, while not an extensive one, is ample to justify a more conservative treatment of many of these cases.

I am well aware that the operative treatment of fissure is a simple procedure and that the disease is quickly cured by its execution; but I am likewise conscious of the fact that many persons object strenuously to any operation. No matter how trifling its import be to the surgeon, an operation to the patient is something which is dreaded, and it behooves the practitioner to remember that the majority of persons are unwilling to submit to an operation until they are personally convinced that such a course is the ultimatum.

It is my purpose in presenting this paper to indicate how over 75 per cent. of the cases of fissure of the anus which have come under my observation, both in hospital and private practice, have been cured by non-operative measures. No less an authority than Allingham ("Diseases of the Rectum," fifth edition, London, 1888, p. 215) states that the curability of this lesion does not depend upon the length of time during which it has existed, but rather upon the pathologic changes it has wrought. He also adds that he has cured fissures of months' standing by means of local applications, where the ulcers were uncomplicated with polypi or hemorrhoids, and where there was not any marked spasm or thickening of the sphincters.

It is essential to the success of the treatment of fissure by local applications, that rigid cleanliness of the parts be maintained; for this purpose the anus and the adjacent portions of the body should be carefully sponged night and morning and after each stool with tepid water. It is also highly important that attention be given to the condition of the patient's bowels. Regularity of habit should be established, and the evacuation rendered semi-fluid,—as figured or hard stools materially aggravate the symptoms. To accomplish these purposes, enemata or mild aperients should be employed, and the diet must be regulated, the use of bland and unirritating food being enjoined.

All drastic purges should be avoided, as they are more or less irritating to the extremity of the rectum. To establish a daily evacuation of the bowels and to render the movement as painless as possible, I am in the habit of ordering an enema of warm water, or one of rich flaxseed tea, say from half a pint to a pint, to be administered every evening; preference being given to the night time, as then the patient can assume the recumbent posture, which, combined with the rest, affords the most relief from subsequent pain.

If the first enemata should prove ineffective it should be repeated in half an hour. In order to relieve the pain and spasm of the sphincters attending the evacuation, it is well to use a suppository about

half an hour before the injection is employed consisting of

R Ext. belladonnæ gr. $\frac{1}{8}$ ad $\frac{1}{2}$
 Ext. opii aq. gr. $\frac{1}{4}$ ad $\frac{1}{8}$
 Ol. theobromæ gr. x

Misce, et fiat suppositoria j.

or an ointment of conium may be used, as recommended by Mr. Harrison Cripps, ("Diseases of the Rectum and Anus," second edition, London, 1890, p. 189):

R Ext. conii ʒij. 8 |
 Olei ricini fʒiij. 24 |
 Ung. lanolinii q. s. ad ʒij. 64 |

A small quantity of this ointment should be smeared on the part five minutes before expecting a motion, and again after the bowels have been moved.

In applying any of the various local remedies to an anal fissure it is necessary first to expose the ulcer to view, which can be done by means of the fingers of the operator or his assistant, and to anesthetize its surface with a 4 per cent. solution of the hydrochlorate of cocain, well brushed in with a camel's hair pencil or with a piece of cotton attached to a probe. The application of the cocain may have to be repeated once or twice at intervals of three or four minutes in order to obtain the desired anesthetic effect. If any ointment has been used about the fissure, the anus should be subjected to a hot water douche before using the cocain, as this drug will not exert its anesthetic influence on a greasy surface, (W. P. Agnew, M.D., "Diagnosis and Treatment of Hemorrhoids," etc., second edition, San Francisco, Cal., 1891, p. 91).

Among the different remedies that have been used in the local treatment of fissure of the anus may be mentioned the following: Nitrate of silver; acid nitrate of mercury; fuming nitric acid; carbolic acid; sulphate of copper; the actual cautery; and chloral hydrate. Of these topical applications the nitrate of silver is the best. Its effects are various: It lessens or entirely calms the nervous irritation which is so important a factor in producing spasmodic contraction of the sphincters; it coats and shields the raw and exposed mucous surface by forming an insoluble albuminate of silver; it destroys the hard and callous edges of the ulcer, and tends to remove the diseased and morbid action of the parts. The form in which I usually employ this salt is in solution (from 10 to 30 grains to the ounce). The stick caustic may be also used.

To accomplish the best results, the solution should be used once in twenty-four or forty-eight hours, according to circumstances. It may be applied by means of cotton attached to a silver probe or to a piece of wood.

The application is made by separating the margins of the anal orifice with the thumb and the index finger of the left hand, and introducing into the anus the probe charged with the solution. The argentic nitrate is to be applied to the fissure only; a few drops are all that is required. If thorough local anesthesia has been induced by the use of cocain, the application of the silver salt produces little (if any) suffering, for by the time the anesthetic has lost its effect the otherwise acute pain of the nitrate of silver will have passed away.

After each application the part should be smeared well with an ointment of iodoform (30 grains to the ounce). The odor of that drug may be disguised by the addition of a few drops of attar of roses. Iodol may be used instead and in the same way, but I prefer the iodoform, owing to its anesthetic qualities.

After the ulcer has been touched once or twice with the silver solution the effect will be, in the cases that are benefited by this treatment, a considerable mitigation of the pain from which the patient suffered when at the closet and afterward, and the sore will present a healthy granulating appearance, and will slowly contract in size.

Unless the fissure be complicated with some other affection in children and in young persons, anal fissure is almost always curable by adopting the mode of treatment laid down.

Some authorities speak highly of the use of the acid nitrate of mercury, fuming nitric acid, carbolic acid, the actual cautery, etc., but in my opinion their employment is attended with more suffering than follows the use of the nitrate of silver. Furthermore, the application of these remedies is not so certain to effect a cure, so that I rarely resort to their use.

The daily introduction of a full sized bougie, made of wax or tallow, will sometimes act beneficially in cases of fissure by stretching the sphincter and producing such an amount of irritation as will set up a healing process in the ulcer. An application of cocain or of belladonna ointment should be made to the part previously to their employment.

In the treatment of anal fissure, Allingham strongly advocates the local use of the following ointment:

R Hydrarg. subchlor. iv grains. | 24
 Pulv. opii ij " | 12
 Ext. belladonnæ ij " | 12
 Ung. sambuci ʒj " 4 |

M

Sig. To be applied frequently.

He states that he has had many cures with this ointment alone. Another excellent ointment recommended by this same authority, is:

R Plumb. acetatis gr. x. | 60
 Zinci oxidi gr. x. | 60
 Pulv. calaminæ gr. xx. | 20
 Adipis benzoinat ʒss. | 16

M

An ointment of the oxid of mercury, 30 grains (gm. 1.80) to the ounce, has cured many cases.

In conclusion, I would emphasize the fact that in many cases anal fissure, when uncomplicated with some other rectal affection, is curable by means of non-operative methods of treatment.

1610 Arch Street.

A PLEA FOR THE PROPER TEACHING OF ANATOMY.

Read in the Section on Surgery and Anatomy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY GEORGE FRANKLIN SHIELS, M.D., F.R.C.S.E.
 SAN FRANCISCO, CAL.

The tripod upon which the whole superstructure of medical science stands is made up of anatomy, physiology and pathology. As it is well known to the student of natural philosophy that when one leg of a tripod is weak or is taken away, the mass which it helps to support either totters, or falling outside of its center of gravity topples and falls, so it is well known to the student of our science that when a knowledge of one of these important subjects is weak or lacking, the whole grasp of general medicine and surgery, no matter how acquired, is either insecure and shaky, or in the face of some slight emergency

trembles, totters and finally falls, carrying with it the reputation of the individual, who when he is dragged out from amidst the ruin is often held up as a laughing stock to his colleagues. If one leg of this tripod be more important than another it is assuredly anatomy, for without it no advance can be made in the study of its fellows. Hence I may state that to each and all of us a knowledge of anatomy is not only of the greatest importance, but is an absolute necessity.

No matter how a man may brace up his weak and tottering knowledge with props of polysyllabic eloquence, quotations from authors, tact in avoiding exposure of his lack of knowledge, flight to specialties which seem not to necessitate anatomic knowledge or with a laughing acknowledgment of once having known the subject and having forgotten it, on account of its being overshadowed by the more important practical branches of science,—no matter what means he may use, I state without hesitation that the time will come, if he live long enough, when his want of knowledge will make itself known either to himself or others by disastrous consequences to his patients, and a subjective sense of shame. For a superstructure no matter how beautiful, if it have an unsound foundation may indeed be likened to a house built upon sand.

If you agree with me in these views and I feel convinced that you do, then of a surety a plea for the proper teaching of anatomy, is one which will gain your hearty and willing support, and by strengthening my weakness with the expression of your opinions and honoring the subject with a free discussion, we may hope our plea will have an influence, perhaps small, but still an influence in directing the attention of schools toward a correction of existing conditions by awakening in them a desire to escape from the trammels of use and custom, and will lead to improved methods of instruction whereby a better and more useful knowledge of this great subject may be obtained.

Anatomy as taught in the past has been the bugbear of the student, the dreary, dry, uninteresting subject of the curriculum. Ask a student picked haphazard from his fellows: "What subject do you find most uninteresting?" In all probability his answer will be: "Anatomy." Go further; ask him which subject he fears most in his examinations, and he will again answer: "Anatomy." He looks upon it as a subject to be learned after the manner of a proposition of Euclid, and sits down with his Gray, proceeding to memorize the text, word for word, or if ingenious enough invents a means of memorizing by the aid of mnemonics, such as the following: "Sala-sap" for the branches of the axillary artery.

"Timothy doth vex all very nervous pupils," for the structures passing behind the internal lateral ligaments of the ankle joint.

"Oe, eighth pair," thoracic duct found there. Vena azygos by aorta stands. Lymphatic vessels and lymphatic glands," for the contents of the posterior mediastinum. Nerves, arteries, veins, muscles, become to him streaks of yellow, red, blue and brown color, formed into intricate diagrams to be memorized by constant conning over.

He attends lectures to find the same methods in vogue, and only too often does he discover that the teacher following the custom and for want of time, narrows down to a few complicated points of the sub-

ject which he, the student, learns to fear at the time of his examination since they crop up in the abominable form of catch questions.

And what about practical anatomy? It appears in syllabus that a candidate for a degree must have dissected the human body once. Curious, and taken by the novelty, the student buys a set of instruments, an apron, a pair of sleeves, and appears in the dissecting room ready for work; and what will he find? If my experience be correct and it extends to the schools of Germany, Austria, France, England, Scotland and America, he will find that his professor is rarely seen in the dissecting room. There may be a single demonstrator, or more rarely a staff of demonstrators, who are supposed to guide him in his work, and who as a rule confine themselves to demonstrations of special regions, such as the axilla, popliteal space, etc. He dreadingly drills through the necessary and specified single dissection and finally appears for examination stuffed full of answers to catch questions, and if he succeeds in passing the ordeal he thanks God, throws away his dissecting instruments and with a sigh of relief leaves anatomy forever behind. A few years later we find him as a practicing physician and surgeon, clothed in a white apron, his sleeves rolled up above his elbows, surrounded by all the appurtenances of modern aseptic surgery and ready to operate upon some poor unfortunate who like a lamb led to the slaughter little knows that the man in whom he has put his trust is ignorant of the very territory which he is about to invade. The operator follows one of two courses; he makes his primary incision, often based upon an erroneous diagnosis due to lack of knowledge, cuts some important vessel, the blood spurts, he is attacked by that condition of mind called "surgical delirium," puts a compress upon the wound, bandages it up and trusts that a clot may form by the time of the first dressing. Or what is worse he damns the mishap and proceeds on the cut-and-tie principle, the result of which is disastrous to the patient and the reward of which comes sooner or later to the operator, especially if he be possessed of a conscience.

Or mayhap our young graduate having an eye to business and seeing that the general profession is over-stocked, chooses what he believes to be a lucrative specialty, for example, the nose and throat. He buys the latest works on the subject, reads them assiduously and grows to believe that all the ills of mankind are centered in the organs, the diseases of which he supposes himself to know so well. A child comes to the office with enlarged tonsils, a guillotine is introduced, the tonsil is removed, but something else has occurred. The blood wells up from the wound by the teacupful, the child's face becomes blanched for the ascending pharyngeal or the internal carotid artery has been wounded. A surgeon is hurriedly sent for while the terrified and ignorant specialist stands by and watches his victim bleed to death. Had he known his anatomy how easy to have avoided this accident, or had it occurred, to have tied the common carotid artery and saved a life. I will not multiply examples—they are numerous and are known to you all. I plead for a proper teaching of anatomy—for a knowledge gained by training and not by cramming. Naturally I expect to be asked what I consider to be a proper method of teaching this subject, and by your courtesy I shall venture to briefly lay before you my ideas.

The teaching of anatomy must be systematic, must be begun at the commencement of the medical studies and continued until their end. The student must begin by learning the anatomy of the cell, and must be able to follow it through all its changes up to the formation of the most intricate tissues. To accomplish this it will be necessary to institute a distinct course of microscopic anatomy in which he will learn the beautiful wonders of the growth of tissue from that simplest anatomic element, the primeval cell. Next he should be taught development from the moment of impregnation to the time of birth. If these two branches of anatomy were carefully and systematically taught, the student would indeed be dull who did not have an active desire to pursue his studies further. Next he should attend a regular course of didactic lectures in which his teacher should aim to use the cadaver and actual preparations as much as possible, as by so doing he would teach the student to recognize the actual structures and not pictorial likenesses thereof. *Pari passu*, with this didactic course he should be taught practical anatomy, but before he is allowed to dissect he should be carefully taken over the bones of the skeleton, having each and every one of them thoroughly demonstrated to him, both from a mechanical and from a physiologic point of view, and in this way be able to understandingly view the skeleton, both in its integral parts and as a whole. He is now ready to enter the dissecting room where he should be made to dissect the body at least three times. His first dissection should be a topographical one, in which he should learn not only the individual parts, but the parts in relation to each other.

His second dissection should be a repetition of the first, with the addition that the teacher should constantly draw the student's attention to the importance of the various structures in their relation to the practice of surgery and medicine.

His third dissection should be one confined to medical and surgical anatomy, when he should perform all the surgical operations and learn to recognize all the tissues concerned therein, and during which he should be further taught the surface markings of all the important viscera. By such a course as this, I believe that the subject could be thoroughly mastered.

I would further suggest that the method of examination should be changed and that a series of examinations should be held, arranged in such a way that the teacher could be sure that his pupil had mastered what he had already gone over before he was allowed to proceed further. This would do away with cramming, would stimulate systematic work and would insure sound knowledge.

It is true that such a course as that which I have laid out would take time, but what of that? The day has passed when the intelligent teacher believes in the remotest degree that a two or a three years' course can be sufficient for a medical education, and the four years' curriculum is being rapidly introduced, while there are still many who like myself, believe that six years should be the minimum time of study for a medical degree.

In closing, let me affirm that no man who will follow out the course which I have here laid down will ever have reason to regret it.

If a surgeon, he will have that *sans froid* and confidence which is begotten of knowledge, that knowl-

edge which is not to be obtained from books and lectures alone or in preponderance, but which is only acquired by long work in the dissecting room. He will not only know the position and relation of parts, but he will have the *tactus eruditus* which carries to the mind an appreciation of tissues and which Treves, so well names, "the anatomy of the individual." His dissections will have further trained him for his future operative work, for surgery is largely a handicraft. He will be self-possessed, cool, ready in any emergency, will know what he wants to do and will never suffer from "surgical panic," for he knows, and knowing fears not.

STRICTURE OF THE MALE URETHRA.

Read in the Section on Surgery and Anatomy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY MILLARD H. CRAWFORD, M.D.

SURGEON U. S. NAVY, SAN FRANCISCO, CAL.

Stricture is that condition where there is an abnormal diminution of the caliber of the canal, induced by pathologic changes in the mucous or submucous muscular walls of the urethra.

Strictures may be divided into inflammatory, true or organic stricture and false or spasmodic stricture, and divided according to their form into linear, annular, indurated, irregular or tortuous strictures. Some surgical authorities make another division according to the condition that exists; for instance when the stricture bleeds easily by use of instruments or becomes inflamed it is called an irritable stricture. Then again they may be divided into small caliber, which will admit only of the smallest size sounds, less in circumference than fifteen millimeters, and of a large caliber, or strictures that will take instruments from that size upward.

A spasmodic stricture is that condition where there is muscular spasm and the normal caliber of the urethra is diminished.

It is a question which all surgical authorities have not fully agreed upon, whether spasm of the urethra takes place without the presence of some organic constriction of prior existence. Sir B. Brodie says: "That a spasmodic stricture may exist independently of any actual organic disease. At the same time it must be acknowledged that the existence of a purely spasmodic stricture is of rare occurrence."

John Hunter states: "There are often spasmodic contractions of these muscular fibers in different parts of the canal, shutting up the passage and obstructing the course of the canal, and often not allowing a drop to pass."

I think it has been proved beyond a doubt that the whole urethra has contractile action, and with a sphincteric muscle which acts especially on one part of it may cause temporary constriction. I will briefly mention the chief causes of spasmodic stricture. Where an organic stricture already exists, this spasmodic constriction may be caused by extreme acidity and irritating effects of the urine. Turpentine, cantharides, spices have the same effects. Hemorrhoids, rectal fistulæ and operations about the anus are frequently followed by retention from spasmodic contractions of the muscle. Strong mental emotions will interfere sometimes with micturition.

ETIOLOGY OF STRICTURE OF THE MALE URETHRA.

I believe that the majority of surgeons agree with Sir Astley Cooper, who says: "That in ninety-nine cases out of every hundred it was the result of an attack of gonorrhœa."

Civiale says: "That gonorrhœa might be placed in the first rank of the list of causes of stricture. He then asserts that this affection may never have been acute, but chronic at its commencement, and not necessarily following impure or even indeed any sexual connection."

He enumerates other and less obvious causes, such as abuse of instruments employed in affections of the urethra, perineal section and abuse of coitus and prolonged erections.

Sir Henry Thompson gives the analysis of 202 cases of the stricture of the urethra. Of this number 81 per cent. was caused by gonorrhœal inflammation; 14 per cent. due to injuries of the perineum; four cases due to cicatrization of chancres, and six cases to congenital origin.

Dr. Otis gives the record of 85 cases of stricture, representing 147 distinct strictures of the urethra:

| | | |
|----|--------------------|--------------------------|
| 75 | or 88.23 per cent. | were due to gonorrhœa |
| 5 | or 5.88 per cent. | were due to masturbation |
| 3 | or 3.53 per cent. | were due to lithiasis |
| 2 | or 2.35 per cent. | were due to traumatic. |

My experience is where an attack of gonorrhœa has existed for some time, it is more apt to cause stricture than a slight attack of but brief duration.

Any injuries to the perineum from a fall or a blow may cause stricture.

The use of strong injections, a sudden rupture of the walls of the urethra during an attack of chordee might result in causing a stricture, or rough and awkward use of sounds and catheters. The location of a stricture of the urethra varies extensively, but I think most authorities agree in finding it most frequently in the subpubic curvature which occupies an inch of the urethra before, and three-quarters of an inch posteriorly, which includes all of the membranous portion. The next place in frequency is about two inches and a half of the first portion of the urethra. The seat of the third most frequent location is about two inches and a half to three inches of the center of the spongy portion of the urethra, or within two inches and a half of the external meatus.

According to the eminent authority of Sir Henry Thompson who made a careful examination of over three hundred preparations of strictures contained in the museums of Paris, London and Edinburgh, he found that out of 320 distinct strictures, 216 cases, or 67 per cent., in the subpubic curvature; 51 cases, or 16 per cent., in the center of the spongy portion; 54 cases, or 17 per cent., at the external meatus, including a distance of two inches and a half behind it.

Stricture in the prostatic portions is extremely rare unless there exists hypertrophy of the prostate gland.

Symptomatology.—The first symptoms that usually causes a patient to consult a surgeon for treatment of stricture is a slight gleet discharge.

Some irritation is felt or slight smarting sensation in the tract of the urethra during the act of micturition; there is a more frequent desire than in the normal condition to urinate. The stream is smaller than usual and presents a twisted, forked or divided appearance.

In the majority of cases there will be found a purulent secretion from the urethra, which may present a yellowish or transparent appearance. In some cases the first symptom the patient has of stricture is a complete retention of urine, the stricture having existed for some time, but after a debauch or over indulgence in eating and sudden exposure to cold, retention of urine develops.

There are marked chemic changes in the urine if the disease is of a chronic character and has not been treated or relieved. The urine becomes almost opaque, and gives a distinct ammoniacal odor and leaves a sediment of mucus and pus, which is of a tenacious character and adheres to the bottom and sides of the vessel. The urine becomes alkaline.

Hematuria is a rare symptom of stricture. In addition to the local symptoms of stricture there are some constitutional disturbances.

The patient presents an anemic appearance, suffers from dyspepsia and becomes irritable and complains of pains in the back and loins. Has chilly sensations, followed by perspiration.

PATHOLOGY OF STRICTURE.

The pathology of stricture of the urethra is that of a simple inflammation which may affect the epithelial and submucous basement membrane of the urethra, and at the same time the corpus spongiosum may be involved. Where the stricture is slight the urethra anterior to the constricted portion is normal; but in severe and chronic cases where the anterior portion of the urethra becomes affected it is contracted.

The urethra posterior to the stricture is almost always dilated, which dilatation is caused by the obstruction to micturition. There is a loss of elasticity in the urethra, and it becomes so enlarged as to easily admit the finger; pouches may form and appear as fluctuating tumors in the perineum.

The gleet discharge, as a rule, comes from behind the stricture where the mucous membrane is in a state of chronic inflammation. The walls of the urethra may become ulcerated with abscesses and fistulæ. The walls of the bladder are hypertrophied, caused by interference with the flow of urine.

The ureters and kidneys are affected. The ureters become dilated; the pelvis and infundibula and calices of the kidneys are distended, while the medullary structure of the organ undergoes atrophy. Not infrequently the penis becomes hypertrophied, especially where the stricture is of long duration.

DIAGNOSIS.

The symptoms I have already mentioned might be considered sufficient to diagnose stricture, yet there are other diseases of the urinary organs that have symptoms so similar to those of stricture that they might be mistaken for it. Inflammation of the prostate gland of a subacute character, and neuralgia of the urethra and hyperesthesia may have all the symptoms that I have described as having occurred in stricture. The safest method of diagnosing stricture is to make a careful and thorough exploration of the urethra with instruments. The instruments necessary for a physical examination of the urethra and to determine the presence of a stricture are a complete set of sounds, solid and flexible bougies and catheters.

I know of no better instruments than the bulbous bougies for exploring the urethra for stricture.

Dick's elastic or gum bougie, and the oral tipped wire bougies of Otis are invaluable.

I prefer to use flexible bougies for exploring the urethra for a stricture. I find them easier to introduce, and they certainly cause less irritation and pain than metallic sounds. The chief kinds of non-metallic flexible instruments are English gum elastic catheters; the most common of solid instruments are the sounds or bougies and the ordinary catheter.

In order to ascertain whether a stricture exists, the number and character of the obstruction and what portion of the canal is affected, I would recommend the introduction of a No. 9 or 10 acorn or bulbous pointed bougie. I have observed that I can detect a slight stricture better on the withdrawal than on the introduction of the sound, since the abrupt shoulder of the bulb impinges more decidedly against it. A graduated bougie can be used in order to ascertain how far the stricture is from the external meatus.

Having found a stricture and its location by exploration, it is important to know its caliber. This can be judged of pretty accurately by the size of the stream; the caliber of the passage is a little less than the volume of the stream. The urethrometer is an instrument by which we can obtain an accurate measure of the urethra in its normal condition.

Dr. Otis contends that there is a relative proportion existing between the caliber of the urethra, and the size of the penis. For example, when the flaccid penis about three-fourths of an inch back of the corona glandis measures three inches in circumference, the size of the urethra is thirty millimeters in circumference or more.

THE TREATMENT OF STRICTURE OF THE URETHRA.

The treatment of organic stricture of the urethra varies according to the type we find in the canal. It is one of the most difficult problems in urinary surgery to make a fixed rule as to the selection of the best mode of treatment in the different types of stricture.

Dilatation is one of the safest and mildest modes of treatment of stricture for the urethra. It is a method more frequently used by surgeons than any other form of treatment, having been employed in the time of Galen and used extensively up to the present time. It can be accomplished slowly by the introduction of sounds and bougies.

This method of treatment may be continuous dilatation or interrupted. Before the introduction of bougies and sounds in the urethra they should be thoroughly sterilized by heat or carbolic acid or by friction with a clean towel. The instrument before introduction should be warmed to the temperature of the body, oiled with 1 to 40 carbolized oil. In order to obtain local anesthesia, hydrochlorate of cocain as suggested by Dr. Kohler can be used. Can inject about half a drachm of a 4 per cent. solution of cocain into the urethra. An ordinary hypodermic syringe may be used, at the end of which I attach Otis' cocain tube. Local anesthesia is produced within five minutes.

In several cases where I have used injection of cocain in the urethra for local anesthesia I have observed alarming symptoms of toxic effects, accompanied by delirium and tetanic fixation of the muscles of respiration.

Stimulants with hypodermatic injection of strychnia

and chloral by enema give the best results in correction of this condition.

In the treatment of a simple case of stricture of the urethra by gradual dilatation, I prefer to use a flexible bougie as large as the stricture will comfortably admit; after it is passed I withdraw it at once, however, there is a great difference of opinion among surgeons as to whether the bougie should be withdrawn at once or allowed to remain in the urethra for ten minutes to half an hour.

The operation may be repeated on the third day, introducing the same sized bougie first, and the next size larger, and so on increasing the size until the stricture is dilated to the caliber corresponding with that of the external meatus. It is important to instruct the patient how to pass the instrument on himself, as the treatment should be continued for several years. Should pass the bougie at least once a week, increasing the interval to once a month.

When a stricture is located more than four inches from the meatus there is no treatment as safe and none that will give better results than gradual dilatation. A quicker method of dilatation than the one I have just described is known as "continuous dilatation." A catheter or one or more whalebone filiform bougies may be inserted in the urethra and retained not longer than forty-eight hours. Within twenty-four or forty-eight hours suppuration takes place; a purulent discharge comes from the constricted portion of the urethra, and the canal is rapidly enlarged.

Other instruments may be passed as in gradual dilatation until the normal diameter of the urethra is obtained.

Many reasons have been given as the *rationale* of dilatation, but the one now agreed upon by the majority of surgical authorities, is that, "so far as it effects any permanent good results it acts by promoting absorption."

Now the first or immediate improvement must clearly have been due to the mechanical action of the dilating body on the stricture.

According to the authority of Sir Henry Thompson most kinds of strictures contain two structural elements, physiologically considered, or one element in two different degrees of development—the one absorbable; the other non-absorbable. The former is supposed to be removable by the act of dilatation; the other not so, but only amenable to mechanical distension, the effects of which are temporary. The relative proportion, then, of these two elements determine the degree of success which dilatation is capable of accomplishing in the urethra.

The operation for the relief of stricture by internal urethrotomy is performed with an instrument known as the urethrotome.

The instruments in use are of many different kinds. The one most frequently used is that of Maisonneuve, which has been modified by different makers at the suggestion of different surgeons. His instrument consists simply "of a grooved staff, which need not exceed No. 7 French catheter scale, provided at its extremity with a screw point, to which is attached a filiform bougie. The blades intended to slide in the grooves and to divide the stricture, are triangular in shape, sharpened before and behind, but blunt at the apex, so that it may pass over the sound urethra without wounding it."

Civiale's urethrotome was a very popular instru-

ment, and is highly recommended by Sir Henry Thompson. At the end of the shaft of this instrument is a bulb, in which the blade is concealed equaling about No. 16 or 17 American scale. It cuts from behind forward. The instrument can not be introduced until the stricture is dilated sufficiently to admit No. 16, which is a great objection to the use of this urethrotome.

Prof. Otis has invented several dilating urethrotomes, known by instrument makers as Nos. 1, 2, 3 and 4. These instruments consist of a pair of steel shafts connected together by short pivotal bars, on the plan of an ordinary parallel ruler. They are separated by means of a screw at the handle, near which is a dial indicating the extent of their divergence. The upper bar of the instrument is traversed by a urethrotome, terminating in a thin, narrow spring blade, which when at the extremity of the groove in which it runs, is concealed in a slot.

The instrument and its contained urethrotome, having been passed down behind the site of the stricture, and dilated until the stricture is made tense, the handle of the urethrotome is withdrawn, causing the blade to rise from the depression in which it was concealed, and the stricture is divided upon its upper wall from behind forward.

This instrument is to be preferred in strictures of large caliber; it is easily introduced and has great strength. Other advantages it has, that it attacks a stretched instead of a flaccid stricture. The incisions are made at a pre-arranged place, extent and depth.

Prof. Otis reports 2,297 operations of dilating urethrotomy without a death or permanent disability of any sort. He contends that re-contraction of the stricture after the operation is rare.

There is but little risk of hemorrhage after the operation of internal urethrotomy; if hemorrhage should occur from the pendulous portion of the urethra, it may be stopped by placing the penis upon the belly, "laying a handful of cotton over the organ and strapping it down with a bandage carried around the pelvis."

The patient should remain in bed for several days and be kept perfectly quiet. Sounds and bougies should be introduced for some time after the operation of urethrotomy, until the urethra is dilated to its normal size.

The operation of urethrotomy is not always a success; a recurrence may follow, especially if the stricture has existed for a long time and is greatly indurated. If the stricture should recur after having performed internal urethrotomy I would advise gradual dilatation.

Strictures at and around the meatus are best operated upon by a blunt pointed tenotome which gives the surgeon greater accuracy in making his cut than by the old method of dividing the stricture by Civiale's concealed bistoury.

In a small percentage of strictures there will be found cases where on account of the tightness of the stricture it will be impossible to introduce the urethrotome until the stricture is dilated sufficiently to pass the instrument. In cases of this kind, dilatation can be done efficiently with Banks' dilating filiform bougies, known as immediate dilatation, or it can be accomplished by the method I have just described, continuous dilatation.

When dilatation has been sufficiently made, the urethrotome can be passed and the stricture cut.

Strictures located near the external meatus may be cut with but little risk and give the best results. Strictures within three inches of the external meatus re-contract so quickly and the surrounding tissues are so unyielding that the operation by the urethrotome is the best mode of treatment.

In some cases of stricture the constriction is so great that it is impossible to pass any instrument, and at the same time it may be complicated with infiltration or retention of urine or abscess. The operation of external perineal urethrotomy should be performed at once in order to save the life of the patient. The stricture at the time that the operation is decided upon may be found in one of three degrees of constriction:

1. The stricture may be opened sufficiently to introduce a grooved sound, which will act as a guide when the knife is passed through the perineum in its division of the obstruction. The operation thus performed is known as external perineal urethrotomy with a guide.

2. When it is impossible to pass the stricture through the normal canal, we may succeed by introducing a grooved staff which terminates with a button-like end until it reaches the obstruction, then perform the usual perineal incision and open the urethra about a quarter of an inch in front of the stricture. The anterior face of the stricture is shown and the proximal orifice is discovered through which a fine probe can be passed, and afterwards a grooved staff upon which a free division of the constricted tissue can be made. When the operation is complete pass a catheter, which is to be retained for three or four days. This method is known as "Wheelhouse's operation."

As a last resort and when unsuccessful by the above methods of treatment open the urethra behind the stricture, at the apex of the prostate gland, known as "Cook's operation."

Resection of the urethra as a radical measure in the relief of severe forms of deep urethral stricture due to injuries, has been done successfully during the past year, chiefly by French surgeons.

Guyon, of Paris, advocates partial resection of the perineal urethra in preference to total resection, especially where the cicatrices involve only the floor of the urethra. If complete resection of the urethra be performed the elasticity of the surrounding tissues produces greater retraction between the resected edges of the urethra than could otherwise take place. Slight resection, the after cicatricial contraction in connection with the floor of the urethra, the roof not being disturbed, tends to increase rather than to diminish the caliber of the urethra at that point. Albarran has operated five times by partial resection of the urethra. All of his operations were successful, and cured in from two to three weeks. He contends that it is more difficult to get union by first intention in a case of stricture due to gonorrhoea than of traumatic origin, as when of gonorrhoeal origin there is always a chance of infection and subsequent suppuration.

Herteloupe, of Paris, reports eleven cases of successful resection of the urethra. He does not advocate this operation when the stricture is of gonorrhoeal origin.

ON THE LIMITATIONS OF SURGERY IN THE TREATMENT OF THE NEUROSES.

Read before the Michigan State Medical Society, May, 1894.

BY DAVID INGLIS, M.D.

DETROIT, MICH.

PROFESSOR OF MENTAL AND NERVOUS DISEASES, DETROIT COLLEGE OF MEDICINE.

A hardy young Englishman who had followed the hounds, fallen from his horse, wrestled, boxed and enjoyed the varied experiences of an out-of-door life takes to sedentary life, hard study with little or no recreation, and having thus changed his mode of life, slips one winter morning on his own doorstep, bumps down the five successive steps on his buttocks—considers the incident simply as rather undignified and amusing, goes down town and, a few hours later, has to be assisted to his home, where he takes to his bed. He becomes paralyzed in both legs, has enormous exaggeration of the reflexes, takes to tears or laughter, elation or depression on trivial provocation, fears yet longs for his doctor's daily visits, perspires, grows cold or flushes, becomes faint, his heart palpitates, he is harassed by insomnia; in short, presents the typical symptoms of railway spine and brain and is confined to his bed and room for many months. Finally his paraplegia passes off completely but three years after returning to the pleasant rural life of his old English home, he writes that he is still incompetent to engage actively in responsible mental labor. He has every inducement to work, for he needs money and he is not kept from trying to work by any expectation of damages to be obtained from any corporation, for he fell on his own doorstep. Here is a pure case of neurasthenia which can fairly be termed traumatic.

But notice that when he used to get a fall while fox hunting no such symptoms followed. There was another cause acting quietly before the injury. A change in the nutrition of his entire nervous system, probably largely due to the great change in his life from an active and out-of-door one to a sedentary and studious one.

A woman of good Christian character, of much good sense, a good wife and mother, who had actively spent her energies in house and church work, is now approaching the menopause, and has the misfortune to entertain, as the family guest, for several days, a fanatic revivalist preacher. He labors with constant prayers and endless assiduity to convince her of the fact that because she had grown quietly into the Christian graces and not experienced any emotional storm, her soul is therefore in jeopardy. So successful is he that he leaves behind him a ruined home, the hostess becomes insane, is removed to the asylum where she remains until her death.

Shall we lay all the blame on the guest?

Great as is our indignation, truth compels us to acknowledge that here again there must have been a cause acting slowly and quietly, which prepared the poor woman for the catastrophe inflicted by the unwise visitor. If it were not so, then this man's track through the world would be like that of a pestilence, for what he preached to her he preached to other women and men.

Several children playing together are suddenly scattered in affright by an immense dog. One of them in a few hours develops chorea. She is tormented for weeks by involuntary muscular movements of almost every muscle, but quite as marked is the change in her intellectual and emotional state. Study is impossible; she becomes so irritable as to render it a burden to her family to live with her; the general bodily nutrition begins to fail and for years to come her life must be adjusted to a different scale.

Why were the other children not so affected?

Because this child's whole nervous organization had been adjusted on a more unstable basis than theirs—this may have been brought about either by defective hereditary endowment, by wrong physical and mental training, or by some antecedent disease or acquired diathesis, but that it was so seems certain. In almost every similar case it can be easily demonstrated. You ask what is the bearing of such common cases upon the matter of surgical treatment of the neuroses? Simply this:

As surely as the various neuroses depend mainly and finally upon general and wide-spread defect in the nutrition of the cerebro-spinal axis, just so surely will the correction by surgical measures of local and secondary causes fail to permanently cure the various neuroses. But just in proportion as any neurosis depends mainly or primarily upon local causes, in that proportion can we hope for help from the removal of the cause.

This last statement needs to be modified, however. Nothing is more certain than that the entire functional life of the nervous system contemplates the establishment of habits. Our whole educational effort can be summed up in one idea: We are trying to establish habits. The violinist has made no progress until his fingers come down on the strings automatically or by habit. The student of books is forming habits—training his mind to follow certain sequences of ideas as a habit, to recognize certain relationships easily or habitually. It matters not how the action is set up, it becomes habitual if continued for a time. I knew an epilepsy set up by the irritation of some late coming and abnormally located teeth. When the abnormality was discovered and removed it was too late; the epileptic habit had been set up and the disease went on unchecked.

So the neuroses which depend mainly or primarily upon local causes are not all capable of being cured by the removal of the cause. Here, then, is a further limitation of the possibilities of surgery. Surgical cures would be more frequent than they are, if surgical efforts were resorted to much earlier than they commonly are.

It is clear, then, that the question of the possibility of surgical help in the neuroses is largely bound up in this: In any given case how important a part in the causation is played by general causes? If local causes are largely to blame, the further question is, How long has the cause been acting?

It has been one of the triumphs of the science of medicine that we have learned to give careful attention to the phenomena of reflex irritation—the fact of an irritation at one point causing a train of symptoms at some remote point of the body, has been known to the profession since ancient times, but it is only in the last few years that we have begun to comprehend how widely these relations extend, and how frequently this relation of cause and effect can be traced.

Probably nothing has done more to advance positive therapeutics than this one discovery. The recognition of the relation of various defects in the eyes to certain neuroses is a case in point. Migraine was, in former years, a stumbling block in the way of the profession. As a rule, the sufferer from sick headache, after trying several physicians in vain, settled down to a life of periodical wretchedness and the physician was no longer regarded.

To-day a large percentage of cases of migraine can be cured by careful correction of ocular defects. It is a great triumph.

Our gynecologic associates were not slow to recognize the bearing of this phenomenon upon their line of work, and to-day the gynecologist can bring forward illustrations, without number, of distant neuroses cured promptly and completely by the proper treatment of some pelvic disorder. That, too, is a great triumph—I would not attempt to lessen it—rather would I urge that the profession in general

should be more diligent in searching for these cases of reflex irritation. There is not a gynecologist before me who can not tell of instances in which it was the gynecologist who first traced the relationship of some nervous disorder to some pelvic error, and that, too, in patients who had been a long time in the hands of one or more general practitioners.

There is not an ophthalmologist who can not confirm this from his experience, and the neurologist sees daily that there is much need yet of a fuller recognition of the part played by reflex irritants. These things are true.

Now it has happened that men have been carried away from sound judgment by their zeal for truth. Certain ophthalmologists have been so impressed with the facts of reflex irritation that they have made impossible claims for the cure of diabetes, locomotor ataxia and other diseases, by means of proper adjustment of the eye muscles. Fortunately, the over-zealous ophthalmologist has been content to leave the eye in the socket, and the worst that has come to the patient has been a series of useless tenotomies.

It has been otherwise with the gynecologist. He, too, has been strongly impressed with the facts of reflex irritation. He has seen women whose lives had been reduced to utter uselessness, to whom existence was a curse, suddenly restored to a happy and useful life by the correction of some pelvic disorder. It is small wonder that he has become thoroughly enthusiastic in his zeal to search out and remove sources of reflex irritation. Still more; he may well have grown weary and dissatisfied with the endless round of applications to the mucous membrane of the genital tract—the tampons and pessaries and douches, and have felt that gynecology must find its glory in some measures which bring more definite and lasting results than these things do—and we all feel just as he does, but the gynecologist is mortal; he belongs to the great gregarious family of man and sometimes his zeal runs away with his judgment.

So it comes about that we are living, in these days, in an era of laparotomies. Unlike the ophthalmologist who still leaves the eye in the socket, the tendency of present day gynecology is to extirpate the genital apparatus, root and branch. I stand here to-day, not to condemn gynecology, but to call for careful judgment.

Let us give to the surgical gynecologist all due honor, there still remain these limitations: First and above all, the greater number of neuroses by far are primarily dependent upon general conditions of the nervous system. This holds true of very many cases in which an evident local cause can be traced as well. This is a fact of prime importance, and can not be too clearly emphasized nor too often reiterated. In the very large class of neuroses in which no evident local defect can be found, even the most enthusiastic operator is quite content to let the patient alone. The real battle ground is in the cases in which some local defect can be discovered.

Here the tendency of the surgeon is constantly and strongly to urge operation. The local defect occupies so large a part of the field of vision as to hide from view those general conditions which are the real and permanent causes of the neuroses. I am confident, from a constantly widening experience, that were surgeons to bring to their work that habit of mind which is fostered by the practice of general medicine,

the habit of taking a comprehensive view of the patient's whole status and previous environment, the surgical treatment of the neuroses would be attempted far less often than is now the case, and gynecology would be spared the condemnation which has been brought upon it by some of its members.

The needless castration of a woman is a permanent wrong to her. It is not to be cast aside as a light matter, for a woman's whole life is changed. It is not simply a question of the sexual life, although to shut a young woman off from the happiness of wife and mother is a most serious thing. The change is more profound, for the whole mental state is in many cases altered. The mental change is of all grades, from a simple lowering of the intellectual activity to the development of pronounced forms of insanity. Women become queer, cranky, unhappy, irascible. The beauty of life has gone; they continue to exist. Some die from the operation—it is a hard thing if it be that the patient might have been restored without operation. There is need of more careful judgment. Again, I am equally confident that were surgeons to keep track of the subsequent histories of their cases, for long periods, operations would not be done as often as now. It is not a sufficient answer to say that the patients recovered *from the operations*. The question at issue is, Did they recover from their neuroses? This question can not be answered by stating the condition of the patient a few weeks or months after the operation. The evidence is overwhelming that the mere fact of operation, in many cases, exerts a remarkable effect upon the patient for a time. This effect of operation occurs when the operation has been a failure, or when it has been performed for various other reasons than the removal of points of reflex irritation. The question is this, How many operations performed for the purpose of removing supposed causes of neuroses accomplish the object aimed at? Let our laparotomists keep records of all laparotomies done for such purposes, for two years after operation, and give us the results. It will result thus: A proportion of beautiful cures, another considerable number of cases in which there is striking temporary improvement and subsequent relapse, another group of cases in which the removal of the generative organs has taken away all hope and left that most wretched of all patients, a neurotic woman confirmed in her despair. All of these patients, with the exception of the first group, come to the neurologist, and in each he recognizes that the operation has not touched the real difficulty; that the same problem in therapeutics presents itself after the operation as before. The limitation of surgery is evident; it can not reach the functional soundness or unsoundness of the nervous centers.

A further limitation of surgery is found in the difficulty of diagnosis. It would seem that an irritated and painful ovary could be easily diagnosed. Yes, the patient can tell that herself. The problem for the surgeon, however, is not so simple. Is this painful and tender ovary the cause of some profound neurosis, or is it a consequence of it? You see the question is a vital one.

I have in mind a beautiful girl of 19 years, who developed a most remarkable series of convulsions, which for a long time seemed to endanger, not only her mental health but life itself. There was in this case an ovary exquisitely tender, the seat of pains of great intensity. The other ovary finally participated in

the same condition. To resist the pressure for removal of these ovaries was the most trying task; the mother, the girl's relatives and friends besieged me in person and by letter to cease wasting valuable time, and let her ovaries be removed.

But always in my mind was this problem: If I have them removed, what then? Knowing the girl's life history and her inheritance, I said to myself, I will have to make the same fight to restore her nervous system to stable equilibrium, ovaries or no ovaries. The girl has still her ovaries, she is a well, happy woman, she has a future before her as wife and mother, and now comes the remarkable fact that, just in proportion as the general nervous upbuilding went forward so the local pain in the ovaries ceased—ceased not because the generative apparatus was treated but, as I believe, because it was carefully let alone. The pains in the ovaries were no more a guide to operation there than neuralgia of the face, occipital or intercostal nerves would have been; they were a result of her nervous condition, not the cause of it. No!

Surgery is limited by the difficulty of diagnosis, the difficulty of deciding upon the real significance of some local symptom.

Surgical treatment of the neuroses is further limited by the fact that surgical operations are themselves the cause of severe neuroses; sometimes lead to worse conditions than the one sought to be cured. The statement has been made that "10 per cent. of the castrations for uterine fibroids bring on insanity." This is undoubtedly an exaggeration, but there is no question whatever that there is a basis of fact in it; many observers have put on record cases of insanity caused by operation. I have spoken thus of the limitations of surgery in the treatment of the neuroses, because it seems to me that the same fundamental principles apply in all the neuroses. The subject more particularly before us this morning has been the gynecologic treatment of the insane, but insanity is in most of its forms a neurosis.

I heartily coincide with the proposition now receiving more and more acceptance, that every asylum should have an attending or consulting gynecologist, and that he should actively study the patients. So, too, the insane at home should be carefully studied on this line.

One of the most valuable papers ever brought to my notice, was one by Dr. Holmes, of Chatham, Ontario, upon the relation of puerperal mania to uterine disorders—particularly subinvolution—and every year's experience has taught me to look more closely for subinvolution or some uterine or ovarian lesion in cases of mania or melancholia occurring after childbirth. And these cases emphasize very clearly the fact that the earlier the local error is corrected, the greater the hope of curative results.

The limitations of surgery in the treatment of the insane, are the same as those which I have already mentioned, but with one added limitation. Much of the benefit of surgical operations upon the neurotic depends upon the effect of expectant attention. This element is apt to be largely lacking in the insane. On the other hand, surgery in the insane is free from one of the usual limitations. I refer to the patient being worse off after the operation than before. Herein the surgeon has a more free field than in the other neuroses.

In conclusion, I venture the suggestion that the

search for removable causes of the insane neurosis ought not to be confined to the female inmates of our asylums, and ought not to be carried on exclusively by gynecologists. There are more males insane than females. There are probably as many insane patients with atrophied testicles and varicoceles, as with hardened ovaries or congested uteri. Hemorrhoids can cause the same reflex neuroses as lacerated cervixes, but when all is done that can be done locally, the population of our asylums will not be materially reduced, for the great facts of defective heredity, of wretched mental culture, of high pressure living, of immoral life and of early or late old age will still remain, as they are now, the causes of insanity, as they are of most of the other neuroses.

SELECTIONS.

Ligation of the Base of the Broad Ligaments per Vaginam Including the Uterine Arteries for Fibroids of the Uterus.—Dr. Augustin H. Goelet, of New York, in a contribution to the *American Medico-Surgical Bulletin*, June 1, reports favorably upon this operation in his hands for the control of uterine hemorrhage and reduction of fibroid growths. He believes it should be done in lieu of hysterectomy when that operation would involve too great a risk, and as a preliminary step with a view of avoiding the necessity of the more hazardous operation. When extensive attachments have been formed which would afford additional nutrition, considerable reduction has resulted even in growths of large size.

When the operation has been done for smaller growths the result has been more satisfactory. In some instances complete atrophy has been reported. This result, as well as arrest of the uterine hemorrhage, is accounted for by interference with the blood supply and nerve supply which are included by ligation of the base of the broad ligaments. It is estimated that the uterine arteries furnish the uterus with two-thirds of its blood supply, and it is reasonable to expect that a profound effect will be produced upon that organ and growths arising from the walls if this is suddenly cut off.

The sole danger in the operation is the risk of including the ureters in the ligature, as they pass down behind the uterine arteries only half an inch from the cervix and are consequently in the field of operation. Dr. Goelet suggests as a preliminary step, to eliminate this risk, that bougies be passed into the ureters through the bladder. He admits, however, that a careful operator accustomed to working in this region may easily avoid the ureters.

The technique of the operation as described by Dr. Goelet shows an important departure from the usual method followed. Instead of ligating each artery in only one place, on a level with the internal os, he applies a second and often a third ligature to the artery on each side as it ascends along the side of the uterus, the result of which is to cut off the compensating blood supply from the ovarian artery to the lower part of the uterus.

Dr. Goelet gives all the credit of priority to Dr. Martin, of Chicago, who has recently suggested and popularized the operation and perfected its technique, but states that he first ligated the uterine artery per vaginam on one side in January, 1889, in the case of a large fibroid the size of a seven months' pregnancy with a view of diminishing the size of the growth by reducing the blood supply. The artery on the other side was not ligated because the position of the tumor made it inaccessible. Six months later the tumor was one-third smaller, and was giving no inconvenience.

He quoted his last case operated upon, to show how promptly uterine hemorrhage may be controlled by this operation.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

SATURDAY, JULY 21, 1894.

ABOUT FOOT WEAR.

"How beautiful are thy feet, with shoes, O! Prince's daughter," says the Song of Solomon, and it must be confessed as a fact true of our time that modern feet must be hidden by shoes to give an approach in appearance to a perfect classic standard. Toes twisted out of shape, thick projections at points of contact, clubbed nails, corns in various uncanny situations, and bunions on the joints, make the actual foot so far from being a thing of beauty that it is only to be viewed in private and then by the chiropodist.

The shoemaker, jolly follower of King Crispin that he is, desires to make "handsome" shoes, and they are usually quite unlike the natural form of the foot, which long having been "cribbed, confined and confined," becomes deformed for life.

We venture to say that the surgeon of experience, familiar as he is with the anatomy, if not with classical models, can scarcely recall an example of a foot perfect in all its parts, and these blemishes or deformities are nearly always acquired. The shoe pinches, it is too narrow, too long, too short, too wide, too heavy, too thin, or too much varnished, but Crispin made it, he has been paid and the shoe must be worn at all hazards. And thus the children's feet are ruined.

Looking at the matter from a purely hygienic standpoint, the Indian moccasin is infinitely superior, for indoor wear, to the stiff soled, unyielding shoes of our times.

The varnished or "patent leather" shoe is surely an invention of the devil. In any case while there remains a semblance of circulation in the foot, there will be some perspiration, and however slight the quantity or however great the amount, it remains in contact with the skin, for the shoe leather has been made impervious to moisture. The skin is thus macerated, and excoriated by being "stewed in its own

juice." It is readily seen that when in addition to the unnatural form common to most shoes, we add the hermetic seal of the patent varnish, we are not so very far beyond the Chinese civilization. Even that curious people limit the foot-deforming process to one sex, the female. We allow our shoemakers to deform all feet alike; we spare neither childhood, maturity, nor old age. All suffer alike. The male Chinaman has a wooden sole shoe with a cloth upper. It is well ventilated and serviceable, perhaps better adapted to the city foot-pavements than the moccasin, and for hot weather it seems greatly superior to the ordinary European shoe.

Common sense should teach us that living in a climate subject to such extreme variations of temperature as our own, we should adapt our style of dress, including foot-wear, to the season. A desire for cleanliness is a valid reason for not using the ancient sandal during the heats of summer; doubtless the desire to conceal deformity is equally potent, but the adoption of the Chinese shoe for outdoor walking during summer, and the moccasin for indoors, would be a great relief to suffering feet.

In winter we might use heavier soles and thicker leather when outdoors, but changes should correspond to the temperature as much as practicable. The tyrant CALIGULA permitted the Romans to wear slippers in the theater, and he himself often wore them in public. It is interesting to recall that this Emperor CALIGULA was so named on account of the soldiers' shoes. The shoe (*caliga*) of the Roman soldier was heavily set with nails. The word "*caligatus*," a private soldier, refers to the foot-gear, and SENECA, speaking of MARIUS, refers to him as "*a caliga ad consulatum perductus*;" that is to say, "led from a private to the consulship."

We have neither time nor space to take up the interesting historical question of the evolution of the modern deforming shoe from the natural skin foot coverings of the people of ancient Latium. It was many centuries before tanned leather came into use in the Italian colony, but wooden shoes were kindly put upon prisoners condemned for parricide, and the very poor wore them then, as now, from necessity.

In conclusion, we assert that reform is necessary to secure sound, healthy and well-shaped feet, and that the nature of the material of which shoes are made is of the highest hygienic importance.

WHAT WAS THE LISBON EPIDEMIC?

In April of the present year, following upon a season of drenching rains, a disease suddenly broke out in the city of Lisbon characterized by all the symptoms—with one exception, to be hereafter noted—of Asiatic cholera. Competent observers described the attack as setting in, without premonitory symptoms of illness, with sudden discomfort, vertigo,

muscular debility, headache and abdominal disturbance; followed quickly by vomiting, profuse mucous and sometimes rice-water diarrhea, sunken eyes, whispering voice, dry tongue, burning thirst, cramps, algidity and cyanosis—"a few hours sufficing for the development of all these symptoms in a person who was before in perfect health." Add to this that the disease was contagious—washerwomen, for example, being infected from the soiled linen of patients; and transportable—one suffering from the disease conveying it to the man in whose house he took refuge twenty miles (thirty kilometers) from the city; and, finally, that "the anatomic lesions characteristic of Asiatic cholera were present." It is little wonder that DR. FEDERICO MONTALDO, sent by the Spanish Government to investigate the epidemic, unhesitatingly pronounced it to be Asiatic cholera or that a quarantine of cholera was thereupon established against the city and province.

The single exception to the ensemble of Asiatic cholera above depicted was that of mortality. It is indefinitely stated that "several thousand persons were attacked within a few weeks;" yet there "were hardly any fatal cases, for among all those affected only a *single death* was attributable clearly to this singular type of cholera."

What, then, was the Lisbon epidemic of 1894?

DR. A. CHANTMESSE, Assistant Inspector General of the Sanitary Service in Paris, has just made public the results of his investigations of a comma bacillus isolated by DR. CAMERA PESTANA, Director of the Bacteriological Institute of Lisbon, from the evacuations of about forty of the Lisbon patients. This bacillus is asserted to be "distinctly different from the typical comma bacillus found in true Indian cholera," and CHANTMESSE claims to have established "a close relationship" between this Portuguese bacillus and that observed by FINKLER and PRIOR in the epidemic of cholera nostras in 1884, and seems inclined, on this ground, to class the Lisbon epidemic with that of Genoa. In doing this, however, he ignores the only symptomatologic difficulty which prevents the Lisbon cholera from being classified as true Indian or Asiatic cholera, namely, the light mortality. In Genoa the disease denominated cholera nostras by FINKLER attained almost the maximum mortality of cholera in India; out of 586 cases in twenty days there were 351 deaths—a mortality of almost 60 per cent. In this Lisbon epidemic the mortality was practically *nil*.

If the bacillus of PASTENA and CHANTMESSE was the epidemiologic cause of the outbreak in the Iberian capital and so closely resembles the bacillus of FINKLER and PRIOR, what *tertium quid* was lacking to produce the mortality of the Genoese outbreak? It begins to look as though we should have to fall back on the theory of "mixed infection" to account for the protean manifestations of cholera.

CORRESPONDENCE.

LETTER FROM EUROPE.

No. III.

PRAG, BOHEMIA, JUNE 28, 1894.

To the Editor:—A clinic in internal medicine here, differs but very little from one given in our own colleges. One advantage, however, is the fact that the cases have all been under observation for some time before being brought before the class, so that all facts concerning the patient are accurately known; this advantage is also possessed by our own schools where patients are brought from a hospital where clinical data have been obtained, and where the sole dependence for clinical material is not upon the dispensary.

It is worthy of note that in every case that comes before the class, not only is the urine most carefully examined but the blood as well, *i.e.*, the blood count is made and the hemoglobin estimated. The Thoma-Zeiss instrument is the one commonly employed here for counting the corpuscles, both white and red, and the Fleischl hemometer for estimating the percentage of hemoglobin. Great stress is laid upon the enumeration of the leucocytes, in many cases their number being of much more importance from a diagnostic point of view than that of the erythrocytes. A marked leucocytosis is always regarded as pathological and usually as indicative of an exudative inflammatory action in some part of the body. The blood is not stained except where there are special indications for it, *e.g.*, in suspected septicemia, malaria, leukemia, etc. Beautiful karyokinetic figures were shown to me the other day, in the nuclei of red blood corpuscles from a case of leukemia. This careful attention to the examination—and to the repeated examination—of the urine, blood, sputum, feces, exudates, etc., leads often to most positive, and sometimes brilliant diagnoses. Yet the attractiveness of these comparatively newer, and not always as yet, fully understood, methods of diagnosis is liable to lead even the best of diagnosticians away from what might be called the grosser details of a case; and carried away by the success of some new test he may overlook that which, twenty years ago, would have been surely found. For instance, a case of "cryptogenetic septicemia" was exhibited to the class and streptococci from the blood clearly proven. Every week the blood was examined and the diagnosis confirmed by the finding of the cocci. But the large retro-pharyngeal abscess, the multiple abscesses of the liver, and the old appendicitis, the starting point of all the septicopyemic trouble, were not revealed until the autopsy. Usually, however, there is excessive care in the examination of patients in every particular and a very accurate diagnosis.

In this University, as in so many others in Europe, there are two medical clinics. I believe the little rivalry that exists between the two clinicians is a good thing for both teachers and students, and particularly where both clinicians are good men and yet, as here, of totally different stamp. Jaksch, as one might judge from his writings, lays great stress upon the aids to diagnosis to be derived from chemic, microscopic and bacteriologic examination; he looks at his case from a strictly scientific standpoint. Pribram, while not underestimating the examination of urine, blood, stomach contents, feces, lays more stress upon the anamnesis and the physical examination of the patient himself. He always speaks at length and most instructively, of the therapy which Jaksch often dismisses in a few words. These words are apt to be—"calomel," "digitalis," or "venesection or wet cups." The amount of calomel given in his cases as anti-syphilitic, purgative, diuretic, alterative

is really astonishing. He employs blood letting quite freely in uremia and in pneumonia. Very rarely is there salivation. Pribram, much the older man, is much more reticent about the administration of mercury in any form. Opium, for pain, is also given by Pribram very cautiously indeed, as it seems, almost over-cautiously. As antipyretic and anti-septic, Jaksch has been using lactophenin and apparently with good results. In chlorosis he employs ferratin.

It is a pleasure to listen to either one of these men and feel that you are listening to an all round medical man and not to a specialist. Either one talks as well of the diseases of the heart as of the kidney, as well of the lungs as of the brain or of the stomach, and I feel sure that the presentation of the cases in the general clinic has a better teaching effect, if I may so speak, and gives the student broader and more comprehensive views of clinical medicine, than where one man constantly presents, and talks about, diseases of the heart, another only of the kidney, another of the stomach, another of the nervous system, etc.

There is no scarcity of material here for clinical work, and one can go into the wards at any time and find cases illustrative of most of the commoner, and many of the rarer affections. The frequency with which carcinoma is met with and the common occurrence of rickets, are remarked by every American coming to these parts of Europe. Suicide is here an everyday affair. If a young man is affected with "unglückliche Liebe," the proper thing for the man to do is to use the revolver on himself or throw himself from the bridge into the river. If the afflicted one is a female, she promptly eats the heads of a few boxes of matches and is shortly utilized to enlighten the students concerning phosphorous poisoning, its diagnosis and treatment, or as not infrequently happens, to illustrate by microscopic preparations the extensive fatty degeneration found in such cases. Münzer, lately Jaksch's first assistant, has written a very exhaustive article upon phosphorous poisoning.

Within the last two weeks I have seen three clinical cases that were very instructive to me, and that may not be without interest to JOURNAL readers.

The first was shown by Prof. Pribram. The patient was a young man, 28 years of age, who has, I judge, been exhibited in Vienna and other cities where the clinician is willing to pay something for the privilege of presenting such an unusual case. In 1885, *i. e.*, at 19 years of age, the patient was confined to bed with headache, fever, pain and swelling in one of the arms. For several months there were fluctuations in the symptoms, now one portion of the body and now another showing the pain and swelling, and again the pain being entirely absent. At the site of the previously painful swellings, bony masses developed, many apparently connected with the adjacent bones, others seemingly free and permeating, if not displacing, the muscular and inter-muscular tissues. The condition of the poor fellow was truly pitiable. The neck was stiff, the spinal column fixed at an angle of about 120 degrees, the jaw immovable so that only liquids could be taken through a tube,—teeth having been removed to enable the latter to be introduced; the arms fixed by the side. He was able to walk with a sort of shuffling gait. Fortunately, so far at least, the muscles of respiration and of deglutition are unaffected. The diagnosis of the case was *myositis ossificans*. As in many of these cases, the large toe was short and blunt and its end joint ankylotic and exostotic. No new light was shed upon the etiology or pathology of this rare and but little understood disease by this case.

A second case was shown me by Jaksch's assistant. The patient, 51 years of age, is a fixture in the hospital, having been here, I think three years and being shown clinically every year to demonstrate Erb's *progressive muscular dys-*

trophy. He is in fact the same man whom Erb eight years ago carefully examined and whose case was fully described by him at that time. Eight years ago the patient, a man, noticed a gradually increasing weakness of the upper extremities, finally incapacitating him for work; walking soon tired him out. All the muscles of the shoulder girdle became parietic, allowing the shoulders to drop. The constant weight of the upper extremity pulling on the shoulders causes much pain when the arms are not supported. There is great weakness also in some of the muscles of the lower extremity. Some muscles *e. g.*, the pectorals, seem to be entirely atrophied. Others, as the deltoid and quadriceps extensor femoris, present the bulging contour and hard feeling of the pseudo-hypertrophic paralytic muscle. That this is the real pathologic condition might be judged by the great weakness of the muscles in spite of their increased size, and is proven by the microscopic examinations made both by Erb and in Jaksch's clinic. The case is carefully watched and any changes that occur scrupulously noted. The quadriceps femoris, for instance, that was observed by Erb to be small and atrophic, has gradually grown larger yet weaker, *i. e.*, is pseudo-hypertrophic, and microscopic examination of a piece of the muscle shows the atrophy of many fibers, the deposit of fat, etc., characteristic of this peculiar muscular change. Aside from this muscular or nervous trouble the patient is well. An ingenious device somewhat corset-like, has been fitted up to assist in holding up the shoulder girdle.

The third case was one of grand hysteria where the phenomena of that marvelous disease so clearly portrayed by Charcot and his school were exhibited in a typical manner. Prof. Jaksch who gave two clinical lectures, each an hour and a half long on this case, was able by pressure over the left ovarian region to throw the patient, a girl about 20, into a condition of opisthotonus as marked as is ever seen in strychnia poisoning or in tetanus. She was readily hypnotized and would then, according to the Professor's directions, manifest the phenomena of monoplegia, hemiplegia, paraplegia, etc., would eat soap and regard it as chocolate, imitate with remarkable accuracy the gait and voice of an old woman of 70, etc. About all the acts of hysteria, hypnotism and mesmerism were seen in this clinic. The patient is to be kept under observation for some time and it is to be seen how far the functions of various organs can be influenced by hypnotic suggestion. Thus she is to have, if the experiments are successful, on one day diarrhea, on another constipation; and in analogous ways polyuria, anuria, vomiting, etc., will be produced.

Two cases that came to autopsy were very instructive. The one seen to-day was actinomycosis of the middle ear, invading the adjacent muscular and bony structures. Death was caused by rupture of the vertebral artery, probably from the bursting of an aneurism, the result of the invasion of the vessel wall by the parasite. The primary focus was not definitely located, clinically or macroscopically post-mortem, though microscopic examination Prof. Chiari thought, would show the tonsil to be the seat of old inflammatory actinomyotic changes and the point of entrance of the parasite.

Another case coming to autopsy a few days ago, was a primary endothelioma of the right pleura with secondary deposits in lungs, pericardium, liver and peritoneum.

The call of Prof. Gussenbauer from Prag,¹ to be the successor of Billroth has caused deep regret that so valuable a man is lost to Prag, but also a feeling of pride that this University possessed a man deemed worthy to fill the chair of the great surgeon of Vienna. Prof. Gussenbauer commences his work in Vienna October 1.

In my next letter, I hope to say a word concerning the work done here in children's diseases and in gynecology.

Truly yours,

JAMES B. HERRICK, M.D.

LETTER FROM BERLIN.

On the Production and Application of Curing Serum-Liquids (Heilserum), for Diphtheria. German Surgical Congress.

[From the Berlin correspondent of the JOURNAL.]

BERLIN W., July, 1894.

The Professors Ehrlich, Kossel and Dr. Wasserman, in Berlin, have published a paper on the application of curing serum as invented by Prof. Behring, assistant of Prof. Koch. Behring had undertaken to give an immunity from the diphtheritic poison and after that, to get a serum from the blood of those animals, by which he hoped to protect individuals of the human race against the results of diphtheria as well as to cure the disease when already developed in an individual. Ehrlich, Kossel and Wasserman have followed Behring in his experiments. They always had in view to use the results of their experiments for curative purposes. They experimented on goats. We will say nothing of the technical dates for giving the serum. Two hundred and twenty patients with diphtheria were treated with the serum. Of these there were cured 168, or 76.4 per cent.; fifty-two died. Tracheotomy was performed in sixty-seven cases, of which thirty died; the rest recovered. But a true insight of the curing effects of the injections is gathered only by grouping the number of the diseased people by the days after the infection on which the treatment was begun:

| Day after beginning of treatment. | Treated. | Cured. | Died. | Percentage of cures. |
|-----------------------------------|------------------------|------------------------|----------------------|----------------------|
| 1st day | 6 | 6 | 0 | 100 |
| 2d day | 66 (9 tracheotomies.) | 64 (7 tracheotomies.) | 2 (2 tracheotomies.) | 97 |
| 3d day | 29 (8 " | 25 (7 " | 4 (1 " | 86 |
| 4th day | 39 (14 " | 30 (10 " | 9 (4 " | 77 |
| 5th day | 23 (10 " | 13 (4 " | 10 (6 " | 56.5 |

It is to be seen by this table of dates that the safety of the serum treatment depends essentially upon the date on which the treatment of the children is begun, and that on the first day results were had never seen before. Of seventy-two children received at the hospital during the first two days of the disease, there were only two deaths; of seventy-two cases treated *without* serum after statistics reaching over twenty-five years, there were twenty-five deaths, or 34.7 per cent.

The above named experimenters give the following points of view for the treatment with their serum of those children sick of diphtheria: 1. *The fate of the children depends upon the treatment during the first three days of the sickness.* Therefore the serum should be injected as soon as possible after the beginning of the disease. 2. As there must be a surplus of antitoxin in the sick body, the dose of commencement should be, in light cases, at least 200 unities of immunization.¹ In cases of gravity and in those tracheotomized, 400 unities were needed. The treatment with serum should be continued some time after ceasing of rise of temperature and of the local inflammation. The total amount of dispensed serum may reach in a single case (in correspondence with the gravity of the symptoms) 500, 1,000, 1,500 unities of immunization.

TWENTY-THIRD CONGRESS OF THE GERMAN SURGICAL SOCIETY.
(Held at Berlin, April 18-21, 1894.)

HOFFA, of Wurzburg. Pathologic Demonstration concerning Operation of Congenital Luxation of Hip Joint. He showed the pelvis of a child operated upon on both hip joints with good functional result afterwards, which had died of diphtheria. A pseudarthrosis had been formed on the pelvis lined with hyaline cartilage. Operation should be performed during the third to sixth years on account of the head of the femur bone getting altered afterwards, as well as the upper parts of the femur. If these deformations are

¹ A dose of antitoxin serum equal to avoid in the body the consequences of the poisoning with diphtheritic poison, is called by the author a "unity for immunization."

present the operation becomes more difficult, especially when the neck of femur is crooked forward. The caput femoris would then leap out of the acetabulum and one was obliged to make osteotomy of femur beneath the great trochanter to bring the femur into straight position. When the luxation is on both sides, generally the ligamentum teres is wanting; when unilateral, the reverse is generally observed. When it is wanting, a slight knock or cracking is heard in rotation. If this be heard, reposition may be effected by unbloody proceedings; if the ligamentum teres is present, operation should be done. In older persons it is well done not to try reposition, on account of the alterations of the head of bone. For such cases he has tried a new proceeding: The capsule of hip joint and the ligamentum teres rendering reposition of the luxated caput impossible, he makes an arthroclasis, cutting from the margin of the capsule upwards to the ilium, shoves back the capsule and scrapes off the periosteum. Then the caput femoris is placed upon the naked bone in strong abduction, and fixed in this position until bone to bone is connected. The caput is then fixed by new grown connective tissue.

SCHUDE, of Hamburg, said that the alterations of the head of femur had nought to do with age. He has seen crooking of the neck of femur (coxa vara) twice in early life, but without disturbing the operation. In older persons, where the caput is strongly misplaced upwards, extension with heavy weights for some months is useful, with or without dividing muscles and sinews of the leg before the operation. The latter proceeding has had good success in two cases; one of congenital, and one of traumatic luxation of hip joint.

LAUENSTEIN, of Hamburg, proposes to prevent the dressings from getting wet with urine in little children, to protect the wound and gauze, etc., upon it, by a bow made of wire, whose ends are fixed on the skin with the usual cambric rolls.

WAGNER, of Konigsberg, has cured the congenital luxation in a girl of 17 years by operation, loosening the muscles and diminishing the very large caput femoris by cutting round like the shells of an apple. Then it could be managed into its place. The former shortening of leg of seven and one-half centimeters was reduced to two and one-half centimeters after the operation. After operation careful mechanical treatment is needed.

WAREWSKI, of Berlin, is of opinion that the deformation of the caput and colles femoris in these cases of congenital luxation is due to hereditary faults of the kernels of bone and cartilage, becoming manifest in the time of growth. If this should be so, such hereditary faults could develop themselves after a well performed operation, overcoming the primary good effect of it. One should not hope too much of Hoffa's operations, at least for permanent good results. Not all the cases offered those hopeful anatomic conditions as those published by Lorenz and Hoffa, but now, where the neck of femur was missing and the head deformed, effects of reposition were very doubtful. There were many transitions between those cases in which the dislocation of the hip was remarked during the first days after birth among other malformations, and those where the children began to walk in their second year of life or later. All those transitional forms had their different anatomic construction, and therefore should also be differently judged as to therapeutics.

MIKULICZ, of Breslau, has constructed a reposing machine working firstly abduction to 60 to 100 degrees, then inward rotation to a right angle, and finally extension with five to ten pounds (old German weight). Three cases cured in this manner. The treatment is troublesome and takes a good deal of time. Only for very young children.

GUSSENBAUER, of Prag, had a good result in one case by the osteoplastic proceeding of Kising. The heads are fixed firmly in the acetabulum of both sides; action of leg satisfactory.

SCHUDE, of Hamburg, on the non-operative treatment of dislocation (congenital) of hip joint. Hoffa had not done well to doubt cures of this disease in the anatomic way (without an operation). Mikulicz already had proved him wrong on this point.

SOHR presented a patient treated after Taylor's method, only in the reverse sense, inasmuch as there is used no abduction, but adduction and extension. The apparatus is able to reduce the caput in the majority of the children, and the trochanter is retained in its place by transverse pressure.

V. BERGMANN recommends the fixation with the dressings of Herzig, by which he had seen perfect cure. The results

of operation were unfavorable in most cases, antiseptics being very difficult.

V. MURANUS, of Leipzig, has also seen very bad results of Hoffa's operations. As for abduction, the important point is the existence of caput and colles femoris. If the latter is wanting the results are bad, even when the cases are not operated.

V. BRAMANN, of Halle, has operated upon fourteen cases of grave character. One died of tuberculosis miliaris; the rest recovered. He had always good success in these operations up to children of 11 years of age. B.

(To be continued.)

Letter from Ex-President Hibberd—His Return Trip from San Francisco.

To the Editor:—On June 11 some of the members of the AMERICAN MEDICAL ASSOCIATION who had return tickets via the Northern Pacific deemed it prudent to accept the arrangement by which their tickets would be honored over the Southern Pacific to Ogden and the Union Pacific to Butte, and on June 12 a larger number availed themselves of the same privileges. This was done for the reason that they discredited the statement that the flood damage to the Northern Pacific would be repaired by the time they arrived at Portland. With more faith about fifty of us took the evening train on June 12 for Portland, which we found still largely under water, but by a long steamer ride down the Willamette and Columbia Rivers—or where the rivers ought to be for the whole country was covered with water—the boat ran into what was usually a creek, and winding among the trees about five or six miles we reached a railroad bridge across the stream, disembarked on the moist earth, climbed into the train, went to bed and woke up next morning in Tacoma with our car on a side track at the wharf, and a steamer alongside to take the party down Puget's Sound to Victoria in Her Majesty's dominion, to return to Tacoma next morning. Having some arrangements to make for Pullman accommodations, myself and ladies remained in Tacoma during the day.

Completing our arrangements in Tacoma we left for the East on a belated train at 3 o'clock on the morning of June 16, and arrived at Spokane the next morning to find the road still impassable between Spokane and Helena on both lines via Missoula and Butte, but the agents declaring they expected dispatches every hour notifying them of a restored road. We waited two days without apparent progress of repairs and then twenty-one of us accepted an order from the Northern Pacific on the Union Pacific, which by a round-a-bout line via Walla Walla, Umatilla on the Columbia River, and Pocatella, covering 1,200 miles, landed us at Butte, Mont., on the morning of June 20. Leaving Butte at 9:20 A.M., June 21, we arrived at Bozeman at 1 P.M., to find that our connecting train was ten hours behind time and might be more. An earnest petition by wire to headquarters at St. Paul to continue our train to Livingston met with prompt response, making our train special, not only to Livingston but to Cinnabar, fifty-one miles further, when we were met by coaches which delivered us at Mammoth Hot Springs Hotel in the Yellowstone Park at 9:30 the same evening.

The next morning we left for the tour of the Park and returned on June 26, to find all further progress arrested by the strike. Here we waited day after day. The hotel made us comfortable, but no mails and no newspapers, with wild rumors about every railroad in the United States being tied up, we felt the burden of imprisonment and isolation to an intense degree. On July 1, we organized the "Association of Distressed and Stranded Tourists" which embraced about 120 persons of both sexes, ladies predominating. The Association at once secured a limited report of the more impor-

tant strike items wired to us from the press dispatches delivered at Anaconda 200 miles west. It was at once learned that the Great Northern Railroad was open from Helena to St. Paul, and Chicago entirely cut off from railroad travel. Helena could be reached by 182 miles staging over the crest of the Rockies, but notwithstanding the severity of the ride and its expensesome of the imprisoned tourists began to leave, the first on July 2, the number increasing from day to day, and so far as advised, all reached St. Paul in from five to seven days. At Helena, through an arrangement between the Northern Pacific and Great Northern Railroad, the tickets on the Northern Pacific were honored on the Great Northern, and parties found no difficulty getting through either to St. Paul or Chicago.

The whole number imprisoned in the Park at first was about 170, all of whom ultimately reached the Mammoth Hot Springs Hotel, but many went to Livingston and then elsewhere as they could find conveyance. The largest number at the hotel at one time was 127.

On July 11 a mail came in, the first since June 26, and we received files of Helena and Anaconda papers to June 9, which gave us the first understandable account of the inauguration and progress of the strike. These papers with some belated letters were boons indeed.

After considerable telegraphing the railroad authorities on July 12 wired us that a train would be ready for us at Livingston to take us to St. Paul on the afternoon of July 13, but in consequence of washouts trains could not be sent to Cinnabar for an indefinite time, so we packed our trunks for a sixty mile stage ride.

Thirty-five of us left the hotel at 7 A.M. on July 13, arrived at Livingston at 10 P.M., the latter part of the road being very tedious, miles of it deep mud and water from a cloudburst the evening before. A merchant on an unpaved street told me the water in front of his place was three feet deep, coming on to his porch. This was the second cloudburst in three weeks.

We supposed from our telegrams the train would be waiting for us at Livingston, but on arrival were informed that it would not be in until the 14th some time.

A train came in from St. Paul on July 14 at 4 o'clock and left about 5. Before the train reached the station the soldiers formed in line on each side of the track, a man fully armed every fifteen feet, and remained on guard until the train left.

At 10 o'clock P.M. our train arrived from the west and the soldiers guarded it as they did the westbound. When the train went west two days before a striker crowded on to the guard line and refused to leave, using defiant and abusive language to the commanding officer, who then cut his head with a saber. Our train was guarded until it left at 1 A.M. on July 15.

This was the first we had witnessed of the actual use of soldiers. True, troops at the Hot Springs in the Park had received marching orders at 4 P.M. on July 7, and at 7 o'clock were in the saddle and off, the public knew not where, but we guessed, and have since learned they were guarding the Bozeman tunnel. Ours was the first train East since the strike, and was picking up delayed travelers wherever it found them. Next morning we found our train consisted of sixteen cars of all kinds and under guard of soldiers carried on board—as every train was—and every bridge, trestle and important culvert guarded by soldiers, and large bodies of troops concentrated at strategic points. The dining car with us had its hands full to feed the promiscuous company aboard, but it was the only resource.

At an early hour Monday morning, July 16, we passed Bismarck, and being out of Montana and out of danger, had left our military guard at Mandan.

From Bismarck our trip was uneventful, and we arrived at St. Paul at 1:30 o'clock on Tuesday morning, and as the railroad authorities offered tourists who wished to take the early trains East the privileges of their sleepers and accommodations for the night, our party with others accepted, and with an early start arrived in Chicago at 9:45 P.M., July 17 well and in good condition, and expect to reach home after an absence of fifty-two days.

We left about thirty tourists at the Mammoth Hot Springs Hotel in the Park; there were no physicians among them, but we found several at Livingston awaiting the first train. Dr. Montgomery took a census of our train and reported ten members of the AMERICAN MEDICAL ASSOCIATION on it with nine ladies, and four tourists, doctors, with thirty-four other gentlemen and ladies who had been prisoners in the Park with us.

J. F. HIBBERD, M.D.

Beaumont Medical College.

St. Louis, Mo., July 10, 1894.

To the Editor:—Dr. W. B. Outen, Dean, requests me to say "that some months ago there appeared what purported to be an unofficial announcement from St. Louis that the Beaumont Hospital Medical College was about to close its doors. Had this statement come to my knowledge before now, I should certainly have asked for its immediate correction, for it had no foundation in fact and must have been promulgated by some one who intended that the Beaumont Medical College should be injured by the publication. Far from closing its doors our school is in a most flourishing condition. We have been so fortunate as to have secured from those interested in higher medical education, such financial assistance as practically to place the school on a firm financial basis, and to insure its perpetuity. We have never been the competitors of those who heralded their schools and incidentally their personality to the medical public. We have gone along the even tenor of our way doing conscientious and, we believe, good work in the cause of medical education, and we feel aggrieved to think that your JOURNAL would publish, without proper inquiry, a statement which is calculated to do us an injury, and we respectfully request that you give to this denial as much prominence as was given the original statement."

REVOCATION OF LICENSE.

The Secretary of the State Board of Health, of Missouri, has been instructed at our last meeting at Kansas City, to furnish to your JOURNAL the proceedings, more especially that portion of them which relate to the revocation of the license to practice in our State, of Dr. J. P. Henderson, a resident of Chicago, who was an itinerant for the last six months in Missouri. Dr. Henderson was a regular graduate and a licentiate of the Illinois State Board of Health, and is President of the Illinois State Institute of Medicine and Surgery. He registered in this State upon a diploma and letters of recommendation from medical men of Chicago and then spread his advertisements broadcast. Physicians of Nevada, Vernon County, Missouri, called the attention of the Board to his advertisements which were so worded as to mislead the public. After a hearing, the Board unanimously decided to revoke his license for unprofessional conduct. Our State has too long been the refuge of just such fellows, and the Board proposes in future to enforce the law, and to protect our people.

(Signed)

F. J. LUTZ, M.D.,

President State Board of Health, of Missouri.

North Texas Medical Association.

SHERMAN, TEXAS, July 10, 1894.

To the Editor:—Having just received the last number of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, I notice in it an account of the meeting of the North Texas

Medical Association which was held in this city on June 19, 20, 21, which notice does the Association an injustice as the program which I enclose will prove. All the papers therein contained were read except those marked out, and a number of cases reported not on the program, all of which were discussed.

There were in fact more than one hundred members present, instead of seventy-five as stated.

This Association meets semi-annually. The next meeting will be held at Gainesville the second Tuesday in December.

Yours very truly, J. T. WILSON, M.D.

Sanitarium in New York.

To the Editor:—The Sanitarium concerning which your correspondent, N. H. P., makes inquiry in the JOURNAL of July 7, page 37, is probably that under the care of Dr. E. L. Trudeau, at Saranac Lake, New York.

A. H. E.

SOCIETY PROCEEDINGS.

Medical Society District of Columbia.

Report on Typhoid Fever.

[Continued from page 82.]

2. The relations of the mortality of typhoid fever and its distribution in different sections of the city to the pollution of the soil by the leakage from privies, and to the drinking of contaminated well water.

The truth of the theory may be considered as established that there is a relationship between pollution of the soil with human excrement and the drinking of well water contaminated with the poison of typhoid fever contained in this excrement. The converse of this has also been absolutely proved that typhoid fever can be diminished—almost eliminated—by a proper purification of the soil and the drinking of pure water. Facts will be alluded to further on, which will illustrate this point.

Out of a total of 1,174 squares in Washington and Georgetown, deaths from typhoid fever occurred in 426 squares, or one death in about two and two-third squares.

If the city is arbitrarily divided into four sections, Georgetown making the fifth, and the number of deaths from typhoid fever during the last five years be marked in the localities in which they occurred, it will be seen that there is a great difference in the distribution of mortality. In region 1 (all that part of the city south of East Capitol Street, and the public grounds, including the southeast and southwest parts of the city), there are a very large number of cases. In this area there were 197 fatal cases in 131 squares, and in region 2 (east of North Capitol Street and north of East Capitol Street) in 59 squares there were 84 deaths. In region 3, comprehending all that part west of North Capitol Street and east of Thirteenth Street and north of the public grounds, in 116 squares there were 179 cases. In region 4, west of Thirteenth Street to Georgetown and north of the river to Florida Avenue, in 82 squares there were 114 deaths. In Georgetown in 38 squares there were 52 fatal cases. Assuming that each death represents 10 cases of typhoid fever, in the five years there were about 6,260 cases in Washington, at the rate of over 1,200 cases a year. Of these there were nearly 400 cases a year in the southeast and southwest districts, 170 in the northeast, 360 in the middle region, 230 in the northwest, and 100 in Georgetown, 400 in hospitals and public institutions, and 190 in the county. If we add the cases occurring in hospitals and the county to those in the city proper we have a total of 9,220 cases in five years, an annual average of 1,444 cases.

The percentage of deaths from typhoid fever in each of these divisions to the contained population is:

| Region. | Population of region. Police census 1892. | Total deaths from typhoid fever in five years in each region. | Annual rate of mortality to 10,000 population in each region. |
|---------------------------|---|---|---|
| I. (South) | 62,218 | 197 | 1.3 |
| II. (N. East) | 26,278 | 84 | 6.2 |
| III. (Central) | 70,865 | 179 | 5.0 |
| IV. (N. west) | 49,969 | 114 | 4.6 |
| V. (Georgetown) | 16,344 | 52 | 6.3 |
| County | 30,429 | 95 | 6.2 |

The interesting fact is to be noted in this table that the annual rate of mortality of the whole District being 6.2, that of the northwest section is 4.6; central region, 5.0; south, east, Georgetown and the county having each the same average, practically as that of the total District average.

The close relation of a soil polluted by sewage to typhoid fever prevalence is admitted to be a causal relationship, and no argument need here be adduced to support a theory so universally adopted. In Washington and the District there are three modes of infection of the soil with human excreta and sewage:

1. The overflow and leakage from privies.
2. The leakage from defective drain pipes in the soil.
3. The backing up of sewage in the sewers draining the lower parts of the city, and the flooding of basements and cellars.

The existence of the privy method of disposing of human excreta in cities is sufficient evidence of a contaminated soil.

Map No. 4 shows the numerical distribution of the privies of Washington. There are in the city limits 8,959 box privies, 5,133 in the county, a total of 14,092.

| | |
|---|-------|
| In the 1st division (South) there are | 8,994 |
| In the 2d division (N. E.) there are | 941 |
| In the 3d division (Cent.) there are | 1,086 |
| In the 4th division (N. & W.) there are | 1,761 |
| In the 5th division (Geo.) there are | 1,177 |
| | 8,959 |

Squares 743 to 795 in the southeast region may be cited as an example of the relative distribution of privies and closets with sewer connections:

| | | |
|----------------------|------------|------------|
| Square 743 | 82 privies | 13 closets |
| Square 766 | 23 privies | 6 closets |
| Square 768 | 14 privies | 3 closets |
| Square 770 | 41 privies | 14 closets |
| Square 799 | 21 privies | 19 closets |
| Square 795 | 24 privies | 22 closets |
| | 289 | 855 |

In 14 squares in the northwest part of the city there were 153 privies and 297 closets.

1. The report of the inspector shows that for the nine years ending June 30, 1891, there were 42,197 full or overflow privies reported, 6,455 boxes with leakage, and 663 old and dilapidated boxes. In one year, 1892, there were 465 boxes noted with leakage. It is difficult to ascertain the extent to which the saturation of the soil takes place in this way, but the above facts demonstrate that the saturation with excrementitious matter is a necessary result of such conditions.

2. Every report of the engineer department of the District government contains a statement as to the relaying of pipe sewers. In the year 1892 there were 1,534 linear feet of sewer pipe which were taken up and relaid; 8,438 linear feet of obstructed sewers were replaced. "These sewers were faulty in gradient, alignment, and because of defective joints, allowing the intrusion of tree roots, and in quite a number of cases, they were of insufficient size. They were all laid under contracts made with the board of public works in 1871-'74."—(Report upon the sewerage of the District of Columbia, by Board of Sanitary Engineers, June, 1890.)

All the pipe sewers laid prior to 1874 require to be replaced by those of suitable construction, with joints protected by concrete. It need not be added that such defective sewerage conditions permit the saturation of the soil with fecal matter.

3. A third cause which prevents thorough drainage of the soil and adds to the dangers from saturation with sewage is found in the fact that from the foot of Capitol Hill westerly to the Potomac River there is a long, flat area only a few feet above high tide. To the north and east the ground rises; the soil of the lower area is moist, that of the elevated territory is composed of compact gravel, clay and loam, and is comparatively dry. "Owing to the absence of slope, and therefore of scouring velocities," in the sewers in the south and east, accumulations take place in the sewers, which are added to by the entrance of tide water. In the Tiber Creek sewer these deposits reached two to three feet in depth and several thousand feet in length, reaching nearly to the present District building. The daily effect of the entrance of the tidal current into the sewer is to prevent the complete emptying of the drains and in times of floods great quantities of noxious sewage is carried into cellars and basements.

The drinking of the infected water of wells has long been known to be a mode of propagation of typhoid fever.

If the soil of the city is receiving a considerable portion of the excreta of typhoid fever cases; if much of that soil is badly drained and wet with returned sewage, is it possible to avoid the danger of the fouling of well water?

In that low section of the city in which there is the most imperfect drainage, in which the soil is most contaminated by the defective sewerage, there are many thousand inhabitants with 3,994 privies, drinking the water from 140 wells.

In the southern region, with 197 fatal cases, there were 140 pumps, now reduced to 87; in the northeast 84 fatal cases and 47 pumps, now reduced to 29; in the middle area 179 deaths, 70 pumps, now 42; in the northwest, 114 deaths, 34 pumps, now 22. (The number of pumps here given is taken from a map published by District Commissioners in 1889, and list furnished May, 1894.) In Georgetown there were 52 deaths with 18 pumps, by May list, 19 by map. It can be assumed that where there are the largest number of pumps there is the largest consumption of well water; that well water is used most largely by the poor, and in those quarters of the city where the water and sewer connections are fewest; and that Potomac water is used chiefly where the water and sewer connections are most numerous.

We know that water from the 310 pumps existing at the report of 1889 was largely used by the people living on the 426 squares in which the 626 fatal cases occurred. The number of wells here given may not be strictly correct, as errors have been found in the map of 1889. It is, however, approximately correct.

Even by those having access to Potomac water, well water is largely consumed on account of its being colder during the hot months of the year.

The object of these considerations is to show that the soil underlying the city is being constantly impregnated with human excrementitious matter, and with all microorganisms therein contained, and that the water of wells liable to be contaminated with such material is being constantly and generally used as drinking water by the people.

It is not an assumption that the well water thus consumed is infected and dangerous to health. It is a matter of chemic and bacteriologic demonstration.

At the end of 1890 there were 271 public pumps in service; 17 of these were abandoned during the year as being no longer fit for use.

In the report of the Engineer of the District for 1889-90 it is stated that 75 per cent. of the water of wells examined was found to be suspicious; in the northwest 71 per cent. was bad or suspicious; in the southwest all examined were bad or suspicious; in the northeast two out of three; in the southeast 40 per cent. and in the county 70 per cent. The report adds that the only excuse "for keeping the wells open is the filthy condition of the aqueduct water and the high temperature which it reaches in the mains in summer, often 85 degrees, which is far from palatable to the poorer classes who are unable to purchase ice."

In the following year nine wells were filled and abandoned. In the year ending June, 1892, of fifty-seven wells examined, 24.6 per cent. were condemned or declared very suspicious; fourteen were filled or abandoned. The wells of the county were, as a rule, more contaminated than the city wells, a condition due to the fact that the soil of the city is better drained by sewerage than that of outlying districts.

The report for the year ending June 30, 1893, states that a larger number of wells were condemned than in the previous year, "owing to the large number examined from the low portion of the city in the southeast and southwest sections." Fourteen were found dangerous.

This is the very section of the city in which the number of fatal cases was so great in the five years.

In the recently published report of the examination of the water of the city wells by Drs. Theobald Smith and Mew, sixteen wells were reported as examined bacteriologically by Dr. Smith, and the conclusions reached were favorable to the general purity of the well water. Five wells only were found to contain fecal bacteria; the water of four was in good condition, and that of seven in need of improvement.

The suggestion is made by Dr. Smith that the wells upon which a favorable report is made should be retained, that others should be improved and that bacteriologic examinations should be made at least once a year to determine the fitness or unfitness of the water for drinking purposes. He also suggests that wells considered safe should be so labeled. But is not the fact that some wells at a particular date contain fecal bacteria a sufficient reason for condemning the whole system?

The following report of bacteriologic examinations of thirteen wells made for the committee by Dr. J. J. Kinyoun fortifies these views of the general unhealthfulness of the well waters:

| Sam- ple No. | Location of well. | Result of Examination. | Condition of water. | Recommendations. |
|-----------------|--|---|------------------------|--------------------------------------|
| 1 | East side 7th street between M and N streets N. W. | Sewage bacteria. Col- on bacillus isolated. | Bad. | Well should be closed. |
| 2 | L street between 6th and 7th N. W. | Sewage bacteria. Col- on bacillus isolated. | Bad. | Well should be closed. |
| 3 | East side 7th street between M and N streets N. W. | Sewage bacteria. Col- on bacillus isolated. | Bad. | Well should be closed. |
| 4 | 10th and S streets N. W. | Sewage bacteria. Fe- cal bacteria. Colon bacillus isolated. | Bad. | Well should be closed. |
| 5 | 16th and Corcoran streets N. W. | Ordinary forms usu- ally found in water. | Good. | Should be kept under observation. |
| 6 | 17th and K streets N. W. | Ordinary forms usu- ally found in water, but in considerable quantities. | Suspicious | Should be kept under observation. |
| 7 | 10th street be- tween B and C N. E. | Sewage bacteria. Col- on bacillus isolated. | Bad. | Should be closed. |
| 8 | 3d street and Ind- iana avenue N. W. | Sewage bacteria. | Bad. | Should be closed. |
| 9 | T and 18th streets N. W. | Ordinary water bac- teria, but in large numbers. | Suspicious | Should be kept under observation. |
| 10 | 23d and G streets N. W. | Sewage bacteria. | Bad. | Should be closed. |
| 11 | 18th and S streets N. W. | Sewage bacteria. In great numbers. | Bad. | Should be closed. |
| 12 | K street between 21st and 22d streets N. W. | Sewage bacteria. Col- on bacillus isolated. | Bad. | Should be closed. |
| 13 | 6th and H streets N. W. | Ordinary water bac- teria in small num- bers. | Good. | Should be kept under observation. |

As long as causes of soil pollution exist, is not one well as liable, or nearly as liable, to contamination as another? And the fact that one well contains no bacteria, another a few and another many, is no proof that all are not liable in different degrees to become at some time infected. To be under the necessity of labeling each particular well as healthy or unhealthy, after annual examination is an endless task and a most unscientific procedure, for how many individuals who wish to quench their thirst will be influenced by the published statement impugning the reputation of a particular well? Even if the individual knows that bacteria are found, he will drink and take the risk. As sanitarians, we must condemn the whole system, and advise an early abandonment of all wells as the only solution of the question. The advice contained in the report of the Sanitary League we believe to be mischievous, and to involve a continued menace to health.

It should be remembered that the water of the sixteen wells reported upon by Dr. Smith is of those which have been permitted to stay, and that over sixty have within the last five years been condemned and filled up. Dr. Kinyoun finds sewage and fecal bacteria in nine out of thirteen examined. For how long a time will these now reported upon as free from fecal bacteria remain so, with the continued presence of typhoid fever among us? Shall we wait for the infection to take place, or shall we remove the possibility of the dissemination of the disease in this way? These are questions to which we should give no uncertain answer.

The lesson of Vienna should teach us what this answer should be. From 1851 to 1874 well water of an impure character was used to a large extent. During this time the deaths from typhoid fever ranged from ten to thirty-four annually in every 10,000 of the population. In 1874 spring water of great purity was introduced, and the well water of impure wells was given up. The annual mortality rate immediately fell to 5.0, and in three subsequent years to 1.1. A good sewerage system was in existence long before this, but it had no effect in reducing the mortality.

One fact to which separate attention should be drawn is that many of our cases of typhoid fever are imported from without. At the end of the summer it is a frequent occurrence for the disease to develop in individuals who have just returned from seashore and other resorts, and a much larger number of our inhabitants go out of town now than formerly. This is one means by which our mortality is increased, and fresh infection is added to that already existing.

INFECTION THROUGH MILK.

The dissemination of typhoid fever by the milk supply in the District has not been investigated fully enough to warrant any extended remarks or conclusions. It would be well to make this a separate matter of study. It is safe to assume from the experience of many observers elsewhere that typhoid fever is to a certain extent propagated by milk; there is nothing in the condition of the dairies from which our supply is drawn to make us think that we are better protected from this danger than other communities where epidemics have been traced to milk infection.

There are sixty-five distinct places in the District where cows are kept and from which milk is supplied.

It has been shown that in Washington there is a coincidence between a soil polluted with the leakage of the excreta from typhoid fever patients, the drinking of infected well water and an extensive distribution of typhoid fever; that where these two first conditions exist to the greatest degree typhoid fever is most prevalent. It remains to be seen whether the purification of the soil, and the abolition of the water supply from pumps, would lessen the disease.

The belief that typhoid fever spreads by "soil contamination" would be much strengthened if other cities with the same conditions have diminished the percentage of the disease by draining the soil and abandoning the use of well water.

Typhoid fever increases in proportion to the saturation of the soil with decomposing organic matter, especially human excreta.

Typhoid fever decreases in proportion as a city is well sewered.

The greatest diminution in typhoid fever has taken place in England and Germany, where expert engineers and liberal municipal governments have combined in the work of sewerage in the principal cities. In the cities of Spain, Italy, Russia and Mexico, where the sewerage systems are less complete, the diminution has not taken place.

The history of Munich offers the strongest evidence on this point.

From 1854 to 1859, when no means existed to prevent the fouling of the soil, the mortality was 24 to 10,000 inhabitants.

From 1860 to 1865 the sides and bottoms of the pits of the privies were cemented, and the mortality fell to 16.80.

From 1866 to 1873, with partial sewerage, it was 13.30; from 1874 to 1880, with improved sewerage, it was 9.26, and from 1881 to 1884, with still greater improvements it fell to 1.75 to 10,000 inhabitants.

The experience of Berlin is very instructive to Washington, as showing the difference in mortality in houses with sewer connections and in houses without them where privies were used.

1. In houses with sewer connections there were 15.5 cases and 4.5 deaths to 10,000 population.

2. In houses without sewer connections there were 56.0 cases and 17.9 deaths.

1. In the sewered houses there was 1 case to each 49.3 houses and 1 death to 137.5 houses.

2. In non-sewered houses there was 1 case to each 9.3 houses and one death to 43 houses.

(To be continued.)

SOCIETY NEWS.

West Baden Medical Society.—The annual meeting of Mitchell District Medical Society will be held at West Baden, Ind., July 26 and 27, 1894. Season tickets on sale at all principal railroad offices. Programs will be issued in a few days.
G. W. BURTON, Secretary.

Colorado State Medical Society.—Prize Essays.—Prize of \$100 voted by the Colorado State Medical Society, June 21, 1894, for the best essay on the following subject: "The Diagnosis of Tuberculosis by Microscopic Examination of the Blood."

Preference to be given to new evidence and the detection of the pre-tubercular stage. All stages, however, to be included and microscopically differentiated. Paper to be condensed to read in thirty minutes time; to be typewritten and the authorship kept secret till the award of the examining committee is made known. Prize open to any one; essay to be written in the English language in comprehen-

sive style and as free from purely technical expressions as possible; accuracy of definition and clearness of diction considered. The committee to reserve the award for an essay they deem sufficiently meritorious, *i. e.*, the rules to be observed enabling a diagnosis to be made from the blood alone without the patient being seen. A prize committee of three was appointed: Dr. Charles Denison, H. A. Lemen, both of Denver, and Dr. S. E. Solly, of Colorado Springs.

All essays to be handed in by April 1, 1895; under seal.

The following test is suggested as not unreasonable: Seven persons being in one room representing a person in health, a case of anemia, one of leucocythemia, one pretubercular, and three representing the three stages of consumption, *i. e.*, 1, infiltration; 2, softening and; 3, excavation (advanced and extensive). In another room the microscopic examination of the blood of several of these to determine from whom the specimens were taken. It is expected that the ordinary use of the 1-6, 1-10, 1-12 or 1-16 immersion lenses will answer. If not or there is any doubt, full explanations as to instruments or lenses used should be furnished.

BOOK NOTICES.

A Clinical Manual. A Guide to the Practical Examination of the Excretions, Secretions and the Blood, for the Use of Physicians and Students. By ANDREW MACFARLANE A.B., M.D. New York and London: G. P. Putnam & Sons. 1894. Pp. 134.

This little book is greatly to be commended, for it brings within the reach of all, the practical application of the recent great advances in physiologic chemistry and bacteriology. As a volume to depend upon in the office in examining excretions for diagnostic purposes, it will be found very useful.

PUBLIC HEALTH.

Milk for the Poor.—Six milk depots for sterilized milk have been established by the Nathan Straus Charity in the tenement house centers of New York city. The milk is sterilized under the supervision of a competent bacteriologist who examines the supply at stated intervals, and the cows which furnish it are inspected for tuberculosis and other diseases. Raw milk is sold at 4 cents a quart, 2 cents a pint, 1 cent a glass; pure milk sterilized (four 8-ounce bottles) 5 cents a quart; diluted sterilized milk in 6-ounce bottles at one cent a bottle.

Diphtheria in London in 1893.—The Registrar General's summary of mortality in London for 1893 shows a net loss of 3,989 lives during the year. That is to say, if the death rate in 1893 had not exceeded the average rate of the preceding ten years there would have been 3,989 fewer deaths registered in London for 1893 than there actually were. Among the causes of death contributing to this excess were preëminently diphtheria, cancer, premature births and diseases of the nervous system. The excess of deaths from diphtheria was 1,985, the total deaths from the disease being 3,265. This is the most disturbing factor of the death rate, amounting to 0.76 per 1,000—by far the highest yet recorded and exceeding the average of the previous decennium by 0.46 per 1,000.

"Naturforscher."—American physicians and sanitarians attending the International Congress of Hygiene at Budapest next September, will have an opportunity also of witnessing the "Naturforscher"—a gathering of scientists peculiar to Germany. Its sixty-sixth meeting takes place at Vienna, September 24-30, and the Austrian Parliament has voted \$5,000 for its objects, which include investigations in astronomy, mathematics, geography, medicine, hygiene, etc.

There will be thirty sections, dermatology and syphilis being added as a separate section this year. Comprehensive preparations are being made and all the resources of the Imperial University will be utilized for the success of the meeting.

Anti-Cholera Inoculation.—During the past fifteen months Dr. Haffkine has inoculated over 25,000 persons with the so-called anti-cholera "vaccine," in Northern India. From such reports as have been made public it would appear that the protection afforded is perfect; many instances are cited where cholera has broken out in places after the inoculations had been performed, with the uniform result, so far as made public, that those who had been inoculated escaped, while numbers of those who had refused or neglected the protection were attacked with the disease and died in the usual proportion. It is stated that M. Haffkine will continue his work in India for another year.

Resuscitation from Asphyxia.—While the drowning season is "on" it may be useful to familiarize one's self with Dr. Laborde's method of restoring the respiratory reflex. It is so simple—using an ordinary tongue forceps, such as is on hand during chloroform or ether inhalation, the tongue is well pulled forwards and regular rhythmical movements are given to it—that it is proposed to issue some plain directions that can be posted in every hospital and be in the hands of every midwife, or any one who may be liable to see asphyxia, such as those who give anesthetics and those called to cases of drowning, etc. It has been tried a great deal in France in the last two years in all sorts of cases of asphyxia, by drowning, electric shock, lightning stroke, and in the cases of apparent death in the newly-born. Some sixty-three cases are given where patients were recalled to life by this method.

Our Diminishing Birth Rate.—There is apparent an increasing tendency to the belief that there are too many people in the world and that thereby the struggle for existence is made harder. Those holding this belief and in whom the logical faculty is strongly developed, naturally decry all sanitary effort on the ground that its success renders more easy the survival of the unfit, who thus live to become not only competitors of, but burdens upon *nous autres*. Without going to this extreme the editor of the *Medical Standard* evidently believes in the general proposition and thinks that the decrease of the birth rate of the United States is a matter for congratulation rather than pessimistic prophecy. "With a rise in the scale of evolution in animals comes a decrease in births and an increase in the period between them. The resulting animal receiving maternal care longer, from a better nourished ancestor, is better qualified to survive the 'struggle for existence.' Not only is the birth rate decreasing in the United States, but the period of pregnancy is most probably increasing, the age of puberty growing later, as also is the age of marriage. All these factors tend to decrease the birth rate, fortunately for the race."

Smallpox in Massachusetts.—The *Boston Medical and Surgical Journal* (July 12, inst.) takes the opportunity of the recent smallpox epidemic being practically at an end to review the situation as presented by the experience of recent years. As compared with the epidemic of 1872-73, and the still greater prevalence in pre-vaccination times the recent outbreak is scarcely worthy of mention; but the collection of more careful records during the past ten years furnishes data for conclusions as to the effect of better methods of control. During the forty years ended with 1893, there were 4,720 deaths from smallpox in Massachusetts, of which 4,412—or at the rate of 170 per million annually

—occurred during the first twenty years (1854-73); and 308 — or 8 per million annually—occurred in the second twenty years (1874-93); during the decade ending with 1893 the smallpox deaths were at the rate of 2 per million annually. By carefully compiled tables of smallpox in the State from 1885 up to and including the first six months of 1894, it appears that the mortality from smallpox among the unvaccinated was 27.8 per cent. as compared with only 4.3 per cent. among the vaccinated—the former being more than six times as great as the latter.

Diet of the National Guard.—The large total of "effectives for duty" and the light sick-list speak well for the medical service of the National Guard in the various States where they have been called out for active duty. This duty will probably largely take the place of the usual summer encampment—an occasion which is generally more or less trying to the medical officer in the supervision of the hygiene and more especially of the diet of his command. Assistant Surgeon Galloupe, of the Massachusetts Light Artillery, furnishes (*The Medical Age*, June 25, inst.,) a timely article on this subject, in which he says: "An experience of six years has shown me that within forty-eight hours of their proud entry upon the field, 5 to 10 per cent. of the men are *hors du combat*, and the enemy that has accomplished this decimation is acute indigestion." Based upon this experience he offers the following suggestions: Sickness in summer camps is due principally to injudicious diet; this could be remedied in great measure by a medical inspection of food: Permanent kitchens would secure better cooking: Issuance of cooked rations by the State would render efficient inspection possible: The duty of such inspection would be a practical training for medical officers: The fixed army ration is not applicable to volunteer troops, and never desirable if better rations can be obtained: State catering would reduce the cost to companies 50 per cent.

Vaccination and Re-vaccination.—During the lull in the smallpox incidence, due to the warm weather and consequent aerial disinfection, it is worth while to add to the arguments for vaccination and re-vaccination. It is by no means certain that there will not be a recurrence of the disease during the fall and winter, and in any event the "anti" we shall always have with us. To the mass of facts and figures furnished by Dr. Quine¹ should be added these from a memorial of Dr. Goldschmidt, of Strasburg:

"Germany is the sole country where compulsory vaccination and re-vaccination have been practiced since 1875, and a glance at the following figures show the striking result of this practice as a means of effectually exterminating smallpox:

"Annual average of deaths from smallpox among 100,000 inhabitants, in Prussia, 1860-69, before the compulsory law, 33.84; between 1875-84, after vaccination and re-vaccination (compulsory) 2.23."

In Berlin, Dresden, Breslau and Bavaria, under compulsory vaccination the smallpox deaths per 100,000 (1875-84) have been 1.68, 1.48, 1.61 and 1.11 respectively; in the following cities where vaccination is voluntary, the deaths per 100,000 during the same period were: Paris, 28.95; Vienna, 84.37, and in London, where one vaccination only is compulsory, the deaths were 25.50 in the 100,000 inhabitants. As to re-vaccination, it has been shown that the proportion of successful operations increases with the age of the subject. Thus the percentage of success in those vaccinated between 6 and 7 years of age, was 32.60; 7 to 8 years, 64.00; 8 to 9 years, 72.52; 9 to 10 years, 79.63; 10 to 11 years, 85.94; 11 to 12 years, 88.64, and adults, 90.00. These facts, and others like them which are accumulating constantly, prove the absolute necessity of re-vaccination, since they show that, in 85 to 90 times

in the 100, the immunity against smallpox conferred by the first vaccination has disappeared in twenty years; they also demonstrate in a most striking manner how certain as measures of public defense against the spread of smallpox are compulsory vaccination and re-vaccination. Health authorities should remit nothing of their recent energy in pushing these measures.

Ne Sutor Ultra Crepidam.—Arthur James Balfour, the eminent English statesman, has been advising the British public to "stick to its last"—to mind its own business and refrain from meddling and muddling in matters of science, and especially in matters of medicine. At a recent meeting of the British Economic Association he told his hearers that he thought the public had never yet mixed themselves up in scientific investigations without spoiling the investigations and doing themselves a great deal of harm. "Take medicine, for instance—if it is not flattering to call it a science; at all events those who pursue it do their best on scientific principles. Directly the public mixed themselves up in it there was a party feeling—which is essential in all public action—that had the most paradoxical, and in many cases the most disastrous results." He would, for a moment, consider the question of vaccination. He was not a doctor and had never studied the medical theory to pronounce upon the subject as an expert. Therefore he looked with a sort of remote interest at the quarrel between the doctors on the one side who had, or thought they had, settled the matter in a scientific spirit, and that section of the public who had never studied the question in a scientific spirit, but who were determined that their feelings should override science. He did not say who was right or who was wrong. Science had been before proved in the wrong and popular feeling, even uneducated popular feeling, had in many cases been proved right. But there could be no doubt that if they were going to allow questions of scientific interest to be decided by universal suffrage, they would not do much good to universal suffrage and they would absolutely ruin science. If science was wrong it could only be got right and placed in the direction of truth by being allowed free play outside altogether of influence of popular forces. The idea that any large body of the public has any opinion worth having on difficult economic or scientific subjects appeared to him to be absurd.

Cholera and Plague.—Baltic sea commerce is seriously threatened by the western extension of the cholera from Russia. The disease has invaded Finland by the northern route, and while the western movement from Poland seems to have been checked, there has been an increase of cases in Poland itself. In St. Petersburg it is reported as assuming alarming proportions; the present visitation is said to be of "a more intense and more fatal character than were the outbreaks of the two previous years." Unusual sanitary precautions are being taken to check the further spread of the disease, and it is announced that the Russian Imperial Sanitary Commission will henceforth continue in permanent session. Public prayers have been offered up in the cathedral at St. Petersburg, by the Metropolitan, that the scourge be stayed. Elsewhere in Europe the disease is disappearing or is well under control, except in Belgium where there still seems to be some spread; but the authorities are on the alert and no alarm is felt as yet. It has again broken out in Mecca and still prevails in many places in Asia Minor. As against Mecca the Sanitary Council at Tangier has taken measures to prevent returning pilgrims from landing at any of the ports of Morocco before they have been subjected to quarantine restrictions on the Island of Mogodor; and, since the death of a traveler from Sivas, in Asia Minor, after his arrival in Constantinople, all persons coming to Constanti-

¹ Vaccination. The Address on State Medicine. By Wm. E. Quine, M.D. JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, June 23, 1894.

nople from the Turkish coast of the Black Sea must now submit to medical examination at Sinope, and also at the entrance of the Bosphorus. Recent advices, received July 14, by the Northern Pacific steamship *Victoria*, from Hong Kong, say that cholera is spreading throughout the Chinese Empire and that the Government officials are suppressing the number of deaths. In Canton alone, Chinamen say that 40,000 deaths have occurred.

A cable from Berlin, July 17, reports an outbreak of the disease in Dantzic, an important Prussian seaport near the mouth of the Vistula, and at other places in West Prussia. A death from cholera is also reported, under the same date, at Kelder, in North Holland.

As a result of the policy of suppression of information and secretion of patients in Canton and Hong Kong the plague is appearing in all the neighboring country places and its appearance at the great shipping port of Shanghai is hourly expected. It is reported that it was by a mere accident that the European authorities first learned of the disease in Hong Kong as the natives carefully concealed the spread of the contagion. One Lau Wai Chuen, a member of the Sanitary Board, proved to be hard-headed. He insisted upon having patients sent from the great native hospital of Jung Wah to the European Hygeia, and then, after examination, to the hulks in the harbor. This was done for a few days. Then the feeling among the Chinese became so bitter that the procedure had to be abandoned. Native members of the Sanitary Board stimulated hostility to European methods and the reports read like those of the anti-vaccination and anti-inspection riots in a civilized American city. When the physicians began house-to-house inspection for patients suffering from the plague there was a tremendous clamor. Placards were posted warning people not to permit the "foreign devils" to enter their homes and declaring that many who were removed were not suffering from the dread disease. These placards and rumors created such an outburst of fanaticism that the doctors were forced to give up the house-to-house inspection for two days. Before they relinquished it, however, they were actually stoned by crowds which followed them in the streets. The police detailed armed Sikhs to accompany the doctors, but this was found to promote danger of an insurrection, and it was finally decided to yield to native clamor. After two days the inspection was resumed, the native Governor having issued a proclamation warning every one from interfering with the doctors. How necessary the inspection was is shown by the fact that no fewer than five dead bodies were found in a single house, with four patients far gone with the disease. The house was reported by the Chinese to be empty, but had been employed by the Chinese to secrete patients. A disease resembling the bubonic plague is reported to have broken out in many Russian provinces and cases are said to have occurred at St. Petersburg, Moscow and elsewhere.

MISCELLANY.

The St. Louis Clinique has passed into the hands of Dr. Emory Lanphear, Professor of Surgery in the College of Physicians and Surgeons. Dr. Lanphear will conduct the journal in the interests of that school, and of the medical profession of the West.

Medical Registration in Massachusetts.—Adverse criticism of the new Massachusetts registration law continues to increase and it is said that there seems to be good reason to doubt whether it "will stand the test of the courts if it is ever brought there. Blunders have been discovered in its phraseology and amendments made in one branch of the Legislature were left out in the other."

No Fee-Bill in Kansas.—Lest physicians should form a trust or combination to the detriment of their patients' pockets the adoption or use of physicians' fee-bills in Kansas is void and unlawful. A physician in that State bringing suit to collect pay for services, basing his rate of charges upon any such fee-bill or agreement, loses the entire account and the legal costs in the case and, if prosecuted in turn, is liable to fine of from \$100 to \$1,000, or one to six months

imprisonment, or both fine and imprisonment. The contention of the law is that such fee-bills prevent that free and fair competition in all trades, professions and callings which is for the best interest of society.

Spanish Smugglers Seized.—One of the most dangerous sources of the introduction of yellow fever along our South Atlantic and Gulf coasts is the smuggler. Lieut. Willey in command of the revenue cutter *McLane*, has made a report to the Treasury Department from Tampa Fla., stating that he had seized six Spanish schooners from Havana for violations of the State quarantine laws and regulations and the federal customs and navigation laws. For some years past fishing schooners from Havana have been suspected of carrying on smuggling operations along the Florida coast on a small scale and the *McLane* was sent to investigate. This vigorous action was found essential to the efficiency of quarantine along these coasts. Previous raids in former years have had the same result.

Physicians in the French Parliament.—The physicians of the French Parliament held a caucus June 21 at the Palais Bourbon, and decided to form an extra-Parliamentary committee to investigate the numerous pending questions which relate to the medical profession, the organization of relief to the poor, and the protection of the public health. The following were selected as officers of the committee: Honorary President, M. Berthelot, (senator); President, M. L. Labbe, (senator); Vice President, M. M. Cornil, (senator), and Lannelongue, (deputy); Secretary, M. M. Dellestable, (senator), and Pedebidou, (deputy); Treasurer M. Guenau (deputy).

There were present at the meeting, according to the *Journal de Médecine* of July 1, twelve Senators, and twenty-two Deputies. Among them were many well-known names.

The course of medical legislation in France should run smoothly when the profession is so ably represented in the legislative body.

The Necropsy of M. Carnot.—We publish a minute of the testimony of the autopsy of M. Carnot, President of the French Republic, assassinated at Lyon, June 24: The undersigned doctors have proceeded to-day to the autopsy of the President; they have found the following lesions: The wound was seated immediately under the depression of the right side, three centimeters below the xiphoid appendix, it measured from twenty to twenty-five millimeters, and the blade had completely divided the corresponding costal cartilage. The blade of the poniard had penetrated the left lobe of the liver about five or six millimeters. About the suspensory ligaments it had perforated the organ from left to right, and from above, downward, wounding in its passage the vena porta which was opened in two places. The length of the wound in the interior of the liver is eleven to twelve centimeters; a fatal intra-peritoneal hemorrhage was the result of this double perforation.

DRS. LACASSAGNE, HENRI CONTAGUE, OLLIER, REBATEL PONCET, MICHEL, GANGOLPIE, FABRE.—Lyon, June 25, 1894. *Journal De Médecine De Paris*, July 1, 1894.

Dr. T. S. Robertson Scores Mr. Croker's Health Officer.—(Special to the *Chicago Tribune*).—Health Officer Jenkins, upon hearing that Dr. T. S. Robertson had publicly stated that he had treated Eugene V. Debs for dipsomania, took the doctor to task for a violation of the ethics of the medical profession.

"If Dr. Robertson," said he, "has been rightly quoted he has been guilty of a gross and unpardonable breach of professional confidence in giving out to the public a statement in regard to Mr. Debs' physical ailments based on knowledge gained in the course of professional treatment."

As soon as this came to the eye of Dr. Robertson he sent this telegram to Health Officer Jenkins:

"Dr. W. T. Jenkins, Health Officer, Quarantine: Your impudence in speaking for my profession, which never rec-

ognizes you, and your ingratitude after I tried to have the Senate confirm you last winter, show that I little understood the man. The whole press will not forget how you treated them. I am willing to be criticised by any educated man, but not by a man not intelligent enough to be my valet. Now try again.
T. S. ROBERTSON."

Dr. Robertson explains that his door man gave the information out thoughtlessly to a reporter and permitted the copying of the message that was sent to Debs.

Medical College Notes.

MISSOURI MEDICAL COLLEGES.—At the recent annual meeting of the Howard Medical Alumni Association, Chancellor W. S. Chaplin of the Washington University at St. Louis, indulged in some comments on St. Louis culture and on medical education in Missouri which have aroused the ire of the St. Louis daily press. Commenting upon this indignation the St. Louis *Medical Review* says:

"We have more medical schools in St. Louis than either France or Italy, and at a time when the great center of medical learning in Joplin was still flourishing, the State of Missouri had the proud distinction of closely approaching the number of medical schools in Germany. Since the enterprising doctors of that mining camp closed the door of its college in consequence of an inexplicable want of appreciation on the part of medical students, our Missouri schools have fallen to the discouraging number of seventeen."

Touching this multiplicity of medical colleges in Missouri and its effect upon medical education the *Review* does "not believe that there is one professor of medicine in this city to-day who is not convinced that there are too many medical colleges and that it would be a blessing if a speedy death would remove them with the exception of one or two—provided, of course, that his college was included in the surviving number." The *Review* thinks that after Chancellor Chaplin has lived in St. Louis "a little while longer he will probably recognize the *raison d'être* of this multitude of medical colleges. We are sorry to say that we feel in duty bound to increase his chagrin over existing conditions, and to impart to him the glad news that at no distant day the dozen of medical colleges will be full. We hear that a number of enterprising young doctors and some dissatisfied older ones, backed by knowledge and capital, are about to start a new college which for facilities of graduation will throw all the rest in the shade."

By the way, Dr. Lutz, whose communication concerning one of the St. Louis colleges appears elsewhere in this issue of the *JOURNAL*, is one of the editors of the *Medical Review*.

UNIVERSITY OF NASHVILLE AND VANDERBILT.—The death of Dr. W. T. Briggs and the resignation of Dr. Menees on account of illness, have led to several changes in the faculty of the Medical Departments of the University of Nashville and of Vanderbilt University. Dr. Charles S. Briggs succeeds his father in the chair of surgery; Dr. S. S. Crockett succeeds Dr. Menees in the chair of anatomy; the following named gentlemen have been transferred or appointed to the chairs specified: Dr. Ambrose Morrison, physiology; Dr. J. H. Callender, diseases of the brain and nervous system and forensic medicine; and these as demonstrators and lecturers: Dr. S. S. Briggs, anatomy; Dr. Larkin Smith, histology and microscopy; Dr. E. A. Riddiman, chemistry and pharmacology; Dr. Owen H. Wilson, operative surgery and gynecology; Dr. J. W. Waters, physiology; Dr. John M. Bass, prosector of anatomy. Hygiene has been added to the chair of principles of medicine and pathology.

Hospital Notes.

INCORPORATED.—Mercy Hospital, Des Moines, Iowa, has become an incorporated institution.

FINLAY HOSPITAL, Dubuque, Iowa, has been thoroughly repaired and reconstructed.

DEACONESSES' HOSPITAL.—A meeting in the Second Reformed Church, Cleveland, Ohio, was held recently by the Deaconesses' Society of the Reformed Church of Cleveland.

It was decided to build a new hospital, to be known as the German Hospital and Polyclinic. The building will be located near the West Side Circle, and as soon as completed the temporary hospital on Scranton Avenue will be abandoned.

STILLWATER, MINN., CITY HOSPITAL.—The annual report of the city hospital board of Stillwater, Minn., shows the receipts the past year to be \$5,227.73, of which \$1,783.60 was paid by the county for the care of county patients, \$1,037.60 was paid by private patients, \$1,363 was from the sale of tickets and the rest was made in smaller sums, by giving entertainments, dinners, etc. The disbursements figure up \$5,135.75, of which the principal item was for help—\$1,576.38; the other items being fuel, groceries, etc. The cash balance on hand is \$90.98. The number of patients cared for during the year was 131, of which 103 were males and 28 females. There were fourteen deaths and three births.

FLOATING HOSPITAL ST. JOHN'S GUILD.—The Floating Hospital, gayly decked in flags and bunting and loaded with over one thousand women and children, was towed down the Hudson River yesterday morning on her first voyage of the season. The Floating Hospital is the property of St. John's Guild, and all last summer she made trips down the Bay to give the poor little ones of the city some sea air, a bath in salt water, two square meals and a good time generally. The boat went down the Bay to New-Dorp, S. I., left a few of the children at the hospital and then cruised around the Bay, returning to the city at 5 o'clock.—*New York Tribune*.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from July 7, 1894, to July 13, 1894.

Major EGON A. KOERPER, Surgeon, granted leave of absence for one month, on surgeon's certificate of disability.
Capt. PAUL CLENDENIN, leave of absence granted for seven days, is extended twenty-three days.
Capt. JAMES D. GLENNAN, Asst. Surgeon, now on leave of absence, will report without delay to the commanding General, Department of the Missouri, for temporary duty.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending July 14, 1894.

Asst. Surgeon AMMEN FAENHOET, ordered to Naval Laboratory and Department of Instruction, New York.
CHARLES F. KINDELBERGER, appointed an Asst. Surgeon in the U. S. Navy.

THE STRUCTURE OF BLOOD AND ITS RELATION TO PRACTICAL MEDICINE.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. H. WYTHE, M.D., LL.D.

PROFESSOR OF HISTOLOGY AND MICROSCOPY, COOPER MEDICAL COLLEGE, SAN FRANCISCO.

Physicians have always realized the importance of the study of blood. The ancient Hebrews regarded it as the life of the body, or the meeting point of body and soul. The humoral pathology, first elaborated by Hippocrates, and which was the prevailing doctrine of all medical theorists for hundreds of years, gave great importance to the evacuation of the blood by the lancet, the scarificator, and the cupping glasses. So universal was this practice, that it attracted the censure and witticism of the literary world, culminating in the immortal "Doctor Sangrado" of Le Sage. Many who are still living can remember the careful directions given respecting blood-letting—how it should be drawn by a full stream into a warm deep basin, so that it may be set aside to coagulate gradually. Then the appearance of the clot, and of the buffy coat, had much to do with the judgment of the physician. A soft and uniform clot indicates deficiency of fibrin, as in typhoid fever, etc. A uniformly great contraction shows a predominance of fibrin over red corpuscles, as in chlorosis. Blood highly buffed and cupped occurs in acute rheumatism and other severe inflammations. These, and similiar aphorisms, were based upon observation of the general structure of the blood as seen by the naked eye. May it not be that the modern practitioner has gone too far in the opposite extreme?

With the invention of the microscope, the study of the blood has been greatly promoted. No part of the animal organism has been more frequently examined, and yet its true structure is but partially known. It may be said of the blood more than of any other histologic structure that there is no end to investigation and research. It has been examined under a variety of physiologic and pathologic circumstances and exposed to different physical and chemic conditions. It has been boiled and roasted and fried, and cooked in all sorts of menstria, in the hope of torturing nature to reveal her secrets, and it has also been treated kindly and delicately with the same hope. Under such circumstances, the opinions of observers have naturally been different, and sometimes contradictory. Many of these discrepancies were due to the imperfection of early microscopes, and the almost universal habit of using too low magnifying powers. The optical improvements of the past few years have doubled our ability to penetrate the arcana of nature. The numerical aperture, or

standard measure of excellence, of the best objectives of eight or ten years ago was but .75 or .80 per cent., compared with 1.33, or 1.50 of our present lenses, or as a circle of three-fourths of an inch diameter compares with one of an inch and a half. With such improved power of research, nothing but lack of industry or care can prevent more accurate knowledge of minute structures. The delicacy of adjustment in our best objectives has also rendered more perfect mechanical appliances and optical accessories a real necessity. In addition to the widest possible numerical aperture in the objectives, the microscope of the future will have a wide-angled achromatic condenser with coarse and fine adjustments equal to those required for the objective itself, and with an iris-diaphragm for regulating the illuminating cone of light. No really critical work can be done without such provision. The images given with high powers and such appliances are so different from those of low powers in inferior instruments as hardly to be recognized as the same structures. It is certainly quite reckless to give testimony affecting human life based on observations made with inferior means.

The brilliant discoveries in bacteriology during the last few years seem to have eclipsed all purely histologic investigation, yet within a recent period microscopic examination of blood is assuming the importance which it deserves, and although it remains to a large extent an unexplored territory enough is known to justify its careful study by the practical physician as a guide both to diagnosis and treatment. To the young graduate, desirous of distinction, no more inviting field is open in all the realm of medical science. To tabulate the microscopic analyses of blood in different ages and diseases, with a comparison of clinical symptoms, will require years of labor, but will be a priceless boon to the medical profession.

When we speak or read of blood, it is natural to think of it as the red stream which courses through the arteries and veins, yet in strict propriety the fluid plasma, continuous with the lymph which bathes every tissue and organ of the body, is the real blood, conveying life to every cell and fiber, while the white and red corpuscles are incidental accompaniments, conveyed by the fluid blood for special purposes. Much has yet to be learned respecting the chemical and vital properties of the plasma, yet there can be little doubt that much of the immunity against zymotic diseases is due to these properties. Dr. Prudden has shown that serum and non-inflammatory exudations in the living human being possess a marked germicidal power, and this has been confirmed by several European observers.

This serum is not only a solvent for bacteria, but for other structures. In August, 1891, I published in the *Pacific Medical Journal* some observations of

the blood in a case of lymphadenoma, in which the red corpuscles were seen to dissolve in their own plasma, but after a month's treatment with iodid of iron and manganese, the corpuscles resisted dissolution. Sterling tells us in his "Histology" that the red corpuscles of a rabbit or guinea-pig are completely dissolved in a few minutes in the blood serum of a dog. The corpuscles of a frog or pigeon dissolve more slowly and their nuclei remain. The dog's serum loses this power after being heated to 50 or 60 degrees for half an hour.

In pathologic conditions, as relapsing fever, anthrax, tuberculosis, etc., the serum loses its germicide power, and bacilli may be found with the microscope, with or without staining.

Changes in the specific gravity may be found by using a single drop of blood in a mixture of chloroform and benzole. When it is just suspended in the fluid, the specific gravity of the latter is taken in the usual way and is the same as that of the blood. The specific gravity of blood varies with the proportion of hemoglobin in the red blood discs, so that this simple mode may be used in anemia, and so forth, instead of resorting to costly apparatus.

Changes in the acidity or alkalinescence of the blood occur in various diseases, and the time of coagulation also varies. The solution of ptomaines resulting from decomposing bacteria is doubtless irritant or poisonous to the tissues, but the leucomaines which are formed by decomposing detritus, of the blood corpuscles or other albuminoid substances, unless eliminated by excretion, will lead to auto-infection, or an alteration of structure or function by a blood poison originating in the body itself.

Dr. Prudden well expresses the significance of the germicide power of serum in the living human being by saying that it consists chiefly in recalling "the attention of therapeutic adventurers from germicidal warfare to what appears to be a natural defense of the organism against bacterial invaders, namely, a healthy condition of the blood."

"Proud of our already long list of well-defined bacterial species; consciously masters of the morphology of many forms of bacterial disease; well on the way to an intelligent and efficient prophylaxis, and glorying in the possession of ptomaines so definite as to enter at our will into the composition of tangible and even formulatable metallic salts, it is a little humiliating, though doubtless salutary, to find ourselves face to face with a series of phenomena, which seem to lie at the very basis of the knowledge of the acute infectious diseases, and yet be able to say only that they are the result of the vital forces, vitality, life. It is fortunate that we have these words and phrases, however, which conceal so much and express so little, since, under their cover, we may take breath for the assault on another of Nature's tantalizing and well-fortified secrets."—*Microscopical Bulletin*, February, 1890.

The white corpuscles are found in lymph as well as in red blood. They are merely embryonic or detached particles of living matter of different sizes. With the best homogeneous immersion objectives, they appear as spherical or ovoid, but are often quite irregular in shape, and made up of a convoluted or sponge-like reticulum. They may have one or more nuclei which consists of a denser or finer network than the rest of the corpuscle. They have amœboid motions, by which they change their shape

and place from time to time. The conventional pictures repeated from one text-book to another give no adequate conception of them.

The white corpuscles are normally increased during digestion, and are in excess of a normal proportion to the red cells in a number of pathologic conditions, as typhoid fever, erysipelas, anemia, etc. In leukemia, the abnormal proportion is long continued and very marked, in some cases showing one white to ten or twenty red cells, or even greater proportion. Ehrlich has shown that the leucocytes or white cells are variously affected by certain aniline stains. In leukemia only he finds some which are distinctly stained with eosin, and calls them eosinophile cells. It was thought at one time that Ehrlich's method of staining would indicate whether the leukemia depended on disease of the lymph-glands, the spleen, or the medulla of the bones, but recent investigations have thrown doubt upon such discrimination, and Jaksch has found eosinophile cells in tuberculosis, in pneumonia and in anemia.

The red corpuscles normally are flat roundish discs with thick edges, so soft and flexible that they readily adapt themselves to the curves and angles of the blood vessels. They are of different sizes, not only in different animals but in the same animal. A few microscopists believe that by careful measurement of a large number of discs and comparing the average sizes, a discrimination may be made between the blood of one kind of animal and another. Some have made themselves ridiculous by testifying that they could distinguish the blood of a man from that of a woman. The consensus of opinion among prominent writers is that the size of the red corpuscles is insufficient for the purposes of medical jurisprudence. A view of the red corpuscles in the field of a modern microscope, with a power of 1000 diameters or more will show such a variety of size, above and below the average, as to render an accurate judgment doubtful.

As to the presence of a nucleus, or of an investing membrane in human red blood corpuscles, writers differ greatly, doubtless because of the imperfection of the instruments or reagents employed.

The protrusion or retraction of knobs, projections, or bead-like processes from the corpuscle has been often described, and termed "angular," "rosette" "stellate," etc. Brucke, Stricker and others consider the red corpuscle as really double, consisting of a stroma or matrix which is permeated by a softer or more fluid substance containing the hemoglobin, or coloring matter. Treatment with astringent solutions, as tannin, boracic acid, etc., causes these constituents to separate.

Klein, Heitzman and Flemming describe a fibrillar network in the nuclei of reptile blood, and others speak of fine radial filaments proceeding from the nucleus to the surface.

Elsberg, in Heitzman's "Microscopical Morphology," describes the examination of fresh human blood in a 40 or 50 per cent. solution of bichromate of potash, with a one-twelfth of an inch immersion objective, and a magnifying power of 1,000 diameters. He states that in a short time, indentations occur in the red corpuscle, producing irregular and stellate forms, which may persist or lead to separation by constriction of minute portions, or the corpuscle may become rounded again. After about half an hour protrusions of knobs take place, which may be again retracted or a pedunculated knob may be de-

tached. Sometimes several corpuscles unite, forming chains or compound bodies. Others appear with one or more vacuoles in their substance. In many corpuscles, a distinct reticulation is seen, with thickened points at the intersection of the filaments which, without careful focusing, might be mistaken for granules. Some of the corpuscles become pale, and mere rings or "ghosts," detached portions of which accumulate as detritus.

The reading of Elsberg's descriptions several years ago impressed me with the thought that such a variety of forms and activities indicated a corresponding variety in the structure and functions of the red corpuscles, and I instituted a series of experiments with analogous but even more complex results than those of Elsberg. The very best instruments were employed, as Zeiss's largest microscope stand, and the modern Van Heurck stand made by Watson. For objectives, I had Powell & Lealand's one-tenth apochromatic of 1.50 N A, the Bausch & Lomb H I one-eighth of 1.40 N A, a Gundlach's 1.20 H I, and several others. I used also an Abbe condenser or a Powell & Lealand's apochromatic condenser of 1.40 N A, together with the compensating eye-pieces of the latter firm. The magnifying powers varied from 900 to 3,000 diameters.

Various solutions were used in the examinations, as 1 per cent. solution of osmic acid, Flemming's solution, and 20 to 50 per cent. solution of bichromate of potash. The latter fluid gave most satisfaction. According to Rollett and Elsberg, bichromate of potash does not alter or seriously impair the living matter, but acts as a preserving medium, and enables us to trace normal development or natural degeneration. I found, however, that the alterations of the red corpuscles occurred sooner in strong than in weak solutions, so that some astringent action seemed due to the menstruum.

A small drop of blood was placed upon the cover-glass and quickly put on a drop of bichromate solution upon the slide. Blood from different persons and of different ages was examined, and although differences in amount and in time of alteration were perceptible, nearly all showed great irregularity in the shape of the red corpuscles.

Many of the corpuscles appeared as concentric rings in a flat disc around a central nucleus. Some showed protuberances around the edge, as if a semi-fluid substance had exuded, or had been squeezed out of the corpuscle. These protrusions differed both in size and number. By the use of the sub-stage condenser and oblique illumination, occasional glimpses of fibers radiating between the rings were obtained. The shape and size of the discs greatly varied. Many were round, but others were oval, square, triangular, finger-like, and sometimes branched, but nearly all exhibited traces of ring structure. Some were merely flat plaques or discs, notched at the edge; others were more globular. Many had irregular knobbed protrusions both on the edge and on the flat surface, as described by Elsberg. Many of these protrusions became detached, and some of them would remain at rest while others showed amoeboid changes of shape, and would rotate or move across the field of view in different directions. Portions of protruded semi-fluid substance would remain for some time attached to the edge of a disc, then with a vibratory or oscillatory motion would detach themselves and form independent masses, some stationary and other motile. Some were attached to the disc by a fiber or

thread, and often such a thread would bind several masses together. In one instance two masses pulled apart so as to form quite a lengthy fiber. In others the fiber formed a tail with serpentine motion or would entirely separate from the mass. Careful focusing showed some of these fibers to be really chains of small granules, many of which appeared as scattered detritus. So similar were these granules, isolated or in chains, to micrococci, that they would have been deemed such if they had not been seen in the act of stripping themselves from the edges of the viscid red corpuscles.

The result of my observations convinced me that the phenomena described were the result of a natural degeneration of the red corpuscles, hastened perhaps by the action of the bichromate solution. The variety in the appearances may be due to essential differences in the corpuscles themselves; differences which are both morphological and physiological. Considering the various offices which the blood performs in the animal economy, embryonic, nutritive, metabolic and excretive, we may reasonably expect the structure of the corpuscles to differ, and the effects of chemical and physical agencies upon them to be far from uniform. The more embryonic forms may not exhibit the fully formed structure, while those engaged in carrying away effete matter may be ready to disintegrate. Thus we may account for the variety in the appearance of the corpuscles and for the ready decomposition of some, while the structural integrity of others persists longer.

Under the name of poikilocytosis, some have described the irregular forms of blood discs occurring in debilitating diseases, especially in pernicious anemia. A large number of minute cells has given rise to the term microcythemia, and abnormally large cells to macrocythemia. Such terms are really unnecessary, and are but additions to a list of technicalities already too large. The varying appearances of decomposing cells, especially when the normal process is exaggerated by morbidly depressing influences can not be described by such terms.

One of the effects of the bichromate solution on the red blood corpuscle is to harden and contract the outer surface so as to wrinkle it in such a manner as to simulate the plasmodium malariae. This has occurred so many times as to throw doubt upon some preparations and observations. I have not been able to examine many specimens of malarial blood, but some European slides, stained after Ehrlich's method, and marked plasmodia can scarcely be distinguished from the wrinkling of the cell in the bichromate solution. The amoeboid and flagellate forms of the organism will afford proof of its presence, but an irregular vacuity in the cell is no proof.

As an example of the relation which such examinations of blood as have been described bear to practical medicine, reference may be made to an examination made by the writer some years ago, of the blood corpuscles in eighteen cases of beri-beri, which had been transferred from a Brazilian corvette to the Marine Hospital in San Francisco. A full account, with microscopic illustrations, may be found in the Annual Reports of the Supervising Surgeon General at Washington. Specimens of the blood from each patient were sent to me, and examination showed that the red corpuscles were in various stages of disintegration. The ring structure of the broken cells and the resemblance of the detritus to micro-

cocci was evident. The clinical history of each case fully confirmed the microscopic examination, although the patients had not been seen and the slides of blood drops were merely numbered from one to eighteen. Acting upon the suggestions of the microscope, iron and quinin were given in large doses, with a generous diet. Under this treatment, the blood corpuscles of the patients speedily recovered their normal appearance, and in a short time all the seamen returned to duty. The surgeon in charge of the hospital (Heber Smith, M.D.), in his report to Washington, says: "It is possible that a microscopic examination of the blood of all the men on board the corvette before she sailed from Brazil, would have revealed just those members of her crew who were to suffer from the disease."

FEVER, AND THE RELATIONS OF MICRO-ORGANISMS TO THE DISEASE.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY WASHINGTON AYER, M.D.
SAN FRANCISCO, CAL.

In the discussion of this question I shall assume the negative position. During the past ten years the medical mind has expended much of its force in the investigation of bacteriology, and no one in our country has more enriched the literature of this department of science than Dr. George Sternberg, and he is entitled to great consideration for the industry with which he has pursued his labors; yet I consider his efforts to be without practical results.

The subject of organisms is as familiar as household words and is filling the human mind with wonder, fear and amazement, and it is proper that the medical profession should pause for a season, take its reckoning and learn the true position it is occupying upon this question. We know much that was unknown to the founders of the healing art, and yet know but little of all that relates to the art and science of medicine; and the student at the close of his life-work will exclaim with Newton: "Alas! I have been but a child picking up pebbles upon the shore of the great ocean of truth!"

Like a dark shadow that creeps over a landscape, obscuring its beauty, transient causes stealthily invade the body until health vanishes into the gloom of disease with its true etiology unknown.

Fever is an important factor in nearly every form of disease, whether idiopathic or traumatic, and its various attendant phenomena can not be explained upon the germ theory, that microorganisms are the only true *materies morbi*. The ebbing of the tides of the ocean is influenced by planetary movements and changes, and so is lunacy, while the electric phenomena of the clouds and the seismic convulsions of the earth produce nervous prostration, fear and consequent disease.

Intelligence and learning are not evolved from any organisms, nor from light and heat, but spring into force and energy by individual application, and the maxim, *mens sana in corpore sano*, finds support in the world's philosophy and the sayings of men.

The different departments of learning belong to the different conditions of mind. We can not all think and reason alike, yet the healthy brain of the cadaver does not enable us to point out the specific differences in the quality and quantity of the minds of men.

Results of these conditions are the sequences of mental toil, as the harvest is gathered in by the strong arms of the yeoman and the charm of plenty fills the household.

So in the abstract does mental toil beget thoughts which enrich the world of learning and become our choicest companions, but the thinking and reasoning must be in the right direction to become profitable. Speculations mislead and error follows, and men of one idea cease to be useful.

"Nature is true to herself." Nature does not deal in fiction but in the great problems of reality, and the earnest medical student is willing to yield his life-work to add one more truth to human learning, still evolving and educating good, ever striving to relieve the sufferings of his fellow men.

While the literature upon the subject of fever is so great and so comprehensive as to appear nearly exhaustive, there yet lies much before us to be learned, and the physician who shall give to the world its positive cause and prevention will build to himself an enduring monument in the hearts and affections of the people, and they will be led upon the borders of the Utopia of human happiness by such a discovery.

Fever, in its generic acceptance, is an exalted or increased temperature of the blood coursing through the body, feeding the surface with accumulated heat as the result of friction and decomposition, and is attended with increased action of the heart, pain in the head and back, weariness in the limbs, a feeling of general exhaustion and great thirst.

By the increased heat of the blood the various functions of the viscera are changed, nutrition is interrupted and gradual decay follows, until the function of assimilation is restored to its normal condition by the slow processes of change in the multiple phenomena of life. Why the exaggerated mutations of temperature and restlessness are greater in one than in another person, in the same type of fever, is a subject which awakens a controversy in the minds of all diligent students of medicine. Here we may inquire what is the fuel, and where is the fire kindled that causes the increased temperature of the body, and why are not similar remedies always employed to extinguish this heat?

Were the theory of germs correct would they not continue to flourish, and why could not some germicide be employed to destroy the microorganisms at once, and place the patient on the highway to convalescence, and not allow him to waste away upon the bed of sickness for a period of three or six weeks?

When convalescence begins, does this change denote that the germs have ceased to proliferate, or that they have become alarmed at the fusillade of remedies that have been discharged into their ranks, and made their escape out of the mouth into the surrounding air to seek some new fields of operation and bring new subjects to the chamber of disease?

As all fevers have their periods of exacerbation, of pyrexia and anorexia, which may be determined at least twenty-four hours before their occurrence, what part of this program do the germs take? What are they doing during this interval? Are they waiting for some new neoplasm to spring up to feed upon?

Typhoid fever upon the Pacific coast is of a much milder type than is found upon the Atlantic seaboard, and, according to the Pasteur theory, the same class of typhoid bacillus is the *casus belli* here as there, when the body is invaded by the fever, and must be

subject to typical climatic influences; and accordingly a humid atmosphere must be the soil where the most virulent forms of these microorganisms are developed and propagated; and the mephitic gases of the sewers can have very little influence over the economy of the physical functions of the various organs of the body of man in producing disease, and this undoubtedly is true. The carburetted hydrogen gas of sewers is one-fifth lighter than common air, and when disengaged flies away, while the sulphuretted hydrogen gas is one-fifth heavier than common air and does not rise high enough to seriously incommode any one sufficiently to affect the standard of health.

Fancy can scarcely picture a more bewildering subject in histology and causation of disease than is witnessed in the disintegration of tissue and general exhaustion of the forces of life, nor better portray the magic effects of the microorganisms of the germ theory than is presented in the various phenomena of intermittent fever.

Were, then, specific bacilli endowed with intelligence and formed into communities of labor unions, with hours assigned to accomplish their work and for rest, they could not possibly be more systematic in deceiving and destroying the comfort of those they have prostrated by their presence. But, unfortunately, they are not discovered until disease makes their presence known, and we are led to conclude they are the spontaneous developments of unknown causes, and should be classed as the sequelæ of unknown forces, rather than the prime cause of disease.

The evidence that these specific microorganisms are alone the *materies morbi* is wanting, and their presence is not *prima facie* evidence of the fact beyond controversy.

The true interpretation given to fever depends upon the thorough knowledge of the functions and changes in the structure of the organs principally affected. One coming from a malarial district, suffering from chills and fever, to the casual observer would be considered as having either remittent or intermittent fever, while upon a close inquiry the fever might be traced to an ovarian cyst or an abscess in the cul-de-sac of Douglas, or to some localized disturbance of the liver, spleen or kidney, and the aid of the microscope would not be required to make a differential diagnosis, nor would the presence of specific germs be required to determine these different lesions involved.

In the two former cases the only germicides required for the student to become familiar with, would be the surgeon's instruments and the technique treatment.

Exalted temperature and increased cardiac action are important factors in nearly all functional disturbances as well as organic disease, and should be carefully studied in the clinics.

Is there a prescient, instinctive reasoning force in the protoplasm which marshals the armies of microbes into distinct and expressive forms of battle array, and assigns to each class or species a specific office to perform, so that one shall destroy the functions of one set of organs, and another overcome the possibilities of health in some other organ, and thus establish a variety of diseases? Is this the teaching of the germ theory? Is the microbe the siren that first pleases, then stirs the soul to fears and moves to resistance the sorrowful tear? Is this the modern ogre that must be banished into eternal exile before

human life can become secure from the ravages of disease? The task is too great to be undertaken; every sunbeam is full of restless germs, and every drop of water full of insect life busy as the coral insects building reefs beneath the waves of the ocean, and the dawning light of every new day will scatter the germs over the earth. They have a perpetual existence, and we must not forget that disease and death are the inevitable sequences of human existence.

The announcement that sterilized milk and sterilized water are the only fluids suitable for domestic use fills the timid with daily fear, and they naturally ask why the air is not sterilized so that the "nasty things" can not get into the milk and bring sickness to their homes.

Hoc opus, and the labor which the advocates of the germ theory must perform to make it of practical importance. As we study the conditions of the atmosphere, as indicated by the barometer and thermometer, we shall find ample reasons why exposure should cause disease, and greater cleanliness should be observed to preserve the purity of the air. While the nursery is reeking with the aroma of neglected duties, the secretions become vitiated and the restlessness of the infant repeats the story of responsibility, and the cause of its sickness.

The art of medicine is the highest expression of medical thought, which has advanced so far that at the close of the nineteenth century we are living in the midst of conditions that were but the shadowy dreams of the early founders of the healing art. These things must not be forgotten.

I have a conscious conviction of the necessity of being conservative in the discussion of this question, that admonishes me that practical knowledge alone offers the greatest encouragement to progressive medicine, while microscopic visions and day dreams lead into the walks of speculation and error.

There are habits of thought that are as earnest in their necessities for the development and health of the mind, as the habits of the body are necessary to be observed for physical comfort and health. The growth of the former is derived from application, and the growth and nutrition of the latter is the result of the assimilation of the elements of concrete foods adapted to the support of physical life.

In the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION an article appeared from the pen of Charles Smart, M.D., Surgeon U. S. A., upon drinking water, in which he states the following, viz:

"Not long ago I saw it asserted that a cholera germ had no more chance of passing along the current of the Potomac undetected by the bacteriologist, than a mad dog had of careering along Pennsylvania Avenue at midday without being detected."
"When the germs of typhoid fever or of cholera are present in a water, they generally enter the water along with sewage, for it is known that these pathogenic organisms are cast out of the sick person by way of the intestinal canal."

The question that is here first presented is, How do these organisms first enter the *prima via*? Certainly not from the sewage, for according to this writer's views, which I believe to be correct, the sewage is the secondary place where the germs are deposited, and in the reports from Marseilles and Toulon during the cholera epidemic in these cities in 1884, in the immediate vicinity of the sewage dumps cholera was scarcely known.

From the simultaneous appearance of cholera in different parts of an infected city it is at least rational to conclude that there is a morbid choleraic wave which falls upon the people like a shadow from a passing cloud, and neither sewers nor sewage can be made responsible for the rapid spread of the disease.

When a relapse follows a slow convalescence, no one can properly say another brood of hungry bacilli have left the sewers and entered the body to bring back the disease and prolong the suffering. Common intelligence points to some imprudence as the cause of the relapse; yet our analysts and germologists cry, Germs! Germs!! Germs!!! and revel in fictitious exclamations, though truth to the contrary be stronger, and stranger than their fictions, they have entered the groove, made their discoveries in histology, and like Bellamy have been looking backward and failed to make a practical application of their learning so as to arrest disease. The death rate remains unchanged *pari passu*, as population increases.

To-day the educated medical thought is leading its research into the occult domains of biology, with the view of raising practical medicine to the high standard of an exact science.

At the present time all investigations have only proved the existence of microorganisms, and have failed to demonstrate that they are primarily the cause of the various morbid conditions of the body.

While light and heat are essential to the healthful growth of vegetation, some species of the algae flourish only in bogs and along the margin of pools of stagnant water. The proper understanding of the correlation of existence—life and growth of vegetation with the life of animated creation—man and his surroundings, is of great importance while considering the influences which change and develop the extraneous growths on the hardy plants and cause disease—decay and death to the tree—and pain and death to man.

DISCUSSION.

DR. W. N. MILLER—While I am a believer to a certain extent in microorganisms, I think in a great many cases it is very uncertain. Yet, at the same time, all that is necessary for a person in diagnosing a case is to tell the patient, "you are a subject of microorganisms." Then you are sure to hit his case, no matter what it is. It is very important for a person to diagnose a case satisfactorily to the patient, and when this diagnosis is given you are sure not to have to go back upon it, and you are always sure in case death ensues that you have been right.

LEPROSY IN SAN FRANCISCO.

Read in the Section on Practice of Medicine at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY DOUGLASS W. MONTGOMERY, M.D.

PROFESSOR OF DISEASES OF THE SKIN, MEDICAL DEPARTMENT OF THE UNIVERSITY OF CALIFORNIA; CONSULTING PHYSICIAN FOR DISEASES OF THE SKIN AND FOR PATHOLOGY, GERMAN HOSPITAL.
SAN FRANCISCO.

In all ages and in all countries the mass of mankind has believed in the contagiousness of leprosy, and even now, when exposed to the sharpened criticism of scientific inquiry, contagion is still the only basis on which we can explain the facts. It is not known how the contagium is carried or how inoculated. We do not know what manifestation it makes at the seat of inoculation, or whether it makes any capable of being clinically appreciated. It is not understood why one person may become infected

from what seems a short exposure, while another may dwell most intimately and for long stretches of time with lepers, and never contract the disease. We are not in a position to explain these nor a host of other facts, but we do know that when we find a leper, we immediately inquire for other lepers with whom he has been in contact and we find them. The fact of lepers being aggregated in localities is so notorious, and so within the ken of every medical man or even layman that it does not need the citation of examples.

If the disease be contagious and in no other way can we understand its propagation, and if it have a tendency to become fixed in a locality because of the continued residence of lepers, or as it might be put, if a locality may become saturated with the germs of this disease, then the question before the citizens of San Francisco and of the United States becomes a grave one, for, instead of passively receiving lepers we may assume the active rôle of a distributing point, and give out abundantly what we have received so thoughtlessly. All the factors going to the formation of a leper focus seem to be present in the San Francisco Chinatown. The Chinese here all come from the Province of Kwang Tung, where leprosy is abundantly endemic; most of the lepers here are Chinamen; most of the Chinamen in San Francisco live in the Chinese quarter, and under unhygienic, overcrowded, filthy conditions. Under such circumstances, from what we know of germ diseases, everything seems favorable to room after room in Chinatown becoming impregnated with lepra bacilli from the occasional sojourn of leprosy Chinese. On the other hand, I must say that although I have seen quite a number of Chinese lepers here, I have never run across one who was born in this country. This may be due to the circumstance that very few of them are native here, as a Chinaman seldom brings his wife with him. They are all married prior to emigrating, and they leave their wives at home. But the failure to find Chinese lepers of American birth might be brought forward as an argument by those who consider the fear of San Francisco becoming a leper center trivial.¹ They might say that leprosy introduced by the Chinese into California would probably take a course similar to the same disease brought to Minnesota, Wisconsin and Iowa by the Norwegian immigrants, not one of whose descendants, according to both Hansen and

¹ From the length of time some of the Chinese lepers have been in this country before showing any signs of the affection, one might infer the possibility of having acquired it here. It is not wished to put it any stronger than a possibility, because in leprosy the time that elapses between an inoculation and the first manifestations of the disease seem to vary within wide limits. The following is a list of some Chinese lepers, with the date of their arrival in this country, and the length of time after that before they noticed the first symptoms of their disease. The figures in either case are just as they were given to me either directly from the patient, or through the intermediary of an interpreter, and I make no pretensions to being scientifically accurate:

Lee Yen, 33 years of age, laundryman and cigarmaker, came to America in 1873, and went back to China for a short visit about eleven years afterwards. A leprosy patch appeared on the right buttock three years ago.

Chan Mui, female, 31 years of age, came to America in 1868, and a small tubercle appeared on the nose in 1888, twenty years afterwards.

Dang Hlung Kuen, male, 50 years of age, came to America in 1881, and about five years afterwards noticed half dollar sized patches on the right side of his forehead.

Ngô Wong, male, 25 years of age, ragpicker, came to America in 1878, and three years afterwards noticed the left ear became swollen.

Chang Kim, male, 25 years of age, farm laborer, came to America in 1884, and five and a half years afterwards tubercles appeared on the anterior surfaces of the knees.

Chung Kan Foke, male, 31 years of age, miner in a silver mine, came to America in 1876, and lumps appeared on the face sixteen years afterwards.

Ma Ying, male, 25 years of age, farm laborer, came to America in 1881, his right hand withered and a white patch appeared on the left side of the face seven years ago.

Gronwald, are lepers.² But one of these observers, Armauer Hansen, thinks the failure of the disease to propagate itself in the case of the Norwegians is due to the improved social conditions in this country. The isolation of separate beds, clean toilet articles, distinct food receptacles, plenty of water, is enough to prevent the spread of the disease. And this brings me to a point which ought to be accentuated; the difference in social conservatism between the Aryans and the Mongolians as we see them in this city.

The European, of whatever nation, comes here to form a home, and the more prosperous he is, the more comfortable the home becomes. The Chinaman, no matter how prosperous he may be, lives under mean conditions and saves his money that he may realize his ideal of living in splendor on returning to China. And besides this he has a conservatism of which the restless dissatisfied Anglo-Saxon can only form an imperfect conception. Look at their colossal conservatism in regard to food. The Italian will give up his polenta, and the Irishman is only too glad to add good juicy beef to his potato diet, but a walk down Dupont Street shows not only shop after shop filled exclusively with imported Chinese food stuffs, but fresh meat stores filled so predominantly with pork that it is difficult to find beef, and apparently never a piece of mutton, in a land where both beef and mutton are cheap.

The Chinese in California live practically the same way they do in China and, as far as social conditions are concerned, leprosy would have an equal chance of propagating itself among them here as there.

We might look upon the presence of leprosy in Chinatown with indifference, thinking of it as simply confined to an alien population, but the possibility of their afflictions being transmitted to us should make us alive to the importance of warding off the danger. Some Americans are necessarily employed in Chinatown, and many Chinese are domestics in American houses. In fact we are intermingled in a thousand ways and unavoidably so. And moreover on a former occasion I have shown that an American, who was never out of the United States acquired leprosy on this coast, probably in a Chinese camp in Nevada, so that there is no doubt of the possibility of Americans becoming lepers in this country.³

² Die *Ätiologie der Lepra* von G. Armauer Hansen. Rudolf Virchow's Festschrift, Bd. III., Page 63. Leprosy in Minnesota, U. S. A., by Chr. Gronwald, M.D. The London Lancet, March 26, 1892.

³ On Feb. 29, 1892, there died at the San Francisco pesthouse a leper with the following history:

B., aged 43; an American; was born of American parents in Massachusetts, and never was out of the United States excepting a few hours in passing from Buffalo to Detroit over the Canada Southern Railway. About twenty years ago he acquired a sore on the penis after connection with a white woman in Nevada; no history of secondary symptoms could be elicited. He did not deny that previous to this he might have had frequent connection both with Chinese and Indians, but he said that if so, it was a long time before, and had no connection with the sore. Shortly after the acquisition of the sore, and while still in Nevada, he had charge of a gang of Chinamen on the railroad. There were several Chinese prostitutes in the camp with whom he had frequent connection. He did not remember that any of the Chinese showed any of the symptoms of leprosy, but admitted that they might have had the disease and escaped his notice, as he did not know anything about leprosy at that time. About seven years ago he noticed areas of brown discoloration on the body and limbs, which were diagnosed and treated as syphilis by the doctors whom he consulted. His malady was first correctly interpreted by Dr. Geo. L. Fitch, of San Francisco, about five years ago, and about six months later he entered the San Francisco pest-house, where he remained for two years. He again entered on Feb. 17, 1890, and remained till his death.

The patient was above medium height, with a well developed bony skeleton. He was bald on the vertex, the remaining hair was brown, and rather dry looking as if not well brushed, but otherwise healthy. The scalp was in good condition. He had neither eyebrows, eyelashes, nor moustache, and the beard was very sparse. The disease was situated especially in the face, hands and forearms, and feet and legs.

San Francisco is a young city, only a little over fifty years old, and leprosy can not yet be said to be endemic here, for it has not had the time to become so. It is therefore not a leper city in the full sense of the term, and we should see to it that this misfortune does not happen. There will always be some lepers coming in from surrounding countries, but the disease ought not to be allowed to gain a foothold.

As an example of a city where leprosy has become firmly seated, Constantinople is instructive. Von Duhring says⁴ that leprosy in that city is only endemic among the Spanish Jews, and that all other cases he has seen came in from the neighboring towns. These Jews, driven out of Spain in 1492 by Ferdinand and Isabella, settled in a quarter of Constantinople set apart for them, where they yet dwell. They still, after the lapse of four hundred years, speak Spanish, wear a peculiar garb, live poorly, and are very crowded and filthy, in all of which respects they form a striking and instructive parallel to the Chinese in our city.

A paper drawing attention to the contagiousness of leprosy, especially when even the laity believe it to be far more virulently contagious than it really is, would seem to be superfluous, but allow me to give you an example of civic carelessness in this very particular:

Until lately our lazaretto was also our smallpox hospital, and the lepers had the free run of the wards, which were liable at any time to be occupied by smallpox patients. The bed occupied by a variola patient might have been used as a lounging place by a leper a few minutes before. The variola patient was forced into the hospital, and he might be a very

There were large nodules on the site of the eyebrows, and from there the disease shaded off upwards into the clear scalp above. The eyelids moved a little stiffly from the infiltration, but there was no lagophthalmos, as is so frequently the case in leprosy. The skin of the nose, and of the whole of the lower part of the face was very much thickened, especially the lower lip, which stood out stiff and useless. The patient originally had a light complexion, but when I saw him the skin of the face, hands, and lower part of the legs, and of the feet was a dark copper color. The skin upon the lesions of the face had the silky soft appearance so often seen in patients suffering from tubercular leprosy. On the skin of the arms and hands, and of the legs and feet there were excoriations, the seat of previously existing pemphigus blebs, which appeared from time to time. The last joint of the ring finger of the left hand was enlarged and stiff; the movements of the hands were not nearly so deft as formerly, but there was no paralysis, and no wasting of the muscles. He had lost appreciation of touch, and on being handled felt as if a substance were between the fingers of the person and his skin. His extremities were analgesic, and he had recently burnt his fingers in picking up something hot without experiencing any pain. His appreciation of the sensations of heat and cold was not tested. There was a discoloration, such as he said constituted the first symptoms of his malady, on the inside of the left leg. It was an irregular, fairly well circumscribed, brown patch about the size of a silver dollar, joined by a narrow isthmus to a similar patch. At the edge of this discoloration there was a lepra nodule, well raised above the level of the skin, and very dark in color. It might have been mistaken for a melanotic sarcoma. This nodule was cut out, and lepra bacilli were found in scrapings from its cut surface. Sections prepared for the microscope showed that its black color was owing to an extraordinary amount of lepra pigment.

The eye-balls were clear and moved normally, and the sight was good. The skin covering the auricles was normal, a remarkable circumstance considering their liability to be affected, and the advanced stage of the disease. The hearing was good. Both nares were almost completely blocked so that he could scarcely breathe through them. The epithelium of the dorsum of the tongue was a glittering white, and the surface was marked off by deep furrows running in all directions, but principally longitudinally and transversely. This condition of the tongue is usually found associated with syphilis, and it was the only symptom I could find at all indicative of that disease. He complained he could not eat fish, because of the difficulty in detecting the bones with his tongue, so that the sense of touch was evidently obtunded. The voice was husky and the breathing was difficult; in speaking he frequently had to pause to take breath, and at times the hospital attendants were afraid he would smother to death. He said he had not had any sexual desire since the commencement of the disease seven years before, and he blamed, as this class of people frequently do, the mercenary treatment for its extinguishment. The skin of the penis and scrotum was absolutely normal, but there was a small solid swelling in the left cord, and the left epididymis was slightly enlarged but of normal consistency. His mind was clear and his answers terse and to the point.—Reported in the *Pacific Medical Journal*, April, 1892.

⁴ *Lepra und die Frage ihrer Contagiosität nach Beobachtungen in Konstantinopel* von Dr. med. E. von Duhring. Monatschrift für Praktische Dermatologie, 15. März, 1893.

decent fellow—as a matter of fact a physician enjoying a good practice died there a few years ago—and it is not fair play to put a man in a bed on which a leper had been taking his noonday nap, thereby exposing him, because of a temporary disease, to the possibility of contracting a malady that would make him an outcast from society for life. This matter is mentioned rather by way of example than as a complaint, as the management has been changed lately and the discipline is better, but even now we ought to be on the outlook for a lapse of city morals in this direction, for, in case of a smallpox epidemic it is to be feared the main building would again be used as a smallpox hospital.

PRIMARY TUBERCULOSIS OF THE PERITONEUM, CURED BY CELIOTOMY. FOUR CASES.

Read in the Section of Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1894.

BY W. F. McNUTT, M.D.

SAN FRANCISCO, CAL.

These four cases of primary tubercular peritonitis, are reported on account of the doubt and speculation that still exist as to the etiology of this disease. Most writers maintain that tubercular peritonitis is necessarily secondary. There can scarcely be a question about these cases being primary; the fact that there were no indications of the presence of tuberculosis, or any other disease, together with the fact that the cases all recovered after operation, and show no evidence of disease since, is almost proof positive that in these cases the disease was primary and confined to the peritoneum. The question might arise as to those inflammatory products being the result of Koch's bacilli. In each of these four cases on opening the abdomen, the peritoneum, both visceral and mural layer, was studded with thousands of miliary tubercular bodies, that is shiny, hard little granules on the surface of the membrane. Unfortunately in only one of these cases were these little bodies examined histologically and inoculation experiments were not instituted. One case illustrated the variety which gives a fibrinous exudation, plastic adhesions with scarcely any serum and greatly thickened membranes; one case the exudation was sero-fibrinous or gelatinous and non-plastic, not adhesive; in the other two cases the exudation was serous.

Case 1.—Mrs. E., aged 58; I was called in consultation on April 7, 1891; her physician stated that for three months she had suffered with abdominal pain and much tenderness; coated tongue; anorexia; bowels irregular, most of the time constipated. For the last two weeks the bowels had only been partially evacuated with large enemata thrown up into the sigmoid, and all cathartic medicine had been rejected. The tympanitis intestinalis and borborygmus were characteristic of obstruction. We tried still larger injections by gravity and by long tubes without effect. A few days after I made a laparotomy finding the peritoneum greatly thickened and studded with miliary tubercles and the fibrinous exudations as described. Plastic adhesions had caused an obstruction of the colon at the juncture of the ascending and transverse. The adhesions were easily broken up, the bowels moved freely a few hours after, a drainage tube was kept in and the recovery was complete.

Case 2.—Age 8, tubercular family history; the family physician brought the child to my office December, 1892, on account of extreme distension of the abdomen. On examination it was evident that the enlargement was due to fluid, but from the shape of the abdomen and dense condi-

tion of its walls there was some doubt if the fluid was not contained in a cyst. I advised celiotomy and assisted in the operation. The peritoneum was found studded with tubercles and the fluid sero-fibrinous. Notwithstanding the tubercular family history (the mother being consumptive) the child is perfectly well at present.

Case 3.—Mrs. W., age 58, was sent to me August 18, 1893, by her physician being in doubt as to the cause of her abdominal distension, whether it was ascites or cystic. The protruding rounded condition of the abdomen resembled cystic disease rather than ascites. Having diagnosed the case as one of ascites, and finding no heart, or liver, or kidney disease, I concluded it was a disease of the peritoneum and made a celiotomy, finding the peritoneum thickened and studded with tubercles. The fluid, about eight quarts, was serous; no adhesions, no fibrinous exudation; drainage and complete recovery with excellent health since.

Case 4.—A boy aged 7; no tubercular history; had been complaining several weeks, when the abdomen was observed to be enlarging; a physician was called in and flaxseed poultices and other appropriate treatment instituted for peritonitis. After a week's treatment and the enlargement increasing, I was called August 29, 1893; finding the enlargement due to a fluid and the disease apparently confined to the peritoneum, I advised a celiotomy. On opening the peritoneum it was thickened and studded with miliary tubercles. A drainage tube was left in; the recovery was complete; the fluid was serous. This last case was the only one examined microscopically; the following is Prof. D. W. Montgomery's report:

"I have examined the small piece of tissue from the M. child, and it shows the structure of tubercle. There are a vast number of giant cells with their nuclei arranged around the periphery, and the center occupied by coagulation necrosis. I have stained repeatedly for the bacilli of tuberculosis but I have been unable to find any. This is not strange, however, as it is very often, I may say in the majority of cases impossible to demonstrate the bacillus of tubercle in the tissue. But as this case shows the presence of miliary tubercles when looked at with the naked eye, and also shows the same minute anatomic structure as tubercle, we must call such cases tuberculosis, till we get proof to the contrary."

DISCUSSION.

DR. McNUTT, (at the conclusion of his paper).—These are the four cases. I simply want to report them. I do so because of the doubt that exists as to whether tubercular peritonitis is primary or secondary. In these cases there was no meningeal tuberculosis, and no tuberculosis of the lungs or of any other organ.

One point, however, I will note upon the diagnoses, and that is that these cases do not resemble ordinary cases of ascites. In ordinary ascites when the patient is put on his back the abdomen flattens, while the abdomen in tubercular peritonitis stands out. That is why it was doubtful in each of these cases whether it was cystic or not. When one cuts into the abdomen and sees the thickened condition of the peritoneum, and sees the exudation into the peritoneal wall, it is easy to understand why in tubercular peritonitis we expect to find the abdomen standing out as if the person was suffering from cystic disease. In each one of these cases there was an indication of cystic disease; there was no flattening of the abdomen as there would ordinarily be in ascites.

DR. J. T. CARPENTER, Pa.—I would like, Mr. Chairman, to ask the operator whether he made thorough drainage, and whether there was any medication of the peritoneal cavity?

DR. McNUTT—I would say that the first two cases were treated with a carbolic solution; in the others, the fluid was simply evacuated and all drained.

THE CHAIRMAN—I would like to ask whether in any of the cases bacilli were found?

DR. McNUTT—No; an examination revealed that it was a tubercular structure.

THE CHAIRMAN—I supposed that referred to the last case mentioned, only.

DR. McNUTT—Yes; that was the only one that was examined microscopically.

LUNG GYMNASTICS IN THE TREATMENT OF CHRONIC DISEASE.

Read by title in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held in San Francisco, June 5-8, 1894.

BY L. P. WALBRIDGE, M.D.

DECATUR, ILL.

Oxygen is the sustaining principle of animal life and of all the ordinary phenomena of combustion. It is indispensable in respiration, and in general is the most universally active and efficient element.

Respiration is the most important function in the human economy. By this method life is sustained. When we consider the tremendous importance of the lungs it must become apparent that any neglect of these great central boilers of the body may result in disease.

Man does not live by bread alone. The food we eat would not nourish us if we did not breathe. The air we breathe burns up the food, and by so doing produces energy and vital force.

It is the air we breathe that supports combustion, and combustion maintains life by creating heat. But the ultimate source of the heat is contained in the potential energy taken into the body with the food we eat and the air we breathe absorbed during respiration. The food stuffs are used up in the body chiefly by a process of combustion. The kinetic energy is liberated only in the form of heat while the mechanical and electrical energies are developed from the potential energy taken into the body by the food we eat and the air we breathe.

Air is free to us all, but it were better if the over-civilized people of our age had to pay for it. Then they would value it. Oxygen is one of our principal nourishments. It is to the lungs what food is to the stomach.

The stomach and its relation to food stuffs have been described from time immemorial, also its relation to digestion. But no mention is made of the tremendous influence the lungs play in the ultimate appropriation of the food to our existence.

To learn to breathe properly is to learn the foundation of physical health. In the evolution of our earth there was a time when the higher order of animal life could not exist, because of the universal abundance of carbonic acid which fulfilled its purpose by filling the granaries of the earth with fuel for man's use. But at the coming of man there appeared another gas for his sustenance, and by that gas we live, move and have our being.

By lung gymnastics is meant the exercise of the lungs by deep and prolonged breathing, expanding and contracting the chest. By this means the lungs are strengthened, the body nourished, and the impure gases of the blood removed. To breathe properly we should take in a full long breath until the lungs seem full, taking care not to strain the lungs. Hold the breath while the lungs are filled, for a few seconds. Then gradually let it leave the lungs. If these practices are indulged in several times a day they will, in a short time become a habit, and under these exercises the respiratory movement will become less frequent, the capacity of the lungs increased, and the substance of the lungs strengthened.

Natural breathing in some people is a mere gasp. The air cells of the lungs are not properly filled and consequently the blood is not thoroughly oxygenated. The person becomes anemic, flat-chested with stoop-

ing shoulders, the lung tissue suffers and becomes an easy prey to disease.

In natural breathing the apices of the lungs are not as completely filled with air as they should be. This may be due to abdominal breathing in man, while intercostal breathing is more common in woman; hence the more frequent lung disease found in man.

To fill the upper part of the lungs one should stand or sit erect, take a deep full breath, and expand the chest upwards and outwards, holding the breath a few seconds, then gradually let it leave the lungs. By this method the apices of the lungs are thoroughly filled, the air pressure acting as a stimulus to the lung substance, strengthening the parts and giving them greater resisting force to disease.

Long breaths represent strength. Brute creation is almost universally found to possess strength in proportion to the length of the respiratory movements; *e. g.*, the hippopotamus who breathes once a minute, the elephant, lion and horse eight times, the tiger six, down to the rat who breathes two hundred and ten times a minute.

In slender developed people where there is slight development of the bust there is nothing that will develop the chest and strengthen the lungs as much as lung exercise. How many are there who know nothing of the exhilarating influence of a full long breath! People who are confined to the house and those accustomed to a sedentary life, who are shut up in small rooms probably never getting a good full breath of fresh air only as they go to and from their places of business, have stooped shoulders, the chest contracted, the head bent forward causing a pressure upon the abdominal organs, and to some extent checking venous circulation, rendering the blood sluggish, and the brain congested from mental strain. The mind has become tired and worried, the respirations lessened, the blood poisoned from impure air benumbing the center of respiration. By five minutes exercise with the lungs in the open air, by deep and prolonged breathing, the poisonous gases in the blood are changed, the headache and tired feeling disappear, and the blood is better oxygenated carrying new life to the tired muscles.

Without good blood one can not maintain good health, but with good blood, health and long life are sure to follow. It is then through the blood that we have our being, acting as a medium of exchange for the outer world and the tissues. Into it are poured those substances which have been subjected to the action of the digestive fluids, and into the lungs it receives oxygen. It thus receives new substances, both from the stomach and lungs. But in its passage through the tissues it gives up some of those new substances and receives in exchange certain waste products; *e. g.*, carbon dioxide and urea. It is then of the greatest importance that the blood contain those natural substances which supply the waste that is constantly going on in the body.

The object of respiration is to supply the oxygen necessary for the oxydation process that constantly goes on in the body, as well as to remove the carbon dioxide formed within the body. An increase in the number and depth of respirations causes an absolute increase in the amount of carbon dioxide given off, and an increased metabolism. Every respiration favors the passage of the venous blood and also of the lymph toward the heart.

Among the Greeks the harmonious development

of all the organs of the human body formed the foundation of education, not only of the youth alone, but of the nation at large. This sentiment pervaded their works on philosophy and is found embodied in all their laws. Lycurgus ordered the establishment of training schools, consisting of jumping, leaping and running. He said that by these exercises they acquired a temper like steel.

My opinion is that the greatest good derived from exercise is brought about by an increased respiration which burns up the food and tissues with greater rapidity, bringing about an increased appetite for food, replacing the waste product by new material, increasing nutrition and a more active metabolism.

The method of treating disease by exercise was practiced more among the ancients than with us. In the oldest literary records of the Hindoos and Chinese, mention is made of the successful method of treating deformities by exercise, and the successful method of treating spinal curvature by definite muscular movements simultaneously with deep and prolonged respiration.

Herodicus, a teacher of Hippocrates, was the first to lay down principles for rational treatment in chronic disease by exercise and breathing. He carried these methods so far that he compelled his patients to walk up steep places and suffer their bodies to be rubbed, and the more the disease weakened them the more he endeavored to overcome that weakness by strengthening the muscular power. He had the good fortune to lengthen the lives of many enfeebled patients, so that Plato reproached him with having acted very unjustly toward these unfortunate people in prolonging their lives.

Hippocrates extended on a scientific basis the principles laid down by his master, and his doctrines in preventing and curing disease by exercise were accepted by the most celebrated physicians of Greece and Rome.

Demosthenes overcame his natural bodily infirmities and his inarticulate and stammering pronunciation by exercise; *e. g.*, he would take long full breaths and run up steep places and declaim while the air was leaving his lungs. In this way he overcame his stammering by gaining control over his respiratory movements.

It was only in the period of her decadence that Rome substituted for these healthful exercises that were the foundation of her developing greatness, the more brutal and coarse athletic circus sports.

During the Middle Ages, medicine was relegated into the background, and the treatment of disease was left to those who believed disease to be of evil spirits, and the method used to drive away these evil spirits was by sorcery and witchcraft.

In the year 1680, Borelli published his work describing the ancient method of treating disease by exercise, and gave his methods and reasons by which chronic disease could be successfully treated by exercise. About the same time Bacon gave those learned theories to the world which have opened new pathways to the science of medicine. His genius embraced every branch of science. He thought the question respecting the prolongation of life worthy his attention and research. He recommended exercise in developing the body, and that running up steep places would strengthen the lungs. Life he considered as a lamp, that would burn out if not replaced by new fuel, and that exercise increased the

desire for food, resulting in an increase of vital phenomena. The most powerful impetus, however, given to the revival of this lost art originated with a Swede, the creator of the modern movement cure, whose methods have spread through the greater part of the civilized world.

What cases are benefited by the treatment of lung exercise? In all constitutional troubles when the object of treatment is to simultaneously improve the quality of the blood and the tone of the heart and lungs. To stimulate the action of the glandular and venous currents the newly oxygenated blood going to all parts of the system feeds it with new life and energy.

In anemia where there exists a morbid condition of the blood, probably both in quality and quantity, increased respiration by lung exercise increases the lung capacity and oxidizing powers of the blood, creating a more active combustion in the body. The blood is constantly loaded with fresh oxygen going to the tissues, feeding them with new life, stimulating the lymphatics and venous currents to an increased activity, stimulating a more active nutrition, improving the quality of the blood, and increasing the weight generally.

In cases where there is a congenital morbid tendency, the aim of all treatment is to modify both qualitatively and quantitatively the process of nutrition. Lung exercise will keep the blood in an oxidizing condition, altering the morbid state by the process of combustion, and an increased desire for food supplying the waste by new material. The seeming uselessness of all medication in some of these cases has long been recognized. Some drugs, however, retain their place as tonics and reconstructives; *e. g.*, quinin, strychnin, iron and arsenic. These may be used in combination or separately in conjunction with other treatment.

Of all drugs that seem to me to be of the greatest value in cases of anemia where there is a condition of mal-nutrition, strychnin is the most useful. It stimulates the circulatory and glandular system, increases nutrition and puts on fat. It is most generally given in too small doses to be of much benefit. It should be given in doses of one thirtieth to one-tenth of a grain three or four times a day. I have given it in doses of one-tenth of a grain three times a day with marked benefit.

In delicate narrow-chested persons where there is a tendency to phthisis, as a prophylactic, lung exercise is of the greatest importance. The lungs are strengthened, the quality of the blood improved, and the vitality increased. Living in the mountains, or the inhalation of ozone, creasote or blowing the spirometer, all have the same object in view. In my opinion the inhalation of medicated substances, in the treatment of catarrh and phthisis, do good only through the increased respiratory movements rather than by the drug used.

In breathing, the breath should be drawn through the nose instead of through the mouth. Hypertrophic rhinitis is more common among mouth breathers than among those who respire through the nostrils. It seems that the mucous membrane lining the nasal cavity requires a certain amount of atmospheric pressure to keep the vessels contracted, and if this pressure is not sufficient the vessels become relaxed, the mucous membrane becomes turgid and congested, and the nasal cavities become occluded.

I will cite a case of mouth breathing and hypertrophic rhinitis:

Mr. E., who had been a sufferer from what he called asthma for more than a year was a mouth breather. He called it asthma because as he stated his nose became so full at times that he could hardly breathe through it at all. On inspection the nasal passage seemed entirely obstructed. After several applications of cocain, a 2 per cent. solution, there was considerable contraction of the mucous membrane, and the breathing became easier.

I enjoined on him the necessity of breathing through the nose, and requested him to return to me in two weeks, and told him if he was not better at that time I would try other means for his relief. At the appointed time he returned stating that he could breathe freer than for months. I told him to continue the lung exercise as I had directed him and to return again in two weeks. At his return his breathing had improved and in two months from his first visit he was well as far as the trouble the asthma gave him.

The only medicine this case had was, at the first visit, a few applications by spray of a 2 per cent. solution of cocain, to determine if the obstruction consisted in congestion or was due to some growth. The remainder of the treatment consisted of lung exercise breathing entirely through the nostrils. The exercises were indulged in four times a day lasting about five minutes each time.

I will cite one case of phthisis treated and cured by lung exercise and the use of strychnia.

Mr. S., 27 years old, a farmer; had been in poor health for more than a year. Had been confined to the house for two months. There existed the usual signs of phthisis; *e. g.*, anemia, cough, diarrhea, night sweats, loss of appetite and a sub-crepitant r le heard over the infra-clavicular region on the right side; chest flattened and shoulders stooping. I prescribed for him strychnin sulphate in one-thirtieth of a grain three times a day, with plenty of good food consisting of eggs, cream, butter and beef, with a cold sponge bath every morning followed by a good rub down.

I then directed him to use lung gymnastics, with long, deep and full breathing, expanding the chest upwards and outwards, breathing through the nose with mouth closed. I directed him to inhale while raising arms from side over head, holding the breath for a few seconds. Then gradually let the air leave the lungs and at the same time bring down the arms to side. Fill the lungs again, bring the arms in front to a horizontal position, then throw the arms backward as far as possible while retaining the air in the lungs.

He was requested to remain out doors during the day and take long walks, and to fill the lungs while walking, holding the breath for a few seconds and then gradually letting it escape from the lungs. These exercises were repeated several times a day.

At the end of three weeks the strychnin was increased to one-tenth of a grain three times a day. His appetite began to improve and the sub-crepitant r le cleared up, nutrition improved and the lung expansion increased. At the end of three months he was discharged cured.

My object in bringing this paper before this meeting is to impress upon the minds of the members of this society the importance of lung exercise in debilitated subjects. The lungs have been neglected to the expense of other organs.

Properly conducted lung exercise will aid digestion, increase the desire for food, improve nutrition, increase the weight, add to the vital force and lengthen life.

A STUDY OF SCARLET FEVER AT HIGH ALTITUDES.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. N. HALL, M.D., AND WM. P. MUNN, M.D.

DENVER, COL.

We wish to present briefly the data which we have at hand upon 285 cases of scarlet fever treated by us separately in Colorado during the years from 1855 to 1894. They were all seen at altitudes varying from 4,000 feet above sea level to 5,500 feet. It is to be regretted that many details which would have added

much to the interest and value of the report are lacking in certain of the cases. One hundred of these cases occurred in adults, this unusual proportion being accounted for by the fact that many homeless adults were seen in hospital, while suffering from the disease, whereas children were doubtless more generally cared for at home.

Two hundred and forty-six of the cases were comparatively mild in nature, recovery ensuing without serious symptoms. In these no exact record was kept of the presence of albumen in the urine, but it was found in very many of them. The cervical glands were enlarged in about 20 per cent. of the cases, suppurating in about 2 per cent. Quite a number had serous or bloody discharge from the nose but not of a serious nature, apparently.

One case was complicated with spasmodic laryngitis, and two with nephritis, all recovering without serious developments. Several had otorrhea, one double, but the exact number is not at hand. Two had mild attacks of rheumatism, with complete recovery.

Of the thirty-nine severer cases, two adults died of uremia, one child of 5 years of convulsions on the second day, and a babe of 2 years on the fourth day of broncho-pneumonia. The other thirty-five cases presented membranous exudation in the throat, nine dying, making a total of thirteen deaths out of the entire 285, or 4.5 per cent. The nine deaths out of forty-three, mentioned as occurring from membranous exudation, give a percentage as compared with the total mortality of sixty-nine. The two uremic cases formed 15 per cent. of the total mortality, the other causes combined also making 15 per cent. (Fractions omitted.)

If we omit the cases complicated with membranous exudation, we have 250 cases with 4 deaths, a percentage of only 1.6. Counting only the membranous cases the percentage of mortality is 25.7 per cent.

Of the thirty-nine severe cases, nasal discharge existed in most of the fatal ones. As in diphtheria, its appearance was indicative of great danger. Abscess of the neck occurred in one case, and paralysis of the soft palate in one, both being of fatal character.

There were observed thirty-five cases in which practically scarlet fever and diphtheria were coincident, if we apply the latter term to those cases in which a membrane having the clinical characteristics of the membrane of diphtheria appears in the throat. There were thirteen instances in which diphtheria alone was contracted from the two diseases combined, two instances in which diphtheria alone was contracted from scarlet fever without membranous complication, and two instances in which scarlet fever was contracted from exposure to diphtheria alone.

These facts furnish very strong arguments in favor of the view that the membranous cases of scarlet fever are really what they appear to be clinically; that is, combinations of the two diseases in question. It should be mentioned further that most of the fatality was in the cases where the combination was seen, these cases assuming the dangerous character of diphtheria rather than the comparative mildness of scarlet fever.

As to the bacteriology of the disease in question, in the present series of cases no investigations were made, this being simply a clinical study. The only logical deduction to be drawn from the work of Klebs, L ffler, Prudden, Morse, Park, Baginsky, Heubner and

Jansen is, it appears to us, that at present diphtheria is a term which is used clinically to cover a number of diseases independent of each other to a certain extent bacteriologically, but of greater severity when the Klebs-Löffler bacillus is present, either alone or in combination. As no constant association of bacteria of any given type is found with the membranous cases of scarlet fever, we should certainly think it best at present to fall back upon a clinical diagnosis, and speak of scarlet fever with membranous exudate as complicated with diphtheria and not as an independent variety of scarlet fever.

In the treatment of the disease, there can be no doubt of the propriety of keeping the patient confined strictly to bed, until desquamation has been practically completed, nor of the advisability of milk diet. Liquor ammoniæ acetatis in large dosage has seemed beneficial. Calomel has been used freely for the bowels, and most of the patients have received the biniodid of mercury in doses of from one-thirtieth to one-tenth of a grain every two to six hours.

The beneficial effects of whisky, given freely where indicated by great prostration, and particularly in cases with throat complications, have been too clear to admit of doubt. We should certainly class it among the most powerful weapons for combating the depressing effects of the poison of the disease.

Before the general use of the peroxid of hydrogen, potassium chlorate and iron were used chiefly for the throat symptoms, but the former drug is, we think, much superior. There can be no longer any doubt of the propriety of attempting to destroy the bacteria of the disease upon the mucous membrane of the throat, and especially as it appears that in this way we are most efficiently promoting the avoidance of the exudation seen in the severer class of cases. Care should be exercised that in the liberation of gas from the use of the peroxid the middle ear is not harmed by its passage through the Eustachian tube, and especially as it might possibly carry the germs of disease into previously exempt territory.

For the discharge from the nose a 1 per cent. solution of carbolic acid has been used with satisfaction. Suppuration of the deep tissues of the neck has been relieved by incision as soon as distinctly made out.

We believe that the use of vaselin as an inunction after scaling has begun does not meet all the indications of the disease so far as the skin is concerned. By beginning the use of a 2 or 3 per cent. solution of carbolized vaselin at the first appearance of the rash, there can be no doubt that the burning and itching of the first stages of the disease are very greatly relieved, and it is rather for this effect that we should recommend its use early in scarlet fever than because of its antiseptic nature. It should be continued throughout the desquamation, as is commonly done by many practitioners.

The uremia, high temperature and other symptoms seen in connection with the severer cases, have been met by such measures as are indicated by their presence in other diseases with which they may be associated.

In conclusion, we may say that so far as appears from the cases considered, there seems to be no reason for thinking that this disease is especially modified by altitude, as it has seemed to us much like the same disease as seen in other localities.

LESIONS OF THE SENSORY FIBERS OF THE INTERNAL CAPSULE.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY H. G. BRAINERD, M.D.

LOS ANGELES, CAL.

Many years ago I observed that in certain cases of hemiplegia of central origin, there was a peculiar burning, neuralgic pain in the paralyzed limbs, arising some weeks or months after the apoplexy and continuing with more or less severity until death relieved the sufferer. In regard to this distressing symptom I could learn little from text-books concerning its cause or treatment. Recently having had a number of such cases occurring within a few months, I have tried to find some rational explanation of the symptom. To show the data from which I draw certain conclusions, I will briefly relate the history of five cases which suffered from post-hemiplegic pain of a burning, neuralgic character:

Case 1.—M. T., age 61. While walking on the street in the evening of Sept. 28, 1890, was suddenly seized with a peculiar sensation, and some loss of strength in his right arm and leg; felt dizzy and faint but was able to walk several blocks to his hotel; was not unconscious at any time, and never wholly lost the use of right arm and leg; face not affected and no aphasia, and in two weeks had made marked improvement so that he could walk without assistance; but the paresthesia and numbness have made but slight improvement. His condition in June, 1892, was as follows: General health fair; walks without limping, but says right leg is not so strong as left; the grip of the right hand as shown by the dynamometer is 42; left 78; decided loss of muscular sense in right hand, but can button his clothes with it if he can see the buttons. The muscles of the right shoulder and upper arm are not so large and firm as those of the left side. There is no reaction or degeneration nor has there been in either arm or leg. There is slight choreic movement of right arm and hand, but no rigidity or contraction, although he says they often feel as if there were. From these symptoms we diagnosed a lesion, probably hemorrhage, involving the posterior limb of the internal capsule, posterior to the facial fibers. Four or five months after the seizure he began to have, in the right side of face, right upper and lower extremities, a burning pain, feeling, he says: "As though the skin were too tight and a mustard plaster were applied." Pain is now worst in shoulder, arm and hand. It is not increased by motion, massage, electricity, or any local application, nor is it improved by them. He has worn out the coal-tar derivatives and now frequently resorts to opium to get relief.

Case 2.—P. O. R., male, age 59. In September, 1891, had an attack of brief unconsciousness followed by left hemiparesis, which was most marked in the lower limb. His heart failed steadily. Complained of pain of a dull character in his head, and of a severe burning pain in the left lower limb, which began a few weeks after the seizure and continued until his death in June, 1892. I saw him first in January, 1892. He was then much emaciated, tongue foul, complained of constant pain in head, mind somewhat impaired; face not involved. Grip in right hand 57; left 23; could move left leg, but could not sustain his weight on it. Knee jerk exaggerated. Complained of numbness and burning pain in left leg, especially in the calf; on account of latter was obliged to use large amounts of opiates. As he had a heart murmur and had the history of several attacks of acute rheumatism, the diagnosis was made of embolism of right lenticulo striate artery and subsequent softening, involving posterior portion of internal capsule.

Case 3.—J. Gould, female, age 35. In June, 1891, became suddenly unconscious and remained so for several hours, which was followed by left hemiplegia. The facial impairment, which was slight at first, soon cleared up; but the paralysis of arm and leg continued until her death sixteen months later. The diagnosis of hemorrhage involving the posterior portion of right internal capsule was made. About a month after the apoplectic seizure the numbness in left arm and leg began to be replaced by pain of a burning and neuralgic character, and soon became so severe that life was

a burden. Galvanism, faradism, ether spray, massage, and numerous lotions and liniments were tried in vain to relieve it; but nothing was of any avail except opiates.

Case 4.—A. H., female, age 61. In August, 1892, was suddenly seized with numbness over whole right side, and half an hour later could not move hand or leg; but there was no aphasia. The paralysis began to improve in a couple of days and the improvement continued for about two months until she could walk without much limping, but the hand remained much weakened. At time of examination, nearly a year after seizure, grip of right hand 15; left 39 on dynamometer; much impairment of tactile sense in left hand, and there is some trophic disturbance as shown by swelling and by the appearance of the skin. Diagnosis: Hemorrhage affecting a portion of both sensory and motor fibers of the posterior limb of the internal capsule. A few weeks after seizure she began to have burning pain throughout right side, which has been very distressing ever since, no relief being obtained from any external applications which she has been able to use.

Case 5.—N. B., female, age 25. In August, 1890, became suddenly unconscious and remained so nearly two weeks. Following this had paralysis, numbness, and various paresthesie of left arm and leg. As she had suffered from several severe attacks of rheumatism, the diagnosis was made of embolism of right lenticulo striate artery with softening affecting internal capsule posterior to facial fibers. Two months after seizure she had recovered the use of leg so she could walk with a crutch; but her hand and arm never regained any usefulness. About the time she regained the use of the leg, she began to complain of burning pain in her arm and leg. This pain was excruciating in character. For the relief of it massage, galvanism, faradism, and all sorts of liniments were tried with no relief. For a time antipyrin, phenacetin, and other remedies of that group relieved her, but eventually nothing but large doses of morphin would keep her comfortable. Nov. 17, 1892, the patient died, and an autopsy showed the cerebral lesion to be a softening of the larger part of the right lenticular nucleus, about one-third of the anterior and external portion of the optic thalamus, and about three-fifths of the posterior limb of the internal capsule, beginning about one-fifth posterior to the knee and extending to the posterior fifth; involving all the motor fibers posterior to the face fibers, and nearly all of the "sensory crossway" of Charcot.

In all of these cases the symptoms would indicate a lesion of the internal capsule involving, more or less extensively, both the sensory and motor fibers, and in Case 5 such was proven to be the case by the autopsy.

In all the cases the pain was of the same sort, being described as a "burning pain" by each of them, though each of them added other disagreeable sensations to their descriptions of the pain. Its severity varied, but each one complained more of it than of the motor paralysis, and more than of any other symptom resulting from the apoplexy. In each of the cases no relief was obtained from local applications to the painful limbs, such as ether spray and anodyne liniments, but was obtained by the administration of drugs that produce their effect upon the cerebrum. The character of the pain was much like that in peripheral neuritis; but I think we may exclude peripheral neuritis, from the fact that manipulation of the painful limbs did not increase the pain; no tenderness along the line of the nerve trunks was elicited on pressure; the failure of external applications to give relief and the absence of the action of degeneration. Neuritis being excluded, it would seem that it must be due to the central lesion. Landois' "Physiology," page 912, in enumerating the numerous sensory and trophic disturbances which may arise from irritation of the fibers of the internal capsule, does not mention the pain which I have described, but I believe that it should be added to the list. My theory is that it is a "referred sensation" very similar to that felt in an amputated limb and is

due, as in the latter case, to an irritation by the lesion of the sensory fibers passing from the periphery to the cortex, and hence is registered in the cortex of the brain as though it really had arisen at the periphery.

THE TREATMENT OF ERYSIPELAS.

Read in the Section on Practice of Medicine at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. M. ANDERS, M.D., Ph.D.

PROFESSOR OF MEDICINE, MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA.

The subject of the treatment of erysipelas falls naturally into three subdivisions: 1, dietetic treatment; 2, constitutional; 3, local.

1. Dietetic.—The proper attention to the diet is of first importance. It must be generous and composed of highly nutritious articles. If the temperature be high, liquid forms of nourishment alone should be administered, giving them in small quantities at definite short intervals. Rectal alimentation should be resorted to if the stomach rejects a suitable dietary. Based on considerable practical experience, I have been convinced of the fact that liberal feeding is of greater service to the patient than any recognized form of medicinal treatment.

This method pursued from the onset of the attack will not only serve to render the course of the disease more favorable than if less energetically fed, but will also lessen the liability to the more frequent complications.

Erysipelas is, as shown elsewhere, a self-limited disease in uncomplicated cases, when occurring between 20 and 50 years of age. In such, the necessity for vigorous alimentation is not greater than in other acute infectious diseases having a comparatively short course. Relapses occur in 11 per cent. of the cases and lack of attention to the patient's diet during the primary attack does unquestionably increase the frequency of their occurrence.

When the disease occurs in persons over 50 years, when complications arise and when the vital processes have been lowered on account of previous chronic disease, such as chronic nephritis, chronic phthisis, organic disease of the heart, etc., the course is much more protracted. The fact that these chronic affections also increase the receptivity of the human organism to the specific germ of erysipelas, as well as the mortality rate, must be recollected. Now it is in the classes of cases just mentioned, or in those in which the duration is prolonged, that correct alimentation is of paramount advantage, fortifying the vital functions, thus abridging the course of the affection. And since death is directly ascribable to exhaustion, with few exceptions in these instances, the life of the patient is thus frequently savable. Again when nourishment is exhibited judiciously, stimulants are required but rarely.

There can be no question but that the typhoid state of the system met with in this and other acute infectious diseases is often attributable indirectly to hypnutrition. I fear we have come to rely too much upon the local and constitutional agents in the management of this disease, to the neglect of proper dietetic means—a more potent factor.

2. Constitutional.—When, however, despite appropriate diet the pulse becomes feeble, the first sound of the heart indistinct and the tongue dry, undoubted

indications for the use of stimulants are present and must be heeded. When needful they should be given with a comparatively free hand. Stimulation is most apt to be required in aged and enfeebled patients suffering from the disease. I frequently order to be taken, from 16 to 20 ounces of whisky or brandy daily in divided portions.

The promptness with which strychnin acts leads me to place it among stimulating agents in the first rank, in these cases. In marked gastric irritability champagne is to be preferred. Numerous antiseptic remedies have been recommended but they have not been, up to the present, available in doses large enough to be of decided advantage. In view of the fact, however, that the disease is known to be caused by the streptococcus of Fehleisen further trial of antiseptic agents should be made. I have been for a decade or over, exhibiting to erysipelas cases, bichlorid of mercury in moderate sized doses throughout the febrile stage, and have found some degree of amelioration of the symptoms as the result.

The tincture of the chlorid of iron first used extensively by English authorities, was formerly regarded by most clinicians as a truly specific remedy. Perhaps the majority of authorities no longer accept this dictum. The profession, as the result of abundant experience, are for the most part of the belief that other preparations of iron are at least equally efficacious. While engaged recently in making a collective investigation into the etiology, complications, mortality rate, etc., of erysipelas, many facts relating to the treatment of this disease were met with and noted. They were taken from the records of several hospitals in Philadelphia. In this connection, reference will be made to points bearing upon the internal treatment alone, the local treatment being discussed subsequently. Through the kind assistance of Dr. M. Booth Miller, important data were obtained from the records of the Pennsylvania Hospital. The cases had been under the care of Drs. Lewis, DaCosta, Longstreth, Meigs and others. From 1872 to 1876 inclusive, there occurred in this institution seventy-four cases of erysipelas, which were treated by the use of the tincture of the chlorid of iron alone (the average quantity being 1 drachm daily in divided doses), with three deaths, or a mortality of 4 per cent. Of these, thirty-six were so-called idiopathic cases and thirty-eight traumatic, those proving fatal being idiopathic. The ages of those who died were 66, 49 and 20 years respectively. The immediate cause of death was noted as exhaustion in the first two instances. No complications were recorded in the first instance, but extensive bed-sores developed in the third, while the second fatal case, (aged 49) developed edema of the glottis. Twelve of the cases reported from the Johns Hopkins Hospital were treated with iron and stimulants, the results being about the same as in those reported from the Pennsylvania Hospital.

From 1877 to 1892, inclusive, some of the erysipelas cases in the Pennsylvania Hospital were treated by other methods which will be spoken of presently. In sixty-six cases, however, during the latter period, iron alone was administered. A single death occurred, and in this instance the fatal termination was due to edema of the glottis. Forty-eight cases were classed as idiopathic and eighteen as traumatic. It is quite probable that during the period in which this series of instances occurred iron was depended upon

only in the milder forms of the complaint for the following reasons: In the first place quinin was exhibited with the iron in very many instances and here the percentage of deaths was, as shown hereafter, quite high. In explanation of this fact we find that quinin was combined with iron in all of the severer types of the affection. That quinin is to be justly held responsible for the increased mortality (which occurred in the cases in which it formed a part of the internal treatment) is altogether unlikely. The value of iron is more reliably shown by the first group of seventy-four cases, above mentioned, than by the second, consisting of eighty-four cases, since in the first group *all* of the cases during the period from 1872 to 1876, inclusive, were treated by this remedy singly, while the death rate was only 4 per cent. These are favorable results when the status of the vital powers of hospital patients in general is kept in remembrance.

I have shown elsewhere that the general average mortality rate in hospitals is 6.57 per cent.; in private practice 4.16 per cent. Not a few of the seventy-four cases treated by iron alone manifested complications, and since some of these modify unfavorably the prognosis they should be mentioned here. In thirteen there were abscesses, (though it has been shown that this complication does not augment the death rate to any extent); in two, delirium tremens occurred; in two, general articular rheumatism and in one, scurvy. As pointed out in a previous paper,¹ preëxisting chronic affections render the outlook gloomy, but we find that one of the cases developed in the case of chronic pulmonary tuberculosis, another in a hemiplegic, both of which, however, recovered under iron.

The number of cases treated by iron and quinin in combination from 1877 to 1892, inclusive, was eighty-one, and of these fifty-five were idiopathic, and twenty-six traumatic. The average daily dose of quinin administered was from 12 to 16 grains. Ten cases proved fatal—a mortality of 12.3 per cent. The cause of death in two instances was acute Bright's disease; in two, delirium tremens; one, pyemia; one, exhaustion during fourth relapse; one coëxisting leg ulcer, and one cerebral sclerosis and bed-sores.

The complications noted from which recovery ensued, (while being treated with iron and quinin) were: Three suppurative otitis media; three abscess of the eye-lids; two delirium tremens; and bronchitis, sciatica, diarrhea, acute nephritis, bronchopneumonia, lobar pneumonia, iritis, abscess of foot, tonsillitis, angina pectoris, mastoiditis and fracture of the skull, one each. One instance arose during convalescence from typhoid ending in recovery. When such facts as the gravity of the type of the present series, and the character of the complications are kept in remembrance, the high mortality on the one hand and the apparent inefficacy of these remedies in combination on the other hand need excite no surprise.

My own experience in the use of quinin in erysipelas has been quite encouraging. During the past decade I have employed it in not less than twenty-four cases, its use being confined to instances in which the temperature touched 103 degrees F. With a single exception, in uncomplicated cases, (eighteen)

¹ The Complicated Conditions, Associated Diseases and Mortality Rate in Erysipelas, International Medical Magazine for October, 1893.

the nocturnal remissions were decidedly greater and the evening exacerbations less marked. In every instance, iron in some form (usually the tincture of the chlorid), was administered simultaneously.

During the years from 1881 to 1892, inclusive, twenty-six cases were treated in the Pennsylvania hospital by the use of pilocarpus, quinin being also associated in four of the cases, and in two, iron. There were seventeen of the idiopathic and seven of the traumatic variety, while the complications consisted in one delirium tremens, one acute articular rheumatism, one diarrhea and in two a relapse occurred. None of these proved fatal. These results create a favorable showing for pilocarpus, but it is to be stated that in but few cases were there manifested serious complicating conditions. Pilocarpus tends to produce increased nocturnal fall of temperature. The fact, however, needs to be emphasized that there is a strong disposition to spontaneous nocturnal remissions in temperature in this disease. Prof. J. M. Da Costa first used pilocarpus in erysipelas at the Pennsylvania hospital. His experience soon showed clearly that when given in the very early stage in one-sixth of a grain doses, hypodermatically, repeated three or four times at intervals of two or three hours, it often aborted the attack. It has been used by myself and others to a considerable extent at the Philadelphia hospital for its antipyretic effect.

If we accept its use to abort the affection, it is only in cases attended with high temperature, without decided morning fall, that pilocarpus should be employed. As a guide to the administration of this drug the conditions of the pulse and the heart can be relied upon. Pilocarpus, then, deserves a permanent place in the therapy of erysipelas.

But though I have been unable to obtain complete data, showing the treatment and its results from the records of the Philadelphia and Episcopal hospitals, the facts so far as ascertainable indicate that for twenty years the tincture of the chlorid of iron in large doses has been most frequently used with the same good results as at the Pennsylvania hospital. Quinin has been another favorite, administered in doses of 2 grains every three hours or 10 to 15 grains once or twice daily. In twenty-four cases gathered from various sources, ergot gave decidedly favorable results.

The treatment of severe symptoms. Of drugs, as antipyretics, phenacetin, acetanilid and antipyrin have been used at the Philadelphia hospital—a method of practice which I regard as being fraught with grave consequences. The best mode of reducing temperature is by means of cold sponges and cold or cool baths. The ice-bag applied to the crown of the head lowers temperature and simultaneously allays delirium and nervous excitement. For the marked nervous phenomena, such as pain, sleeplessness and active delirium, hyoscin hydrobromate, .01 grain hypodermically has been tried in numerous instances at the Medico-Chirurgical, Pennsylvania and Philadelphia Hospitals, and has given promise of being a valuable remedy. It should not be employed where the heart power is found to be greatly deficient. To fulfil the same indications the following remedies and recipes named in the order of their value and importance, have been utilized: Sodii bromidi grs. v, every two hours; or grs. xx-xxx at night; morphin one-eighth grain, and chloral grs. x in combination

every half hour for three doses; potassii bromidii gr. x, and tincture cannabis indica mx. at bed-time, atropin one-eightieth of a grain and morphin one-sixth of a grain hypodermatically.

Local Treatment.—Local measures have always held a prominent place in the treatment of erysipelas. The list of agents which have been used topically is long and embraces all classes of therapeutic substances. Thus in the three series of cases before cited, which were treated at the Pennsylvania Hospital together with a few collected from other sources, no less than fifty different remedies and preparations have been employed. Among those most frequently used were: Elm in thirty-seven cases, lead-water and laudanum in twenty; subcutaneous injections of carbolic acid (1 to 40) in eighteen; oxid of zinc in fourteen; corrosive sublimate in solution in fourteen; vaselin or cosmolin in thirteen; solution of bicarbonate of soda in nine, and benzoated zinc ointment, cocain with laudanum, and ichthyol ointment with lanolin, eight each. Among the many measures of which trial has been made in a smaller number of instances are, collodion, glycerin, laudanum, unguentum potassii et belladonna, unguentum plumbi, liquor acid carbolic, liquor chloralis, liquor sodii hyposulphites, liquor sodii sulphatis, aqua calcis, mistura ol. lini et bismuthi, unguentum sulphur, mistura ether et camphor, (employed until a distinct coat is obtained), iodoform and dry gauze once daily, together with such simple and yet curiously varied measures as to dust affected parts with flour, zinc and starch; sassafras, hot flaxseed, poultices (every two hours), cold water cloths, warm water cloths, ice-bag, wet cloths, lotions and so on.

I have mentioned a large number of external applications—by no means all of them, at the risk of exhausting the patience of my hearers, for the express purpose of showing thereby the highly unsatisfactory condition which has characterized the local treatment of this disease down to the most recent times. Doubtless many of the preparations before mentioned were prescribed for their effect in excluding the air. To my mind this is a leading indication, and to meet it I prefer carbolized vaselin or cool carbolized oil.

A knowledge of the microbic nature of erysipelas has led to the employment by the profession of various antiseptic drugs and their application in various ways. I do not doubt that it is along this line the greatest advances are to be expected. Allusion has been made to the injection of carbolic acid. Here the aim is to check the spread of the inflammatory process by inserting the needle at numerous points just beyond the inflamed border. This method, introduced by Heuter, has been much practiced by Henry at the Philadelphia Hospital, and more recently by Osler at Johns Hopkins Hospital. The success thus attained is encouraging and the method is especially applicable in erysipelas migrans. As before stated, the solution of the bichlorid of mercury, (1 to 4000) was used locally in fourteen instances; and to these I can add the results of twelve others, treated at the Medico-Chirurgical Hospital and in private practice. It may be applied in the form of lotions to the inflamed surface, or it may be injected beneath the skin, just beyond the border of the inflamed area as in the case of carbolic acid. Quite recently it has been recommended to scarify the affected part and follow by

the application of a solution of mercuric bichlorid. This method of treatment I regard as being most promising as well as rational. It was certainly, in three instances in which it was resorted to in my own practice, followed by rather brilliant results, moderating more particularly the severity of the local inflammation.

Dr. Morris Booth Miller observed in the wards of the Pennsylvania Hospital quite uniformly good results from the local use of ichthyol ointment with lanolin, in the service of Dr. Da Costa and others. Before making trial of the corrosive sublimate solution I had used ichthyol locally, but the results were not brilliant. Dr. Charles J. Whalen has reported, in a recent issue of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION (April 28, 1894), most strikingly favorable results in four cases of facial erysipelas, from the use of external applications of guaiacol—a mode of treatment which richly deserves a more extended trial.

Lastly, from the results of these statistical investigations into the subject of the treatment of erysipelas by personal observation and experience, I have arrived at the few brief conclusions following:

1. Proper attention to the diet is of paramount importance.

2. Stimulants are rarely necessary if the dietetic requirements are fully satisfied, but may be freely exhibited when indicated.

3. Of drugs, iron has been widely tested and found to be of great value, though it matters little which salt or preparation is employed.

4. Quinin when administered with iron, reduces the temperature, supporting at the same time the vital functions.

5. The use of antiseptics *per oram* is to be recommended.

6. Pilocarpus is in a small proportion of cases, powerful to abort the affection. To reduce temperature merely, pilocarpus should be employed in intense pyrexia, particularly where the favorable morning remissions do not occur.

7. The question of the local treatment of erysipelas has not as yet been set at rest, but agents intended to exclude the air and such as possess a germicidal power, especially corrosive sublimate, are highly useful.

8. That the erysipelococcus of Fehleisen which is found chiefly in the more superficial channels of the corium, may be attacked directly by the corrosive sublimate solution when the latter is used after scarification, is quite probable.

9. In erysipelas migrans the germicide should be injected beneath the skin, just beyond the edge of the part inflamed.

CHAMPAGNE AND STRYCHNIN IN CHEST TROUBLES OF THE AGED.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held in San Francisco, June 5-8, 1894.

BY G. EDWARD BUXTON, M.D.
NATIONAL CITY, CAL.

From these few remarks, which shall be presented briefly, do not conclude that my dependence upon the *vis medicatrix nature* is sublime, and faith in the medicinal value of drugs microscopic.

It is true my graduating thesis was upon the action of mind in medicine, but that was nearly a score of

years ago, before the faith cure fad and, as the years increase so does my confidence in medicine intelligently administered; when failure comes, as frequently it does, it is because the situation has not been fully grasped or the vital forces have ceased to act.

A physician living on the shores of San Diego Bay sees many invalids from east of the Mississippi, a large proportion of whom come from the Atlantic seaboard; and among them are many advanced in years who come expecting to find in our perfect climate the perennial spring of youth and by partaking of its waters live forever.

While the tendency of this equable climate is to prolong life and, in some instances to an astonishing degree, as has been shown by Dr. P. C. Remondino in his researches in this direction, still the aged come to us sick, and here the aged sometimes die.

It has always seemed to me important that the sick, the feeble and advanced in years, should make the long journey across this entire continent, not in a few days as is now customary—from the Atlantic to the Mississippi, from the plains of Kansas to the high altitudes of the Rockies, and then drop down again to the sea—but on the other hand, that they should come in slow stages from point to point, occupying weeks or months in covering this great distance.

I have myself witnessed great distress on the trains bringing invalids, due to these changes; and patients have repeatedly told me of their sufferings on the way, especially in the higher altitudes.

In former times when the journey was made by team from the Missouri, west, the change came gradually, and when this "golden shore" was finally reached the health seeker was in full harmony with environment and likely long to outlive the time limit set by Holy Writ.

We do not see in the region about San Diego Bay the same good old pneumonia, double and otherwise, that we used to treat, for instance, in Boston or Pittsburg.

There is pneumonia and pneumonia; and this probably in some measure accounts for the great variety of treatment which has been and still is in vogue; why should we follow the authority recommending phlebotomy who wrote fifty years ago, and of patients living in the humid, insular climate of England, and about the disease as seen among those malt liquor drinkers—those roast-beef and plum-pudding eaters. Why should such medical experience be taken as the guide to proper treatment of cases in the high altitudes of the upper Missouri Valley, or among the corn- and hog-fed malarial dyspeptics of the lower Mississippi Valley, or how can we reasonably follow treatment appropriate to the sturdy young farmers of New England, and apply the same remedies in cases among the closely confined factory operatives? Or how apply any one of these methods, successfully, to the health seekers coming, physically bankrupt, from the Eastern States, to our land of perpetual sunshine, fruits and flowers; here where he may freely partake with no restrictions, of ozone from nature's vast laboratory reaching thousands of miles to westward and from which, wafted by the gentle Pacific zephyrs, it comes to these Californian shores.

There being then chest troubles—pneumonia is the name which like the broad mantle of charity

covers so much—manifesting their symptoms under such a variety of conditions in the old, the young, the feeble and the strong, it does seem to me impossible to settle upon any one plan of treatment which shall be appropriate to all cases and fit all alike well; and so I have used for my theme not pneumonia, but chest troubles, that the range might be sufficiently wide to still embrace a treatment applicable.

I am ready to believe that all the methods of treatment recommended by men of large experience have been appropriate and helpful in many cases to which they were suited.

But it is to the condition of the lungs, alone or mainly, that we are to look for guidance in our treatment; or, rather, shall it not be in a large proportion of these cases to a tired and worn out heart, which if not relieved gives up the struggle; thus rendering all treatment useless and the end fatal.

“Find out the cause of this effect,
Or, rather, say the cause of this defect,
For this effect, defective, comes by cause.”

Bartholow says: “The mortality from pneumonia has been and continues to be a subject of warm discussion on the part of those who advocate some special plan of treatment. Accuracy in diagnosis and skill in treatment are such uncertain elements in the statistics of mortality, under different plans of treatment, that but little reliance can be placed on the statistical method as applied to therapeutic questions. In determining a fatal result in pneumonia so much depends upon the condition of the individual attacked, or the diathesis with which his system is tinctured, that no comparison of systems of treatment can be accurate that does not take note of them.

“Death is usually due to collapse—that is, cardiac failure, and obtunding of the nervous centers. This state is not necessarily caused by purulent transformation—it may be due to failure of heart, and lungs, and brain, before the end of the stage of red hepatization. The effects of the pulmonary changes are enhanced by the stasis in the cerebral veins and ischemia of the arteries and by cardiac paresis.”

It is surprising how little breathing capacity will suffice to carry on the functions of existence, as witness the model fashion plate for instance, or the “one lungers” in Southern California; which reminds me of the inspector on the boundary line who stopped three Chinamen trying to steal across to the United States; their names suggested Lung, and having lived some time in a health resort he entered them on his report as One Lung, Two Lung and Three Lung.

While we do not see any patients of the three-lung variety in San Diego County we do have many with but one, and often those with less than a whole one; and while these individuals do not, perhaps, consider themselves as strong as ever, still well enough to dispense with the doctor and able to attend to their daily duties.

And so in many of these pneumonias the lung capacity would seem sufficient to prolong life, but the blow falls upon the heart; it labors to force blood through choked channels and obstructions; the blood is impoverished by deposits of important elements; the heart muscles and others involved in the circulatory process weakened; the stimulating presence of oxygen in the blood current to encourage the over-worked organ absent, but, on the other hand,

unusual quantities of carbonic acid present with its enervating influence on nerve and brain. And just here is the indication for the treatment mentioned; champagne and strychnin.

I am not going to tell you just how these do good—presenting this, that and the other theory with which you are all familiar; maintain that the alcohol is a food, or that it prevents rapid metamorphosis, conserves force, soothes and anesthetizes irritable nerve centers and satisfies a complaining stomach; but I simply say they do good and recommend, if you do not already use them often, to hereafter use them oftener. The strychnin as a tonic to the heart and muscles involved, seems to back up and sustain the good work begun by the champagne.

Whiskey does not act as favorably when given in these cases and the benefit, I conclude, does not depend solely on the alcohol administered.

Do not ask me what particular brand of champagne I recommend, for no fee having yet been paid by the proprietors, and having before my eyes the recent and awful warning of Hart's Apollinaris water and Hammond's testicular juice I forbear to name the mark. I do not say California champagne is the best in the world—it is unnecessary, for the doctors are on the ground, and they will test the matter for themselves and so be able to determine.

In 1884, while practicing in the city of Pawtucket, R. I. I was called in consultation to an aged lady of 74 years; she had been sick a week with pneumonia: both lungs badly involved; temperature 105 degrees; pulse 140, weak and irregular; respiration rapid; expectoration of prune juice character; delirium of a low muttering type; mouth open, tongue dry and dark brown; with picking at the bed clothes and involuntary evacuations. The case seemed altogether hopeless.

I suggested champagne and strychnin, and her attendant requested me to carry out that line of treatment and assured me he would esteem it as a great personal favor if I would assume the entire care and take charge of the case, for he frankly admitted he believed the patient would surely die.

Hypodermics of strychnin, 1-60 grain each, were given until the system manifested an increase of the reflexes especially of the lower extremities, every two or three hours at first, then at longer intervals and, as matters mended, granules of the same strength were administered by the mouth twice or three times a day; and a tablespoonful or two of meat juice was given every two hours, followed with pepsin and washed down with two or four tablespoonfuls of champagne.

Within twenty-four hours there was improvement; the heart steadier and less rapid, pulse fuller, the muttering ceased, the muscular agitation was quieted and the bed pan called for when needed; additions were made to the nourishment, of hot milk and Vichy water; the champagne was given in larger quantities but less frequently, and in a few days the old lady was convalescent.

No cast-iron rules are given to regulate the administration of these remedies; every case will be a law to itself, and the amount required will vary—give here, as always, remedies for results—give until the pulse steadies, becomes slower and fuller, until the heart does its work better, and then be governed by the subsequent needs of the particular case.

Under our heading, “chest troubles,” we may speak of cases following la grippe; when the acute symptoms have subsided and that state supervened of prostration, with general collapse threatening, and the weight falling upon heart and lungs, with impeded circulation and the lungs in an edematous or hydrostatic condition; then, champagne and strychnin is appropriate treatment, and with suitable nourishment become ministering angels to restore and lead back to better things.

Quite recently an aged lady came to our city from Phila-

delphia; her family physician had carried her through an attack of la grippe and sent her here to Southern California, hoping she might more rapidly gain strength; but, in crossing the mountains by train she had taken what she called "a fresh cold," and reached her destination seriously ill; and when I saw her soon after she had a pneumonic deposit in the lower lobes on both sides.

She passed her eightieth birthday delirious with fever, rapid respiration and brick-dust expectoration; and the consulting physician did not help quiet the now thoroughly alarmed family by saying she would die; but she got her strychnin, champagne, meat juice and milk regularly, and in quantities which to my judgment seemed necessary to meet the indications; and she made a good recovery notwithstanding her last will had been made and her friends had said good bye.

In continued fevers, especially of that type which in Kansas City in the old days we called typhomalarial, this treatment is of great value; when the heart and lungs are distressed it arouses nature to make the supreme effort, and thus free the patient from those depressing influences which if not relieved would end in death.

In these days when the coal-tar products are so recklessly administered, the warning voice can not be too often raised, and a heart stimulating rather than a depressing course advised.

These few thoughts are presented rather as suggestions and not as dogmas; having no pet theory to promulgate and sustain at all hazards, no long list of cases and statistics has been made out, with quotations and extracts from an exhaustive roll of writers and authorities.

Some one has said: "The bibliography has become what the bearskin is to the British grenadier—it makes him look tall and imposing.

"You may be excused for being abashed in the presence of one who reels off a list twenty pages long of authorities consulted; unless he remind you of certain persons who make it a point of parading before you the names of all the eminent men with whom they have a bowing acquaintance."

My experience with this line of treatment during the past dozen years has not been invariably successful—what man saves all? But in a large number of cases, both in my own practice and coming to my knowledge, under the care of *confrères*, the results have been highly satisfactory; and such as that when compared with other methods have recommended this to more general use.

And while I do not expect to carry universal conviction by premises somewhat narrowly drawn, still I may expect this treatment or some modification of it in chest troubles of the aged, not only to maintain an excellent reputation but to increase in favor on closer acquaintance.

DIGITALIS IN THE TREATMENT OF CROUPOUS PNEUMONIA.

Read in the Section on Practice of Medicine, at the Forty fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1894.

BY WM. WATT KERR, M.A., M.B., C.M.

PROFESSOR OF CLINICAL MEDICINE UNIVERSITY OF CALIFORNIA; VISITING PHYSICIAN CITY AND COUNTY HOSPITAL, SAN FRANCISCO.

It is not my intention to claim that digitalis is a specific in the treatment of croupous pneumonia, nor to insist upon its administration in every case of the disease that presents itself, but simply to state why it may be used and when, in my opinion, it ought to be used.

During the last three years there has been consid-

erable discussion, both in Europe and America, upon the use of digitalis in the treatment of pneumonia, and the various writers may be divided into three classes: 1, those who claim that digitalis is a specific in the treatment of pneumonia cutting short or, as they express it, jugulating the disease if given in the first stage; 2, those who have found that the disease is but little if at all influenced by the use of digitalis; 3, those who on theoretical grounds maintain that the administration of digitalis in the treatment of pneumonia is inadmissible. It is not necessary for me to trouble you with the names of the gentlemen holding those different views; it is sufficient to state that in each class will be found men who are recognized in Europe and this country as prominent clinicians and reliable observers.

The objections urged against digitalis are that in pneumonia the congestion and consolidation offer an obstruction to the flow of blood through the lungs, so that the strain on the right ventricle is increased until that chamber is over-distended, and, as it can not empty itself, the blood accumulates in the venous system behind it; it is therefore urged that the administration of digitalis is liable to result in the heart becoming paralyzed in a heroic attempt to overcome the resistance. Such are the only important objections that have been offered, although one or two writers have devised a pharmacology of digitalis to suit their own views, as in the statement that "digitalis stimulates a weak heart by contracting the arteries and arterioles, by throwing the blood back upon the heart itself," a statement which is absolutely at variance with the results of experimental investigation. In estimating the value of a drug we must look upon all its effects and not only upon one. Briefly stated, digitalis increases the force of the systole by directly stimulating the cardiac muscle and intra-cardiac ganglia; it produces contraction of the arteries and arterioles which, together with the increased force, results in a rise in blood pressure; and lastly it shows the heart's action by stimulating the vagi and thus prolonging the diastole. Clinical experience shows that one result of these combined actions is to diminish venous plethora.

It would appear that in the study of the question before us there is a tendency to regard the divining power of the right ventricle as the only power by which the pulmonary congestion and the tendency to venous stasis can be overcome, and also to look upon the obstruction to the pulmonary circulation as the essential cause of cardiac failure; a very few minutes reflection will show that both experimental and clinical observation makes such a position untenable.

The depressed cardiac action in pneumonia is due to a variety of causes, chief among which are: 1, the toxic influence in the nervous system of the specific poison and the proceeds of tissue waste; 2, the pyrexia influencing not only the cardiac muscle but also the nerve centers; 3, the obstruction to the circulation through the lungs. It would be foreign to the purpose of this paper to enter into a discussion of these causes at present, but nearly every one can recall cases of pneumonia occurring in persons of fairly robust constitution where the disease assumed an adynamic type from the commencement, and cardiac depression was marked before the pulmonary congestion was at all extensive, affording positive evidence that other causes than obstruction to the cir-

culatation through the lungs are accountable for the cardiac depression. Again, when crisis takes place the pulse becomes slower and steadier although physical examination shows that the consolidation is fully as great as it was twelve hours previously when the pulse was rapid and irregular. Surely if the embarrassed heart action be entirely due to the condition of the lungs the change in the pulse should not be sudden but a gradual improvement as the process of resolution progresses. A recognition of all the causes that may lead to depressed cardiac action in pneumonia is a very important aid to the proper treatment of the case.

The motive power of the left ventricle is an important aid to the onward flow of blood through the lungs into the left ventricle. Some years ago Goltz and Goule conducted a series of experiments upon dogs which showed that the endocardial pressure during ventricular systole was:

Left ventricle on an average about 140 mm. (mercury).

Right ventricle on an average about 60 mm.

At the commencement of diastole a negative pressure was established.

Left ventricle varying from — 52 mm. to — 20 mm.

Right ventricle ranging from — 17 mm. to — 16 mm., or that the average motive power of the left ventricle at the commencement of diastole corresponds to about two-thirds of the propelling power of the right ventricle. It must be remembered, however, that this motive power does not remain constant throughout the diastole but is greatest at the commencement, and rapidly diminishes as blood enters the cavity. Further, this negative pressure is partly due to aspiration of the thorax during the respiratory movements, but a pressure of — 24 mm. has been obtained in the left ventricle after the thorax has been opened.

Again, the driving power of the left ventricle is nearly four times that of the right, and the increased momentum given to the stream of blood by its more forcible systole will do much to overcome venous stasis; furthermore the more vigorous and complete the contraction of the left ventricle the greater is its motive power, and consequently the more active will it be in abstracting blood from the lungs.

The prolongation of the ventricular diastole is of great advantage as it rests the cardiac muscle, gives longer time for the blood to pass from the overfilled lungs into the left ventricle, and permits the ventricles to become fully dilated. The contraction of the blood vessels is the only action that remains to be considered. It is very questionable whether this is an objection, certainly it is not so with all men, as many physicians recommend the use of ergot for the purpose of producing this condition in a marked degree. Personally, I never have known digitalis produce more than that slight amount of tension which most of us are pleased to find. It should be remembered that any strain consequent upon contraction of the systemic arterioles must come upon the left ventricle; and the increased motive power due to the more complete systole of the left ventricle will go far to compensate for any pulmonary resistance due to contraction of the vessels in the lungs. There are only two conditions in which it is evidently a disadvantage: *a*, when pneumonia occurs in a patient who has fatty or degenerated heart; *b*, when the patient is extremely plethoric and the physician

desires to distribute the blood as much as possible throughout the general system so as to delay its return to the right side of the heart. Under such circumstances the arterial contraction may be overcome by occasional doses of nitro-glycerin administered whenever the arterial tension rises higher than is desired.

While for the above reasons, and as the result of considerable clinical experience it is my belief that the administration of digitalis is not only permissible, but may be of great advantage in the treatment of pneumonia, I do not wish to be regarded as claiming for it any specific action; the hunt for specific remedies has not been profitable so far as the treatment of any disease is concerned, and the best results are still obtained by the physician who, as a consequence of knowledge and careful observation of each individual case, is able to recognize the approach of unfavorable changes and anticipate their effects by his treatment.

Recently some clinicians have given digitalis from the commencement of an attack of pneumonia, on the basis that the increased force of the cardiac contractions will tend to prevent or diminish pulmonary congestion; this is unnecessary. So long as the heart is doing its work well it should be left to itself and attention devoted to other parts of the treatment, such as reduction of temperature, elimination of waste matter, maintenance of the patient's strength, etc.; but just as soon as there is any sign of the heart becoming weak, digitalis should be given in such doses and with such frequency as the case demands. An average dose for such purposes is 15 minims of the tincture every three hours until there is some influence on the pulse, after which the dose may be gradually reduced.

Should the patient not come under observation until the venous system and right side of the heart are engorged to such an extent that there is too much blood for the ventricle to conveniently handle, I do not know of any treatment that will give better results than the administration of digitalis and the simultaneous removal of blood by venesection. In plethoric persons the same line of treatment is preferable to the administration of the vaso-dilators and cardiac depressants, such as aconite or veratrum viride, a process that has been justified under the claptrap phrase, "bleeding a man into his own veins," but which really means an effort to increase the capillary area and leave the tissues full of imperfectly oxygenated blood without diminishing the amount of blood that the right ventricle has to accommodate. As the systemic is quite distinct from the pulmonary circulation, an increase in the systemic capillary area will only relieve the resistance against which the left ventricle contracts by allowing a more ready flow of blood into the venous system, but will not diminish the current of blood that has to pass through the right ventricle and pulmonary capillaries in order that it may be properly oxygenated.

Digitalis frequently fails in the treatment of pneumonia because its action is essentially on the nervous system, and this is often deranged by the effects of temperature and toxic agents, so as to be insusceptible to the influence of the drug. Under such circumstances the simultaneous administration of strychnin will frequently increase nervous sensibility so that the effects of the digitalis can be obtained.

In closing, let me again protest against the indis-

criminate use of digitalis, and urge that the condition of the pulse should be the guide. Unfortunately, the introduction of the thermometer, sphygmograph and other mechanical aids to diagnosis have greatly supplemented the use of the fingers, and comparatively few of us can equal the physician of thirty years ago in interpreting the pulse. The thermometer and similar agents are invaluable in showing the existence of certain conditions; the fingers on the pulse show how the patient is being affected by them. When we give as much attention to the pulse as did our predecessors, and view the condition of the pulse in its relations to morbid anatomic conditions and the changes which these are liable to undergo, then shall we be able to follow a more rational line of treatment and more frequently conduct our patient through a serious illness.

DISCUSSION.

DR. AYER—Mr. President, I was very deeply interested in the paper just read. One thing that presented itself particularly to me was the Doctor's approval of venesection. I believe there are some cases of pneumonia in which no remedy is so efficacious as the lancet, but it needs to be used with very great discrimination. When the pulse becomes extremely feeble the expectoration is of a cellular mucous nature, respiration is very difficult and the patient appears to be in *articulo mortis*, I believe that venesection is the only agent that will restore him, or give him any prospect of recovery. I have used digitalis in my practice for many years, and in certain conditions of the heart I believe it is indispensable, but it should not be used, as has been stated by the author of the paper, without proper consideration. But that which specially impressed itself upon my mind was that we ought to return again to the much abused lancet in the severe and dangerous forms of pneumonia.

DR. DEWITT, San Francisco—Mr. President, I want to say in regard to the dose in pneumonia and in the latter part of the treatment, the paper, as I understood the Professor to read it, advocated as much as 15 minims. I want to say that in my practical experience I do not go beyond that, and I have never been able to give 15 minims to my series of patients, especially in continued doses, without developing what I term reflex action, which would really make me fearful to continue the dose at 15 minims. In many instances with this dose I have found nausea to follow. I have talked with a great many physicians in regard to this very treatment and many of them agreed with me, while others do not. I would like to know if the practitioners find much nausea in the latter stages of pneumonia.

DR. YOUNG—Mr. President, I have listened with great interest to the admirable paper just read. I do not know of anything that pleases us more than to have this tribute paid to those of us who in the past have followed this line of treatment. While I do not desire to be regarded as among the back numbers, I feel that possibly the institution of so many of the newer devices may possibly relegate the natural senses to the rear. I am very sure that good practice has been done by the touch and by the ear and therefore I appreciate especially that portion of the Doctor's paper.

With regard to the use of digitalis, I presume there is scarcely a man here whose hair has grown silvery, who has not had experience with it. I have never been able to use digitalis in the doses suggested by the Doctor. I generally accomplish my purpose with smaller doses. Among the remedies used none has served me to better purpose. I rise to commend both the papers that have been read, and regret that some discussion was not elicited by the first paper read before the Society, for it is a very exhaustive one and very interesting one from a scientific standpoint.

DR. FIRTH, Indiana—Mr. President, in the paper just read I have felt an interest from the fact that in my early practice, some forty years ago, I think I saved two patients by being suddenly called in where digitalis had been given. In both of the cases they had been given digitalis in the form in which we all used to carry it at that time, in the leaves; taking out a pinch and making a tea. In the first case the man had severe pneumonia. The doctor was giving digitalis tea in teaspoonful doses every two hours. I found him with a pulse of 40, the sweat profuse and he was very sick at the stomach. I told them to give him some whisky and set the tea aside until the Doctor came back. The man recovered.

The next case was something very similar—that one died and I think he died from too much digitalis. My experience has been that doses from 5 to 8 drops are all that I have been able to give without producing some sickness of the stomach. I believe that it is a most admirable remedy and I believe, as has been stated in the paper also, that we frequently find cases where the lancet is as valuable as the digitalis or more so. I believe in later years we have neglected to use the lancet as much as we should, and I think those of us who were in practice before the thermometer came into use had our fingers better trained than we have at the present time, when we have relied almost entirely upon the thermometer. I think the paper a valuable one.

THE CHAIRMAN—The gentleman in the rear of the room inquired about the dose of digitalis. We should like to hear any experience in that regard.

A MEMBER—If there is a drug in our rational materia medica that is unreliable, I think it is ordinary digitalis. In some cases we get an immediate effect, and in others we get little effect or practical failure on the part of the drug.

DR. KERR—I used the tincture of the United States Dispensatory.

There are a number of tinctures in use throughout the country; some use the German tincture, some the extract, some the tincturine and so on. In answer to the question of the gentleman calling upon old practitioners, I will say that I have used it for a great many years in the treatment of pneumonia, as well as of other diseases, but never for more than one or two doses in the quantity recommended by Dr. Kerr, and I have generally accomplished my end with small doses—4 or 5 drops. Seldom have I had nausea, except where there was an idiosyncrasy. With regard to the action of the drug in the larger doses there is almost universally nausea. I think the paper is one of exceeding value and of great interest to us all.

DR. HOLTON, Vermont—Mr. President, I think much of the paper we have just listened to, but I think we are getting away from the point in a measure. We want to bear in mind the action of digitalis; how it affects the heart through the nerve centers. When you first begin to give digitalis you get an action upon the heart in which there is occasionally an intermission, and then that intermission increases, and the result of that increased intermission of the pulse is the slowness of the pulse which you get. If you give digitalis in the inflammatory stage, as has been recommended in large doses, it seems to me you are simply whipping up a horse that is going about as fast as he can go, and by and by down he comes. The place for digitalis is plainly indicated when the action of the heart has become weakened. I think there should go with digitalis the nitro-glycerin in the early stages of pneumonia, so as to produce paralysis of the vasomotor system, keeping the blood away from the heart and not requiring it to pump against a dead wall of consolidated blood. Keep the blood in the extremities by dilatation of the vessels as much as possible, and you are accomplishing what our friend referred to as the purpose of venesection.

I am not so sure that our fathers were altogether wrong in their constantly using the lancet. They may have gone too far with it, but we certainly have not improved upon their treatment of pneumonia. When the whole vascular system is dilated from the poison of the retained material with pressure upon the brain and upon the vasomotor system, then give digitalis in 4 or 5 drop doses. I think the effect is better with this than with the infusion. If you want to get the effect upon the kidneys, use an infusion of digitalis. If the effect upon the heart, use the tincture. That has been my experience for a long time.

DR. JENKINS, Iowa—Mr. President, I want to emphasize what the last speaker has said. So far as my experience goes, there is nothing better than digitals and nitro-glycerin, particularly when you come to that stage of pneumonia which is near the crisis. When you want to give strength to the heart and you have that slow irregular pulse, probably coming partly from digitalis, and partly from failure of the heart itself, it is then that I have seen a good many cases tided over. In such cases I give nitro-glycerin and digitals with plenty of whisky, and I am certain that I have within the last two or three years saved a good many cases of pneumonia that formerly I would have lost. I have watched this carefully, and for that reason I mention this fact. I am sure that with these two remedies, with careful nourishment and whisky, we can save a great proportion of our asthenic pneumonia—those that seem to have about reached the crisis, but have not quite power enough to recuperate.

DR. AYER—Just one word more, Mr. Chairman. When the heart becomes irregular under the influence of digitalis I have never used nitro-glycerin, but have given freely of whisky and carbonate of ammonia. It is more immediate in its effect. It must be resorted to and followed up with the same degree of diligence, otherwise that irregular condition of the heart which indicates a great weakness (I will not say heart failure because I think we are running "heart-failure" too far into the ground) that we want to stimulate; otherwise there will be anemic astasia, and we will find our patients get out of our hands and in the hands of the undertaker.

DR. KERR—In regard to the different points taken up by the gentlemen discussing the paper: First, about the dose. The dose I recommended for an adult was about 15 minims of the tincture taken every three hours for a few doses until you begin to find some action upon the pulse, then diminish the dose according to the condition of the patient. Strange to say, I have found less nausea; in fact, it is rare that I get any nausea in pneumonic patients when using digitalis. I often have this trouble in pure cardiac cases, but in ordinary hospital or private cases it is rarely I am troubled with patients suffering from nausea. I do not mean to approve of the indiscriminate use of digitalis in all cases of pneumonia. Many cases do not require it at all. I think a great deal of trouble has arisen—and many of the cases where digitalis has done harm,—are not to be attributed to the use of the drug so much as to the bad judgment of the doctor. The amount of literature issued, the cheap medical literature of the present day, goes a great way to injure the practice of medicine. Many of these text-books are simply therapeutic memoranda which consist of a list of diseases down one side and a list of medicines opposite them. They do a great deal of harm, especially with medical students. They turn to one of these books and see digitalis recommended for pneumonia, regardless of the stage or individual character of the case. It is under such circumstances that the most of the harm arises. Those works are positively injurious. When men had less books and less literature with more expensive, and perhaps the average quality of the

books was better, a man had but few books but he would digest them and would do some thinking. But with this cheap form of literature and these many books that are put under our noses comes the plea for the busy practitioner that he has not the time to read, and a man gets into a routine and does not think what he is doing.

DR. JENKINS—I did not recommend in every case the use of nitro-glycerin, but in those that I have referred to.

THE USE OF TURPENTINE IN THE TREATMENT OF DIPHThERIA.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY E. W. KELLOGG, M.D.

MILWAUKEE, WIS.

"I dressed his wound, and God healed it!" modestly exclaimed Ambrose Paré, and his trite saying contains a truth too often forgotten in theory, and overlooked in practice.

No remedy cures. The utmost we are able to do for any disease is to remove, as far as possible the cause, and allow natural forces to carry on the various processes of repair, and the rational treatment of diphtheria whether situate in the fauces, nose, larynx or trachea should include surgical cleanliness as far as it can be attained.

Primarily, we must have correct hygiene; secondarily, nourishment, and lastly, drugs. The selection of a well ventilated room, isolation of the patient, absolute confinement in bed, fresh air and sunshine, the toilet, frequent changes of linen, immediate destruction of soiled cloths, thorough disinfection of the fauces, nose, throat and mouth, should not give place in any stage to internal treatment.

Few facts in medicine are better established than that this is a disease of local origin caused by the Klebs-Löffler bacillus, and that the subsequent constitutional symptoms are due to a poisonous principle secreted by this microorganism.

If this be true how important it is that the lives of these microorganisms be rendered as short and ineffective as possible. But whatever care may be taken, in a certain proportion of cases the larynx becomes involved, we hear the stridulous inspiration and crowing cough, and every physician knows the usual sequel.

There are exceptional cases of recovery, possibly one in ten, but the great majority die. In hospitals with trained attendants and all the numberless advantages which attend hospital work, tracheotomy and intubation doubtless save many lives.

Johann Bokai reported 109 intubations with 37 per cent. recoveries; Rauchfuss 85, with 30 per cent. recoveries; Muralt, in 318 tracheotomies, had 35.6 per cent. recoveries, and in 56 intubations 37.5 per cent.

Van Runke reported 365 intubations with 40.5 per cent. recoveries.

Marseilles intubated 68 cases with a recovery of 30.8 per cent.

Dillon Brown 350 intubations with 28.5 per cent. recoveries; Moll 92 cases with recovery of 40.2 per cent.; Waxham reported 1,072 intubations with about 27 per cent. recoveries; Agnew 11,696 tracheotomies with 26.25 per cent. recoveries; Monte, 12,000 tracheotomies with 26.8 per cent. recoveries; Lovet Monroe, 21,853 tracheotomies with a recovery of 28 per cent.

But it must be borne in mind that these are the

reports of specialists and are largely hospital cases. Tracheotomy in ordinary private practice is a dismal failure, shocking to the survivors, adding terror to a terrible disease and in the great majority of cases the precursor of a fatal result, disappointing to both physician and friends. Intubation in skilled hands has somewhat increased the percentage of recoveries but requires an extraordinary manual dexterity not possessed by the general practitioner, and only acquired by extensive practice upon the cadaver or living subject. This is an insurmountable objection to its general employment. Friends of the patient often will not submit to either operation, because so little can be promised, and thus we are often obliged to depend upon drugs for aid.

Prof. George suggested the use of oleum terebinthinae several years ago, on account of its antiseptic action upon the air passages. It arrests fermentation and putrefaction and is very destructive to all forms of bacteria. The bronchial secretions are increased during its use, and without doubt its effect in croup is largely due to its local antiseptic action during its elimination from the system.

I do not advise turpentine as a certain remedy. The majority of cases will die in spite of any treatment, whether medicinal or surgical. But I wish to urge its employment at least as an adjuvant to other treatment, and to insist upon giving it in extraordinary doses. It is useless to give a few drops hourly. It must be given in frequent large doses and persisted in as long as there is any chance whatever. A child 2 years of age will take a teaspoonful every two hours without exhibiting any untoward symptoms whatever. I have given it in nineteen cases and have had eleven recoveries.

Dr. Shimonek, of Milwaukee, kindly reported three cases with one recovery. Dr. Malone, of the same city, four cases with two recoveries, making a total of twenty-six cases with a recovery of fourteen, or about 54 per cent.

Case 1.—The first case was a Polish child 2 years of age. She had diphtheria for four days when croup developed and she grew rapidly worse. In two days after the laryngeal symptoms began, Dr. Walbridge, of Milwaukee, was called in consultation. The child was cyanotic. The sternum was strongly retracted with each inspiration and we informed the father that the only hope for the child was tracheotomy or intubation. This he absolutely refused, and Dr. Walbridge proposed trying ol. terebinthinae as an experiment, relating a successful case in which he had used it. The child was put on drachm doses every four hours and when seen on the following day was decidedly better though the laryngeal symptoms, difficult breathing and crowing cough were still marked. On the following day she was still better, and in three days all symptoms of diphtheritic croup had entirely disappeared and the child made a slow but complete recovery.

Case 2.—German boy 4 years of age, one of four cases of diphtheria in one room. He developed croup on the fourth or fifth day. His pharynx and nose were filled with false membrane. He, with the others, had been taking corrosive sublimate and iron in alternate doses. This treatment was continued and ol. terebinthinae was given in teaspoonful doses every two hours. The cough was easier after a few doses. The retraction of the sternum disappeared. Inspiration became normal and he made a complete recovery.

Case 3.—German girl, 10 months of age. When first seen she had no visible false membrane. She was in the third stage of diphtheritic croup, cyanotic and greatly depressed. She was given brandy and ol. terebinthinae in alternate hourly doses, but died in twelve hours.

Case 4.—A Norwegian boy, 5 years of age. Membrane was confined to tonsils and pharynx with a small patch at one corner of the mouth. Developed croup on the second day; characteristic cough and inspiration. Was given ol. terebinthinae in drachm doses every two hours for four days and

nights. The effects of the drug in this case were especially prompt and efficient. Although the laryngeal symptoms were continuous and severe, the effects of each dose could be seen in slower, easier respiration and a stronger pulse. He made a complete recovery.

Case 5.—A Polish boy, 4 years of age. He had been under the care of another physician for a week. Croup had developed when I was called to see him. A sister in the same condition died on the day before I saw him. When first seen his respiration was very difficult. The sternum falling in about two inches with each inspiration. He was given drachm doses of ol. terebinthinae every hour for six hours; then drachm doses every two hours. The following day he complained of some strangury and the turpentine was given every three hours instead of every two. The strangury disappeared during the day, and on the following day he was so much improved that the family discharged the doctor. He was on the street three weeks later.

Cases 6 and 7.—Polish girls. Two of five cases in one room. The treatment was not carried out. Four of the five cases died, five successive physicians being called in four days.

Case 8.—German girl, 4 years of age. Third stage of croup. No membrane visible. Had only been sick twelve hours. Teaspoonful doses were given every two hours, alternating with brandy, but there was no appreciable effect and she died in four hours from suffocation. There was no visible sign of diphtheritic membrane in this case.

Case 9.—Three days later I was called to see a brother 3 years of age, and found his throat filled with false membrane. Four days later it reached the larynx. He was put upon the same treatment and took 8 ounces of turpentine during the next four days. Slowly but steadily all symptoms of croup disappeared and he made a complete recovery.

Case 10.—German boy, 6 years of age. Diphtheria followed by croup. He was given drachm doses every two hours for nearly forty-eight hours, but there was no effect. He grew steadily worse and died from suffocation.

Case 11.—A Polish girl, 2 years of age. Four children in the house had diphtheria, and her throat was filled with false membrane. When first seen she was breathing with the greatest difficulty. The parents positively refused to have further medical attendance as she was expected to die but they promised to keep up drachm doses of terebinthinae every two hours. She made a slow but complete recovery.

Case 12.—A Polish boy, 4 years old; one sister with diphtheria followed by croup had died within a week. Every inspiration could be heard in any part of the house or out upon the walk. His face was cyanotic and his extremities cold. He was given drachm doses every hour during the day and every two hours at night. He grew no worse though the improvement was but slight for two days, when he began to improve and made a rapid recovery.

Case 13.—An Irish girl, 4 years of age. Treatment began about twelve hours after laryngeal symptoms developed, and it was kept up steadily for twenty-four hours but without benefit and she died from exhaustion.

Case 14.—German boy, 2 years of age. Diphtheria for six days followed by croup. Drachm doses were given early and regularly but without visible effect. He died forty hours later.

Case 15.—Polish child 1 year old. Diphtheria followed by croup. Strong retraction of sternum, crowing cough and difficult inspiration. He was given half drachm doses every two hours and improved from the beginning. The laryngeal symptoms disappeared in three days and he recovered.

Cases 16 and 17.—Polish boys 6 and 7 years of age, living in adjoining cottages. Both had marked symptoms of diphtheritic croup. The friends of both were informed that they would in all human probability die. Both were put upon drachm doses hourly. One died within twenty-four hours; the other slowly recovered.

Case 18.—German girl, 1 year old. Malignant diphtheria with invasion of larynx. Given drachm doses hourly, but without effect. She died some time during the following day.

Case 19.—German boy 3 years of age. Diphtheria followed by croup. Glands of neck considerably swollen, crowing cough and difficult respiration. Given drachm doses of ol. terebinthinae every two hours alternating with brandy and iron. Recovered in four days.

Cases 20, 21 and 22.—Dr. Shimonek. All in one family. Turpentine was pushed until each one took a teaspoonful every two hours. The oldest, 6 years of age, recovered. The other two aged 3 years 6 months and 1 year 6 months, were

not improved. Both were intubated and both died. The turpentine was commenced as soon as laryngeal involvement manifested itself.

Cases 23, 24, 25 and 26.—Dr. Malone. All cases of diphtheritic croup. All were given teaspoonful doses in milk continuously. Two recovered and two died from strangulation.

SOME SUGGESTIONS AS TO THE TREATMENT OF ACUTE MANIA.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1894.

BY JOHN W. GIVENS, M.D.

MEDICAL SUPERINTENDENT OF THE IDAHO INSANE ASYLUM,
BLACKFOOT, IDAHO.

The phenomena of mind are of such infinite variety and complexity that it is impossible to describe or measure them accurately. Likewise the changing conditions of the mind organs that accompany these infinitely varying and complex phenomena are so minute and complicated that they are fully known only to Omniscience.

There is a wide practical difference, however, between the regular coherent mental phenomena of ordinary health and the wild, incoherent phenomena that we have labeled acute mania. And so there is a wide practical difference between the soft pulse, the clean tongue, the moist lips, the cool skin and normal temperature of ordinary health, and the quick, hard pulse, the furred tongue, the parched lips, the hot, dry skin and elevated temperature of acute mania.

The mind organs are, especially the brain and the end organs of the brain which constitute, not a simple, but an exceedingly complex structure. The cells of which this structure is composed are as unlike and as independent of each other as the cells of the liver are unlike and independent of the cells of the kidneys, and the blood supply of different portions of the brain is independent of other portions. These different cells, of which the brain is composed, are associated with the most varying phenomena. Some of them may be very active while others are correspondingly inactive.

The end organs of the brain, which are as surely instruments of mind as the brain itself, are even more complex, and a recognition of their place in the mind system widens the field of mind to a vast area, but anything less than this would not comprise the realm of mind and its disorders. This is a most difficult field to work and there yet remains very much for observation and experiment to reveal, but it is now settled that the brain is a complex organ, associated in its different parts with widely varying mental phenomena. This fact of complexity of the structure of the brain has much importance in the practical treatment of the various forms of insanity.

It is now a well established fact that function, or the manifestation of that mysterious something we call life, as surely affects structure as it is certain that structure affects function, and indeed it is true that the fact of function influencing structure is of greater practical importance than the fact that structure affects function.

In the trouble now under consideration, where there is excessive incoherent mental activity, it is a question of the greatest practical importance as to what is to be done towards controlling this incoherency and excessive mental activity.

The tendency of thought, in regard to this and kindred questions, has been that as there was underlying this incoherent excessive mental activity an abnormal structure, though ever so microscopic, of the brain cells or an abnormal condition of the blood, which was the immediate environment of the brain cells, or some disturbance of the end mind organs, as eye-strain, it was not worth while to try to do anything towards controlling or affecting at all directly the abnormal mental phenomena, but the patient was practically left uncontrolled, both mentally and physically, so long as he did not kill himself or some one else. In fact, it was thought to be as foolish to try to control these abnormal mental phenomena directly, while the abnormal structural condition continued to exist, as it would be to try to prevent the escape of steam through the safety valve by tying it down as long as the fire was kept up under the boiler.

One eminent author suggested that it would be as reasonable to hope to cure chorea by restraining the involuntary muscular manifestations of that disease. I do not know from what the practice originated, but this is undoubtedly the most successful method of treating chorea that has been brought to our notice; viz., enforced muscular rest. But to return to our question. We are learning that in all excessive functional activity there is great danger of the structure being permanently and injuriously affected, and that to prevent this and to aid the structure in returning to its normal type, rest; or, in other words, functional activity diminished to the smallest possible degree, is of prime importance. This principle of affecting structure is justly permeating the whole domain of treatment of disease, is bringing infinite blessing and relief from suffering to the human family, and is giving to every individual a better opportunity to live his little day with all of his parts fairly intact, instead of faltering out a wretched existence with a partially dead or distorted mind. This diminution of functional activity applies also to the end organs of the brain which may be perverted. I have found it easiest to obtain physical rest by confining the patient to his bed and allowing only quiet orderly nurses about him. To arrest the incoherent mental activity, I have found that requiring the patient to memorize prose compositions, insisting on absolute accuracy, to be of great service. This substitution of regular, orderly mental operations for the disorderly, incoherent mental activity can only be done with more or less success, but much can be accomplished by persistent effort.

This rest in bed will accomplish more for the patient in a few days than will months of ordinary treatment, allowing him to be about. If the patient with only incipient acute mania could be put to bed and kept there until his temperature, pulse and alimentary canal were brought into a normal condition, most cases of acute mania would be prevented. And if, after the full appearance of the phenomena of acute mania, this practice were invariably and strictly adhered to, I believe most of the cases would speedily recover.

Now in regard to the diet of the patient. It is certain that what goes into the alimentary canal will be a very important factor in influencing the various phenomena of the patient. The toxic or impoverished condition of the blood must be corrected largely by the influence of this factor, and it is one of the

defects of medical thought and study that they give too little attention to food.

It is not to the honor of medical teaching that the graduate knows more about the preparation and properties of drugs, than he does about the properties and qualities of suitable foods in disease.

The blood of the acute maniac is in both a toxic and impoverished condition. The toxic element is perhaps the more important, especially if the patient is now in bed and needing only a minimum of nutritive matter. The question of food is now, as always, of first importance and should receive as careful attention as the medicine. And be assured, oh ye of little faith, that the food of the acute maniac is not a matter of indifference in determining his condition, but is one of supreme importance and should always be recognized as such.

An ideal food in this condition would be one that, in the first place, would be attractive to the patient; 2, one that would not easily break up into toxic materials; 3, one that would afford that degree of nutrition needed by the organism in its diseased condition; 4, such as would be favorable to elimination to the end that the toxins in the blood might be eliminated.

Such an ideal diet is furnished by fruits in large variety, raw and cooked, fresh and dried, bread made without yeast, the very best butter, cream and milk. Meat should be given not more than once a day and in very limited quantity, much less than the average patient desires.

The fruit, mostly cooked, will afford a diet that is attractive to the majority of patients. It does not break up easily into toxic matter; it affords what nourishment is needed and it, above all other forms of food, favors the action of the eliminating organs.

In acute mania the circulatory apparatus seems to be in a tense, almost spasmodic, condition, and I know of nothing better to allay this irritation than equal parts of tincture of aconite and tincture of gelsemium in one drop doses with half an ounce of water every hour during the waking hours. This also favors gentle diaphoresis with its elimination.

Strychnia has justly a high reputation in the treatment of acute mania of alcoholism and I think it is very useful in the ordinary acute mania of debility, toxemia and overwork, and it may be safely used in all cases where there is not an acute inflammatory condition of the brain or its membranes, but this is an exceedingly rare condition.

In regard to the use of laxatives, they will rarely be needed with the diet mentioned, but when they are needed they should be used in small quantities and given as often as each meal time, with a view to establish a physiologic function of the alimentary canal and not the pathologic condition of even moderate purgation, much less the violent purgation of the good old navel divider.

In regard to sleep, which is usually disturbed, its physiologic character should be kept in view and, while drugs probably can not produce that balmy sleep, "Nature's sweet restorer," because natural sleep is a resultant of antecedent conditions and these conditions can not be produced by medicines, I believe that when medicines are given for the purpose of inducing some kind of sleep they should be given in sufficiently large quantities to secure the condition of profound slumber, but not oftener than every second or third night and less frequently if possible. If the organism is clean and well nour-

ished—and this means physiologic perfection, sleep will take care of itself, and it is this cleanliness and nutrition of the organism that is the aim and end of all treatment, whether it be curative or preventive.

The physician who studies the preventive side of insanity; the side of broadest and grandest service to the human race, must come more and more to consider the elements of rest and food in connection with those defective organisms to whom a slight variation from health means the darkness and despair of insanity. In this work of prevention of the most blighting evil of our civilization, no effort or experiment should be left untried, for though,

"The brain within its groove runs evenly and true;
But let a splinter swerve, 'twere easier for you
To put the water back when floods have split the hills,
And scooped a turnpike for themselves and blotted out the mills."

A CASE OF LITHEMIA SIMULATING CEREBRAL TUMOR.

Read by title in Section on Practice of Medicine at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, Cal., June 5-8, 1894.

BY H. G. BRAINERD, M.D.
LOS ANGELES, CAL.

The researches of Garrod, Haig, Herter and many others have shown so conclusively that a gouty condition may be the cause, or at least an important factor in the production of asthma, bronchitis, pleuritis, gastritis and nephritis, and the careful study of the urine in migraine, chorea, neurasthenia and many cases of hysteria and epilepsy, leave little ground for doubt that the retention of the uric acid in the system is an important factor in their causation, and often the sole cause; but the symptoms usually attributed to organic cerebral disease are so rarely due to gout that I report the following case:

On June 20, 1893, J. S. was brought to me by his attending physician (Dr. King) with the following history: Age 47, married, farmer, weight in health about 180, height 6 feet, family history good, with the exception that an older brother died from some brain disease; for many years was very dissipated, but for the past ten years has been a moderate drinker. Denies syphilis, and all his four children are healthy. In the last two years has had a short attack of rheumatism, and considerable gastric disturbance, and quite frequently severe headache. In March, 1893, began to have a constant headache, lost his appetite, became easily fatigued, and for two months has been unable to attend to his usual duties. Exposure to the sun increases the pain in his head, and often without any exposure has paroxysms of intense pain. Has spells of vomiting, explosive in character, and occurring most frequently in the night or early morning. Complains of sudden seizures of vertigo, at other times numbness and weakness of left arm and leg. Thinks he has never entirely lost consciousness in these attacks. On attempting to walk there is a constant tendency to go to the left. Has grown dull and moody, irritable and very forgetful. Lies in bed most of the time in a semi-conscious condition, but sleeps only two or three hours out of the twenty-four, and then is distressed by frightful dreams. Is obstinately constipated, and has lost about twenty pounds in weight in the last few weeks. Has little fever and often temperature is subnormal. To-day, his countenance indicates suffering. Gait somewhat uncertain. Can not walk in straight line with eyes closed, but goes to the left. Can not stand on left leg alone, but stands fairly well on right leg. Face and neck have a congested appearance. Speech slow and hesitating, which his attending physician says is unnatural. Pulse 80. Temperature 99 degrees. Pupils moderately dilated, left more than right. Reaction to light sluggish; no strabismus. Says he can not read much without blurring of vision and increase of pain in the head. Percussion on skull is painful but no locality seems specially

sensitive. Grip of right hand shows 85 on dynamometer, while left only gives 54; and there is great loss of muscular tone everywhere, and decided left hemiparesis. Ophthalmoscopic examination shows retinitis in both eyes. Urine scanty; about twenty-four ounces in twenty-four hours. Specific gravity 1024; sharply acid; no albumen. No casts, but immense quantities of uric acid, urates and oxalates.

This train of symptoms, viz., persistent headache with frequent exacerbations of intense pain, the mental change, slowness and hesitancy of speech, vertigo, sudden attacks of left-sided numbness and weakness, explosive vomiting, rapid emaciation, slight left hemiparesis and slight double retinitis, led me to strongly suspect an intercranial growth; but the examination of the urine gave me hope that his condition might be due to lithemia, and accordingly all alcoholic stimulants were interdicted. A rigid milk diet, with the free use of pure water, and the daily use of one to two drams of soda bicarbonate, well-diluted, was advised, together with broken doses of calomel sufficient to keep the bowels freely open.

A few weeks later was gratified to receive a note from his physician saying: "I placed S. upon the treatment suggested and he made a perfect recovery," and I learn (May 18, 1894) that he has with slight exceptions enjoyed good health since.

The rapid and continued improvement, together with the decided change shown in the character of the urine under the line of treatment outlined, convinces me that this was one of the protean manifestations of gout.

HYSTERICAL VOMITING, RESULTING IN DEATH.

Read in Section on Practice of Medicine at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, Cal., June 5-8, 1894.

BY H. N. RUCKER, M.D.
OAKLAND, CAL.

During the latter part of February, 1893, I was invited by my friend, Dr. J. H. Todd, of Oakland, to see a single lady, aged 21 years, who was suffering from severe vomiting, which had continued for several days without abatement. The Doctor had patiently tried almost every remedy recommended for such conditions, without benefit. The patient could receive no food except by enema; the vomiting was so frequent that but little sleep was obtained, and she was fast becoming exhausted. After a careful examination, I was ready to agree with his diagnosis—hysterical vomiting. Nothing short of large doses of morphin, a half grain hypodermically, gave any rest, and this afforded but a short respite from the vomiting. Thus the case went on till death took place; the vomiting continuing in the very last throes of dissolution. A careful examination of the abdominal viscera revealed nothing to account for the severity of the symptoms. The stomach was slightly enlarged, and its walls somewhat attenuated. The uterus was normal in size, and free from disease. The ovaries were natural, except they were dotted over with irregular white spots about the size of an ordinary pea, which resembled more the effect of an application of strong carbolic acid than anything else it could be compared to. The ovaries were removed and preserved in equal parts of alcohol and water, and in three or four days the mottled appearance had entirely disappeared. The father of this patient is now 63 years old, and in fair health. The mother died suddenly in a convulsion at the age of 49, while talking to a visitor. She was of high nervous temperament, but always retained fair self-control. She suffered from a severe fright a short time before the patient's birth. The patient began menstruating at the age of 13, and was never so well afterward. At the age of 16 she went a year without menstruating; during which time she had free leucorrhœa. Shortly after the death of her mother, she received quite a shock in a railroad accident; was ill for a time, being very nervous and much depressed; menstruating profusely every two or three weeks. She was treated two

months in the East for "womb disease," by local applications and with electricity. She then changed her residence to California and was for a time fairly well. One evening while playing the piano, she suddenly became pale, nervous and tremulous, and was pronounced on the verge of convulsions. This prostrated her in bed for two months, during which time she suffered greatly from nervousness. After getting better, was treated again for five months continuously for "womb disease;" took a deal of medicine but was not benefited. She then placed herself under the care of another physician who treated her four months for "enlarged ovary," by electricity, with no good results. She then went to a hospital under the care of still another physician, who treated her for two months for "enlarged ovary;" was kept in bed on milk diet. At the end of the two months she had an attack of vomiting lasting two weeks, and was for three days without any food whatever; then became better and her appetite returned. The womb was then treated locally for a time, and afterwards she was treated by another physician by very vigorous massage over the ovaries. This had the effect to greatly increase her nervousness, and she began vomiting again, and in this condition she came under Dr. Todd's care.

Cases of such gravity are seldom met with; but cases of striking similarity fall to the lot of almost every physician. Such an instance adds wonderfully to experience, and teaches a lesson that should not be forgotten during a lifetime. Viewing this case on its merits as revealed by its history and the result of the autopsy, we become profoundly conscious of that lack of intuition and professional acumen which as physicians we strive to attain. There are two dominant features that simply eclipse everything else in considering the case of this unfortunate young woman: 1, a pernicious inheritance; and 2, the treatment during nearly all her adult life for something she never had. To a hasty consideration of these two propositions I invite your attention for a few moments. The physician's skill may be totally inadequate in eradicating the faulty inheritance which the hysterical or otherwise neurotic patient brings to him for treatment, and his duty lies, in so far as is possible, in recognizing its protean forms and directing the most intelligent treatment, chiefly of a hygienic nature. The laws of heredity and the survival of the fittest, pervade all nature. While we are powerless to change the temperament and character of individuals, we may do much to aid in maintaining their mental equilibrium, the preservation of health, and the well-being of their offspring. Impressionable subjects are so by inheritance; but nearly all show sufficient nerve stability till the age of puberty, at which time one of the great metamorphosing periods takes place, and a test of the equalizing forces is made. If perchance the individual has been surrounded by the best influences, moral and hygienic, the predisposition may remain passive, and the tendency to disease averted.

It has been said: "Every being has thousands of complex inherited traits that it can not use—latent gifts from the past." This thought suggests the boundless scope of our professional science in dealing with the hygienic conditions of mankind. In some respects our obligation is coequal, if not paramount to that of the clergy in directing and developing those traits which will best conduce to the welfare of the individual, and to that of his progeny for all time to come.

There is nothing in all the realm of nature that differs so essentially from its primitive type as does the human race; and on this account no one knows better than the intelligent physician the difficulties in the way of the successful practice of medicine.

The activity and vigor which gave such promise in early manhood, suddenly yields to inherent taints and the rapid oxidation of tissue; while the apparently grave physical condition will be changed by a renewal of normal functions, and existence crowned with ripening years. In one instance there is a fitness for adaptability to the exigencies of life as they may arise. In the other, there is sorrowful evidence of violated laws somewhere in the economy of nature. While the physician may find it impossible to bring health to one cursed by faults of inheritance, yet in passing to the consideration of the second proposition, the observation is offered, that too much care can not be used in the proper diagnosis of ailments in neurotic subjects. To tell a young, nervous, hysterical girl, that she has ovarian or womb disease because she may have leucorrhœa, menorrhagia or neuralgia, may have the effect to blight her life, and make an invalid of her during the remainder of her existence. Yet that is the mistake that was evidently made in this patient's case, and is too frequently made to the discredit of our profession. When she received the intelligence that she required treatment for ovarian and uterine disease, she was prepared to believe it; for her first thought was, that she had some of the symptoms that were common to those diseases. The suspicion and dread which she formerly entertained took full possession of her, and she became morbid on the subject.

When the treatment she was receiving did not afford her relief, she became despondent and expressed the fear that it would be but a question of time until she would be obliged to submit to the removal of her ovaries. When her physician failed to give her the hoped-for aid, she sought others in turn, with but one fixed purpose; that of being cured of disease affecting her generative organs. Had she received in the beginning kind encouragement, and the assurance of her medical adviser that she had no disease of her generative organs, but that the symptoms which she had observed were but the signs of anemia from an over-taxed nervous system, how different her life might have been. If with changed environments and proper medicinal treatment she had not grown strong and rugged, she would have at least been relieved of the horrible phantasm that haunted her day by day, and was in the main the expression of morbid mentality. During all the months of treatment she says she did not grow any better, but on the contrary grew worse. When we consider her history it does not seem surprising. What good could we expect from making topical applications at stated intervals to the uterine and vaginal canals of a young woman suffering from exhausted nerve force with all its attendant ills?

Exhausted nerve cells produce disordered circulation, resulting in general and localized anemia. Deficiency of blood supply, or of improper quality, result in irritation and instability of muscular tissue together with trophic changes. Hence in cerebral anemia, we may look for headache. Tremor is the chief symptom of weakened muscles. The heart deprived of nourishment, beats rapidly and unsteadily. Unnatural erethism, is due to exhaustion of the sexual powers, the result of lascivious thoughts and sexual excesses. The bladder may be affected with spasm, and become so irritable as to give rise to the suspicion of stone. In this connection I venture the assertion, without fear of intelligent contradiction, that in eight-tenths of

the cases of tenesmus and frequent micturition in females, when there is not positive evidence of organic disease, the fault is in the nerve centers of the sympathetic system. Through disturbed functions of the great sympathetic nervous system whereby the caliber of blood vessels are regulated, we may account for the increased secretion, at times, of mucous membranes. I offer the opinion, after a somewhat varied experience, that a large proportion of the cases of leucorrhœa, and menorrhagia, especially in young unmarried women, are due simply to neuroses. The best examples of this kind are to be found in the modern boarding school; or among those who have passed the regular course in such institutions.

A few lines from Dr. Thomas A. Emmet are pertinent to this question: "On the approach of puberty the nervous system becomes dominant in the female organization, and is as susceptible to external influences as the barometer is to atmospheric changes. But the simile is not applicable later on, since an impression for good or evil once made upon the nervous system, especially while in the adolescent period, is permanent. It may lie dormant in the after-life of the individual, but will almost surely be transmitted to future generations. . . . The girl's transition to womanhood is rapid; her organs of generation acquire a preponderating influence in her complex organism, and her nervous system is fully taxed to secure and maintain that general harmony of function which constitutes health. The slightest defect in her sexual organs may, through the medium of the sympathetic nerves, produce functional derangement elsewhere. . . . At the period of life when the young girl's whole nerve force is taxed for the full development of her organs of generation this force is deflected by hard study. . . . She is subjected to the emotional influences of music and light literature, which, in a sensitive nervous system, are capable of arresting the development of the uterus and ovaries. The spirit of emulation which is encouraged in all schools has a deleterious influence on the nervous system of girls at any age, but particularly about the time of puberty."

No examination of the brain and spinal cord was made in the case of this patient; nor would such examination have revealed anything, except, perhaps, a most patient and searching microscopic one. When the elements of an electric cell become unduly consumed or corroded, or the fluid too weak, the current loses force, becomes unsteady, or ceases entirely. In one sense, the illustration would seem to offer a ready solution of the real condition of this patient. The nerve cells were exhausted, had lost their functions, were worn out. Nerve counter-balance was gone, and the muscles of the stomach were thrown into spasms which nothing but death relieved. Two of her many physicians informed her she had enlarged ovaries; one claiming the left ovary to be as large as a man's fist; and said she would not be better till it was reduced. She continued worse instead of better, and I submit these morbid specimens for your judgment as to whether they bear evidence of ever having been enlarged.

Ingratitude.—Two of the principal hostelrys in the famed Adirondacks region notify the world that consumptives are not wanted as guests under their roofs. Another instance of kicking away the ladder after one has mounted. It was the consumptives who largely advertised and built up the region.

DIAGNOSIS AND TREATMENT OF DISEASES OF THE STOMACH BY THE STOMACH TUBE.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY ALFRED W. PERRY, M.D.
SAN FRANCISCO, CAL.

The diagnosis and treatment of diseases of the stomach, which had been so uncertain, has during the last few years become as satisfactory by the employment of modern means of investigation as that of any important organ. The use of the stomach tube and improved chemic methods of testing the stomach contents dates historically back only about fifteen years, yet it is within the last five or six years become popular.

Most disorders of the stomach depend chiefly for their painful symptoms and consecutive disorder of nutrition on fermentations, or abnormal accumulations in quantity or quality of the stomach contents. These fermentations may be the acetic, lactic, butyric, cellulose and others less known, which last produce various lately discovered poisonous alkaloids or so-called ptomaines.

In health the so far known conditions for normal gastric digestion are: Gastric juice containing 14 to 24 parts for 1000 of hydrochloric acid; an active peristaltic motion of the stomach; a proper amount of pepsin; a temperature of about 100 degrees F.; a complete emptying of the stomach within six or seven hours.

An absence or deficiency of any of these conditions disorders digestion to some extent and leads to fermentation.

The germs of the acetic, lactic, butyric and cellulose fermentations are always present in the gastric contents, but the above named conditions for normal gastric digestion do not favor their rapid development, except the lactic, which develops normally during the first fifteen to thirty minutes of gastric digestion, and it is then arrested and kept with the other germs from increasing by the augmenting hydrochloric acidity of the gastric contents.

A deficiency of some of these is frequent, but produces no disease for a long time, for these functions are largely complementary and failure of one may for a long period be compensated by greater activity of another. Digestion of albuminoids in the stomach may be absent for months by total want of hydrochloric acid, without failure of nutrition. The acetic and butyric fermentations, which take place in the absence of hydrochloric acid, are prevented by a more active peristalsis, and quicker emptying of the stomach.

USE OF THE STOMACH TUBE IN DIAGNOSIS.

By means of the stomach tube we remove portions of stomach contents at any period of digestion, and determine the amounts of hydrochloric acid, peptones, starch, dextrin, pepsin, mucus and of abnormal products, by appropriate chemic tests.

By the stomach tube we alternately fill and empty the stomach with air, to determine dilations and displacements by percussion.

The introduction of the stomach tube is generally easy, but sometimes impossible from the production of a spasm of the glottis. I have had cases where the tube introduced with great ease, seemed to be in

the larynx, although no air came through it. I was only certain it was not, when I found the same spasm of the glottis and suffocation was caused by touching the back of the pharynx with my finger. The use of cocain locally, of ice, and chloral by the mouth will often not present the spasm. I find it a good test where use of the tube is indicated to touch the back of pharynx with the finger; if this can be borne without suffocative symptoms, the use of the tube is possible.

The too frequent use of the stomach tube often produces a sense of soreness lasting several hours. I find that its use every three or four days is sufficient in most cases where indicated. In the intervals of lavage, an antifermentative is useful, and for this purpose I prefer resorcin in 5 grain doses immediately after meals. It is a derivative of phenol, has a pleasant taste, is caustic in very strong solutions, is a local sedative and antiseptic. It is usually given in 5 grain doses but 30 grain doses are not dangerous. It does not interfere with the conversion of starch into sugar by the ptyalin of the saliva, or the digestion of coagulated albumen by the gastric juice. This I have found by its action in a mixture of saliva and boiled starch containing 1 part per 1000 of resorcin, and also in an artificial gastric juice containing the same proportion of resorcin acting on boiled egg; 1 part per 1000 is three times the strength which would exist in the stomach, taking 5 grain doses after meals.

In the diagnosis of ulcer and cancer of the stomach, the stomach tube has great value, but the conclusions are not positive. In simple ulcer the amount of hydrochloric acid is increased above the highest norm of .24 of 1 per cent. In cancer the hydrochloric is absent or below .14 of 1 per cent. the lowest norm.

The mere presence of a cancer in any part of the stomach does not stop the formation of hydrochloric; it is only when besides the cancer tumor there is an infiltration of the greater part of the stomach walls with cancer elements that atrophy of the secreting cells occurs.

The treatment, by the stomach tube, of emptying and washing out the stomach gives better and quick results than any other in the following diseases: Acute gastric catarrh; so-called bilious attacks; chronic gastric catarrh; cancer of the stomach; obstinate hiccough; vomiting persistent; the various fermentations in the stomach; dilatation of the stomach.

Attacks of acute gastric catarrh, which from one to four days, are shortened to a few hours by lavage of the stomach.

Chronic gastric catarrh yields the most brilliant results to lavage; it is almost incurable otherwise. Relief is immediate; cure usual in a few weeks.

Obstinate hiccough threatening death by exhaustion is cured immediately.

The various fermentations in the stomach causing severe headache, epigastric and intercostal pains, lumbago, ecthyma, are promptly relieved and usually soon cured with their consequences.

Dilatation not depending on pyloric structure is usually the result of fermentations; occasionally after a severe acute disease it may be a cause of fermentation. It is only curable by the use of the tube. In cancer, lavage two or three times weekly gives great relief.

DISEASES OF THE ALIMENTARY CANAL. TREATMENT.

INTERNAL AND EXTERNAL HYDROTHERAPY. MEDICATION.

Read before the St. Clair County, Ill., Medical Society, June 7, 1894.

BY JAMES OSBOURN DeCOURCY, M.A., M.D.

ST. LIBORY, ILL.

Cleanliness is said to be next to godliness—a very old adage which I have found to be no less true in the treatment of all diseases which have come under my observation. It is my custom to first make clean my patient, outside and inside so far as practicable, by the free use of pure water and good soap. I have never seen nor had a bad result from the use of these agents. I am of the opinion that in many cases all the medicine that is needed is the free judicious use of water, abstinence from food, plenty of pure air and sunshine.

These agents, together with a clear conception and observation of the laws of hygiene will figure very conspicuously in the future of medicine.

While I am a strong advocate of the free use of water in the practice of medicine, I also have confidence in the therapeutics of drugs, and as I believe, have seen many good results from the intelligent use of them.

In the treatment of disease there are three distinct steps. They are: 1, a correct diagnosis—ascertaining the cause; 2, absolute cleanliness by irrigation internally and the free use of water externally, and by the use of disinfecting agents; 3, repair the damage—heal the wound—restore nature—rather assist nature in her work of reconstruction. This should be done by the skilful use of the tools best adapted to the work to be done.

In treating disease of the alimentary canal generally, and in the three following cases which I report to you I have endeavored to follow the foregoing principles. My results have been all that could be desired. They have been both interesting and profitable to me, and I trust they may be of some interest to this Society:

Case 1.—Miss Mary, aged 29; American; farm type; medium size and rather stout; was taken at night with pain in lower bowels, followed by watery stools.

I was called in the early morning, March 15. Found her excited and suffering very much pain in the bowels; also complained of severe headache. Temperature was slightly elevated. Pulse regular, but rapid and weak. She gave history of having had several severe attacks of ulcerative colitis, during one of which she came very near to death's door.

There was some tenderness on palpation and percussion over the major part of the abdomen and the bowel was very active in evacuating itself. The stools were thin, and contained mucus with a little blood. When food was taken into the stomach, especially milk, it was usually ejected in curdy masses within a few minutes.

The usual agents were used to abate the pain, to check the vomiting; also to restore the bowel to its normal condition.

The pain was greatly reduced and the rebellious condition of the stomach almost entirely overcome; but the bowel persisted in its active work of draining the system. The stools became offensive, containing more blood and mucus.

A portion of the lining membrane of the intestine about eight inches in length was passed with the feces the fourth day. Having a four ounce bottle of Marchand's glycozone, I concluded to try it. Soother internal agents were discontinued, and 2 drachm doses of glycozone given every four hours in a wine glass of water. The bowel was washed out morning and evening with warm soap water, followed by an ounce of tepid water containing a half drachm of tr. opium.

At the end of the first day after beginning the last method

of treatment there were marked signs for the better; and the patient expressed herself as feeling less bad. The treatment was continued with constant improvement in the case until the glycozone was all taken, at which time the bowel and stomach were under good control. Pain was all gone; and after a few days of convalescence the patient made a perfect recovery without any further treatment.

Case 2.—Ely, aged 32, medium-size man, general health uniformly good; a blacksmith by trade. First saw the case with Dr. S. at 4 P.M., March 30.

On arrival at bedside of patient, found him in what seemed to be a semi-comatose state. The odor of whisky was very marked. Examination of the matter ejected showed it to contain blood and mucus.

A few drops of chloroform with cold water were given, and a cold pack placed over the epigastrium to check the vomiting. The following powders were given to quiet the stomach and to move the bowel:

R Calomel grs. viii.
Podophyllin " ii.
Subnitrate of bismuth " xii.
Bicarbonate of soda " iv.

M. Pulvis. No. 4. Sig. Dose, one powder every hour.

The father, mother and wife of the patient gave the following history:

"For the last five years the patient has been drinking whisky, and for the past two years, in particular, he has been drinking too much. Last October he had an attack somewhat like this, but recovered in about one week.

"His general health has always been good. He has been drinking too much every day for a week now—keeping his whisky in the shop. He was well this morning. Worked in the shop until noon. Ate a hearty dinner, but was taken sick soon after eating and in a short time began to vomit."

Called again at 5 P.M. Found him quiet, but suffering. Left some Dover's powders to be given during the night if necessary.

At 2 A.M. March 31, was called again. Found him excited and suffering very much. Quick pulse and slight elevation of temperature. Gave him hypodermatic injection:

R. Morph. sulph. gr. $\frac{1}{4}$.
Atropin " 1-150.
(Parke Davis.)

His wife gave history of his vomiting at irregular periods until 10 P.M., after which time nothing could pass either up or down. Impossible to swallow water. Upon careful inspection, the whole mucous membrane lining the mouth and throat as far as could be seen was in a state of hypertrophy. Indeed, it was simply cooked. (Pardon the use of the word, cooked; but it expresses the condition.) The stomach, also, was in a state of inflammation. What was to be done?

Internal medication and alimentation was out of the question. Recognizing the emergency of the case, I determined, if possible, to dissolve the mucus about the affected parts, and to attempt to reduce the edema of the membranes.

The nose and throat, therefore, were sprayed every twenty minutes for awhile with Marchand's peroxid of hydrogen, and a 40 per cent. solution of the same used as a gargle every hour, until he could swallow water, which required forty hours. An enema of warm soap-water was given, and repeated, which produced a soft stool; and he expressed himself as feeling better.

The spraying of nose and throat, together with the gargle, also the enema, were continued every day. The inability of the patient to swallow made alimentation by the stomach impossible, to say nothing of the inability of the stomach to perform the work of digestion. Boiled milk and warm soups were regularly given in small quantities by the rectum.

On the morning of April 7, the whole lining membrane of the esophagus was expelled in the attempt to vomit. The membrane was neither broken, nor perforated; but was turned inside out. I have preserved the specimen in an alcoholic solution; and take pleasure in presenting it herewith for your inspection and examination.

There was some fever most of the time. The temperature running up as high as 102. The pulse varied from normal to 90, and a few times went up to 100.

The general condition of the patient was fairly good—indeed, much better than could have been expected.

There was very little headache, but a lancinating pain in the left hypogastric region, was greatly accelerated by coughing, and there was more or less tendency to cough during the first week.

I might state here parenthetically, that, in my

judgment, the trouble in the side had no connection with the condition of the mouth, throat and stomach; but, on the contrary, was entirely and wholly independent of it.

The history given of the case showed the last named trouble to have been produced some five years ago by prolonged arduous labor in which the abdominal muscles were in a constant strain for hours. Since which time the trouble has returned at different periods; and almost invariably following protracted, or great straining of the muscles in that region. The treatment given was palliative.

The odor coming from the mouth of the patient was offensive from the first, and continued to grow more and more offensive until after the expulsion of the membrane.

The kidneys performed their work admirably well. The stools which followed the enemata of warm water were rather soft and of a greenish color.

There were no hallucinations, no delirium; and for the most part sleep was good.

To prevent septicemia, to assist nature in the work of reconstruction, as well as to counteract any miasmatic influence that might be present the following preparation was given:

R. Quinæ sulphatis. ʒii
Acidi sulphurici aconi. cc. v
Aquæ camphoræ
Aquæ distillatæ añ ʒii

M. Sig. dose, one dessertspoonful every two hours, being alternated by half drachm doses of peroxid of hydrogen 40 per cent. solution given in a third of a glass of water.

Gradually, but slowly, the condition of the patient grew better, with the exception of one day, at which time he had no peroxid of hydrogen. The other medicine "would not work without the gargle," as he expressed it; but worked well together."

Immediately after resuming the use of peroxid of hydrogen he began to feel better. Saw him April 9. Found him in good condition. Pulse and temperature normal. Expressed himself as feeling very well.

He had been sitting up most of the time for several days. I recommended that the treatment should be continued for some time.

A week later his wife called at my office stating that she thought he was doing very well. Since which time I have had no official report from the case.

My candid opinion is, that of all the agents used, the one to which he owes the preservation of his life during the first seven days of the attack is peroxid of hydrogen.

Case 3.—Bennie, little boy, aged 9 years, orphan, German, was brought to my office May 20. Had diarrhea which had become chronic. Also had intermittent fever—mild form. He was very much reduced in flesh and emaciated.

Various and numerous agents from the list of ordinary remedies were used during the four succeeding days; but the diarrhea was growing worse rather than better. The stools became very numerous, the actions amounting to ten or twelve at night with as many more during the day. The malarial fever received appropriate treatment and was readily subdued.

May 26 I planned a new treatment. The patient was thoroughly sponged from head to foot once a day with tepid alkaline water. The bowel was washed out *clean* morning and evening with soap-water, just warm enough to be comfortable to the patient. After the bowel was washed out, 2 ounces of starch water containing 10 drachms of glycozone was thrown into the rectum and left to be absorbed. The internal treatment consisted of a milk diet, fresh water to drink impregnated with hydrozone, and dessertspoonful doses of glycozone taken every two hours during the day in a wine glass full of fresh water.

Improvement began with this treatment. The skin and bowel were kept thoroughly cleansed every day as well as medicated, the bowel being irrigated twice each day. June 4, the child was reported well. His general health is rapidly improving.

Good or bad, this treatment is purely original with me.

What effected the cure? My answer is this:

1. Removing the cause. This was done by abstinence from all solid food. Aliment was restricted to

small quantities of pure fresh milk, beef, and chicken soups, given at regular periods.

2. By cleansing the affected parts, as before stated.

3. By healing the wound. This was done by the use of glycozone which I have found to be one of the most reliable and rapidly healing agents that I have yet used. The hydrozone was used as a disinfecting agent.

May we not reasonably expect that during the remainder of the present decade, and for all time to come, internal as well as external cleanliness shall be to suffering humanity a boon—an heavenly unction.

NEW AND IMPORTANT PHARMACEUTICAL PRODUCT.

THE GLYCERO-ACID PHOSPHATE—A BRAIN AND NERVE TISSUE CHEMICAL FOOD.

BY EDWARD C. MANN, M.D.

NEW YORK.

Member Medical Society of the County of New York; Member Brooklyn Pathological Society; Honorary Member Medical Section Imperial University of Kharkof, Russia; Medical Superintendent Sunnyside Private Hospital for Diseases of the Nervous System and Mind, Inebriety and the Opium Habit.

Preventive medicine or the prevention of disease is the highest art of the physician. The prevention of nervous and mental disease in the nineteenth century, which requires of professional and business men such an enormous expenditure of nervous force, is to be accomplished only by the most careful attention to the due nutrition, stimulation and repose of the brain. A study of the physiology of the nervous system teaches us that nervous force is generated in or by the vesicular neurine and that the tubular or fibrous neurine conducts it. The normal activity of the vesicular neurine of the brain is the occasion of all our mental capabilities and powers. The little cells in the cortex of the cerebrum and cerebellum are composed of lecithin, from the Greek word, *Lekithos*, a nitrogenous fatty substance to which the formula $C_{44}H_{90}NPO_8$ has been given. It is practically a phosphorized fat. There is a great deal of glycerin-phosphoric acid in its composition. Nervous and mental health depend upon the conditions of the exhaustion and reparation of the nerve substance of the brain being maintained in a healthy and regular state. Nervous prostration or neurasthenia and mental disease result from the interruption or disturbance of these conditions. If nerve waste exceeds nerve repair, nervous and mental disease result from the interruption or perversion of nerve function. The conditions of civilization in the nineteenth century are such that there is a brain stimulation so excessive as in many cases to hasten the progress of brain decay and waste beyond the powers of reparation. The fundamental truth of physiology is the activity of the cell, and this activity being accompanied by its decay and demanding its renovation. The chemico-physiologic points of importance in the relative position of the brain cell are: Its relation to the nerve fiber, from which it receives and to which it conveys impressions, the taking and giving of which are the main cause of its exhaustion; and 2, its relation to the blood capillary, which exudes a plasma in which the cell is bathed and renovated, and from which new cells are formed to replace those which are finally exhausted. The only force capable of explaining any of the phenomena of life

is the chemic one and this only in a state of constant activity and change. Disease consists in a perversion of the functions of the structures of the body and if we expect healthy nervous and mental function we must furnish the proper chemic nerve cell and nerve tissue food, and this is the true physiologic antagonist to nervous and mental disease. It is with this purpose that I present to the medical profession the new brain and nerve tissue chemic food which I term the glyceric-acid phosphates. Its formula is almost identical with that of the lecithin of the brain cell and nerve tissue. Its therapeutic use is indicated in health by brain workers and in the educational period of youth where, if we are not very careful, brain waste exceeds brain repair, as a preventive of nervous and mental disease. Its therapeutic use is indicated in disease, whenever the patient complains of being unable to do what he could either mentally or physically when in health; when there is mental depression, neuralgia, loss of energy, lassitude and insomnia and in all cases of neurasthenia. I consider this preparation the most important adjuvant I have at my command in my private hospital in the treatment of nervous and mental diseases, in the treatment of inebriety and in the treatment of the morphin habit. If we do not feed the nerves, if we do not cause the brain cell to be bathed in a healthy blood plasma containing the proper materials for nutrition, we shall not cure the patient. In all cases this chemic food will be found to act on the nutrition of the centric nervous system which it tends to preserve in its organic integrity by building up the exhausted nervous system and having a special stimulating power which is a permanent and not an evanescent one. Patients taking it improve in personal appearance and in weight, and the mental irritability of overworked business and professional men and of nervous hysterical women, decreases in intensity and finally disappears, and a permanent cure will be obtained, to the satisfaction of the physician and of the patient.

A sample for physicians use will be sent upon application to the author, at 801 Madison Ave., New York.

CONSTIPATION AND DEFECACTION.

BY JOHN ASHBURTON CUTTER, M.D.

NEW YORK.

As some members complain of being written at over their heads, perhaps a few practical points as to the above may not be out of order.

Constipation is largely due to lack of nerve force; this lack may be caused by many things and it is the physician's business to find out what the leaks in the patient's economy may be. One man eats impoverished food; another works too hard; another is always troubled by his affairs; another may have some chronic disease sapping his vitality; in women pelvic disease takes away nerve force and causes constipation; habits of life are also to be blamed if they cause constipation; nature's calls can not be neglected with impunity, for if so, nature soon forgets how to do her regular work; want of exercise causes constipation, yet those leading sedentary lives who pursue a healthy course of feeding are not constipated. Indeed in studying constipation one has to make a most thorough examination of his patient often, by physical exploration, the use of instruments

of precision like the microscope, and the use of chemistry in the study of fluids; find out what the trouble is in the body, remedy that and the constipation will cease in time.

One summer I had three cases of constipation; two were men suffering from neurasthenia characterized by protoplasmic colloid discharges in urine, one case appearing like a man in the third stage of consumption; he was also a large user of sulfonal; his course of treatment was over two years, but has been cured; the third case was a woman who had chronic rheumatism; these cases led me a merry dance because what would help one would not relieve another, and for that matter no medicine helped any of them long; the causes of defective secretion and lack of muscular power in intestines were due to lack of nerve force.

As to treatment; fruits, sweets, molasses and so forth apparently cure constipation and are largely used; their effects are produced by fermentation and nature's efforts to get rid of the ferments; this action is really a diarrhea; give such cases lean meat and they become temporarily constipated; but feed them lean meats, and wheat preparations made of the whole wheat thereby retaining the gluten and using with such a dietary but few other articles of food, (for these neurasthenic cases must not have their digestive systems overwhelmed with too many foods to digest); feed them thus simply, giving them California prunes without sugar and such medication as may be indicated and the constipation will be cured in time and the patients will do better on a lean meat diet with whole wheat preparations and few other foods than ever before, because the feeding of such produces more nerve force; I say nothing about any other disease present or methods of life which must be treated; what I wish to emphasize here is to so feed that there will be the minimum of expense of nerve force in digestion and maximum of nourishment.

I believe the inordinate use of fruits bad, because they tend to acid fermentations and have not the chemic elements in abundance to amply nourish the body.

Medicines as Adjuvants.—The standard pill of aloin, belladonna, nuxvomica and podophyllin is a good assistant; fluid extracts of boneset, dandelion and cascara sagrada are fine tonics for the bowels and stimulants of the secretions. Exsiccated or chemically pure sulphate of soda in water is the best form I know of to administer salts; this salt and in this form is a finely powdered, beautifully white substance that has very little of the disagreeable taste of the sulphate of magnesia; one case that I had to treat of fibrous structure of the sigmoid flexure of colon, to whom I was giving under the skin from 1 to 2 grains of morphin daily, would have a fine movement by the use of this form of the salt.

I have used this preparation in many other cases and patients always express satisfaction when it is exhibited as not being unpleasant.

Glycerin by the bowel, either free or by Parke, Davis & Co's suppositories is a good adjuvant; some cases need a thorough flushing of the colon by enemas; a gentleman in this city has made a small fortune by the sale of his pamphlet on this subject claiming that it should be used very often; it is said that the Egyptians followed the same practice and that there are carvings on their pyramids to show such practice. But constant flushing of the colon is

also a dangerous thing; the putting of two to four quarts of water into the colon will not only clean out the big bowel but it will syphon or suck out of the small bowel the nutritive forms of food that are about to be absorbed and greatly prostrate a patient; I have seen the same thing in consumption of the bowels; if the patient could hold his bowels closed for two days he would get along well, but large daily movements prostrated him.

Beef tea and beef extracts, if largely used, will produce painless movements of the bowels; there are some beef extracts that should never be given; I will not animadvert against any now, but say that the fluid Bovril, as imported by Bovril, Ld., and as yet little known to the American profession, should be thoroughly tested.

Many cases of constipation do not drink enough water, whether hot or cold; there is not enough fluid in the body for the normal secretions and eliminative fluids in such; this condition should be remedied.

The injection of oil into bowels to soften hard fecal masses is not a new idea but one that is used altogether too little; to have a patient suffer for hours after passing a hard fecal mass is useless; *painless defecation* should be obtained by this use of sweet oil; it sometimes will stay in the bowels over night, gradually softening the hardened fecal concretions; movements will come in the morning with or without further assistance from drugs or chemicals according to the case.

In closing; let the physician find out in cases of constipation the leaks of nerve force; stop those leaks; feed plainly; use drugs as indicated *and pro- cure painless defecation.*

Heartrest Sanatory, New York, June 26, 1894.

SOCIETY PROCEEDINGS.

German Chirurgical Society.

Twenty-third Congress, held in Berlin, April 18-21, 1894.

FIRST DAY—AFTERNOON SESSION.

The President v. ESMARCH, presiding.

HABS, of Magdeburg. On eighteen cases of exarticulation of knee joint with demonstration of persons operated. Ten years ago Volkmann had uttered some objections against the proceeding of Prof. Hagedorn, of Magdeburg, who in the exarticulation of knee joint formed a square cut forward of the joint, enclosing the patella. He showed that the objections of Volkmann had no cause. The stump answers all uses for cosmetic and functional purposes. It is round and large in its surface upon which the leg leans. The scar is removed backward into the hollow of the leg, to avoid its being rubbed by the prothesis. The patella has shifted upward on account of shrivelling of the quadriceps muscle. A girl operated upon in this manner, fourteen years ago, told that she was wont to dance with her stump, half-nights long, without omitting any hours. A man could bear bags of two hundred weight, using no more help but a stick to give direction in marching. As for breadth and length the femur has somewhat reluctantly grown, being shorter for two to four centimeters than the sound bone. The stump will only bear its burdens and remain unaltered provided the marrow of the bone is closed up by compact bone-tissue.

KUSTER, of Marburg. A case of rhinoplastic cut of the skin of the arm, with demonstration of the patient.

Patient, a girl, was suffering with lupus of the nose in its lower part. The tissue was cut out into the sound skin and a patch formed out of the skin of the left arm, which was placed upon the defect. The patch was not transported bleeding (after the manner of Grafe) but in the stage of granulation. To prevent its getting dry it was placed between two linen shreds with bor. vaselin upon them and not cut through earlier than six days. The septum and side parts of the nose (also nares) were attained by incisions afterward so that the cosmetic result is satisfying now and will remain so, return of lupus and shrivelling of the patch excepted. This proceeding is best, especially to form the point of the nose, when we are bound to save the skin of the face.

SCHMIDT, of Stettin, has operated in the same manner in a case of much larger lupus of the nose and arrived at a pretty good cosmetic result, the cure having taken eleven weeks. However, a little shrivelling is to be remarked already.

v. BARDELEBEN, of Berlin, is of opinion that in using this method shrinking of the transplanted skin is ever to be feared, even when the graft is doubled. For total rhinoplastic, König's method (with transplantation of skin from the forehead) is to be preferred, the skin of the arm being profitable only for partial rhinoplastic.

KRAUSE, of Altona, has made use of the Vagliacorro method in one case of lupus to save the skin of the face. Good results.

HEIDENHAIN, of Griefswald. On resection of foot with dorsal cut. (With demonstration.) In 1886 Bardenhuer published a method of resection of foot, forming a skin cover of the dorsum and going through all the layer of soft parts. In seventeen cases of his, the tendons were not sutured after operation, and yet function was good, and immobility of the toes satisfying. He has imitated this proceeding in eight cases with the same good results.

RYDYGIER, of Krakau, adds that this method originated from Küster some years ago; the incision across the joint he had placed formerly higher than lower. He has often made use of this proceeding with good results, not only in bad cases.

BRUNS, of Tübringer, has made this operation several times and nailed the calcaneus to the tibia. Which form of incision is adopted is no matter. If incisions are made the length of the joint as usual, a T-cut may be added, either in front or back of the primary cut.

v. FÖGE, of Manteuffel, prefers the incisions by the length, by which the joint becomes anatomically accessible without hurting arteries or tendons. If the joint is then luxated, perfect insight is possible.

BARDENHUER, of Köhn, has made the forward cross-cut very often and with good results, even in cases of wide-spread tuberculosis. The incision passes upward to the tibia, downward to the tarsus.

HEIDENHAIN said that in using Küster's incision, which was higher up, the tendons should be sutured afterward.

PETERSEN, of Kiel. On the treatment of Colles fracture. He recommends in the typical fracture of the radius, after reposition of the fragments to maintain the hand toward the ulna and in flexion to the palm. The bones grow thus together in an excellent position. The case presented was that of a physician of Kiel.

v. ESMARCH could support the remarks of Petersen in all respects. The method is used also by him.

v. BARDELEBEN said this was the twenty-first proceeding in Colles fracture, and he would use it no more than his twenty predecessors, when the patient was unintelligent, and when the broken bones were not in good position beforehand.

LAUENSTEIN, of Hamburg. Notes for the treatment of

inward rotation in cases of pes-equino-varus congenitus. He recommends a machine constructed by him, whose principle is that the foot with its long axis is fixed to a staff, and thereby leaning upon the back parts of this staff and by its own weight, together with that of the whole leg, is forced to an outward rotation. The machine is apt for those children who can not yet walk, or for the after treatment of somewhat older children. It can also be used for the slow correction of pathologic inward rotation of legs.

SECOND DAY—AFTERNOON SESSION.

KÜSTER, of Marburg. Introductory notes on early operation of osteomyelitis. By osteomyelitis we take a purulent and non-purulent inflammation of bone tissue, which concerns not only the marrow, (but in the beginning of the disease seldom otherwise but also the periosteum and cortical substance of the bones. Symptoms are therefore different, although Carl Müller, of Halle, has stated for all cases the staphylococcus pyogenus as causating bacterium, which Küster approves. Jordan found that the bacteria intruded to the system by the respiratory and digestive tract, as well as by open wounds, which was afterward granted by Garre and Schimmelbusch. However, the latter experimenters by rubbing the staphylococcus upon the skin could only generate furunculosis and in correspondence with this fact, in children furunculosis is very often the preceding symptom to osteomyelitis. Osteomyelitis may also be established by scratching, which is proved by the fact that it occurs oftener in the poorer classes where bathing is not so frequent. Prophylaxis could, therefore, do much in this direction. When osteomyelitis is present, the suppuration should be cut off by bloody intervention, to remove the necrotic bones. Küster restricts himself upon the first operation, and having performed an early operation in twenty-seven cases, comes to the result that we should make the operation as early as possible for preservation of life. It was equal to herniotomy and tracheotomy. As for diagnosis, when we look only on the osteomyelitis of long, marrowed bones, there scarcely is a combination or sequel of symptoms so typical. Characteristics of the disease are: Appearance in early age before the growth of bones has come to a closing; high temperatures; aching, following pressure in certain places, as in hollow of leg, etc. Of the twenty-seven cases, fourteen were operated upon during the first two weeks. No deaths. Of three operated on the third week, there were two deaths. In the fourth and fifth week, results are again more favorable.

The operation consists in an incision in cases of deeply situated abscesses, and eventually chiseling up of bones which can be made in an osteoplastic manner (Lücke), although necrosis must be expected in the latter case.

KAREWSKI, of Berlin. On abortive treatment of osteomyelitis by operation, in the ambulatory of the Jewish Hospital, as well as in his private *clintelè*, Karewski has a very ample material of osteomyelitis, among which, however, early cases are exceptions. Karewski has made early operation in fourteen cases; operated during the first ten days of the disease, and were without grave symptoms of generalized septic infection—which cuts short every hope of success and where the local symptoms showed either none or very insignificant suppuration. Only in such cases are we permitted to speak of early operation. Widespreading suppuration, necrosis, inward metastasis bring always danger to life and to the limb contracted. We should look in our therapeutics to discern acute osteomyelitis in its first beginning, when the first symptoms of inflammation present themselves. Fever, disturbance of function, swelling of the limb and aching bones. The diagnosis is not so very difficult, if we remember that in children other diseases with the same symptoms are very rare.

Of the fourteen cases, six were operated before any suppuration could be found. The periosteum showed hyperemia and an edematous complexion. On the bone there was here and there to be found a fistula, thin like a hair, with some drops of pus coming out; the marrow flowed forth from its channel when this was opened, showed a reddish-blue hyperemia and speckled with fine points of pus. In other cases an abscess under the periosteum had developed itself, and the alterations of the marrow were more distinct.

Of the first cases three were on their third to fourth day, as could be seen; three on the fourth to seventh day; the rest on the seventh to tenth day. Of the first cases none had other heads of suppuration; of the rest, six cases either co-existing with the first remarkably, or presenting itself later on. The reckoning was made by the day of a trauma which had gone before, or by the day when the first symp-

toms were noticed. Karewski has always chiseled up the bone its whole length and totally removed the diseased marrow. The operation is not dangerous and is borne well by the youngest children, provided it is made with care against profuse hemorrhage. These fourteen cases all recovered in about six months without necrosis or fistula remaining. No disturbance of growth or relapses. Some of the younger children died later by other diseases. There were presented a boy operated on eight years ago; a girl two years ago; a boy operated eight weeks ago, in health now for four weeks; a man 50 years of age, operated upon for influenza-osteomyelitis who afterward died of septicemia already developed. Karewski is of opinion that the early operation of osteomyelitis may duly be called an abortive treatment of this disease.

In the discussion of these papers, NOLL, of Hanau, protects his countryman against Küster's objection, that osteomyelitis is caused among them by uncleanness. During 1878-90 he has not observed a single case, although practicing in the same region with Küster. Since 1890 till now, six cases in undoubtedly clean families. In this period not only manufactories of soap have been established at Hanau, but also public baths and school bathing rooms have been opened.

SCHUCHARDT, of Stettin, has in all cases of osteomyelitis done no more than open abscesses, and as early and amply as possible. He has neither trephined or chiseled up the bones, and most of his cases, even multilocular ones, have recovered without necrosis and fistula coming on. The opening of the marrow-channel of bone is to be reserved only for the gravest cases.

V. BERGMANN asks somewhat ironically whether Mr. Schuchardt saw necrosis at all in his cases. He replied: "None in those early operated upon." Thereupon v. Bergmann: "I presume necrosis will not fail to show itself in Stettin."

KORTE saw twenty-two cases of osteomyelitis in his hospital during three and one-half years. They were all grave cases and operated immediately, *i. e.*, the bones were opened and the suppurating marrow removed. Two cases died before the operation and six after. The rest recovered readily without any suppuration. Fever remained very often for some days after the operation, but the bone aching ceased at once. Large necrosis was never observed. Korte thinks osteomyelitis a severe generalized disease, occupying the whole body. Nevertheless he recommends opening of the bone to facilitate drainage of pus.

SCHEDE, of Hamburg, would, after his more early observations, (forty cases) come near in his opinion to Küster's, but on account of his later experience approves Korte's idea, that our help avails nothing in grave cases of osteomyelitis. He has treated 153 cases in 11 years. The femur was engaged in forty-six; the tibia in fifty-four; the humerus in ten; the forearm in three; the pelvis in twelve; the lower mandible in eleven cases; the rest in the short bones. Two classes of the disease are to be distinguished: One always fatal with the symptoms of generalized septicemia; the other more local but with so turbulent signs that decision is at once set on the knife's point. Falling of temperature does not, however, follow an extensive trephining of bone. After a fever lasting for weeks and months, the patient may die of pyemia. Of his 155 cases, 33, *i. e.*, 20 per cent. have died.

The most unfavorable of all is the osteomyelitis of the lower mandibles, which often follows extraction of teeth; and osteomyelitis of the pelvis.

LINDNER, of Berlin, is also of the opinion that osteomyelitis is a part of a general infection with varying malignity in different countries, but mostly in the regions around the Baltic. He could never prevent necrosis by operation.

NASSE, of Berlin, gives the statistics of the last eleven years concerning osteomyelitis in the clinic of Prof. v. Bergmann. Those cases are omitted which recovered after simple incision, or where after trephining no significant signs of alteration in the marrow could be distinguished. For these cases were doubtful. Thirty-seven cases were operated upon during the first three weeks of the disease. Of these thirty had osteomyelitis of a *single* bone, of which eighteen were trephined at once; several recovered without necrosis. In four cases multiple osteomyelitis set in, which in all probability in two cases had made its entrance before the first operation. One of these four succumbed. In the remaining eight, necrosis offered itself, but the disease remained localized. There had been made an incision outside of the clinic in two cases; recovery in one of them without necrosis. Ten cases were treated only with incision

without instantaneous trephining; two deaths. The rest had necrosis which were in general larger than in those trephined. Results were much more unfavorable in those which were brought into the clinic with multiple heads already. Of seven of these, four died of pyemia or sepsis. Those operated upon in the first week showed less favorable results than those operated upon later on. He could not, however, judge therefore that early operation was at fault. It only showed that the gravest cases were brought to clinic early. Nasse then runs briefly over those cases recovered without necrosis. Part of them were benign and of a more subacute course, but it was striking that of multiple cases, immediate trephining of secondary heads very often had had a full success. In the multiple cases which had recovered, secondary heads in larger bones were observed seven times. No necrosis in four of them. These results advocate an early operation and we could thus prevent necrosis sometimes.

In many cases the spreading of the disease had been prevented after necrosis of the primarily diseased bone had been cut short. But where osteomyelitis was multiple from the beginning, it was clear that operation would come short of this effect. Nasse laid some stress upon the age of the patients. Of ten patients under 5 years of age there were five deaths; of twenty-seven over 5 years, there were only two deaths.

SONNENBURG, of Berlin, is of the same opinion, as for the general character of the disease, as Schede and Korte. In osteomyelitis the same bacilli are found as in sepsis, viz: *Staphylococcus pyogenus albus*, and *streptococcus*. He should decide separately for each case, whether operation should be done or not. In one case a simple incision will do; in another the most extensive measures will be bootless. The cases here demonstrated as cured by early operation are cases belonging to benign osteomyelitis.

(To be continued.)

Medical Society District of Columbia. Report on Typhoid Fever.

[Concluded from page 126.]

In Dantzic, with a wretched system of privies, there were 10 deaths to 10,000 inhabitants. The introduction of an abundant water supply in 1869 produced no effect on the death rate. The city was sewered in 1872. In the following twelve years the average mortality was 2.4 and in the last five years was only 1.5. In Breslau in 1866, without sewers, the mortality was 15.2; in 1876, with sewers, it dropped to 5.5 to 10,000 inhabitants. In the cities of England, before any extensive sewerage systems were introduced, from 1850 to 1871, the mortality was 9.0; from 1876 to 1884, it was 3.6, the change following upon a general introduction of sewer drainage.

Brooklyn and New York have the best sewerage systems in this country. New York has 300 miles of sewers, but Brooklyn is perhaps the best sewered large city. New York has a mortality of 3.0 and Brooklyn 1.5. The mortality of Brooklyn, our best sewered city, is lower than Munich, Berlin, Hamburg, London, Vienna, which are the best sewered cities of Europe. And when a city is said to be sewered this means that water closets are substituted for privies, and the soil is kept free from contamination.

To turn now to other cities in this country, Baltimore, as Osler in his excellent report says, "has practically only surface sewerage. . . . The excreta pass, for the most part, into privy pits, of which it has been estimated there are from 70,000 to 80,000, occupying one-twentieth of the entire surface of the city, exclusive of streets and parks." Leakage, he says, unquestionably occurs in a very large number, with saturation of the ground in the vicinity. Baltimore has a mortality of 4.8 more than three times that of Brooklyn.

Washington, whose sewerage system is very good in most respects, but with fatal defects which diminish its efficiency and with that equally great danger from soil pollution from its 9,000 privies, has an average annual mortality of 6.2 in the last thirteen years. This is four times the death rate of Brooklyn, twice that of New York and the same as that of Philadelphia.

The daily pollution of the soil by the fecal discharges of our patients suffering from typhoid fever, with the resulting contamination of well water, must be recognized as the chief source of the diffusion of the disease. It is a case of auto-infection. We are daily breeding the poison which poisons us, and the inevitable round from intestine to soil, from soil to well and from well back to intestine, goes on and on with

most tragic uniformity. We sustain all the conditions favorable to rapid and perfect propagation of the bacilli. Granches and Deschamps have experimentally shown that typhoid germs placed on the surface of frequently moistened ground will penetrate nearly two feet into the soil, and will there retain life for five and a half months. They multiply rapidly in illy drained soil, live for an indefinite time in privy vaults, and have a much longer existence in cisterns and wells than in running water.

In Washington we supply all these necessary conditions—leaking privies for the reception of excreta and their contained germs, a damp and illy drained soil for their reception and rapid growth, neighboring wells for the resulting—the inevitably resulting—contamination of drinking water consumed by a thirsty population. What more conveniences can we supply? What more successful means can we adopt to raise our mortality to a point higher than that of Brooklyn, New York, Baltimore and Boston? We are among the most successful cultivators of the deadly bacillary plant in this country.

RECOMMENDATIONS.

The committee would urge upon the Medical Society the importance of taking the initiative in the effort to control the spread of this destructive but preventable disease, by urging upon our municipal government and upon Congress the prompt adoption of measures to remove the causes to which this report has drawn attention.

The measures to be recommended are:

1. The immediate abandonment of all wells within the city limits, exception only to be made in case of the absence of the Potomac supply, and where the wells, after repeated chemic and bacteriologic examinations, have been found to be free from all possible sources of danger. But even these to be abandoned as rapidly as possible.

2. Purification of the sewerage system already existing, by replacing as rapidly as possible all damaged or defective drains.

3. The introduction of new sewers in advance of other improvements in parts of the city not now supplied with drainage, and the extension of the system as far outside of the city limits as the rapidly growing population demands, so as to prevent soil contamination.

4. The adoption of some system by which the lower sections of the city can be more completely drained, and the risks arising from the backing up of tide water and sewage prevented.

5. The final and safe disposal of the sewage.

6. The early completion of the plans recommended by Col. Elliott, in charge of the Washington aqueduct, and now in course of execution, which have in view the sedimentation of the Potomac water, and ultimately the completion of works for filtration, the only proper method of purification.

7. The suppression of all privies and the enforcing of the law to make sewer connections.

8. Careful inspection of all dairies in the District from which our milk supply is drawn, and the enactment of a law by which no milk shall be sold in the District without a permit from the health office. The inspection should cover an examination at the dairies of all possible sources of infection, including the water supply.

9. The urging upon the members of the profession of a careful collation of all facts bearing upon the mode of infection in each case, and the advantage of reporting such facts to the society, and the propagation of the doctrine that immediate disinfection of the stools is the first duty of the physician as guardian of the health of the community.

G. L. MAGRUDER,

W. W. JOHNSTON,

C. M. HAMMETT,

Committee.

TYPHOID STATISTICS.

The most striking chart exhibited in connection with the report was one which showed the number of deaths from typhoid fever to each 10,000 inhabitants in sewered and unsewered cities on an average during five years, 1880-1884. In cities with good sewers and general water supply the averages were as follows: Munich, 1.7; Dantzic, 1.5; Frankfurt, 1.4; Breslau, 3.3; Hamburg, 2.6; Berlin, 2.9; Brussels, 3.3; London, 2.3; twenty-eight English cities, 3.2; New York, 3; Brooklyn, 1.5; Vienna, 2.1; Washington, 4.6; Washington (1885-90), 6.7. In cities without sewers or very imperfectly sewered the yearly averages for each 10,000 residents were as follows: Paris, 9.9; Marseilles, 12.8; Turin, 9.5; Naples, (1881-84), 7.1; Palermo (1881-84), 13.1; Catania, 19;

281 cities in Italy (1881-82), 9.5; St. Petersburg (1883-84), 9.9; Riga (1881-82), 15.8; Buda-Pesth (1877-81), 9.2; twenty German cities (1878-82), 9.8; New Orleans (water supply from cisterns above ground), 2.7; Baltimore (abundant water supply), 4.8; Cincinnati, 7.3.

BOOK NOTICES.

Clinical Medicine: A Manual for the use of Students and Junior Practitioners. By JUDSON S. BURY, M.D., Lond., F.R.C.P. Illustrated. Large 8vo. Cl., pp. 468. London: Chas. Griffin & Co. Philadelphia: J. B. Lippincott Company. Chicago: A. C. McClurg & Co. Price \$6.50. 1894.

"The chief aim of this manual," says the author, "is to assist the student and junior practitioner in the examination of medical cases." The book is divided into twelve chapters, as follows: Chapter 1, Introduction; 2, Symptoms for the most part Subjective in Character; 3, Examination of the Surface of the Body; 4, Temperature; 5, Examination of the Skin and its Appendages; 6, Examination of the Respiratory System; 7, Examination of the Circulatory System; 8, The Blood; 9, Digestive System and Abdominal Organs; 10, Examination of the Urine; 11, Examination of Puncture Fluids; 12, Nervous System. There are numerous illustrations explanatory of the text. In Chapter 10 will be found a most interesting feature of the book. The various fluids are classified according to the official nomenclature as Exudations, Transudations and Cyst Contents. The Transudations are those formed without pre-existing inflammation, as a result of obstructed or altered circulation. The work is an excellent one.

Manhattan Eye and Ear Hospital Reports. No. 1. January, 1894.

The insignificant character of our hospital reports as a class, has long been a subject of lament among American physicians. A few of our hospitals have published reports of scientific value, such as the Boston City Hospital, the Johns Hopkins Hospital, the U. S. Marine Hospital Service, and the Pennsylvania Hospital, but the fact remains that as a class these reports have consisted of lists of officers, financial tables, lists of donations of miscellaneous articles from a cucumber to a knitted stocking.

These details belong rather to the quiet committee room than to the public, and however it may thrill the generous impulses of the good ladies on the committee to be told that Mrs. John Smith on such a day donated a cake, a watermelon, or a jar of pickles to the hospital larder, it is questionable whether the general public care much about it.

The report under consideration has a number of scientific papers of the highest interest and value. It is well edited and carefully printed.

Inebriety or Narcomania; Its Etiology, Pathology, Treatment and Jurisprudence. By NORMAN KERR, M.D., F.L.S. Third Edition. 8vo. Cl., pp. 780. Price \$2.15. London: H. K. Lewis. 1894.

The second edition of this well known work appeared in 1889, and in the interval between the appearance of these editions public opinion has come to concede the strength of the position assumed by the author in the first edition, "that inebriety is a disease, as curable as most other diseases, calling for medical, mental and moral treatment."

The present edition is larger and more complete than former editions and contains much added matter, a study of etheromania, and eighteen other new chapters. It concludes with a chapter, "Drunk or Dying," in which it is clearly set forth to be the duty of the police, in cases where a man is found dead drunk to take the victim to the hospital rather than the station house—a position frequently taken in this JOURNAL. (See an editorial, March 3, 1894.)

The author predicts that the "inebriety center" will yet be discovered. The work is one of great interest and should be possessed by all interested in the subject, as a standard treatise.

Human Physiology. By JOHN THORNTON, M.A., with two hundred and sixty-eight illustrations, some of which are colored. Pp. 436. Crown 8vo. New York: Longmans, Green & Co. 1894. Price \$1.50.

The biologic phase which medicine entered into some twenty years ago is now bearing fruit in the more exact knowledge of the operations of the body. Some of the older works on physiology read like romances and were embellished with many literary graces, but the modern physiologist has so many facts at his disposal all of which must be prosaically catalogued, that no space is left in his book for "fine writing."

The volume before us is very much condensed and the general topics of physiology brought fairly up to date. A little more elaboration might make the book more readable, but as it is the "essentials" are all duly mentioned. We commend the book.

The Graphic History of the Fair; containing a sketch of International Expositions, a Review of the Events leading to the Discovery of America and a History of the World's Columbian Exposition held in the city of Chicago, State of Illinois, May 1 to Oct. 31, 1893. With nearly one thousand illustrations. Imperial, 4vo. Cloth. Chicago: The Graphic Company. 1894.

This book is a pleasant reminder of the great World's Fair which closed all too soon for those who were frequent visitors. This marvelous creation of the brain and sinew of the world seemed to increase the fascination of the spectator at each successive visit, and the Graphic history with pen and pencil and photography, makes it possible to visit in spirit the great White City on the lake, now, alas! only a reminiscence. The doctor's table in his waiting room, could have few more attractive books upon it than the volume under consideration.

On Double Consciousness. By ALFRED BINET. Chicago: The Open Court Publishing Co. Paper, pp. 93. Price 15c. 1894.

This monograph consists of nine chapters: 1, Experimental Psychology in France; 2, Proof of Double Consciousness in Hysterical Individuals; 3, The Relations between the Two Consciousnesses of Hysterical Individuals; 4, The Hysterical Eye; 5, Mechanism or Subconsciousness; 6, The Graphic Method and Doubling of Consciousness; 7, The Intensity of Subconscious States; 8, The Role of Suggestion in Phenomena of Double Consciousness; 9, Double Consciousness in Health. These topics are treated with the judicial fairness, the deep knowledge and the skilled literary touch characteristic of Mr. Binet.

NECROLOGY.

BOLING A. POPE, A.M., M.D., a native of New Orleans, La., died at Dallas, Tex., July 3. Dr. Pope was a graduate of the University of Bonn in 1859; one of the leading oculists of the South, and formerly a professor in the College of Physicians and Surgeons, New York. He was 69 years of age.—Sol. Etten, M.D., Port Jervis, N. J., July 7, aged 65. He was surgeon of the 124th N.J. Regiment during the war.—D. B. Woods, M.D., of Warren, Ohio, July 8.—George Warne, M.D., of Independence, Iowa, July 5. He was a member of the Iowa State Board of Health.—O.W. Berdan, M.D., of Cheboygan, Mich., July 8, aged 41.—C. A. Hentz, M.D., of Quincy, Fla.—Chas. Pemberton, M.D., of Asbury Park, N. J., July 13.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

SATURDAY, JULY 28, 1894.

INFANT FEEDING IN HOT WEATHER.

The first thing to be secured, in feeding a baby during hot weather, is to keep the little animal comfortably cool, in order to aid the processes of oxidation that are retarded by excessive heat. But there is the difficulty. In the spacious mansions of the rich, much comfort can be secured by opening the house at an early hour of the morning, and then closing it up for the day, imprisoning the cool night air for daily consumption. The introduction of the electric fan is a blessed boon to invalids and sick babies, quite equalling the punkahs with which oriental magnates render tolerable the air of their houses. But in the narrow quarters of the poor, such luxuries are out of the question. The baby must be either stripped entirely naked, or be clothed in a thin gauze or woolen stuff, and laid upon a rug in the largest and coolest apartment or corner of the tenement, and the mother or nurse must be instructed to give sponge baths often enough to render the child comfortable. If the lake-side or the sea-shore be accessible, great efforts should be made to secure a daily promenade by the water. Where ferry boats and excursion steamers exist, they may be utilized for the benefit of the broiling infants. If these advantages can not be secured, the little sufferer may be taught to swing in a hammock, and thus a little comfort may be obtained.

Having thus aided the child to procure fresh pure air with which to feed its red corpuscles, we must seek for a supply of pure water with which to replenish the fluids of the body. A discourse on filters and boilers for the purification of the family water supply is usually received with silent contempt, because such appliances are not within the reach of the poor. But with a little tact it is often possible to win the confidence of the mother so far as to inspire faith in the virtues of cold tea, or some other weak and harm-

less infusion that is made with boiling water, and drank after it has been cooled. In this way the tissues of the body may be irrigated with sterilized water without anybody but the doctor being wiser for the fact.

Now for the principal difficulty. Have we a healthy mother nursing her infant of less than a year—all goes well. But even in such case the doctor must see that the child is steadily gaining in weight. If during hot weather the nursling ceases to grow there must be at once a general investigation of the nursery. If the mother be hopelessly incriminated, a wet-nurse must be summoned to the rescue. But, if this be impossible we must set up a sterilizing battery, and prepare the best sterilized cow's milk that can be furnished. If, however, the health of the mother be found satisfactory, it will often suffice to add something to the diet of the baby. Every infant over six months of age, should be taught to drink milk from a cup; and as it approaches the end of the year, to eat crackers soaked in beef-tea, and delicate broths containing barley or rice. Malted milk, condensed milk, and various artificial foods are sometimes useful as the child advances in age and approaches the period of weaning. At this time an egg, or the white of an egg may be usefully given every day, either beaten up with milk, or served in clear broth. The child may be allowed to suck beefsteak, and to gnaw on chicken bones. Only by degrees should it be permitted to advance to a diet of vegetables and fruits, for every infant is at birth a carnivorous animal, and only after the lapse of many months do its digestive organs become adapted to the disposal of vegetable food. It is for this reason that so many infants of tender age succumb when compelled to take an artificial food that would be admirably nutritious at a later date.

The dietetic changes that are necessary in the treatment of disease are not to be considered in this connection. They must be studied together with the particular diseases that render them necessary.

ACROMEGALY.

It is a curious, though when we come to consider it, not a remarkable fact that almost every new disorder, as it is described from time to time, is all at once found to be rather frequent than otherwise. Attention once called to any special syndrome, and every one begins to recognize what had been overlooked or the importance of which had been underestimated before.

When in 1886, P. MARIE described the collection of symptoms that have come to be known as MARIE'S disease or acromegaly, it was thought to be a rare affection, but within six or seven years the number of reported cases is nearly or quite a hundred, and their number has been constantly increasing. We

meet readily recognizable cases on the streets in our large cities, and the prevalence and features of the condition have come to be discussed by the laity and have formed a theme for sensational articles in the daily press.

It is not to be understood that the disorder itself is actually a new one because its recognition has become more general. It may be becoming more frequent, like some other diseases, such as parietic dementia, for example; but it more probably is, like ectopic pregnancy, myxœdema, etc., only more watched for and recognized than was formerly the case.

In spite of the great number of observations up to the present, it can hardly be said that the true pathology of the disorder is any better known than when attention was first called to it, and it was connected with alterations of the hypophysis. In the comparatively small number of autopsies that have been reported, alterations of the pituitary body have apparently been recognized in the majority, but the exceptions are too numerous to prove the rule. Alterations of the thyroid are also very general, and these can be detected during life. On the other hand we have exceptional cases, like those of VIRCHOW and SARBO, where no change was detected in either the pituitary body or the thyroid, so a recognizable abnormality of neither one of these, either by itself or in combination with that of the other, can be positively claimed as an essential feature of the disease. Moreover, the effects of isolated lesions of the thyroid body and of the pituitary body, as experimentally investigated by VASSALI and SACCHI, and clinically observed and reported by BOYCE and BEADLES and others, do not correspond with the prominent symptoms of this disorder.

Notwithstanding the above facts, the very general implication of the thyroid and the hypophysis in this disorder is exceedingly significant as to its pathology. The relations of these two glandular bodies to each other and to the nervous system, especially the sympathetic system, have been shown by HOFMEISTER, ROGOWITSCH and STIEDA, and the importance of the pituitary gland in the nutrition of the body has been confirmed by the recent experiments of VASSALI and SACCHI, and the biologic deductions of LLOYD ANDRIEZEN. When, therefore, we find these important organs, one or both, so generally associated with this disorder, the deduction is a natural and a valid one that their lesions have a part in its mechanism. The exceptional facts of cases where both were apparently intact only indicate that we are not yet at the bottom facts of these special cases nor of the general pathology of the disease. There are functional diseases of other organs without visible lesions, and the possibility of such in these cases must not be altogether ignored. That disease of these organs does not always produce the symptoms

of acromegaly is not positive proof of anything, certainly not of their having nothing to do with it.

If we examine the various theories as to the pathology of this disorder we find them mainly unsatisfactory. That of KLEBS, that it is due to persistent thymus seems to have very little basis, and the same is true of that of VIRCHOW that it is a later degenerative phase of former (hereditary?) disease. To call it a neuratrophic disorder, as is done by some others, is doing little more than give a new name expressing our ignorance. It is superlatively a trophic disorder, involving as it does nearly every tissue in the body, and the suggestion of the influence of the nervous system is everywhere prominent. Its dependence on changes in peripheral vasomotor or sensory nerves, as held by certain authorities, is clearly as yet undemonstrated, nor is there anything more than a strong suspicion of any special part played by the sympathetic system in its production. It is worth remarking, considering the tendencies of modern pathologic ideas, how little has been said of a possible infectious origin, which is at least suggested by some of the symptoms observed in certain cases of acromegaly.

The most, perhaps, that we can say at the present time, is that acromegaly is a nutritional disorder or a combination of symptoms that is, in a majority of cases, associated with lesions (both hypertrophic and destructive) of the thyroid and pituitary bodies, two organs that seem to have a positive though not yet clearly defined influence upon systemic nutrition.

"RULES AND REGULATIONS" UPHELD.

Another illustration of the bias of courts in favor of legislation founded upon the police power of the community, to protect the public health by regulating medical education and medical practice, is furnished in the decision recently given by JUDGE WINDES of the Cook County Circuit Court in the case of *The People, ex rel. McCandless, vs. the Illinois State Board of Health*. The suit was referred to in the JOURNAL¹ during its trial, as the occasion for comment upon some defects in the practical execution of such legislation; and the points were then made that members of the faculties of medical colleges which confer degrees and issue diplomas should be debarred from membership on examining and licensing bodies, and that such bodies should ignore schools of practice by confining examinations to the fundamental branches common to all schools.

The case was a petition for a mandamus to compel the State Board of Health to issue to the petitioner a license to practice upon the diploma of a certain institution, and which license the Board had refused on the ground that the institution was not in good

¹ Schools of Practice. JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, June 30, 1894.

standing as a medical college, and its diplomas were, therefore, not recognized by the Board as the basis for license. The petitioner set forth that the refusal of recognition was arbitrary, prejudiced and unjust, inasmuch as the President and other members of the Board which determined the standing of the institution were members of the faculties of rival medical colleges, and had, therefore, a personal bias; had made no study of the tenets of the school of practice to which the institution belongs and, consequently, were not competent to judge of and pronounce upon its "standing;" and that the Board had refused to give the faculty of the institution a timely, full and impartial hearing. Other pleas—against the constitutionality of the medical-practice act, against the exercise of judicial functions by the Board in pronouncing upon the "standing" of a medical college, and against the right of the Board to establish and enforce rules and regulations for the conduct of medical schools—were also set up; but these the Court swept aside as matters already adjudicated and subject to further review only by the Supreme Court, to which it was assumed the case would be carried in any event.

The Court seems to have had greater difficulty with the methods of the investigation upon the results of which the Board refused to recognize the institution as "in good standing."

"There is much evidence on this point, pro and con; but it is clearly established from the evidence that the principal part of the investigation was delegated by the Board to a committee of three, only two of whom took part in the investigation, though the third member of the committee signed the report which was made to a full meeting of the Board. This report it seems was mainly the basis of the action of the Board, and was concurred in by the whole Board, which, at the time of the adoption of the report, refused to hear the President of the college with respect to the standing of the college. It fails to appear from the evidence that the college, or the relator, at any time ever had a hearing before the full Board, or ever had any notice to appear before a meeting of the Board for the purpose of a hearing.

"Whether this college was in good standing was a question of fact which it was the duty of the Board to investigate, and the Court says this upon the basis that the Act which I have read is not in contravention of the Constitution. I say it was the duty of the Board to investigate, not by a formal trial, if you please, but on notice to the parties in interest, and before the whole Board. It could not be delegated to a committee."

Then, after further dealing with the constitutionality of that section of the statute which empowers the Board to determine for itself the "good standing" of a legally chartered medical institution, the decision proceeds:

"It therefore seems to the Court that this act does not violate the Constitution in the respect claimed by counsel, but that the Board has gone beyond its power in depriving the relator of a certificate to practice medicine, and in holding that the college is not in good standing, because the Board has proceeded without proper notice to the relator and the col-

lege, and made its decision without that full and fair hearing which justice and right, as well as the law, seem to require."

Nevertheless, the Court—obviously reluctant to break the chain of precedents in favor of the legislative control of medical education and practice—refuses to grant the writ of mandamus on the ground that the Board has the right to prescribe and enforce rules and regulations for the conduct of medical colleges; that in the exercise of this right it has prescribed a certain degree of preliminary education before entrance upon the study of medicine; and that, failing to furnish evidence of such preliminary education, the "relator has not shown a compliance with the rules of the Board, and has not, therefore, established a clear and undoubted right to the writ of mandamus, irrespective of the question as to the good standing of the college. The writ will, therefore, be denied."

Licensing and examining bodies intrusted with these important judicial functions can not be too punctilious in their observance of the forms and procedures of other judicial bodies; and especially is this binding upon boards whose membership embraces those against whom colorable charges of prejudice or self-interest may lie. But it is gratifying to be able to record the discretion with which a learned jurist, while reprobating laches in this regard, preserves intact the spirit and intent of the law and vitalizes its letter by such a decision as that under consideration.

CORRESPONDENCE.

The Status of an Eclectic.

To the Editor:—In a recent number of the *JOURNAL* (July 14, 1894), a gentleman from Texas asks if a graduate from an eclectic college may be properly elected to membership in a local society affiliated with the *AMERICAN MEDICAL ASSOCIATION*.

There is nothing either in the Code or the Constitution and By-laws that prohibits such membership. In some, at least, of the subordinate societies, graduates from eclectic schools have been received. Indeed, men who have not received a medical diploma have been honored with offices in local medical societies in affiliation with the *AMERICAN MEDICAL ASSOCIATION*. It is undoubtedly true that some of these non-graduates, and many of those who have graduated from homeopathic and eclectic institutions, are more worthy of fellowship and membership in medical societies than some graduates of our best schools.

In Art. IV., Sec. 1, of the Code, we read: . . . "No intelligent regular practitioner, who has a license to practice from some medical board of known and acknowledged respectability, recognized by this *ASSOCIATION*, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship," etc. In the next sentence we have a definition by exclusion of the meaning of the word, "regular."

A common sense interpretation of this section and of other portions of the Code, would indicate that ours, being a *liberal* profession, should deal with such subjects in the

broadest possible manner. He who sanctimoniously draws his cloak around himself as he meets a conscientious and respectable practitioner who did not chance to graduate from the University of Pennsylvania, is certainly no honor to our guild.

It has been my pleasure to be personally acquainted with several good physicians who graduated, by accident, from homeopathic schools. Their practice is not based upon an exclusive dogma. They do make use of the facts even of bacteriology so far as known to them. I should consider myself less honorable should I refuse such men fellowship because in their ignorance they went to a sectarian school.

As I wrote in my article on homeopathy (JOURNAL AMERICAN MEDICAL ASSOCIATION, March 17, 1894): "The obliteration of the homeopathic sect is not secured by ignoring its members. . . . If homeopathy is a delusion, rational medicine will lose nothing by association with homeopaths, while the latter class may thereby be better able to see the truth as it is."

In practice there is nothing to separate the majority of homeopaths from regular physicians. So far as I can find there is absolutely nothing to distinguish the modern eclectic. When cant is thrown aside there is little left for "schools" of medicine to thrive upon.

The exact qualifications for membership are by the law of the Association left largely to the local societies. These regulations vary greatly, and I regret to say they do sometimes exclude all as unworthy, who have not been "baptized" in a particular manner.

On the other hand, he who advertises himself as a sectarian thereby shuts himself out from recognition by a liberal profession. He who decrys the profession and extols his own practice to the exclusion of the information to be received from the science of medicine, is not to be encouraged.

HENRY BIXBY HEMENWAY, M.D.

Value of a Lost Eye.

KNOB VIEW, CRAWFORD CO., MO., July, 1894.

To the Editor:—Would you give me your opinion on the following questions:

1. Is ophthalmia ever the result or effect of malarial exposure, poison, fevers and the like? Does loss of vision sometimes or often result from this cause—especially among soldiers?

2. What is the relative *earning* value of an eye, as compared with a leg or an arm? Would loss of eye equal or approximate loss of arm at elbow or leg at knee?

This information is asked for in the nature of a charity—to assist an old blind soldier to get what clearly appears to be his due.

Respectfully,

CLARK W. HARRINGTON, P.M.

Ophthalmia being only another term for conjunctivitis, we should know what kind of conjunctival inflammation the questioner refers to, in order to give a definite answer. In a general way we may say a simple conjunctivitis is often found in fevers (especially measles and scarlet fever), but it does not impair the vision; granular conjunctivitis, which often affects the sight more or less, is not caused by such diseases as referred to in the above question.

The earning value of an eye depends on various conditions; it is evidently greater if the remaining eye has poor sight than if the remaining eye has good sight; for in the first case its loss would practically be equal to the loss of both eyes. Prof. Zehander has furnished us with a formula by which the earning capacity of the remaining eye (and consequently the earning value of the lost eye) can be appraised for the manifold conditions of sight. The normal sight of an eye being valued at 100, the earning capacity of the remaining eye is $2 \pm 1 \frac{0}{3} \pm 0 = 66\frac{2}{3}$ per cent., hence the loss of one eye amounts to $33\frac{1}{3}$ per cent. of the former earning capacity, provided both eyes had full vision. But suppose the vision

of the remaining eye is only four-fifths, its earning capacity would be $2 \pm \frac{8}{5} \pm 0 = 53\frac{1}{5}$; hence the lost eye would have an earning value of $46\frac{2}{5}$ per cent., and thus the loss in earning capacity can be estimated under all conditions if in the above formula the degree of vision of the remaining eye is substituted for 100.

SOCIETY NEWS.

The Nicollet County (Minn.) Medical Society held a meeting July 14.

The Central Texas Medical Association held its semi-annual meeting at Waco, Tex., July 10.

The Orleans County (N. Y.) Medical Association at its recent session voted that its members charge clergymen and their families the same for medical services as other persons. A different rule has prevailed.

The Chautauqua Medical Society held its annual meeting July 10 and elected officers for the ensuing year: President, N. G. Richmond; Vice-President, Morris N. Bemus; Secretary and Treasurer, C. A. Ellis.

The Stephenson County (Ill.) Society of Physicians and Surgeons held a meeting July 17 and elected officers for the ensuing year: President, Dr. Buckley; Vice-President, Dr. Thompson; Secretary, Dr. Stoskopf.

The Wayne County (Ind.) Medical Society held its annual meeting at Richmond July 11, and elected officers for the ensuing year: President, J. R. Weish; Vice-President, Dr. Howe; Secretary, G. H. Grant; Treasurer, J. F. Hibberd.

Wyoming County (N. Y.) Medical Society.—The quarterly meeting of the Wyoming County, N. Y., Medical Association was held in Warsaw, July 11. The following officers were elected: President, Dr. M. J. Wilson; Vice-President, Dr. John C. Fisher; Secretary and Treasurer, Dr. A. B. Straight.

Iowa and Central Illinois District Medical Association.—The Iowa and Central Illinois District Medical Association held its regular annual meeting July 19, at Davenport, Iowa. The meeting opened at or about noon, and was attended by a large proportion of the medical men and women of Davenport, and a number of those living and practicing on the Illinois side of the river, with a few visitors from other cities. After the banquet the following program was given:

Address of the President—Dr. G. C. Craig, Rock Island.
Catarrhal Inflammation of the Middle Ear—Dr. C. M. Robertson, Davenport.

Fracture of the Skull with Brain Lesions—Dr. J. R. Hollowbush, Rock Island.

Officers were elected for the ensuing year as follows:

President—Dr. J. P. Crawford.

Vice-President—Dr. C. C. Carter, Rock Island.

Treasurer—Dr. A. W. Cantwell.

Secretary—Dr. G. L. Eyster, Rock Island.

Program Committee—Drs. Allen, of Davenport; Hollowbush, of Rock Island, and Myers, of Moline.

Drs. R. A. Nash, of Tipton and Charles Hunter, of Hampton, Ill., were elected to membership.

PUBLIC HEALTH.

The Memphis Board of Health has sent a communication to the Tennessee State Board of Health, calling for such action as will lead to legislation prohibiting infant and child life insurance within the State, on the ground that the practice leads to criminal negligence of the proper care of children, and is to that extent prejudicial to public health.

Cholera.—Notwithstanding some increase of Asiatic cholera in Europe, which was to be expected as the season advanced, there is nothing in the situation to occa

sion serious alarm and the outbreaks, except in Russia, seem to be kept well in hand. The occurrence of fresh cases or the appearance of the disease in new localities is the signal for renewed sanitary effort and increased precautions—as in Turkey, where the Imperial Government has again established quarantine restrictions on all European arrivals because of fresh cases at Adrianople on the 23d. Previous reports of the prevalence of the disease in Canton and elsewhere in China are now officially denied.

Vaccination in the Courts.—The Supreme Court of Pennsylvania has confirmed the decree of a lower court to the effect that school boards have the right to exclude from the public schools children who have not been vaccinated. In a similar case, pending before the Supreme Court of New York, the attorney for the Anti-Compulsory Vaccination League said that he had "reached the conclusion that vaccination is the most dreadful thing that has ever blackened medical theories." He had consulted many authorities and claimed that the *Encyclopedia Britannica* (!) sustained his argument. He urged that the Court had a right to review the question whether vaccination was "healthy" or not; but, upon the corporation counsel requesting time to prepare a scientific argument upon the subject, the Court (Mr. Justice Bartlett) replied that it was not necessary. "The vast preponderance of medical opinion throughout the civilized world is in favor of vaccination."

Rapid Vaccination.—Dr. George F. Cott, one of the District Physicians of Buffalo, was delegated to vaccinate the children in eight of the public schools of that city during the recent smallpox "scare." He has furnished the results of his experience to one of the local papers—not alone his experience in vaccinating, but of the methods of teaching and the hygienic conditions, etc., of the schools. Concerning vaccination he says:

"It has been contended that it is impossible to vaccinate 100 in an hour. I have vaccinated 150 in thirty-five minutes with the help of an assistant. I have operated on sixty in twenty minutes without assistance. It will be found by dipping the ivory points into water that the virus is dissolved and easily removed by a little friction, and that, all other arrangements being perfect, three children per minute can thus be easily treated."

This, too, when, as he takes occasion to state:

"The instrument for scarifying is thoroughly sterilized after each operation and fresh ivory points are used, thus making the inoculation of disease from one child to another absolutely impossible."

"Won Wek."—Canton letters to Chinamen in the United States report that the plague—"won wek"—is subsiding; that the mortality has been frightful; that neither in Canton nor Hong Kong were there "ye youen" or hospitals enough to contain one-tenth of the cases; and that rigid "ging" or quarantine has been maintained. Well-informed Chinese who have seen previous epidemics of "won wek" do not think the disease will reach this country whether precautions are taken with ships' cargoes or not. *Per contra*, Dr. Stuart Eldridge, Health Officer of Yokohama and member of the Imperial Board of Health of Tokio, advises that "the most stringent measures may need to be taken to protect the United States, particularly as regards certain classes of goods from China likely to convey infection—rags, old cotton, etc., and also such manufactured articles as are made in the native workshops, with perhaps a case of plague dying in the same room; such things as straw matting, embroideries, and every sort of textile fabric." Dr. Eldridge adds that so long as the disease is kept out of Japan, so long will that country be the best bulwark for the United States against the importation of the disease. A letter from a young Englishwoman in the British government hospital at Hong Kong to friends in Harrogate, Tenn., gives a graphic pic-

ture of her experience as a nurse on the smallpox ship which had been turned into a temporary plague hospital. She says: "My first night on the smallpox ship was a ghastly one indeed. I had thirteen deaths in the twelve hours that I was on duty, and most of the other patients were delirious. That was my worst experience. Since then about eight or ten deaths in twelve hours has been the average." Reports of the extension of the plague into Russia are not confirmed.

An Anti-Vaccinist Testifies.—One of the "big guns," from the use of whose ammunition the anti-vaccinists have hitherto derived much satisfaction—in the matter of noise, if not of execution—is Prof. Crookshank of King's College and Hospital, London, Eng., in which institution he has the chair of Comparative Pathology and Bacteriology. He has been quoted in season and out of season by the "antis," who "Kick against the Inseartion into the Pure Blood and Vile flow of our Inosent offspring of that Diseas of the animals cowpox," and his acknowledged reputation as a bacteriologist is cited as proof that what he says must be so. But, like other heavy artillery, the Professor's recoil is sometimes more dangerous to the friends in the rear than is his shot to the enemy in front. In his recent evidence before the English Vaccination Commission he testified that, in his judgment, nurses in smallpox hospitals escape the disease not because they are vaccinated but because of improved hospital conditions and cited the analogy of typhus fever in support of his position. He wholly ignored the undisputed fact that it is only the revaccinated nurse who is absolutely secure, while the unvaccinated or the only once vaccinated contract the disease in greater proportion than those of like classes not living under the "improved hospital conditions." But the Professor's scattering at the breech was most disastrous when asked how he would protect the nurses if he himself were in charge of a smallpox hospital. Pressed for a reply he said he should "inoculate them with variola itself;" and, to a similarly direct question whether he believed that vaccination as generally practiced does protect many persons, he finally answered "Yes; for a time." If the "antis" can get any comfort out of further citation of Prof. Crookshank they should be welcome to it.

Restriction and Prevention of Rheumatism.—At the July meeting of the Michigan State Board of Health, the President, Mr. Frank Wells, of Lansing, said that he had long noticed that the weekly health bulletins published by the Board show that of the twenty-eight diseases reported upon by the regular observers around the State, rheumatism is usually at the head of the list as causing the most sickness in Michigan. Mr. Wells raised the question whether there was anything that the Board could do in the way of publication of information which might tend to lessen the amount of sickness from this disease. Dr. Vaughan said he knew of nothing tangible yet relating to the restriction and prevention of rheumatism, which could be imparted to non-professional people. He thought no work should be undertaken now which will interfere with the effort being put forth by the Board for the restriction and prevention of tuberculosis—the most important of all diseases. Dr. Baker said that the Board has already done much for the diffusion of knowledge respecting the causation of rheumatism, which knowledge is essential to proper action for its prevention. "But we must wait for an advance in two lines of investigation not much entered upon by this Board—that of bacteriology and that of physiologic chemistry. Several times in the past it has seemed that facts were about to crystallize into a tangible theory; but just as appearances were most favorable, ideas of medical investigators regarding the causation of rheumatism have changed. Much has been learned from the sickness statistics collected and published

by the Board. Curves have been made showing that rheumatism has a direct relation to meteorologic conditions. The facts in the Secretary's office show that tonsillitis follows the cold atmosphere and that rheumatism follows tonsillitis. It is quite probable that if rheumatism is a germ disease, tonsillitis prepares a soil favorable to the reproduction of the germ and a way for its entrance into the body. We are waiting for the bacteriologists to find the specific organism. So far as I know only the pus-forming germs have been found in connection with rheumatism, and it is quite possible that they are the cause of the disease; if so, its increase, following the sore throats caused by raw cold weather, is explained by the facts on record in the State Board of Health office. Diagrams exhibiting the rise and fall of rheumatism by seasons of the year prove that its course is similar to that of smallpox, consumption and other diseases known to be caused by germs, and known to enter the body by way of the air passages." Secretary Baker suggested that a committee might be appointed to investigate the subject and report to the Board at some subsequent meeting. Dr. Vaughan said that at present, all is speculation as to the causation of rheumatism, but he thought it quite probable that Dr. Baker's idea of the causation of rheumatism may be nearly the proper explanation. He would, however, explain rheumatism as being the result of an over-exertion or unusual destruction of the cells of the body in trying to protect the body from an attack of a germ disease; in other words, it is an over-drugging-on the part of nature in order to throw off an attack of some germ disease. The uric acid, which is not excreted rapidly enough and which accumulates in the body and causes the rheumatic pains, is formed by the action and destruction of cells. On motion of Prof. Fall it was voted that Dr. Baker prepare and read at a future sanitary convention a preliminary paper on the causation, restriction and prevention of rheumatism.

MISCELLANY.

The Two Dromios.—A monthly medical journal published in Pittsburg, and a weekly medical journal published by a book publishing house in Philadelphia, lash themselves into a high temperature over the report of the Trustees of the AMERICAN MEDICAL ASSOCIATION made at the last annual meeting. It is to be presumed that with the growth of the country and general increase in the volume of business, that the two Dromios will eventually have to devote more time to the conduct of their own publications. The proof reader of the Pittsburg sheet has apparently been on a vacation for some weeks.

The Columbus Medical Journal.—The *Columbus Medical Journal* is now a bi-weekly instead of a monthly, and Dr. R. Harvey Reed is the editor-in-chief. That he will make the publication a power in the Buckeye State, every one who knows Dr. Reed will admit.

The Regular Semi-Annual Meeting of the Washington State Board of Medical Examiners was held at Spokane, Wash., July 2-5. There were seven applicants before the Board for license to practice within the State and but four were successful. The Board decided to continue the high percentage of requirements adopted at the previous meeting.

Delegates Abroad.—Drs. Theo. B. Schneideman, Philadelphia; Giles C. Savage, Nashville, Tenn; Julian J. Chisolm, Baltimore, Md; S. D. Risley, and G. E. de Schweinitz, Philadelphia, have received credentials as foreign delegates from the Permanent Secretary. These gentlemen go abroad particularly to attend the Ophthalmological Congress.

Octogenarian Ovariectomy.—J. Paul Bush, Surgeon to the British (Eng.) Royal Infirmary, is thus far entitled to claim the oldest ovariectomy patient. She was a widow, aged 84; operated on Sept. 12, 1893, and a large thin-walled multilocular ovarian cyst removed; sent home October 16, and reported "alive and well and able to get about some months after." Her exact age was carefully inquired into at the time of admission and was confirmed by papers and documents.

A Medico-Historic Exhibition.—At the "Naturforscher" to be held at Vienna next September there will be an exhibition of articles illustrating the historical development of medicine. It will embrace diagnostic, therapeutic, surgical and obstetrical instruments and appliances of former ages; plans and pictures of hospitals; portraits of former physicians and surgeons; medals struck as memorials of plagues, and other objects useful as historical illustrations of past stages of the healing art.

Pasteurized Milk.—Pediatric authorities advise that all milk fed to children should be Pasteurized in warm weather—that is raised to a temperature of 168 degrees F., to destroy ferments and prevent souring. This temperature kills tubercle bacilli, typhoid and other germs that may be present in the fluid. It is true that it also renders the casein of the milk less easily digestible, destroys milk-sugar, and causes proteid matter to adhere to fat globules, thus retarding their digestion; but these results are of little importance clinically, except in the care of weak children, while the benefits are many and obvious.

They Don't Go.—Steerage passage to Europe may now be had for \$8.00 and thousand of aliens, disgusted with Coxeyism, Debsism, Federal bayonets and other exanthemata of the body politic and social, are taking advantage of the cheap rates to return to their native lands. One scans in vain, however, the returning passenger lists for the names of the hordes of "feldschers," barber-surgeons, valets and others with purchased medical qualifications who have flocked hither in recent years to help make up the aggregate of over 118,000 persons who are getting some kind of a living out of the practice of medicine among 65,000,000 of the healthiest people under the sun. There is a ripe harvest here for the steamship agent in this superfluous factor of the medical profession.

New Drugs and Names.—The *Medical Record* thinks that our English brethren must be especially keen on new drugs, and in particular on new names of a proprietary character. The following list of "new drugs" is taken from a single issue of the *London Lancet*: "Nepenthe, malakine, virol, pepsalia, pumiline, cactina, celerina, antinervine, cerebrine, papain, anestile, opiatine, lintus tussi, kreochyle, vaporesoline, chiralta liq., cocoatina, izal, bynol, bovril, liquor sedans." These are not all, but they are sufficient to show the pharmacist's fancy, and the appreciation of it by the British mind. To the student, and even the recent graduate of medicine, all these things must appear quite unintelligible, and he must feel that having learned the materia medica of his text-books, he must begin again and learn that of the manufacturer.

A New Parasite in America.—The announcement of the discovery in this country of the *Distoma Ringeri*, by Prof. Ward, of the University of Nebraska, is attracting more attention abroad than at home. This fluke has hitherto been found only in the far East—China, Japan, Corea and Formosa—where it infests the lungs of man, giving rise to periodical hemoptysis (Foster's Med. Diet.) and chronic cough with rusty mucoid expectoration. Already we are told that if this parasite "is now endemic in America we may expect to hear more about it soon, not only as a parasite of the lower animals but as a cause of endemic hemoptysis in man." Here is a brilliant opportunity for the men who are "in love with a microscope" and prone to "flirt with pathologic specimens." Endemic hemoptysis may soon become as fashionable as appendicitis.

Aerial Diffusion of Smallpox.—In a recent London report appears a contribution to the controversy upon the aerial convection of smallpox, in which it is asserted that "the

diffusion of smallpox through the air does not extend to a distance of 1,000 feet." *Public Health*, in commenting upon this assertion, points out that the patients who had been exposed to the influence of a smallpox hospital about 1,000 feet away, were only those "who showed evidence of previous vaccination," and their failure to contract the disease from such exposure should be attributed to this vaccinal protection rather than to distance. It also appears that the "smallpox hospital" in question was so in name only, since it was used solely "for the reception of convalescent smallpox and fever patients." One of the conclusions arrived at in 1882 was that the diffusion of smallpox had not shown itself "while the use of the hospital has been for convalescents only," and the absence of danger in the accumulation of convalescent persons was then noted. There are, in fact, many proofs in support of the contention that smallpox is contagious only in the acute stage of the disease and the positive evidence of Dr. Priestley, cited in the *JOURNAL* editorial, "Hospital Spread of Smallpox,"¹ far outweighs this negative testimony.

Health and Morals of Congress.—Section 40 of the Revised Statutes of the United States directs that the Sergeant-at-arms of the House of Representatives shall deduct the proper amounts from the salaries of members who are absent for other causes than sickness of themselves or members of their families. After remaining for years a dead letter it was revived this session as a means of securing a quorum, but its enforcement proved so farcical that Representative Powers, of Vermont, has introduced a bill for its repeal. In support of his bill Judge Powers urges that "it is apparent that the excuse of sickness is one easily made, and it is suspected that it is sometimes assigned as a reason for absence without any diagnosis of ailment by medical experts. In other words, the enforcement of this section practically makes every member a pathologist on the subject of disease, which is not a qualification for Congress mentioned in the Constitution, and so for this reason the law is plainly unconstitutional. It is believed that each House of Congress can, by an appropriate rule, better enforce the attendance of members than by a statute operative as a penal statute and evaded by every subterfuge. Obviously the manly way to get rid of objectionable legislation is to repeal it, and in this case such repeal will manifestly improve both the health and morals of the House."

Representative Powers is the wise and witty Judge who, as the readers of the *JOURNAL* may recall, in refusing a writ of mandamus against the Vermont State Board of Medical Censors to compel it to recognize the Vermont Medical College—a "diploma mill," organized under a general incorporation act—said that: "To suppose that the Legislature meant by this act that any three persons could organize a college and confer medical degrees would be to make the title M.D. of as little account as Richelieu threatened to make a dukedom in France. He would create so many dukes that, while it would be no disgrace not to be a duke, it would certainly be no honor to be a duke."

If He Should Undertake a Cyclopaedia!—A "catechism" is popularly understood to mean a compendium or summary of rudiments or principles, concisely stated in the form of questions and answers; Webster defines it as: "An elementary book containing a summary of principles in any science or art," etc. Patrick Hehir, M.D., F.R.S.E., F.R.C.S.E., D.P.H. (Camb.), is the author of "A Catechism of Hygiene and Sanitary Science," the first volume of which has just been issued in Calcutta. This volume deals with the subject of water exclusively, and consists of 610 octavo pages of print smaller than that in which this item is set. There

will be fifteen such volumes in this "Catechism!" Among the *facetiae* of the bookmen there is the story of an author—Smalgruenius according to some, Thomas Aquinas according to others—who wrote a work, *De Omnibus Rebus*, followed by another entitled *De Quibusdam Aliis*. More recently and better authenticated is that of the German philologist who at the end of a long life spent in the study of one solitary Greek root, died lamenting that he had not had time to exhaust its derivatives. To these must now be added this gentleman of the epicene cognomen who undertakes to write a "catechism" of over nine thousand octavo pages. Let us pray the gods that our latest dictionary with its 300,000 words be kept from him until he is through.

"Faith Cure."—The current number of *The Arena* contains an article by Dr. James R. Cocke on the so-called "faith cure," mind cure or mental therapeutics. The writer concludes that it is of value: "1, as a curative agent in cases of functional neurosis; 2, in correcting vicious habits formed by the mind of the individual; 3, in removing some of the acute symptoms of organic disease; 4, I consider that its greatest value is in the department of preventive medicine. I believe that more diseases could be prevented by studying the minds and souls of youth and by correcting abnormal tendencies in them than can be cured in later life by any amount of treatment, no matter of what kind." If this be true then "faith cure" has a wide field open to it, since, according to the *Spectator*: "The rapid increase of suicide must be due not merely to the dwindling religious faith of the day, but to that horror of trouble and grief which indicates a dwindling power of endurance and an almost extinct sense of hope. No doubt this dwindling power of endurance, this extinguishing of hope, undermines also the sources of faith. Faith without hope is hardly possible, and fortitude without hope is still less conceivable. We have little doubt there are a much larger number of persons who are born into the world without any elasticity of nerve nowadays than there were in less exciting times." In the judgment of the *JOURNAL* the trouble with this class of persons is that they failed to select their ancestors properly. If "faith cure" will correct the defects of heredity by all means apply it, for "faith without works is dead."

Woman in Medicine.—A French compiler, M. Marcel Baudouin, furnishes a *résumé* of the légal status of women in the medical profession in various countries, in which, singularly enough, he omits all but the merest mention of the gentler sex in France. According to M. Baudouin women are rigidly excluded from the advantages of a university education in Germany, and consequently may not become candidates in any medical examination; "it naturally follows that no medical woman can be the possessor of a certificate carrying with it the slightest value in Germany," since a state license upon examination is necessary to practice in that country. In Austro-Hungary the situation is even worse; there the admission of women to higher grade instruction is formally forbidden by law. Spain is quite as bad; in fact the difficulties are said to be even greater in the Iberian peninsula than in Germany and Austria. In England, Ireland and Scotland the universities—through which lies the registration necessary to the right to practice—are now all thrown open to women, Scotland having been the last to yield to the new order of ideas; in Ireland, however, while a woman is afforded every facility for obtaining a medical qualification she may not fill any public office under the State. Similarly in Sweden, Norway and Denmark, the medical career is open to all without distinction of sex—save in the matter of State appointments. In Belgium, Holland and Roumania the broadest views prevail

¹ *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, June 16, 1894.

regarding the medical rights of women; they may do and be, as physicians, all that men can and are, *cæteris paribus*—which they are not. The right of women to practice is fully recognized in Italy, and a woman occupies the Chair of Histology in the Medical Faculty of Bologna.

In 1893 there were 308 women attending medical lectures in Zurich, Geneva, Berne, Basle and Lausanne, but there are only ten women practicing in Switzerland; after graduating the students return to their own countries to practice, principally to Russia. In this latter country, Russia, there were 546 women practitioners in 1893, and women are there allowed by law to become assistant surgeons in all railway administrations; in 1890 a special medical school for women, after the American model, was established in Moscow. Universities in many of the English colonies have been open to women since 1875, and in France woman first obtained foothold in a university in 1863, but five years later there were only four female students in l'Ecole de Medecine of Paris; the more beautiful women of a most beautiful country do not seem to take kindly to the practice of physic, notwithstanding the illustrious examples of Mesdames La Chappelle, Bourgeois and Boivin, concerning whom it has been said that "if their mantle could be made to fall on the shoulders of their sisters of the present generation female delicacy would be saved many a rude shock and the cause of science would in no sense suffer."—(Leishman, *System of Midwifery*.) M. Baudouin concludes with the following tribute to this country:

"Only a moment's consideration of the following statistics is necessary to convince an inquirer that he must proceed to the United States of North America if he wants to study effectually the question of medical women. According to a statistical report drawn up by M. Louis Frank, of Brussels, there were in 1893 on the other side of the Atlantic fully two thousand women practicing medicine in one or other of its forms and inclusive of 130 'homeopaths.' The majority were general practitioners, but there were also 70 hospital physicians or surgeons; 95 professors in the schools; 610 specialists for the diseases of women; 70 alienists; 65 orthopedists; 40 oculists and aurists, and, finally, 30 electrotherapeutists. In Canada there is but one medical school exclusively for women, but in 1893 there were ten such in the United States. It must not be forgotten also that all medical schools in America are freely open to women, and that mention of this is by no means omitted from their published announcements."

This latter statement is not entirely accurate, since many schools refer women applicants to their special colleges, preferring to avoid a certain embarrassment that sometimes arises in medical co-education. M. Baudouin might have also included mention of the fact that medical women in the United States are eligible to governmental appointment, and at least one woman, Dr. Sarah Hackett Stevenson, is a member of a State Board of Health which examines and licenses applicants for the right to practice.

Hospital Notes.

BURBANK HOSPITAL.—The new Burbank Hospital of Worcester, Mass., was opened July 16.

THE TESTAMENT of Mary McMullen, who died recently at St. Agnes' Hospital, Philadelphia, gives property to that institution valued at about \$65,000.

A HEBREW HOSPITAL AT PITTSBURG.—A fund of \$20,000 is held in trust by the Hebrew Benevolent Association of Pittsburg for the building of a hospital.

THE HERMAN HOSPITAL of Elgin, Ill., was tendered a benefit under the auspices of the St. Mary's and St. Joseph's Catholic churches July 13. The concert was successful, and a handsome sum was presented to the hospital.

ELECTION of Miss Hopkins.—The Board of Directors of the Western State Hospital July 18 elected Miss Charley Hopkins, of the Warm Springs, an assistant physician at that institution. Miss Hopkins takes the place lately made vacant by the resignation of Miss Haines.

THE BOARD of DIRECTORS of the Grace Hospital at Detroit, Mich., held a meeting July 13 and elected officers for the

ensuing year. The report showed that the receipts for the first six months of this year were greater than those for the corresponding time last year. The charity wards have held their maximum capacity during the entire year.

BELLEVUE HOSPITAL.—Plans are being made for the reconstruction of certain portions of Bellevue Hospital, New York, that part which is used as reception office, examination and admission rooms, besides store room of the hospital. The accommodations have been inadequate and reconstruction will be of great benefit to those interested.

ROCHESTER (N. Y.) HOSPITAL.—The board of managers of the Rochester State Hospital held its quarterly meeting July 17, at which meeting the plans and specifications for a new building and repairs made necessary by the recent fire were forwarded to Albany for approval. The appropriation for the new building is \$65,000.

A PROTESTANT HOSPITAL.—Articles have been filed for the establishment of a new hospital in the city of Seattle, Wash. The objects are to found and maintain a hospital under the management of Protestants, for the medical and surgical treatment of sick and infirm persons, with the object of furnishing such treatment, as far as possible, gratuitously to the poor.

Medical College Notes.

A NEW medical college has been organized in Kansas City under the name of the College of Physicians and Surgeons of Kansas City, Kan. The capital stock will be \$10,000. The directors are Drs. J. W. May, S. I. Harrison, R. Roberts, J. C. Martin, W. C. Boteler, W. F. Wilkins, E. J. Dennis, A. L. Michaels and E. M. Heatherington.

THE PUBLIC SERVICE.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from July 14, 1894, to July 20, 1894.

Capt. RICHARD W. JOHNSON, Asst. Surgeon U. S. A., is granted leave of absence for two months.

First Lieut. FRANK T. MERIWETHER, Asst. Surgeon, leave of absence granted on surgeon's certificate of disability, is extended two months on surgeon's certificate of disability.

No. 5.

ADDRESS.

CHAIRMAN'S ADDRESS.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOSEPH EASTMAN, M.D., LL.D.

FORMERLY PROFESSOR OF ANATOMY, AND PROFESSOR OF GYNECOLOGY AND ABDOMINAL SURGERY, CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS, INDIANAPOLIS, IND.

It seems best on this occasion to turn aside from the usual custom of reporting progress in the Department of Obstetrics and Gynecology, a subject which has been so often and ably presented and discussed by my predecessors, and call your attention to the present status of suprapubic hysterectomy as viewed from the standpoint of personal observation and clinical research, with the hope that I may contribute in some small measure to the profitable discussion which I am quite sure will follow the reading of the valuable papers on your program.

It is not my intention to report a series of operations made for the removal of symmetrically formed pear-shaped tumors, with well-defined broad ligaments, with uterine arteries easily accessible and seen pulsating in their anxiety to be ligated; tumor, ligaments and arteries dealt with by some definite method; each operation made in exactly so many minutes; and all the patients making uneventful recoveries. The literature of the subject is already cursed with such productions. Therefore, I would rather suggest such means and methods as experience has taught me will furnish the best possible results in dealing with tumors by no means symmetrically formed; with broad ligaments displaced and disorganized by nodular masses interfering with the ligation of arteries and the easy formation of pedicles.

Despite the efforts of some to name a distinct method of operating because a flap is made here, or a ligature placed there, the problems of suprapubic hysterectomy are rapidly nearing their solution. Those engaged in the work are divided into two classes: Those who have been and are yet satisfied with forming a pedicle and fixing the same in the abdominal wound; and those who were not satisfied that this method was the best that could be devised, and have been earnestly endeavoring to reach some method which shall disregard the morphology of tumor, of broad ligaments, and the location of uterine arteries.

On Feb. 3, 1887, knowing full well that abdominal fixation of the pedicle in suprapubic hysterectomy had at that time given the lowest rate of mortality, I decided *not* to operate in that way, but planned and executed an operation which in every essential feature was an extirpation of almost the entire cervix. A large cautery passed three times down through the cervix in reality destroyed a large portion of what little cervix I had left. A rubber drainage tube was inserted for vaginal drainage.

In a recent discussion in the *New York Journal of Obstetrics and Gynecology* they speak of the operations by Stimson, Krug, Baer and myself as if they were all operations of total ablation of the uterus. If these operations are to be considered, then the operation of Stimson in November, 1888, was antedated by my determination to secure something better than the abdominal fixation of the pedicle, on Feb. 3, 1887.

It is not my purpose to occupy time in discussing questions of priority in making an operation, although the operation, including the use of my hysterectomy staff, as I demonstrated it at the International Medical Congress in Berlin, has since been made many times by Krobak, of Vienna, and numerous American operators with great satisfaction, and while I have received many congratulatory letters from distinguished operators on account of the rapidity and definiteness of the operation made possible by the use of the staff, I have been working to still further simplify and perfect the operation.

I concede the fact that where a given fibroid tumor has no nodular masses in the region where we would form a pedicle, or imbedded in the broad ligaments, and where the abdomen is not exceedingly fat, that abdominal fixation has given results in the hands of expert operators in a very high degree satisfactory. So far as I have been enabled to read the writings of its warmest advocates, none of them have mentioned the very strongest point in its favor, namely, that in this method we have practically *one wound*, whereas in the total or partial extirpation method we have two wounds; the one in the abdomen, the other in the pelvis, the latter extending through connective tissue, rich in lymphatics, down to the vagina,—(an incubator for many varieties of bacteria,) which can not always be sterilized and maintained aseptic during an operation. Notwithstanding the strong points in favor of abdominal fixation of a pedicle, which I have mentioned, it has been the subject near my heart for nearly eight years to study out the anatomy and its displacements by pathologic neoplasms, and perfect a method as speedy of execution, followed by as successful results, as any or all other methods,—a method applicable not only to tumors where a pedicle for abdominal fixation could be formed, but also to those cases where *nodular masses* have completely *disorganized the cervix*, and *intra-ligamentous masses* are found in the *broad ligaments* of one or both sides.

I became well convinced a number of years ago that the use of the clamp of Keith or the serre-nœud of Koeberle for controlling hemorrhage from the neck of the uterus, was based upon the idea that the spiral or curling branches given off from the uterine arteries really penetrated the tissues of the uterus including its cervix. Some seven text-books on anatomy which I have examined state that these branches penetrate the uterus. I have a number of times, with fingers on the broad ligaments and their contained

vessels, cut directly through, seizing the spurting vessel and securing it later. Many times a single uterine artery has been ligated in many places in its zigzag course, the operator thinking he secured a distinct vessel each time. I have also peeled off the uterine arteries from the sides of the uterus and then cut off the cervix with little or no hemorrhage. This was for the purpose of reducing the number of ligatures,¹ long or short, to become incapsulated or slough off through the vagina, and also to economize the time required for their thorough application.

Here is a nodular mass fed and nourished by a capsule, a capsule containing the venous and arterial capillaries. It is well known to every gynecic surgeon that these nodules can be peeled out of the capsule without ligating a single artery. What I have stated regarding the nourishment of this nodule by its network of capillaries and *not* by the penetration of arteries (for surgical purposes), holds true with reference to a uterus disorganized by a fibroid tumor or tumors, no matter how large or how small; not only the fibroid uterus, but the normal uterus as well; not only the uterus but its entire cervix down to the external os.

I here present a specimen (a photograph of which you may see in the *American Journal of Obstetrics and Diseases of Women* for the past month), and to my mind it marks a new era in the removal of fibroid tumors by hysterectomy for the reason that the uterine arteries were not ligated at all. I went down between the uterine arteries and the uterus. The uterine arteries were absolutely left in the pelvis of the woman, not a single ligature being used except those which tied off the ovarian arteries and a small portion of the upper border of the broad ligaments.²

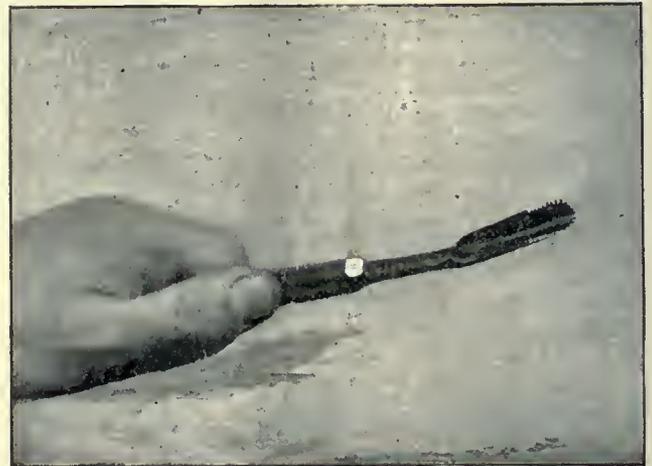

Then in addition to solving the problem as to what to do with the pedicle, by deciding not to have any, we now solve the problem as to what to do with the broad ligaments and especially their contained uterine arteries by simply leaving them in the pelvis of the patient.

In this case I simply controlled the circulation in the ovarian artery by ligating the upper portion of the broad ligaments with a strong ligature, then cut-

¹ A ligature to secure the uterine arteries will often secure a certain amount of muscular and connective tissue and is one of the possible sources of infection of the wound, hence the importance of having as few ligatures as possible.

² Sauter, three-quarters of a century ago, removed the uterus per vagina, without clamp or ligature. (See article by Dr. Guido Bell, *Indiana Medical Journal*, February, 1894.) Further, the enucleation of the cervix per vagina was made by Langbeck in 1813, by Recamier in 1829, and by Malgaigne at a later date. (See article by Dr. Robert Reyburn.)

ting the broad ligaments above the ligature; began with the serrated gouge to peel down the broad ligaments, keeping the gouge close to the tumor, being especially careful in the interspaces between the nodules not to puncture or tear the uterine artery or any of its branches. From time to time nicking the edges of the peritoneum with these button pointed scissors, with the serrated cutting edge I pushed it forward under the peritoneum anteriorly and posteriorly so as to make anterior and posterior flaps. Then pushing with the serrated gouge I carefully worked around the tumor until I had reached the uterine cervix, and then proceeded with still greater caution not to cut the cervix nor its capsule, but to push it down as I now slip my cuff towards my elbow with the fingers of my right hand. The enucleation of the lower portion of the uterus including its cervix, reminds me of Prof. Sayer's admonition when removing the head of the femur for hip joint disease. He says: "I take this oyster knife and work my way past the trochanters, major and minor, then make sure to get beneath the periosteum close to the bone." Then, he used to say: "D—n the anatomy; stick

close to the bone," and proceeded in peeling off the periosteum until he had the entire head of the femur out of the acetabulum.

As I reached the lower portion of the cervix my hysterectomy staff was passed up the vagina by my son, Dr. Thomas B. Eastman. I then removed the entire cervix, cutting a little opening on to the staff, slipping a strip of gauze in the fenestra of the staff. When the staff was withdrawn this was brought down in the vagina, the upper portion of the gauze being packed into the pocket from which the cervix had been enucleated. The flaps which I had dissected off from the tumor and cervix were brought together by buried suture over the ligatures which had included the ovarian arteries so that their raw ends also came into the wound. Several rows of buried suture were used so that all raw edges made by peeling out the cervix were deeply buried and prevented leaking into the peritoneal cavity, the gauze being dragged down into the vagina a little each day, facilitating perfect drainage in that direction. This operation is the realization of the ideal. Heretofore all of us had simply been idealizing the real. In my lecture delivered to the Post-Graduate School of Chicago in July, 1893, I closed with a series of conclusions. From them I quote the third, to-wit: "Where the

neck of the uterus remains small, abdomen not too fat, after the ovaries and tubes have been tied off, the pedicle may be fastened in the lower angle of the wound and give satisfactory results." To this conclusion stated at that time I have this to add: Where such anatomic conditions exist, enucleation of the cervix can be done in less time than the manufacturing of the pedicle, the adjustment of the serre-nœud or elastic ligature. Furthermore, abdominal fixation of the pedicle can not be accomplished in all cases.

In conversation with several distinguished abdominal surgeons, including Dr. Bantock, of London, I find that these gentlemen meet with cases where no pedicle can be formed to fix in the abdominal wound. It is to this class of cases I would invite the best directed efforts on the part of those who have a heartfelt interest in this class of suffering women.

One's per cent. of recoveries would undoubtedly be much better if after making a careful examination which discloses a tumor deeply imbedded in the pelvis, we would discourage operative procedure; but in my first 100 hysterectomies I found a number of cases were gangrenous tumors and tumors containing gangrenous nodules, causing slow death in some cases and rapid death in others from septicemia. Within the last six months I have operated on seven women who had either gangrenous fibroid tumors or tumors with gangrenous nodules. In five of the cases the nodular masses were deeply imbedded in the pelvis, and two of the cases were operated on within one week. In each case a nodule as large as a cocoa-nut was completely imbedded in the broad ligaments, having been developed from low down on the side of the uterus, and in both cases the nodular masses were in a state of gangrene, they having caused temperature ranging from 100 to 103. In two other cases the subserous tumors had become gangrenous from small twisted pedicles. In each case rapid and well pronounced septicemia threatened the life of the patient. Surely the technique of suprapubic hysterectomy is not complete until guided by sound surgical principles. We have *methods and means suitable for such emergencies*. In this class of cases I have been pleased with the rapidity with which we can ligate the upper portion of the broad ligaments, cut the same loose from the tumor, peeling the peritoneal covering off from the tissue leaving a little subserous tissue beneath it; enucleating nodular masses, and directly find ourselves down close to the external os with only an occasional bleeding from some enlarged arterial twig.

The most serious question in my mind in these cases is how to properly drain the cavities from which these nodular masses have been enucleated. In a recent case I packed the cavity in the broad ligament from which I had enucleated a gangrenous mass as large as a cocoa-nut, with iodoform gauze, bringing the same out at the side of the pedicle which I had fixed in the abdominal wound. In addition to the gauze I placed a metallic drainage tube well down into the pocket. I wished to be absolutely certain that this cavity was thoroughly drained, believing that in other cases where I had trusted to gauze alone for drainage that it was not satisfactory. In the first forty-eight hours we pumped out of this drainage tube fully a pint of black blood, which coming from the cavity occupied by this gangrenous nodule gave a considerable odor, notwithstanding the thorough washing of the cavity through the

drainage tube. I believe it would be better in such cases to secure the most thorough vaginal drainage—not only through the opening made by the enucleation of the uterine cervix, the same being packed with gauze surrounding the drainage tube, but by making a free and direct opening from the bottom of the cavity in the broad ligaments into the vagina. It has been taught that the dangers of removing cysts or fibroids from the broad ligaments lies in the disturbance of important plexuses of the nerves. My observation leads me to believe that the shock is not materially great in such enucleation, and that the bad results following such operations are due to the use of drainage which does not properly drain. But while I secured the most perfect drainage in the case referred to by bringing the drainage tube up to the side of the pedicle, I would not advise abdominal fixation of a pedicle in cases where nodular masses are enucleated from the broad ligaments and even imbedded in the region of the cervix where we would form a pedicle, believing that these cases can be more successfully treated by removal of the entire cervix with free vaginal drainage.

As I suggested at the beginning of this paper, one of the great objections to total extirpation of the cervix and vaginal drainage is that we make an additional wound and have a possibility of vaginal infection.

I concede further that it is not always possible to render the vagina surgically aseptic. I have had a number of cases where I used the most thorough antiseptic douches, and then sought to wash out the cavity of the uterus for the purpose of packing the same with iodoform gauze and also to close the external os by firm suture, and found the cervix and external os so retracted into one of the cul-de-sacs or behind the pubes, that it was impossible to reach it with any form of speculum in such a manner as to enable me to pack the cervical cavity or stitch the same so but that during our handling of the tumor we found a large quantity of bloody purulent discharge in the vagina which had escaped from the external os. In a large per cent. of cases a thorough washing of the uterine cavity, packing the same with iodoform gauze and then stitching the external os will prevent this purulent fluid from escaping into the vagina during our handling of the tumor. Then thoroughly washing and even scrubbing the vagina with a brush and packing the same, including all its cul-de-sacs, with iodoform gauze, will give us a reasonable assurance that this tube has been made aseptic and reduces the dangers of infecting the peritoneal cavity to the minimum.

In a conversation with Dr. Bantock, of London, I expressed the hope that in the near future we would be able to remove fibroid tumors with the same low rate of mortality which follows our work in removing ovarian cysts. The good Doctor replied: "This can never be done for the reason that the anatomic conditions are essentially different." Carefully reflecting over this statement I have become thoroughly convinced that a more thorough study of the essential anatomic conditions which exist in an abdomen containing a fibroid tumor, as compared with one containing an ovarian cyst, would enable us to bring the mortality of the two operations to something approximating equality.

I have a number of times left the greater portion of the uterine arteries to remain in the pelvis of

the patient, but from the results I had, I was thinking that the possibility of infection through the rich chain of lymphatics at the side of the uterus was greater in such cases than where broad ligaments were thoroughly constricted by ligature all the way down to the opening in the vagina. This led me to express, in the Chicago lecture heretofore referred to, my preference for cutting around the cervix rather than enucleating it. But carefully reflecting over the statement of Dr. Bantock that the anatomic conditions were essentially different in fibroid tumors from what they are in ovarian cysts, I became convinced that we often blame the technique which we have used in treating the pedicle when the cause of death ought to be explained in some other way. For example, when the parietes of the abdomen are rendered thin by the pressure of an ovarian cyst, the blood supply is reduced so that all the intra-abdominal viscera are more or less anemic. This condition is in marked contrast with the hyper-nutrition often present in and about the pelvis which contains a fibroid tumor. I am quite sure that deaths occur in consequence of our almost losing our heads in the determination to make the pedicle and all pertaining thereunto as perfect as possible and neglecting perfect approximation of the abdominal incision, always as large as the tumor, including its peritoneum. I have many times cut through two inches of fat to reach a fibroid tumor, and unless such a wound be thoroughly closed by three rows of sutures, the internal one being of fine or cyron tendon, with stitches not more than one-fourth of an inch apart, and then making absolute sero-serous approximation, there is danger of infecting the peritoneal cavity by the wound leaking into the abdomen. Too often we take extreme precautions to nicely adjust the outer integument, when it would be better if any leakage from the wound is to occur that it shall pour outward and not inward. Again, the more vascular condition of the peritoneal cavity and its contained viscera in cases of fibroid tumors, as compared with ovarian cysts, warn us of the greater intolerance of rough manipulations, making it necessary to protect intestines and viscera as much as possible during operation by hot sterilized towels and sponges, by temporarily bringing the wound together over the intestines with a temporary stitch or volsella, and *above all, and over all, by the most thorough irrigation* of the peritoneal cavity with water at a temperature of not less than 110, not only after the work has been completed, but at intervals during the work, so as to undo the harm we do to the vasomotor nerves distributed to the pelvic and abdominal viscera. Half a dozen pitchers full of water are none too many and if we have produced material shock as evidenced by the pulse, a few pitchers of water poured through the drainage tube and allowed to pour out again has at times, as I believe (permit me to say I absolutely know), saved lives that otherwise would have been lost. The operator of to-day who seeks to do away with the "wash out" and the drainage tube on all occasions on theoretical grounds, is rolling the wheels of progress backward. The skilful management of a patient during shock is of very great importance indeed. The use of opium to put the disturbed tissues at rest has the genuine ring of surgical wisdom. The use of strychnia to keep up the tone of the nerves distributed to the intestinal tract and thereby counteract the tendency to gaseous distension of the

bowels, is one of the precious comforts to the anxious abdominal surgeon when his patient is low in shock.

When Ephraim McDowell made his first ovariectomy, the citizens surrounded his house threatening his life because he was about to "butcher a woman." The sheriff of the county interfered. At first they refused to listen to his pleadings for the Doctor's life. Finally he struck a compromise, the mob agreeing to let him alone if the woman recovered, the sheriff agreeing not to interfere if the woman died. This was a crucial test of the Doctor's heroism. Other heroic surgeons did not hesitate to remove ovarian cysts, but allowed women to pass on to their graves if the diagnosis convinced them that it was a fibroid tumor. Still later, surgeons removed fibroid tumors if they were pear-shaped and a pedicle could easily be formed, allowing women to pass to their graves if the examination showed the tumor to be deeply imbedded in the pelvis by nodular masses. Even the great and noble Dr. Thomas Keith, after battling with fibroid tumors with as good a per cent. of recoveries as any one at that date, finally abandoned fibromectomy, resorting to the use of electricity and only wished he had back from their graves the patients who had died from his operations for fibroids. Thank God there were others to take up the work when he became discouraged.

The old adage that the qualifications of a surgeon were "the head of an Apollo, the eye of an eagle, the heart of a lion and the hand of a woman," is eminently true, especially as regards him who would seek to be successful in removing fibroid tumors. The head to plan and to meet the surprises which spring on us during such work; an eye to see quickly the exact constriction of every ligature and adjustment of every suture; the lion heart to forge forward in this aggressive work when our per cent. of recoveries might be better if we would let fibroid tumors alone, especially bad ones; the nimble wit in the ends of the fingers, backed by an indomitable will to skilfully and speedily perfect the adjustment of the last suture with the same precision as the first, make a combination of qualifications suggesting that the surgical type of a man is not to be found thirteen times in a dozen.

No operation so thoroughly demands that the trinity of surgery be carried out—thorough preparation of the patient, thorough operation and skilful after treatment.

As American surgeons we have a right to be proud that no other nation leads us in the originality of methods or successful results in removing fibroid tumors. Almost every State of our Union has operators who would venture to give a woman with a fibroid tumor the chances of life which surgery offers.

With a more thorough and perfect understanding of the essential anatomic conditions which make an abdomen containing a fibroid tumor different from one containing an ovarian cyst, with the realization of the ideal method applicable alike to all fibroid tumors regardless of their morphology—a method as successful in the hands of the many as the few skilled operators, may we not hope to say with all sincerity that fibroid tumors can be removed with the same low rate of mortality which has placed ovariectomy among the brilliant triumphs of the century. Then shall the torch lighted by McDowell in the midnight darkness shine forth with resplendent

glory in this brilliant noonday of abdominal surgery. The century which in a few years will have rolled on to the eternal past, has placed in the magnificent temple of medicine many pillars of surpassing beauty and grandeur, while its surgical columns have risen high toward Heaven where as gilded towers, they fain would vie with the God-given sunshine in dispelling the chill and gloom of human agony.

Chirurgia's tower, thy lights resplendent blaze
Dries woman's tears, and lengthens out her days;
McDowell and Sims of our Columbia's clime
Began the work moved onward high sublime.
To women, then, these blessings shall be given—
Queen of the home and home the type of Heaven.

Abdominal surgery is *proud* of her past because it is prophetic of her *future*. Even now in the vital present it shall stand forth unchallenged as the crowning glory of all science and of all art.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

TUESDAY AFTERNOON—JUNE 5.

This department of the AMERICAN MEDICAL ASSOCIATION met in Covenant Hall, Odd Fellows Building, San Francisco, on Tuesday at 2 P.M. June 5, 1894. DR. JOSEPH EASTMAN, of Indianapolis, presided, and delivered the opening address and read a paper on "Removal of Fibroid Tumors."

It was moved and seconded that the paper read by Dr. Eastman be received for publication. Carried.

The regular Secretary being absent, DR. EASTMAN appointed DR. H. P. NEWMAN, of Chicago, to fill the position during this Convention.

DR. F. H. MARTIN, of Chicago, then read a paper on the "Treatment of Fibroid Tumors of the Uterus," followed by DR. E. E. MONTGOMERY, of Philadelphia, with a paper on "Removal of Fibroid Tumors through the Abdomen."

A discussion of the three papers was then taken up. A motion was made, seconded, and carried, that DR. R. E. HORTON, formerly a surgeon of Indianapolis, should open the discussion.

DISCUSSION.

DR. HORTON—This is unexpected that I should be called upon in this way to discuss this question, and I may be excused, probably, if I only make a few remarks on the occasion.

I have in my past life pursued this line of thought and practice. I have operated a number of times on this class of trouble. While it is true that we have three methods presented to us for the purpose of dealing with fibrous tumors, it is also true that medical men are not yet agreed as to the methods which shall be selected. I am one of those who do not believe that we can bring this question of operative method to a single method alone.

I have had a little remarkable experience on some lines. I have one case in my mind which would be difficult for these gentlemen to decide on any one of the three lines suggested here to-day. I recognize the fact that this question is a difficult one, but it has been opened up very much by our methods in ovarian procedure, by the removal of ovarian tumors, etc.

I occasionally came across this class of trouble, of fibrous tumors, and I found difficulties, as they have already related—difficulties in my own mind as to the proper course to be pursued. As the chairman has remarked, a man needs a clear thought and a steady hand, and a determination to win on the side of the patient, or else he certainly would not succeed with the class of tumors we are considering. The method of enucleation is one of those customs which is open to discussion. The abdominal method is one which has been pursued both for tumors that were not fibroid and ovarian as well.

Now the question comes back to us, What method shall we pursue, the abdominal or the vaginal? It can only be determined, as I apprehend, by the relative conditions of the case after having made a clear and careful examination. I have found it so in my own experience at any rate. I have had to decide these cases for myself when there was nobody to help. In these last few years I have been out on the western plains of Texas seeking health, and still continuing my work, and I have found it necessary to decide these questions entirely by myself, as I had nobody to go to and no one to call to my aid. These questions have come before me as they are presented here to-day.

I want to say in reference to ligation of these vessels, it is a question that years ago I determined in my own mind would be a successful method of controlling hemorrhages, not only in matters connected with tumors, but in other matters of hemorrhage. I am satisfied that we have come close to the time, if not already presented to us, when uterine hemorrhage can be controlled by ligating these vessels. You have all heard in a paper that has been read that the broad ligaments may be tied in such a way that it adds but little to the danger of the patient in hand. That is an effect which I have worked for in my own experience. I will very briefly allude to a case in which I think these gentlemen would neither enucleate or ligate the vessel. They would be forced, as I believe, to resort to the abdominal method in preference to any other method in the removal of the tumor.

I was called to a case of fibroid tumor where there was a mass of forty-five pounds in weight to be removed. It was growing out around the neck of the uterus. It was a question whether to remove it, as the patient had already been reduced to an extreme degree, or to let her die by letting it remain. I decided to operate upon it. She was advised as to the possibility of her death even upon the operating table, and also that she might recover. An abdominal operation was performed. The uterus was entirely imbedded in this mass of fibrous tumor. It had grown out from the base of the uterus and around its neck in such a way that the pelvis and the abdomen was entirely filled up with this growth. I decided that it could not be removed by an incision of the vagina and that the only method was the abdominal method, also that this was the only possible chance for the patient. I decided that we would have to ligate these vessels, as has been suggested here—ligate in such a way as to avoid the possibility of hemorrhage in the abdominal cavity. That operation was successfully made—successful so far as the operation was concerned, but not saving the patient's life. I am not ashamed to say that I made a failure.

ORIGINAL ARTICLES.

REMOVAL OF UTERINE TUMORS THROUGH THE ABDOMEN.

Read in the Section on Obstetrics and Diseases of Women at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY E. E. MONTGOMERY, M.D.

PROFESSOR CLINICAL GYNECOLOGY JEFFERSON MEDICAL COLLEGE;
OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL; GYNECOLOGIST
TO JEFFERSON AND ST. JOSEPH'S HOSPITALS AND CONSULTING
SURGEON TO LYING-IN CHARITY HOSPITAL,
PHILADELPHIA, PA.

The earliest abdominal operations for uterine growths were undoubtedly not deliberately premeditated but were errors in diagnosis. The abdomen had been opened for removal of an ovarian tumor. Between 1825 and 1851 fourteen such operations were reported, of which five had a fatal termination. Some surgeons then became bolder and ventured to extirpate subserous pediculated tumors. Granville had an unsuccessful, and Atlee and Lee successful cases.

Burnham in 1853 was the first American surgeon to undertake a partial extirpation of the uterus, while Kimball first practiced hysterectomy for an interstitial fibroma the cause of violent hemorrhages, and his patient recovered.

Partial extirpation of the uterus, in which the cervix uteri was used as a pedicle, early developed two methods of treating the stump,—the intra- and the extra-peritoneal.

The ligation and return of the stump to the abdominal cavity would seem the natural and more desirable procedure, but the elastic character of cervical tissue would permit the stump to shrivel so that its vessels were no longer compressed, and violent often fatal hemorrhage would follow the closure of the abdomen. The stump could not be secured *en masse* with sufficient firmness to insure against its occurrence. Koeberle made a great advance over ligation *en masse* when he suggested the metallic loop. Péan in 1870 reported a successful case and later published a work in which he presented such precise rules for the various details of the operation as to permanently associate his name with the extraperitoneal treatment of the stump. The operation consists in making an incision sufficiently large to permit the mass to be raised up and brought out. Where the cervix is long and readily affords a pedicle, fixation pins may be introduced beneath which the wire of the serre-nœud is applied. If the pedicle is short it will be necessary first, to ligate and cut through the broad ligaments. The pedicle is placed in the lower arch of the wound and its peritoneal covering which has been stripped back stitched fast to the parietal peritoneum,—unless the two surfaces can be held in apposition by the serre-nœud. The wound is closed and the stump so treated as to produce desiccation and separation of the strangulated portion without suppuration. The rubber ligature may be substituted for the metallic wire.

The great advantage of the extraperitoneal method is that the stump is under observation and the occurrence of hemorrhage immediately recognized and readily arrested. It has a number of disadvantages.

1. The tumor may have so distended and involved the cervix as to render the establishment of a pedicle sufficiently long to be treated externally very difficult, and the resulting traction may be so great as to cause severe pain and extensive ulceration from the pressure of the pins.

2. It is difficult to keep the external devitalized portion of the stump aseptic and prevent suppuration.

3. With separation of the external portion there is retraction of the stump leaving an excavation to fill up by granulation, thus prolonging convalescence.

4. With a large stump and its subsequent retraction there must necessarily result a weakened ventrum, greatly increasing the danger of subsequent hernia.

Kleeberg, of Odessa, in 1876 suggested the use of the elastic ligature to control hemorrhage and favor the intra-abdominal treatment of the stump. It is certainly efficient in the first object but the strangulated stump does not always obtain sufficient nourishment to prevent it sloughing, and thus become a source of danger from infection. A similar danger occasionally attends the formation of flaps which are subsequently sutured with deep buried and superficial catgut sutures as suggested by Martin.

In one case the writer had the entire surface of the stump slough. Fortunately he had used gauze drainage which afforded an escape for the mass and thus saved the life of the patient.

The greater familiarity of detail secured through frequent operations, and the desire to avoid the disadvantages of the extraperitoneal method, have led to a marked revision of the former methods of operating, in which the entire uterus is removed, or only a small portion of the cervix is retained. As a preliminary to the operation the vagina should be thoroughly cleansed by scrubbing with a 2 per cent. solution of creolin which contains tr. sapon. virides 3i to the pint. The solution should be removed by washing with sterilized water. The mucus should be curetted from the cervix and the canal be packed with gauze. The vagina should be tightly packed with gauze for the double purpose of raising the uterus and rendering plain when the vagina is reached. This procedure enables the operator to more readily secure the uterine arteries and displaces the ureters from the field of operation.

When the tumor is small it is better to place the patient in the Trendelenburg posture, as the deeper pelvis can thus be better inspected. After raising the tumor upon the abdomen, the peritoneum should be incised and pushed down, forming anterior and posterior flaps, the uterine arteries ligated and finally the ovarian. The broad ligaments cut and the posterior wall of the vagina opened. The removal of the tumor including the entire uterus is now easy. The tissues are cut with scissors hugging closely the cervix. The pelvis should be carefully sponged, any bleeding vaginal vessels secured and the peritoneal flaps united with fine silk or animal continuous suture. The closure of the peritoneal wound excludes from the abdominal cavity all the ligatures. The gauze should now be withdrawn from the vagina and a gauze drain be loosely placed between the raw surfaces to insure drainage.

The alternate operation to this, denominated the Eastman, Goffe or Baer operation consists in securing in a similar manner the ovarian and uterine arteries and cutting through the cervix, leaving that portion which is inclosed by the upper part of the vagina.

The cervical canal may be sterilized by cauterizing it with the thermo-cautery by carbolic acid, or it may be left alone. Some stretch the canal and pass through it a piece of gauze which serves to drain the cavity beneath the peritoneum; while others avoid any drain. The peritoneal flaps may be apposed by continuous suture or be held in apposition by one or two central sutures. Either of these operations indicate a marked advance in peritoneal surgery, as they afford an escape from the disadvantages of the extraperitoneal treatment of the stump.

Of the two procedures, the entire removal of the uterus seems, to the writer, the preferable procedure. The retention of the stump does not afford any especial facility in the operation, it is of no especial subsequent advantage to the patient and when large, through the decreased nutrition after ligation of the uterine arteries, it may be a source of sepsis.

ENUCLEATION.

All the methods for the removal of fibroids we have thus far discussed involve the sacrifice of the uterus. In subperitoneal pedunculated growths where the uterus was otherwise free, the sacrifice of

the organ would certainly be unjustifiable and myomectomy would be the proper procedure. There are growths, however, which involve the wall of the uterus, in which the tumor may be enucleated and the genital functions remain undisturbed. The operation consists in opening the capsule of the tumor and displacing the growth from its bed, then after trimming away shreds and drying cavity, introduce sutures so as to completely close the cavity. The peritoneum should be closed over the deeper sutures.

DISCUSSION.

DR. LAPHORN SMITH, MONTREAL—I have nothing to say but words of highest praise for the excellent papers we have listened to with so much appreciation. I think Dr. Montgomery has presented very fairly the present ideas he holds with regard to the treatment of fibroid tumors by the various methods which are now in use. But I think we may say a few words more about a few points which have not been touched upon. I think that I express the feelings of nearly every practitioner who has to deal with these cases, that were it not for the inevitable death rate, we would all be in favor of the total extirpation of the uterus. But that terrible point of death rate is the one shadow that is overhanging us all the time, and the only thing that is following me all the time when I am deciding how to treat a woman who puts her case in my hands, suffering from a fibroid tumor. That is why I risk being called slow sometimes—when I treat that woman with electricity for two or three months before I decide to have an operation. But I am glad to say, and it is my duty to say it here, that I have a great many women, perhaps thirty or forty, who have within a few months or half a year been restored and are enjoying good health, are free from pain and hemorrhage, and were treated only by galvanism and general constitutional remedies. But, unfortunately, electricity does not cure all cases. Now and then a case we treat for two or three months with electricity is not cured. Then we must do something more. In deciding what to do next I think I must still keep that death rate in view, and if I can cure the hemorrhage by an operation which has no death rate, or almost no death rate, that is the one I would give her the choice of next. It is for that reason I admire so much the operation of Dr. Martin, of Chicago, and why I think his paper has been so valuable to all of us. That is an operation, it seems to me, almost free from danger, and one we should be in favor of before we resort to one, which in the very best of hands has a death rate of 5 per cent. We can not expect that many can attain the splendid results which Dr. Eastman has. It is only after a long time and with unusual experience and unusual ability that a man can remove large tumors by this method with so small a death rate. In a few years, perhaps, when the operation has been so perfected that many more of us can hope to attain his results, we may say that is the operation to choose next. I wish to be understood, however, that I have nothing but words of admiration for the operation that Dr. Eastman performs. I am speaking for the majority of practitioners, even for the majority of specialists, and I say we should give the women the benefit of Dr. Martin's operation before we subject them to an operation which, in the best of hands, will give a death rate of 5 per cent., and in the hands of those less skilled a death rate as high as 10 or 15 per cent.

I wish to answer the question as to whether I punctured the tumor when using electricity. I wish to say distinctly that I do not, for the reason that I believe it would introduce an element of danger.

I also wish to answer another question that has been asked, and which is a question of great interest: Does electricity ever cause degeneration of a tumor which had not

been degenerated before? At one time I thought it did so, but on studying two or three cases subsequently I found the fault was not in electricity, but in the one who diagnosed the cases. A patient was sent to me whom five experienced physicians decided had a fibroid tumor. I applied electricity for six weeks, and finding the patient no better I advised an operation, and found, not a fibroid of the uterus but a great big sarcoma of the ovary. The fault was not with electricity, but with the diagnosis.

I have also had two cases of sarcoma occurring in the uterus which I believed was fibroid. So it looks as if the fault is more in diagnosing than the application of electricity.

DR. F. H. MARTIN—I have been very much pleased with the reception given to my part in the meeting this afternoon. I wish to eradicate one idea that may have been left on the minds of a few who are not acquainted with me, and that is in regard to this so-called conservative operation that I have brought forward. I think the key-note was struck by Dr. Laphorn Smith when he stated that we should not be afraid of conservatism. If you have all got the idea that I never did any work except to play with electricity, or do some little minor operation in the cervix, you are very much mistaken. My operation is not one that applies to all cases, and I want it distinctly understood that I do as much abdominal surgery in Chicago as any one, and it is not a conservative operation that I have developed and adopted because my courage is not great enough to do abdominal surgery. This operation was developed for the purpose of avoiding the necessity of submitting a patient to that inevitable death rate of 5 per cent. I have been unable to get below that, and I know of very few that have. I believe that I have been able to get as low as any one. This hysterectomy is a thing that brings gray hairs to the abdominal surgeon. From the time we operate on these cases until they are "out of the woods," as we say, they are a constant worry to every abdominal surgeon.

I do not want you to think for a moment from the remarks that I have made that I would adopt this operation for every case of fibroid tumor—that I would do hysterectomy in every case where I could not do this operation. I want you to bear in mind that in the great Gynecologist Convention held in Washington in 1876 that I was one of the chief contributors and that I then reported a great many cases that I had operated on at that time. I have had the pleasure of being called an electric crank with my friend Dr. Laphorn Smith, and others. I do not want you to forget that I believe in the use of electricity. The day before I left Chicago I operated upon a case sent to me by a physician. I did the operation, but I believe if I had the time to do over again and had a little more time I should have used hysterectomy. I ligated the broad ligaments, and fortunately succeeded in ligating enough to include not only the uterine artery, but I think, all the branches.

I wish to add my testimony in regard to the effects of electricity in these fibroid tumors. I have never known malignant trouble to follow its use; and I have never known malignant degeneration to follow this process I have described to-day. Although it is only two years old, I can speak from a good deal of experience on that point. I have had malignant cases, so-called, referred to me, and one case in particular was referred to me by one of the best diagnosticians in this country as having a tumor as malignant as sarcoma. He said: "If you can cure the hemorrhage by electricity I believe you can cure the case." I treated the case, and succeeded in checking the hemorrhage and reducing the tumor, and as he expressed it, cured the patient. I said: "Doctor, you made a mistake in your diagnosis." He said: "I don't believe it."

Now in the discussion of hysterectomy there has been one method that has been somewhat slighted; I don't believe in slighting any one, and especially if that one happens to be from Chicago. In my article I stated that in the operation of abdominal hysterectomy, if I could take my choice it would be this way: Payne last, Byford first, and Eastman next. The reason I prefer Byford is because we leave that key to the arch that has been spoken of in the vault of the vagina and cervix. The operation is performed down through that point exactly as Baer's operation is performed; the broad ligatures are ligated, and the tumor is cut off above the cervix; the cervix is cored and sewed up, the perineum is sewed over that, and then a small opening is made anterior to the cervix in the vault of the vagina, and the cervix is introverted into the vagina. If we have not succeeded in tying the uterine artery thoroughly, as we sometimes fail to do, you have the hemorrhage where it can be controlled. This makes, to my mind, an ideal method; your stump is outside and at the same time you have all the spring and give; there is no pressure on the bladder, no drawing of the abdominal wall; there is no absolute fixation, and you have preserved the key of the arch.

I will now take up the point made by Dr. MacMonegle as to the advisability of allowing a woman to become pregnant following an operation, as to the advisability of ligating so much of these tumors, and as to whether degeneration would not occur—that is, so much of the nutriment would be shut off that gangrene will occur.

In the first case I operated on I ligated one side, and after ligating thoroughly I noticed that the cervix changed color and the woman was flowing badly at the time. The hemorrhage ceased and I started in to ligate the opposite side and did a very poor job—that is, I was really afraid to ligate the opposite side of that broad ligament for fear I would get gangrene. That case is not one of my star cases. It has not done as well as I would have liked, although the woman is very much improved in health. I believe I made a mistake in not ligating thoroughly. We must remember this: We wish to cut off the enormous blood supply and starve the tumor; we must understand that the tumor in order to have growth must of necessity draw upon the blood supply. After I had ligated the broad ligaments enough to include both ovarian arteries, while I cut off two-thirds of the blood to the tumor, there was probably more blood going to that tumor than would go to a normal uterus. And for that reason I believe we can safely cut off three arteries—two on one side, and one on the opposite—and there will be blood enough to supply a normal pregnancy. I am sure that in a very few years I will be able to settle that point definitely. I believe that two or three of these cases I have operated upon for genuine fibroid will be put into a condition so that pregnancy will occur.

Now in regard to the preparation of the patient: It is impossible to make the vagina clean without cleaning out the uterus. The first thing is to bring it down, dilate it and thoroughly clean it. I would not have an aseptic stump in the operation. I would pack it with gauze and allow it to remain long enough so that my side incision healed before the gauze was removed. I have had, as you noticed, suppuration in one case. An abdominal wound, even where everything is favorable, occasionally suppurates—at least in my experience.

I wish to thank the Association for their kind attention. (A motion was made by Dr. F. H. Martin that the Chairman close the discussion, which motion was seconded and carried.)

DR. EASTMAN—Patients and tumors talk more eloquently than doctors. Some of you will remember that the main argument which I advanced in connection with the method which I have just described, was a method applicable to all

cases, regardless of the form of tumor. I am well convinced that Dr. Martin's method is a very good one. I, at his suggestion, used it in one case. But if a man is going to be an abdominal surgeon he must have a good deal to do with the women, and if he does not please the women he will soon have no business. The women in whom I have removed the ovaries and allowed the tumor to remain, and the women in whom I ligated the uterine arteries, the tumor still remaining, are very unhappy; they are following me by faith and not by sight. They may obtain sight later on, but thus far they say: "I wish that tumor was gone; it haunts me the last thing when I go to sleep and the first thing when I wake up in the morning."

But I can conceive of cases where the operation is advisable and, as I say, I used it in one case. I think the woman following me by faith a little further, can see I did a wise thing in not removing the tumor. But it is necessary for us to seek the truth and to get at the actual facts in the advocacy of any particular method. As my friend suggested, set out the peculiarities of a given case and apply our remedy.

Now I wish to ask Dr. Martin how he could tell the gangrenous mass existed in the tumor. I have dealt with some five or six cases this year where I had gangrenous nodular masses in the tumor. If I had ligated the arteries in those cases I surely would only have contributed to the death of the patient. The operation of ligature is applicable in some cases. But I would like to ask any one how it is we are going to determine in any given case that the tumor is gangrenous or not. This "grip" that has been going around has seemed to spend its force in the point of least resistance, in the tumor, and gangrene has been the result in a number of cases.

I will call your attention to this tumor before us. Right here is the cervical canal. Now I want to ask the gentlemen who fix the pedicle in the abdominal wound what they would do in this case. Electricity will not do, ligating will not do, for here is a gangrenous mass. Dr. Baer can not tie the uterine arteries, as he suggests, because here is a mass absolutely filling up both sides of the uterus. How are we going to get at the uterine arteries?

It is especially to this sort of case that I have directed my attention—and which is the subject of my paper—and I ligate the artery at this point here (showing), and I see no necessity for ligating the same artery again. As has been proven in the specimens here, we can peel back and go between the arteries of the uterus and enucleate the mass.

I had another case where I thought of ligating the arteries as suggested by Dr. Martin, but the tumor was imbedded in the pelvis to such an extent that it was very difficult to reach them; the pelvic roof was drawn up, and I could not reach them in that case. Those are simple cases where it is not available. So that all methods are not applicable. If there is any method available in all cases it is the one I have been describing. The point I make is, that where there is a good cervix, where it is not disorganized, that this can be enucleated in less time than you can adjust the ligatures and perform the other operations. This enucleation method will bear you out when the other methods are absolutely ruled out and can not be considered in that class of tumors.

It was suggested by some gentleman in the discussion that a little piece of gauze be put through the cervix for drainage. I most emphatically protest against this. If there is a drainage down into the vagina it must be thorough, so there can be a thorough washing out. If you are going to drain into the vagina, cut wide enough so you can pack in plenty of gauze. I prefer a rubber drainage tube. A drainage which is not perfect is absolute worthless and decidedly dangerous.

I want to be fair with the advocates of all these methods. It has been said: "Why fix the pedicle in the abdominal wound?" As I said in my paper, you have practically but one wound, whereas in all these other methods of total extirpation you have two wounds.

I have not, for reasons, referred to any gentleman across the water so far as dealing with fibrous tumors are concerned; we need go no further than Boston, for we are as advanced in methods and have as much success as in any part of the world.

It seems to me that nothing could make me happier than such perfection of methods (I put that in the plural) as will make the mortality so low that women will not dread the operation, and that we can point them to patients here and there who have been entirely relieved of fibroid tumors. This century of surgical triumph will surely accomplish all this. We are in the right line in discussing all these methods, weighing every method for what it is worth. There are those who are dying little by little; they are living in death; they are dying in life. They have repeatedly said to me that their life was not worth living, and they would be willing to be launched into eternity from the operating table rather than to feel that tumor there.

I refer in my paper to some seven cases in as many months where the patients were dying of tumors which were gangrenous. One lady came from Chicago with a fibroid tumor which she had carried for fifteen years. It seemed as if the patient was dying from internal hemorrhage. She was brought to me on a stretcher. I opened the abdomen and found several quarts of bloody serum. I succeeded in removing it. That case is a warning to all women who have fibroid tumors.

So I most emphatically say the statement that there is such a heavy mortality following hysterectomy must be put beside the statement that fibroid tumors are dangerous, and we can never know when they are harmless; when dangerous I think the fibroid tumor had better come out, and if there are nodular masses low down, take it out by the roots.

A CASE OF GANGRENOUS NECROSIS OF THE MAMMARY GLAND.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. SCHNECK, M.D.

MT. CARMEL, ILL.

On Dec. 3, 1891, I visited Mrs. C., who lives three miles in the country. She is a large, healthy woman with a good family history as to health, morals and cleanliness; has always lived on a farm. The house in which she lives is a large, new frame building, situated in a healthy location. She was then, at the age of 39 years, nursing her second child, which was healthy and in its seventeenth month. The mammae were of medium size, and had never given her any trouble previous to this attack. The family had not been using rye bread or buckwheat cakes.

I found a deep gangrenous ulcer on the left breast, extending from near the nipple toward the median line; irregular in outline and about three inches in diameter. The margin of the ulcer was a black color, the bottom being covered by the characteristic ashy-gray coat. The healthy skin along the margin of the ulcer was overhanging the undermining soft parts. The whole gland was swollen, imparting a soft, baggy sensation to the touch. The border of the ulcer was a deep red color which gradually faded off into the natural tint. The odor was very offensive and was that which is characteristic of dead tissue. She stated that about ten days previous to my visit she first felt a hard, tender lump at this point in the breast, and feared it would prove to be a small abscess, although the skin was not red over the hard part. She could not remember a time when the gland had been injured or bruised. As the hard nodule developed, the skin immediately over it changed to a black color, the discoloration gradually spreading from its center.

She had poulticed the breast for several days before I saw it. I ordered that the child be weaned; removed all the dead tissue I could with forceps and scissors; gave full doses of muriated tincture of iron and quinin, and directed her to have concentrated animal diet. The breast was to be washed clean with bichlorid of mercury solution every two hours, then to be covered with a charcoal and flaxseed meal poultice. At the end of forty-eight hours the progress of the disease had not been checked by this treatment, the gangrenous surface was larger than the palm of a hand. I now made daily applications of nitric acid, diluted one-half with water, to the margin and under the overhanging skin. Otherwise continued the former treatment. This checked the progress of the disease in three days; but it was necessary to apply the nitric acid to a few small points where the disease would begin to spread, for several days more. In due time the diseased surface became covered with healthy granulations and in six weeks was entirely covered with skin. Eighteen months later I attended her in her third accouchement. The breast was then smaller than natural and deformed by a large scar. Milk was secreted freely by this gland after the confinement. The child nursed from both glands for about twenty months and was then weaned.

I have searched quite extensively in medical literature but have been unable to find a parallel case. I find reports of cases in which the extremities, lungs and pleura, tongue, pancreas, penis, vulva and mouth were involved by idiopathic gangrene; and other instances where it has involved wounds and other injuries, but have found no instance in which a healthy mammary gland was involved.

The mammary glands are so well supplied with comparatively large blood vessels, derived from different parts of the arterial system, that it is surprising to find destructive processes taking place in their tissues without a special cause. They are supplied with blood: 1, by branches of the internal mammary artery direct; 2, by the long thoracic artery direct, and by anastomosis with the internal mammary; 3, by anastomosis of the superior thoracic with the internal mammary artery.

The blood is collected at the base of the nipple in the *circulus veinosis*, and thence conveyed to the axillary and internal mammary veins.

The causes of gangrene usually given are more or less vague, especially when the exact process by which the resulting death is produced is asked for. The causes assigned are: 1, arrest or interference with the nutrition of the part; 2, atheromatous condition of blood vessels; 3, obstruction in capillaries; 4, obstruction in arteries; 5, obstruction in veins; 6, diminution of cardiac power; 7, diminution of vasomotor energy; 8, old age; 9, severe bruises; 10, intense inflammation; 11, debility from disease, as cholera, typhus, typhoid, measles, diphtheria, erysipelas, scarlatina, exophthalmic goitre, dysentery, anemia, diabetes and cerebro-spinal fever, all of which are reported to have been connected as causes of gangrene; 12, in hospital gangrene, some specific infection is supposed to exist. None of these causes appear to be applicable to the case just reported.

I find that authors give various shades of meaning to the words, mortification, gangrene, necrosis and sphacelus.

"When a soft part is dying, it is said to be in a state of gangrene; and when dead, in that of sphacelus."—Bryant, "Practice of Surgery."

"Gangrene is the arrest of the function of organic life in a circumscribed portion of the soft parts of the body, leading to complete death of the same."—W. MacCormac, "Quain's Dictionary of Medicine."

"Gangrene is death of a part of the body from the gradual or sudden arrest of its nutrition. It is usu-

ally applied to the process of mortification in the soft structures. The analogous condition of bone is called *necrosis*. Animal tissues have two modes of dying—the one is *molecular*, or death by granular metamorphosis, in which no trace of the anatomic or histologic properties of the tissues remain; the other is death in *bulk*, in which, although the tissues deprived of life undergo rapid decomposition and ultimate disintegration, they retain for a time something of their original form. It is to denote this last variety of tissue death that the term, gangrene, is employed.”—Wyeth, “Text-book on Surgery.”

“The death of any part of the body is called necrosis. Necrosis of external parts of the body, attended by shrinkage and mummification of the tissues, is called dry gangrene. Necrosis accompanied by putrefaction of the dead tissues is called moist gangrene.”—Flint, “Practice of Medicine.”

“By the term, mortification, is meant the death of any portion of a living body. Gangrene may be said to imply a spreading destructive process, attended by progressive loss of vitality in the living tissues, of which sloughing phagedena, or hospital gangrene, affords a good example. When soft parts are dead, they are said to be in a state of sphacelus. A more limited dead portion of the body is a ‘slough.’ Death of bone is termed necrosis; a dead piece a sequestrum; the process by which a dead bone is separated from the living is called exfoliation. Some authors apply the term ‘necrosis’ to death of any tissue; others extend it from bone to death of cartilage only.”—Holmes Coote, “Holmes’ System of Surgery.”

“Mortification may be defined as the death of a part, the rest of the organism retaining its vitality. The word, as usually employed in this and other countries, is synonymous with gangrene, so much in vogue among French writers. Formerly the term gangrene was used to denote that state of a part which immediately precedes its dissolution, while sphacelus was employed to signify the complete extinction of life, without any possibility of recovery. In speaking of the death of a bone, necrosis is the expression generally used. It would save much trouble, and prevent confusion, if all these terms, excepting the first, were abolished.”—Gross, “System of Surgery.”

“Necrosis, gangrene, mortification and sphacelus are terms used synonymously to indicate the death of a part. English and American writers have usually restricted the meaning of the word, necrosis, to death of bone, while the remaining terms were used to express the same condition affecting the soft tissues. Recently a sharp distinction has been made between necrosis and gangrene from an etiologic standpoint, according to which necrosis is said to have taken place when the circulation and nutritive changes in a part have completely ceased, to be followed by gangrene as soon as saprophytic bacteria invade it and give rise to putrefaction.”—Senn, “Principles of Surgery.”

Much of this confusion might be avoided if all would bear in mind the meaning of the words in their original languages.

Sphacelus is derived from a Greek word which means “I slay.” Necrosis is derived from another Greek word which is translated, “I kill or make dead.” Mortification is formed of two Latin words and means in the original, “I become dead.” So that the three words are practically synonymous in their meaning and should be applied to a part that

is dead, or in process of being destroyed, without reference to the nature of the tissue involved.

Gangrene is derived from the Greek language, and means “to gnaw” or “to eat,” hence is applicable to rodent or phagedenic ulceration, which also results in destruction and death of the tissue involved. Clinically it can not be applied distinctively from the other three terms. I have used the word, gangrene, in its adjective form in the above title, for the reason that death of the tissues occurred by phagedenic processes.

THE PATHOLOGY OF TETANY.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOHN T. CARPENTER, A.M., M.D.

POTTSVILLE, PA.

1. By way of introduction, a brief sketch of the literature and history of tetany may not be inappropriate, since very few observations have been published or papers written in this country upon the disease in question.

The recognition of tetany (though Steinheim is credited by Stewart, of Montreal, as the first to give a true clinical description of tetany in 1830) dates from the memoirs of Dance, published in 1831 in the *Archives Générales de Médecine*, and entitled, “Observations on a Form of Intermittent Tetanus.” The attention of the French physicians of this period having been directed to the new malady, various papers and memoirs were contributed by them from 1832 to 1855, elucidating its characteristic symptoms and conditions so thoroughly that it may be fairly conceded that to their labors is due all our present knowledge of this disorder. Several names were proposed to be given to this neurosis, some of them expressing the special pathologic view taken by the author, *e.g.*, rheumatic contraction occurring in nurses (Trousseau); intermittent tetanus (Dance); idiopathic muscular spasms (Delpech). Of other titles, conveying no necessary theory, that which has finally prevailed is “tetany,” proposed by Dr. Lucien Corvisant in 1852. To this designation there can be no valid objection, and it happily calls attention to a marked feature in the symptomatology, *viz*: That there is, by reason of extension of the muscular contractions to the muscles of the jaws, a superficial resemblance to idiopathic tetanus.

Among other nations than, the French the more recent contributions have been made by Buzzard, Gowers, and Horsley, of England; Berger, Erb, Eichhorst, Meinert, Mueller and others of Germany; Hun, J. Lewis Smith, Lyman, Carpenter, and Stewart of America.

Under the light thrown upon the course of tetany, its conditions, and its characteristics, by the various writings referred to, it has become well recognized as a neurosis, and been given a definite place among the nervous diseases.

2. Definition. Tetany is perhaps best defined as a nervous disorder, evidenced by tonic spasms of an intermittent character, which may involve any or all the groups of voluntary muscles from the extremities to the muscles of the jaws, and which may be reproduced at will, during a period of intermission, by compression of the nerve trunks or great vessels which supply the muscles which have been involved in the spasm.

3. Pathology. It will be noticed that this descriptive definition does not go beneath the surface. It does not attempt to deal with the underlying pathology of this disorder, which up to this time has not been definitely settled. Two reasons may be adduced for this pathologic ignorance, first: That in the few instances "where a histologic examination of the nervous structures has been obtained after death, no lesion to account for the symptoms present during life could be discovered."—(Stewart, *Trans. of Assoc. of American Physicians*, Vol. iv, 1889). Indeed, according to Lyman, the "later observers, particularly Berger, in the "German Encyclopedia of Medical Sciences," and Eichhorst, take the ground pretty strongly that there is no definite lesion connected with the disease." In other words, no information can be looked for from lesions found post-mortem, to instruct us in the pathology of tetany. It will be, later on in this paper, possible to give sufficient reasons why such a state of things might be expected to exist.

The second cause of pathologic uncertainty in the study of tetany lies in the various forms under which it has been observed to appear, and in the various conditions and circumstances which attend its approach and development. Four forms of tetany may be safely stated to be established by competent observations: 1, rheumatic or epidemic tetany—acute, usually not lasting over two or three weeks, rarely fatal; 2, a more chronic form, due either to chronic diarrhea, prolonged lactation, or other debilitating influences. Recovery is usual; 3, tetany occurring in the course of dilatation of the stomach—very often fatal; 4, surgical tetany, following the removal of the thyroid glands. This is frequently fatal.

But besides its different forms, tetany is attended and preceded by many and various phenomena which may well perplex attempts to reduce them to conformity to any common law. If diarrhea has been a common antecedent, cases are on record where constipation was the observed condition. Women in the puerperium and during lactation have been largely contributive to the lists of tetany—but so have children and men. Typhoid fever and phthisis have furnished a number of cases. So has exudative disease of the pharynx. What of surgical tetany, or of dilatation of the stomach as a cause? Can we make any generalization among all these varying conditions? Can any fundamental peculiarity be made to appear common to all these morbid states? This very difficult problem has seemed to me only solvable on the hypothesis of septic infection, and upon that hypothesis to be satisfactorily explained. Every antecedent disease that has been observed connected with tetany may be proved capable of inducing septic infection; or in other words:

Tetany, as a general rule, follows upon such diseased conditions of the system as are observed to produce morbid discharges from mucous surfaces, whose absorption is known to cause symptoms in remote parts of the body, due to the circulation of septic poison.

I will venture to speak more in detail of the antecedent diseases or morbid conditions most frequently connected with tetany. And first may be mentioned the puerperium or post-partum state. Trousseau speaks of it in connection with tetany, as an intermediate condition between health and disease. But it is more. It is very frequently a state of disease, due to septic inflammation of the generative tract.

Modern obstetric physicians know that sepsis (mild or severe) is usual at this period. To it they justly attribute the so-called "milk fever," the puerperal inflammations, and many other of the diseases of puerperal women. If, then, a septic condition may and often does exist, sufficient to produce these diseases in the post-puerperal woman, it is not difficult to see that it will also account satisfactorily for the causation of tetany. This explanation will include necessarily the cases of tetany among wet-nurses in lying-in hospitals, where it was so frequently observed that one of the names bestowed upon the disorder was "rheumatic contractions occurring among nurses."

Next to the post-puerperal state may be mentioned diarrhea—and especially when chronic. It is almost unnecessary to more than advert to the conditions of putrefactive and septic intestinal catarrh as competent to produce systemic infection by absorption, and, consequently, any of the so-called septicemic results. Under my own observation, in the war of the Rebellion such results were very frequent, and septic poisoning from chronic diarrhea was fully recognized by all army surgeons of experience. Certainly, then, tetany may well have occurred after chronic diarrhea if it be a result of sepsis. Bearing immediately upon this point, I may note that Trousseau records "many cases in individuals who had suffered from cholera," and that some instances which were observed after the septic diarrhea of typhoid fever have been recorded by Demarquey and Delpech.

Tetany has been noted where the precedent condition was that of chronic constipation. Such a case has been recently been published by Dr. J. Lewis Smith (*Med. News* Aug. 31, 1889). But we all know that in many instances constipation is attended by a catarrhal inflammation of some part of the intestinal mucous membrane, or even by putrefactive changes in the food, resulting in the production of poisonous alkaloids, which by absorption result in serious septic infection.

Certain cases of phthisis have been observed to precede the development of tetany. There is no difficulty here in the proposition that a sepsis which is competent to produce hectic fever is equally effective in causing conditions favorable to the development of the disorder which we are now considering.

In the recorded cases preceded by dilatation of the stomach, the putrefactive change in the gastric contents, the ptomaines generated and absorbed continuously for a long period of time, sufficiently explain the sepsis and the tetany as well.

To sum up, I will say that so far as my study of this subject has gone:

In all cases of recorded observations of morbid processes antecedent to tetany a probable sepsis may be inferred, and no other cause common to them has so far been discovered. It is therefore logically necessary to assign the causation of tetany to this fundamental peculiarity, as the antecedent factor, and to consider tetany not as an independent disease, but as a disorder consequent on some one of those diseases which generate septic poison.

5. I will adduce a few cases to illustrate the connection of septicemia with tetany:

Case 1.—Cecil D., age 13 months, was seen by me Sept. 29, 1883, for an apparently poisoned wound near the hip joint. An area of inflammation over a hardened base was found, apparently extending outward from a central puncture.

Pain and fever were noted. In a few days a small abscess was opened, and thin sero-pus escaped. Under antiseptic measures this healed readily enough, but nervous irritation persisted in spite of sedative treatment. Soon a tonic spasm affected the eyeballs, fixing them and directing them to the right. The left arm and hand were contracted typically, the flexed thumb and fingers inclosing it being fixed in the position of the so-called accoucheur's hand. No ordinary convulsions occurred, nor was there loss of consciousness. Some relief was obtained by the use of chloral. Later in the day, however, the eyes were again contracted by toxic spasm but were drawn in the opposite direction, to the left instead of the right, and now the right arm became involved. Some difficulty in administering remedies made me discover that the jaws could not well be opened. On the third day the condition of affairs was much worse. There was alternation of tonic spasm first upon the right side and then upon the left side of the body, in a curious manner, with completely locked jaws. I relaxed the contraction by chloroform inhalation sufficiently to allow the introduction of wedges of soft wood between the jaws; and to my great surprise the entire spasm relaxed. The pressure of these contracted muscles upon the wood seemed to exhaust their contractility. The eyes became straightened, and all muscles relaxed. Relief was, however, only temporary. The spasms returned. No treatment availed to stay the progress of the disease, and death ensued in about a week from exhaustion.

In this case the whole train of symptoms must be traced to the abscess. The child was previously in perfect health, and its surroundings unexceptionable. No local results were left. The abscess healed, but septic material had been absorbed, and tetany followed. There is absolutely no other explanation of the case possible.

Case 2.—Sophie S., aged 11 months, was seen Sept. 29, 1880, and underwent an attack of scarlatina. Septic poisoning was incurred from foul secretions in the throat. Purulent effusion into the right shoulder joint followed. I opened the joint freely, and evacuated a quantity of sero-pus. Under antiseptic management the wound healed kindly, and the joint was restored to usefulness, but nervous symptoms persisted. Restlessness, twitchings, and finally laryngeal spasm ensued. A fit of crying would bring on a paroxysm of "crowing croup" and fits of crying were not infrequent. The muscular contractions of tetany were then observed, and at first were mistaken for ordinary convulsions, but as the spasms were tonic and not clonic spasms it is very evident that their true significance was only recognized at a late date. The child eventually recovered, but for several years afterwards was liable to attacks of tetany (which I then recognized) from very slight causes, such as taking cold, or during attacks of ordinary diarrhea from subsequent teething.

Any comment upon this case which would ignore the principal part taken by the blood poisoning in the production of the tetany would be entirely illogical and unsatisfactory. If this case teaches anything, it is that tetany was here a nervous disorder consequent on previous disease, and that the sepsis, which caused purulent effusion into the shoulder joint produced also the tetany.

Case 3.—A little girl, 21 months old; recorded by Trouseau. Symptoms observed were edema of the feet and limbs, with the contractions of tetany very well marked. The child was of weak constitution, and was suffering from membranous, ulcerative stomatitis. The exudations which were of a grayish-white color extended over the tongue.

In this description we recognize a condition of vitiated and septic secretions, in which every opportunity exists for absorption into the blood of the material of the poison which I have assumed to be the efficient cause of tetany.

With these cases I will close the direct argument, and pass to other indirect and corroborative reasons why septic infection may produce tetany.

5. For, in a general way, it may be shown that many other nervous affections do directly follow

sepsis, whence it is an easy deduction that tetany is not unlikely to be in the same category.

The following case, in which laryngismus stridulus occurred after a surgical procedure, which unfortunately ended in septic absorption, will be to the point:

Case 4.—E. A. C., aged about 6 months, was operated on for a very extensive erectile tumor of the scalp which was rapidly increasing. Hemorrhage being feared, ligation was done under chloroform. The strangulation was not perfectly accomplished, owing to the size of the tumor, and death of the parts proceeded slowly. Erysipelas was observed in the scalp about the ligatures, and the tumor was immediately removed by the knife, and wound dressed antiseptically. Infection, however, had already taken place. The left shoulder joint became widened, the superficial veins enlarged, and fluctuation was evident in the synovial sac.

I opened the joint, washed out its contents, and treated the wound antiseptically. A perfect cure resulted, with restored motion of the joint. But nervous disorder was left. Restlessness was extreme, and the child became the subject of severe laryngismus stridulus, which came on after the least distress or fright, or even after a crying spell. This, although, alleviated by every device and every attention possible, remained through life, the little sufferer dying eventually of malignant diphtheria.

The remarkable resemblance between this case and Case 2 will be noticed. Sepsis after scarlatina, and after a surgical operation, equally, produced purulent effusion into the shoulder joint. The final result of septic absorption was expended on the nervous system—in one instance tetany, in the other laryngismus stridulus resulted.

Case 5.—Leonard F., aged 28 years, sustained a fracture of the clavicle. From neglect and mismanagement secondary abscesses occurred under the axilla. I was called to see him for a violent attack of chorea, which set in after the evacuation of the pus from the axillary region. This chorea was attended with disturbance of the higher nerve centers, as shown by attacks of irrepressible rage, delusions, and other symptoms of acute mania. Entire recovery in about seven months took place.

I need not cite any other illustrations of the fact that serious nervous disorders may occasionally follow sepsis. It is sufficient for my purpose to direct attention to these ordinary medical facts, and show from analogy that it lends great weight to my theory of the pathology of tetany.

Why remote effects of septic absorption are expended on the nervous system is not very hard to understand. In the first place such a condition of blood poisoning produces a profound anemia. This was evident to army surgeons in cases of chronic diarrhea. It is equally observable in the septicemia of puerperal women. The absorption of ptomaines from the stomach and the intestinal canal equally impoverish the blood, and produce the anemia which is the proximate cause of nervous irritation. And, as pertinently remarked by Dr. Jacobi, anemia, particularly in infants and children, in whom the irritability is very great and the inhibitory centers very insufficiently developed, often predisposes to convulsions. To this I will add, and to other nervous disorders, including tetany.

Another observation which ought to be made here is as to the influence of habit in keeping up for a longer or shorter period the attacks of tetany. Given the septic absorption, and the consequent anemia, after nervous disorder (tetany for instance) has been induced, a condition of unstable equilibrium is set up in the nerve centers under which very slight influences will reproduce from habit, if from nothing else, the nervous symptoms which were at first inaugurated by septic absorption.

6. It may have occurred to many of us, since the investigation of tetany has been attempted, how rare a disorder it is. Forty or fifty years ago it challenged attention by its frequent occurrence in epidemics, among wet nurses in hospitals and others. Twenty years ago it was not commonly met with. Now, few of us can testify to having treated a case. What is there in the management of post-*puerperal* women which has hindered the development of tetany as a sequel? What is there in the diarrheas of the present day to produce a like immunity? Is it not because we recognize *puerperal* and intestinal sepsis, and make antiseptic medication our principal treatment, using douches of hydrargyric bichlorid for the *puerperium*, and so modifying by resorcin, sulphocarbolate of zinc, creosote, or other antiseptics the intestinal secretions that a septic poisoning from diarrhea is now an exceptional result?

And so with all other diseases; so thoroughly have antiseptic measures been employed in treatment that septic poisoning promises to become almost a memory of the past. With the extinction of septicemia will come virtually the disappearance of septic disorders and sequelæ, and among them of tetany itself. Just as the *puerperal* inflammations have become less and less frequent under the rise and perfecting of antiseptic midwifery, so with tetany. It is even now a record mostly of past days in medicine.

And this to my mind is the most convincing proof of the pathologic considerations which I have had the honor to lay before you.

AUTO-INFECTION IN DISEASES OF THE NERVOUS SYSTEM AND SUGGESTIONS AS TO ITS TREATMENT.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY DANIEL R. BROWER, M.D.

CHICAGO, ILL.

PROFESSOR OF MENTAL DISEASES, MATERIA MEDICA AND THERAPEUTICS IN RUSH MEDICAL COLLEGE; PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM IN WOMAN'S MEDICAL COLLEGE AND POST-GRADUATE SCHOOL OF CHICAGO.

The present is preëminently the time of the study of the etiology of disease, just as the past has been characterized by an almost exhaustive study of anatomy, physiology and pathology. In this connection the subject of infection has been the most profitable, as it has been the most interesting of all investigations; most interesting because little by little it has brought to light the knowledge of microorganisms that produce diseases, the causation of which was hitherto inexplicable; profitable because it has and will result in the discovery of the conditions that arrest their development and the agents that will neutralize their toxic influence.

Infection from without we may safely say produces the various forms of meningitis, including cerebro-spinal meningitis, tetanus, hydrophobia, acute poliomyelitis, acute ascending paralysis, the *puerperal* and syphilitic diseases of the nervous system.

The infections which arise from within are also important etiologic factors in developing diseases of the nervous system. The principal source of this auto-infection is the gastro-intestinal tract. The microorganisms there developed may produce simple indispositions or the graver conditions of delirium, coma, eclampsia, excessive elevation of temperature, acholia, cardiac failure and paralysis of the medulla

oblongata. They bring about these results in several different ways. They may act mechanically by obstructing blood vessels of the lungs, kidneys and brain; they may develop anatomic lesions in epithelial cells, in muscular fibers and other elements, thereby producing edema, hemorrhage, suppuration and gangrene. They doubtless consume for their own nutrition that which is necessary for the nutrition of the individual, and they do produce toxins. We have long been familiar with the toxic agents produced by fermentation in the laboratory, such as carbonic acid, marsh gas, hydrogen, ammonia and such complex alkaloids as indol-phenal and skatol, and as toxic agents may be produced in the laboratory of the chemist, so may they be in the laboratory of this great tract.

The reality of this intestinal auto-intoxication can be shown by demonstrating the toxins in feces and in the urine which owe their presence therein to putrid fermentation in the intestines, and diminish *pari passu*, with diminution of the intestinal fermentation, and by the prompt appearance of grave symptoms when the progress of the fecal material is arrested; as, for example, in strangulated hernia.

These toxins are formed at all times in the ordinary gastro-intestinal tract, and the individual is saved from intoxication, first by the liver that stands as a watchful sentinel, shutting out or destroying the poisons carried to it by the portal circulation from the digestive tract, and made by the rapid elimination in a state of health of the toxic products by the intestines, the lungs, the skin and the kidneys. The toxic products of these several emunctories have all been carefully studied, especially those of the urine, notably by Prof. Bouchard, of Paris.¹

The relation of this subject to the psychoses is most important. The subject was discussed at the Fourth Congress of Mental Medicine, held at Rochelle in August, 1893.

Drs. Regis and Chevalier-Lavaure, referees, stated² that they had been working on the line of autogenous poisons and had made many chemical and clinical researches to elucidate the relations of auto-intoxications to mental diseases. The toxicity of the urine was found diminished in maniacal states and augmented in melancholia. The urine of maniacal patients when injected into animals produces excitation and convulsions; that of melancholic patients, restlessness, dejection and stupor.

The mental disorders that arise during the course of the infectious diseases are clearly recognized as the result of pathogenic organisms, with the clinical observation that in the febrile stage the psychosis is usually an acute delirium resembling alcoholic; in the post-febrile stage, it is usually of an asthenic character, a state of mental cloudiness and confusion. The visceral psychoses are also in great measure the consequence of auto-intoxication, and they present as their clinical aspects if the intoxication is acute, delirium; if the intoxication is slow, a state resembling melancholia or more rarely paralytic dementia. Not only are we to recognize many of these mental diseases as auto-infections, but also such diseases as epilepsy, megrim, chorea and neurasthenia, and probably others of the nervous system.

We find in these cases a coated tongue, a foul breath, a gastric and intestinal indigestion, flatulency,

¹ Lectures on Auto-Intoxication in Disease.

² Bost. Med. Surg. Journal. Sept. 14 1893.

palpitation, irregularity of heart's action, a peculiar complexion, constipation, and occasionally diarrhea, all evidence of a condition of perverted function in the gastro-intestinal tract that will develop microorganisms and toxins.

The indications for treatment are to prevent the development of the toxic products and to promote as rapidly as possible their elimination. To meet the first indication a carefully regulated diet is of paramount importance, and this must be selected with reference to the capacity of the patient. Milk and its preparations are the ideal diet, because under proper direction they introduce into the body the least amount of toxins or microorganisms, and leave the minimum amount of waste material; but we must bear in mind that this diet contains a considerable excess of fats and a deficiency of carbohydrates, and therefore will not properly nourish all persons. I know no more difficult and important question in these cases of auto-infection than the selection of a diet that will furnish nutrient material in abundance, with the minimum amount of intestinal and gastric fermentation. Each case must be carefully studied by itself, and the diet adjusted to the individual peculiarities. The patient should be weighed frequently to determine the precise condition of general nutrition.

To further promote the first indication, a judicious course of gastro-intestinal antiseptics must be maintained. The use of lavage and enteroclysis are valuable aids that are almost always required, and sterilized water is amply sufficient to produce all the results possible. The condition of gastric digestion should be carefully determined by analysis. If the amount of hydrochloric acid is deficient, antiseptics can be promoted by a combination of hydrochloric acid, with bitter tonics and aromatics such as the tinctura gentianæ comp. and tinctura cardamoni comp. If there is hyperchlorhydria then alkalies are indicated, and I frequently prescribe with benefit equal parts of salicylate of bismuth, magnesia and the bicarbonate of soda. Charcoal powder and oil of cloves are also useful agents in correcting gastric fermentation.

We need to-day a reliable gastro-intestinal antiseptic. Intestinal antiseptics is difficult to produce. A careful study and experience with many of the drugs recommended for the purpose have resulted in the almost exclusive use of benzo-naphthol, salophen, papaine (carica) and oleum carophylli. These must be given in full doses frequently repeated and can often be combined together with advantage.

The second indication that is, the elimination of the toxic products, is to be accomplished: 1, by judicious purgation, calomel and the salines being especially valuable; 2, by promoting renal elimination and for this purpose again calomel stands at the head of the list; 3, by increasing the activity of the skin, as by baths and massage; 4, by increasing respiratory activity, as by judicious chest gymnastics and the inhalation of oxygen. The use of static electricity by insulation and by the static induced current will materially aid in this work of elimination.

The treatment of the various diseases of the nervous system that result from auto-infection not only require the indication above mentioned to be fulfilled, but the damage done by toxins and microorganisms must be treated, and each individual case will require special treatment.

MORPHINISM IN MEDICAL MEN.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. B. MATTISON, M.D.

MEDICAL DIRECTOR BROOKLYN HOME FOR HABITUÉS.

It is a fact—striking though sad—that more cases of morphinism are met with among medical men than in all other professions combined. It is too true that a very large proportion of cases in general are found in our own fraternity.

In a paper, "Opium Addiction among Medical Men," presented in the *Medical Record*, eleven years ago—June 9, 1883, reference was made to the dismissal within a week of a half dozen doctors recovered from this disease, and attention called to the surprising frequency with which it occurs in this particular class. Another decade of professional work exclusively given to the betterment of such patients has brought no decrease in this number; indeed the reverse has quite steadily obtained, so that in a paper, "The Ethics of Opium Habitués," *Medical and Surgical Reporter*, Sept. 8, 1888, in a résumé of 300 cases, we noted 118 doctors, and of 125 most recently under my care, 62 were medical men; and the latest reference to my record shows a still larger proportion, being more than 70 per cent.

Again and again I have been asked with surprise, "Why do doctors so often fall victims to morphia, when they, more than all others, should know the risk attending its use?" Various factors make up the answer to this query. Insurance statistics prove that medical men attain a shorter average lease of life than those of other professions, and the causes that tend to this lessened longevity play a part in the rise of morphinism. It is also true that the wear and tear of their calling provoke a large share of painful non-fatal disorders. Neuralgia, in one or other of its protean forms—especially migraine—which leads the list in the genesis of this toxic neurosis, occurs among physicians with a frequency that may well excite surprise. Add to this the anxious hours, the weary days and wakeful nights which the experience of every busy doctor so often involves, and which, though acting indirectly, still swell the sum of causative conditions in this chronic toxemia, and little wonder that we have a soil specially rich for a sorrowful harvest if, unhappily, the seed be sown.

It has been asserted that medical men become morphinists through their calling involving frequent handling of morphia, but that statement in my opinion is not true. Erlensmyer shares in this disbelief. Druggists, whose vocation largely exposes them to the same risk—more so in the city than the doctor—do not often become morphinists.

A cause peculiar to the medical man, in some cases is that careless curiosity which prompts him—generally a junior—to note the effect of morphia upon himself and in so doing incur the risk of addiction. Obersteiner refers to such cases. A young physician asserted that while on hospital duty a patient was dismissed who had suffered from carcinoma of the stomach and been treated with morphia injections. Next day he returned, begging for more as otherwise he must die. This was in 1869, when chronic morphinism and its results were less known than now. As the doctor was inclined to think the patient was romancing, he tried the experiment upon himself to ascertain the effect, became a morphinist and never

recovered. Another case was that of a young physician who, being assistant in a physiological laboratory, thought himself an interesting subject for experiment. More than one doctor whose disease had a like origin has been under my care.

Another cause obtains with physicians to the same extent as in non-medical men, that is the all-too-frequent use of morphia which the modern practice of medicine involves. Of this there is no question. Indeed, it holds more largely with the doctor than with the layman, for the former fully aware of the opiate's power to ease pain, pressed by his duties to get relief with the least possible output of time, and declining to make himself an example of the precepts tendered his patient, as to the value of patience under suffering, that will permit the using of non-opiate remedies, or, if the morphia be demanded, which, at least, will secure its giving at infrequent intervals, or alternating with other anodynes, and so lessen the risk of addiction—lacks a certain inhibitory, so to speak, protection which serves as a shield to the non-professional patient.

Still another genetic factor and in my opinion the one which outranks all others relative to the frequency of this disease in medical men, is their ignorance or unbelief as to the subtle, seductive, snareful power of morphia. It is to me quite beyond belief that any doctor *fully* realizing how swiftly and how surely the trebly pernicious power of this drug takes one captive will deliberately give himself up to a servitude galling alike to body and mind, and which in most cases ends only with life. Such a suicidal course is opposed to reason, to common sense and to fact.

In expressing this disbelief you will quite likely infer my skepticism as to the common opinion regarding the ethical status of our *confrères* whose ill-starred fortune has brought them such wretched result. I have long held, and still hold, with steadily growing belief based on nearly twenty-five years study of this disease, and an acquaintance intimate more or less with the history of many hundred cases, that medical men do not become morphinists from an innate propensity to evil, from a merely vicious desire to indulge in the pleasures of the poppy—pleasures which, be it never forgotten, soon and surely give place to its pains—but rather that they are impelled thereto by force of physical conditions that, with the largely prevailing failure to realize the risk incident to incautious morphia using are practically beyond control. This phase of the subject need not detain us for it has been noted with detail in two papers, "The Ethics of Opium Habitues," *Brooklyn Medical Journal*, August, 1888, and *Medical and Surgical Reporter*, September, 1888.

In reviewing the various causes of morphinism in medical men, the most hopeful feature is the fact that they are largely preventable. In this lies the strongest incentive to presenting this paper, the largest promise that it may do good.

Regarding the cause first cited—the wear and tear of an over-active professional life—we must be specially sanguine who would expect to improve conditions along this line to an extent likely to largely lessen such untoward result; though it can not be denied that the cares of a medical calling are less exacting than a decade or two ago, and so figure less as a genetic factor in this disease; yet I am bound to confess the outlook much more encouraging should

careful and concerted effort be made to make less active the other causes to which we have referred.

Regarding the misdirected zeal of the hapless seeker after self-evidence of the effects of morphia we can only again warn him—and earnestly—that the experiment is fraught with danger, and the rash act may prove his ruin, for the spark thus applied may set aflame that which will only be extinguished with life. He is a fool who does it; and the truly wise man will curb his spirit of inquisitive research along this line, if only on the score of personal well-being; besides no such self-sacrifice is called for, inasmuch as the peculiar effects of morphia, both as to blessing and bane, are now quite patent to all.

No one who has given the subject special thought will be likely to question an assertion that the use of morphin in the medical practice of to-day is in excess of what an actual need demands. And in direct proportion, more or less, to this excess stands the increase of morphinism. As a factor, applying to cases in general, it outranks all others though as regards medical men it holds in my opinion second place. Custom and convenience share in its causation. Custom, because experience has brought a belief in the anodyne-soporific power of morphia, which while well founded, has not been attended by an equally well-grounded belief in its possible power for ill. Convenience, because its promptly pronounced effect favors it as first choice when speedy relief is desired, and especially where as too often happens with the younger men in the profession, the wish to score such a brilliant result as may prove a stepping stone to rapid professional advancement outweighs a due regard for untoward remote effect, from which appreciation a frequent giving of morphia or any opiate should never, it is well to say, be exempt. This is a truism the force of which should never be forgotten.

Leading all others as a genetic factor in morphinism in medical men, is their failure to realize the insidious power of morphia to speedily get a grip, disturbing and destructive alike to functional well-being of brain and brawn, and in almost every instance, one too great to be broken by any self-effort they can command. At this writing I am consulted by a young physician whose case emphasizes this point. Sixteen months ago death left him wifeless and childless. In a specially unhappy moment of his grief he took a dose of morphia. It acted kindly, brought transient relief from his mental pain. A week went by before the second dose was taken and then—the old story: Quite mistaken as to the poppy power and his own strength to resist—again and again till his capture was quite complete. Commenting on his case he assured me he knew the risk attending morphia taking, and never should have incurred it had he fully realized how direful the result of that risk to him would be.

It is quite beyond credence that a doctor gifted with sound sense would wittingly put his neck in such a noose. Granting this, the only reason for taking such a perilous hazard is as before asserted, an inadequate appreciation of the morphia's power to enthrall.

Touching this point, enlarged experience confirms an assertion made ten years ago, that "the subtly ensnaring power of morphia is simply incredible to one who has not had personal observation or experience." One of the finest specimens of physical man-

hood we ever knew, a physician who survived the horrors of Salisbury prison when the death rate averaged 80 per cent., fell a victim after only one month's hypodermic using. Since then, case after case has been under my care in which the initial stage was still shorter. The most notable was an athlete of superb physique, who withstood the rigor of an Arctic winter as surgeon to a polar expedition, and then went down before a three weeks' daily quarter grain dose of morphia to ease the pain of an injured ankle!

So much for the genesis of this disorder. What the remedy? It is easy to moralize on the weak will—as many, mistakenly, are wont to put it—of our hapless brother living under this blight, but talk about "weak will" as a reason why strong men succumb to morphia—and I make bold to say that the man does not live who, under certain conditions can bear up against it—is twaddle. Far better is it to face the fact that morphiism finds most often its favorite victims in the noblest profession known, and then recognizing the causes that make this fact, bestir ourselves to such precept and practice as will tend to remove this blot on the scutcheon.

Can this be done? Very largely, yes. In this hopeful belief lies the one redeeming feature of the prevalence of this toxic neurosis in our own guild. Morphiism is on the wane in my opinion and I am optimistic enough to think the day not distant when it will be largely a thing of the past. But to reach this happy result it becomes the bounden duty of every physician to inculcate by teaching and by example the paramount importance of the causes we have cited that tend to the rise of this disease.

Two points call for special comment. These are the over use of morphia and the under thought of its danger. Regarding the latter, let me warn with all the weight I can command, every doctor who may be dallying with this drug or who may think its self-taking called for—and this warning holds with special force if the subdermic method be practiced—let me warn him that he is inviting disaster by jeopardizing interests vital to his well being, and let me urge him to pause and to ponder well whether, despite this warning, he dare take such risk. Let him not be blinded by an under estimate of the poppy's power to ensnare. Let him not be deluded by an over-confidence in his own strength to resist; for along this line history has repeated itself with sorrowful frequency, and—as my experience will well attest—on these two treacherous rocks hundreds of promising lives have gone awreck.

I have no wish to pose as an alarmist, but I tell you, gentlemen, that many a doctor who gives himself a daily hypodermic dose of morphia for a fortnight will come perilously close to the danger line—beyond which bondage begins.

Let him not chance it; rather let him, if the opiate demand be imperative, consign its giving to other hands; let it be by mouth; and oftener, let it be codeine which as an anodyne and sporic, has not yet had the measure of merit it deserves, and which, as tending to tolerance, is vastly less riskful than morphia. In a paper before the AMERICAN MEDICAL ASSOCIATION two years ago, "The Prevention of Morphiism," (reprint at command, and by the reading of which I would have every one of you the gainer) attention was called to the value of codeine. Enlarged experience has confirmed the opinion then expressed,

and while I am glad to note the demand for it is steadily increasing, I earnestly urge its still larger use as one of the most promising factors to favor a decline of the morphia disease.

Regarding the over use of morphia, never was there so little excuse for it as now, for never were the means at command to ease pain and bring sleep equal to those of to-day. Modern medicine is richly equipped in this regard, and if these resources be fully availed of, it will go far in a decrease of this ill.

As tending to this, teachers in medical schools should realize that they have opportunity to wield great influence for good and by word and deed they should improve it. To do so would strike right at the root of this evil, for I truly think the junior members of the profession are the greatest sinners in this regard; and if by timely counsel from their preceptors and college instructors the thousands who year after year begin a medical career can be brought to believe the danger incident to an incautious or needless giving of morphia, and then shape their practice in keeping with that belief, the good work will be largely done.

Slowly yet surely the therapeutic trend is in this direction. More and more the older medical men, impelled by larger wisdom or an experience often unhappy, are quitting the syringe; more and more rarely are they using morphia. The influence of this example must make itself felt on the younger men, and when to this is added the teaching we have commended the dawn of a better day will not be distant. May that good time coming soon come.

INFLUENCE OF ATMOSPHERIC PRESSURE ON THE PREVALENCE OF PNEUMONIA.

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held in San Francisco, June 5-8, 1894.

BY C. MAX RICHTER, M.D.

SAN FRANCISCO, CAL.

More than ever, physicians try to discover the cause of disease. Great discoveries have been made and for a number of diseases certain bacilli have been found to be the specific agents. More than ten years ago it was believed that such a bacillus had been discovered as the direct cause of pneumonia, and many consider pneumonia to-day an infective disease caused by a diplococcus. Still it is a relatively rare occurrence that this bacillus pneumoniae is found in pneumonia, and the riddle of the nature of this disease is by no means solved.

If I am ready now to bring indirect proofs of the nature of pneumonia before you, without referring to bacillar origin, I am induced to do so from the extraordinary exactness of such proofs. We understand that under the heading of pneumonia a number of different forms of this disease are included and we have reason to believe that a small percentage of it is certainly caused by a bacillus. Such may be the case in epidemics in prisons, etc. In this paper I refer to the two most common forms; fibrinous pneumonia and broncho-pneumonia. We know that these two forms appear in certain years on certain parts of our globe in epidemics, and that the greatest epidemics are probably isochronous with epidemics of influenza, other acute diseases of the respiratory organs and a great mortality from phthisis. We

know that they affect principally children under 5 years of age and adults above 50 years, and we know that the epidemics occur almost invariably in our winter or spring season in the northern hemisphere.

The continents of our globe suffer from epidemics often in the same year, and often in the same month, and furthermore different parts of the continents show a greater prevalence of the disease than others. Parts of the southern hemisphere have epidemics at the time of their winter and spring. Edward F. Wells, in his "Study of Pneumonic Fever," published in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, describes the territory suffering mostly from pneumonia as follows: "Beginning at the poles, its frequency increases in a gradual manner until the maximum is attained at a certain latitude in either temperate zone, and from these points it diminishes as we approach the equator." This description furnishes at the same time a concise statement of the extent of high atmospheric pressure on our globe, and when we follow Wells and Hirsch¹ in their enumeration of the different countries, as subject to epidemics of pneumonia, and the seasons or months in which such epidemics have prevailed in such countries, we get an almost accurate description of the areas of high pressure, as distributed over the globe, and of the season when they prevail. Both hemispheres have a belt surrounding the globe and marked by about 15 to 30 degrees latitude, where the mean pressure exceeds 762 millimeters, thirty inches. North and south of this belt the mean pressure is again diminished. Centers of highest and lowest pressure which are constant in one season of the year, as in winter for instance, have almost the reverse character during the opposite season, with a more or less gradual turn from one to the other—at least above the continents. In January as the representative of winter time, we find the area of highest pressure on our globe, in Siberia or East Asia. This area has its extension north and south over the greatest part of Asia, but spreads principally in a westerly direction into Europe which is almost entirely under a pressure of 752 millimeters (thirty inches). Areas of a somewhat higher pressure exist at that time in northern Italy, Switzerland and the southeast of France, in the center of Spain and of Sweden and Norway. All of the United States and most of British North America, Mexico and Central America have high pressure in winter time. On the southern hemisphere only part of Chile and Peru, the south end of Africa and a small part of southern Australia come under the influence of high pressure during our winter. The oceans have certain constant areas of high pressure during the entire year. All the above named parts of our continents with few exceptions have low pressure in the opposite season of the year. It could naturally be inferred that if an increase of air pressure would affect human health, that such disturbance would be experienced at that season and in those parts of our globe, principally and first, when and where centers of high pressure appear. At the time of low pressure such effects would be least noticeable or wanting.

I shall not speak of what we know about the effect of high pressure on animal life. We know very little about it but we do know that the decrease of pressure, as experienced in higher altitudes, is easily borne to a certain degree. It is also known that great oscil-

lations of pressure during a short period, are probably not detrimental to our health. Certainly the effect of excessively high pressure, continued for a great many days or weeks, has not been studied. The parallelism of the extent of high pressure and the prevalence of pneumonia at certain seasons invites us to examine more closely into their relationship—although strange to say, the fact of this parallelism has not been noted by any author. Wells and Hirsch and every other writer on the subject discards air pressure as a causative factor. The reason is that whenever an attempt has been made hitherto to follow up air pressure in its relation to pneumonia the mean pressure, daily or monthly, or the mean maximum or mean minimum pressures have been consulted. But if we wish to detect immediate effect of an extreme pressure, high or low, we can not judge from the mean figures. For the same reason mean figures of temperature would be deceptive. If a cold spell comes over the country as California or Florida, for instance, it may happen that the extreme minimum temperature of one or more degrees below zero is encountered in a locality otherwise exempt from such freezing temperature. This event happening perhaps once in ten years for a few days or one day in one month, may suffice to kill certain vegetation. The mean minimum temperature of such a month may not at all indicate the extreme of temperature which had such an effect. In a similar manner, atmospheric pressure, when augmented in certain years to a great extreme and if such extreme pressure continues for a period of days or weeks, may affect animal life, where the figure of the mean maximum pressure does not differ from that of other years which had no such deleterious effects. The extremes of atmospheric pressure as they come to us in daily life have never to my knowledge been scrutinized as to their relation to diseases to which animal life is prone. On Chart 1 are found the extremes of pressure as observed in every month of ten years or more, in different cities of Europe and America.

The figures of these extremes are all corrected for temperature (reduced to 0 Celsius) and for instrumental error. These lines show a certain periodicity in every one of the many years given, in having a lowest extreme of high pressure always in one of the summer or more rarely fall months, and in having the highest extreme always in one of the winter or more rarely one of the spring months. In some years more than one month will show such highest or lowest extremes.

Speaking only of the extremes of high pressure, the year 1882 has the highest extreme during January in Paris, London, Berlin and St. Petersburg, and in February in San Francisco. In 1883 the highest extreme is found in February in Paris, London, St. Petersburg, New York, San Francisco and New Orleans and in March in Berlin. In 1884 it is again in January in every one of the cities with the exception of St. Petersburg. In 1885 the first three have it in December, the other four in January. In 1886 five of the seven cities have the highest pressure in February and November. In 1887 six of these cities have it in February and only one, San Francisco, in January. In 1888 every one has it in January. In 1889 every city has it in December. It is the month in which grip first appeared. In 1890 every city shows high extremes in a number of months. In 1891 it is principally November and December which show the

¹ Hirsch Handbuch der Historisch—Geographischen Pathologie, 1886.

high extremes. In 1892 it is February, March and April that show the highest figures. The same regularity is found when we compare the different cities in the different years in regard to the month or months in which the lowest figure of extreme high pressure is noticed.

Sometimes this month will be early in the year as in 1884, sometimes in July as in 1887 and 1888, sometimes in August and September and rarely in October, but in most years different cities have the lowest high pressure during the same month. Still it is not unusual that the high pressure will remain low for two, three or four months. London and St. Petersburg being rather out of the centers of high pressure exhibit the greatest irregularities. San Francisco and New Orleans, remaining also in summer somewhat under the influence of high pressure, show the greatest regularity and the smallest amplitude. The extremes of low pressure are highest in summer time or at the beginning of fall, and lowest generally at that part of the cold season which has the highest figure of high pressure. Generally the extreme of low rises in one month and descends in the following, showing an almost continuous zigzag line. I add that in some years the extremes of low pressure have the same *minima minorum* in different cities during the same month. In short, we may say that *periods of excessively high pressure appear in certain years in different cities of the northern hemisphere in the same month and that this month is generally a different one in the different years.* The same regularity we notice for the time of low pressure at the opposite season of the year. On Charts 2, 3, 4 and 5 we find again the figures of extreme pressures, and besides, the figures of mortality from phthisis, pneumonia and bronchitis for Berlin, Munich, New York, Cincinnati and San Francisco.

During the twenty-two fiscal years (June 1 to June 1) for which I present these figures for San Francisco, the mortality from pneumonia and consumption was highest first in the year 1889-'90 when influenza first appeared, and then in the winter of 1891 to 1892. In none of the twenty-two years had there been such a continuous rise of pressure, covering a period of eight months from June to March, as in the year the grip appeared, although the difference of the highest and lowest "high" amounted only to 9.39 millimeters (.37 of an inch). This difference amounted to 12.70 millimeters (.50 of an inch) in the winter of 1891-'92 and was reached in four months from August to December. The highest rise happened in December, and the highest figure of pressure of the twenty-two years reached. This was accompanied by the heaviest mortality from pneumonia in the twenty-two years, in San Francisco.

A similar rise occurred in 1887 to 1888, from August to January. The high rise in January at that time also being followed by a very high mortality from pneumonia.

During the twenty-two years, the extreme of high pressure was lowest five times in September, seven times in August, four times in July, once in June, four times in two of the above months during the same year. The month during which the mortality from diseases of the respiratory organs was lowest was in nine of the nineteen years, for which records are kept, the same as the one in which the extreme of high pressure was lowest. In seven years the mortality was lowest one month after. In one year one month

before, in one year two months before and in one year four months before the month in which the extreme of high pressure was lowest. The mortality from these diseases was highest in eight years of the observed eighteen years during the same month, in which the high pressure was highest; in two years, one month later; in four years two months later, and in two years one month before the pressure was highest. This month was January five times, December four times, March six times, April twice and November once. Thereby it is demonstrated that the lowest mortality from pneumonia is generally or always found during that month or near that month which has the lowest figure of the extreme "high" and the highest figure of the extreme "low" pressures. When the high rises during the fall then the figure of mortality rises. If it happens that the low shows a lower extreme at the same time, and if this descent continues for the following month or months in which the high pressure continues to rise, then the figure of mortality shows a higher figure in proportion to this occurrence. However, it happens only rarely and not in every year that the low shows a continuous decline when the high has its incline. In some years it is found that the mortality is not in proportion to the ascent of the extremes of high pressure, as for instance, 1890-'91; then the continuity of the rise and perhaps the extreme fluctuations of the low during that period are the important features.

Any one who is conversant with figures of atmospheric pressure, as given by the barograph for the day, week or month, will know that the figures of extremes of pressure will hardly ever represent the result of an oscillation, happening only on a certain day of the month. Chart 6 exhibits the daily high and low extremes for two seasons, December—March, in San Francisco and helps to explain how large a part of the month may be under the influence of the one extreme of the month. In the instance given on the chart an extreme of pressure above 774.7 millimeters (30.50 of an inch) is found eleven times during the season the grip appeared first and only one time the season previous. Chart 7 demonstrates for Berlin how the weekly extremes correspond with the weekly figures of mortality. They show plainly that the mortality rises generally from the very week in which the pressure rises, and that the period of high mortality sets in after the pressure has become unusually high. It is seen here again that if during a rise of pressure for one or more weeks the low descends for the same period, then the mortality shows a corresponding increase and *vice versa*.

Every city as exhibited on the other charts shows the same regularity and periodicity of mortality. In every instance the law repeats itself, that *during the month in which the extreme of high pressure rises to a higher extreme, and that of the low pressure to a lower extreme, the mortality increases correspondingly, but it does so in proportion to the higher rise and not to the lower fall.* This law shows such *regularity, that in any given month of the year probably in any part of our globe we may be able to predict in future whether a greater mortality from pneumonia may be expected or not.* For San Francisco, for instance, during the twenty-two years, the lowest extreme of high pressure was never higher than 763.3 millimeters (30.05 of an inch) and never was found later than September. If then, as in the season of 1891 to 1892, the

highest extreme in August was only 760.0 millimeters (29.92 of an inch) and in September rose to not quite 762.0 millimeters (30.00 of an inch), then no increase of mortality could yet be expected. In October it rose nearly 2.5 millimeters (.1 of an inch) and the same in November, but during the same period the extreme of the lowest pressure had risen to the same extent as the high pressure. This precluded the appearance of high mortality. During December the extreme of the high had risen higher than during the two months previous, and the low had descended lower at the same time to such an extent that a high mortality could be expected, and San Francisco experienced during that month a very high mortality from pneumonia. During January the pressure showed the reverse from December and the mortality fell rapidly. The same in February. *Every one of the different cities shows the same relation of mortality from pneumonia to the course of atmospheric pressure.* The mortality from bronchitis runs almost parallel to that of pneumonia and the one of phthisis shows about the same direct relationship. Wells gives the following figures of mortality from pneumonia per mille of population for the following cities and countries:

Berlin 52 years, 1.21 per mille; London 17 years, 1.69 per mille; Paris 26 years, 2.56 per mille; Boston 42 years, 1.23 per mille; Cincinnati 20 years, 1.54 per mille; New York city 32 years, 2.03 per mille; Philadelphia 48 years, 1.30 per mille; New Orleans 2 years, 1.5 per mille.

I found that the figure for San Francisco 1870 to 1884 was 1.4 per mille, and during 1891 to 1893, 1.5 per mille. For all cities on the immediate coast line of California, it is 1.6 per mille; and excluding San Francisco, only 0.8 per mille. For cities in the coast valleys the figure is 1.3 per mille; for the great central valley it is 1.2 per mille; and for Southern California, inland, it is only 0.4 per mille. Wells found very low figures for Ceylon, 20 years, 0.7 per mille; Jamaica 0.3 per mille; Newfoundland 0.3 per mille. The three latter are outside of centers of high pressure and as Chart 8 shows, Southern California and the immediate coast line with the exception of San Francisco, do not have the high pressure found in the coast valleys and in the central valley.

The good effect that Southern California is reported to have on diseases of the lungs is put in a new light when judged by the character of atmospheric pressure. Normal air pressure shows the least difference during the year, of any California station, in San Diego; next in Los Angeles and San Francisco, and greatest difference is found in the stations of the central valley. Mortality from pneumonia shows similar proportions. It has been noticed that a northerly wind has generally been prevalent during epidemics of pneumonia. Since we know that the relation of wind to air pressure is a constant factor and that northerly and northeasterly winds prevail inside the area of highest pressure during winter all over the northern hemisphere this appears to be an additional proof. From this direction of the wind it will be clear that areas of high pressure will generally travel from East to West. We know that they travel with a velocity of from 500 to 1,500 miles a day. It is no wonder, then, that we find *maxima maximorum* of pressure in different cities of the northern hemisphere during the same month of some years. Ziemssen in his work on

pneumonia said a great many years ago: "After all we can not help but assume that there must be general conditions, perhaps multiplied by local circumstances, which appear and disappear simultaneously in great expanse of space. Of what nature these influences may be is perfectly dark. We would not be forced to think of miasm or contagion. We are more led to believe that fluctuations of atmospheric conditions extending over great areas of the surface of our globe, at the same time, furnish an analogy." To-day we know that atmospheric pressure will appear in such eruptions which are felt at the most populated regions of the northern hemisphere in the same month and perhaps week.

In over 80 per cent. of the forty-nine years observed by me in Berlin, Munich, New York, Cincinnati und San Francisco, a direct coincidence of the highest and lowest figures of air pressure and mortality from pneumonia, is fully established.

If we take into consideration the inaccuracy of mortality statistics in general, then the high percentage must appear striking. There is certainly a parallelism between the two figures that we do not find for any other disease, when compared with this or any other meteorologic feature. The simultaneous appearance of the great epidemics of pneumonia in late years, greater than during the many years previous, together with a continuous rise of high pressure and the great mortality from other acute diseases of the lungs during the same period, the reappearance of influenza at a time when high pressure had continued to exercise its influence for an unusually long period, these circumstances point to the fact that there must be a predisposing cause in high pressure. The figures for Berlin and Munich during the season, 1889-90, indicate directly that the figures of highest general mortality are parallel to the extremes of high pressure as they appear during the different weeks. In both cities the extreme of the highest pressure coincided with the figure of the highest mortality, which had been increased enormously during that period by mortality from phthisis, acute diseases of the respiratory organs, heart disease and old age. Influenza itself furnished the least number of deaths. If a certain increase of air pressure will have such an effect upon the health of the people as to cause pneumonia, or to make them subject to pneumonia, and since "feeble" and a low action of the heart are identical, the first object of future research would seem to be to study the peculiar action of increased air pressure on the blood or circulation of blood in the respiratory organs. If an appearance of an area of high pressure may have such disastrous effects upon human life, then we will not wonder any more why the incubation of pneumonia or influenza may last only hours or a day, why ships on the ocean may get an epidemic of either disease, traveling into an area of such pressure, why remote islands may suffer from these diseases without a possibility of a transferred infection. People living on high mountains may have to suffer when the air pressure becomes relatively higher during such periods. Feeble persons who had an attack of pneumonia one month or one season, may encounter a repetition of the attack as often as the high pressure is repeated. It is almost a relief to know that a phenomenon exists which shows a parallelism to the cause of influenza or pneumonia. Still what we know to-day is not suf-

ficient to explain in which way an extreme air pressure may cause pneumonia. We know from experiments that high pressure will reduce the force of the heart's action. The pressure in the arteries is diminished by it and at the same time a greater amount of blood is found in the inner organs. All this may be called a *postulatum* for the beginning of pneumonia. We practitioners will have a chance in the future to prepare those intrusted to our care, to acquire a proper power of resistance during the time the appearance of a high extreme pressure is telegraphed over the country by the weather bureau, and I trust that it may become more important to us in future to know whether an extreme "high" is hanging over our heads than whether it will rain or be cold on that day. The ideal for the physician is not to discover the cause for disease, nor to cure it, but to prevent it, and if my remarks to-day should be a proper move in that direction it would be another stimulus to continue the arduous and yet pleasant life of a physician.

CEREBRAL LOCALIZATION—WHAT IS KNOWN, WHAT SURMISED, AND WHAT IS ITS SURGICAL VALUE?

Read in the Section on Practice of Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held in San Francisco, June 5-8, 1894.

BY J. W. ROBERTSON, M.D.
LIVERMORE, CAL.

The physiology of the nervous system and the functional differentiation of its component parts has been but recently investigated, and is now in many particulars so well established that it seems proper before entering the domain of neurologic pathology to briefly recapitulate, not only that which has been scientifically proven, but the many speculations of eminent investigators that are as yet mere hypotheses. Without going into a detailed history of the evolution of cerebral physiology, I will refer to the great advance made by the anatomists of the seventeenth century. Before that time anatomy and physiology were necessarily theoretical, for as a basis they rested on speculation and tradition, not on the dissection of the human body. But the opinions held regarding the nervous system were even more crude than those that prevailed regarding other portions of the body, for the philosophers, led by Aristotle and Herophilus, had outlined a physiology based on their psychologic theories, and twenty centuries had served but to confound the already existing confusion.

Willis accomplished for the nervous what his contemporary, Harvey, did for the circulatory system. He not only delineated and named the cranial and spinal nerves, but recognized the important fact that the brain is not only divided into gray and white matter and correctly explained the functions of each, but also showed that the gray matter was convoluted simply as a wise provision for inclosing the greatest surface in the smallest space, realizing that there was a direct ratio between intelligence and the volume of gray matter, and further suggesting the possibility of its function being still more differentiated.

The next great advance in the differentiation of the nervous system was Sir Charles Bell's discovery that the spinal nerves subserved the two-fold purpose of sensation and motion; the one entering through the

posterior root bearing sensation from the periphery, the other solely motor, making it exist by the anterior root. This he proved by experiments on living animals and his results, published in 1811, were elaborated with so much detail that our own text-books do not contain any amplification of the theory there propounded. When in 1870 Fritsch and Hitzig announced the result of their experiments on dogs and monkeys, they were but confirmatory of views already advanced by Hughlings Jackson, whose investigations, both clinical and post-mortem, had suggested the existence on either side the fissure of Rolando, of special centers which presided over the movements of the leg and arm. But even earlier than this, Dax had pointed out the close relationship existing between aphasia, right-sided hemiplegia and injury of the frontal convolutions; though it was Broca who definitely located the speech center at the base of the third frontal convolution of the left hemisphere.

The original experiments performed by Fritsch and Hitzig consisted in the removal of a portion of the skull of dogs and monkeys, exposing the brain and irritating the cortex. Before this it had been believed that irritation of the cortex resulted only in convulsions, but when electricity was selected as a stimulus and very weak currents used it was found that irritation of certain convolutions produced definite motions, and so localized were these areas that it was possible for the experimenters to foretell the motion that would follow the application of the electrodes to a given area. This conclusively proved that there was some definite relation existing between these localities and movements of various members of the body.

Ferrier and Horsley in England, and Monk in Germany, modifying the methods of Fritsch and Hitzig, have so extended and varied these experiments as to eliminate all possible errors; the areas have been so incised as to separate them from other cells of the cortex, and portions of the cortex containing these areas have been removed and the resulting paralyses noted. Thus have the old theories been revolutionized and most plausible arguments advanced to support the assertion that not only the special senses, but that motion and sensation are located in well defined and accurately differentiated regions of the cerebral cortex.

So brilliant and so essentially scientific were these experiments that the deductions made from them as to cerebral localization have been accepted not only by the majority of physicians, whose judgment can not be based on personal investigation, but especially by many leading neurologists. But this acceptance is not universal, and it may be said that neurologists are ranged into three schools.

The very weighty names of Brown-Séquard and Goltz appear among those who altogether repudiate localization in the sense that one portion of the cortex intrinsically so differs from another as to possess a different function. They believe that each half of the cerebrum acts as a whole, but that certain portions may be educated and probably do preside over the special senses, motion and sensation.

The second school, represented by Exner, Obersteiner and other conservative neurologists, teach "that certain regions of the cortex are to a greater extent than the rest associated with certain functions." Obersteiner defines his position as follows: "Individual centers and cortex fields are not to be

considered as sharply outlined and definitely marked off from neighboring regions; the so-called centers are rather the spots of maximal relation to functions which fade away into neighboring areas. Hence it follows that the cortex fields to a certain extent overlap one another. We shall speak of the centers in this sense as comprehending the spots of maximal physiologic relation."

The third, known as the English school of localizers, is led by Ferrier, Horsley and Beever. These teach the absolute segregation of centers in the cortex; that they intrinsically differ the one from the other and that consequently their functions differ, and that there are not only regions presiding over the special senses, sensation and motion, but divide the last into finger, hand, arm, mouth, etc., centers; and further contend that these areas are sharply defined, are easily located and, when exsected, produce a permanent paralysis in that member of the body over which they preside.

It is this last which has brought this subject into such prominence. Granting that either the first or the second school be right, it is only a step forward in the study of cerebral physiology, but if the teachings of the abrupt localizers be correct, a vast field

Left hemisphere, brain of monkey.

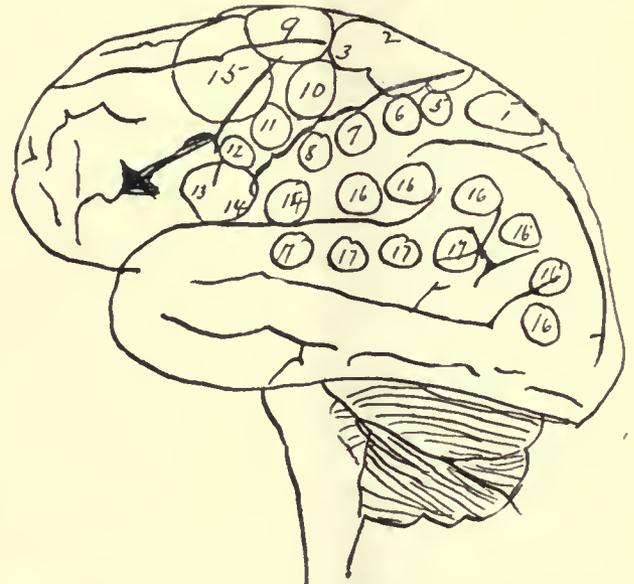

of practical importance has been opened and cerebral surgery will at least receive a scientific recognition, rather than occupy the invidious position it even yet holds among conservative surgeons. For this reason it seems well to review the work of these investigators and to point out what they have demonstrated, as well as the many questions that are still under investigation and to show that some, at least, are unsolvable.

What has been proved is that when certain regions of the cortex of the brain of monkeys, dogs and other animals are irritated by mild currents of electricity, motion is produced in corresponding parts of the body. That portion of the cortex which has been shown to be closely associated with motion is known as the Rolandic region, from the fact that it is composed principally of the two convolutions which are separated by the fissure of Rolando, as well as the parietal lobule.

This region is subdivided into special centers. Irritation of the parietal lobule and upper junction of ascending frontal and parietal convolutions produce advance of the opposite hind limb, flexion of thighs and toes as in walking. When the middle

portion of the ascending convolutions is irritated, movements of the hand and arm follow. The lower junction of the convolutions are in like manner shown to preside over, or at least closely associated with, movements of the mouth, tongue and nose. Posteriorly, near the angular gyrus, irritation results in movement of the eyes and eye-lids, and still farther downward on the superior temporo-sphenoidal convolution there is pricking of the opposite ear, head and eyes turn to the opposite side and the pupils widely dilate. Other regions, though irritable, are not connected with coördinated movements, while much of the cortex is insensitive. Thus it is shown that motor activity, though present to the greatest extent in the so-called motor area, is not confined to it. These experiments have also demonstrated the fact that while each hemisphere is closely associated with the opposite half of the body, to a subordinate degree it also presides over the same side.

What is surmised? That the brain of the monkey and other animals resembles the brain of man to such a degree that what is true of the one holds equally true of the other; that both in man and animals the brain is so differentiated that certain areas

preside over allotted functions and that they are capable of being subdivided. Especially is this true of motion. To a lesser extent it is true of the special senses, and the brain has been mapped out into centers of sensation, hearing, sight, smell, taste and speech, and these have been located as follows:

Motion.—The ascending frontal and parietal convolutions, their superior junction and the paracentral lobule. This, known as the Rolandic or motor region, has been subdivided into finger, hand, arm, mouth, etc., centers, every muscle or group of muscles being represented by a definite area in the brain cortex. In fact, the cortex may be compared to the key-board of a piano, and just as harmony depends on the combination of notes which are touched in succession, so can any given action or series of coördinated movements be obtained by irritating the proper area of the denuded cortex. These conclusions are the result partly of comparison with animals and partly of pathologic research, and may be thus summarized:

Superior parietal lobule (1) advance of hind limb. Upper portion ascending parietal (2, 3, 4),

complex movements of leg, arm and trunk as in swimming. Ascending parietal (5, 6, 7, 8) individual and combined movements of fingers and wrist of hand; prehensile movements. Posterior extremity of superior frontal convolution (9) extension forward of hand and arm. Ascending frontal (10) supination and flexion of forearm. Lower third of ascending frontal and junction of ascending frontal and ascending parietal (11, 12, 13, 14) movements of mouth and nose. Superior and middle frontal (15) and supra-marginal lobule and angular gyrus (16) Movements of mouth, eye deviates, pupils change and head turns (sight). First temporal (17) pricking ear (in animals), head turns and pupil dilates (as in hearing).

Visual Center.—In Ferrier's original experiments this center was located in the angular gyrus (16), as blindness resulted when this was destroyed. But other operators claim that sight is centered in the occipital lobe (16), and showed that when the gyrus only was destroyed and the life of the animal was prolonged beyond a few days, sight returned. On destroying the occipital lobe with the angular gyrus the resulting blindness was more prolonged. Ferrier says: "After extensive destruction of the occipito-angular region in one hemisphere, the temporary amblyopia of the opposite eye leaves a more enduring homonymous lateral hemiopia to the opposite side, yet unless the destruction of the cortex is absolutely complete (and in none of the recorded experiments was this the case), restoration occurs, to such an extent at least, that the defect ceases to be perceptible by any tests applicable to the lower animals." In other words, provided this be the center, some other portion of the brain assumes the function and is able to successfully receive and transmit visual impressions. It is further claimed that the simultaneous destruction of occipital regions in both hemispheres may produce permanent blindness, and Ferrier even goes the length of claiming that these regions are the central expansions of the optic tracts and consequently structurally differ from other centers, and that in his experiments atrophy of the nerves and tracts has followed destruction of these zones. But localizers are by no means agreed among themselves as to many of the minor facts, though the occipital lobe is the accepted center.

Auditory Center.—Experiments made on the lower animals as to the center of hearing are, from the very nature of the facts to be elicited, extremely unsatisfactory. It has been found impossible to eliminate the complications incident to the difficulty of intelligently interpreting the phenomena following the various lesions. Experiments seem to point to the superior temporal convolutions and it is claimed that post-mortem researches bear out this location.

Olfactory Center.—This has been selected from purely anatomic considerations. The roots of the olfactory nerve have been traced to the hippocampal region and the sense of smell has been assigned to the tip of the temporo-sphenoidal lobe. Comparative anatomy teaches us, however, that the olfactory bulb itself is a portion of the brain, and it would seem that if any portion of the brain were selected for special functions this would alone preside over the olfactory sense.

Tactile Center.—There is no question in cerebral localization more undetermined and apparently more undeterminable than is this. It is well known

that the sensory fibers when they pass through the internal capsule are differentiated from the motor tract, but the region of the cortex to which they are distributed has not been determined. Ferrier and his school locate this center in the hippocampal region, but the majority of neurologists agree with Fleisching who believes that the cortical fields of motion and sensation overlap each other, both occupying the Rolandic region.

Center of Speech.—By this is meant an inability to articulate, not to properly understand and appreciate what is heard. Situated at the base of the third frontal convolution of the left hemisphere, known as Broca's convolution, it has received much attention at the hands of pathologists, and medical literature teems with post-mortem facts that prove the close relationship this region bears to articulate speech. It has been further claimed that only in right-handed persons is this center on the left side, while in the left-handed it occupies a corresponding position in the right hemisphere. There is no fact in cerebral localization more generally recognized by the profession than is this speech center, and it may be a matter of surprise that it is not included among those questions of cerebral physiology which has been proven. Nevertheless, that this center presides solely over speech and that its functions can not be assumed by other portions of the cortex has by no means been demonstrated. It is not possible to here enter into a discussion of this point, but it can be stated positively that while many facts point to a connection between this center and articulate speech, it has been conclusively shown that tumors involving this region have not produced aphasia. One such well authenticated case is sufficient to overcome any number of facts which are adduced to support the theory of a well defined speech center. Not only have tumors been found which interfered with the Broca convolution, but embolisms have been recorded in which this whole area was softened and disintegrated without causing a loss of speech. Leading authorities, notably Bateman in his recent work on aphasia, take the middle ground. While they recognize the close relationship between the destruction of the Broca center and aphasia, they deny absolutely that it is in the strict sense of the term a *center*. They believe that it, as well as other regions of the brain bear some, as yet undetermined, relation to the faculty of speech. With all the light before us the most that can be said is that when the Broca center is involved in some destructive process there is often right-sided hemiplegia with aphasia.

From the above summary it will be seen that very little has been demonstrated. The great majority of questions that are of practical importance are by no means settled. The one fact that coördinated movements may follow electrical irritation of the motor area is regarded by many neurologists as simply one of the curiosities of physiology, and they by no means accept the deductions which the localizers have drawn from such experiments.

Ferrier explains these phenomena by supposing that cells in certain areas—not necessarily disassociated because a sulcus happens to intervene—possess an essentially motor function and that when irritated this irritation passes directly to the white fibers which spring from these cells, and that these fibers are collected into differentiated bundles, pass out through the internal capsule, become the anterior

and lateral pyramidal tracts and convey impressions through the anterior cornua into the anterior root. In other words, he teaches that the motor area is the cortical expansion of the motor tract and that consequently the cells from which the fibers spring are functionally differentiated from other cortical cells. Those who are not localizers find much to criticise even here. No one familiar with Ferrier's work doubts the experiments recorded. What they are not willing to accept is the legitimacy of his conclusions. Granting that the brain of the monkey differs from that of man merely in number and complexity of convolutions, rather than any intrinsic quality, and that the cells of the cortex are irritable, they still maintain that each cell is so closely connected not only with adjacent cells and those in neighboring areas, as well as widely separated regions even of the opposite hemisphere, but that an irritant could not be applied which would not equally irritate all the ramifications and connections of these cells. But even the irritability of the cortex is denied. It is well known that nerve fibers can be irritated by many agents, both chemical and physical, but it has not yet been proved that the cerebral cortex is susceptible to other than electrical irritation, and this electrical irritation is attributed to its quality of diffusion. It has been shown that when the exposed sciatic nerve of a frog or the still more delicate galvanometer was connected with the brain, the application of even light currents at a distance resulted in movements of the leg or deflection of the needle, thus showing that there was extrapolar conduction. Therefore, it is claimed that the electricity does not necessarily irritate the cells of the cortex, but may penetrate to the white fibers as they pass through the internal capsule. It is conceded that in this location the fibers are differentiated and that they are susceptible of irritation. The so-called motor region is therefore "motor," only because it happens to be contiguous to the internal capsule, and Dupuy, of Paris, points out the further fact that this region is unusually rich in deeply penetrating blood vessels: "The pia mater over the Rolandic convolutions is almost a complete network of vasomotor fibers and cells, and blood vessels which penetrate into the convolutions. One system of blood vessels only ramifies and ends in the cortex proper; the other enters the white substance by means of larger vessels accompanied by nerves and ganglion cells. It follows from this arrangement that the cortex proper is much more vascular and the white substance or fibers a great deal less so; and moreover that while the vessels irrigating the cortex are spread well over, those going into the white substance are isolated from one another. Now I have shown that those points which when 'excited' by electricity give rise to a motor action, coincide with spots where arteries with nerves penetrate into the white matter or strands of fibers. The best method to demonstrate this fact consists in injecting one carotid artery after having marked with ink the position of the motor centers ascertained beforehand by means of electricity."

Ferrier and his school while not denying the diffusibility of electricity claim that in their experiments its action can not be thus explained. Ferrier says:

"Irritation of the ventricular aspect of the corpus striatum causes general contraction of the muscles of the opposite side of the body; and it is impossible

by applying the electrodes to the surface of this ganglion to produce differentiated contraction in any one muscle of a muscular group." "We know therefore by direct experiment what irritation of the basal ganglia should produce; but the phenomena of irritation of the cortex are of a very different order." And again: "The great and significant feature of the reactions produced by electrical excitation of the cortex is that they are definite and predictable and vary with the position of the electrodes. But there is no fact more strongly urged by the localizers than that of the differentiation of white fibers in the corona radiata and the internal capsule, and Ferrier would be the last to deny that could these fibers after differentiation be separately irritated that corresponding movements would ensue. In fact this is far better established than is cortical differentiation. Dupuy claims that the electricity following the penetrating blood vessels and being so circumspectly applied to the strands is capable of producing coördinated movements—and at least in his recent writings does not say that this irritation necessarily takes place in the basic ganglia.

Another point that has given rise to controversy is the interpretation of the results that follow destruction of the cortex. Having measured the strength of the minimum current that will produce motion, the cortex is sliced off and left *in situ*. It is found that on reapplying the electrodes a stronger current is required to produce the same movement. The localizers claim that in the one case the electricity acted physiologically; in the other physically, and point to the increased strength of the current as proof. Their opponents explain the necessity of the increased currents because of the two new surfaces which have been created and the coagulation that necessarily takes place in the cut vessels, and they moreover urge that no better proof can be adduced that the electricity acts by diffusion of current than the fact that motion will follow the application of electricity to the cortex, even after it has been mechanically separated from the brain and lies merely in apposition. Another fact that is claimed will substantiate this same view is that when the cortex is frozen it is still susceptible of electrical irritation, a statement which Ferrier denies but other and later authorities consider well established.

Another experiment of Frank's consists in freezing the motor center and then irritating the hard frozen surface. It is found that whereas before the freezing the motor action in the limb was longer in duration than the current used and was epileptic, and besides only occurred after a lapse of about six and one-half hundredths of a second, when the same current is applied during the frozen state, the time of reaction is only about four and one-half hundredths of a second and the contraction is only tonic. The claim is made from these results that the reaction time is greater (six and one-half hundredths of a second) when the cortex is not frozen, because it reacts physiologically and the time is shorter (four and one-half hundredths of a second) when the cortex is frozen because it acts physically. This I consider a very unacceptable interpretation; it is unnecessary to state that the white substance, as well as the cortex, is influenced by the freezing process and the irritability of both endangered and altered.

These cortical destructions and alterations of the

motor centers, are, perhaps, the most important proof the localizers have brought forward, but they are by no means agreed as to the interpretation of experiments supposed to be identical. For instance, Ferrier destroyed the angular gyrus with resulting hemianopsia and so placed the visual center in this region but others have shown that this blindness was temporary. As already explained, others have shown this blindness was but temporary, and then placed this center in the occipital region where the results of destruction seemed more permanent, but no experiment yet performed seems conclusive, for the reason that complete removal of the cortex without destruction of the underlying fibers in the higher animal is not possible, while in simple brained animals even great destruction is well borne with but few motor or sensory symptoms. Here, however, the localizers claim that automatism comes into play and can not therefore be compared with brains markedly convoluted.

Another objection to experiments of this kind is that when the brain cortex is mutilated the animal's disposition is so entirely changed that no just deductions can be drawn by comparing it with a normal animal, with whom at best we can not intelligently communicate.

The true and only test as to the truth of this theory that has so far been applied is the observation of lesions in the human brain. Numberless cases are on record where cortical lesions have resulted in paralyses and disturbances of the special senses. Cortical destruction of the motor region is often followed by paralysis, in the frontal lobe by mental weakness, in the occipital lobe by visual disturbances and in the temporal by deafness. Left-sided paralyses accompanied by aphasia are frequently found to have their origin in lesions near the base of the third frontal convolution. On the other hand, equally well defined lesions impinging on or completely destroying these centers have not resulted in corresponding deficiencies.

The importance of these researches is undoubtedly great, for they have opened up a new and fertile field for the experimenter and have added vastly to our knowledge of the physiology of the brain. On the other hand, they have been a basis for the justifications of the many operations performed for the removal of localized growths or deposits in or on the brain, and as such their accuracy and diagnostic value are rightly questioned. Surgeons have interpreted these researches in a manner that conservative investigators can not approve.

Our medical journals are filled with accounts of operations which have either justified the diagnoses, or where the results were not so bad as to completely confound and condemn both the operator and the operation. Unfortunately the many unsuccessful or otherwise disastrous operations remain unreported as regards tumors, even were the localizers able to absolutely and definitely point the way to the surgeon, yet post-mortems teach us that at least 75 per cent. of such growths could not be successfully removed; and were all the results of such operations known, characterized, as many of them are by mistaken diagnoses and surgical mishaps, 95 per cent. would more nearly represent the proportion of the operations which are either useless or criminal failures. Granting that 5 per cent. of the operations result in improvement or cure, this small proportion

does not justify the readiness with which such operations are undertaken. But surgeons have gone further than this. Not content to interfere with pathologic cerebral tissues they have opened brains practically normal, removed the recognized centers and noted results. This has frequently occurred in the so-called Jacksonian epilepsy where consciousness is seldom lost and only one limb or group of muscles is involved. Some of our recent text-books have even gone further and advised exploratory incisions as an aid in diagnosis, as if the trephining of the brain was as simple a procedure as is the opening of the peritoneal cavity, or the results which follow healing as insignificant.

While granting the advance made by experiments on animals in elucidating the physiology of the brain, the modern cerebral surgery based on this is not justified, either by reason of the possibility of accurate diagnosis or the probability that the operation *per se* may benefit. The results of operations even those selected for publication are not encouraging, much less do they lead us to regard the operation as one of minor surgery.

YELLOW FEVER: PATHOLOGY AND TREATMENT.

Prepared for the Pan-American Congress and for the International Congress at Rome.

BY F. PEYRE PORCHER, M.D., LL.D.

CHARLESTON, S. C.

I wish in this paper, based on the study of several epidemics of yellow fever in Charleston, to make three points which are of the first importance; also to give some of the results of my experience as regards treatment and pathology, which I do not think have attracted the attention they deserve:

1. That this fever in Charleston has always been accompanied by what is known as "breakbone fever;" this, though extremely mild, is not distinguishable, but being counted in with cases of true yellow fever, prevents all accuracy in the mortality reports,
2. That yellow fever is fully susceptible of successful management in fair cases, seen early,
3. That life is compromised in the first six to ten hours of the disease; so that it is essential that treatment should be begun early.

Co-existence of Yellow and Breakbone Fever.—Invariably two forms of fever existed together, namely, yellow fever, and a milder and more ephemeral, intercurrent species known and designated as "breakbone." Yet this was also not by any means ephemeral, for it often had a duration of several days. Whether they constituted two distinct species, or were only varieties of one and the same malady, has, strange to say, never been decided—no distinct lines of demarkation between the two have ever been satisfactorily established—no physician, however acute, having clearly pointed out any precise diagnostic difference. Though many cried "Eureka," upon more rigid scrutiny the hopes they offered of a solution of the difficulty proved fallacious.

Among the observers there were to be found the lax and the strict constructionists, so that the usual confusion prevailed; *quot homines tot sententiæ*—there were as many opinions as there were persons to utter them. The question was, it must be confessed, surrounded by many difficulties, for while some forms of fever were very mild, and some characterized by black

vomit and suppression of urine were very fatal, others presented every intervening shade of difference between the two; and though the access of what proved to be the simplest cases was sometimes severe and violent, the intensity of the disease was dependent for the most part, I think, upon the amount of climatization enjoyed by the party suffering; and its gravity and its termination, whether favorable or unfavorable, would be modified, it seemed to me by neglect, by delay, or methods of management injurious or beneficial in their effects.

Individually, I am of opinion that, with many who by careful and assiduous attention on the part of the attendants were rescued from falling into a dangerous condition, and who recovered—the result would have been quite the opposite had they been managed otherwise. So that it was the early treatment and the appliances, and the eternal vigilance which sufficed to change the issue, and which did change it; and I hold that such cases, so metamorphosed by the simple, but important difference of management, would have had a very different termination; and would then, even by the most skeptical, have been placed in the category of true yellow fever, which was denied them if they did not get almost or quite into the third stage. The mild cases (breakbone, so-called) may get well with little or no interference. The difficulty was that they could not be surely distinguished at their early inception; and the stranger, in my experience, sometimes had attacks which, when vigorously managed at the beginning, were fully as innocent as those from which natives suffered, and which in these received the designation of breakbone. But in a fever like this which does its work so rapidly, it was at least plausible to believe and to argue that neglect, delay, the avoidance of the proper means and appliances for reducing temperature, etc., would have very much to do with modifying the nature, history, and ending of each case. This need not excite surprise, for did we treat scarlet fever or even measles with agents as active as those we were in the habit of administering in yellow fever, they would inevitably be made quite as fatal.

Pathology.—The peculiar poison when first introduced in the system produces (through nervous paralysis of the capillary arteries, perhaps) intense fever and great excitement of the circulation, with torpor of the glandular and secretory apparatus. It shuts up all the secretions and excretions, and with a high fever which it creates, rapid destructive metamorphosis of the tissues occur, caused by the intense combustion going on; so that spoliative treatment, in the shape of mercurial, saline, or other purgatives, is imperatively demanded at this inceptive stage. These are to be accompanied by revulsives, hot foot baths, and the application of cold to the upper extremities, in order, severally, to empty the intestinal canal and the torpid glandular organs, to diminish temperature, and to contract capillaries. All these means, also, serve incidentally, but powerfully, to lessen the tendency to nausea, and to irritability of the stomach. The latter does not decidedly lead to, or induce black vomit, as is commonly supposed, though the one often accompanies or precedes the other. Both result from the same efficient cause, namely, the altered condition of the blood, induced by the fever. The peculiar vomit is probably owing to what Warren calls "mortified blood," blood thinned by the decomposing action of excessive fever (a

quality peculiar to the yellow fever poison alone) transuding into the stomach and blackened by its acids. I could discover by the microscope,¹ frequently used, no distinct difference between this and other bloody matters vomited, which have been acted upon by the gastric juice, as where blood from a cancer is poured into the stomach and afterwards ejected.

The temperature in this peculiar fever, if unsubdued, leads infallibly and of necessity to subsequent trouble, to destructive tissue changes, to blood poisoning, to black vomit, to albuminuria, to coma, or to convulsions. I have seen thorough and persistent sponging with ice-cold water, when combined with the use of the other agencies advised, reduce the temperature, lessen all the bad symptoms in a surprisingly short time; having the power seemingly to change the entire character of the disease and imparting comparative mildness to its whole subsequent career. I will stand to this truth, for in the perception and practical carrying out of it lies the whole virtue of the plea which I advocate and assert to be successful.

In general terms, then, our first efforts must be directed to the relief of the intestinal and glandular torpor which always exist and which is marked by costiveness; we must diminish the cutaneous and general heat, empty the vessels of the system which are laden with impure blood, and obviate the tendency to renal engorgement indicated by the frequent presence of albumen. This is effected by the revulsives, aided by a mild alkalin diuretic, to be referred to subsequently. Then we must strive cautiously at construction, and while allowing the recuperative powers full exercise, we are to do nothing to impair the strength remaining, or weaken the energies of the constitution which have become greatly enfeebled. The unacclimated who are seized with the fever are nearly or quite always in a quasi-critical state, ready at any moment to take the descending path and to become dangerously ill; hence they require as careful handling as children do with scarlet fever. While, therefore, nothing is omitted which will tend to diminish the fever their strength must be carefully husbanded, for the slightest neglect, the failure to keep down the temperature by the application of cold water, or too much medication, though these may seem light transgressions, are powerful and weighty in turning the balance.

Mercurial and antiphlogistic purgatives used at the beginning, serve to diminish the heart's action, to lessen the inflammation by spoliation, by the drain of fluids from the body, augmented by the cooling operation of the salines. All of these are measures only to be employed at the beginning, using the agents in sufficient amounts to effect our object, which is to empty the bowel once thoroughly and effectually, without, as I urged, weakening the patient any more than is absolutely required. Purgatives are on no account to be persevered in. The failure to discontinue them after the efficient action of those used on the first day is procured is, I am sure, a grievous error.

Several authorities commit the fatal mistake of repeating the mercury and cathartics and pushing their use much too far. Even Blair, though in my judgment eminently on the right track, and for this reason very successful, permitted his xx of calomel and xviv

¹ Illustrations of Disease with the Microscope. Prize Essay. Charleston, C. S. A., 1861.

of quinin to be repeated under emergencies, and be used again and again as often as four times; I prescribe it invariably, but never more than once, unless it is not retained or does not act.

In a fever like this, of one paroxysm (but with a remission somewhere between the twelfth and thirty-sixth hour, occurring more distinctly when the proper means are used early,) which is exceedingly violent at the beginning, if unchecked, it does all the violence it is capable of in a very brief period.

I have been the first, I believe, to make a most important declaration; that life is virtually compromised in the first fifteen hours of its career. In such a fever, where the danger and the terrible sequelæ are owing entirely to the extreme intensity of the eremacausis, and the injury worked in the system by the high combustion which acts principally upon the blood, a certain treatment flows logically. There is no time to be lost in setting about it, and it is only to be regretted that our measures can not anticipate the invasion of the attack.

I sincerely believe that thousands of lives could have been, and can be saved by a system of management begun at the very commencement of an attack of the disease, before the fever has had time to produce its direful effects, and by methods simple in their operation, perfectly compatible with reason and common sense, and also based upon a view of the pathology and progress of the disease.

That, consequently, where the demand for medical aid is so urgent, when physicians can not see their cases early—such precious time being lost by their enforced absence—an exception must be made to our usual procedure, and the people in such need must be told what to do before the physician arrives. This is required by the fact, which should be recognized by every one, that death results from the insidious and peculiar fever of the first six to ten hours—whenever this is permitted to go on unchecked—through failure to use these means which are perfectly adequate to restrain and keep down the temperature. So that when a man has been ill for twenty-four hours or forty-eight hours with yellow fever, the attendant is not responsible, and treatment which would have been efficient used early is not to be condemned because it fails at the stage where irremediable organic changes have taken place; and the practitioner who boasts that he has fifty or sixty patients on his list does not know that the last installment (those he can not see for ten to fifteen hours) are, in many instances, already irretrievably doomed.

In fair cases and temperate individuals, treated early, there is no need for any violent third stage, for any black vomit, albuminuria, suppression of the urine, etc.

It is a mistake to suppose that yellow fever is necessarily a fatal malady, that epidemics vary greatly in malignancy, and that we must fold our hands supinely. The truth is that physicians in this city and elsewhere report at the end of the season very few deaths. Belot, of Havana, claims that 95 out of 100 fair cases seen early may be cured, and I agree fully with him. I have practiced with success the method to be related in detail (see also *Charleston Medical Journal and Review*, since 1858, and President's address before State Medical Association of South Carolina, 1872). Dr. C. W. Horsey adopted the treatment in the fever of Fernandina, Fla., 1878, others

have employed it successfully, and Surgeon Sternberg refers to it approvingly in his elaborate and able article in Wood's Hand-Book of the Medical Sciences. I had long shown by the adoption of Blair's system, materially modified, the application also of cold water was the foundation fact in the treatment. In confirmation of this, Prof. T. O. Summers, of Nashville, says: "Cold water is the remedy in yellow fever." (Paper on treatment of yellow fever in 1879).

Treatment.—The treatment consists: 1, in sponging assiduously the head, hands and arms with ice-cold water at the very commencement of the attack, not losing an hour, and repeating this at intervals whenever the temperature rises, ice-water being quite capable of reducing the temperature. Towels soaked in the ice-water are preferable to sponging; fifteen to twenty minutes generally suffice for each application, its necessity being determined by the existence of pyrexia. Few perform this simple but essential procedure as efficiently as they should do; 2, give immediately Blair's "calomel, grains xx; quinin, grains xxv" (in proportion to ages), and but once. I have never seen the quinin produce a single ill effect, though given when the fever is intense; 3, follow in three or four hours with a saline cathartic (sulphate of magnesia), which is cooling and antiphlogistic; 4, apply mustard plasters to the entire abdomen, and use hot mustard pediluvia from the beginning of the attack, and repeat them frequently. These may be followed by a cantharides plaster upon the abdomen—which certainly does no injury. After the saline has acted, give an effervescent or antacid mixture of this nature (which also had the support of the late Prof. E. Geddings): Potas. acetate, 1 dram ad 2 drams; potas. citrate, 1 dram; morphia, 1 grain; water, 6 ounces. A dessert-spoonful every two or three hours. Used to quiet gastric irritation and to act slightly as a mild antacid and diuretic.

No other treatment or active medication are required, save the continuance of the cold application and pellets of ice given internally if necessary. Doubtless a few drops of tincture of aconite added to the mixture, or given separately, might prove serviceable.

By this method those recover, according to my experience, carefully recorded, who are seen early; who possess their organs in a state of integrity; with the intestinal canal, liver, kidneys, and other emunctories in a fair condition. This surely is not asking too much; and to claim that recovery will almost invariably ensue in such cases, under the plans detailed elsewhere, and on this occasion, is, if I am correct, making what I can not but regard as a true and important advance. This I hope and believe will one day be fully acknowledged. It is spoken seriously and earnestly without lightly coming to the conclusions, and I sincerely trust that the expression of them will not be regarded as presumptuous or premature.

How different is this from a former system of mercurial purgatives repeated every five or six hours, or a constant effort to induce ptyalism by giving mercury with opium at any and every stage of the disease—with the omission of other measures insisted on here as of the first importance. Persons seized with such a fever, who are seen for ten or twenty hours, those who already suffer from organic lesions,

whether of the stomach, liver, or kidneys, whose digestive organs (so essential to the nutrition, growth, and repair of the system) are irritated and inflamed by the use of intoxicating drinks, can not be expected to respond to any treatment, however judicious and appropriate.² In such subjects there is great tendency to irritability of stomach; the purgatives are not retained, the inflammatory stage (fever) runs high, and can not be subdued. Congestion of the internal organs, kidneys, etc., with albuminuria, occurs; black vomit sets in; and uremic poisoning, with coma, generally closes the scene—during attacks of violent convulsions. Under such conditions, all agents prove nugatory; every effort is necessarily unavailing; and these cases—falsely and illogically reasoned from—bring reproach upon true and legitimate treatment, which can be shown to be serviceable in those who, from the beginning, are not plainly beyond the reach of art.

In my humble judgment, if not the height of folly, it is at least extremely unfair to decry or, which is worse, to abandon, a course of management which is eminently and strikingly successful in nearly or quite all the cases of the class previously described, because it fails to cure those who have no right to expect a miracle to be worked in their behalf.

Any treatment which is successful is not so by accident, but because it is based upon the requirements and real nature of the disease and throughout does the patient no harm. It is high time for the intelligent members of our profession, particularly if they be at all apathetic, to give up the pleasing idea that the practice of physics is all guesswork, in which one artist does full as well as another; that fate and the disease have the control, and that always when a child or man dies the "physician who heals is Death."

THE CAISSON EXPLOSION OF BATTERY F, SECOND REGIMENT OF THE U. S. LIGHT ARTILLERY.

BY EDMUND ANDREWS, A.M., M.D., LL.D.

FORMER SURGEON OF FIRST REGIMENT OF ILLINOIS LIGHT ARTILLERY;
PROFESSOR OF CLINICAL SURGERY IN MERCY HOSPITAL, ETC.

The writer is at present in charge of a number of soldiers wounded by an accident so rare, that hardly any officer in the United States service has seen an example of it.

The singular character of the wounds produced, and the rarity of the causes producing them, render the cases most instructive for study.

The late riots in Chicago, by obstructing the United States mails, and arresting commerce on interstate railways obliged the general government to send to Chicago about 2,000 regular troops to maintain order.

On the 16th of July, Battery F of the Second Regiment of U. S. Light Artillery was moving at a trot on Grand Boulevard, supported by a company of the Seventh Regular Cavalry, when suddenly the three ammunition chests of the first caisson exploded with terrific violence.

The caisson was drawn by four horses, which were guided by two mounted drivers. Two cannoneers sat on the limber, or forward chest, but fortunately there were no soldiers on the two others. Two sergeants were riding beside the column, and also part of the

cavalry escort. A number of citizens were on the sidewalks, and at the doors and windows of the adjacent houses.

The two cannoneers on the limber were literally blown to pieces and the fragments scattered hundreds of feet. Two of the mounted men were also killed, and fifteen men were wounded. Three citizens received injuries. Nine horses were killed.

The singular character of the wounds will be noted below.

There were 126 cartridges of cannon powder in the chests amounting to over 400 pounds, besides a large number of shrapnel, and other loaded shells.

The subjoined cuts, and some of the facts about the nature of the shells, etc., are from an article furnished to the *Chicago Tribune* by an educated military officer.

There were two kinds of projectiles in the caisson; one, the simple steel shell with a time fuse. These were all picked up afterwards unexploded. The other kind were the complicated shrapnels which have percussion as well as time fuses, and exploded all

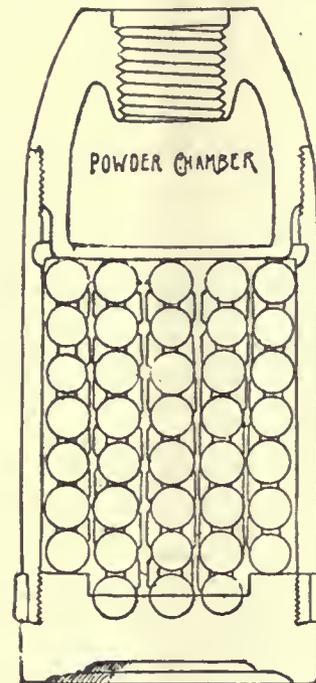

Fig. 1.—Longitudinal section of shrapnel.

about wherever they struck the ground. The shrapnel shell is named from its inventor, Gen. Shrapnel. Fig. 1 shows a longitudinal section of one.

The top of the shell is closed by a metallic plug screwed in and containing a complicated arrangement for firing the powder in the shell, whenever it strikes, or sooner if desired. Below the plug is a chamber filled with a small charge of powder—two and three-fourths ounces—just enough to burst the shell as it flies toward the enemy, while the pieces spread out in the form of a cone and continue on their course, making awful destruction. Below the powder chamber there is a larger cavity containing 162 lead bullets mixed with rings of cast iron. The bullets, added to broken rings and fragments of shell make for each shell over 300 pieces of metal to be shot fiercely into the faces of the enemy.

Experiments made to determine the effect on a target showed that the flying pieces pierced the wood

² "There is no hope for the drunkard."—S. H. Dickson.

so closely that there was hardly a spot as big as two hands which had not been struck. It is one of the most terrific instruments of war.

Fig. 2 is a transverse section of the bullet chamber.

Fig. 3 shows the cast-iron rings for holding the bullets steady.

It will be observed that in shrapnel the bursting charge is small, so that when a stationary shell explodes, the pieces do not fly laterally with great velocity. The terrible effects in war are caused by the forward velocity given by firing the shell from the cannon. In the present case the shells were not fired from the gun and hence though fifty-three of them exploded, few of the wounds contained any bullets or pieces of iron.

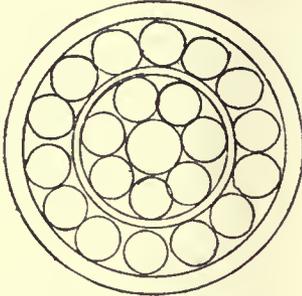

Fig. 2.—Transverse section showing the arrangement of balls.

The remarkable feature in the injuries placed under my care is that nineteen-twentieths of the wounds were made by the big unconsumed grains of modern cannon powder which are nearly half an inch in diameter and penetrate like bullets. Those who were most severely injured were under too much shock to bear transportation to the distant camp, hence five were brought to me in Mercy Hospital, and one to Prof. E. W. Andrews at Michael Reese Hospital.

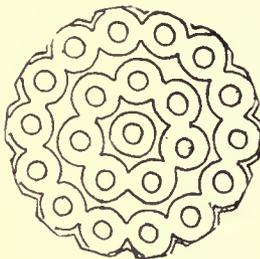

Fig. 3.—Cast-iron rings.

The latter soldier, Private Stoltz, sat on his horse in front of the exploding limber chest, receiving the projectiles in his back. The grains of cannon powder in the chest were large and irregular in form, averaging about the size of chestnuts. Thousands of them flew in every direction like bullets, some burning as they flew, and many probably not even on fire. Aside from the flying pieces of powder, a great globe of flame enveloped the whole area near the caisson. Stoltz's hands and the back of his neck were blistered by the flame. The parts covered by clothing escaped blistering but his entire back down to the line where the posterior elevation of the saddle-tree protected the nates, was perforated by hundreds

of cannon powder masses, so that there was hardly room to touch him with the point of a finger without inserting it into one of the orifices. Generally the wounds penetrated about three-quarters of an inch and the surfaces were black and pulpy as if the connective tissue were half crushed and half burned. The grains themselves could not be found in definite form, either having been burned up in their beds, or else been softened by the blood into a paste. Some of the larger wounds contained broken chips of wood from the limber chest. One large piece of wood five inches long and an inch wide had pierced the skin endwise and lay along the seventh rib. No bullets nor pieces of iron were found, but some of the wounds were deep, and bullets or pieces of iron may have been in the interior depths. As he was in a dying condition thorough search was impossible. The patient was delirious and died in six hours of shock.

Sergeant L. Leiner was brought to Mercy Hospital suffering severe shock so that great fears were felt that he would not rally. However, in twenty-four hours he had pretty well reacted. At the time of the accident he was riding beside the column a little to the rear of the exploding caisson, so that he received the blast in front. His face and hands were blistered by the flame, the whole front of the body, from head to ankle was punctured with powder lumps similar to those of Stoltz, but fewer in number. Perhaps a hundred in all. One of the wounds penetrated through the rectus abdominis muscle, so that the finger could be inserted, but the peritoneum was not penetrated. Pieces of wood were extracted from that wound and from several others, but most of the orifices contained nothing tangible. One wound over the ligamentum patellæ allowed the finger to run up into the patellar bursa and the front of the bone was chipped. A piece of iron about half an inch long lay there, but the capsule of the joint was not opened. He is now out of bed.

Private O'Donnell received the charge also in front, and had perhaps a hundred powder punctures. The shock was severe. The face and hands were blistered. One wound of some size was received on the eyebrow and others in various parts of the face and body. Several pieces of wood from the ammunition chests were extracted, and also a piece of copper, derived from the copper ring that encompasses the base of each shrapnel shell.

Trumpeter H. Antes, Seventh Cavalry, received numerous wounds over the front of the face and body, one of them chipping the end of the clavicle. Pieces of wood were found but no metal, yet he had apparently been struck by a large fragment of iron or wood, for the right deltoid muscle was torn away, the acromion process was shattered, the tuberosity of the humerus was carried away bodily and the shoulder-joint was laid open along its outer border. Several small pieces of wood and chips of bone were removed, but no metal. The wound extended behind the scapula below the spinous process. It was cleansed and dressed antiseptically. In a few days he was removed to Fort Sheridan, where Surgeon-Major Girard exerted himself to get rid of all septic remnants of bruised flesh and crushed bone and then trimmed the flaps and brought up the remnant of the deltoid and sutured the flaps together, thus covering the wound and the opening of the joint, with an excellent prospect of saving the articulation from sup-puration and ankylosis.

The wounds of the other soldiers were similar in character.

One lady in an adjacent house had her arm cut, probably by flying pieces of glass.

Another lady received a projectile from a shrapnel cutting off the tendon of Achilles.

A boy of 14 years passing on a bicycle, received two shrapnel shots in the calf of the leg.

So far as I had opportunity to observe, none of these men received any injury to the globe of the eye, though their faces were perfectly peppered with wounds. This seems to show that the explosion was not absolutely instantaneous, since they had time to shut the lids before receiving the blast.

As to the rarity of this accident, it is well known that ammunition chests are occasionally exploded in battle when struck by the shells of the enemy, but to do so when simply traversing a smooth road is so unprecedented that only four cases are on record in the U. S. Army, and in only two of them are the facts clearly established. The investigations already ordered will doubtless discover the causes, and prevent such disasters in future.

2520 Prairie Avenue, Chicago.

TWO CASES OF INTESTINAL OBSTRUCTION.

Specimen presented and remarks made at a meeting of the Medical Society of the District of Columbia.

BY I. S. STONE, M.D.

SURGEON TO COLUMBIA HOSPITAL, ETC., WASHINGTON, D. C.

Case 1.—R., colored, age 21, had been sick three weeks with specific pelvic suppuration. She had no symptoms of intestinal obstruction or of nephritis. She had the usual preliminary treatment incidental to laparotomy for pyosalpinx. Salts were administered freely and acted well the day before operation. Her urine was examined on entering the hospital and again the day of operation and pronounced free from albumen. A microscopic examination was not made. The operation was made on June 6 at 10:30 A.M. Everything passed off in a satisfactory manner. Intestinal adhesions were not difficult to overcome. The patient was placed in the Trendelenburg posture and every precaution was taken to complete the operation in a thorough and satisfactory manner. The pelvis and lower abdomen was flushed with rather more than the usual care, as quite a large quantity of pus had escaped in the removal of the greatly distended pus sacs. A glass drain tube was placed as usual. Nothing unusual occurred after the operation until the next morning when the transverse colon was found distended greatly. The administration of enemata had but little effect in dislodging the collection of gas, and the stomach refused at first to retain fluids. Afterwards during the afternoon and evening of the day following operation, salts and castor oil were both retained in full quantity without overcoming the fatal obstruction. The patient did not suffer greatly from pain. There were few symptoms of peritonitis and, in fact, the prompt occurrence of the symptoms after operation did not suggest peritonitis as a cause of the distension. The drainage tube was removed in thirty hours and a long forceps with a piece of gauze was used in the drain tract to ascertain if the intestines were anywhere adherent. The forceps moved freely and easily, thus demonstrating the absence of pelvic peritonitis. At the autopsy this was proved correct, as there was only one point where the intestine was adherent, namely, to the pedicle on the right side.

The quantity of urine passed was estimated by the house physician at eight and one-half ounces during the forty hours the patient survived the operation. This decrease in the quantity of urine was thought due to the obstruction, and the kidneys were not thought diseased. Ether was used as the anesthetic but only a small quantity was required, as the patient very rapidly came under its influence.

The operation was not more difficult than usual, and was done with deliberation and care in every detail in less than forty-five minutes. The patient died forty hours after operation. The autopsy six

hours later revealed two points where the intestine was occluded. One specimen shows the large bowel at junction of the transverse and descending colon just under the spleen. A stenosis exists at this point. Air could easily be forced through this narrow passage before the specimen was laid open by the pathologist. When the autopsy was made I thought this stricture might be due to change in the intestinal wall after the operation, or due to intestinal spasm. But the section plainly shows an organic stricture permeable during life when intestinal peristalsis was not diminished. But this was not the only source of obstruction. A diverticulum was found tightly drawn across the ileum about three inches above the cecum. The greatly distended ascending colon appeared to press the lower end of the small bowel forward and thus added to the twist of this diverticulum, which completely occluded the bowel at this point. The small intestine was distended with fluid and intestinal gas to this point. This diverticulum is two inches long, three-fourths of an inch wide at its central portion and gradually narrowing toward each end. It appears to be a congenital abnormality and much resembles an abortive mesentery or mesenteric fold.

The theory of the case is somewhat as follows: After the operation very little flatus was forced through the lower stricture even with the aid of enemata. The transverse colon soon became distended causing pressure upon the stomach and displaced the diaphragm with heart upwards. Rapid and feeble heart action supervened and the patient had the appearance of secondary shock. The obstruction near the cecum did not permit the entrance of fluids into the large bowel, and in consequence the narrow structure of the colon would not yield to the feeble peristalsis of the distended bowel.

Still another element of unseen danger entered into the combination which produced the fatal result. The quantity of urine was greatly diminished, and as above stated this was thought due to obstruction high up in the small intestine. At the autopsy, the explanation was found in the kidneys. Both kidneys present undoubted evidence of nephritis. This fact affords another instance of the very unreliable nature of our usual tests for this disease prior to surgical operations, and especially in view of the influence of ether upon the kidneys. The examination of the patient's urine was made upon two occasions by internes in whom I have perfect confidence as to integrity and capability. No albumen was found. Finally there would appear but slight probability that the nephritis in this case could be of only forty hours duration, or in other words be entirely due to the use of ether.

WASHINGTON, D. C., July 10, 1894.

DR. I. S. STONE, 1504 H Street, N. W., Washington, D. C.:

Dear Doctor:—The specimens in the case of the colored girl, Ragland, consisting of the large intestine and kidneys, have been subjected to a microscopic examination in the laboratory of the Museum with the following results: The stricture at the junction of the transverse and descending colon shows, on section, marked thickening of the longitudinal and circular muscular coats of the bowel, as well as increase of the submucous layer. The mucous membrane lining the stricture was somewhat atrophied. From this examination I am led to believe that the stricture was organic in its nature, and probably congenital in origin. The kidneys show an advanced degree of fatty degeneration of the epithelium lining the secreting tubules, as well as that lining Bowman's capsules and covering the Mal-

pighian tufts. There is also a perceptible increase of connective tissue throughout the kidneys.

Very respectfully,
WALKER REEDE,
Maj. and Surg. U. S. Army, Curator Army Med. Museum.

The next case of obstruction was one of great interest although the cause was entirely different, being due to the presence of a dermoid cyst of the ovary with a twisted pedicle:

Mrs. P. had been taken ill on June 6 with severe abdominal pain, nausea and vomiting. The use of enemata failed to afford any relief, after several days of vigorous efforts on the part of her physicians, Drs. Harding and C. W. Brown of this city. I was called in on June 10 to see if operative measures might afford relief. A tumor was found filling the pelvis nearly to the umbilicus and appeared to be more upon the left side. The very great distension of the abdomen made a careful examination difficult but sufficient was learned to justify prompt abdominal section which was done an hour later. A very dark sac of an ovarian tumor was found and removed. Four twists of the pedicle caused the almost gangrenous condition of the cyst. Light adhesions of intestines to the sac, and also some adhesion to the parietes and sac were soon disposed of, the abdomen flushed and closed without drainage. Including the time of giving the anesthetic until the abdomen was closed occupied about thirty minutes. The patient's condition before operation was very precarious and caused her physicians great uneasiness. Under morphia and heart stimulants she bore the operation very well and rallied from shock in a very satisfactory manner. Her bowels discharged great quantities of gas the morning after the operation and the recovery has been uninterrupted and without incident.

SOME UNUSUAL EFFECTS OF QUININ ON THE SKIN.

BY J. SCHNECK, M.D.
MT. CARMEL, ILL.

Perhaps the most common dermal effect of quinin, when administered internally, is a form of hives or urticaria in which the surface is fairly covered with irregular shaped reddish colored blotches, varying in size from that of a dime to the palm of the hand. The skin is slightly elevated, has a hard, tense feel to the touch; there is usually intolerable itching and burning; sometimes the skin is so sensitive that even the slightest touch causes severe pain and feels as if a raw surface had been touched.

In other cases the eruption is in the form of a rash; similar to that seen in scarlet fever. Often there is a uniform flush of the surface of the skin as in an erythema. Quite frequently a herpetic eruption follows the administration of quinin, which may be located on the lips, ear, cheek or prepuce. I have a lady patient in whom a 5 grain dose will produce an acute coryza.

There is a rarer form in which a small circumscribed area is affected whenever quinin is administered. I have treated an old lady for years in whom 10 grains of quinin, given during one-half a day, will cause large reddish-purple blotches to appear on the ulnar margin of the left hand, and another, about the size of a half dollar, on the upper portion of the left concha; the eruption is accompanied by a hot tingling sensation and disappears during the following twenty-four hours after the remedy has been given; the same train of symptoms invariably occur when she takes quinin.

Another case is that of a carpenter in whom a course of 20 grains of quinin, given in 4 grain doses two hours apart invariably produces a similarly colored condition of the skin, on the back of the left thumb, between the first and second joints. The

burning sensation is very severe, the epidermis is raised into a blister and afterward shed.

A still more singular case is that of a young farmer in whom 20 grains of quinin will cause the mucous membrane covering the glans penis to change to a dark purple color, accompanied by intense itching, followed by the shedding of the epithelial layer in the course of the following week.

Another instance is that of an intimate friend in whom 4 grains of quinin will cause a most annoying itching of the glans penis in from thirty to sixty minutes after it has been taken. If taken at bedtime the itching will continue until morning. The party is about 50 years old, and during the last eight or ten years of his life this effect has invariably followed the use of quinin, while previous to that time this effect was not noticed, although he has taken quinin frequently since early childhood. This last instance is of especial interest as it indicates the length of time required from the ingestion of an ordinary dose of quinin until its physiologic effects are produced.

In the lower forms of animal life the sloughing of the skin is a common and useful function. May not the shedding of the cuticle which we see in many skin diseases and the similar effect of some drugs on the epidermis find a rational explanation in this primitive function? In either case it is an angioneurotic process, which is either circumscribed or general in its manifestations. May they not both be forms of erythema, which are easily induced, from the presence in the skin of hereditary peculiarities? It can make no difference whether we adopt the theory of Lamarck; that man has been evolved from the lower forms of life by the ever present law of heredity; or that of Darwin, that man is the highest resultant of the law of the survival of the fittest in the struggle for existence in the ever changing environments on the earth; or to the more modern doctrine of Weismann, that these changes are due to an innate energy in the germ-plasm which tend continually to the production of higher forms of life and to the adoption of better and more complex organs and organisms. In either case we find ourselves so very closely related in the physiologic functions to the lower forms of life that one naturally concludes that the ease with which the epidermis is raised and shed in man, may be due to the reappearance of a former condition.

What it is to be One's Physician.—To be one's physician, the Supreme Court of Arizona holds, in the case of the Mutual Life Insurance Company of New York v. Arhelger, decided March 8, 1894, means to attend upon him or consult with him in a professional capacity about his state of health; that is to say, to prescribe treatment, if necessary, and give directions and advice calculated to relieve from sickness and restore to health. This definition has an important practical application, because it is usual for life insurance companies to include among the subjects to be covered by the medical examination inquiries with regard to when the applicant for insurance consulted or employed a physician. In this case, where the applicant was asked when he last consulted a physician, to which he answered, "Not since childhood," and warranted his answer to be true, the Court holds that if he consulted any physician in a professional character, or received any treatment or advice at the hands of one, it was his bounden duty to disclose the fact in answer to the inquiries, and if he failed to do so his warranty was thereby broken.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO. 68 WABASH AVE., CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

SATURDAY, AUGUST 4, 1894.

THE PRESENT STATUS OF MEDICAL EDUCATION IN
THE UNITED STATES.

A rapid evolution in medical education is apparent in this country. Not content with the extension of requirements for the degree of M.D. from two to three courses of lectures, there is most convincing evidence in the events of the last few weeks that point to the immediate adoption of the four course requirement by every reputable medical college in the country. The action of the College Association in adopting the four years' course with attendance upon four courses of lectures goes into operation in 1895. All the colleges in Chicago, Harvard University, University of Pennsylvania, College of Physicians and Surgeons New York, Jefferson Medical College, University of Michigan, University of Minnesota, and many others have already adopted the four-term requirement. The indications point to definite action in the adoption of the four-year course at once by all the colleges in Ohio, Missouri, Iowa, and by a limited number of the Southern schools. The extension of the courses of medical instruction will reduce the number of students somewhat, but not enough to affect the income of the colleges. Experience has shown that in the last few years colleges extending their courses have had increased attendance and largely increased incomes. The increase from laboratory fees has been particularly noticeable. With the four-year requirement in practical operation in this country we shall hear less regarding the poor quality of medical education. The appointment of a committee in the College Association on minimum of professional study and to prepare a curriculum of study for each branch to be taught in the proposed four years' course was most wise. This Committee consists of PROFS. CONNOR, of Ohio; VAUGHN, of Michigan; QUINE and

DAVIS, of Illinois; STEMEN, of Indiana; and MILLARD, of Minnesota, all of them teachers of experience.

There has been a noticeable lack in uniformity of grade and entire lack of uniformity in methods. The amount of work upon each branch has been greatly governed by the views or wishes of the individual instructors. In one college the student would be offered a thorough course of instruction in hygiene; in another no instruction whatever. In the division of work under the four years' curriculum our colleges will follow in the footsteps of foreign schools. The work will be divided into the scientific and clinical departments; the scientific work being largely embraced in the first two years. In the first two years of the course we trust that didactic methods will rapidly give way to recitation work, and in the last two years bedside instruction will greatly displace the old method of massing the students into an amphitheater for a general clinique.

We trust the Committee will go to the bottom of this all important subject, and that at next year's meeting the Association will scan their labors most thoroughly. We hope also that the Committee will give the study of pathology and therapeutics a prominence in the work of the last two years, that their importance merits. Systematic laboratory and classroom work should be provided for in pathology during the last two years. The course in therapeutics can not be too thorough. In short, the entire work of the four years' course should be greatly confined to the so-called fundamental branches, with the elements of the special branches, reserving thorough courses—the specialties—to post-graduate schools or the so-called "special courses" approved by the undergraduate colleges.

NARCOMANIA.

Experts and noted writers agree that this term describes more accurately the condition of many inebriates, than dipsomania. The latter indicates a thirst mania, which is very rarely seen, and of short duration, while narcomania is a mania for relief, or the intense desire for the anesthetic effects of alcohol, opium or any drug which will quiet the physical or psychical sufferings of the organism, and is common to most cases of alcoholism. An inebriate who has become powerless to control this alcoholic impulse, and who gives way to it continuously, or at intervals, is a diseased man requiring medical recognition and care.

Such men are what may be termed defectives, and in most cases are of bad judgment, weak, erratic, changeable feelings and morbid enthusiasts. Recently the prominence which a few men of this class have taken in the affairs of the country, bring up the question of their mental condition, and suggest a new study and change in public sentiment. A practical illustration is that of a business man, at

the head of a large industry, who drinks to great excess at intervals, and whose bad judgment and insane-like reasoning has on several occasions caused great suffering to those whom he employs, and the community in which he lives. Lower down, a man who drinks at intervals has attacks of delusional mania and causes distress and suffering to those about him; or commits crime which perils the interests of the community.

Another class growing more prominent, are so-called reformed inebriates, who after years of excessive use of spirits, seemingly stop drinking, and become wild agitators, and sensational leaders of impractical theories. They call themselves pioneers, socialists, and are active to change and disquiet the existing order of events. They are prominent in all new schemes for money, power and popularity; and after an uncertain period relapse, and become wilder and more irregular. They are becoming prominent in every community, as supporters or opponents of every possible good or bad theory, quackery, delusion, socialism, anarchism, and are so-called reformers of every degree. As advocates of "gold cures," they have tried the treatment and then enter upon the business of curing others. Becoming officers of branch cures, they urge the most extravagant expectations in pecuniary returns, and possibilities of curing others. Later the institution is bankrupt, and they relapse and disappear. The head centers who provide the secret remedies, wisely receive all pay in advance, and never trust, while the credulous stockholders and supporters of these branch cures, trust to the pretensions of these reformed officers.

Many of the extreme reformers, who create a large following for a time, then disappear under a cloud, are of this class of narcomaniacs. Sometimes in medical circles these cases appear, urging some very startling innovations in remedies and treatment, or claiming some discoveries which threaten to change all existing order of events. Not unfrequently they pose as enthusiastic advocates of some half way proprietary medicines.

The general public overlook the fact that such cases are "border briars," and not unfrequently pass over into the realm of insanity, both acting and reasoning like insane men. In the interval they may pass unobserved in many circles, and be credited as of sound mind. But when they commit crime and become objects of study, a new chain of symptoms appear, pointing out states of degeneration not noticed before. Physicians should enter upon this neglected field of psychical and obscure mental symptoms, and be able to make diagnoses of cases, that are seldom recognized until they fall into the hands of specialists. Narcomania is only one of many of these obscure degenerative mental disorders, which may go so far, then stop, or continue to some pronounced

phase of insanity. An early diagnosis of a paranoiac and defective brain, and appropriate care and advice, would save most disastrous consequences later. So-called habits, conduct and methods of reasoning, should be the subjects of medical study as much as the heart's action, the temperature and reflex of the body.

The narcomaniac is diseased and requires medical care and treatment, and the general practitioner is in a position to study and understand these cases more clearly than the specialists.

THE REDUCTION OF THE ARMY MEDICAL DEPARTMENT.

Congress has cut down the Medical Department of the Army. If a bill had been introduced for this special purpose and the arguments for and against its passage had been heard, we take it for granted that our Federal legislators would not have crippled the Department. The blow was dealt by a proviso to that part of the Army appropriation bill which provides for the 1894-95 expenses of the Medical Corps. This proviso, which reduced the number of Assistant Surgeons from 125 to 90, was on the bill when it was reported to the House of Representatives by the Military Committee, MR. OUTHWAITE of Ohio, chairman. Although we now know why the committee made this attack upon our medical *confrères*, it was at the time a great surprise, for we were under the impression that the Medical Corps was in good repute and deservedly so, at the Capitol Building. The energy and ability of the Surgeon-General had just created an Army Medical School out of nothing, or which is the same thing, out of materials which although ready at command had not up to this time been utilized. Its first session had closed and the value of its work was fully recognized. An Examining Board had been ordered and over fifty candidates invited to compete for the six vacancies then existing, when this proposition of the Military Committee became known. To the disappointment of the candidates the order convening the Board was revoked and the examinations postponed indefinitely, depending on the action taken by Congress. The Surgeon-General would have been warranted in filling the vacancies under the existing law, but he evidently preferred to manifest his readiness to obey, in a military way, the spirit of legislative control.

It was only after the bill had been reported to the House of Representatives that this proviso became generally known to those interested in the welfare of the Department. One of MR. OUTHWAITE's arguments in favor of the reduction was that no protest against the proposed action had been made by the medical profession. The ASSOCIATION telegraphed from San Francisco, California, sustaining the Corps and commending it to Congress, but this, with similar

action by state and local medical societies was too late to influence the action of the House of Representatives already taken. The Senate expressed its views by rubbing out the proviso, but when the bill came to conference a compromise was adopted, reducing the number of Assistant Surgeons from 125 to 110.

There can be now no appointments in the Medical Department of the Army until this reduction has been effected. But for this there would have been ten vacancies to be filled now; six more places must therefore be vacated before an appointment is made. Under the law, examinations may be made at any time, passed candidates being held for appointment to such vacancies as may occur within two years after their successful examination. The Surgeon-General will no doubt issue a circular of information on this subject to those concerned.

This reduction necessarily postpones the second session of the Army Medical School so far as passed candidates for the Medical Department are concerned, and delays experience in its management and work; but no doubt each member of the faculty will keep his course in view and make use in perfecting it, of the time and experience already gained. This School of Sanitary Science and Preventive Medicine as applied in the Army should not be permitted to lapse.

Moreover, an effort should be made to have Congress re-consider this ill-advised legislation. The Army needs its full complement of specially trained sanitary officers. On them we rely for the protection of our camps in time of war, for the organization of our field and general hospitals and the induction into each newly formed organization of that *esprit du corps* needful to its successful operation. It is difficult to see how the Medical Corps can accomplish its work, deprived of 8 per cent. of its young men. Medical officers sometimes break down under sickness, and all are entitled under the laws to a certain allowance of leave of absence, which each can only get when there is a spare officer for his relief. Many large posts have only one surgeon on duty, and troops are frequently ordered out from such posts without a medical officer. Instead of reducing the Corps there should be enough of spare officers at the command of the Surgeon-General and his medical directors to have qualified medical attendance with every squadron patrolling the Mexican frontier, and with every detachment subject to the dangers of field service.

We trust that this action may be reversed at the next session of Congress.

DENGUE AND YELLOW FEVER.

An epidemic of dengue is reported in the U. S. military barracks at Key West, Fla. DR. JOSEPH Y. PORTER, State Health Officer of Florida, says that

there had been, up to the 18th ult., 75 cases out of the garrison of 115, and that "this epidemic has been characterized by some phases not described usually in the text-books and has been an interesting study." In his report (*Abstract of Sanitary Reports*, July 27, 1894), DR. PORTER does not specify the features which constitute the unusual phases of the epidemic nor the characteristics which make it an interesting study. From the report of G. B. YOUNG, Passed Assistant Surgeon, M. H. S. (*loc. cit.*), it appears probable, however, that the features of interest consist in some abnormalities of the pathognomonic relations of pulse and temperature; he says: "There has been a marked disproportion between the pulse and temperature in about all the cases; the temperature has not been high; I noted, however, two cases especially interesting—in one the temperature was 104 degrees, pulse 85; in the other, temperature 103.4 degrees, pulse 78." In dengue the pulse usually increases in frequency as the temperature rises, until the maximum is attained, and then falls, *pari passu*, as the fever declines—unlike yellow fever in which the pulse generally falls on the third day while the temperature continues to increase.

This "epidemic" derives whatever of practical importance it may possess from its value as an illustration of the great gain to the material interests of the country which accrues from increased knowledge and more exact diagnosis of the so-called quarantinable diseases. Within a very few years this occurrence, coupled with recent arrivals of yellow-fever infected vessels, might have caused a panic throughout the South Atlantic and Gulf States, and the enforcement of the unscientific, illogical and even barbarous quarantine restrictions of the period resulting in untold injury to commercial interests and values.

Prior to the introduction of the clinical thermometer, dengue was looked upon by many physicians as a mild form of yellow fever, a view which gained color from some of its symptoms, but especially from its tropical habitat, the influence of locality and its association with certain seasonal influences—all in common with yellow fever. For example: A continued high temperature being an essential condition of its epidemic prevalence, and this being put an end to on the first appearance of frost; its limitation, for the most part, to towns, and of these, to the filthy, low-lying quarters of seaports; its intense foci being in the 'tween decks of ships and in the crowded centers of squalid population, etc.

Epidemiologists are now agreed that epidemics of dengue figure to an undue extent in the "tabular statements" of yellow-fever epidemics, in the history of this latter disease prior to 1860, and are disposed to consider many of the reported cases of recurrent attacks of yellow fever in the same individual as mistakes in diagnosis. There is now, however, little

danger that the appearance of dengue shall be mistaken for that of yellow fever, and so throw a group of States into a paroxysm of unreasoning terror and the establishment of "shot-gun quarantines," as happened so lately as 1880, in Tennessee, Arkansas, Mississippi and Louisiana on the occasion of the passage of the towboat *Raven* and its barges up the Mississippi River with cases of this disease on board.

The lessons of dengue at Key West in 1894 are that advances in medical science are the only reasonable foundation for the modification of quarantine restrictions affecting travel and traffic—the bases of commercial prosperity; that one of the best investments for the Nation would be the necessary appropriation and adequate legislation for the promotion and utilization of such advances; and that a Department of Public Health operating through existing Bureaus, is the logical and ultimate agency through which to give potency and effect to these advances in preventive medicine.

VITAL STATISTICS.

A correspondent (DR. S. B. GRIFFIN, of Stockton Springs, Me.) asks the JOURNAL to furnish him "the statistics for 1890, or later, of the mortality of each State in the Union and, especially, the number of deaths from consumption in each thousand deaths in each State."

As the JOURNAL is in frequent receipt of similar queries from its subscribers—and which have hitherto been answered individually from the best sources of information at hand—it seems well to say that there are no trustworthy vital statistics for "each State in the Union." The only authoritative compilation of such data is that of the decennial census of the United States, and this covers—for such purposes as these inquirers have in mind—only those States and cities which have in force some legally authorized system of registration of deaths and causes of deaths.

In the following summary, which is of interest to the general reader sufficient to warrant its presentation in this form, will be found such authentic information of this character as is at present available. It covers only those States which enforce a registration of deaths and causes, to-wit: Alabama, Connecticut, Delaware, Massachusetts, New Hampshire, New Jersey, New York, Rhode Island and Vermont, and the District of Columbia. In addition to these, the census embraces also the vital statistics of some thirty-six "registration" cities, for the details of which reference must be made direct to the census reports.

In the States above enumerated, and in the District, the total deaths during the census year were 427,538, which, in a population of 21,093,320, gave a rate of 20.27 per thousand. In the States in which no regis-

tration system was in force with a population of 41,528,930, the death rate, as computed from the enumerators' returns, was only 10.79 per thousand—a figure obviously unworthy of any serious consideration.

As to deaths from consumption in these registration States and in the District the following are the figures per thousand of all deaths: District of Columbia, 139.16; Delaware, 158.98; Massachusetts, 134.28; Rhode Island, 124.17; Alabama, 115.55; Vermont, 125.76; New York, 121.44; Connecticut, 121.36; New Jersey, 112.33; New Hampshire, 106.24. The total deaths in this group from this cause were 31,743, which, with the population above given, would make an average death rate from consumption of 1.50 per thousand.

On the other hand, the enumerators' returns for the non-registration States, show 70,456 deaths from consumption in a population of over 41,000,000—a death rate from this disease of 1.69 per thousand, or largely in excess of the rate shown in the registration group.

Similar, if unequal, discrepancies are shown in the death rates from other diseases in the States which register deaths and the causes thereof and those which do not. Obviously there is no basis upon which to compute the relative frequency of any given disease in any given State. The best that can be done is to compare the death rates from given diseases in the baker's half dozen of registration States and the thirty-six registration cities.

There are no vital statistics worthy the name in the United States, as a whole.

BOOK NOTICES.

Text-Book of Abdominal Surgery. A Clinical Manual for Practitioners and Students. By SKENE KEITH, F.R.C.S., Ed., assisted by George E. Keith, M.B., C.M. With illustrations. Pp. 508. Philadelphia: J. B. Lippincott Company. Chicago: A. C. McClurg & Company. Price \$4.50. 1894.

The book before us teaches fairly the existing state of abdominal surgery. It is divided in two sections. Section I comprises eleven chapters and is devoted to the surgery of the abdomen. Section II has five chapters, in which "the Surgery of the Abdomen Peculiar to Women" is discussed. The chapter on "Examination of the Abdomen" is especially valuable and interesting. We notice, however, that no reference to air inflation as a means of aiding auscultation is made. The air bag is so common an adjunct to our armamentaria in America that its omission seems strange. The book bears evidence on every page of the vast experience of the immortal Thomas Keith, under whom the authors practiced for seventeen years. It may, therefore, without much stretch of the imagination, be taken as coming from the master himself. The great candor, the simplicity of its style, and its direct statement are among the chief characteristics of the work. The advice as to measures in emergencies is sound, and the instructions on after treatment are such as may be implicitly followed. If we might venture an exception it is that the practice of the authors seems to encourage the administration of morphia to a degree not

usual in this country, and indeed quite unnecessary if we accept the dicta of some of our recent authorities. In controlling thirst where there is vomiting, we notice that our authors commend rectal injections of milk and water (page 79.) We commend the book as one destined to become a favorite.

Transactions of the Vermont State Medical Society for the Year 1893. Published by the Society.

This volume records the proceedings and papers of the eightieth annual meeting, which was held in Rutland, Oct. 12 and 13, 1893. One of the most interesting features of this meeting was the plea of the accomplished Secretary of the Society, Dr. D. C. Hawley, for a stronger organization. He recommended the members to rally around the standard of the AMERICAN MEDICAL ASSOCIATION, and the support of the JOURNAL, and volunteered to receive the annual subscription of any who desired to become members.

The prize papers for the year were respectively by Dr. O. W. Sherwin, of Woodstock, on "Septicemia" and by Dr. E. M. Pond, of Rutland, on "Peritonitis." The President's address by Dr. H. R. Wilder, of Swanton, was an interesting one. The Vermont Society seem to have solved the problem of what to do with Vice-Presidents as they have here an excellent address by Vice-President Brewster, on "The Treatments of Phthisis Pulmonalis." He divides the treatment into three heads: 1. Prophylactic; 2. Medicinal; 3. Climatic. In the discussion which followed, the creosote treatment had several ardent advocates. There are many interesting papers in the volume and all are well written. A biographical sketch of the late Dr. Walter Carpenter, by Dr. Henry D. Holton, followed by a reprint of the constitution and by-laws, conclude the volume. Many societies have more pretensions transactions than this Green Mountain octogenarian, but few are of more solid worth or more carefully edited.

A Modern Wizard. By RODERIGUES OTTOLENGUI. New York and London: G. P. Putnam's Sons. Chicago: Brentano. 1894.

This novel has for its heavy villain a Dr. Medjora, a very learned physician, who hypnotizes people at will. He kills his second wife with cultures of diphtheria bacilli, and by means of a poison which he has discovered—"sanatoxine"—he makes himself a raving maniac to escape the consequences of his crime. He has, however, in the meantime carefully educated his son in hypnotic and other lore, and is firmly of the opinion that the son will discover the antidote to "sanatoxine" and then restore him to his senses. The "sanatoxine" Dr. Medjora has carefully prepared from the cerebral insanity center. The story is cleverly told, and from a detective standpoint is effective, but on the whole leaves a bad impression.

When to Send Patients Abroad for Water Cures and Climatic Treatment. By DR. THOMAS LINN. Detroit: George S. Davis. Paper, pp. 76. Price 25c. 1894.

This is one of the series of the Physicians' Leisure Library, as useful in its way as any of its predecessors. Since a certain class of patients must be sent or will go abroad anyway, to health resorts no better than those to be found at home, it is well to know where to send them and this knowledge Dr. Linn furnishes concisely and intelligently in this little hand-book.

NECROLOGY.

JACOB HART, M.D., of New York, at Ohiopyle.—Harold Groffe, M.D., of St. Paul, July 29.

SOCIETY NEWS.

American Electro-Therapeutic Association.—The following is the preliminary program of the American Electro-Therapeutic Association which will hold its fourth annual meeting at the New York Academy of Medicine, New York, September 25, 26 and 27.

President's Address—Dr. W. J. Herdman, Ann Arbor, Mich., Professor of Diseases of the Mind and Nervous System and Electro-Therapist in the University of Michigan.

REPORT OF COMMITTEES ON SCIENTIFIC QUESTIONS.

On Standard Coils—Dr. W. J. Morton, New York.
On Standard Meters—Dr. Margaret A. Cleaves, New York.
On Standard Electro-Static or Influence Machines—Dr. W. J. Morton, New York.
On Constant Current Generators and Controllers—Dr. W. J. Herdman, Ann Arbor, Mich.
On Standard Electrodes—Dr. A. Laphorn Smith, Montreal.
Stand and Electrode for Static Electricity, exhibit of same, Dr. Lucy Hall-Brown, Brooklyn, N. Y.
On Electric Light as a Therapeutic and Diagnostic Agent, Dr. Margaret A. Cleaves, New York.

THE CONSTANT CURRENT.

Physics; Current Distribution—Mr. W. J. Jenks, M.I.E.E., New York.

Physiologic Effects—Prof. H. E. Dolbear, President Tufts College, Boston, Mass.

Therapeutic Uses; General—Dr. A. D. Rockwell, New York. Gynecology, The Galvanic Current in Catarrhal Affections of the Uterus—Dr. G. Betton Massey, Philadelphia.

Suites e'loignes du Traitement Electrique Conservateur Gynecologie. Grossesses consecutives—Dr. Georges Apostoli, Paris.

Metallic Electrolysis—M. le Docteur Georges Gautier, Paris; Dr. W. J. Morton, New York; Dr. Margaret A. Cleaves, New York; Dr. A. H. Goelet, New York.

Treatment of Urethral Stricture, Report to date—Dr. Robert Newman, New York.

Diseases of the Eye, Electro-Therapeutics of—Dr. L. A. W. Alleman, Brooklyn, N. Y.

Notes on Goitre and Improvements in Apparatus for Treatment of same—Dr. Chas. H. Dickson, Toronto.

Diseases of the Throat—Dr. D. S. Campbell, Detroit, Mich. The Action of Electricity on the Sympathetic—Dr. A. D. Rockwell, New York.

Diseases of the Nervous System, The Treatment by the Galvanic and Faradic Currents—Dr. Landon Carter Gray, New York.

Electric Sanitation—Prof. John W. Langley, Ph.D., Case School of Science, Cleveland, Ohio.

Physics of the Electric Light in Relation to Organized Matter—Prof. John O. Reed, Ph.M., Assistant Professor of Physics, University of Michigan.

Hydro-Electric Methods, Physics and Appliances—Mr. Newman Lawrence, M.I.E.E., London.

Special Hydro-Electric Applications—Dr. Margaret A. Cleaves, New York.

The Hydro-Electric Therapeutics of the Constant Current—Dr. W. S. Hedley, Brighton, England.

INDUCTION CURRENTS.

Interrupted Currents, Physiologic Effects—Dr. W. J. Engelman, St. Louis, Mo.

Therapeutic Uses; General Faradization—Dr. A. D. Rockwell, New York.

Gynecology—Dr. A. H. Goelet, New York; Dr. H. E. Hayd, New York; Dr. A. Laphorn Smith, Montreal.

SINUSOIDAL CURRENT.

Physics—Mr. A. E. Kennelly, F.R.A.S., Philadelphia. Physiologic Effects—Dr. W. J. Herdman, Ann Arbor, Mich.; Dr. J. H. Kellogg, Battle Creek, Mich.

Therapeutic Uses—Dr. Margaret A. Cleaves, New York; Dr. Wm. Jas. Morton, New York; Dr. J. H. Kellogg, Battle Creek, Mich.; Dr. Holford Walker, Toronto; Dr. A. H. Goelet, New York.

Le Courants Alternatifs; Leur Transformation; Leur Mesure et Leurs Applications Therapeutiques—M. le Docteur Gautier et Larat, Paris.

On the Sinusoidal Current Method of Regulation, the E. M. F. and Resultant Current—Dr. Lucy Hall-Brown, Brooklyn, N. Y.

STATIC AND STATIC INDUCED.

Physics—Prof. Edwin Houston, Ph.D., Philadelphia.

Therapeutic Uses, General Therapeutic Uses—Dr. Wm Jas. Morton, New York.

The Treatment of Chorea—Dr. D. R. Brower, Chicago.

Static Induced—Dr. Margaret A. Cleaves, New York.

High Frequency Currents derived from Static Machines as per Method d' Arsonval—Dr. J. H. Kellogg, Battle Creek, Mich.

IN MEMORIAM.

Dr. Wm. F. Hutchison, Providence, R. I., and Dr. John Chambers, Indianapolis, Ind.—Dr. Robt. Newman, New York.

Dr. Plymon S. Hayes, Chicago—Dr. W. J. Herdman, Ann Arbor, Mich.

PUBLIC HEALTH.

A Summary Proceeding.—Upon the motion of the Indiana State Board of Health thirty-three of the principal citizens of Whiting, Ind., have been arrested under an indictment for maintaining nuisances prejudicial to the public health, and a summons has been served upon the Standard Oil Company in an action alleging that it allows impurities to flow into Lake Michigan, thus polluting the water supply of adjacent towns and cities.

Intensification of Measles.—The London *Lancet* sees, in the increased mortality from measles during the past decade, ground for believing that the disease is undergoing an intensification of type and regrets, in the interest of preventive medicine, the diverse views which obtain among the several sanitary authorities who have added measles to the list of notifiable diseases as to the value of the proceeding. "A disease which in this country exacts a death toll of from 6,000 to 14,000 persons annually, and an uncertain but far from insignificant amount of partial disablement for life, can not be a matter of indifference to us," more especially in view of the increased death rate noted.

Boston and Philadelphia.—In a popular article in the *Forum* for July, presumably based upon special census reports, the relative mortality rates of Boston and Philadelphia are discussed. Contrary to the usual rule that the larger a city the higher its death rate, Boston had, in the census year, an average mortality of 23.59 per thousand, while Philadelphia had a death rate of only 21.86. Some of the causes leading to this are the lower average level of the site of Boston, the larger proportion of foreign-born inhabitants and the greater density of population. Concerning a factor of urban mortality, upon which the *JOURNAL* has heretofore dwelt, it is noted that "the low proportion of tenement houses in Philadelphia, and the fact that in that city each family, as a rule, occupies a separate dwelling, has a powerful influence in reducing mortality." Whatever of consolation the citizen of "the Hub" may derive from the comparisons in the article is to be found in the statement that "the man who lives in his own house in Boston has as long an expectation of life for himself and his family as the man under similar circumstances in Philadelphia."

Heat and Health.—What is claimed to be the hottest season on record does not seem to affect injuriously the public health. On the contrary, except in isolated localities, the summer death rate from the seasonal diseases is believed to be below the average. On the other hand, there is an unusual number of deaths from insolation—seven deaths in one day being attributed to this cause in Philadelphia—from violence, and especially from suicide. Theorists, who have heretofore speculated on the thermal relations of crime and other sociological factors under the alliterative titles of "Sun and Sin," "Heat and Hades," etc., may find further data for their excogitations in the records of the present summer. Possibly they may trace some connection between

the present delay in tariff legislation and the temperature of Washington. Certain it is that never before have our National legislators been called on to endure a more momentous session under more trying seasonal conditions. Senators McPherson, Voorhees and Vest of the upper house alone, are already reported as invalided—the first from the unspeakable ventilation of the Capitol, the second from a chronic ailment aggravated by the same cause, and the last by an erysipelas said to be due to the notoriously unhealthy environment of the District in hot weather. There are reasons other than political why Congress should make haste to adjourn.

"Newspaper Cholera."—A Chicago daily paper (the *Mail*) furnishes intrinsic evidence of reading the *JOURNAL* to good purpose. In a recent editorial under the above heading it says: "The usual deaths from 'genuine Asiatic cholera' are taking place—in the newspaper columns; there was one yesterday at Meredosia, in Illinois, another at a whistling station, somewhere in Indiana, and still another at Confederate Crossroads, Ky., or some other equally likely locality. There is little excuse for these efforts of the imagination this season; surely there has been thus far no dearth of legitimate sensational news that it should now be necessary to conjure up a conjunction of cholera and Congress. As a matter of fact this country has rarely been favored with so healthful a summer season as the present. Except in New York and one or two other unfortunate localities, where sickness and the death rate have been swelled by excessive heat, there is a remarkable paucity of the usual seasonal diseases, and there is nothing threatening in the health conditions abroad. There is hardly cholera enough to 'go round' in Europe, and the plague is subsiding in Canton and Hong Kong; while health authorities, both in this country and elsewhere, were never before so vigilant, so well informed, nor so thoroughly equipped for efficient service."

Should We Vaccinate?—"Ought we to continue to vaccinate if we can not give a scientific why and wherefore for our work?" is the question which the *Hospital* (London) essays to answer. And it answers, Yankee fashion, by asking other questions. "Ought a baker to bake bread, and his customers to eat it, if he can not give a scientific demonstration of the process of fermentation which takes place in the dough? Ought a farmer to sow corn who is not able to explain the chemic-physiologic process of the development of the radicle and the plumule?" Facts and empiricism, arts and manufactures, all take precedence of science in the order of human development; and we must test vaccination as we do other matters for which, as yet, we are unable to give a scientific explanation—that is, ask of vaccination this question of questions: "What has it done in the world?" And the answer is, that it has defeated in open conflict one of the deadliest enemies of mankind and has put us upon lines of investigation which may yet rob all pathogenic organisms of their terrors. If such should be the grand result it is obvious that the mind of man, by as much as it is delivered from ignoble bodily fears, by so much it will rise to greater and greater heights of boldness and intellectual achievement. "But medical men, as the custodians of the science as well as of the art of healing, must constantly remember that vaccination and inoculation can never achieve these magnificent results until they are firmly established upon a basis of scientific reason as well as upon a foundation of solid and unchallengeable fact."

Foreign Epidemic Diseases.—Asiatic cholera continues to manifest itself with sufficient frequency and in localities enough to keep the sanitary authorities of Europe on the alert. The Prussian Commission of the Vistula basin reports

twenty-two deaths from cholera and eleven new cases of that disease during the week ended July 28. The sickness was mostly among laborers and raftsmen. At Emmerich, on a Rhine vessel towed from Holland, the Health Commission found a cholera patient. A strict river inspection has been instituted at Dusseldorf and Cologne. Suspicious cases have been reported from Granberg, Thorn, and Bohnsack. The Cholera Commission of the Health Office met at Berlin, July 28, to decide upon the precautions to be taken along the Russian frontier. The pioneer and pontooning exercises of the military on the Vistula have been postponed as a precaution against cholera. A dispatch from Travemuende, Germany, says a stoker of a steamship, arrived there from St. Petersburg, died July 30 from cholera. The Governor of Warsaw has forbidden the usual pilgrimage to Czenstochav on account of the prevalence of cholera. The Spanish Consul at Marseilles, having telegraphed that cholera is epidemic at that place, the number of deaths very large and the authorities concealing the actual situation, the Government has ordered stringent precautions to be taken at all Spanish ports on the frontiers. A medical commission has been sent to Marseilles with instructions to report the facts. And so on *ad infinitum*; all of which redounds to the benefit of this country, inasmuch as these items are made the text for sermons in many keys by the daily press on the virtues of sanitation and the necessity for "cleaning up," and inspire such utterances as this from New York:

"The existence of Asiatic cholera in European seaport cities and the ravages of the plague in China do not cause the least uneasiness to the officials of the health department here. The rules regarding the inspection of immigrants before they sail are now enforced, and it is next to impossible for cases of cholera to find their way aboard ships."

"Won wek" the bubonic plague, seems to be dying out in China, but its ravages have by no means been overestimated; a "blue book" issued, July 28, by Sir Walter Robinson, English Governor of Hong Kong, says that 120,000 people died from the disease in the Canton district alone.

MISCELLANY.

Change of Address.—Dr. A. P. Ohlmacher, of Cleveland, has removed to 54 Fifth Avenue.

Illness of Bismarck.—A Berlin cable of the 30th ult., announces that Prince Otto von Bismarck is suffering from an attack of prostration from the heat which was intense everywhere throughout Germany. Since the Prince is in his eightieth year much solicitude is felt for the result.

Another Woman Honored.—Dr. Jessie M. Weston, one of the graduates of the Woman's Medical College of Philadelphia in 1893, has been elected to the medical staff of the Connecticut State Hospital for the Insane at Middletown, occupying the only medical position which the Nutmeg State government has thrown open to women.

Pest-House Site Purchased.—The city of Chicago has just acquired title to a tract of ten acres within the city limits whereon to erect a contagious-disease hospital. The city architect, Mr. Finkler, has prepared elaborate plans for a model construction upon the site. The price paid for the land is \$20,000.

Studying Hospitals.—Drs. John Osterman, G. F. Edenbailer and F. G. Scherer, Indianapolis, J. L. Carson, Fairland, and Z. H. Hauser, Columbus, all of Indiana, are making a study of hospitals in the leading cities for the purpose of obtaining information for the use of the Indiana State Board of Health. They visited the hospitals of Chicago early this week.

Bacillus of the Plague.—Rival discoverers of the bacillus of

the bubonic plague are already announced. Kitasato, the Japanese pupil of Prof. Koch, claims to have identified the microbe as first cousin to the cholera vibrio—but, according to the newspaper accounts, it is a "slender, short bacterium," totally unlike the spirillum of Koch. A Dr. Ericsson, practicing among the French residents of Hong Kong, has also isolated the "simon pure" plague germ. Meanwhile the bacteriologic world awaits "a bill of particulars."

"Caprination."—At the suggestion of Dr. Daniel F. Wright, of Clarksville, member of the Tennessee State Board of Health, the Paquin Vaccine Laboratory at Columbus, Mo., is conducting a series of experiments with a view of determining the relative merits of the cow and the goat for the production of anti-variola virus, on the theory of the immunity of the latter animal from tuberculous and syphilitic infection. In his letter Dr. Wright says: "I think it important that the words 'vaccine' and 'vaccination' should not be used in reference to the new inoculation, but 'caprine' and 'caprination.' 'Vaccine' being derived from 'vacca,' the Latin word for the cow, would be inappropriate for an operation in which the cow is not used at all; 'caprine' and 'caprination,' derived from 'capra,' a she goat, being the proper substitutions." How about the anti-cholera "vaccination," *et id genus omne*?

A Peculiarity of Messages Relating to Sickness or Death.—It is usually the duty of every person who would hold another responsible for the consequences of an act to give him such notice as will put him on his guard. Telegraph companies frequently escape liability for damages resulting from errors in the transmission of messages, or unjustifiable delay in delivering same, because there was nothing in the messages to put them on notice that such damages would ensue. But the Court of Civil Appeals of Texas holds, in the case of the Western Union Telegraph Company v. Porter, decided May 3, 1894, that when the general nature of a communication is plainly described by its terms, and when it relates to sickness or death, if the agent receiving such dispatch desire information about the relationship of the parties concerned he should seek it from the sender, and, if he fail to do so, his principal is charged with the information which inquiries would have developed.

Women as Sanitary Inspectors.—Dr. Moreau Morris, of the New York City Board of Health, is quoted in the *New York World* as having the utmost confidence in women of medical attainments as sanitary inspectors. Dr. Frances G. Deane has had two years' experience as a member of the sanitary corps, and Drs. Alice Mitchell and Helen Knight have recently been appointed to similar positions. Dr. Morris believes "that the fact of their being women will enable them to get into the homes of the poor where a man would be received with suspicion. The work that these women are engaged in is not the easiest, consisting as it does of a thorough canvass of the tenement houses in the district set apart for their work. They must visit every room, inspect sinks, peep into closets and climb innumerable stairs. Then, too, the people the sanitary physicians come in contact with are very apt to eye with displeasure the intrusion of strangers. On the whole, the work of the woman doctors of the Health Board is undeniably hard."

Rules Concerning What Patients Tell Experts.—The established rules of evidence, it is well-known, exclude hearsay testimony. As a consequence, the physician who makes an examination, as an expert, for the purpose of giving testimony in a case, will not, as a general thing, be permitted to state what the patient told him in reference to the specific cause of the injury giving rise to the litigation. But there is another rule, which is just as well settled: the United

States Circuit Court of Appeals holds, in the case of the Union Pacific Railway Company v. Novak, decided April 2, 1894, that the physician may testify to what the patient said in describing his bodily condition, and the character and manifestations of his pains, when such statements become necessary to enable the physician to give his opinion as an expert, on account of the latent nature of the facts to be proved by it. The action or non-action of the internal organs can not readily be seen. In such cases the statement of the injured party is ordinarily admissible, in order to enable the expert physician to determine the real nature of the trouble at the time of the examination.

Power of Indiana Township Trustee to Employ Physicians.—

The township trustee is by statute in Indiana the overseer of the poor. He has no power to make a contract binding upon the county, when the board of commissioners has employed a physician for the purpose of treating the poor of the township, except in cases of emergency. But the Appellate Court of that State holds, in the case of Board of Commissioners of Lawrence County v. McLahlon, decided May 16, 1894, that in the event the board of commissioners of the county fail to employ a physician, or make suitable provision for them, in sickness, the trustee may do so, and the county will be liable therefor. And it further holds that although it appeared from the evidence that the board of commissioners had employed a physician for a certain township, who was acting in that capacity at the time the services in suit were rendered, yet if it was true that this physician lived seven miles from a poor person requiring attendance, that the physician was old, and in ill health and unable to attend, the trustee had power to employ a physician, and the county would be liable for the services rendered.

For the Medical Student.—As an antidote to that plea for the unfit,¹ in which the hardships that the medical student suffers under the present curriculum of medical colleges is portrayed, pray regard the following regimen for the summer interregnum—mark you—prescribed by Dr. E. R. Axtell incumbent of a chair in the Medical Department of the University of Colorado:

"On every week day you are to rise at 6 a.m. One hour is given for the toilet and for breakfast. On Tuesdays, Thursdays and Saturdays, the days on which you recite, review your lesson from seven until seven forty-five. If you recite from eight to nine, walk to the place of recitation, and after it is over return to the room at once and study until twelve. From twelve to one get your noon-day meal, which under the schedule I am giving you should be the main meal of the day. From one to two in the afternoon you should go to bed. Do this in earnest. Throw off your clothes, don some cool sleeping gown and darken the room. Your alarm clock will tell you when it is two o'clock. From two to five you study. From five to six you exercise. Walk, ride, use some Indian clubs, box or wrestle. Some of the greatest tussles of my life occurred between my room-mate and myself, between the hour of five and six. Supper is taken from six to seven. Then a rest until seven thirty. Then study until ten. Go to bed at once."

The Professor rather naively adds: "This advice I am free to say I did not always follow, but it is good advice." And the average student will follow the example rather than the precept of the Professor.

Another Strychnin Antidote.—In the *Archives de Physiologie*, 1894, p. 32, M. G. Grigorescu announces that in the course of some experiments to determine the action of toxic substances upon the excitability of peripheral nerves and muscles he has developed the fact that butyl-chloral opposes the toxic action of strychnin. He found that if injections of strychnin were made (in frogs), those which received also

the butyl-chloral remained torpid, while those with strychnin alone were tetanized. After some hours the butyl-chloral was eliminated, and then these frogs were seized with tetanus, as were the others. On repeating the antidote up to the elimination of the strychnin, complete cures resulted. The observations demonstrate that butyl-chloral energetically opposes its physiologic action to the physiologic action of strychnin.

Hyrtl's Law.—"Damning with faint praise" is a feeble characterization of the effort of Dr. Thomas Dwight¹ to sustain the law of Hyrtl, that "the manubrium of the female sternum exceeds half the length of the body, while the body of the male sternum is, at least, twice as long as the manubrium." In his, as yet unpublished, observations, Dr. Dwight has found that in 342 sterna—222 male and 120 female—there were almost precisely 40 per cent. of exceptions to this law. And yet this conservative anatomist affirms that "the averages of my measurements confirmed that law, but—that the exceptions were equal to the cases in accord with it." (The *JOURNAL* inserts the dash for the purpose of emphasizing the exceptions.) What Prof. Dwight says, in effect, is that while Hyrtl's "law," as to the sternum in the identification of the sex of a given skeleton is correct, it would fail in two cases out of five. A judgment based upon Hyrtl's law as thus confirmed would hardly do to go to a jury of the average American citizen. The odds are not enough.

The Physician's Wife.—In a notice of "The Physician's Wife," by Ellen M. Firebaugh, the reviewer of our contemporary, the *British Medical Journal* (July 14, inst.) pays the following tribute to the American wife of one physician:

"If France may claim to have founded the school of realistic romance, in which the passions, the crimes and the vices of life are exposed with the ruthless veracity of the dissector, to America belongs the honor of having developed that daintier and more delicate style of realism in literature, in which the common everyday life of common everyday persons is portrayed with such sympathy and intimate knowledge of circumstance that all who read feel the truth of the description. The physician whose life the wife illustrates with such delicate touches and an art which simulates simplicity, is no hero of romance nor worker of miraculous cures; he is only the country doctor whom we all know, who may be seen any day driving in his gig from house to house, giving friendly nods to passersby, or who wends his way night after night along the dark lanes under the stars to carry aid to a distant sufferer. But the sympathy of his wife makes us henceforth better understand his long toilsome days, his broken nights, his disappointments, his sense of the world's ingratitude, his loving service of others. His wife quietly notes it all; she misses none of the humor and pathos, and even the doctor himself does not escape her gentle irony."

The book must be worth reading.

Power of Court to Exclude Non-Expert Opinions as to Sanity.—One of the instances where non-expert witnesses may express their opinions is on questions of sanity. But their right to do so is not unrestricted. In the case of *Denning v. Butcher*, decided by the Supreme Court of Iowa May 25, 1894, it was insisted that all that is necessary to qualify the witness is a statement of the facts and circumstances upon which his opinion is founded, and their sufficiency can not be questioned. The right of a non-expert witness to give an opinion based upon facts fully disclosed to the jury has always been recognized, says the court; but, it adds, It is equally clear that the trial court has the right to determine whether such facts have been disclosed as to entitle the witness to express an opinion. That is a preliminary question and a power which must be possessed by the court, else

¹ *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, June 23, 1894 p. 960.

¹ The Shattuck Lecture for 1894, on "The Range and Significance of Variation in the Human Skeleton," delivered before the Massachusetts Medical Society, June 12, 1894.

such a witness, on stating a single fact of such a character that no opinion of sanity or insanity could properly be based thereon, would be permitted to give his opinion as to the party's mental condition. True, it may be impossible to lay down a rule as to just what statement of facts would show a sufficient foundation to warrant the giving of an opinion by a non-expert witness. That must depend upon the circumstances of each case, and must be left for the trial court to determine in the exercise of a wise legal discretion; and its ruling in that respect should not be disturbed, unless it clearly appears that it has not properly exercised the discretion with which it is vested.

Allowances for Autopsies.—The case of Moser v. Boone County as decided by the Supreme Court of Iowa May 18, 1893, was reviewed at length in the JOURNAL of July 15, 1893, (Vol. xxi, pp. 97, 98), on account of the remarkable position which the Court there took. It held, it will be remembered, that, under the amended statute of the State, the compensation allowed by the county board of supervisors to physicians or surgeons summoned by the coroner to make a scientific examination at an inquest is conclusive, in the absence of fraud, and that a physician is not entitled to maintain an action to determine whether his services are not in fact worth more than the amount allowed.

From this position the Court has now receded. It granted a re-hearing, and May 23, 1894, rendered its second, and more satisfactory decision. The two cases before relied on to support its determination, it now points out arose before the Code was amended, and are not conclusive on the principal question. The claim for services rendered under the law as amended, it holds, is not liquidated when it is presented to the board of supervisors for allowance. That board has power "to examine, settle, and allow all just claims against the county unless otherwise provided by law." Ordinarily, it continues, the action of the board on an unliquidated claim is not final, but suit may be brought thereon after it has been presented to the board as the statute requires. For these and other reasons, the Court now holds that it is the duty of the board of supervisors to allow a reasonable compensation for such services, and that, if it does not, the physician or surgeon who renders them has a right to collect such compensation by an action against the county.

More Newspaper Medicine.—A London, England, dispatch speaks of an American found dead recently in the slums of Glasgow, at whose post-mortem examination it was found that "the body showed that he had died of fright." Whereupon our esteemed contemporary, the *New York Medical Journal*, expresses a desire to learn what the post-mortem signs of fright are, and adds that newspaper medicine is almost always amusing, but generally without intention. An entertaining example of intentional humor in connection with medical matters was given in an editorial article recently published in the *New York Times*, in which the writer evolved a theory of the American tendency to use middle names. He says: "The middle letter made its appearance in America immediately after the first great epidemic of influenza. We may therefore feel reasonably certain that it was one of the innumerable sequelæ of that exasperating disease. It attacked nearly every boy and girl in the country, and in most cases assumed a chronic form. The recent epidemic of influenza, which has for the last five years devastated the noses and throats of America, has been followed by the development of the middle name in full, and this in its turn will become chronic. The fact that the middle letter appeared in England before the influenza merely shows that so far as Englishmen are concerned, the two have no relation to each other. When, on the other hand, we find that

immediately after a severe attack of influenza Mr. W. D. Howells becomes 'William Dean' Howells,' and Mr. James W. Riley becomes 'James Whitcomb Riley,' it is impossible that we should fail to see that these facts stand to each other in the relation of cause and effect."

Abandonment of Sidney Barracks, Nebraska.—During the past ten years a change has been taking place in the character of the military posts of this country. At the close of the War of the Rebellion the regular Army became scattered over the Western Territories in small commands of one or two companies to protect settlers from hostile Indians. These commands, when not in tents, were usually housed in poorly constructed huts of adobe, logs, or boards. The country furnished the material in the rough and the soldiers the labor, so that but little money was expended in providing shelter for the troops. The water supply was wagoned in barrels from the neighboring creek or river; waste water sank into the ground or ran off its surface according to the porosity or inclination of the site, and sewage was deposited in pits as in the temporary camps of active service. A few years later as railroads opened up communication, the necessity for many of these posts ceased and the troops were concentrated at railroad centers where they could be dispatched to various points as occasion required. At most of these larger posts excellent barracks have been built of brick or stone, well lighted and ventilated, provided with free supplies of pure water and with satisfactory arrangements for the disposal of waste water and sewage.

Sidney Barracks, Nebraska, has recently been added to the list of abandoned posts. Troops camped on its site in 1867 to protect the line of the Union Pacific Railroad, and two years later accommodations were completed for a troop of cavalry and a company of infantry. On account of its position on the line of rail, the buildings at this post were superior to most of those constructed in the West at that period. They consisted of frame buildings, lathed, plastered, ceiled, shingled and ventilated by shafts through the roofs. The site was on Lodge Pole Creek, about forty miles above its junction with the South Platte River. The Creek is a small stream running through the arid plains of Wyoming and Nebraska in a valley one or two miles wide, with sandstone bluffs about seventy feet high on either side. Outside of the valley the general appearance of the country is that of a vast undulating plain unbroken by trees or high grounds. An irrigating ditch carried a plentiful supply of clear water from the Creek through the post and the adjoining village of Sidney, and permitted the growth of box elder and cottonwood as an attractive feature of the locality. A post garden furnished an abundant supply of vegetables and the hunters of the command kept the messes generally supplied with venison. The post has been a healthy one during the twenty-seven years of its existence; and as its postal, telegraph, supply and traveling facilities were good, it has always been regarded by the medical officers as one of the better class of stations in the country of the Platte River.

Not a Candidate for Congress.—The editor of this JOURNAL is not a candidate for Congress as announced in various contemporaries. His name will not be mentioned in the convention which will be held on this date. The editor, however, can not refrain from expressing his sincere thanks to those of his contemporaries who have kindly and favorably noticed his candidacy as announced in the secular press.

Hospital Notes.

NEW HOSPITAL, ELGIN, ILL.—The new hospital at Elgin, Ill., for infirm male patients, was opened July 23, with thirty-two inmates.

INVESTIGATE MINNESOTA INSANE HOSPITALS.—The report of the Board of Physicians appointed by the Governor of Minnesota to investigate the insane hospitals of the State, favors the establishment of a separate hospital for epileptics, and also the building of another insane hospital, to be located near St. Paul and Minneapolis.

MINNEAPOLIS CITY HOSPITAL.—City Physician Weston has appointed the consulting staff of physicians for the City Hospital. None but regulars have a place on the Doctor's list.

The appointment of the staff settles a vexed controversy, several irregulars having applied for appointment.

Following is the list:

Physicians—J. H. Stuart, M.D.; W. P. Spring, M.D.; C. L. Wells, M.D.; C. J. Ringnell, M.D.; H. B. Sweetser, M.D.; J. W. Bell, M.D.

Surgeons—W. A. Hall, M.D.; J. W. Little, M.D.; C. G. Weston, M.D.; J. H. Dunn, M.D.

Obstetrics and Children—A. B. Cateo, M.D.; P. M. Holl, M.D.

Nervous and Mental—W. A. Jones, M.D.; L. M. Crafts, M.D.

Pathologists—J. C. Stewart, M.D.; A. F. Irwin, M.D.

Gynecology—A. W. Abbott, M.D.; F. A. Dunsmond, M.D.; F. R. Woodard, M.D.; W. G. Byrnes, M.D.

Eye and Ear—Frank Allport, M.D.; C. J. Spratt, M.D.

Washington Notes.

THE MEDICAL DEPARTMENT OF THE COLUMBIAN UNIVERSITY.—The announcement for 1894 and 1895 is just published. The clinical facilities have been greatly increased and at a meeting of the clinical professors last week many important matters were arranged. Practical instruction will be the watchword.

DR. H. L. E. JOHNSON in charge of the Department of Women's Diseases, has organized a maternity service for the purpose of giving clinical advantages to medical students and young graduates.

THE CENTRAL DISPENSARY AND EMERGENCY HOSPITAL.—Three hundred emergency cases were treated in the hospital during the month of July. Many operations were required including abdominal section. The unfinished wards have been completed and furnished and will greatly increase the usefulness of the institution. The annual report to June 30 shows a large increase over last year's work. Miss West, the Superintendent, has found by experiment that the asphaltum and artificial stone floors can be rendered aseptic, whitened and made to look new by washing them first with a saturated solution of permanganate of potash and then, while wet, with a saturated solution of oxalic acid in water. This is inexpensive and does not injure the floors.

THE COXEY AND INDUSTRIAL "ARMIES" which have located in the outskirts of the city number about one thousand and more are expected in a few days. Their condition is deplorable to the highest degree. During this heated season without shelter and badly clad they are eking out a most vicarious existence, depending for food upon a few berries picked from the fields and "threadbare" charity. On account of the unusually large number of persons who belong here who have to depend upon charity, much less can be given to the "army" and they can hardly keep body and soul together. Why these poor deluded creatures continue to come here, or remain after they arrive and see the condition of affairs, is beyond human mind to explain. Sooner or later this persistent violation of hygienic laws must be followed by some grave epidemic which will carry off a large number of them, previously weakened and debilitated. What degree of immunity other citizens will have, is a mere conjecture.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from July 21, 1894, to July 27, 1894.

Major CURTIS E. PRICE, Surgeon, order assigning him to duty at Ft. Custer, Mont., is revoked, and he is granted leave of absence for one month, to take effect upon being relieved from duty at Ft. Porter, N. Y. By direction of the Secretary of War.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending July 28, 1894.

Medical Inspector B. H. KIDDER, ordered as member of Board of Medical Examiners, Navy Department.

Surgeon C. G. HERNDON, detached from Board of Medical Examiners, Navy Department.

Surgeon G. P. BRADLEY, detached from receiving ship "Wabash," and to the Navy Yard, Mare Island, Cal.

P. A. Surgeon E. P. STONE, detached from Marine Recruiting Rendezvous, Boston, and to the "Wabash."

Surgeon F. B. STEPHENSON, ordered to the Marine Recruiting Rendezvous, Boston Mass.

Marine-Hospital Changes. Official list of changes of stations and duties of medical officers of the U. S. Marine-Hospital Service, for the four weeks ended July 21, 1894.

P. A. Surgeon D. A. CARMICHAEL, granted leave of absence for thirty days, July 20, 1894.

P. A. Surgeon A. H. GLENNAN, to inspect unseviceable property at Delaware Breakwater Quarantine, July 6, 1894.

P. A. Surgeon W. D. BRATTON, to report at Bureau for temporary duty, June 27, 1894.

P. A. Surgeon J. J. KINYOUN, to proceed to Cape Charles Quarantine for special temporary duty, June 30, 1894. Designated to represent Department at International Congress of Hygiene and Demography, July 9, 1894. To inspect unseviceable property at Boston, Mass., July 17, 1894.

P. A. Surgeon H. D. GEDDINGS, to report at Bureau for temporary duty, July 20, 1894.

P. A. Surgeon C. P. WERTENBAKER, to proceed to Delaware Breakwater Quarantine for special temporary duty, June 30, 1894.

P. A. Surgeon G. B. YOUNG, to inspect quarantine stations, July 20, 1894.

PROMOTION.

Asst. Surgeon B. W. BROWN, commissioned as Passed Assistant Surgeon, July 19, 1894.

ORIGINAL ARTICLES

OPERATIVE TREATMENT OF FIBROID TUMORS OF THE UTERUS.

Read in the Section on Obstetrics and Diseases of Women at the Forty-fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1894.

BY FRANKLIN H. MARTIN, M.D.

VICE-PRESIDENT CHICAGO GYNECOLOGICAL SOCIETY; PROFESSOR OF GYNECOLOGY, POST-GRADUATE MEDICAL SCHOOL; SURGEON TO THE WOMAN'S HOSPITAL OF CHICAGO; CHAIRMAN SECTION ON OBSTETRICS AND DISEASES OF WOMEN, AMERICAN MEDICAL ASSOCIATION.

Under three heads may be considered the operative treatment of fibroids of the uterus:

1. Hysterectomy.
2. Removal of the appendages.
3. Vaginal ligation of the broad ligaments.

The only absolutely sure cure for fibro-myomas of the uterus lies in the total removal of the uterus. This may be accomplished when the accompanying tumors are small, by vaginal hysterectomy, but as a rule abdominal hysterectomy alone is reserved for these difficulties.

While in hysterectomy, we have a certain remedy for the removal of fibroids, we also have in the method a definite percentage of danger. While experience, antiseptics and skill have put the method on high scientific grounds, and made it highly justifiable, yet even in the hands of the most experienced, when we operate on each new case, no matter how favorable it may appear, the grave responsibility of that certain mortality of 5 per cent. hangs over us.

There is much in the last few years' work in this line of surgery to encourage us. The old extraperitoneal method of Péan's of attaching the pedicle immovably in the lower angle of the abdominal wall is giving way to the intraperitoneal methods of Baer, the more elegant vaginal fixation of Byford's, and the total extirpation of Eastman's. The results have given us shorter convalescence, eliminated serious sequela and the development of several well-nigh perfect methods, gives the operator who is wedded to none, a freedom to adopt the one of several well-tried methods which may best apply to the case in hand. During the last year, in my operating I have drawn upon the methods of Péan, Eastman, Baer and Byford indiscriminately, as the particular method seemed to me to best fit the particular case in hand. So far as my experience goes, however, I feel safer after having performed an abdominal hysterectomy when I have found the case suitable for Byford's method and the operation is done according to his technique.

REMOVAL OF THE APPENDAGES.

This is an unsatisfactory operation for fibroids and I seldom resort to it except in a complicated case, where the abdomen has been opened for the purpose of removing the uterus, and where for some reason the latter operation is impracticable.

When the tumor is small and hemorrhage has been a distressing symptom, relief and occasionally a cure may be expected by this method. Frequently, however, the tumor will continue to grow and occasionally the hemorrhage will not be modified. If you *do* remove the appendages for the purpose of establishing an artificial menopause and for the purpose of causing a reduction of the size of a fibroid by modifying its nutrition, remove not only the ovary and the tube thoroughly, but draw these organs sufficiently high, and make your ligature sufficiently low to include the main trunk of the spermatic artery as well as its branches to the tubes and ovaries. It is not difficult to remove both the ovary and the tube of a given side and leave the ovarian artery (its main trunk) entirely outside of the ligature. In removing the appendages for fibroids, if I had to leave the main trunk of the ovarian artery untied or Johnson's menstrual ganglia intact, including the uterine third of the Fallopian tube, I should feel safer in leaving the latter and tying the vessel. It will assist, too, in these cases while the abdomen is open, to place a ligature deeper in the broad ligament as suggested by Dr. F. B. Robinson, in a manner to include the ascending column of the uterine artery.

If the appendages are to be removed then, in the case of fibroids a thorough job should be done, including not only the removal of the tube and ovary but also the thorough tying of the main trunk of the ovarian artery.

VAGINAL LIGATION OF THE BROAD LIGAMENT.

This operation which was original with me and first described in an article read by me before the Chicago Gynecological Society, Dec. 16, 1892, consists in ligating the contents of the base of the broad ligament from the vagina. In suitable cases the ligation may be carried sufficiently high on one side to include the ovarian artery.

OBJECTS OF THE OPERATION.

The objects of this operation may be summarized under the following heads:

1. To deprive by a comparatively simple procedure an abnormally over-nourished uterus of the bulk of its blood supply by ligating the main channel and trunks of the uterine arteries.
2. To still further deplete the uterus in desperate cases by including, where practicable, not only the uterine arteries of both sides but also the ovarian artery of one side.
3. To cut off the nutrition of the uterus by ligating a large proportion of its nerve communication as well as its blood supply.

THE PHYSIOLOGIC EFFECTS OF THE PROCEDURE.

The deprivation of the tumor of its blood supply causes starvation and rapid atrophy of the growth, and has a direct and immediate effect in checking uterine hemorrhages. The severing of the nerve

communication to the hypertrophied uterus modifies profoundly its nutrition and favors atrophy, and also renders the uterus powerless to communicate its blood draught; thus retarding collateral circulation.

The technique of the operation has been described frequently; I will, therefore, but briefly summarize it here:

1. Patient should be prepared exactly as for a vaginal hysterectomy.

2. Place in an exaggerated lithotomy position and insert two retractors so as to expose the cervix.

3. Transfix cervix with a strong handling ligature.

4. With curved scissors incise the mucous membrane of the vaginal vault to the right and left of the cervix to the extent of about one and one-half inches on each side.

5. Draw the cervix strongly to one side and with the finger dissect the tissue of the base of the broad ligament of the opposite side, free from the bladder in front, and from the rectum behind, until it can be grasped to the height of one and a half to two inches free from all attachments.

6. With a strong handled, curved, pedicle needle armed with a double No. 12 silk ligature, the exposed ligament should be transfixed at its center, the lower ligature tied firmly and the upper one carried to the limit of the exposed ligament and also tied. They should be cut short.

7. Close the vaginal vault incision with a running catgut suture.

8. Treat the opposite side in the same manner.

9. After douching the vagina thoroughly with an antiseptic fluid, pack it loosely with iodoform gauze.

As this operation is new, and still on trial, I will take the liberty of reporting briefly my last two cases and giving a general summary of my first cases:

SUMMARY OF CASES.

I have now operated on eight cases of uterine fibroids by this method.

Case 1.—Was a tumor of considerable size extending to or above the umbilicus. The hemorrhage was exhaustive, and the patient greatly reduced in consequence. She was operated on Nov. 15, 1892. Considerable time has therefore elapsed since the operation. The tumor has decreased in size, but is still easily outlined, the patient writes me. The hemorrhage is now much modified and is no longer a source of alarm. She has had a severe attack of la grippe since the operation; is a chronic dyspeptic, and having these disagreeable complications I feel that I can pronounce the case a success. The patient considers her condition greatly improved—hemorrhages cured, tumor materially reduced and pressure symptoms have subsided.

Case 2.—Is a perfect cure. I have had an opportunity of seeing this patient almost every month since she was operated on (Dec. 3, 1892). "The hemorrhage has ceased completely. There has been very scanty flow at menstrual period. All pain has ceased." The patient's health has improved so that from a state of almost complete invalidism she is transformed into a strong and healthy woman. The improvement was progressive from the day of the operation. The enlargement of the uterus, or tumor, is now scarcely perceptible.

Case 3.—I have heard from but once—four months after the operation. She was operated on early in January, 1893. The flowing which had been, previous to the operation, excessive, had decreased in duration and amount one-third.

Case 4.—Was a large adherent myo-fibroma extending above the umbilicus, profusely hemorrhagic, for which laparotomy had been unsuccessfully performed—neither the appendage nor the tumor being removable. The case was a desperate one. The patient had not been out of bed on account of the loss of blood and general weakness, for several months. She was operated on Jan. 5, 1893. The hemorrhage ceased immediately and has never been excessive since. The tumor has decreased until it is not now more

than three inches in diameter. The woman is strong and vigorous, in good flesh and in perfect health. Menstruation is regular but scanty and there is no pain. The case in its course and behavior has been gratifying in the extreme.

Case 5.—Has not been under observation since June, 1893. She was operated on Jan. 8, 1893. Four months after the operation Dr. F. H. Geer reported "the menstruation only lasted two days; very scanty; no pain. Fibroid diminished in size until the uterus is about normal. Patient claims that she is cured."

Case 6.—Upon which I made a preliminary report in the *American Journal of Obstetrics*, Nov. 1, 1893, on which I operated Aug. 2, 1893, is still under observation. The last report from her husband (who is a physician of unusual ability), contained in the article referred to, was for Oct. 26, 1893. The amount of menstrual flow was normal in quantity, lasting but a few days. The pain was slight. By referring to the preliminary report it will be seen that this patient had been an invalid. She flowed excessively and almost constantly. The tumor was about the size of a four months' gravid uterus. The pain at and following the excessive flow was excruciating. The next report was, in January, 1894: "I have to report," the husband says, "that Mrs. X. menstruated from December 19 to 24. That the amount was about the same as before, *i. e.*, slightly above normal. Pain rather excessive for two days (possibly due to rheumatism and neuralgia). After flow had ceased I examined, and found ligature in vagina and also small sinus opening to left side of cervix. Since then there has been slight discharge from same. She had been suffering some pain at that point, no pain since ligature came away." He adds enthusiastically: "Taken all in all, the result so far is a grand success. Jan. 17, 1894, he writes: "Mrs. X. is up to-day (the fifth day) after the easiest menstruation she has had in her life—pain moderate and on one day. This in face of the right side still discharging. In the next two months I expect to have a well woman. The uterus is now practically normal."

Dr. Wm. H. Humeston, of Cleveland, Ohio, reported to me in private correspondence the following interesting case bearing on this subject. The case was afterward published in the *Western Reserve Medical Journal*, of Cleveland. He says:

"I had an extreme case in a lady 47 years of age. The tumor is as large as one's two fists—an interstitial fibroid. She was reduced to the lowest extremity, exsanguinated, frequent attacks of syncope and constant flowing for three months. It was out of the question to do any other operation. I ligated the left uterine artery and a good portion of the broad ligament. I had some difficulty but not a great deal. I believed, on account of her bloodless condition, that if I ligated both sides she might have had subsequent sloughing. She has done exceedingly well. Flowed a little for two days following the operation but none since. Her condition is rapidly improving, appetite, strength and blood returning. I shall not do the other side unless occasion demands. I endorse your operation heartily. It is reasonable and practical."

LAST TWO CASES—(NOT PREVIOUSLY REPORTED).

Case 7.—Mrs. S., aged 35, from Denver, Col., with a uterus about double the normal proportions, containing two or more centers of development and of an extremely hemorrhagic tendency was the seventh case operated on. The case had been treated unsuccessfully by curettement, electricity and the ordinary remedies for checking uterine hemorrhages. The uterus was retroverted but free from adhesions. The patient was prepared carefully, and at the Woman's Hospital, on Nov. 11, 1893, I ligated the base of both broad ligaments, and shortened the round ligaments. The uterus was drawn well down, and each broad ligament after incising the mucous membrane covering them in the vault of the vagina, was dissected free from the bladder and rectal attachments and then ligated with two strong silk ligatures. These ligatures were placed high enough to include the uterine artery and all its branches, and all of the contents of the base of each broad ligament. The ligatures were cut short after they were tied, the mucous membrane of the vagina was re-united with a running catgut ligature, the vagina packed with iodoform gauze. The round ligaments were then shortened and the uterus left in a position of anteversion. Three days later the gauze was removed from the vagina, an antiseptic douche was given and a Smith-Hodge pessary was inserted. The antiseptic douches were then continued daily. The first menstruation was due four days after the operation. It did not appear. The second menstruation also failed to

appear, notwithstanding the fact that menstruation had ordinarily been exhaustive.

One of the wounds caused in the operation for shortening the round ligaments suppurated, and necessitated the patient remaining in the hospital until the latter part of January. The patient complained of dizziness about the time when the menstruation was due. This symptom continued with different degrees of severity for some time, gradually disappearing. February 13, three months after the operation, the first flow appeared. The patient writes: "First menstruation came on the 13th of this month, without pain, but quite profuse for first two days. Since then, has continued including to-day (the 18th). Discharge light."

March 19, 1894, the patient reports: "Am feeling fairly well this month. Had pain in back with last menstruation which commenced March 13. First three days quite profuse; last four days very little. No dizziness this month." April 18, she writes: "Menstruation came four days in advance of schedule time; continued one week. Am in fairly good health."

Case 8.—Mrs. Z., Muscatine, Iowa. About 35 years of age. No children. Multiple fibroid of uterus approximating in size a four months' pregnancy. Hemorrhage profuse, followed for a week by excruciating pain. Patient became extremely ensanguinated at each menstrual period. Frequently the flowing would last for two weeks. The uterus had been curetted. Electricity failed to control the hemorrhage and only partially modified the pain. The irregularity of the uterine canal undoubtedly accounted for the failure of the electricity. Nov. 28, 1893, the patient submitted to my operation for ligation of the broad ligaments. The tumor was developed more to the left side into the left broad ligament. I succeeded in separating the broad ligament for a height of two inches. On the right side a large double ligature was employed, while on the left side first a double and finally a second one higher and farther away from the uterus was applied. The ligatures were cut short, the vaginal vault closed with catgut, and the vagina packed with iodoform drain. The first menstruation was due three days following the operation. A slight watery discharge occurred instead of blood. Two days following the operation the patient complained of pain similar to that which ordinarily occurred after menstruation. Feb. 1, 1894, the patient's husband writes: "She commenced her menstruation January 25, and it has continued until to-day, February 1. One day less than last time. Had one day of some pain,—not bad. She is getting stronger and can get around the house without being very tired, although she has not yet ventured out." February 26, the report is: "Mrs. Z. was sick this time six days, the same as last time. Had considerable pain, two days of which was very severe, the same as she complained of before the operation. She is getting along very nicely. She is now able to go out, and takes a walk every day." March 26, the husband writes: "I am ready to make another report but not as good a one as I would like. Mrs. Z. was sick on time and the flow was very little compared to what it has been, lasting but three days; but she had a great deal of pain—some before she was sick, and it was quite bad for two days after the menstruation. . . . Everything seems to be working very well if she could only get rid of that pain." April, menstruation still decreasing in quantity. The pain decreasing. "There was one day of pain," the husband writes, "and the flow did not amount to but very little." May 6, he writes: "Mrs. Z. has been feeling splendidly all this last month. Last week was her time to be sick again. The flow did not amount to anything, just enough to show. . . . In regard to her general health it is excellent. Eats well, sleeps well and goes out every day the same as other women. Has gained her natural amount of flesh and a little more." I examined the patient May 19. The uterus was reduced in size one-half. Patient in perfect health.

GENERAL CONCLUSIONS.

1. In hysterectomy we have an operation which is bearing the test of time well; in selected cases in the hands of well trained men it is the only absolute cure yet demonstrated for a certain class of fibroids.

2. The objections to hysterectomy as a cure for fibroids are, the long training necessary to safely equip an abdominal surgeon for this most formidable of pelvic operations, the great rate of this operation in the hands of the tyro, the long prostration, accompanied frequently with nervous symptoms fol-

lowing otherwise successful hysterectomies, its inapplicableness to extremely exsanguinated and otherwise reduced patients, and finally its inevitable death rate of at least 5 per cent. in the hands of expert surgeons.

3. Removal of the appendages as an operation for fibroids is usually unsatisfactory, and should not be resorted to except as a last resort in a complicated case where the abdomen has been opened for the purpose of removing the uterus, which operation for some reason has proved impracticable.

4. If the appendages are removed for the purpose of establishing an artificial menopause and for the purpose of reducing small fibroids by modifying their nutrition, make sure to include in the ligature the main channel of the ovarian artery.

5. Vaginal ligation of the base of the broad ligament for fibroid of the uterus is an operation still on trial. As far as we have history of cases to back the theories of the operation it has stood the test.

6. Vaginal ligation of the broad ligament is a minor operation from the standpoint of mortality, and it is a minor operation from the standpoint of immediate and remote shock to the patient. It can be performed on any patient without risk, in almost any condition of physical prostration or weakness, so long as she is capable of taking an anesthetic.

7. The operation is prompt in saving blood. It succeeds in cutting off one-third more blood to the uterus than does the Battey-Tait operation. Theoretically and practically it immediately checks uterine hemorrhages, and at once begins the diminution of the myoma by depriving it of its nourishment.

8. The operation of ligation of the broad ligament does not leave an abdominal scar, does not unsex the woman, as does both hysterectomy and the Battey-Tait operation.

9. There are no good reasons why ligation of the broad ligament should not be an early procedure in all conditions of uncomplicated fibroids of the uterus in which the operation is practicable, even though in a few cases, subsequently, a more radical operation might be necessary.

10. The operation of vaginal ligation of the broad ligament is practicable in all interstitial or moderately subperitoneal fibroids in which it is possible by careful dissection to expose the base of the broad ligament high enough to include in a ligature the uterine artery and its branches.

Venetian Building, Chicago.

DISCUSSION.

DR. McCALL of Mich.—I have watched the evolution of this subject with a great deal of interest from the early methods of removing fibroids to the ideal and complete method, as described by the gentlemen here to-day. If that method can be made a success in all operations, it certainly is as nearly ideal as we could wish.

The method I have pursued mostly has been the abdominal method, although I felt at all times that that was not an ideal perfect method. I have in a few instances removed the entire uterus by complete ligation of the broad ligaments. That operation has probably been done by Dr. Martin, of Berlin, more frequently than by any other of this class of operators. I saw Dr. Martin perform that operation a great many times, and on very large tumors, and very difficult ones; ligating the whole of the broad ligaments from above downwards, and removing the whole of the uterus. His success in that operation was, perhaps, as good

as we could expect in the character of cases he had to deal with. Still the mortality was large.

Our President, in removing the whole uterus without using any ligatures except on the upper part of the broad ligament, leaving the uterine arteries entirely in the pelvis, gives us the ideal operation. Still I suspect in a great many of the cases that we have to operate upon we will not be able to do that as nicely as our President has done in the cases he has reported to-day. I know it must be a very difficult operation where there are large masses in a broad ligament—very difficult to get around those, and very difficult to enucleate the whole mass without opening the tissue of the tumor or without disturbing the capsule of the tumor. If we do that we get hemorrhage, and in either way there is difficulty.

The time has not been sufficiently long to say anything with regard to ultimate results in my own cases. Present results are very good. I think I shall make use of this operation much more frequently than any other, where we get our cases early, provided the results prove to be as good as described by Dr. Martin to-day. It is certainly the best conservative method we have.

As Dr. Martin has said, the great difficulty has been that we have not tied deep enough and close enough to the uterus. It would be well in many cases to tie as close as possible to the uterus; tie deeply so as to involve the whole of the ovarian artery. In a certain number of cases an operation will arrest the menstruation and arrest the development of the growth of the tumor, and be a success.

Dr. Martin's operation is more simply and easily performed, and certainly will diminish the quantity of blood going to feed the mass in its growth, and I think by that operation performed very early, in a large number of cases it would save the trouble we might have afterwards.

DR. BEVERLY MACMONEGLE, of California—I feel that it is necessary to bring out all we can on this important subject. All the modes of treatment known to us have been gone over by these distinguished gentlemen. I regret that I was not here in time to hear the paper of our distinguished President. Therefore I can not say what I think of his operation, as I do not exactly understand it. However he made a small report in one of the journals, which I had the pleasure of reading, which leads me towards the direction in which he is working. I can say that an operation which leaves no ligature in the abdominal cavity, an operation which causes no more hemorrhage than his does is most commendable, and as safe an operation as can be done in the abdominal cavity.

I want to bring before you the question of malignant degeneration, which has not been brought out, that I have heard. I have enjoyed very much Dr. Martin's paper on his operation for tying the uterine arteries and not resorting to total extirpation. It is our duty to consider our patients always, and in order to do that we must give those patients the benefits of the least dangerous treatment; we must combine the different methods of treatment and give such medicines as seem to add to the good results of the case. We want to have at our disposal an operation which shows no deaths. I think it is possible that we might combine the three methods and get a result even better than what our friends here have attained.

But the question in my mind is whether there will be malignant degeneration after tying the arteries. The operation is more or less experimental. What the result will be we will have to wait and see. The reason I raise this point of malignant degeneration is that I have had the misfortune to continue with my electric treatment so long that I have turned, as near as I can judge, a fibroid tumor into a malignant type. I have recently operated on a girl whom I have treated for a good while. I treated her with electricity for

a period of two or three years, giving her always benefit and comfort and relieving her hemorrhage. The tumor appeared to grow softer. Eventually she became so ill that she came to me to perform a radical operation. The electricity had possibly been applied too strong. I removed the uterus entirely. I tied the ovarian and uterine arteries and drained through the abdomen.

Now understand me that I mean the possibility of malignant degeneration is an argument against Dr. Martin's operation, but I think we should have this point in view. Therefore I ask Dr. Martin to give us another report later on, whether or not after reducing the tumors by the abdominal method there is simple degeneration of the tumor or malignant degeneration.

I can not criticise the President's operation in any way, and from what I know of it I have nothing but praise for it.

The fixing of stump outside of the abdominal wall is an operation that is still supported by our best men and should give us the best results. Dr. Keith, whom we ought never to forget to mention, has done most of his surgery in this way. His results are better than mine, I am sorry to say. But they are enough to justify us in following this method if we are not accustomed to working inside the abdomen. I don't want to disregard that operation entirely, because I feel that it has been the means of letting me out of a tight place and saving my patient's life.

If we have a uterus the tumor of which is growing and the hemorrhage is so great that we are about to lose our patient, it is necessary to remove the tumor by the abdominal section and total extirpation. The operation and results of Dr. Baer are good. He leaves an aseptic stump, and opens a canal so as to prevent drainage into the abdominal cavity and create poison. That operation I have not done myself.

We have neglected to mention an operation (which I tried once or twice and found very satisfactory) called the extra-peritoneal method, and which is described by Dr. Gough. In my cases I had good results. The objection I have had to it is the time it requires, and exposing the patient during the operation.

I want to ask a question of Dr. Smith in regard to the use of electricity, and that is if in his treatment he punctures the tumor. I do not do so.

I also have a question to ask Dr. Martin, and that is, if a woman can become pregnant after this operation of tying the uterine arteries. We have still remaining the ovarian arteries and the Fallopian tubes supplied with their natural amount of blood. If the woman does become pregnant will injurious results follow?

DR. MARCY, of Boston—I labor under a disadvantage in not having heard these speakers, and yet it is possible there is something to be gained. Sidney Smith once declared it was better for him to review a book before he had read it as he was then entirely unprejudiced. Therefore I am in a state for discussion. I have thought and written a good deal upon these subjects, and an experience through two decades has caused me to have some pretty positive ideas as to the treatment of fibroid tumors. We have all been co-working in these directions for a good many years.

A word in regard to electricity: In a very early day when Dr. Cutter, of New York, used electricity in the treatment of tumors, I had my own experience. I saw patients go to their deaths that I had myself put in the hands of these masters, and I became satisfied that the use of electricity as thus applied was not a wise procedure.

Some of you may remember that when the International Congress was held at Washington I presided over the Section on Diseases of Women. Some of the strongest advocates of this system were present, and all were anxious to give their experience. It was an experience meeting day

to those who were present and will never be forgotten. I returned home a convert to this new method of treatment I used this treatment and I had an experience that I might summarize in two or three sentences. I do not declare that patients were not benefited, and that means a good deal; but I will also say that I discourage the application of electricity in the arrest of the growth of fibroid tumors almost without exception. We may regard these cases from one or two standpoints:

1. If the case is or is not operable. If it is an operable case, we may divide it into several classes. In a case where the tumor is small and the patient is young the probabilities are that small tumor will be larger; that patient will become an invalid, and by and by there will be regret that we have neglected an opportunity most favorable for her relief or her cure. This class of cases I believe are best treated by abdominal operation; by ligation of the vessels and the removal of the appendages. I think we have a large consensus of opinions in this direction and that it is wise teaching. It is an operation that should be encouraged. This operation of Dr. Martin's is in this direction. In small fibroid tumors it is not dangerous to remove the appendages. In larger growths from my own experience I am positively of the opinion that this operation ought not to be performed without the removal of the appendages. If the patient is a well woman and comparatively young and the growth is increasing, then I am sure the President of this Section, and the men whom I face in discussion will agree with me that it is wise to remove it. But why is it that this has so slight a hold on the profession? It seems to me that we do not have the ability to treat the wound as we would like to, for the reasons that we are fearful of hemorrhage first, and that there may be something left in the abdominal cavity which will prove injurious.

You and I know full well that the class of cases we can thus treat are the exception, and that we must have some device that shall enable us to remove those growths that fill and crowd in such a way that the functionary organs can not go on. And we are driven to one or two extremes in treating those cases. One is advocated by your President. I give it full approval in certain cases. I believe the results are admirable. I believe ideal surgery is the one that gives the greatest number of cases the greatest possible relief.

I have for a long time felt it was not necessary to open the vaginal cavity for a variety of cases. In this method advocated by the President the abdominal incision is at once closed, and that ends the operation, and drainage tubes may be avoided.

This subject is so large that I hardly know what to omit in the discussion. In these cases a great many things have to be taken into account. But when it is determined that there is a foreign body in the abdominal cavity I think it is better to remove it. I know there are dangers; and yet that is the reason why we discuss these questions to-day, so that we may minimize our dangers. As we look back we see that every year adds very materially to success in treating this class of cases, and the percentage of cures increases.

Dr. MONTGOMERY—I feel we are greatly indebted to the President for his excellent presentation of his method of operating. He has shown us how to do away with the ligatures, but I must confess that in performing operations of this kind I feel much safer in having ligatures applied to the uterine and ovarian arteries. I have used two ligatures, and cut away the uterus without any subsequent hemorrhage or trouble.

There are a number of cases in which it is impossible to perform an operation and leave a stump, the uterus has been so taken up by the large growth of the organ. In my ex-

perience I have found it better to have a cervix left. We are then certainly much better able to sterilize and render clean the vagina, and to insure thorough and complete drainage. When we consider those cases in which we may be able to leave a small stump, we find that those patients who have had the uterus removed through the vagina subsequently experience no inconvenience for want of support.

This operation of Dr. Martin's has many advantages in cases where hemorrhage is a source of danger; those cases where it may not be thought desirable to resort to so severe an operation as the removal of the entire organ. In such cases it may serve a very useful purpose. In such case, however, it would be a question with me whether the patient would be safe in an operation by ligating the uterine artery upon either side and ligating an ovarian artery upon one side; whether the removal of so large a supply of blood from a tumor of considerable size would not be dangerous. But the fact that it has been done and the patients have recovered is certainly a better demonstration than any theories upon this subject.

With regard to the application of electricity, I am very glad that Dr. MacMonegle has spoken of the danger of malignant degeneration. In my experience I do not think that the application of electricity to the uterine canal is a safe method of treatment; it causes irritation of the mucous membranes, it seems, which is not beneficial.

I would like to ask Dr. Martin if he has had experience in the use of electricity in treating fibroid tumors.

PLACENTA PRÆVIA—A PLEA FOR ACCOUCHEMENT FORCÉ.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY LLEWELLYN ELIOT, A.M., M.D.

WASHINGTON, D. C.

At the last meeting of the Section of Obstetrics and Diseases of Women, I presented a paper, "Accouchement Forcé in Certain Obstetric Complications," and mentioned placenta prævia as one of the complications. (See JOURNAL, Vol. xxi, September, 1893.)

It will not be necessary to speak of the causes or the symptoms of placenta prævia, nor shall I refer to statistics to show the relative frequency of centralis, marginalis, and lateralis, or the mortality of the mother and the child, since statistics collected upon this subject are misleading. All varieties are usually included under the general heading, placenta prævia. Next to a case of puerperal convulsions, this is the most appalling accident to be met with in the lying-in room. Called, as we are, only at or after the occurrence of hemorrhage, there is little time to draw the lines of fine distinction. Time is only for action, and upon that action frequently depends the lives of two human beings. To tampon will stop the hemorrhage so far as external appearances go and will lull the medical attendant into a feeling of false security, while delivery frequently increases the hemorrhage, during the time of delivery. Many perform version, bringing down the feet, so as to tampon with the child's body; others proceed to immediately dilate the os and force delivery.

I believe no woman should be allowed to continue to suffer from these hemorrhages after the child has reached the age of viability, but that she should be delivered in accordance with the severity of the hem-

orrhage. This I consider conservatism, for it is just as possible and as easy to resuscitate a child in the seventh month, when it has not been subjected to the effects of repeated hemorrhages, as it is to resuscitate one that has been subjected to the effects of these hemorrhages in the ninth month. The woman, certainly is in a better condition before these losses, to withstand operative interference.

Cæsarean section, as recently successfully performed by Dr. A. C. Bernays (*JOURNAL*, Vol. xxii, May 12, 1894), is an operation I would hesitate a long time before performing for this trouble. The same applies to the Porro operation.

We all admit, even its most enthusiastic advocates, that there is danger in performing accouchement forcé, that serious accidents may occur, that it may become abused and thrown into disrepute by adoption by every one engaged in medicine; still should a cervix be lacerated an immediate trachelorrhaphy may be done by placing the woman upon her back, drawing the uterus well down and introducing our sutures; should a rupture of the uterus occur an immediate laparotomy and suturing the rent will be necessary; septic infection may occur through use of dirty hands; hemorrhage may be continued through division of the circular artery, but this can be controlled with a ligature. But on the other hand, in natural labors how many times will the cervix be lacerated with forceps, or the passage of the child's head and shoulders; how many times will the uterus be ruptured; how many times will septic infection occur even in the practice of the most rigid follower of antisepticism; and how many times will the circular artery be injured? I believe they will occur as frequently in the one case as in the other. Even should these accidents or any of them follow accouchement forcé, does it in the least militate against the operation, in the proper hands? Accouchement forcé is a simple operation; its performance requires patience but boldness with entire confidence in his ability on the part of the operator. The fingers are introduced one after the other into the cervix and separated to their fullest extent; the uterus contracts, the hemorrhage checks and labor is terminated very shortly, either spontaneously or with the forceps. The fingers appreciate the dilatation as it progresses and do not therefore exert any undue force. To me, nothing appears simpler. The difficulty we will most frequently meet is an old cicatrized os, which will give way to patience on the part of the operator. Whether to give an anesthetic—chloroform—or not, will rest with the operator, although chloroform is believed to increase the danger of relaxation of the uterus after delivery. I should be guided in its administration by the suffering of the woman. The child is born, the pressure is relieved from the bleeding points, and the uterus is usually relaxed; if hemorrhage again occurs, we must resort to active measures to contract the uterus and stop the bleeding. Fluid extract of ergot in drachm doses, irrigation with hot or cold water, pressure, introduction of ice, electricity, massage, or better still packing the uterine cavity with iodoform gauze. Rectal injections of strong infusion of coffee, or of a solution of table salt will assist in reviving the patient.

While obstetric text-books, in general ignore this method of treatment, it would be much better were more attention paid to it.

1106 P Street N. W.

DISCUSSION.

DR. ESCHELMAN—I do not want to talk myself; I am not accustomed to talking. But I recollect many years ago in Philadelphia, we had a doctor there, now deceased, who would start up and talk and take a false position just to start the boys talking. I will try and do the same thing. In Philadelphia where I practiced medicine—(I am now in California for my health, and have been more or less for seventeen years, and of course I am far behind in everything; but on the subject of placenta prævia I have taken considerable interest in my practice,) it was my misfortune to be called to attend a case that was in the care of a homeopathic physician, and not caring to take the responsibility too much on myself and not having much experience with placenta prævia I sent for Dr. Ackley or Dr. Wilson. Well, the gentleman who was sent brought both by mistake so that there were three of us together there. It proved to be twins, with the placenta prævia presenting great difficulty on account of the interlocking of the children, and our patient died after ten days.

This case set me to thinking considerably on the subject, and with some prejudice I had against placental delivery I made my mind that the forceps was the best instrument in placenta prævia, and for the purpose of preventing hemorrhage to use the child as a tampon. In watching these cases, however, I found that there was a great deal more placenta prævia than I had ever dreamed of before. A good many of my miscarriages were placenta prævia, and in a large number of cases they are generally disposed of in that way by hand; but my experience is that with the os uteri dilated, I have never had any trouble in introducing a narrow-bladed forceps, grasping the head, bringing it down upon the placenta and using it to tampon and check the hemorrhage and deliver with labor pains gradually a living child. That is all that is contained in it. Dr. Davis, of Wilkesbarre, read a paper before our State Medical Society assembled in Philadelphia, and after dwelling considerably upon that (he was the principal consulting physician as I understood in obstetrics, in Wilkesbarre, had met a large number of cases and made it his study) he ended up by saying that the whole credit of this method in the delivering and treating was due to myself. I have thought during these many years that I have been out of practice that it would be interesting to me to hear something of placenta prævia, and know how the profession are treating it now.

DR. WHITNEY, of Oregon—I rise to speak because I want to ask for information. About four weeks ago I had my first case of placenta prævia. That was a case of placenta lateralis. While I did very well with that case, saving both the life of the mother and the child, yet it has made me think more about these cases and I would like to know more about what I would do if I had a case of centralis. This paper does not talk very much nor give us a great deal of information on centralis, and I would be glad if some one would discuss that phase.

DR. CHESNEY, of Philadelphia—One naturally has some hesitancy in discussing a paper when the writer thereof is not present to close the discussion. The paper is valuable, if only that it brings before us for consideration one of the most practical subjects that we have to consider in our daily work. Fortunately, indeed, it comes rarely to any one of us to meet such an emergency. I have in the past when engaged in the active duties of an obstetrician had a number of instances where such difficulties were presented for my immediate action. It goes without saying that none of the many emergencies that come before the obstetrician, present graver causes for alarm than the terrible hemorrhage which may meet him at the threshold of such a case. He then has no time for the weighing of nice distinctions, and

he must necessarily in many cases—in all cases—employ such means as will enable him rapidly or as rapidly as possible to dilate the cervix. It is a question of comparative safety with him then. Many of the cases I think are just as Dr. Eschelmann stated who quoted from Dr. Levinger, formerly a distinguished practitioner of Philadelphia, they are cases of lateral placenta where the placenta does not very materially interfere with the delivery of the child, when a certain degree of dilatation has been obtained. But practically it comes down in my opinion to this—that we must as rapidly as possible dilate, turn and deliver; and in the case of the question that was asked by the doctor from Oregon, the case of central implantation, it is my opinion that the finger and then the hand of the physician should rapidly pierce through the placental mass and if possible bring down the child as a uterine tampon. It will not materially delay delivery, and will of itself be the best dilator; and as was also remarked it will frequently be found that the first hemorrhage will increase the dilatation of the cervix, if it had not been found already somewhat considerably dilated, and that comparatively little difficulty will be found in its further dilatation and in the delivery. There is no criticism at all as to the many means suggested for the after treatment of the hemorrhage, save that very few of them are at our command at that time. The rapid massage of the uterus through the abdominal walls, the injection of copious quantities of hot water, as copious as will be permitted by the contraction—the hoped for contraction of the womb—the introduction either by the mouth, of hypodermic injection of strychnia, or strychnia and ergot, will in a great majority of cases answer every purpose. I would, however, feel disposed to note the suggestion or information of the writer that there is little danger or comparatively little danger to the child after seven months' gestation, that is in regard to resuscitation. On the contrary, I think there is great danger in all cases of placenta prævia, but particularly where hemorrhages are manifested comparatively early—great danger to the child in its delivery.

DR. MARTIN, of Chicago—I can not discuss this question intelligently, Mr. Chairman, but like the doctor from Oregon I would like to ask one question. We have here practical obstetricians; I see a number of them, and in the last year or eighteen months we have been startled by the reports of Cæsarean section for placenta prævia; in the last ten years from time to time we have been met by propositions that at first seem equally as startling as this, and I would like to ask the question simply to bring it up for discussion. You must remember that the gynecologic department of the AMERICAN MEDICAL ASSOCIATION ought to take the lead in the discussion of all such matters, and I would like to have that point dwelt upon by some of the practical obstetricians present. I, also, with the doctor who has just spoken, am sorry that the author of the paper is not present. I remember last year at Milwaukee he read a paper advocating the gradual dilatation of the cervix by the fingers, and it precipitated a very lively discussion which was taken part in by Howard Kelly and a number of the other lights of the Section; the whole point gathered around those finger nails, and it brought up the old discussion of antiseptics, and the danger it was stated there was, of bringing such a procedure before a mixed society or advocating such a procedure before a mixed society. And while it does not seem necessary any longer to insist upon cleanliness in obstetrics, at the same time there is that element of danger to any one who should be a little careless; and the whole question, then, of the cleaning of the hands came before the meeting for discussion. I remember twelve years ago in a clinic given in Mercy Hospital by Dr. Quine, one of the most brilliant physicians of Chicago, he made this statement, and

it seemed remarkable then and there was really no explanation for it—he made this statement, that he had noticed that after delivery, in all cases where it became necessary to introduce the hand in the uterus, that fever invariably followed. We know now what that means. And the question of importance is, now, Do we know all of us what it means? It means simply that we must watch our hands, that we must wash our hands, not only a minute, or a minute and a half, but that we should prepare them with the same carefulness that we prepare them for a laparotomy; and a physician in general practice can not prepare his hands for laparotomy with soap and water, one of the best methods of preparing them, without employing some twenty minutes or a half an hour. Any man, to assist in laparotomy, must employ not less than twenty minutes with a scrubbing brush and nail brush, with a file and with hot soap and water. And I believe that if we would adopt the method adopted in the Johns Hopkins Hospital for these cases, we would be more certain of cleanliness, and that is to wash our hands first until they are thoroughly mahoganized in a saturated solution of permanganate of potash until this matter is thoroughly scrubbed into the hands, then with a saturated solution of oxalic acid we should thoroughly scrub it off—not entirely, because of the cleansing power of the permanganate of potash and of oxalic acid, but to insure thorough scrubbing. And in any post-graduate work where we are obliged occasionally to ask men whom we are not acquainted with, to assist in important operations, I always insist upon that preparation of scrubbing in order that the hands should be thoroughly cleaned; not that we would be any better prepared after half an hour's scrubbing but that insures the scrubbing. Therefore in this method of procedure if it is the proper method, the one point most to be borne in mind is that the hands must be thoroughly cleansed. I hope some one will discuss the point of Cæsarean section.

DR. MONTGOMERY—After having the privilege of hearing this paper on placenta prævia, I will say that it is one in which I for a long time have had a great deal of interest. It is the one condition in which I think that the life of the child should not be considered, but that the life of the mother should take the first consideration. Whether you consider particularly placenta prævia, lateral or central, you have the woman in a condition where hemorrhage begins early, probably the fifth month; where she is likely at any time to have hemorrhage so serious as to endanger if not to take her life, it is unwise it seems to me to temporize in such a condition. Just as soon as the diagnosis of placenta prævia is established, in such a case the product should be evacuated, running no risks, of the life of the individual being endangered. In those cases in which the hemorrhage takes place later in the period of gestation, in those cases in which it is evident that the placenta prævia is one of lateral rather than central, in which the hemorrhage is slight, we may then possibly temporize, taking occasion to provide against a serious emergency. But even in such a case it is wise to bring on premature labor, not permit the patient to go on and take the risk of completing the full term of gestation. The important consideration is that of thorough antiseptics in every procedure. It is well recognized that the nearer we bring an obstetrical case to the surgical stand, the better will be our result, and the less frequently will we have the unpleasant sequel to follow it. In these cases we may readily and rapidly produce labor by placing the woman under anesthetic, introducing the finger into the cervix, dilating gradually until first one and then two fingers get introduced, rupturing the membrane, turning by Braxton-Hicks method, and drawing this into the cervix. This of itself prevents hemorrhage and enables you to control the subsequent operation.

I don't think that the operation of the Cæsarean section or the Porro operation, as was suggested some years ago, is necessary or advisable in placenta prævia. I don't think that we should consider the life of the child as a matter of great importance, when we realize the great frequency of the death of the mother and child from such a condition.

DR. NEWMAN—Some one asked in regard to the treatment of cases of placenta prævia centralis. As the previous speaker, Dr. Montgomery, has said, there is little question but what those ought to be treated after the Braxton-Hicks method, that is, immediate perforation of the placenta with one or two fingers, turning and delivering, the child to be used as a tampon. Here we check the hemorrhage immediately, whereas it is frequently at the sacrifice of the child. It is the most prompt, safe, and I think generally recognized method of handling those cases. Certainly a case of so great importance as a case of placenta prævia, should be treated strictly on surgical principles, as all obstetric cases ought to be. The surgical conditions are only properly performed by having everything necessary the same as we have in capital surgical procedures, and we have a lying-in room for such cases as those. We should by all means have the woman on a table. Do not attempt to do turning or difficult obstetrical procedure with the patient lying in bed. There are more advantages than one in having the woman on a proper elevated surface, where you can do what you try to do easily and much more efficiently. A word in regard to the anesthetic. The author of the paper hesitates about using an anesthetic. I think that hesitation is well founded, certainly as regards chloroform. Chloroform is a dangerous anesthetic after extreme hemorrhages. Many of these cases are such that chloroform acts badly. An exsanguinated condition is extremely dangerous to the use of chloroform. I think, however, that better work is done ordinarily under an anesthetic than without it, but ether should be the anesthetic under these circumstances. It is a very profitable subject and I wish more would engage in its discussion, as it is extremely useful for the practitioner in rural sections. I think the treatment in rural sections must be a decided, prompt, efficient and surgical procedure. In our hospitals or in large centers where we have nurses, capable nurses, almost equal perhaps to a physician in managing obstetric cases, sometimes perhaps we can temporize, certainly in placenta prævia emergencies; but we can not do so in rural sections where the woman's life is in danger at any hour of the night or day. After the discovery of the condition, the woman should be delivered as promptly as possible, certainly so where good attention can not be had in constant attendance.

DR. GARRISON, Illinois—I for a long time have wondered why we in the rural sections did not have as much septicemia as we did in the hospitals. Dr. Price, of Philadelphia, explained the matter; he said our soap was better; we used home-made soap. Supposing I should be called ten miles to attend a case of placenta prævia, I would not probably have any permanganate of potash in my case. Should I go back to my office and get it and scrape my hands twenty minutes when the woman is dying? No; I keep my soap for the rural districts in the kitchen perhaps, and scrub my hands thoroughly and my woman goes through without any septicemia.

DR. WESLEY, California—In a practice of a little over fifteen years in general practice, I have met with some fifteen or twenty cases of placenta prævia. I have adopted different methods in treating those cases, sometimes perforating the placenta, getting hold of a leg and bringing it down for the purpose of tamponing and arresting hemorrhage. Practicing in a rural district where we are frequently called fifty miles, we find the patient often exsanguinated when we get

there. There is no chance then to save the life of the child; the child is already dead. We must not take the life of the child into consideration at all; and I believe in that class of cases that Dr. Simpson's is the proper treatment: To at once detach the placenta entirely, bring the placenta down, then stimulate the uterus and get the head down, do not turn at all, put on your forceps and deliver the woman. In cases where there is no such great loss of blood and there is a probability that the child is alive, then I should adopt a method of perforating the placenta, turning, bringing down one leg and delivering the child gradually; but I believe where you find the patient has lost much blood and where the child is dead that the proper method is Sir James Simpson's method, to remove the placenta at once.

DR. ESCHELMAN—I would like to say as regards the question of turning and delivery and the use of the forceps, in turning and delivery you have to have a dilated womb of about the size of a practitioner's hand, about two inches and three-quarters, at the risk of septicemia; but in introducing the forceps you have always less danger from hemorrhage—I have never met anything else. You only want about an inch of dilatation; you introduce the forceps by perforating the placenta if it is central implantation, or one side if it is most convenient, you grasp the head—and as a general rule with the manipulation outside of the abdominal walls you feel how your forceps applies to the head—you can bring down the head and tampon the placenta at once. You have no more hemorrhage. If you grasp the head and bring it down upon the placenta your hemorrhage ceases. Then if your forceps are not properly adjusted, you can adjust them between pains and work with the pains, and deliver your child usually in fifteen to thirty minutes' time, with the result of saving mother and child both. That is my experience and the experience of Mr. Davis who works with me. Now I can not see any object in introducing the hand and turning the child crosswise in the uterus, for the length of the child to distend the lateral diameter of the uterus. You have the size of the hand and the danger of manipulating with the hand, when with a narrow-bladed forceps about one inch—seven- or eight-tenths of an inch, one of my forceps is, and another one an inch—you can introduce the tips of your two fingers, and if you are skilled at all with the forceps you can apply it to the head and know by holding the handles, as a man knows when he holds the fishing-rod when to pull, and you can manipulate without any hemorrhage; that is my experience.

DR. CARPENTER, of Pennsylvania—I have listened to the discussion of this subject with great pleasure, and I would not rise at this time excepting that it occurred to me lately to have three cases of placenta prævia, two of which I treated in the manner which originated in our State, if I am not mistaken, by applying the forceps after first having by proper manipulation gotten the head in position where it could be grasped, and by chance or by skill getting the head brought down so as to compress the placenta previously pushed to one side by the hand against the uterus so as to stop all hemorrhage. In one of those cases I held the head for half an hour, the os not having been thoroughly dilated, until the constant, steady pulling force accomplished the dilatation and then delivered the child. In that case the woman was exsanguinated and the gentleman who called me in, and his assistant, was engaged the entire period of over an hour in giving her constant hypodermic injections of whisky and strychnia.

The second case I treated in the same way but had no assistance. I was several miles away from any assistance, and I delivered the woman of a dead child the same way.

The third case I was called in consultation; it was central implantation, and as I tore through the placenta I

found and brought down the foot and delivered her, but she died ten minutes after the shock. I am satisfied that if in that case I had avoided the temptation of seizing the foot, if I had pushed it aside by external manipulation and got it so that I could have held the head against the placenta for a long enough period to enable stimulation, I could have saved the life. The point being that in such cases you have no time to waste, if the woman requires to be kept alive by hypodermic stimulation; in other words you have no time to do it. With hypodermic stimulation you can wait as long as you please and you can hold the head down against that hemorrhage. I regret to this moment that the temptation to the rapid extraction caused the loss of a life.

SOME OF THE USES OF STRYCHNIA IN OBSTETRIC PRACTICE.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOHN MILTON DUFF, M.D.
PITTSBURG, PA.

In February, 1893, I read a paper before the Pittsburg S. S. Medical Society on, "Strychnia in Obstetric Practice," a synopsis of which appeared in the *Therapeutic Gazette* of May 15, 1893. Incidentally, in a paper "On the Care of Pregnant Women," read by me at the last meeting of the American Association of Obstetricians and Gynecologists, published in the annual transactions of that Association for 1893, I referred to some of the indications for the administration of strychnia in obstetric practice. R. Bell, in the *British Medical Journal*, page 715, 1890, refers to strychnia as an aid in parturition, as does Dr. J. C. Edgar in the *New York Journal* of May 12, 1894. Almost simultaneously with my own paper of May 15, 1893, there appeared in the *Medical and Surgical Reporter* of May 13, 1893, an article on "Strychnia vs. Ergot in Obstetric Practice," by G. V. Hall, M.D., L.L.D., of Wheaton, Texas. Various other articles have been published, directly or indirectly pertaining to my subject. I do not present it to-day with the idea that I may say anything new, but rather that I may say that my observation and that of a few friends, who have kindly worked along the same lines, emphasizes the fact that strychnia is a most valuable agent in obstetric practice; and I shall be most happy if I can only awaken a general interest on the subject such as will assure a more general use of it during the next year, so that we may the more correctly define its uses and merits.

The very limited field given for observation in the practice of a few men will not warrant us in drawing conclusions of a radical character. However, I have no hesitancy in asserting, that with the judicious use of strychnia, the indications for instrumental delivery will be far less frequent, and ergot will only occasionally be called for during or after the third stage of labor. It reduces the number of abortions, and especially premature deliveries, by giving tone to the uterine muscles and nerves, as well as by its general tonic influence. It improves the appetite and digestion, keeps the bowels soluble, prevents insomnia, regulates the circulation, and in the weak insures a more rapid and less painful labor. After its use after-pains are not so frequent and the danger of post-partum hemorrhage is greatly reduced. That it is constant in its action and that benign results follow

its administration in every case I can not claim, as I have occasionally given it when it completely failed to produce desired results, and I am not unmindful of the fact that I have seen apparent evil results from its administration in a few cases.

Case 1.—Mrs. S., mother of six children, has always had tedious labors, instrumental deliveries; on two occasions severe post-partum hemorrhage. Now pregnant eight months. She is given strychn. sulph. one-thirtieth of a grain three times a day. First stage of labor two hours; second stage one-half hour; third stage ten minutes.

Case 2.—Mrs. N., gave birth to a child at term fourteen years ago; since then has had three premature births at seven and a half months, and five miscarriages at about four and a half months. She is now four months pregnant. One-thirtieth of a grain of strychnia given per diem for ten days, reduced to one-sixtieth of a grain twice a day, which was kept up every other week. She carried to term and was delivered of a nine and a half pound boy.

Case 3.—Mrs. K., belongs to a family of bleeders. There is history of post-partum hemorrhage in mother and grandmother and in two out of four sisters. Has had two children; lost a large quantity of blood after first labor, but could not say it was a hemorrhage. After second labor had severe hemorrhage. In third pregnancy was given one-thirtieth of a grain strychn. sulph. for three weeks prior to labor; no hemorrhage.

Case 4.—Mrs. S. A., mother of seven children; after last six labors has had slight hemorrhage, and after-pains very severe. Her last three deliveries have been instrumental. She is given one-thirtieth of a grain strychn. three times a day for seventeen days prior to labor. Her labor was natural, of two and a half hours duration; no hemorrhage and only very slight after-pains.

I might thus report over fifty cases, in which I felt I might in justice refer the results to the effects of strychnia, but they would simply be repetitions and unnecessarily take up the time of this Association.

Aside from the conditions I have just referred to, the woman who has been subjected to the strychnia treatment will, all other conditions being equal, suffer less shock from the throes of labor, and if an anesthetic be necessary will submit to it more kindly and with less danger than the woman who has not had the preparatory treatment. With this conviction in mind it is now my habit, on all occasions where I am called upon to apply instruments or administer an anesthetic, to first give a hypodermic injection of from one-twentieth to one-thirtieth of a grain of strychnia; more especially would I insist upon this if the woman had not had previous strychnia treatment.

As I have already in an article upon that subject condemned the routine practice of administering ergot after the third stage of labor as unscientific, unnecessary and not devoid of danger (See *Therapeutic Gazette*, May 15, 1893), I would say that the treatment I here recommend is not suggested as routine, but as indicated in each given case, for every case in the hands of the scientific obstetrician is treated of itself, by itself, and for itself. My observations, however, warrant me in making the broad assertion that with the judicious administration of strychnia, prior to labor, the cases in which ergot will be indicated after the third stage of labor will be very rare. The action of strychnia is effective and more prompt.

For the purpose of further study on this subject, I will regard it as a personal favor if those who have adopted or may adopt this treatment, will communicate with me on the results of their observations, to the end that I may tabulate them.

DISCUSSION.

DR. LAPHORN SMITH—I should not have risen to speak upon this subject had any one else taken the floor. I think the paper and subject is of too great importance to pass

without some discussion to fix it a little more in our minds.

I have not myself had a very large experience, or any experience in fact, with strychnin used in the manner which Dr. Duff has brought to your notice; but for ten years past I have been in the habit of giving to confinement cases that I had under my care, previously to being called to them, a mixture of strychnin, phosphoric acid and iron. I have been peculiarly fortunate in cases of post-partum hemorrhage in my practice, and perhaps that may be explained by the fact that I have given these women strychnin of about one-fortieth of a grain three times a day.

The advantages of strychnin over ergot are very evident. I must confess that I have always been a great believer in ergot; I dislike to go to a confinement case without the very best ergot that can be got, in my bag. I give 1 drachm of fluid extract by the mouth a little after the delivery of the placenta, and I don't feel safe in taking my hand off the uterus until that ergot has had time to take effect. But that is precisely the objection to ergot; that it takes fifteen or twenty minutes to be absorbed. I have never used hypodermic injections because I have heard of so many cases of abscesses from it; but I have used very largely the fluid extract of ergot given by the mouth.

I have heard of a great many cases of death in different parts of the country from post-partum hemorrhages. Now if a dose of strychnin used hypodermically will control that hemorrhage and cause contraction of the uterus, we can be sure of obtaining results in a short time—a few seconds I think would be enough to take effect—it is a great advantage over ergot.

Another objection to the use of ergot is, that it is difficult to get a first class preparation. I don't know whether this is the experience with other physicians, but it is with myself. If you ask a certain number of physicians whether they are sure of ergot acting, they will tell you they are not. I have always taken great care to use a preparation that I had tried and tested and found reliable.

Strychnin is a standard drug; it is always the same, and is much more reliable than the various preparations of ergot. I think it is well worth our while to try strychnin, and report the results at the next meeting of this Section. I shall certainly do so, and report to Dr. Duff what I think of that method of controlling post-partum hemorrhage. Strychnin is a great tonic, and I think its use before confinement will be of great benefit.

DR. CARPENTER—I think that the matter of dose has a great deal to do with the administration of ergot. As Dr. Smith has just told us, a teaspoonful of fluid extract of ergot is given. It seems to me that is a very unnecessary dose in ordinary cases. The effect is a greater persistent spasm of the muscles of the uterus—a very painful thing and increases the after pains. Simply used as a preventive, a teaspoonful of fluid extract of ergot is an unwarranted large dose. It is a great deal better if you feel bound to take precautionary measures, in the absence of any immediate indications of danger, to give 15 drops of a good preparation, and then wait to see if any further doses are needed. Otherwise you will have a patient in twenty-four hours suffering from after-pains, and you have to undo that which you have been doing, and give this patient some comfort.

As to Dr. Duff's method, it commends itself very much to a man in general practice, and who has all sorts of work to perform. There are one or two points that may be noted

Anesthetics—which are so valuable and so constantly used by many of us in cases of labor—are antagonized by strychnia so far as their dangerous effects are concerned. I remember that twenty-nine years ago Prof. Gobrecht, formerly of a medical college in Philadelphia, and afterwards surgeon in the army, had a case of chloroform poisoning. The chloro-

form was taken with suicidal intent in a hotel where Dr. Gobrecht was fortunately staying. He resuscitated and eventually saved that case by the hypodermic injection of strychnia and artificial respiration. That case made a great impression on my mind, and in respiratory diseases, since then, where the respiratory power is feeble—paresis, perhaps—I have been in the habit of giving strychnia constantly. I believe it is valuable in other diseases than those that pertain to parturient women. I have found it so useful that for a month before the pains come on I have put strychnia into their medication, whatever it might be.

Chloroform is the best of all anesthetics in labor, and the use of strychnia with it is better than anything else; it enables you to give chloroform with a certain freedom and comfort that you can have in no other way. Not only does strychnia influence the muscles of the uterus, but it has a decided effect upon the whole nervous system. The patient gets up better, and I think it is the best means to bring a woman safely through her parturient state. I have used it for many years.

DR. F. H. MARTIN—I hope I may be pardoned if I talk on a few more papers. I am very much interested in this subject, because I have had experience with it, but not exactly on the line indicated by the Doctor. The physiologic effects of strychnia are well known. It is a powerful constrictor of muscular fiber; it is a tonic constrictor. It has also in the same way a powerful effect upon the vasomotor nervous system—whether through the nerves or through the muscles of the uterus, this has not been determined—but it has a powerful influence in constricting blood vessels. It also is a powerful tonic. If strychnia is to be used for the purpose as indicated by the Doctor, it should be used, it seems to me, in good stiff doses; used as the abdominal surgeons use it in their efforts to get a tonic contraction of the muscular coats of the bowels.

Now pain in the bowels in the parturient state is caused by cramp, and the cramp is a clonic spasm; anything that will produce a tonic contraction of the bowels will accomplish the desired effect without pain; anything that produces a clonic spasmodic contraction will produce pain. I suppose nine-tenths of the abdominal surgeons in this country use strychnia more than they use morphin; simply because it overcomes the clonic contractions of the bowels and relieves wind pain.

I use strychnia in this way: I begin six hours before an abdominal section to give one-twentieth of a grain of strychnia hypodermically every hour until five hours after the abdominal section—until I get a half grain in the abdomen, until frequently my patients, while they will not complain of gas pain, will reach a point where they begin to get a little stiffening in the back of the neck—a tonic contraction. By administering strychnia that way once an hour, you can use it safely. It is impossible to use too much of it, for the nurse watches the effects. In giving one-twentieth of a grain doses you can reach as high as half a grain without deleterious results.

Used as a tonic for a month before confinement I believe it would bring good results, and used, as may seem to some of you, in heroic doses.

DR. JOSEPH EASTMAN—I can not let this paper pass without making a few remarks. I see at once that the surgeon can learn something by association with obstetricians; surely the obstetricians can learn something by association with surgeons. It is very clear to my mind to-day—never before—that the more we study obstetrics on surgical lines, the better success we will have. For example, laying aside all conclusions as to parturial fever that have been advanced by the eminent teachers of the day, studying all forms of fever, of elevations of temperature, studying its prevention,

studying its treatment, and following out on surgical and other lines, we will have as good success as we will have in any other way, and a thorough preparation of the vagina for the child. If the forceps should be used, if a laceration should occur, or a wound of the cervix, then the patient has the same preparation as I give to a patient for surgical effort.

The use of strychnia, as has been mentioned by the author of this paper, is exactly in the surgical line. None of us would think of performing a surgical abdominal section without giving the patient a powerful tonic before, and frequently during the operation, and directly after.

I use *nux vomica* a great deal in place of strychnia. Two years ago its use was impressed very forcibly upon my mind. I stopped at a harness shop to have a bridle repaired, and after waiting awhile I discovered my horse was gone. I found him right away in a livery stable near by, and the stable keeper was pouring a bottle of medicine down his throat. He said the horse was nearly dead with wind colic and he was giving him *nux vomica*. He said he always kept it and it cured wind colic at once. That is practically what the livery stable men and the horse doctors knew all along, and I found there was something that could be learned from them.

The effect of ergot is not as well understood as it ought to be, and perhaps I shall advance nothing new. The normal contraction and relaxation of the uterus is rhythmical—there is a period of contraction and a period of relaxation. If we wish to get water out of a sponge we squeeze it, and then relax the fingers and squeeze again until the water is all out. The uterus empties itself of blood by a rhythmic contraction and relaxation, an alternate contraction and relaxation. The accumulation of this blood in the uterine cavity is frequently the exciting cause of after pains. After pains are but nature's effort to expel clot. Strychnia given as we give it in surgical cases secures a clonic contraction, while the effect of ergot is a persistent tonic contraction without the normal relaxation which the uterus should have.

Hence I would insist that ergot is frequently the cause of an interruption, in that normal clonic contraction, and prevents the uterus contracting down to the size it should be.

So, studying these questions from a surgical point of view, it seems we would study them about as thoroughly as in any other way.

I thank the Doctor for reading this practical paper here. I know his study of the subject is very thorough, and will be of decided advantage to many of us in substituting (if I may so express it) strychnia for ergot, for it goes to the fountains of life and gives a better contraction; it will carry a patient through this ordeal just as it carries a patient through the shock.

The use of strychnia is larger doses than heretofore taught is becoming evident. Dr. Hare, of Philadelphia, says in reference to large doses of strychnia: "We will find in hemorrhage that it goes to the fountains of life and gives a better tone to the vasomotor nerves, and in that way it is a better thing than ergot."

DR. WESLEY—We all believe in strychnia in surgical shock. We are taught by therapeutics that strychnia acts directly upon the spinal nerves. Now I can hardly understand how it will hasten labor by taking one-thirtieth of a grain for ten to seventeen days prior to labor. And I can hardly understand how it would prevent miscarriages and abortions. This seems paradoxical.

DR. J. MILTON DUFF—In presenting this paper I intentionally limited myself to practical illustration in a very few cases. As I distinctly stated it is for the object of securing further study. I did not make any strong statements, as

you will bear me out; this I think we ought to avoid until we have perfect knowledge, for otherwise we may do harm. I always want, and so I believe does every member of this Section, when we bring out anything that is new as a remedy, we want to be able to stand by it, and have everybody see that what we say and recommend is all right. I can not with my knowledge of the use of strychnia in obstetric practice yet say that it is what I have hopes it will be. In the limited experience of any one man there are not enough cases arise, or even in a hospital, to justify one in coming to correct and positive conclusions.

I did not want to take up the subject of ergot particularly to-day, as I had a discussion upon the subject two years ago and a year ago I was answered by Dr. Barker, of Philadelphia, in a paper in which he spoke in favor of the routine practice of administering ergot.

Now I only claim for strychnia, in answer to the last gentleman who spoke, that it produces a normal condition of the muscular tissue; produces a normal condition where a muscle is apparently paralyzed, as muscles of the abdomen will be if not used. By the term, "paralysis," I mean that they are weak, infirm, and have not contracting power. Strychnia gives them this tone. Therefore it applies in some of the cases of miscarriage we have where the uterus in expanding is irritable; the muscles are not in a normal condition and as it expands they become irritable, a clonic contraction comes on, and as a result we have miscarriages, whereas, if those same uterine muscles were kept normal by the use of strychnia the woman will go on to term.

Then again, strychnia in acting in this same way is the best remedy we have for keeping the bowels solid, just as has been indicated by its use upon the muscles of the bowels, when given after abdominal section.

But the grand point, coming back to the subject of ergot, if subsequent investigation proves that my theories are correct, it is going to be a less dangerous remedy than ergot, and gives us the good results of ergot without the dangers.

Dr. Carpenter made some excellent suggestions, but one of the suggestions he made I feel is contrary to what experience and observation would lead me to say. He said if he was giving ergot he would give 15 drops instead of a teaspoonful. I have great confidence in ergot, and I do not want to be understood as saying that it should not be given sometimes. But I do not believe in the routine administration of ergot after the third stage of labor; I think it is dangerous and unscientific, and frequently is harmful. If I were going to give ergot at all it would be a teaspoonful or a tablespoonful dose, not a 15 drop dose. Why? The action of ergot is upon the circular muscles of the cervix, and if you give a small dose not sufficient to have action upon the muscles of the uterus you close the uterus and close up the uterus *débris* inside. If you repeat it you will bring on the contraction of the whole body, and bring that clonic contraction, and thus hold in the *débris*. I do not claim at all that this would always be harmful but it might be harmful. If that theory is not correct, then all your theories with regard to giving ergot as a prevention against miscarriage must fall to the ground.

You say you give 5 or 10 drops of ergot where an abortion is threatened, under certain conditions. Why give it? Because of its action upon the cervix and muscles of the uterus; and this theory is pretty generally believed. If it is true, then my theory is correct; on the other hand, if it is not, then my theory falls to the ground.

I am thankful for the discussion this paper has received. I find a good many physicians are using strychnia. I want to say that it is very seldom that I use strychnia just by itself: I give phosphate and iron, and I combine, as the indications of the case may be. I feel that we have a wide field here for study, and I hope that at the end of another year we may have something definite.

TETANUS PUERPERARUM.

Read in the Section on Obstetrics and Diseases of Women at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY ALLISON MAXWELL, A.M., M.D.

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE, CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS, INDIANAPOLIS, IND.

Mrs. Jas. H. D., aged 29, mother of five children, was confined at term Oct. 13, 1893. She had always been a strong healthy woman. She was attended during labor by her husband, who was a laboring man, and by a woman next door. Her husband told me he had been instructed in such matters by his physician where he lived in Illinois when the other children were born.

A healthy child was born, and she went through her confinement, her husband stated, easier and felt better afterward than she had in previous confinements. I asked him in regard to the expulsion of the placenta, and he said he had examined it carefully and it seemed to be all there. On the ninth day after confinement there was some aching and drawing about the fauces. On the tenth and eleventh days she seemed to feel better again. On the twelfth day, however, there was some dysphagia and slight opisthotonos, for which Dr. Nash, a physician near by, gave at her request, medicine for a sore throat. On the thirteenth day I saw her for the first time. She was sitting propped up in bed because dyspnea was troublesome on attempting to lie down. Dysphagia and opisthotonos were prominent and she presented the anxious countenance, and the objective and subjective symptoms of well marked tetanus. Temperature 100, pulse 140. On the fourteenth day the symptoms were intensified, while the head seemed to draw backward, there was so marked emprosthotonos that she was bent over in a sitting posture in the bed. Her pulse in the morning was 146, temperature 100.5. On the thirteenth day when I first saw her in the evening I gave her a hypodermic of morphia one-third of a grain, atropia one one-hundred-and-fiftieth of a grain, which caused her to rest fairly well until 5 o'clock the next morning, when the dose was repeated. In addition, on the fourteenth day, she was given chloral hydrate, twenty grains in milk, per rectum, every two hours. This treatment for twenty-four hours gave some temporary relief so that she could open her mouth much better. The dysphagia was not so pronounced, and she could lie down a part of the night.

On the fifteenth day the symptoms became more aggravated, pulse ran up to 160, temperature 101, and in spite of morphia hypodermically and chloral per rectum, she died from exhaustion at 11 P.M. The patient was unable to swallow from the time I first saw her, and absorbed from rectal injection only a moderate amount of nourishment.

Autopsy.—An examination of the body was made, assisted by Drs. W. S. Beck and G. W. Nash, fourteen hours after death. Post-mortem rigidity well marked; body fairly nourished: no bruises or signs of any internal injury upon the body. On opening the abdominal cavity we found the small intestines much congested in several places. The uterus was removed from the pelvic cavity. Involution had gone on normally and the uterus was entirely within the pelvis and contracted to about the size of a normal spleen. There was no laceration of the os uteri, vagina or perineum. On longitudinal section of the uterus we found the endometrium natural and smooth in every part, except near the fundus and slightly to the right side there was clinging to the mucous membrane a small portion of the placenta, elevated less than a line above the surface, and about the size of a silver quarter. There was more redness at the point than elsewhere, and this was probably a focus of irritation and infection.

Having no knowledge of puerperal tetanus, on returning to my office I began to investigate the subject, and to my surprise could not find it mentioned in Bedford, Byford, Leischman and other obstetrical works, but found a page devoted to it in Parvin's "Obstetrics." As the literature on the subject is so limited, by reporting such rare cases we may arrive at a better knowledge of the etiology, pathology and finally treatment of this very fatal disease.

Dr. H. J. Garrigues, in the *American Journal of Obstetrics*, a few years ago, gave a collection of all the cases that had been reported from the earliest period. The total number of cases he could find was

fifty-seven, twenty-five following abortion and thirty-two at full term. The first case was reported by Currie, *Memoirs Medical Society, London, 1792*. The disease made its appearance in this series of cases as early as the second day, and as late as the thirtieth.

Dr. David W. Yandell, in an article on the subject of traumatic tetanus, *American Practitioner, 1879*, showed that the earlier the disease began after an injury, the more fatal, and where it began after the tenth day, the better the prognosis. The reverse seems to prevail in puerperal tetanus. In looking over the fifty-seven cases recorded by Garrigues, seven recovered, all of which became afflicted by the eighth day, unless one, time not stated.

Etiology.—In regard to the causes of the disease, they are predisposing and exciting. While very few cases of puerperal tetanus have been recorded, all writers upon the subject agree that a hot climate is a predisposing cause, and that many cases occur in India. In Garrigues' classical article written eleven years ago it is shown that primiparæ at full term are more apt to have tetanus than multiparæ, and we can explain this from the fact that we are more apt to have lacerations of the os uteri, vagina or perineum in the former, which may be foci of infection. Other predisposing causes are cold and dampness about the house, mental worry or excitement, dirty and unhygienic surroundings and lack of proper cleanliness of the accoucheur and instruments.

Our patient may have been worried about the household duties, for three days after confinement she got out of bed and went to the kitchen and washed the supper dishes. Like cases have been cited where it has been thought that the patient by some indiscretion, as getting out of bed on the second and on the fourth day and going to the pump for a drink, was a predisposing cause.

Say what we will about predisposing causes, it is now recognized that the bacillus tetanus is the final factor in the causation of the disease. Nicolaier first established this point in 1885, and by the inoculation of rabbits and guinea-pigs, not only from cases of tetanus, but from soil and dust and filth over a wide area, proved that the bacillus tetanus was not confined to an injured member, or even to man. Later, however, it was demonstrated that the bacillus was not found in virgin soil.

Treatment.—The above fact in regard to the etiology having been firmly established, we can understand the prophylactic importance of aseptic midwifery. This poor woman's husband, being a laboring man, the probability is that in removing the placenta, or in other ways, he may have conveyed the bacillus tetanus to the vagina, and thence to the endometrium, where was a focus of irritation and absorption.

If, in spite of aseptic midwifery, tetanus develops, what shall be our course of treatment? Remove or counteract the cause if you can. If you have any doubt about the placenta being entirely removed,—by a curette or by Emmet's forceps you may ascertain, and then afterward wash out the uterus as often as may seem necessary, by an antiseptic solution. Any abrasions from which the disease may have originated should be promptly cauterized with carbolic acid. Those remedies that are valuable in general tetanus are useful in puerperal tetanus. It is not the province of this paper to speak of all the

remedies for tetanus. One prominent writer gives thirty-three remedies, ending with antitoxin.

The writer has had two cases of idiopathic tetanus recover by the use of morphia hypodermically and chloral hydrate. Also a boy 10 years old recovered from a severe attack of tetanus resulting from a crushed thumb, by the use of the same remedies, the morphia given at long intervals, once or twice daily when the chloral failed to control the convulsions.

The most recent remedy is the antitoxin of Tizzoni and Cattani. This remedy is a solid material obtained by treating blood serum with alcohol and drying in a vacuum. Finnoti reports a case in which antitoxin was prepared from the blood serum of a dog which had been rendered immune, probably by hypodermic injections of attenuated cultures. This antitoxin was used on a boy in whom tetanus resulted ten days after a surgical operation. He was given from 15 to 20 centigrams daily, dissolved in three cubic centimeters of sterilized water. The boy improved daily from the treatment and made a good recovery. The *International Medical Annual*, 1892, gives an account of the first case cured by this remedy.

Tarruffi reports six cases treated by antitoxin with one recovery, the man being 75 years old; 25 centigrams of the immune serum being injected daily.

Pacini reports a traumatic case in a man 21 years old, who was promptly relieved by the hypodermic injection of 25 centigrams of antitoxin at 10 A.M. and 4 P.M.

Up to 1894 as many as eleven cases of traumatic tetanus have been reported as cured within two years by antitoxin. In general, the remedies used most successfully in non-puerperal tetanus would act similarly upon the bacillus of tetanus puerperarum. Besides prophylactic measures and a supporting and stimulating diet, and the reliable antispasmodics, it would be well at once to use the antitoxin as soon as the first symptom appears. This is the rational and scientific treatment, and one which it is hoped will become more and more efficient in this very fatal malady.

DISCUSSION.

THE CHAIRMAN—Dr. Montgomery has a very ingenious instrument here which he may show you.

DR. MONTGOMERY—While passing through Kansas City the other day I met a Dr. Baum of that city, and I was shown an instrument by him and was given a paper, a short description of it, which I will now read. (Reads paper.)

DR. MARTIN—I hope the Section will not get sick of seeing me get up, but I wish to say just a word in regard to what I should call a sort of infernal machine. In the first place I am very sorry that the author of the instrument is not present; at the same time I am glad to have the opportunity of expressing my disapproval of a Professor of Gynecology of Jefferson College, Pennsylvania, bringing such a machine before an audience of intelligent physicians—I think that he is almost a party to the crime. Now the objection to the instrument, besides a number of minor ones, are these: First the operation is entirely in the dark. While we are afraid of this certain mortality in abdominal operations, I would prefer to have a certain mortality to a very uncertain one that we would have with this. In other words, if the uterus is to be fixed to the abdominal walls, I would prefer to open the abdomen and fix it; I would prefer to open the abdomen, scarify the uterus, scarify the peritoneum and sew the uterus to the abdominal wall in a secure manner with a certainty of its becoming fixed. That

we are not positive of with this instrument. I do not believe that this instrument would fix the uterus to the abdominal wall, in nine cases out of ten, longer than the stitches would remain. The author of the little paper or sketch read by Dr. Montgomery states that the stitches by pulling and drawing and tearing might produce enough denudation to produce a cause of adhesion. That is just the essence of poor surgery—he depends upon an accident; something that ought not to occur to make it a success. Then I would like to know how on earth Dr. Baum or any one recommending this instrument would avoid always the bladder. Dr. Montgomery and every man who has done abdominal operations has found, time after time, great sacculated bladders which it was impossible by means of a catheter to evacuate before doing the abdominal section—large sacculated bladders, which can not be entered, and in which a sound will not reach the bottom. I would like to know how a bladder of that description—and they occur very frequently—could be avoided by this instrument; and if it is not avoided, what is the result? Death, every time. Now, the physician will throw the intestines out of the way, nine times out of ten if they are not adhered, but how many times did Dr. Montgomery and everybody else who performed the abdominal section, not only find the intestines adhered to the fundus of the uterus but adhered to the inner basin of the pelvis? And I would like to know how, with an empty intestine after the patient has been prepared for laparotomy as Dr. Baum suggests, and the intestines are entirely emptied, how by what manipulation even the most expert will be able to state that the intestine is not adhering to the fundus of the uterus? Then what would happen if we ran these things through? The patient will die every time. I believe sir, that this instrument is an infernal machine, and I hope that it will find its oblivion right here before this Section. As we are here to propagate things that are good, I believe that we are here to bury the dead.

THE CHAIRMAN—I want to say that Dr. Montgomery is not responsible for bringing that here. I am responsible myself for allowing it to come here. He even approached me with fear and trembling at the thought of suggesting it, and was filled with hopes and despondency and much hesitation, struggling prayerfully toward his duty in the matter. I said: "Why, of course, present it," and the thought that came to my mind was prompted by a remark that a distinguished professor made some years ago. He brought an immense instrument before the students, took it out of a box, paraded it before them in all manner of shapes and styles, and he said: "Gentlemen, I brought this instrument here to-day for the purpose of saying to you that it cost me \$80 and isn't worth a damn." I am not quite sure, however, but what in a given case, with the patient in a proper position and a thorough exploration of the bladder, this might afford some relief. I am not disposed to say that the instrument has no merit. (A doctor asked: "Would you like to try it?") That is like the colored man who when he was asked: "Who made God," said: "If you keep on asking questions you will bust my religion."

DR. MONTGOMERY—Mr. Chairman, I feel that the Section and particularly Dr. Martin is under obligation to me for the privilege of affording him the opportunity of standing up as the sponsor of good method, and it is not but what some of us think of the injury he did to the profession in his earnest advocacy a few years ago of electricity. In the remarks I made after exhibiting this instrument, I said: "Its position must be a limited one; that if I was going to offer such an instrument I should prefer to use this one that has been introduced and has been advocated by a number of surgeons of this country for displacements of the uterus, and known as the shifting machine, and which in a

great majority of cases necessarily resulted in an injury to the child. I say that this instrument is not one which should be used in those cases in which there were pelvic adhesions or possible adhesions of the abdominal wall to the uterus, and there would be a certain amount of danger of injury to the child. That is certainly true, what Dr. Martin said, but such an instrument would be serviceable in a very limited number of cases. I can see, however, that with proper procedure with proper care, in the matter, that this instrument might in a limited number of cases serve a useful purpose.

DR. CHESNEY—Mr. Chairman, it has occurred to me that I might with some profit relate an experience that has some bearing on the paper read in regard to tetanus, although the experience was not carried out on the strictly scientific lines laid down in the paper. Dr. Maxwell relates in his paper that a post-mortem examination revealed a small portion of adherent placenta with points of irritation which he supposes may have been foci or a focus of infection. Without entering into any discussion as to the special bacillus of tetanus, it may fairly be presumed in all cases of puerperarum tetanus that the offending cause was some kind of dirt. And if the practitioner neglected the wise precaution of Dr. Garrison, of Illinois, to go into the kitchen and get the kitchen soap and scrub thoroughly, or was unfortunate in not having the opportunities of Dr. Martin, of Chicago, to use the permanganate of potash or oxalic acid, we would not be surprised if we had some such after development. But, practically what should be done in the case detailed? The Doctor did not employ the antitoxicon; he employed morphia hypodermically and chlorate hydrate by a rectal enema without success. Now in my opinion, he might have presupposed, as I say, some point of infection in the puerperarum surroundings, and have directed a local treatment to cleansing and removing such foci, or such points, or such infected material as may still have remained there. This brings me to the case in point: Several years ago I had a case in which the initial symptoms of tetanus made themselves manifest—rigidity of the muscles of the throat and some slight symptoms of opisthotonos, and without knowing it, and on those general principles that we are obliged to have recourse to, I used a solution of 1 to 3000 parts of bichlorid of mercury and washed the cavity out thoroughly; then afterward washed it out thoroughly with water that had recently been boiled, and had this procedure repeated once in eight hours for several days; the symptoms within six hours began to show some amelioration. I used a hypodermic injection of atropia alone with benefit, and with rectal injections of peptonized milk—I do not know that that had any advantage but it was used. I am inclined to believe, however, that the recovery of the case depended on the thorough washing, first with the bichlorid solution, and afterward abundantly doused with boiling water.

I suggest, as a practical suggestion in all such cases, where there is the least doubt, that the uterine cavity should be thoroughly cleansed by injections if possible, by curetting if necessary. It goes without saying, also, that I make this suggestion only in cases where no instrumental assistance has been necessary in the delivery. I take it for granted that under ordinary circumstances where the practitioner has not had, or has not employed, either facility in his delivery (where he has not had opportunity to place his patient upon the table as suggested by our Secretary, but had been obliged to use the bed as he almost always will be obliged to do) that in all cases where the instruments have been employed or where the hand has been employed in the uterine cavity that the douche could always be used. But the suggestion is that in those cases where no such procedures have been necessary and where no untoward symptoms

develop afterwards that then the first procedure should be a thorough cleansing.

In regard to the little instrument that has been designated, I am confident that all of us who know Dr. Montgomery are abundantly assured that he presented this instrument under a sense of duty to a member of the profession who could not be present. We are abundantly confident that no necessity could arise that would induce a gentleman of his judgment to use such an instrument himself. There might be some circumstance or set of circumstances where its consideration would be justifiable; but it is undoubtedly true that it would be infinitely wiser, infinitely easier and infinitely safer for the patient, to open the abdomen with the certainty of cleanliness, with no danger of carrying matter from an open uterine cavity into a concealed peritoneal cavity.

In reply to a question addressed to Dr. Montgomery as to whether this case was a recent one, or whether it occurred in 1881 when there was such a prevalence of tetanus throughout the United States, it was ascertained by reference to the paper in question that the case occurred Oct. 13, 1893.

DR. EASTMAN (Chairman of the Section)—While I would not renew the discussion of yesterday in regard to abdominal surgery, I would simply refer to one point in connection with that subject. I have been induced to do this by some comments which I see in public print made yesterday, in the Surgical Section striking at one of the most important means of securing successful results in suprapubic hysterectomy. I mean the private hospital.

The gentleman seems to impugn the motives of those who conduct private hospitals; he seems to entertain the idea that a man who conducts a private hospital might possibly get onto the hotel plan of keeping his guests a long time; that the longer he would keep them the more money he would secure. While I am not very well versed in the Holy Bible I do recollect that it says somewhere: "All things are pure to him that is pure." I would particularly refer to what I said at the beginning, yesterday, that the time had come when as I believe we should rescue abdominal surgery from the general surgeon and bring it to the gynecologists and to the Gynecologic Section. I am now convinced from the remarks of the Chairman of the Surgical Section, yesterday, that it is no longer *safe with them*; that they would strike at the very life so to speak of abdominal surgery. I would have such gentlemen to know that abdominal surgery was born in a private hospital, has been nursed in private hospitals and has grown up to fully developed manhood in private hospitals. I would have the gentleman to know that Ephraim McDowell who made the first operation on Mrs. Crawford on Dec. 13, 1809, did so in a private hospital. It was therefore in a private hospital that he, McDowell, struck out on the trackless desert of abdominal surgery which now blooms and blossoms as a most fertile field. I would have the gentleman to know that it was in a private hospital that Thomas Keith electrified the world with the publication of his great work in abdominal surgery. I would have the gentleman to know that it was at a private hospital, the Samaritan Hospital of London, where Sir Spencer Wells did his most important work in abdominal surgery (practically a private hospital). I would have him know that it was in a private hospital that Lawson Tait first woke up the world with his marvelous announcement reporting 140 cases of abdominal section without a single death. And therefore I can not allow the Chairman of the Section to make such an expression without this Section replying to it in some measure, and I hope the reply will go on record, to the end that he may inform himself by reading. He may say that I am particularly interested in a private hospital. If so, I would simply say

my private hospital began by taking a patient to my home as McDowell did, to watch over and care for her, and to have such results as only a private hospital could secure. I can not conceive of any such remark coming from anybody but a bachelor who has not the warmth of heart to make a good gynecologist; or to preside over a home in which he could do as McDowell did, take the patient there and care for her with paternal care, and secure such results as can only be secured in a private hospital presided over by the operator. I do particularly resent the imputation that a surgeon would be dishonest. I am not over and above honest, so far as comparison with other men is concerned; but while I have a private hospital and while many of my colleagues, including such men as John Homans, J. A. Emmet, T. Galiard Thomas, R. S. Sutton, E. E. Montgomery and others in America; August Martin, Keith, Tait and many others in the old world, have private hospitals, and are doing good work, I will say we are just as honorable, and would not keep a patient a moment longer to secure a dishonest dollar, than the man who would impugn our motives in running private hospitals.

RECTO-VAGINAL FISTULA; ITS ETIOLOGY AND SURGICAL TREATMENT.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY AUGUSTUS P. CLARKE, A.M., M.D.

CAMBRIDGE, MASS.

The rectal tissue appears to be often the seat of morbid processes which may extend to neighboring structures; when the vaginal wall is also involved the result may be attended with much inconvenience. An abscess may form in the lower section of the sigmoid flexure or in the cellular tissue about the rectum and the exudation may be discharged or may break through into the vagina. Ulceration may take place in the small intestine and also open into the vaginal tract. The employment of the obstetric forceps has been looked upon as productive of rectal fistula, though I have never met with a case in which I could feel certain that the lesion was so produced. Prolonged pressure of the fetal head or of some other portion of the child upon the posterior vaginal wall has not infrequently been associated with the occurrence of this mishap. When the fistula occurs from this cause the openings vary; sometimes there is only a small perforation, at other times a large portion of the posterior vaginal tissue may slough or be destroyed.

Recto-vaginal fistula may occur from violence or direct injury to the parts, as took place in a case which came under my care some few years since. The patient who was the subject of the accident was aged 30 years; she sustained a direct fall of five feet upon a sharp wooden peg, four and a half inches in length. This penetrated the anus and passed through the rectum two inches above the perineal bridge into the vaginal canal. The shock for awhile was severe; but she rallied, however, and recovered with a fistula opening into the vagina, and of size sufficient to allow the passage of a No. 27 sound, of the French scale. The opening has since been closed by an operation performed by a flap splitting method as recommended by Max Saenger, of Leipzig. Rectal fistula may result from fecal impaction and sometimes from stricture of the rectum; when associated with stricture we may entertain a suspicion that the patient is affected with syphilis.

In rare instances an abscess communicating between the rectum and vagina has been known to have its origin in the caput cecum coli; and in suppurative pelvic cellulitis, and pelvic peritonitis and in other morbid processes connected with the sexual system. Fistulous channels resulting from malignant disease, such as sarcoma and carcinoma, and from syphilitic infection are according to the consensus of authority the most unsatisfactory to treat. I have met with a few cases in which the communication between the rectum and vagina was caused by tuberculous infiltration which had extended from the abdominal cavity to the peri-vascular structures at the seat of the abdominal opening. Vestibular recto-vaginal fistula may result from attempts at plastic operations in the vicinity of the rectum and especially from flap-splitting for repair of a lacerated perineum. Such a fistula may be of the recto-perineal variety, or be a recto-laquearis when situated in a higher level in the fornix of the vagina. This would most likely occur in cases in which there had been an hyperplasia and a subsequent induration of the recto-vaginal septum. I have met with at least two such cases in which an operation for the closure of the opening was necessitated. An abnormal communication through the posterior vaginal tissue into the rectum may be established by the occurrence of pelvic peritoneal suppuration, and by suppurating dermoid and other cysts and by ectopic pregnancy; the products of the morbid processes attending these conditions may result in their escape through the vagina and rectum.

The cases in which the greatest success is expected to be achieved are those that may be denominated the traumatism of parturition. Recto-vaginal fistula arising from peri-rectal suppuration or peri-vaginal inflammation or lesions should be treated according to the several indications in each individual case. In one case in which the solution of continuity occurred from processes leading to suppuration, I succeeded in effecting a cure by a thorough curettement of the margin of the fistulous tract and by removing all the fungoid growth; then undermining at some distance and lifting away the vaginal tissue so as to expose to view the rectal portion beneath. The edges of the rectal tissue were then brought together by deep buried continuous aseptic animal sutures so adjusted as not to penetrate the rectal mucous tissue. After the rectal structure had been united, the vaginal portion was then replaced and so affixed by the sutures as to close completely the abnormal communication; the parts were then dried and covered with the compound tincture of benzoin and iodoform and protected with tampons of iodoform gauze. The wound closed by primary union. In the treatment of fistula, cauterization of the edges may sometimes be successfully resorted to. In carrying out this method the thermo-cautery or the galvano-cautery will sometimes be helpful; in some instances the hot iron, formerly more often employed than now, may occasionally be tried with advantage. The cases in which such a course is indicated are not numerous; in those cases in which there is any considerable phosphatic deposits about the edges, or in which there is indurated and thickened tissue around the fistulous margin the adoption of this method will not prove successful. It is only in cases in which there are healthy granulations springing up about the edges of a fistula with comparatively narrow opening that

the employment of cauterization in any form will be likely to yield favorable results. The method of flap-splitting as employed in perineorrhaphy comprises the best procedure as a preparatory step in a typical surgical operation for closure of such a fistulous tract. By this procedure there will be no loss of normal tissue; the openings in the rectal tissue should be closed by continuous aseptic animal sutures. The suture obtained from the kangaroo tendon is to be preferred. In no event should the suture penetrate the rectal mucous membrane; after the rectal septum has been sutured the vaginal portion should be closed from its under surface.

I can not advise the use of Lauenstein's sutures for the reason that in extensive lesions the many knots which this method necessitates to be tied in the sutures are liable to prevent speedy and complete cicatrization of the wound. In attempting to raise a flap or to undermine the vaginal tissue the line of incision should extend 1.5 centimeters above and below the fistula, as is advised by Saenger, and should be in depth in the tissue upward 1.3 centimeters. In some cases, after first undermining the vaginal tissue, the flap can be turned up by drawing merely upon the tissues, using the knife or scissors only at the point in which the parts are adherent; in other instances the subvaginal tissue may have undergone such changes by a previous hyperplasia that the recto-vaginal wall can not be separated without great difficulty. Recto-vaginal fistula may sometimes be closed by a mere denudation of tissue, but when the opening is near the perineum the vascularity of the tissue at that point may be so deficient that union will fail to take place.

The old method by transplantation of flaps from other parts as from the anterior vaginal wall, or from the rectum, and even from the cutaneous surface for certain peculiar conditions, may be occasionally tried, though operative attempts by such method have rarely been attended with success. Fistulae situated high up in the fornix are more difficult to reach; if the opening is small and the pressure through the intestinal wall is not great, division of the septum may be effected, and the recto-vaginal portion should be sutured after the manner above mentioned. If, however, the communication is of a large size the closure may be attended with greater difficulty.

Saenger,¹ of Leipzig, to whom reference has been made speaks of a method of treatment by perineotomy. The perineum is split transversely and the levator ani is partially divided; the portio vaginalis is then drawn down and the opening in the vulvovaginal canal is thus closed and the sutures are applied to the vaginal wound. The operation by splitting the recto-vaginal tissue is the one best adapted in those cases in which there is a due degree of vascularity in the vaginal structure for insuring immediate union; in the higher segments of the vulvovaginal canal the arterial supply is the most plentiful. In the lower portion the nutrition is often extremely limited. Saenger uses fine aseptic Chinese silk for buried sutures in this work; he prefers silk to catgut in effecting closure of the rent. He makes no mention of the use of tendon sutures. In his paper he calls attention to important points in methods of operating by the splitting of the recto-vaginal septum

from the perineum. His method though not complete in all respects contains principles that are capable of being utilized to the highest advantage in procedures necessary in this kind of plastic surgery.

Recto-perineal fistula though not as serious a lesion as when the rent is situated higher in the vaginal wall proves for the most part very annoying. In my practice I have met with a number of cases of this variety and have found that operative measures similar to those for fistula ani have been necessary for speedy and complete cure. As already stated, recto-vaginal fistula can not be easily cured by merely freshening and suturing the edges of the opening, nor can it be readily overcome by a triangular denudation of the vaginal layer. Such a loss of tissue by procedures of this kind does necessarily weaken the normal vascularity of the parts and so prevents closure of the communication and also entails danger of the occurrence of a greater opening.

The cure of a recto-vaginal fistula located at or near the sphincter ani may be prevented or delayed on account of frequent contractions occurring in the muscular tissue of that part. In such cases thorough division of the sphincter and sometimes of the perineum either by incision or by stretching of the parts by digital dilatation as was formerly recommended by Van Buren should be had recourse to. Recto-vaginal fistula is often more difficult to heal than a vesico-vaginal one. This is especially so when the fistula is situated on a higher level and where it can not be brought down and exposed to view. The location of a fistula situated very high up or not within easy reach may be inferred from the character of the fecal discharge which is usually much more yellow than when occurring at a lower point. The fact that the opening of a recto-vaginal fistula is much more extensive on the vaginal than on the rectal aspect necessitates a resort to the method by division or splitting of the septum; by this means the rectal portion may be more easily reached. It should then be carefully sutured in order to insure at least closure of that portion of the structure which separates the two canals from each other. If the opening in the rectal portion can be made to unite by the first intention that of the vesical side if interrupted may subsequently close by granulation. In all cases after the sutures have been inserted the parts should be irrigated again with the warm sublimate solution and should be dried, and protected by the application of iodoform or aristol or iatrol. For the first few days the bladder should be regularly emptied by the employment of the catheter. The bowels should be kept in a solvent condition, and the wound should be subsequently irrigated with the sublimate solution or with warm water, whenever any urinary or fecal excretion or other septic matter may have come in contact with its edges.

Ovariectomy Performed During the Course of a Puerperal Septicemia.—Pinard (*Bull. Acad. Med.* 20 Fevrier 1894) reports a case by Le Roy des Barres. Young multipara, four days after childbirth had symptoms of peritonitis; fifteen days later pleuritic effusion, and phlegmasia dolens. There was also a suppurating cyst of the ovary. Aspiration evacuated six litres of purulent liquid. Eight days later laparotomy was performed; there was found a unilocular cyst with a normal pedicle; a cure resulted.—*Revue des Science Médicales*, July, 1894.

¹Operative Treatment of Recto-Vaginal Fistula. Transactions of the American Association of Obstetricians and Gynecologists. Vol. 3, 1890.

VENTRO-FIXATION IN EXTREME ANTERIOR DISPLACEMENTS OF THE UTERUS.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY H. R. HOLMES, M.D.

PORTLAND, OREGON.

It is fairly understood that gynecologists are at variance in regard to their ideas of the clinical import of extreme anteversion and anteflexion of the uterus. Some there are indeed, who believe that these unnatural positions are of so little consequence as to merit little or no consideration. Some writers, however, do give these pathologic conditions some attention and cast about in a somewhat doubtful manner, hopeful of remedies for relief from the symptoms and consequences which they are supposed to sometimes produce.

Personally, I am inclined to regard anteversion and anteflexion of the uterus as being of little importance ordinarily, but when the displacement is extreme, or if certain complications are present, the aspect of the case is so changed that much suffering may be the consequence.

I am sure that retroversion of the uterus often exists for years without causing particular distress and I am much inclined to believe that, "all things being equal," retroversion, will ordinarily, rarely require attention from the gynecologist. That retroversion does often imperatively demand attention I do not desire to question, but I suspect that it is so from the coincidence of neighboring ailments in active process. To illustrate: A retroverted uterus with no complications, giving rise to irritation, congestion or inflammation, will find a convenient biding place somewhere within the sacro-cocecygeal curve, but if there be any kind of rectal trouble, particularly of inflammatory nature, by pressure the mal-posing womb may cause circulatory and nervous disturbance.

Retroversion and retroflexion are often accompanied by rectal troubles, such as hemorrhoids and anal fissure. So in such instances it is not more strange that distressing symptoms should be excited, than that functional proprieties should be offended if a square meal be taken by one who has gastritis. Assuming then, that there is indubitable evidence that extreme anterior displacements, although rarely, sometimes produce very great distress, such as pain when pressing upon an inflamed bladder, to which may be added dysmenorrhea with all that goes with it, it is natural that we should compare the remedies in use at present for the treatment of these troubles, and if they do not seem to give satisfaction it is natural, too, to court some measure that may.

In the few cases (six in number) which have come under my care within the last two years, (I would be understood as meaning that of all cases of anterior displacements that I have seen within the time named, this number imperatively demanded treatment), the cases of anteversion could not be treated with pessaries with such skill, or possibly lack of skill as I could apply them with, for the use of pessaries considerably intensified the bladder symptoms. In the anteflexion variety pessaries did, to an extent, relieve a tenesmus, but the dysmenorrhea was not favorably altered. In one case where a distorted broad ligament seemed accountable for the malposition, an intelligent practical trained nurse was em-

ployed to treat the case with massage, and at the end of the second month the position of the uterus was thought to be normal, and it was gratifying to note the absence of all symptoms referable to the uterus. Digital exploration also found everything satisfactory. It was annoying, however, to a sensitive nature, to observe during the next four months all the old symptoms, subjective and objective, gradually return. These symptoms were dysmenorrhea, pelvic tenesmus, irritability of the bladder, backache and excessive irritability of the nervous system.

It occurred to me that suspension of the uterus by ventro fixation in anterior displacements might, by taking pressure of the tender bladder afford relief, as is done in ventro-fixation for posterior displacements, by taking pressure off the rectum and other tender structures. I also hoped that in some cases the procedure might measurably relieve dysmenorrhea, as the body of the uterus being fixed, the weight of the bladder and vagina would tend to alter the direction of the uterine canal so that the menstrual flow would meet with less obstruction.

During the last eighteen months I have treated, after giving the milder means a fair trial, six cases which suggested the title of my paper, and I beg to respectfully submit a report of these as testimony in support of the plan:

Case 1.—In June, 1892, an unmarried woman, 30 years old, came to me complaining of dysmenorrhea and constant pain in the region of the bladder. Her complaint had been growing worse for ten years. A careful examination resulted in diagnosis of acute anteflexion of uterus. Dilatation and a stem pessary were tried according to the practice of Dr. Hanks. The next period was attended with less than her usual amount of suffering and the pain in the region of her bladder was for several weeks less than before, but it soon returned as did the dysmenorrhea. I persistently employed pessaries, tampons, and massage, and yet all that I tried gave no permanent relief, and I began to think of raising the uterus up and fastening it to the anterior abdominal wall. November 10, following, I was called in the night to see the patient and found her suffering from an intense pain which had attacked her as she ran to avoid a storm, and from the great shock she suffered together with the physical signs and further history she gave, I was led to diagnose a ruptured tubal pregnancy. Next day the abdomen was opened and a fetus of about ten weeks was removed, as was the ruptured tube and corresponding ovary. On account of an extensive follicular degeneration of the other ovary, and an inflammation of the tube on that side, their removal was practiced also. The uterus was raised up and the fundus was attached to the abdominal wall about an inch and a half above the pubes. Convalescence was uneventful.

Two months later she informed me that she had no pain about the bladder, and instead of having to urinate every hour or two as formerly, she was able to retain her water four or five hours without annoyance. May 11, and just eighteen months following the operation, I called to see the woman and she declared that since the operation, she has never had bladder trouble, or indeed any other trouble, excepting the flushings and such other manifestations as usually, come along with a precipitate menopause.

Case 2.—Miss C., age 26; sent by Dr. Mac H. Whitney of Portland, March, 1893. Extreme anteflexion; os closely approaching fundus uteri; had painful menstruation and frequent painful urination for eight years; the dysmenorrhea even antedated this period three years; she was now neurasthenic. Attempting to pass a uterine sound, it was found impossible until, while a Sims speculum was being used a tenaculum applied to the anterior cervical lip, gentle traction so changed the direction of the canal that the sound readily entered at about the ordinary curve. Ventro-fixation was done May 3, 1893. In a recent conversation Dr. Whitney said to me: "Miss C. is quite well and has been so ever since the operation. The uterus hangs from the point where it was fixed; the flexion seems to be overcome. She menstruates regularly and with very slight pain. Her bladder symptoms have gone, as the frost vanishes before the sun."

Case 3.—Mrs. R., age 28; consulted me June, 1893, with following history: Married eight years; 2-para; always had good health until second child was born, three years ago; cervix uteri torn, perineum was very much relaxed; leucorrhœa and irritability of the bladder were the first symptoms to show themselves and were soon followed with constant pain in region of the bladder; the vesical manifestations were considerably increased at monthly periods; the periods came on regularly as to time, but after twenty-four hours there is an intermission of the flow for twenty-four hours and then the flow continues two days more with quite severe pain; there is an extreme anteversion of the uterus; the urine passed during the night and morning when examined is found to be of alkaline reaction sp. gr. 1010 and there is an abundance of mucus contained in it.

Benzoic acid improves the quality of the urine for a time, but for a short time, for the drug deranges the digestion. For four weeks the bladder was washed out every fourth day, using first warm normal salt solution, then a solution of borax ʒi—Oj, and during the last two weeks 2 grains of nitrate of silver to the ounce were tried.

All I can honestly say of the effects of the remedies employed is that they were of marked temporary benefit. The treatment of this patient by a number of physicians, including myself, marks a range of several years and not being satisfied with results, suspension of the uterus was suggested and practiced September, 1893. Within a fortnight following the patient ceased complaining of bladder symptoms and within three months had taken on an appearance of general well being and I am permitted to report that at present writing she is enjoying good health.

Case 4.—Mrs. M., age 40; multipara; sent by Dr. Cathey, of Woodburn. Had been in bed most of the time for the last eighteen months; had lacerated cervix and perineum, as well as chronic cystitis and extreme anteversion of the uterus.

The cervix and perineum were repaired according to Emmet's method. The sutures were removed from the perineum in ten days and good union found. Six weeks later the cervical sutures were removed and the mechanical result was pronounced good, and yet there were annoying bladder disturbances, pressure symptoms. The abdomen was now opened, and uterus sutured with two No. 8 silk sutures to the anterior abdominal wall, an inch and a half above the pubes.

In a paper read before the Portland Medical Society, Jan. 3, 1894 entitled, "A Year's Work in Gynecological Surgery Without a Death or Stitch-hole Abscess," I reported this case stating that although there was yet some inflammation of the bladder all the pressure symptoms had gone. The paper being published in the *Medical Sentinel* for January, 1894, and Dr. Cathey having read it, wrote me Jan. 24, 1894, from which I copy the following: "In regard to Mrs. M., your report does not do you justice, in that her vesical trouble is comparatively gone. She has not had an attack of vesical irritation since she came home from the hospital. She is entirely free from the pressure symptoms which she had constantly for years before the operation of ventro-fixation. She is walking about and to use her husband's language, seems a different woman."

Case 5.—Mrs. S., age 29; married ten years. Never had been pregnant. Consulted January of present year. Briefly, had dysmenorrhœa vesical pain and tenesmus at menstrual periods. Examination led to diagnosis of extreme anteversion; the uterus directly pressing upon a chronically inflamed bladder. After a month's treatment with discouraging results, ventro-fixation was advised and accordingly done February 9. On May 12, Mrs. S. called at my office to express her gratitude and said she had, since leaving her bed two weeks after the operation, felt perfectly well. Had menstruated three times since operation with very slight pain and no vesical tenesmus.

Case 6.—was operated on in the last part of April and it is too early to report. It was the counterpart of Case 2, and there is every reason to hope eventually for even as good results as were had in that case.

CONCLUSION.

I am not aware that this operation was ever suggested until by me in 1892. I presume it was never practiced until November of that year. That I was deviating to an extent from popular professional sentiment regarding the significance of anterior displacements of the uterus, I was well aware, and yet,

while the staggerer who falls upon his face is just as apt to suffer, or to cause suffering to those he falls about, as he who falls upon his back, I am just as willing to lend a helping hand to one as to the other. It is not likely that this procedure would have yet been introduced had not our own Dr. Kelly proven in this country the utility of ventro-fixation in posterior displacements. I trust I may be pardoned for the remark that I have seen, I think, certainly as much relief from the procedure in a case of anterior displacement as I ever have in the posterior variety, while I am a believer in the operation in posterior displacements and practice it frequently.

My cases, true, were not uncomplicated, but will not the advocates of ventro-fixation for other conditions have observed that their cases were also complicated?

In cases of dysmenorrhœa due to anteversion, I should do the fixation with a hope of best results only when the tenaculum applied to the cervix by moderate traction, the uterine canal could be changed to the extent of permitting the ready introduction of a sound, believing in such cases that traction of the bladder and vagina would so alter the direction of the canal that the menstrual flow would meet with no considerable obstruction. I recognize that this operation has not had sufficient trial to appraise its value and yet the uniform results of the few cases reported, do seem to me, to speak no uncertain sound, and I desired that the world should hear it.

DISCUSSION.

DR. H. P. NEWMAN—In regard to Dr. Holmes' paper, I was much pleased to hear a paper upon this subject. However, the indications for treating introversions or introflexions of the uterus, as you all know, are not to be compared with retro-displacements. We have a different class of troubles to deal with, and the surrounding circumstances are in strong contrast to those of retro-displacements. The indications for operations in anterior displacements are not so marked as compared to those of retro-displacements.

It is well known that in operations for retro-displacements we have in mind this factor: The aid of abdominal pressure in sustaining the uterus. In the anterior displacement there you have the abdominal pressure probably as a factor in keeping it up, in place of aiding you in keeping up the pathologic condition.

But my experience is, if there are symptoms associated with anterior displacement of the uterus, it is usually dependent upon conditions outside of the mere position which the uterus holds, and as the previous speaker has just said, very often it lies in some broad ligament affection, and not in the uterus itself. I would have these points thoroughly weighed before we put forth any other methods for anterior displacements of the uterus. However, I commend the author of the paper for his fortitude in presenting it, and in being a pioneer in that class of work.

DR. McLAREN, St. Paul—I would like first to speak in regard to Dr. Holmes' paper. We have here a large and important subject. I am very glad that Dr. Holmes has been able to make these experiments in the direction of relief from inversion and introversion, although I believe as he does, and perhaps even more strongly, that they are given altogether too much prominence even to-day. The uterus naturally lies against the bladder. That the small weight of the body of the uterus lying against the bladder can produce chronic inflammation I don't believe; that it may produce an irritable condition of the bladder perhaps we must admit.

The Doctor takes up the position of fixation of the uterus to the anterior abdominal wall, and relates six cases. To my mind some of those cases should be included under the head of chronic endometritis. There are a number of these cases which give the exact symptoms which Dr. Holmes describes who have their leucorrheal discharge, and still can be relieved by other means.

In the third case the Doctor mentions there was a laceration of the cervix. I did not understand whether he operated on the laceration or not. I believe a longer period should be given than is often the case before laparotomy is resorted to. Laparotomy is still a serious matter. If there is only 3 per cent. of mortality, if the 3 per cent. happens to be in your own family, it presses upon you as it would in no other way; and I feel that it is only in the hands of the experts that the mortality is as low as 3 per cent.

In the fifth case the Doctor speaks of chronic inflammation of the bladder, which he may not have meant exactly in that way.

It is not proven that the fixation of the uterus for retro-displacements is everything that may be desired. I have seen several cases operated on by Dr. Howard Kelley, and by Dr. Lusk, of New York, all of which had broken away in a short time. Some of them returned to their distress, and others gaining some relief. As Dr. Holmes says, many cases of retro-displacement are not pathologic. In many cases there is a complication with either disease of the tubes or ovaries.

DR. E. R. HOLMES—Mr. President: I sanction every word said by yourself in regard to that training which is necessary to a specialist in order to fit him for the work before him. I must say, too, that I approve more fully the ideas of the first speaker than he understands from my paper. Now I may be pardoned for calling attention to the fact that I stated in the beginning of my paper that I was proposing an operation to be used only in exceptional cases. I assure you that my diagnoses in these cases have been carefully made that I have presented to you.

I am reminded of my own position by the gentleman who insists upon a certain training that one must have in order to fit him for special work. Something like seven years ago I became a specialist through force of circumstances. I engaged in the practice of medicine seventeen years ago, and the character of work I was doing was general, as I was in a remote district, and it was necessary for me to do gynecologic work, which led to my making it a specialty. I studied gynecology with Prof. S—, of Brooklyn; afterwards took a special course in the Post-Graduate School in New York; I took a special course in ovarian tumors, and a special course of gynecology with Wm. Baker; and during most of a year spent in London I was continually associated with Dr. Keith. I have habituated myself to diagnosing carefully. I have been the gynecologist of the Portland Hospital, and have had an active practice.

I have culled these six cases I presented to-day from a great number of cases, in order to emphasize the possible value of this plan which I present to you.

I want to present one more case, and then I have done. This patient for the last eight years had been suffering from the trouble I am speaking of, and had spent half of the time in bed, and the last six months all the time, still having bladder pressure symptoms. After the uterus was raised and fastened to the abdominal wall she was relieved from her trouble. This seems to indicate that it was the operation of raising the uterus and anchoring it to the abdominal wall that gave her the much desired relief.

A PLEA FOR MORE THOROUGH TRAINING IN GENERAL MEDICINE AND OBSTETRICS ON THE PART OF THE GYNECOLOGIST.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY HENRY P. NEWMAN, A.M., M.D.

CHICAGO, ILL.

In the pursuit of any calling or profession, as time advances and experience widens, certain conclusions force themselves upon us as the result of individual observation. These develop into positive opinions and generally strike us as original, since they are born of our knowledge of things as they are and our convictions of things as they should be. But very often we find that other workers in the same lines have been impressed with like certitudes, and have arrived at conclusions identical with our own. If, then, it happens that certain necessities or reforms are urged simultaneously by many careful and competent observers, it follows that there must be strong indications for their iteration, and if the matters be of any moment too much attention can not be given them. With this in mind it has occurred to me to offer to my colleagues in the gynecologic specialty some suggestions relative to this branch of medicine in its present aspects and its immediate outlook.

It is evident from the testimony of many good authorities that, in spite of the wonderful progress of modern medicine and the brilliant attainments in surgical and mechanical methods of healing, we have reason to fear for the unity, integrity and honor of our profession. It is useless to shut our eyes to the fact that danger threatens, or to put it aside as sensationalism *sans* foundation, for the warning comes with greatest insistence from those who have so far sustained reputations for accuracy of observation and calmness of judgment.

Many eyes are fixed with apprehension upon the little cloud, now hardly bigger than a man's hand, which is appearing in the fair skies of this successful era of gynecology and threatening to overcast the whole horizon. Its presence there may cause this generation little positive harm, but it is gathering portent for the future. So long as the substantial wisdom, clear-sighted diagnostic ability and sound practical judgment of those who control affairs in medicine to-day shall continue to prevail we have little to fear. It is the on-coming period for which we plead.

The ease with which the most delicate surgical operations can now be accomplished, and the skill which can be acquired by frequent operating, together with the comparative freedom from fatal consequences which has been secured by modern aseptic and antiseptic methods, offer a menace to the public weal whose proportions are destined to give serious trouble to the next generation.

That there is a growing tendency among graduates to enter at once upon the practice of a specialty without suitable preparation is too apparent to be gainsaid; and it is in this tendency that the greatest danger to the profession lies, more especially affecting the future of the art and science of gynecology.

The field of pelvic surgery has widened and fructified until it offers too conspicuous a temptation to that class of men who are on the lookout for

every opportunity to profit in pocket and reputation by the misfortunes of their fellow-beings.

We may see one kind of specialism in our large stock yards every day where exceedingly clever surgery is done by the man whose duty it is to make the sweeping incision, which with lightning dexterity severs this or that organ from its surrounding structures. He becomes expert almost beyond belief, and does vastly better work than many a professional man—in a purely mechanical way—but his skill is manual only, and is amply remunerated by his daily wage. And yet this man offers the most striking analogy to that specialist who fits himself to do but one thing in surgery, and that for the money there is in it, as we are forced to admit some are doing. As one member of the American Gynecological Society has said:¹ "It is a melancholy truth that tyros in the profession, so far as general medical knowledge is concerned have become expert abdominal surgeons, and have acquired proficiency in technique but without the diagnostic skill which should accompany it, and which some experience in general medicine alone furnishes. *Such men as these are not fair representatives of the best gynecologists of the present time.*"

The italics are mine, to emphasize the thought which is comforting as far as it goes, but painfully suggestive of the situation which may supervene when the present shall give place to the future, and these representative, well-balanced, well-equipped specialists have resigned the careful and conservative knife into the eager hand of rising ambition.

This is not, understand me, a plea for conservative surgery, in the sense in which the term is often used to designate cowardly hesitance or dangerous dallying with morbid processes, often denying to the sufferer the single hope of prompt and radical intervention; for often the success of the operation and the life of the patient depend upon the intelligent seizure of the golden opportunity. No! All honor to the pioneers in fearless surgery, and to the advanced and progressive leaders who have carried the art forward to the present stage of perfection, but let such honors always be vested in just such men;—men who have climbed the ladder, round by round, and carried with them the cumulative benefits of each upward step,—rather than bestowed upon those who would clear the distance by the new, aerial, rapid transit route.

Morell MacKenzie, advocating the still more elaborate subdivision of medicine into yet more restricted specialties, sees the tendency of this advice in threatening the unity of medical knowledge, and qualifies it by insisting that: "No medical specialist is to be trusted who has not received the best and widest education in medicine and surgery, and they undoubtedly make the best specialists, who either as physicians or surgeons, at general hospitals, or as family practitioners, have had the largest and most varied family experience. If under these advantageous circumstances the change be not made too late in life, all previous work can be brought to a focus on one special point."

The dangers of the popularization of specialism in medicine suggested themselves strongly to the thinking mind as long ago as 1850, before the practical working of the system had also demonstrated the counterbalancing advantages, and we find Dr. Worthington Hooker addressing the medical students in old

Yale, after this manner: "With a special attention to any one thing is naturally associated the idea of special skill. But to say nothing of the fact that this special attention does not always result in imparting skill, it often occurs in medicine that a reputation for skill in some particular department is built upon the mere show of study and research."

It may be perfectly safe for any of the old-line specialists to assert that the future of gynecology turns on an enlightened and conservative surgery, for no one questions his ability to comprehend what is enlightened and conservative surgery, and to apply it to properly selected cases, always with an eye single to the benefit of the patient; but what of some of the newer apostles of the creed, "surgery first, last and all the time," whose field of vision is covered with the glittering allurements of many and remunerative operations?

Ten years ago, W. O. Priestley, then President of the Obstetrical Society of London, said to that body: "It has occurred to me in making a general survey of our ground, and weighing our present position, that the great impetus given of late years by many admirable workers to the progress of uterine surgery has tended to throw the balance somewhat too much over to the surgical side of the scale, and that operative and mechanical methods of treatment have displaced somewhat unduly and hurtfully the medical and psychical considerations in uterine cases."

The years which have elapsed since then have only altered the situation, in so far that such a mild statement of the case is no longer adequate to express the situation.

"Psychical considerations" is Greek to the current language of gynecology, and yet it holds a meaning which should appeal to every thoughtful investigator to-day. Woman and her diseases are the professed objects of our scientific care, but is it not evident that her diseases are receiving a paramount degree of attention?

The disease first, the woman second—if at all. A glance through the exhaustive and exhausting indices of current literature in gynecology will illustrate this fact.

Reports of cases, pathologic phenomena and records of astonishing deeds of daring on the part of this or that surgeon repeat themselves *ad infinitum* and *ad nauseam*, while only here and there in the heroic list, a lonesome title appears: "Is woman degenerating physically?" or, "The importance to woman of hygienic occupations," or again, "Some errors in female education and regimen." A carefully selected list of all the feats accomplished by pelvic surgery during the last decade would prove the statement. Thousands of lives have been saved by ovariectomies and thousands more relieved of menstrual troubles and reflex neuroses by the same means, to be no idle boast.

And, since the number of sufferers applying to the specialist for relief is really only a small proportion of the whole number who ought to do so, it also proves that in addition to these thousands of women who have been rendered sterile by surgery, there are many more who are incapacitated by disease from producing healthy offspring.

To be sure, if a woman can not retain her uterine appendages and live, she is better without them: "If thine eye offend thee, pluck it out"; but the man who professes to be an authority upon the diseases

¹ Dr. Edw. W. Jenks.

peculiar to women is criminally superficial if he is content to accept such a state of things as it is, and does not inquire into the responsibility for the terrible alternative.

The outlook for posterity is getting rather bad, and something must be done in its interest very soon. The subject of woman's health touches society at its most vital point, and in this progressive age the eyes of the public will soon be turned this way. If there is to be a movement in favor of health among women let it be directed by the gynecologist, not against him.

The profession has educated the public to high views in many departments of sanitation, and taught it to cope with contagious diseases, epidemics, filth diseases, and others from the rational standpoint of prevention. Just as the prevention of smallpox is more important than its cure, so ought it to be with gynecic disease, which last is a far more dangerous foe to the community. We want to save our women from the suffering which is coming to be the passively accepted inheritance of the majority of the daughters of Eve.

A full discussion of this question would bring us into the domain of sociology, and involve us in complex considerations which are beyond the scope of the present article, but a few points must be touched upon in regard to the duty of the gynecologist to inform himself upon all subjects relating to woman in health and out of it.

The age of idealism is gone for the nonce. Perhaps a return of the ideal woman might bring back the old days of chivalry, when woman occupied a lofty pedestal and the light of romance shone about her head; one can not tell, or whether, indeed it would be a welcomed renaissance—in this material age it is so natural to picture her on nothing more exalted than Chadwick's table, in Sim's or Trendelenburg's or the genu-pectoral position, with the full glare of Edison's illuminator—alas! not on her head.

Whatever relations these matters may bear to woman's rights and wrongs, or to ethics in general, there is a physiologic certainty involved which concerns us as specialists very positively. The future of the race depends upon the manner in which woman performs her physiologic functions, and these in turn upon the success with which her constitutional health is guarded.

The causes of disease in the female being generally acknowledged to be defective development, including congenital defects and inherited tendencies, depraved muscular tone through errors in dress, diet and regimen, disturbances of the circulation, constipation and the like, from similar causes; lacerations and trauma in childbirth and septicemia following parturition; and gonorrhoea, it follows that a practical knowledge of all these etiologic conditions is necessary to the successful practice of gynecology in its broad sense, all of which makes the office of the gynecologist no sinecure and behooves him to be a man of wide observation and special intelligence. There can, then, be no short road to skill in such a specialty. Several years of conscientious work in general practice and hospital work, with particular attention to the province of obstetrics, are none too much for suitable preparation.

As I have said in speaking upon another topic: "Prophylaxis is the text of what the future has to teach us, and hygiene is the key-note of success."

This means that the point of vantage in attacking disease is "before taking," not "after taking." Especially is this true in regard to womankind; therefore a thorough understanding of all that is beneficial and all that is detrimental to her growth and development, and above all a humanitarian interest in the same, is essential to the higher science of gynecology.

Not only to cure the diseases of women but to prevent them, not only to be dexterous in the surgical arena but to be competent to judge of indications and prevent the inroads of physical evils, should be our highest aim.

"The grand difference between men in their power to serve the science or art which they cultivate, lies in the amount of the world's experience, which by the testing processes of observation they have made their own."¹

DISCUSSION.

DR. JOSEPH EASTMAN—I can not help thanking the gentlemen for these two valuable papers, and I would like to speak particularly for a moment upon Dr. Newman's paper. Several thoughts presented in his paper are essentially the same as I expressed some years ago. But they need repeating, and the valuable additions he has made thereto make the paper one of very great importance.

The fact that a large number of men as soon as they leave a medical college take up some specialty and seek to practice, is getting to be a very serious matter. They forget that women have stomachs and livers and kidneys and other organs, as well as those contained in the pelvis, and the practice is based upon the simple one idea.

I call to mind the meeting of a medical society that I recently attended, where a great big six foot two inch sort of a man, his hair parted in the middle, who had taken up the specialty of diseases of the nose and throat, read a paper on that subject. It had been about a year since he had left the medical college. I became thoroughly convinced that he was a type of the men who seek to become specialists immediately after leaving college. I also became as thoroughly convinced that there was one cause of his becoming a specialist, and none other, and that was about like the Kentuckian who had a dog to sell. He said he was a coon dog. He was asked if the dog had ever chased a coon, and he said, "No." "Why do you want to sell him for a coon dog?" "Why," he said, "he isn't worth a damn for anything else." He was simply a specialist because he was too lazy to take up the labors necessary to make him a competent specialist.

Dr. John T. Hodgen, of St. Louis, in his address as President of the AMERICAN MEDICAL ASSOCIATION, made this expression, and I shall never forget it: "The specialist should be a most accomplished physician and surgeon, and something more; too often he is something less."

It would not hurt a young man, as I believe, to have a good manual training, and it would be a means in the line of fitting him to be a competent specialist. I remember hearing a doctor say that it was a sin for a man to take up a saw for the first time to saw off a bone, when he could more profitably have used the saw, and with less damage, in sawing boards and joists.

Mrs. Eastman often twits me for telling people that I worked for three years at the blacksmith's trade when I was about 18 years of age; and some of my professional friends have asked me to quit mentioning that for nine years I was a country doctor practitioner, living in a small village. I insist that if I am a specialist at all, I am such largely by

¹ Prof. Worthington Hooker, of Yale College, 1852.

what I learned in the blacksmith shop and in general practice. The best ideas I get to-day to help me in gynecology are such as I secured in taking private lessons in diseases of the chest, and such as I obtain from general practitioners in consultation, rather than from the medical journals filled up with authorities from the youngsters who are attempting to become specialists, like some of these Democratic Senators, "a tariff for revenue only."

DR. McLAREN—In regard to the excellent paper we heard from Dr. Newman, I can most heartily and most thoroughly agree with every position he has taken. It seems to me that the division between obstetrics and gynecology, as seen in America, is wrong to a great extent, and that we would do better work if our clinic hospitals were conducted like those of the German clinics, where the professor of obstetrics is the professor of gynecology.

A man should not expect to become a specialist at the very hour of his graduation. If he expects to be a specialist in gynecology, after his three or four years course he should have service in a hospital devoted to this class of practice, because no matter how thoroughly learned we are in the theory we must learn it practically. Let a man read and write and work to a great extent on his specialty, but let him do all the general work that he possibly can.

DR. GIBBONS, Idaho—I do not belong to this Section, but there is one thing I would like to say to the specialists. I have charge of an insane asylum, and I have been connected with the treatment of the insane for a number of years. I want to say to the specialists that if you can find a way by which you can unsex the men, you will not have to unsex the women so much. (Applause).

I have observed that my patients in the insane asylum without any special treatment for the uterine organs usually get well. In the insane asylums you will find very little uterine trouble.

MRS. BROWNELL—I do not agree with Dr. Newman's pessimistic views in regard to the women of the present day. I was in Chicago last year and I noticed everywhere the business energy and life of the women of that city, and with what rapidity they moved about.

The older ones will remember that forty or fifty years ago cloth shoes were worn by the women; look at the common sense shoes they wear to-day. I think the ladies of to-day have advanced 20 per cent. within the last ten years in regard to health, and I expect to see the advance continue.

DR. HENRY PARKER NEWMAN—The subject of my paper would be favorable for prolonged discussion I am sure, but owing to the lateness of the hour I think it is best to adjourn. Some one, however, evidently misunderstood the purport of it, by crediting me with attacking the health and development of woman. I do not do so. On the other hand, as a gynecologist and a specialist I hope, and we all hope, to see womankind raised to a higher standard; that is our aim and that is our purpose.

The only idea I had in presenting this paper was to sound the alarm of some of the mischief that is being done, or will be done, if gynecology degenerates into simply surgical procedures. It is a field which covers so much and means so much, that it is certainly pitiful to read some of the gynecologic literature, and even to attend some of the special societies, in which the subject of gynecology seems to have become circumscribed and belittled until we hear nothing but surgery, plastic operations, and matters of like importance from beginning to end.

The Gynecologic Sequela of Grippe.—Ballentyne in the *Edinburgh Medical Journal* has observed among the sequela of grippe a tendency to produce metrorrhagia, menorrhagia, and hemocele. In newborn children the author has noticed the great mildness of the disease as compared with its effects in adults.

A CASE OF DIDELPHIC UTERUS WITH LATERAL HEMATOCOLPOS, HEMATOMETRA AND HEMATOSALPINX, WITH SOME REMARKS ON THE TREATMENT OF THESE CONDITIONS.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY X. O. WERDER, M.D.

PITTSBURG, PA.

The uterus didelphys is undoubtedly one of the rarest malformations met by the gynecologist. Until recently it was thought to exist only in connection with deformity of other organs of such serious nature as to interfere with the life of the fetus; at present, however, there are on record a number of well authenticated cases in adults; in a cursory examination of the recent literature I have been able to find ten or eleven, a few of them with lateral retention of menstrual blood in vagina, uterus and tube, as in my own case.

By uterus didelphys we understand two well formed and entirely separated uteri, with no partition wall, which have either no connection with each other at all, or at least a very loose one, but with only one cornu and, therefore only one tube and ovary accompanying each organ; in other words, two complete uteri unicornes. In connection with this anomaly we may have a double vagina, one for each uterus, or there may be only one single vagina or a complete vagina with an incomplete one, as in the case to be described.

The history of the case is briefly as follows:

On January 13 of this year (1894) I saw, in consultation with my friend, Dr. Jos. H. Hoffmann, Miss Olga M., age 18, who had been confined to bed for several days with severe pains in the pelvis, especially marked on the right side. The temperature was but slightly increased and the pulse a little accelerated. The pains were constant but she had paroxysmal exacerbations which were described as cramps of an expulsive character. In addition, there was frequent and painful micturition. Abdominal palpation disclosed a tumor located in the pelvis and reaching about three or four inches above the symphysis pubis and extending over to the right inguinal region, and also to the left to a point midway between linea alba and left anterior superior spinous process of the ileum. This tumor on the right and in the median line was smooth, elastic, but not fluctuating; along its left upper surface a projection was noticeable which at the time was compared to a thumb, but was of larger size. A digital examination revealed normal external, virginal parts; about two inches from vestibule the finger encountered a round, fluctuating mass almost entirely blocking the vagina. To the left of it the finger was able to pass the tumor along a very narrow, slender canal, but no cervix could be reached. This mass was continuous with the mass felt above the pelvic brim, where it became broader and wider, filling up almost the whole pelvic cavity. On the right side it reached to the ileum; on the left, however, a small space was left between the iliac bone and the tumor. The latter was distinctly fluctuating in its lower segment, but felt harder and firmer, although elastic, in its suprapubic portion. The projection attached to the left side above described, was a firm body of the shape of a normal uterus, recognized as such, carried up out of the pelvis by the growth. The tumor was tender but not extremely sensitive though the examination proved very painful.

On further questioning it was learned that the patient began to menstruate at 15, periods recurring regularly every three and a half weeks, till the winter of 1893, when they came every two weeks for awhile; since then, every three and a half weeks again; duration, two to four days, quantity normal until recently, but much increased of late; always accompanied since first appearance with paroxysmal pains chiefly in right side and back before, during and after menstruation; has been especially marked during last year. They were principally of a bearing-down character; also

pain on walking and sitting. This pain was so severe that she was scarcely able to attend to her work and at times she was compelled to go to her bed for several days. Bowels regular until last six months, during which time they were only moved after medicine. The only diseases had were diphtheria twice and measles. Occupation, domestic since 12 years of age. She was well developed, of healthy rather robust appearance, weighing about one hundred and twenty-five pounds and of more than medium height. As it was impossible to arrive at a satisfactory diagnosis and the case seemed to demand prompt surgical interference, exploratory laparotomy was advised, to which she readily consented. It was performed at Mercy Hospital, Jan. 20, 1894. The tumor was not adherent, presented a dark purple appearance, something like a myoma, was tense, elastic, but non-fluctuating. Attached to its left upper portion was the uterus forming a projection which was recognized before; it was of normal size and appearance, though unicornis with one normal ovary and tube. The surface of the tumor was smooth and convex, with a slight roundish, dome-like projection in the center. The true nature of the tumor was only ascertained when the tube on the right side was found greatly distended and of a purplish color; right ovary normal.

There was no doubt that we had to deal with a double uterus, the right one enormously distended with retained menstrual blood. With a scalpel the tumor was punctured a little to the right of the median line and over a quart of tarry-looking, tenacious fluid escaped, which was at once followed by contraction of the uterus: The Fallopian tube was removed; it measured six inches in length and four and a half inches in circumference at the fimbriated end where it was largest; the latter was sealed and all traces of a fimbriae had disappeared. A long dressing forceps was introduced through the uterine incision and pushed down to the lower end of the sac where a counter-opening was made. Through this a long strip of iodoform gauze was drawn up to the uterine wound, but not through it, the forceps removed and the incision in the uterus closed with silk sutures. The right uterus was now of about twice the size of the left, the distance of the fundus of one from that of the other measured about three inches, the bodies were distinctly separate, there being a triangular space of at least two inches deep between the two organs. Some of the menstrual blood had escaped into the peritoneal cavity which was therefore washed out with distilled water and the abdominal wound closed without drainage. The patient reacted well and made an uninterrupted recovery. A week later she was again placed on the operating table, the strip of gauze packed into the menstrual sac removed and replaced by another. On this occasion we found that the lower end of the tumor was formed by an incomplete vagina, the vaginal canal in its upper half was double, the left vagina being complete, the right terminating in a closed sac.

February 9, she was again placed under the influence of an anesthetic, the vaginal sac freely incised and washed out, the septum between the two vaginae completely excised and its edges sutured together with catgut. Measurements showed the distance from the right cervix to the lower part of the blind vagina to be two and a quarter inches, and from this to the vulva two inches. The right cervix was fully an inch higher in the pelvis than the left one and larger in size; the right uterine cavity measured four inches in depth, the left one three inches.

She was anesthetized again March 7, a few days before her discharge from the hospital, in order to make another careful examination and to take accurate measurements. The vagina had now only one compartment from vulva to both cervixes; a slight linear cicatrix in the right vaginal wall and between the two cervixes uteri indicates the former location of the septum. The speculum exposes both cervixes very plainly to view; they are now almost at the same level, though the right one is still about a quarter of an inch higher and a little posterior to the left one; the right one is a little less accessible than the left and the slightly projecting remainder of the septum between both uterine necks conceals a portion of the right cervix. Bi-manual examination finds both uteri distinctly separate in an oblique position with their fundi pointing towards the anterior superior spinous processes of both sides. The internal surfaces of both uteri meet at an acute angle about an inch above the external os where they are connected; the connection being, however, quite a loose one, allowing distinct separate motion of each organ. The bridge connecting the two uteri is about one-third of an inch thick. When a sound is introduced into each uterine cavity at the same time they cross each other in the vagina at an angle of about 45

degrees. Both cervixes present a normal appearance and are of normal size, perhaps a little larger than usually found in a virgin; there is a scanty purulent discharge from the right os uteri.

Last examination made May 22 during menstruation, to ascertain whether the menstrual flow came simultaneously from both uteri. There was a characteristic bloody discharge from the right os uteri, but only some glairy mucus from the left.

The patient has been in good health since the operation; she has menstruated every two and a half weeks, lasting from three to five days with very little pain.

The case is interesting, not only from an anatomic and embryonal point of view, but also from a clinical one, inasmuch as it opens the question of diagnosis and especially the treatment in all cases of gynatresia with retained menstrual blood. It would be beyond the scope and intention of this paper to treat of all these points thoroughly; it is simply my purpose to refer to them briefly, hoping that the discussion will augment and complete what I can only barely allude to.

Embryology gives us a ready explanation of this very interesting and rare anomaly. As we know, the tubes, uterus and vagina are formed entirely by Müller's ducts. These may be divided into three parts; the first and upper part is destined to become the Fallopian tubes, the middle part the uterus and the lower third the vagina. They are formed parallel with those of the Wolffian body, and are in their upper extremity far apart, but in their downward course toward the uro-genital sinus they approach each other, coming close together in the lower third. After the eighth week this portion begins to fuse, the fusion always commencing at the lowest extremity and extending upwards until the lower and middle third have become firmly united, completing the vaginal and uterine canal at about the fifth month; but the upper third always remains apart. If for some reason this union at this early period of embryonal life is interrupted at any portion along the course of Müller's ducts, each duct may develop separately and independently, resulting in the formation of double organs. If fusion of the lower third of the ducts has already begun before the inhibitory influence has been brought into play, that portion will continue to grow as a single organ, while those parts whose union has been prevented will develop separately and independently as double organs. In the case reported, no doubt some such impediment to the fusion of Müller's ducts arose in the early part of the third month of fetal life, after a portion of the lower third had already become fused, which latter continued to develop into a normal vagina, while those sections of the ducts which remained separate formed double organs, a partial double vagina and two separate uteri.

The diagnosis of this malformation should not be very difficult when both vaginae are patent and both cervixes accessible to touch or vision, or where there is only one vagina containing two distinct and visible uterine necks. More difficult or impossible is the diagnosis in such cases as mine, where menstruation is going on regularly from one uterus, while the other perforate genital canal is the seat of a complete retention of menstrual blood with hematocolpos, hematometra and hematosalpinx. In such cases including all forms of gynatresia with double genital canals, a positive diagnosis will usually only be made after an exploratory puncture or laparotomy.

The treatment is naturally limited to those cases

of genital malformation accompanied by gynatresia with menstrual retention. It is essentially the same whether the retention is due to a simple imperforate hymen or a vaginal atresia with single or double canal. The indication in all these cases is to establish an outlet for the pent-up menstrual fluid. Where the retention is confined to the utero-vaginal canal this is accomplished easily, and, with ordinary precautions with comparatively little risk to the patient. But when complicated with tubes distended with blood, a hematosalpinx—and I believe this is the usual result of long continued menstrual retention—a great element of danger is added which requires our most careful attention. The tension caused by the retained blood has usually produced such a marked atrophy of the tubal walls, reducing them to a mere thin membrane, as shown by a number of autopsies that the slightest pressure is sufficient to cause rupture. In addition to the imminent danger of rupture there is that of septic infection, which not infrequently has led to a fatal termination. Fuld (*Archiv für Gynakologie*, Band 34), has collected sixty-five cases of gynatresia with hematosalpinx, of which forty-eight were fatal. He divides them into two groups: Those with a single and those with double utero-vaginal canal. In the first group, containing twenty-seven operated cases, fourteen recovered; of the second, consisting of twelve cases only, three were cured; in only four cases was laparotomy performed, all of which got well. This collection of cases can not fail to impress us with the great mortality attending this condition, and it is therefore not surprising that such great authorities as Dupuytren and Cazeaux discouraged operations for hematometra, which were nearly always followed by a prompt and certain death, preferring to leave them to nature, though the final result seems to have been equally unfavorable. With the aid of antiseptics and our greatly improved operative technique, much of the fear formerly entertained in dealing with these cases has disappeared, but it can not be denied that even at present they are not devoid of considerable danger. It is often very difficult to guard against sepsis, and the possibility of rupture of a distended tube should not be overlooked.

To prevent these two most frequent accidents it is necessary to provide for very slow but thorough drainage of the closed utero-vaginal canal. This can be best accomplished by a very small incision into the obturating membrane, and inserting a small rubber or what is better, a glass drainage tube, the projecting end of it to be well covered with iodoform gauze. Injections for the purpose of aiding the outflow of the thick tarry fluid had best be avoided. When the vagina has become completely emptied, a careful examination should be made to ascertain the condition of the uterus and tubes. If after thoroughly draining the utero-vaginal canal the tubes have failed to empty themselves into the uterine cavity, laparotomy becomes indicated and the more promptly it is performed the better it will be for the patient. In cases of complete absence of the vagina with hematometra, an attempt should be made to reach the sac through the natural channel, the closed uterus incised, and drainage provided for by inserting a small glass drainage tube.

In the cases where the uterus can not be made accessible in this way without injuring the neighboring organs, especially bladder and rectum it would

be better, in my opinion, to do a laparotomy, puncture the distended uterus, wash it out thoroughly and closing it by sutures, at the same time removing the adnexa. This would be preferable, in my judgment, to an incision either through rectum or bladder, as is usually recommended, or to a parasacral or a pararectal incision, as suggested by Pozzi.

MASSAGE IN GYNECOLOGY.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY OSCAR J. MAYER, M.D.

SAN FRANCISCO, CAL.

No branch of medicine has made such rapid advance in a comparatively short space of time as gynecology. Though ovariectomy had been performed successfully for more than seventy years, it was not until the publication of Marion-Sims' work on "Uterine Surgery," some thirty years ago, that diseases of women forced a recognition from the medical world as a separate branch of medicine. From that time on, gynecology has, as it were, leaped full-grown into existence. New operations and methods of operations were successfully tried, improvement followed upon improvement, and operative gynecology became a source of admiration to the profession as well as to those whose lives have been relieved by the surgeon's knife, of manifold burdens.

But while there is so much light, there is much darkness. How many ovaries, how many wombs have been sacrificed, how many women have been made sterile, to satisfy this *furor operativum*. While one mutilating operation was thus succeeding another, very little thought until of late years, was given to the manner of preserving the generative organs by more conservative treatment, and of bringing about restoration without intervention of surgical procedures. The indisputable merit of having given to the medical profession a therapeutic agent to successfully combat many uterine and ovarian disorders belongs to Thure Brandt, of Stockholm. Since his publications on "Massage in Gynecology," the foremost gynecologists have tried this method of treatment, have expressed themselves as fully coinciding in all that is claimed for it, and have pronounced it valuable as rendering unnecessary, in very many cases, operative interference. The object of uterine massage is to bring about a healthier state of the circulation and to impart *tonus* to the various structures of the genital tract. It is indicated in all disorders due to chronic inflammation, as well as in such diseases as cause uterine displacements, produced by relaxation of the ligaments, or by pelvic exudations, with or without adhesions.

Before describing the technique of massage, I will mention some of the general directions to be observed. The patient should be placed in the usual position on her back with legs well drawn up, as is customary in gynecologic examination. Antiseptics should be observed as in gynecology or obstetrical work. As massage in the beginning of the treatment is somewhat painful to most patients, it should be given gently, and the force should be gradually increased; it will thus be borne even by sensitive women, especially if the physician encourages them. To reduce the pain caused by the hand (particularly in nulliparæ) on the abdominal parietes, it is well to

apply oil or some vaselin. The most important thing of all is certainly a correct diagnosis of the disease and the exclusion of all pyogenic disorders such as pyo-salpingitis, ovarian abscess, etc.

Massage in pelvic disorders is divided into the external, internal and combined methods. The latter is almost exclusively used. Four different kinds of massage may be used:

1. Effleurage (rubbing).
2. Petrissage (kneading).
3. Pressure with drawing.
4. Lifting—stretching.

1. *Effleurage* is the mildest form and alone is rarely used, as it is included in the second form of massage, viz:

2. *Kneading*.—This is a manipulation carried out as follows: The diseased parts are taken between the fingers of the inner and outer hand and are rubbed, pressed, squeezed, kneaded; to be sure this is not so easily done as said. It must be done in such a manner that the patient will not object to further treatment, and thus be deprived of its benefit. *Internally*, it is, in most cases, an easy matter to reach the diseased spot with the finger; but *externally*, unless the uterus itself, is to be masséed, it is often very difficult. By slowly and gently pushing the abdominal parietes inwardly must we try to reach the parts, constantly inducing the patient to relax the abdominal muscles. When thus the parts are distinctly felt between the fingers, the inner hand is mainly used as a point of support, while the external hand manipulates the parts. Kneading is the typical form of massage for chronic thickened exudation and hemorrhagic infiltration of the cellular tissue of the pelvis. In those cases the fingers in the vagina can reach the parts more easily and can work with more force, but unless the diseased parts are firmly held between the fingers, the external hand would be a poor counter-prop, and the result will be unsatisfactory. The amount of pressure used at first when the parts thus held are between the fingers, should not exceed that which is necessary to mash a cooked potato between the index and middle fingers of one hand and the tips of the four fingers of the other hand. Gradually the pressure may be increased in the succeeding sittings. The first few sittings should last only a few minutes, rarely exceeding five minutes. Later on, the time may be increased to ten and fifteen minutes. During the first few days it is advisable to keep the patient quiet in bed, if possible, and the temperature should be carefully observed. The kneading must be commenced from the circumference of the exudation. Often the uterus must be pushed to one side in order that the hand used externally may reach the deeper parts of the parametria. In special cases it may be necessary to displace the uterus downward by means of a volsellum forceps in the hands of a nurse or an assistant. If such a procedure is necessary, utmost care must be observed that the patient remain in bed, especially if there is any suspicion that the peritoneum is in relation with the diseased parts. Less apprehension is to be entertained in the application of

3. *Pressure with drawing*.—This form of massage is used almost exclusively in gynecology. It is a combination of pulling and pressure, and as in *kneading*, the parts are taken between the fingers of the inner and outer hand. This is more difficult, as the object is generally smaller, but at the same time it is easier

as it gives the patient less pain. The inner hand fixes the part, and the outer hand presses and draws with moderate force, not letting the part slip back, but gently allowing it to glide back under constant equal pressure. This is repeated eight or ten times at first, increasing to twenty times at subsequent treatments. After every three or four manipulations, a short intermission is allowed without releasing the pressure. This form of massage is the most effective in old adhesions, and when old inflammatory products exist in the cellular tissue of the pelvis, as well as in the parametria. The direction in which to pull is usually from the uterus toward the large vessels, or *vice versa* if the uterus is to be included in active massage. The effect of this form of massage which is a pulling with a certain amount of contra-pressure, is that stiff and fixed masses of connective tissue are thereby made elastic, and that through continued stretching, changes take place in the vascular supply tending to stimulate absorption. Most typically is this observed in retroversion and retroflexion of the uterus caused by contractions of cicatricial tissues in the parametria. These cases are seemingly cured in a very short period without the aid of a pessary; but the disorder will return if treatment be suspended at too early a period; the contraction will recur and cause uterine displacement. It is therefore necessary to continue massage until the cellular tissue has become perfectly movable and free from infiltrations for some three or four weeks after the exudations were apparently sensible to the touch. In connection with this treatment it is necessary to observe that the surrounding parts be stimulated to exert an influence toward more healthful circulation, by either extended massage, or other treatment such as hot injections, baths, tampons, medicated with glycerin or ichthyol-glycerin, etc.

4. *Lifting or Stretching*—makes the greatest possible use of the elasticity peculiar to the pelvic organs. If the ligaments be in a relaxed state, the fundus may be raised as high as the umbilicus.

Besides active massage, some authors highly recommend passive massage, especially for patients who through lack of time are able to take only two or three treatments in a week, and in cases where a beneficial result is observed under this treatment. Passive massage results from the introduction into the vagina of Bozeman's vaginal ball dilators. Just how it acts is unexplained, but its beneficial influence can be observed more especially in cases where dense cicatricial tissue is softened, and in vesico-vaginal fistulæ where the borders are hardened and infiltrated, causing sutures to break through when an operation is attempted in this state.

The factors indicating massage in gynecology are the same as those calling for massage in surgery, viz: Injury and infection, exudation and immobility of parts. Sometimes it is indicated by sequelæ of pre-existing disease as contraction of cellular tissue after parametritis, or retroflexio uteri resulting from relaxation and atony.

The following schematic table for indications of massage is not complete and is the same as used in massage in surgery. By massage treatment we wish to produce:

1. Acceleration of the absorption and retrogression of inflammatory and traumatic exudation and deposits. (Pelvic exudations and hemorrhagic infiltration.)

2. Stretching, loosening, disintegrating, cicatricial, contracted or hypertrophied connective tissue, caused by inflammatory processes. (Thickened and contracted scars, contractions in the pelvic cellular tissues, adhesions and swellings caused by chronic inflammations, as also sequelæ, resulting from those conditions, viz: Abnormal position of the pelvic organs.)

3. Stimulation of the circulation and restoration of the normal elasticity and *tonus* in: *a*, contracted, hardened and hypertrophied tissues; or *b*, relaxed tissues. (Chronic metritis, subinvolutions, prolapses impending on relaxed tissues and anomalies of position.)

The sphere of usefulness of this method of treatment in diseases of women may consequently be tabulated as follows:

1. Pelvic exudations and hemorrhagic infiltrations.
2. Chronic parametritis and perimetritis.
3. Retroversio uteri.
4. Chronic metritis.
5. Prolapsus uteri et vaginae.

1. *Pelvic Exudations and Hemorrhagic Infiltrations.*

—This category of disorders is the most difficult amenable to massage treatment and by no means devoid of danger. Authors disagree as to the time when massage should be given in these diseases. While some recommend massage from the outset, even in the acute stage, others do not commence until the febrile disturbances have subsided. I believe the latter course more proper and never give massage until one or one and one-half months have passed after the beginning of hemorrhagic infiltration. I discontinue massage and let a few weeks pass before attempting treatment again, should febrile disturbances make their appearance during massage treatment, exercising every precaution and carefully watching the temperature. Kneading is the form of massage most advantageous in this class of disorders. It is best to commence on the circumference of the exudation, gradually encroaching upon the primary center of the disease. Perfect rest in bed, careful observation of the temperature and watching of the pulse, are necessary in the beginning of treatment. Should the least suspicion arise that there are purulent processes present—rise of pulse or temperature—massage must be discontinued. The most promising results are obtained with exudations in the pelvic cellular tissue, while those in the pelvic peritoneum give much less satisfactory results. Massage should especially be avoided in perimetric exudations which can be felt as tumors as they often give rise to pelvic peritonitis. This latter disorder belongs to the domain of operative gynecology. If the perimetric exudations are desiccated and have led to adhesions and contractions, or if we find chronic perimetritis, then we may safely rely upon massage as a valuable therapeutic agent. Massage acts most quickly in cases where the disease follows labor. The sooner these cases come under treatment the more quickly we can effect a cure, especially if the organs are still in a state of subinvolution.

2. *Parametritis and Perimetritis Chronica.*—Acute inflammation of the pelvic cellular tissue, though it may not present violent symptoms and the formation of exudations, is accompanied by lymphangitis or phlebitis, causing after subsidence a change of

anatomic structure. This may sometimes be avoided by proper treatment, or even if the various changes have taken place absorption will often follow without any treatment whatever, when the organs will be restored to their normal position or function. In the majority of patients this favorable condition does not take place. Inflammatory deposits remain exacerbating at times, contracting at others, causing an abnormal position of the various pelvic organs, which in turn cause a change in the pelvic circulation. In most of these cases we are led to give an empirical diagnosis as retroflexio or anteflexio uteri, mistaking the action for the cause. During the puerperal state, as is well known, the cellular tissue shows a marked tenderness to absorb and in this way brings about subinvolution. It should therefore be our aim to produce a condition of the parts similar to the puerperal state, when we want to cause absorption of old inflammatory deposits and contractions of the parametric cellular tissue. This condition we may reach with hot douches, glycerin and iodine. But unfortunately all these agents lose their therapeutic value before restoration of the parts is achieved. We must aid this treatment by mechanical manipulation. This should be continued until all deposits have been absorbed and the parts have become perfectly movable. The same treatment holds good if the disease is located in the cellular connective tissue surrounding the vagina. We often succeed in improving and even curing this class of disease after all other treatments have failed. More tedious are the cases of para- and peri-metritis caused by gonorrhœic infiltration.

The most favorable time for massage treatment in chronic parametritis is not long after an acute exacerbation. This is especially true in cases of chronic parametritis atrophicans. The prognosis in chronic parametritis after an acute exacerbation is a most favorable one; the longer the time allowed to elapse or the further away the focus of acute disease is located from the atrophied cellular tissue, the less likelihood is there of completely eradicating the disease.

Inflammation of the pelvic peritoneum is a disease of a serous membrane, contrary to parametritis, constituting a disease of connective tissue. It is due to this anatomic difference that we derive entirely different conclusions as far as this latter class of disorders is concerned as to the advisability of massage treatment. The therapeutic measures usually adopted were either to influence this condition in a general manner by rest, baths, depletion or application of iodine; or, if these measures were not successful, operations were resorted to, to remove the primary cause of disease. To introduce massage successfully in perimetritis it became necessary to show that we could accomplish more than with the usual methods of treatment and render operative procedure unnecessary. Unfortunately we can not treat these cases with the same impunity as those spoken of above. We must select our cases and watch them most carefully lest an acute pelveo-peritonitis may arise from latent inflammatory causes remaining in the exudations and becoming active. Even with this gloomy aspect we do not fare any worse than if we had followed the principles of operative gynecology, which only too often give negative results and are certainly more questionable as to results than massage. Besides it is our duty at least to try a more conserva-

tive plan of treatment before subjecting a patient to an operation.

3. *Retroversio Uteri*.—If retroversion of the uterus is not due to neoplasms causing displacement of the uterus, this disorder is almost always dependent upon inflammatory conditions in the pelvis or upon relaxation of the uterine ligaments. Consequently retroversion of the uterus is not a disease but a cardinal symptom of some existing disease. This fact is often not recognized and we are apt to make a diagnosis without duly considering the causes, but simply perceiving the effects. To the general practitioner it almost always suffices to have recognized a retro-deviation of the uterus, and accordingly he will introduce a pessary without trying to find the exact pathologic factors producing this anomalous condition, much less will he attempt a removal of the same.

Each retro-deviation should be classified under one of the following divisions:

1. Congenital or acquired arrest of development.
2. Inflammatory processes of para- or peri-metric origin.
3. Relaxation of the ligaments or vaginal support.
4. Combinations of Nos. 2 and 3.
5. Mechanical displacement by tumors in or surrounding the uterus.

It is not to be denied that despite the recognition of all these factors, we often are obliged to be satisfied with a symptomatic cure, but this should not prevent us from trying to find a means by which an anatomic *restitutio in integrum* may be established. The reposition of the uterus should never be attempted by force, as by sound or repositor, but by bi-manual manipulations, especially when fixed by adhesion. In these cases, massage should be resorted to and when the uterus can be raised to its normal position it should be supported by a well fitting pessary. As treatment progresses the pessary may be abandoned. In some cases we may be forced to keep it in position, or resort to operative gynecology, viz: Ventreresp. vagino-fixation. Opponents of massage may claim from this statement that massage does not benefit this class of disorders, but statistics show that over 50 per cent. can get along without pessary. In the other 50 per cent. we must permanently make use of some kind of support. It would be irrational to look upon this treatment as a cure for all diseases. We must individualize and not forget our other therapeutic agents; especially must we see that the pelvic floor gives the proper support. (Remedy perineal lacerations, vaginal prolapses, cystocele, rectocele and other factors tending to displacement of the uterus.)

4. *Metritis Chronica*.—Massage, as we have already said, seeks for its third object to induce a healthier state of circulation in and around the diseased pelvic organs, be this diseased condition due to induration, contraction or relaxation. Accordingly, two classes of conditions come under this head:

1. Induration and hypertrophy—the typical example of chronic metritis.
2. Prolapsus of the uterus (depending upon changes due to inflammatory processes). Chronic metritis is almost always found in connection with some other disease arising from inflammatory changes which spread to the connective tissue of the uterus, the inflammation spreading from the mucous membrane

of the uterus or its adnexa. It is true that if we can master the primary affection, the chronic metritis will often depart of itself; but too often the chronic metritis will keep up the pathologic process, and despite all treatment and though the patient be apparently cured from the primary disease, will prevent total eradication of the morbid conditions existing. It is in these cases that massage is a therapeutic agent of high value, and under its influence we soon witness permanent relief for the sufferer. We can feel the thickened and hardened uterus gradually return to its normal state. Measurements by sound will verify its decrease in size, the discharge will change in color and quantity, and soon cease altogether. In the rare cases of primary metritis we can not expect any more of massage than of the older methods of treatment. While improvement and a symptomatic cure will take place, if massage be discontinued the condition of the patient will soon be the same as it was originally.

5. *Prolapsus of the Uterus and Vagina*.—Until a few decades ago the introduction of a pessary constituted about all that was done to remedy these disorders. The causes of prolapsus were but little understood. With a clearer understanding of the pathology of the female generative organs, operative gynecology with its numerous methods of operations tries to restore the integrity of the pelvic floor. More attention is paid to the regimen during the puerperal state, so that perfect subinvolution may take place before the woman leaves her bed, and that prolapse through relaxation of the various structures of support may be avoided. The causes of prolapsus may be classified under one or the other of the following three divisions:

1. Relaxation.
2. Pressure weight and traction.
3. Decreased support.

But the manifold therapeutic agents and operative procedures we possess are not complete without electricity and massage. Only the faradic current, however, is of any avail, in using electricity, as the galvanic current despite its action on both varieties of muscular fibers has no influence in restoring the elasticity of thickened or rigid connective tissues. In these conditions we can obtain the best results with massage. No positive explanation or proof of its action can be offered, but the presumption is, that the continued and constant stretching of the tissues, and the stimulation of the capillary circulation, thus promoting healthier nutrition of the parts, is directly responsible for the restoration of lost tonicity.

Contra-indications of Massage.—Manifestly massage is contra-indicated in all diseases of the genital tract requiring perfect rest of the whole body or of the genital tract alone. In pregnancy complicated with retroflexion of the uterus, even should that body be fixed by adhesions, it is best to adhere to the older methods of treatment, as an abortion would surely result were mechanical manipulations resorted to.

The use of massage in cases of chronic gonorrhœa should be very carefully guarded against. While at times massage beneficially affects the sequelæ of this pathologic process, it is liable to produce serious disturbances if existing latent causes of inflammation are forced into activity. Old encapsulated abscesses either of ovarian or tubal origin, as well as pelveo-peritonitis contra-indicate massage, though often they are only recognized after treatment has begun.

Therefore where there is any suspicion of their existence we should insist upon an examination under anesthesia, so as to eliminate the possibility of the presence of any such disorder. And just at this point it is proper to observe that should uterine massage fail to realize the expectations of the practitioner employing it, its use is not therefore to be decried, nor its value depreciated. No remedy or therapeutic agent exists in medicine that is infallible. And, moreover, is it not a very pertinent inquiry in this connection whether massage itself is at fault, or the practitioner employing it? If the manner of treatment be incorrect, *e. g.*, if the manipulations be too rough, massage will do more harm than good. Such results will also come from its use by persons who ignore the pathology and anatomy of the pelvic organs, and will most certainly follow where the case has been incorrectly diagnosed as one demanding massage. The apparent failure of massage in individual cases affords no argument against it, until the reason of such failure is known; and if shown to be due to any of the above causes or kindred causes, far from negating the efficacy of massage, where this treatment is properly called for, it will only add the weight of its testimony in favor of it.

CONCLUSIONS AND RESUME.

Massage is valuable in parametritis and hemorrhagic infiltrations, in that it causes quicker and more complete removal of the exudations. It is valuable in causing absorption of contracted hypertrophied pelvic connective tissue, be it the remains or sequela of acute pelvic cellulitis, or be it due to an idiopathic circumscript chronic thickening. Massage is a therapeutic agency of high potency. It is very effective in combination with other therapeutic measures, such as baths, douches, medicated tampons, etc., and we often notice that where these remedies have been resorted to with failure, by the use of massage alone a permanent cure will be obtained. The best and quickest cures are observed in chronic diseases following the puerperal state; while a longer time is required in diseases following acute inflammatory processes, also when coincident with anomalies of position of the pelvic organs, especially in retro-deviations of the uterus.

In chronic perimetritis, the results, while not so good as those observed in parametritis, are encouraging enough to warrant the use of massage, since resort to operative procedures does not accomplish more for the patient. The same may be said of anomalies of position of the pelvic organs accompanying perimetritis.

In retro-deviations of the uterus due to adhesions or relaxation, massage is a remedy not to be underestimated; the indication for its use depends on the causes of the malposition. In these cases massage is free from danger and gives more satisfactory results than all procedures requiring force. Even if we do not succeed in some cases in restoring the uterus to its exact normal position, we can obtain a symptomatic cure without recourse to surgical procedures. The time required for reposition of the uterus is usually short; on an average of a month to a month and a half. In all cases that have their origin in the remains of inflammatory products or exudations, massage is invaluable.

The combination of massage with electricity is to be recommended in relaxations of supports of the

uterus, provided the structures are intact; (perineal and vaginal lacerations, etc., have to be repaired). In senile atrophy the action of massage is very transitory. In retroversions and retroflexions, massage gives more favorable results than any of the older remedies. The time required to cure prolapsus and reposition of the uterus is sometimes quite long, depending on individual dispositions. At times, especially in bad cases, a pessary is required to support the uterus. By exercising proper circumspection, we can often achieve more by alternating massage treatment with other treatments than by long continued massage.

In conclusion, I have to say that massage does not set up for itself the claim that it constitutes an independent and sufficient form of treatment. It is only a mechanical therapeutic agent, intended to be used in combination with other tried and accepted remedies, in effecting a permanent cure, or in considerably lessening the time formerly required therefor. American gynecologists have been somewhat slow in accepting massage as a new remedial agent to be employed in diseases of women, and have been suspicious of the beneficial results that have been claimed for it. But the constant encouraging reports of European authorities, many of them erstwhile bitter opponents of massage, reports that are full of successes beyond the expectations of the most sanguine, are bound to work a change in this American sentiment. The skepticism of to-day will soon be converted into the faith of tomorrow.

In this paper I have omitted all mention of my individual cases; a history of them will furnish the matter of a subsequent paper.

801 Sutter Street.

DISCUSSION.

DR. J. H. BARBATA, San Francisco—I have had the pleasure of seeing some of the cases that have been under treatment by massage, and who had been advised to have either the ovaries or the uterus or both removed, by some of the most prominent gynecologists of the city. By means of massage treatment combined with electricity, they have been restored to almost perfect health without resort to any operative procedure. As we all know the great difficulty in restoring a retroverted and retroflex uterus to its normal position by ordinary treatment, we should certainly look forward to massage as one of the most efficient remedial agents of the present day.

DR. S. I. SHUEY, Oakland, Cal.—I make use of massage in cases of pain in menstruation of young girls, with good results. In long standing cases where a great deal of medicine had been taken, cases standing nine or ten years, I have given massage every day for three or four weeks, and always during the menstrual period, and I have found this treatment very beneficial.

DR. OSCAR J. MAYER—As I said before, my report of my cases will follow in a future paper. But for the benefit of those who think favorably of massage treatment I will mention something I found out within the last two weeks. There has been a good deal of difficulty in applying massage, in multiparæ, of the abdominal muscles when relaxed, because it causes pain to introduce the hand, and the patient is inclined to give up massage treatment. This difficulty I have tried to overcome. I have a patient of this character whom I shall probably use in a demonstration before some society in this city. She was in such a condition that she was willing to try almost anything and to stand almost any amount of pain. It was extremely difficult to get at the uterus, and especially in the ordinary position. So I made use of what is known as the extreme Trendelenburg position. This is easily arranged by using an ordinary chair and a mattress—raise the lower end of the mattress and place the chair under it in such a way as to make an incline. Upon this I placed the patient with the head in a downward position. By this means I was able to reach the fundus in four treatments, whereas before I was not able to do so in a treatment covering four weeks, and excellent results have followed.

GASTRO-HYSTERORRHAPHY WITHOUT OPENING THE ABDOMINAL CAVITY.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY FRITZ BAUM, M.D.

KANSAS CITY, KAN.

Our negative results in treatment of prolapsus uteri by pessaries and supporters have proven conclusively that we can never gain our point in supporting the prolapsed uterus from below, and that we must find some means to uplift same from above, and in this way substitute the office of the relaxed round and broad ligaments. For this purpose we have constructed the following instrument, consisting of a hollow tube, like a big uterine sound; within this there is a piston-like rod with a handle at the outside and two needles threaded to one thread at the end inside. Now our idea is the following one: Place the patient in Trendelenburg's position, insert this instrument, called uterine ventro-fixator, into the uterus, and after correcting misplacement of same bring the fundus as high up as possible in direct contact with abdominal wall; then push the rod up until the needles protrude through the skin, unthread the needles and draw the piston back, thus removing the needles and withdrawing the instrument. Pull the thread up as high and tight as feasible, then tie a strong knot after having made a little incision through the skin of the abdominal wall to imbed the stitch, in this way fixing the uterus to the abdominal wall. The place is then dusted with iodoform and sealed with collodion.

As far as we can see, the first question which would arise would be the following one: Is there danger of sepsis? We claim not, if properly managed. The patient should be prepared as if she had to undergo a laparotomy, abdomen and pubis shaved. The vagina should be first well cleansed and packed with antiseptic gauze until rendered aseptic. Then on the day of the operation the uterus should be curetted and washed out with a strong antiseptic solution and then after perfect boiling of the instrument, needles and thread, we think this danger would be eliminated.

The next question would be, Will we get adhesions by holding the uterus in contact with the abdominal wall in this way? We think we should, because by pulling the uterus up against the abdominal wall, these stitch holes must naturally give a little, perhaps they will even tear some; this will set up some local inflammatory action, which will result in adhesions, which "Report of Cases" has proven, if the uterus is brought in *firm* contact with the abdominal wall.

We may either leave this stitch in there permanently, or may remove it after two or three weeks. The only contra-indication for this operation, as far as we can see, would be adhesions of the intestines to the fundus uteri, or portions of the abdominal wall, or firm adhesions of the ovaries or tubes to the back, or presence of pus about the uterus and appendages. The interference with a large bladder can easily be avoided by keeping a sound in it during the operation.

Whoever has operated or seen the operation, will be convinced that the danger of wounding the intestines is almost eliminated, because the uterus can be so plainly felt through the abdominal wall and

manipulated in such a manner that all intervening tissues can be positively excluded.

Case 1.—Miss M. D., age 19. Retroversion with strong adhesions, after severe fall four years ago; since that time frequent painful urination, backache, difficult menstruation. I made the first operation at Bethany Hospital, Kansas City, Kan., April 21, under assistance of Drs. J. D. Griffith and S. I. Harrison, of Kansas City. Uninterrupted recovery; highest temperature recorded was 99.4. Patient had no pain or inconvenience whatever and was discharged after three weeks stay (two weeks in bed in the Hospital) with her uterus firmly adherent to abdominal wall hardly within reach of the finger in the vagina.

Case 2.—Mrs. F. O., age 37. Three children, youngest 5 years old. After last confinement, prolapsus uteri with pertaining complaints; operated April 22; highest temperature 99.7; very little pain; remained in bed thirteen days. Discharged after three weeks; uterus in proper place. Uterine supporter was fitted to be worn about one or two months.

Case 3.—Mrs. R. T., age 26. After tedious labor case and forceps delivery, patient complained of backache, headache, and frequent painful urination. Examination showed retroflexio uteri. Operated April 24; temperature remained normal; slight pains over region of stitch. Contrary to my custom I did not imbed the stitch in abdominal tissue but severed it the seventh day, in order to test adhesions, which proved strong enough to make the uterus adhere to the abdominal wall. Uterine supporter was fitted and patient was discharged seventeen days after operation completely cured.

Case 4.—Mrs. A. K., aged 43. Prolapsus uteri of nine years standing. Operated April 25; clipped stitch May 2; found uterus strongly adherent and fitted uterine supporter. Discharged May 19, completely relieved.

Case 5.—Miss F. L., age 18 years. Kicked by a horse in the abdomen about one year ago; since that time dysmenorrhea, headache, backache, fatigue feeling, etc. Diagnosis, retroflexio uteri. Operated April 26. No elevation of temperature; had a circumscribed peritonitis around the stitch as large as two silver dollars. Made uninterrupted recovery and was discharged two weeks after the operation.

Case 6.—Mrs. A. B., age 25. Gave birth to twins; forceps delivery two years ago. Diagnosis, retroflexio uteri. Was unable to do her own housework because of backache, headache, and constant desire to urinate. Operated April 29; highest temperature 99; very little pain. Did not imbed stitch but cut it twelve days after operation; uterus remained in place. Uterine supporter fitted and patient was discharged twenty days after operation completely relieved.

Case 7.—Mrs. L. M., age 36. After fall from a wagon two years ago had adhesive retroversio uteri; difficult menstruation with constant backache and headache. Operated May 1. No rise of temperature; was discharged relieved within two weeks after operation completely relieved.

Case 8.—Mrs. J. K., age 26. Had three children. According to her own report had miscarriage two years ago; after that puerperal fever. Examination shows retroverted uterus almost immovable. Operated May 4; greatest difficulty in destroying adhesions. Rise of temperature second day to 102.2, third 101. The following day 100.3, but found in changing the vaginal tampon, that the uterus had dropped back, as I expected. There were three more cases operated upon which gave complete satisfaction though they are still under treatment, therefore reports later.

CONJUNCTIVITIS MEIBOMIANÆ.

BY JAMES A. LYDSTON M.D., Ph.G.

LECTURER ON OPHTHALMOLOGY AND OTOTOLOGY IN THE CHICAGO COLLEGE OF PHYSICIANS AND SURGEONS; MEMBER OF THE AMERICAN MEDICAL ASSOCIATION, THE CHICAGO MEDICAL SOCIETY, AND FELLOW OF THE CHICAGO ACADEMY OF MEDICINE. CHICAGO.

Notwithstanding the many varieties of conjunctivitis, the above title suggests itself as being particularly descriptive of a variety of lid inflammation which has recently fallen under my observation and care. The condition in the case that I have noted was so strikingly characteristic that no other cause could possibly be defined as the source of the inflammatory reaction, but a microbic or chemical irritation induced by the extrusion of the decomposed secretion from the meibomian glands, and hence the

above name seems particularly suggestive and appropriate. To my knowledge, no one has described such a condition, and I am unable to find any reference to the subject in the ophthalmologic literature at my command. The appearance of the conjunctival tarsi was quite picturesque, there being irregular, island-shaped, roseate elevations distributed over its entire surface (with distinct and well defined interspaces of uninflamed conjunctival structure,) which were marked like the efflorescence of a vernal catarrh, with a pronounced tendency to recur. The appearance of each crop of inflamed papillary areas was coincidental with the extrusion of the condensed sebaceous-like material which had evidently accumulated in the meibomian glands to full distension, and then, with the elements of decomposition superadded was in full readiness when discharged to excite a marked inflammatory reaction in the lids, asserting itself in the form of conjunctivitis with enlarged papillæ. Some discharge of a muco-purulent character accompanied each attack, and could be seen to take its departure from each focal point of infection or irritation. The conjunctiva fornicis or retro-tarsal fold seemed perfectly free from inflammatory disintegration or ulceration, and aside from slight hyperemia did not seem to participate in the singular process.

The treatment, which consisted in pressing out the contents of each gland with the fingers, irrigating the conjunctival sac with bichlorid of mercury, 1 to 5000, and carefully cauterizing each elevated patch of inflammation with nitrate of silver, 30 grains to the ounce, soon caused the disease to abate and thoroughly disappear, only to recur again as soon as the meibomian glands refilled, and observing the same course would under treatment disappear. Then I was led to adopt the plan of cauterizing the palpebral edges with a concentrated solution of nitrate of silver, and by thus stimulating the meibomian ducts and glands obliterated the recurrent tendency of the disease; and at the present writing, about a year since the patient was treated the last time, the conjunctival surfaces are perfectly free from injection, much less inflammation, and the patient expresses himself as wholly relieved of his annoying trouble.

The points of interest relative to the affection are:

1. Its rarity.
2. Its novel recurrence and speedy relief under treatment.
3. Its apparent resemblance to trachoma or follicular conjunctivitis (so far as the papillary enlargement or hypertrophic elements were concerned.)

Conjunctivitis meibomianæ in its different phases adds but another form of conjunctivitis to the varied types of conjunctival inflammation, and appears to be strongly supportive of the fact that the conjunctiva is, by reason of its peculiar anatomic arrangement, extremely prone to acquire inflammation as a result of various irritants, and that there subsists a certain relationship between the pathologic or morbid appearance and the special type of irritant.

HOW TO AVOID ADHESIONS IN ABDOMINAL SECTIONS.

BY FRITZ BAUM, M.D.
KANSAS CITY, KANSAS.

The progress in abdominal surgery during the last decade has been so astonishing, that it seems almost as if we must soon come to a standstill, and as wonderful as our success has been there are some draw-

backs, which remind us that we have still to study, fight and strive for improvements, as perfection is far distant yet.

Interfering adhesions have been one of the most important obstacles in abdominal surgery, and our efforts to avoid them have so far been in vain. The application of iodoform, aristol and other drugs to the surface of loosened adhesions have proven inadequate. The most frequent occurring adhesion is that of the retro-misplacement of the uterus, which in most cases can be broken loose during laparotomy, but they return as readily and continue after the operation more severely than they have been before, so that after ovariectomy with adhesions the uterus sometimes becomes entirely immovable, leaving the organ firmly embedded in adhesions, so that the patient often complains more after than before the operation.

Again, in intestinal operations we find that the success of intelligently performed operations is so often frustrated by forming adhesions, which are specially felt in herniotomies. I have for some time been making experiments with animal structures to prevent adhesions in abdominal sections. These structures are rendered aseptic and being placed between the surfaces of loosened adhesions are absorbed in a comparatively short time preventing reformation of adhesions. After obtaining very good success from the use of these structures in abdominal sections, I feel as if I should make a report of my investigations, in order to give the medical profession the opportunity to try this procedure.

My first experiments were made upon dogs. After opening the abdominal cavity I scratched and denuded the external coat of the intestines or the uterus, then I closed the abdomen again, giving from two to three weeks time to form strong adhesions. During the second laparotomy I tore loose these adhesions, placing my anti-adhesive structure between the two surfaces, using a few superficial stitches of fine silk to keep it in place. These stitches were used only in animals.

My anti-adhesive structure first consisted of catgut woven into a cloth, by having one layer of thread crossing another one, which procedure proved to be very tiresome and I soon abandoned this structure, using fish-bladder, which we find in drug stores as so-called gold-beater's skin. This seems to act much nicer on account of its pliability, being easily rendered aseptic. At last I have been using animal peritoneum, taking it from a young calf immediately after being butchered.

I have prepared either of these structures by keeping them in sulphuric ether for about one week and then leaving it in alcohol absolute for ten to twelve days before using it. In regard to the time which it takes to absorb the different material, I found the catgut cloth, after opening the dog's abdomen the eleventh day, fenestrated and partly absorbed; the twentieth day it had entirely disappeared. The fish bladder was almost totally absorbed in from ten to thirteen days.

The practical use of these anti-adhesive structures has been proven to me in such startling success in three laparotomies, especially with very extensive uterine adhesions, which, after being torn, never returned since placing my anti-adhesive structure between them, the uterus being as movable after the operation as it should be physiologically, that I am convinced of their practical value.

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
 SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

NO. 68 WABASH AVE., CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

SATURDAY, AUGUST 11, 1894.

OUTDOOR CASES OF COMA.

The diagnosis of coma on the street, is almost entirely made by policemen, young ambulance physicians, druggists and passing physicians. The next diagnosis is by police surgeons, or political doctors who attend at station houses at half a dollar a visit. Later the coroner and his "ring" finds that death was from alcoholism, exposure or heart failure. If a doubt exists a post-mortem seldom reveals more than some transient inflammation seemingly confirming the above conclusions. These are facts which every city in the country presents. Occasionally some of these haphazard diagnoses come into notice, and hemorrhage, concussion, fracture of the skull, embolism, and other serious injuries are found, that have been diagnosed as drunkenness or the coma of intoxication. There is no doubt many most serious mistakes are being constantly made in the diagnosis of these cases of coma found on the street. Because the case has an alcoholic odor, the impression prevails that spirits are the cause.

The Medical Society of the city of Brooklyn and county of Kings, New York, appointed a committee to report on the present methods of treating persons found unconscious on the street. The Secretary of this committee, DR. L. D. MASON, of Brooklyn, N. Y., has recently presented a very suggestive report which has appeared in the *Journal of Inebriety* for July. DR. MASON gives a clear review of the common blunders of throwing all cases found stupid with an odor of spirits, in the station cells, to be found dead next morning, and the folly of trusting to the diagnosis from the most causal view of cases so serious and complex. The facts of the differential diagnosis are given with the opinions of authorities, and the experience of eminent men, and the different methods of treating these cases in other countries.

The experience of surgeons in London, Berlin and Paris and their efforts to determine the cause of the coma are given with minuteness. Some very startling cases are mentioned of recent date, and the committee concludes, asking time for a more exhaustive study of these cases and promising to make another report in the near future. The following are some statements and conclusions:

"The instances given might be greatly multiplied, and indicate a deficiency in the public service in most cities which in the name of humanity demands a remedy. The frequent occurrence of mistaken diagnosis makes it necessary that special attention be given to this subject. The differential diagnosis between alcoholic coma, and cerebral conditions simulating it, is not easy; indeed, it is sometimes impossible. Fracture of the skull, concussion of the brain, cerebral hemorrhage, embolism, thrombosis, uremia, epileptic coma, narcotic poisoning, and heat apoplexy have all been mistaken for alcoholic coma. This is especially the case when an alcoholic condition has accompanied the other condition. Such mistakes have been made by well informed medical men, and it is therefore not surprising that policemen, or recent graduates, or ambulance surgeons should err in the diagnosis.

"Your committee while not prepared to make a final report feel justified in offering recommendations.

"1. That while they believe that the system which exists in Paris is, perhaps, the most perfect, by which all persons found unconscious in the streets are taken to a special hospital where they have the most enlightened treatment possible, still it is a question with them whether the distances are not so great as to make such a system impracticable in Brooklyn. They prefer, therefore, to keep this question under advisement for a longer time.

"2. That all persons found upon the street in an unconscious or semi-conscious condition, or wandering about in a state of mental aberration, shall be removed to their homes, or if they have no homes, or their residence can not be ascertained, then to the nearest hospital, and a visiting physician or surgeon shall be at once summoned.

"3. That alcoholism or suspected alcoholism should not exclude such persons from the benefit of proper medical treatment inasmuch as simple cases of alcoholic coma, partial or complete, are serious and demand treatment, and again, alcoholism often obscures and is associated with serious cerebral lesions. In any event, therefore, such cases should have proper medical treatment.

"4. If for any reason such cases can not be taken either to their homes or to the hospital, and must be taken to a station-house, they should be placed in rooms properly warmed, and a physician should be summoned to examine them. If they remain in the station-houses, they should be visited every half hour by the watchman, and if any alarming symptoms intervene, a physician should be immediately sent for. The practice of locking in a cell for hours without inspection a person unconscious from alcohol, whether the same is complicated with injury or not, is inhuman.

5. In case of doubt, as between the police and the ambulance surgeon, a police surgeon should be summoned, and the disposition of the case should be determined by him."

It will be apparent to every one that this is a very important and timely topic, especially in the heated period of summer. This is the first society that has attempted to gather the facts, and make some studies which would be authoritative in this field. We commend this effort and hope that every reader who may

have any facts bearing on this topic will give DR. MASON all possible aid. There is a wide field for original work, and the clearing up of many obscure points, that should be recognized practically in the profession.

INFECTIOUS SWINE DISEASES.

So many of the diseases which affect the lower animals are communicable to man, that pathologic investigations of infectious diseases of any of the domestic animals have a direct bearing on the infectious diseases of man, and consequently are of great interest to all engaged in pathologic study.

Scientific inquiry in no branch of our Government has been more active than in the Bureau of Animal Industry. A production of that Bureau by PROF. THEOBALD SMITH and DR. V. A. MOORE, under date of April 21, has just been made public by the Chief of the Bureau, DR. SALMON, by order of the Secretary of Agriculture.

These investigations have been continuously carried on since 1889, and have had "for their object the endeavor to find out upon what factors the great diversity in the characters of infectious swine diseases depends." PROF. SMITH says:

"Thus far we have found a well-defined bacillus associated with outbreaks of hog cholera in a considerable number of localities, both in the East and the West. The relation of this bacillus to the disease is unquestioned. Furthermore, this bacillus occurs under a number of varieties, whose chief distinguishing character lies in the varying degree of pathogenic activity. Some are more, others less virulent, and the type of disease produced in swine is correspondingly varied. The outbreak from which a few cases are reported in full (on page 27), and from which a well-defined variety was isolated, differs in important particulars from other types of uncomplicated hog cholera in the greater duration of the disease and the peculiar diphtheritic character of the inflammation of the intestines. The confusion existing even to-day in the minds of many authorities on the subject of swine diseases, expressing itself in the multitudinous names which have been given to them, evidently rests in part on the different types which hog cholera assumes as a consequence of the pathogenic variability of the bacillus.

"Our experiments have furthermore shown that the different degrees of susceptibility may produce quite a variation in the character of the disease, and that when a certain degree of immunity has been produced in rabbits it would be impossible to foretell what form the inoculation disease would assume. It might become localized in the intestines or the lungs, or even in the brain. Swine plague might appear as a peritonitis or a pleuritis with or without pneumonia, or in the form of one or more abscesses. This interesting fact is at present of most service to the investigator, because he will be better able to identify obscure diseases. It is needless to insist on the importance of this knowledge. The presence of mild, chronic hog cholera or swine plague in a herd may be fully as dangerous as the more acute disease, for mild disease is frequently caused by highly virulent bacteria. This has been fully brought out in the foregoing pages. Rabbits which, through vaccination, have lived many months after inoculation, have continued to carry disease germs in their body virulent enough to kill unvaccinated rabbits in twenty hours."

Concerning the immunity produced by vaccination, PROF. SMITH says:

"Another fact of considerable importance is the relative character of the immunity produced by vaccination. An animal which before preventive inoculation possessed a high degree of susceptibility may after treatment, no longer contract an acute rapidly fatal disease but one of a more chronic character which, dragging itself along for months and rendering the animal worthless, may form the starting point of subsequent outbreaks among newly introduced or younger animals. This state of affairs has been noticed in Europe after vaccination against rouget, or swine erysipelas, a disease of swine thus far not found in this country. While it is not of sufficient importance to militate against the use of successful vaccines, it should nevertheless not be lost sight of in a final estimate of the value of vaccination methods as a whole. Our observations on hog cholera lead me to believe that even if a fairly successful and cheap method of vaccination against hog cholera could be devised, the result would be that a number of animals would contract a chronic type of the disease after infection, and these would have all the objectionable features of worthless animals scattering infection about for months."

The results of the observations thus summarized by PROF. SMITH are conservative, and should serve to put a stop to crude uncontrolled experimentation by observers with insufficient facilities. Much injury to the cause of science has been done by vaccination of herds with virus of uncertain character. Definite and beneficial results are only to be expected from long continued and careful experimentation by trained bacteriologists, such as the Bureau is now developing.

RAILWAY TRAVEL OF CONSUMPTIVES.

Among other things which the settlement of the great strike will give railway managers opportunity to attend to is the provision of proper accommodations for the segregation of consumptive railway travelers from ordinary passengers in the obvious interest of the public health. This provision will doubtless be hastened by the publication of such observations as the following from a letter to the *Pacific Medical Journal* by DR. DOUGLASS W. MONTGOMERY, written on "a trip to the Eastern States." The writer says: "In our sleeper were three consumptives returning home to die, and that alone was depressing enough, but when, on getting up in the morning, one sees a considerable amount of dry, yellow sputum on one's *vis-a-vis* neighbor's bed linen, it is neither dainty nor reassuring. Morning cogitations, usually so pleasant, are apt to turn to the uncomfortable possibility of all the bedding in the car being subjected from time to time to the same infection, and being probably imperfectly washed, or simply rinsed. Then it is impossible to clean the upholstery and carpeting without taking them out of the car, and an infected sleeper should be dangerous as the continual vibration keeps the dust and bacteria in the air. The space is also necessarily confined. Moreover, travelers are apt to catch cold from drafts

and from sleeping close to the windows, thereby rendering the mucous membranes receptive to germ implantation."

They order these things better in Europe; on some of the Continental lines special coaches are provided for consumptives, and these are constructed with particular reference to ready cleansing and disinfection at the end of every trip—which, it should be noted, are much shorter than the "runs" in this country, and the need of precautions is, therefore, and for so much, greater here than abroad.

CORRESPONDENCE.

Status of an Eclectic.

COLUMBUS, OHIO, July 14, 1894.

To the Editor:—I hope you will answer with care the question of Dr. Q. C. Smith, on page 86 of your JOURNAL. Three Eclectics have just formally applied for membership in our local society—our Society being auxiliary to the AMERICAN MEDICAL ASSOCIATION—and some of our members are in a quandary. Two of these applicants are members of a local, eclectic medical society, and one is President of the State Eclectic Medical Society, and I understand they wish to retain membership therein. The three are all excellent gentlemen, without a personal enemy in the Society, but they are graduates of the *Eclectic Medical Institute* of Cincinnati, and some of our members hold them not eligible under the Code. They have never, by card, sign or otherwise, announced themselves other than simple "physicians," and furthermore, consultation is never refused them by their "regular" brethren. Indeed, some who bring forward the Code argument against admitting them, confess to meeting them in consultation whenever asked.

Personally, I am strongly in favor of admitting these applicants; and not only these, but all other *intelligent medical gentlemen* who will sign our Constitution and By-Laws, which include the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION.

"Regular" intolerance has been the bane of our profession and the key-stone of the success of all 'pathies.

Very truly yours,

J. F. BALDWIN, M.D.

ASSOCIATION NEWS.

Notice.—Officers of Sections are requested to hand in all remaining Section papers at once, as owing to the greatly enlarged size of the JOURNAL they will be reached earlier than heretofore. There are several Sections from which no papers have been received.

Section on Ophthalmology.—The Transactions of the Section on Ophthalmology of the AMERICAN MEDICAL ASSOCIATION for 1894, will be published in separate volume, uniform with 1891 and 1892; the cost per volume being, as heretofore, \$1.00. The publishers of the JOURNAL desire to know the exact number of subscribers before commencing the volume. If you desire a copy of the Transactions please notify me, enclosing amount.

Very truly,

LEWIS H. TAYLOR, Secretary.

41 South Franklin Street, Wilkesbarre, Pa., July 2, 1894.

Blank Applications for membership in the ASSOCIATION at the JOURNAL office.

SOCIETY NEWS.

The regular monthly meeting of the York County (Pa.) Medical Society was held August 2.

The Nicollet County Medical Society will meet at the State Hospital, St. Peter, Minn., August 11, at 7:30. Dr. Baker will present two cases of Huntington's chorea.

Southern Minnesota Medical Association.—At the annual meeting of the Southern Minnesota Medical Association, held at Winona Aug. 2-3, the following officers were elected for the ensuing year: President, J. B. McGaughey; Vice-Presidents, S. W. Ransom and A. S. Adams; Secretary and Treasurer, H. H. Witherstine. The next annual meeting will be held at Rochester, Minn.

Mitchell District Medical Society.—At the meeting of the Mitchell District Medical Society held at West Baden, Ind., July 25-26, the following officers were elected: President, Dr. J. A. Eastman, Indianapolis; Vice-President, Dr. Chas. W. Murphy, Salem, Ind.; Secretary, Dr. G. W. Burton, Mitchell, Ind.; Chairman Committee on Program, Dr. Samuel Kennedy, Shelbyville, Ind.; Chairman Committee on Arrangements, Dr. J. G. M. Yost, Mitchell, Ind. The next meeting will be held at Mitchell, Ind., Dec. 27-28, 1894. Arrangements are being made for one of the largest and most successful meetings in the history of this Society.

Iowa Public Health Association.—The fourth annual session of the Iowa Public Health Association will convene at Des Moines, Iowa, Thursday, and Friday, Sept. 6 and 7, 1894, at the Capitol Building. The meeting will be one of unusual interest and a large attendance is expected. Occurring as it does during the State Fair reduced rates are assured to all who wish to attend. This Society has upon its roster the names of some of the most noted scientific men and women within the State. Bear in mind that this is *not* a medical society. While many of the subjects are clearly allied to medicine and can not be divorced from it, yet physicians are in no sense an essential, though an important and honorable part of the Association. All persons interested in the prevention of sickness and in the promotion of the highest type of physical well-being, are cordially invited to become members. Physicians, lawyers, clergymen, school teachers, newspaper men, mechanics, artisans, farmers, officers in civic and military services, are all eligible to membership; and it is especially desirable that health physicians, mayors of cities and towns, presidents of boards of township trustees and township clerks shall be present and take an active part in the proceedings. Every point of sanitary science will be touched upon by some of the most prominent sanitarians of the State. We have the honor of enlisting among our collaborators the following persons who will address the meetings: J. F. Kennedy, Des Moines; E. H. Carter, Des Moines; Henry Sabin, Des Moines; A. R. Amos, Des Moines; W. W. Harris, Sioux City; Paschal Davis, Keokuk; J. F. Kempker, New Burlington; J. S. Stevens, Cedar Falls; F. W. Weiland, Dubuque; H. L. Getz, Marshalltown; A. P. Hanchett, Council Bluffs.

All persons wishing to prepare and read papers will please send their names with title of paper to the Secretary at once.

J. F. KENNEDY, Pres.,
Des Moines, Iowa.

P. J. FULLERTON, Sec.,

Raymond, Iowa.

The American Association of Obstetricians and Gynecologists will hold its seventh annual meeting at Toronto, Ont., Wednesday, Thursday and Friday, Sept. 19, 20 and 21, 1894, to which a cordial invitation is extended to the medical profession. The following is the preliminary program, sub-

ject to amendment until September 1, namely: President's address, George H. Rohé, Catonsville, Md.; Personal Experience with Pus Tubes: When to Operate, How to Operate, and the Results of Operation, Jas. W. Ross, Toronto, Ont.; Relation of Hysteria to Structural Changes in the Uterus and Adnexa, A. P. Clarke, Cambridge, Mass.; Demonstration of a Mechanism of Intussusception (rabbits), Robert T. Morris, New York; Nephrectomy, L. H. Dunning, Indianapolis; Treatment of Distension of the Fallopian Tubes without Laparotomy and Removal, F. A. Glasgow, St. Louis; Hysteria in Pregnancy, W. P. Manton, Detroit; Relations of Renal Insufficiency to Operations, Carlton C. Frederick, Buffalo; *a*, Importance of Recognizing Septic Puerperal Endometritis Early, and its Treatment; *b*, Demonstration of a Portable Operating Table for Gynecological and Abdominal (Trendelenburg) Work, Edward J. Ill, Newark, N. J.; Suspension of Retroflexed Uterus by the Uterovarian Ligaments, with report of Cases, Reuben Peterson, Grand Rapids, Mich.; The Element of Habit in Gynecic Disease, Geo. F. Hulbert, St. Louis; Some results of Ether Anesthesia in Abdominal Operations, I. S. Stone, Washington, D. C.; Report in Abdominal Surgery, presenting cases, A. Van der Veer, Albany; Supplementary Paper on Abdominal Section in Intrapelvic Hemorrhage, M. Rosenwasser, Cleveland; Conservative Midwifery, J. M. Duff, Pittsburgh; The Cause of the Thirst following Abdominal Section, Eugene Boise, Grand Rapids, Mich.; The Care of Pregnant Women, W. B. Dewees, Salina, Kan.

Discussion: Inflammatory Disease of the Uterus and Appendages and of the Pelvic Peritoneum. *a*, Introductory Remarks, William Warren Potter, Buffalo; *b*, Historical Sketch, Edward J. Ill, Newark, N. J.; *c*, Clinical History, C. A. L. Reed, Cincinnati, Ohio; *d*, Causation and Pathology, Lewis S. McMurtry, Louisville, Ky.; *e*, Diagnosis and Prognosis, James F. W. Ross, Toronto, Can.; *f*, Treatment, M. Rosenwasser, Cleveland, O.; A. Van der Veer, Albany, N. Y.; J. H. Carstens, Detroit, Mich.; A. H. Cordier, Kansas City, Mo.; *g*, Results: *a*, When Untreated; *b*, Under Various Methods of Treatment, Joseph Price, Philadelphia, Pa.

Intercurrent Typhoid Fever in Pregnancy, Thomas E. McArdle, Washington, D. C.; Notes on a Case of Cholelithiasis, Frederick Blume, Alleghany, Pa.; Perineal Operations, Joseph Price, Philadelphia; Remarks Bearing on the Surgical Treatment of Intussusception in Infants, Based on Two Successful Cases, Henry Howitt, Guelph, Ont.; The Limitations of Surgery in the Treatment of the Uterus and its Appendages, William H. Myers, Fort Wayne, Ind.; The Incision in Abdominal Surgery: Methods and Results, J. H. Carstens, Detroit, Mich.; Abdominal Section in Ectopic Gestation, where the Fetus is Living and Viable, X. O. Werder, Pittsburg, Pa.; Subject to be announced, William E. B. Davis, Birmingham, Ala.; Hysterectomy for Cancer of the Uterus, E. W. Cushing, Boston, Mass.; Chronic Progressive Atrophy of the Vulva (Kaurosis Vulvæ); its Pathology and Radical Treatment, Charles A. L. Reed, Cincinnati, Ohio.

PUBLIC HEALTH.

The Environment of the Capital.—A valued correspondent—may his days increase—invites our attention to a lapsus calami whereby we were made to say that the environment of the District is notoriously unhealthy. This was the case many years ago, but not now, when the sanitary conditions have been improved by the reclamation of the Potomac flats, better sewerage and better surface drainage.

Dengue at Key West.—Dr. John Guiteras, Sanitary Inspector M. H. S., has investigated the reported epidemic of dengue at Key West, Fla., and confirms the views expressed in the JOURNAL of August 4. He reports that Dr. J. Y. Porter, State Health Officer of Florida, has made a careful study of some eighty cases and that his records will be of much value in establishing the differential diagnosis between dengue and yellow fever. Dr. Guiteras adds: "In my opinion it is not true that dengue fever is a premonitory sign of a yellow fever epidemic. The two diseases have nothing in common. There are no cases of yellow fever in Key West and the epidemic prevailing is, without possible doubt, one of dengue."

The disease is spreading from the military post to the city.

Parva sed Apta.—The city of Zurich in Switzerland is about the size of Toledo, Ohio, and one-seventh the size of Philadelphia; but the press of the Quaker city is holding up the little burg as a fit model to follow. In 1884 when Zurich found typhoid fever in its water supply—a discovery, it is noted, made even earlier for Philadelphia—this little Swiss town set out to improve its supply, spent \$100,000 on new filters, \$200,000 on new reservoirs, and by using the water power thus secured, set up an electric light supply at a cost of \$235,000 and furnished light, arc and incandescent, at a profit of \$13,000. The Philadelphia Press pertinently asks: "We Americans think we are enterprising, but how long will it be before Philadelphia matches the work of this slow Swiss town and reduces its typhoid cases 90 per cent?"

Spread of Cholera.—Reports from Consular officers through the Department of State and from other sources furnish totals of 5,907 cases of Asiatic cholera, with 3,064 deaths, in 115 localities in Europe between May 15 and August 1, inst. These were distributed as follows: Russia, including Poland and Finland, 3,418 cases, 1,917 deaths, in 25 governments, towns and cities; Turkey, 1,984 cases, 951 deaths, in 32 localities; Belgium, 212 cases, 85 deaths, in 9 localities; Austria-Hungary, 209 cases, 91 deaths, in 11 localities; Germany, 44 cases, 13 deaths, in 17 localities; France, 33 cases, 6 deaths, in 16 localities; Sweden, 4, cases, 1 death, in 2 localities; Holland, 2 cases in 2 localities; Italy, 1 case. That these reports are incomplete is obvious—the St. Petersburg correspondent of the *British Medical Journal*, for example, reports 1,973 cases and 770 deaths in 19 days in that city alone; but the summary gives a fairly correct impression of the cholera situation in Europe up to date. Nowhere on the Continent, except in Russia and Turkey, has the disease assumed threatening proportions or appreciably affected the death rate. And yet there has been and still continues a sufficient spread to thoroughly test the sanitary régime of the countries exposed. Late Amsterdam dispatches report one cholera death in that city; seven new cases at Maestricht on the 4th; five new cases and three deaths at the same place on the 5th and 6th; one death at Haarlem and five cases at Halfweg. A dispatch of the 7th states that between July 29 and August 4 there were 313 new cases and 240 deaths in St. Petersburg; that in the city of Warsaw during the last week in July there were 159 new cases and 83 deaths, and that in the Province of Warsaw during the same period there were 394 new cases and 213 deaths. A Vienna dispatch of the 7th says that 16 districts in Galicia are infected and that during the previous two days there had been 127 new cases and 83 deaths in these districts. A London dispatch of the same date reports the arrival from St. Petersburg at Gravesend of a steamer on which a seaman had died from cholera the previous day. These and similar occurrences serve to keep sanitary authorities on the alert and the Local Government Board (Eng.) has issued a circular upon the desirability of the notification of diarrhea in order to facilitate the early detection of sporadic cases of cholera. Sanitary officers are reminded that the localized outbreaks of cholera in England last year were usually preceded by diarrhea, generally quite excessive in amount and often choleraic in type, and that the existence of this diarrhea was only discovered, in season to be of any use in detecting early and ill-defined cases of cholera, after the disease had been made the subject of notification. It is also seriously discussed whether Asiatic cholera is not becoming endemic in Europe—especially in Russia, where in the third consecutive year of its prevalence the disease has attained a severity greater than in either of the two preceding years. This probably is also made the

occasion for renewed sanitary effort and for further emphasis of Mr. Ernest Hart's axiom that one can not "catch" cholera—"However cholera may rage, it can not spread unless man swallows it. This protection is surely within the reach of civilization, namely, that man shall not drink defiled water; and in truth this is enough."

Diphtheria.—The increasing gravity of diphtheria as a factor of the public health is causing health authorities to put forth unusual effort for the prompt bacteriologic diagnosis of suspected cases. To the list of American cities whose boards of health undertake to make the necessary cultures and furnish the results to physicians free of charge must now be added Chicago. Notwithstanding the unusual recent demands upon the *personnel* of his department and upon its limited appropriations, Health Commissioner Reynolds has made a satisfactory beginning in this direction. The work is under the immediate supervision of Dr. Adolph Gehrman, director of the laboratory of the department, who has just issued the following circular to the profession:

The ability to differentiate cases of diphtheria quickly and certainly, by means of cultures of bacteria obtained from the throat, renders it important that such a method should be used as far as possible by the profession. Certain difficulties however prevent the general practitioner from carrying out all the details of the examination himself. In view of this the Department of Health offers the method as an aid to the profession at large.

The bacteriologic diagnosis of diphtheria cases involves the following:

1. Preparation of the proper culture medium and its distribution to doctors.
2. Inoculation of tubes from patients and return when so inoculated to the Department.
3. Cultivation and examination of the tubes in the Laboratory.
4. The rendering of reports of the results of the inoculation of the cultured tubes.

The Department has prepared wooden boxes containing tubes of culture material, throat swabs and the necessary blanks. The following directions and blank form accompany each box:

CITY OF CHICAGO, DEPARTMENT OF HEALTH.

(Directions for the Use of Cultures in the Diagnosis of Diphtheria.)

The wooden cases containing culture tubes and throat swabs may be obtained at any time by a physician or upon his order from the Department Clerk, Room 4, City Hall.

The blank form is to be filled out down to the double lines, and always returned with the case.

When making an inoculation the throat should be first well gargled with plain water to remove mucus and antiseptics. Remove the sterile swab from its tube and, without contact with other objects, rub it firmly against the suspicious area in the throat. Remove the cotton plug from the other tube, and rub the swab over the surface of the culture medium. Replace the swab in its own tube, and replace the cotton plugs. Send the outfit to the Department *at once*.

Cultures from diphtheria cases should be made as early as possible, as the bacillus sometimes disappears from the throat before the membrane.

In all cases when the outfit is not used, it is to be returned to the Department.

[Blank form].

The examination of cultures obtained and demonstrations as to the presence or absence of the diphtheria bacillus is a part of the work of the laboratory of the Health Department. Here the tubes will be incubated and examined when colonies appear. From here also the reports will be returned to the physicians. The culture medium used in this work is Löffler's blood-serum mixture, and also the urine-agar mixture of Schlöffler, upon which the diphtheria bacillus grows almost as readily and gives as characteristic results as upon the blood-serum. The bacillus will grow within twenty to twenty-four hours; that is, before any of the pus or other bacteria, that may be present in the throat, grow to any extent. In this way a growth of the diphtheria bacillus preceding other growths is obtained and a diagnosis is made. In general, reports may be returned by the noon of the day following delivery of the inoculated tubes.

Physicians who make these bacteriologic examinations themselves may be interested in the discovery of Dr. Klein, who has found that in diphtheritic membrane, formed while the progress of the disease is still active, the diphtheria bacilli abound, not only in the characteristic form, but also with the protoplasm segregated into spherical, cubical or cylindrical particles, with a knob-like or club-shaped enlargement of one or both ends, sometimes of great size and containing vacuoles; after from twenty-four to thirty-six hours in agar culture, when the growth is in its initial and most active phase, large numbers of the bacilli occur which are shorter or longer threads with marked segregation of the protoplasm and with terminal knobs. Dr. Klein thus finds that "though the Löffler bacillus under many conditions conforms with what corresponds to a typical bacillus, these threads, with the local accumulation of their substance, and with the terminal knob-like or club-shaped enlargement of their protoplasm, do not harmonize with the fundamental character of a bacillus, but rather suggest a close alliance with the form of a mycelial fungus."

As to the curative treatment of diphtheria by antitoxin its present status is summed up in the address of Sir Henry Roscoe at a recent meeting of the British National Health Society. The diphtheria antitoxin—produced by the immunization of goats through the injection of increasingly virulent cultures of the diphtheria bacillus—is contained in the serum in varying proportions; but Behring and Kitato have devised a method of measuring accurately the exact amount present, and have thence established an immunity unit or standard of antitoxin potency. With injections of quantities of serum containing antitoxin representing 130 to 200 immunity units, as thus ascertained, 220 children suffering from diphtheria in all its stages—as proved by bacteriologic examination—were treated in various hospitals in Berlin. Of 6 cases treated during the first twenty-four hours all recovered, and of 66 treated during the second twenty-four hours only 2 died; thus of 72 cases treated during the first forty-eight hours only 2 died. Tracheotomy was necessary in 9 of these cases and the 2 deaths were of this group. During the third twenty-four hours 29 cases were treated and of these 4 died; during the fourth, 39, of whom 9 died; and on the fifth, 23, of whom 10 died. The percentages of recovery, according to period of treatment, were therefore 100 per cent., 97 per cent., 86 per cent., 77 per cent. and 56.5 per cent. In most of these cases only one injection, representing 130 to 200 immunity units of antitoxin, was used, and it is now believed that some of those who died might have been saved had repeated injections been made. In their preliminary report the physicians, Ehrlich, Kossel and Wassermann, who conducted these

investigations, submit the following as their conclusions:

"1. The fate of patients depends on the treatment during the first three days of the disease; hence the serum should be injected as soon as possible after its commencement; 2, in mild cases the amount introduced should be at least 200 immunity units; in severe cases, and in those where tracheotomy is necessary, 400 units; 3, the injections should be repeated on the same or the following day, according to the general and local symptoms; the total amount varying according to the severity of the case, from 500 to 1,500 immunity units. In 30 cases where repeated injections were employed—some of them very severe cases, 16 of them requiring tracheotomy—only 4 died; these 4 having had tracheotomy done with little or no relief to the breathing." The *British Medical and Surgical Journal*, which editorially anticipates the antitoxin treatment of diphtheria as "a new boon to humanity," promises that full details of the methods and cases will be published as soon as possible and urges that the treatment be put to the test elsewhere—as it has been already in Paris with most satisfactory results.

NECROLOGY.

ALBERT B. MILES, M.D., of New Orleans, died August 5. Dr. Miles was born at Prattville, Ala., in 1852. At the age of 16, he entered the Gordon Institute of Southern Arkansas, where he remained two years. In 1870 he entered the academic department of the University of Virginia. In 1875 he graduated in medicine in the University of Louisiana and delivered the valedictory of his class. Two months after graduation he was elected Demonstrator of Anatomy in the medical department of the University of Louisiana. In 1876, he was elected Visiting Physician to the Charity Hospital. In March, 1881, he was appointed physician-in-charge of the Hotel Dieu, the infirmary of the Sisters of Charity. In the following year he was elected House Surgeon to the Charity Hospital, a position which he held until his death. In 1886, he was elected Professor of Materia Medica, Therapeutics and Hygiene of the Medical Department of the Tulane University. In 1893, after the death of Dr. Samuel Logan, he was selected to fill the chair of surgery, which he held with distinction up to the time of his death.

He was a member of the New Orleans Medical Association, the New Orleans Parish Medical Society, the Louisiana State Medical Society and the Southern Surgical and Gynecological Association. Dr. Miles was unmarried.

Judson B. Andrews, M.D., Superintendent of the Buffalo (N. Y.) State Hospital for the Insane, died August 3. He had been in charge of the Asylum since it was opened in 1880, and was a pioneer in instituting new methods of treatment for the insane. He was ex-President of the Erie County Medical Society, a founder member, and ex-President of the New York State Medical Association and President of the Section of Psychological Medicine and Nervous Diseases of the Ninth International Medical Congress, held in Washington in 1887. In 1892 he was elected President of the American Medico-Psychological Association. He was a frequent contributor of papers to medical societies and journals. For many years he was Assistant Superintendent of the State Insane Asylum at Utica, and for ten years working editor of the *American Journal of Insanity*. He was a captain and later a surgeon in the Connecticut Volunteer service during the rebellion. Dr. Andrews was a prominent Mason, and member of the G. A. R., and many other orders. He was 60 years old.

Francis M. Knipe, M.D., of Pottstown, Pa., Aug. 4, aged 60. He served in the Legislature in 1875, 1876 and 1878.

E. B. Dunning, M.D., of PawPaw, Mich., August 3, aged 65.

A. H. Kimball, M.D., of Battle Creek, Mich., August 6, aged 44.

James F. Fraley, M.D., of Fairbury, Ill., July 31, aged 83.

MISCELLANY.

Resignation of Pettenkofer.—The veteran sanitarian, Prof. Max von Pettenkofer, has resigned from the University of Munich, through pressure from Berlin exerted, as is alleged, on account of the Professor objecting to certain of the anti-cholera measures recommended by Dr. Koch. It is reported that a great deal of public indignation has been aroused in consequence.

A Lapsus Calami.—In the issue of June 30, we noted a gratuitous combination of items, in which the notice of a meeting of a medical society was immediately followed by a prescription for sexual debility, and erroneously attributed the same to the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. Our esteemed contemporary very properly confines advertisements of proprietary medicines to the outside pages where they belong, and we regret having, through pure accident, done this injustice.—*Medical Record*, Aug. 4, 1894.

Canceromyces.—In a recent number of the *Centralblatt f. d. Medicinischen Wissenschaften*, Dr. van Nissen, of Wiesbaden, furnishes a brief account—which he promises to supplement shortly by a fuller description—of a microorganism which he has found in cancerous tissue and which he is led by his experiments to regard as the cause of cancer. In cultures the cell-groups bear a very close resemblance to the so-called epithelial cell nests of carcinoma. Van Nissen calls this new microbe *Claspodium cancerogenes*—or canceromyces, for short.

Kentucky Medical Practice Act.—Notice is given that the Kentucky State Board of Health will meet in Louisville some time during September, for the purpose of examining those physicians not possessing a diploma, and who have not already passed a satisfactory examination. This will be the last opportunity for non-graduates to qualify for practice in Kentucky under the new law. Thenceforth the only recognized qualification will be the diploma of a reputable college secured by regular attendance upon the prescribed course of lectures and compliance with the other requirements for graduation.

Use of Death Certificate Does not Waive Privilege.—The plaintiff in an action on a life insurance policy does not, by the introduction in evidence of a physician's certificate of death, waive the protection which he or she might claim under the provisions of such a statute as section 834 of the New York Code of Civil Procedure, which prohibits a physician testifying as to information received in the course of professional employment. So holds the General Term of the Supreme Court of New York in the case of *Redmond v. Industrial Benefit Association*, decided May 8, 1894. Nor does such certificate, it further declares, absolve the physician making it from all the duties and obligations imposed upon him by that return.

Medical Practice in France.—Under the new French medical law the government no longer has the power to authorize medical men having only foreign diplomas to practice in France. No physician is now allowed to practice in that country unless he possesses a French diploma of doctor of medicine; and this is to be obtained only by passing such an examination as may be prescribed by one of the recog-

No. 7.

ADDRESS.

CHAIRMAN'S ADDRESS.

Read before the Section on State Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY GEORGE W. STONER, M.D.

BALTIMORE, MD.

SURGEON UNITED STATES MARINE-HOSPITAL SERVICE.

It affords me pleasure, ladies and gentlemen of the Section on State Medicine, to congratulate you on this, the forty-seventh anniversary of the birth of the AMERICAN MEDICAL ASSOCIATION.

In 1847 great discoveries¹ were made in California, and that year marked the beginning of gigantic strides in the development of a great State. But great as that discovery was and rich as have been its results, who will say that the advent of your ASSOCIATION was not even of greater moment to the people of the whole country?

It is not within the chairman's province, nor would it be possible in the few moments at my disposal, to recite even the faintest outline of the work of the ASSOCIATION during the forty-seven years of its existence. Suffice it to say that the volumes of Transactions and the JOURNAL are in themselves a library of such monumental proportions that comparatively few practitioners have the time or opportunity to peruse their contents. Fortunately, for us, this is not necessary, for the very fountain-head of the ASSOCIATION is still with us, and no reference to the history or active work of the AMERICAN MEDICAL ASSOCIATION or the Section of State Medicine would be complete without mentioning the name of Prof. N. S. Davis, M.D., L.L.D., of Chicago, Ill.

It is only necessary to refer to his paper on "The AMERICAN MEDICAL ASSOCIATION and its Relations to Public Health," read in this Section at the annual meeting in June, 1889, to learn that "although the primary and potent influences that prompted the movement that resulted in the assembling of the convention of delegates in the City of New York, May, 1846, to effect a permanent National organization of the profession of the United States of America, was the desire to elevate the standard of professional education and thereby increase the usefulness and honor of the profession; yet even that preliminary convention did not pass without initiating important measures having a direct bearing on the interests of public health." A committee of five was appointed "to urge" and it did urge "upon the several State Governments the adoption of measures for the registration of the births, marriages and deaths of their several populations." The next year when the convention assembled in Philadelphia a standing committee was appointed with the same object in view, and when the whole organization was

completed—or rather after it was commenced and had been christened the AMERICAN MEDICAL ASSOCIATION, the work of the said committee was so persistently and effectually prosecuted that one State after another fell into line until, at the time of his writing in 1889, "but few States in the Union were without laws of more or less efficiency on the important subject of vital statistics."

It would be impossible to over-estimate the importance of this early movement in the direction of the proper registration of vital statistics, for it is only after the attention of the people of any community is called to the mortality reports that any active or substantial support can be obtained in efforts at sanitary improvement; and as a matter of fact it is only by this means that health officers and sanitarians themselves can arrive at a proper understanding of the healthfulness and relative salubrity of different localities or, on the other hand, can see the necessity for ways and means for the discovery and, if possible, for the eradication of disease and death producing agencies.

At the next meeting, the second of the ASSOCIATION proper, in Baltimore, 1848, a "Committee on Hygiene" consisting of twelve members was appointed; and at the fourth meeting of the ASSOCIATION, in Boston, 1849, general reports were presented on the subject of street cleaning, water supply, drainage, ventilation, disinfectants, etc., and special papers on the sanitary condition of different cities. These reports and papers are masterpieces of the time in which they were written, and without them the sanitary history of a number of cities and towns and of States in the East and South would be incomplete.

Two years later, in 1851, the standing committees were abolished and the work was divided among a large number of special or district committees, covering the several States of the Union.

In the course of a few years the reports of these committees became so voluminous that notwithstanding their value concerning public hygiene, practical medicine and epidemic disease, many of them were of necessity read by title only and referred for publication.

At the annual meeting of 1859, on motion of Dr. J. B. Lindsley, of Tennessee, supported by Dr. Daniel Brainard, "a committee of three was appointed by the chair to inquire into and report upon the propriety of dividing the ASSOCIATION into Sections, for the purpose of performing such parts of its scientific labor as may relate to particular branches of medicine and surgery."

The committee recommended five divisions, and after a strong speech in its favor by Dr. N. S. Davis, the report of the committee was adopted and an amendment to the By-laws was authorized, limiting the general sessions to the forenoon of each day, and providing for the division of the ASSOCIATION into

¹ Gold.

five Sections: 1, Anatomy and Physiology; 2, Chemistry and *Materia Medica*; 3, Practical Medicine and Obstetrics; 4, Surgery; 5, Meteorology, Medical Topography, Epidemic Diseases, Medical Jurisprudence and Hygiene.

The Section plan was brought into active operation the year following and, with some changes and more additions has been in existence ever since that time. The short and somewhat comprehensive title of this Section, State Medicine, being the legitimate outcome of Section 5 already referred to.

What this Section, as part of the General Association, has accomplished in all these years of its usefulness is a matter of history. Previous to the organization of the AMERICAN MEDICAL ASSOCIATION there were comparatively few medical societies in existence and there was no *medical code* of National scope. State and county and city societies are now numbered by the thousands; and boards of health are no longer the exception but the rule in nearly all the States and municipalities, and in some instances have extended to the smallest divisions and subdivisions of the counties; as for example the law recently enacted in the State of Pennsylvania, providing for the establishment of boards of health in every borough and township in the State.

But if the ASSOCIATION has done so much in directing the thought and action of physicians collectively in the management of disease and in the line of preventive medicine or State medicine, if you please, how much more has its influence accomplished in the making of the physician himself? A mere comparison of the curriculums and the methods of teaching the science of medicine to-day with the method, or lack of method, that prevailed only a comparatively few years ago will answer the question satisfactorily to all who have eyes to see and ears to hear.

In these reform movements, however, and in our gratulation we must not forget the younger sister associations. Too much credit can not be given to the American Public Health Association now just coming of age,² and to the Medical College Association, and especially to our friend and associate and former chairman, the late Dr. John H. Rauch. To him, more perhaps than to any other individual, must be ascribed the credit for the rapid advancement towards the higher plane of medical education and sanitary science in this country. Dr. Rauch was, as you all know, for many years Secretary of the Illinois State Board of Health, and what that Board has accomplished need not be recited at this time. Its annual reports are entitled to a high place in medical literature. Ten years ago the *Boston Medical and Surgical Journal* in commenting on the report of that year said: "It represents a stupendous amount of labor, reflecting infinite credit upon its author, Dr. John H. Rauch, the Secretary of the Board, who deserves the thanks of every physician, student and patient in North America, for his unwearied efforts to obtain and present in available form the valuable information it supplies."

This encomium for the Illinois State Board of Health may also be applied to other State boards. All are doing good work, and some of them are said "to rival the boards of health in the general governments of the most enlightened countries in the world, especially in the immediate practical results of their work."³

The principle seems to be firmly established that it is the duty of the State to pass laws for the restriction or prevention of contagious or infectious disease, and it is through the proper enactment and execution of such laws that the most powerful argument can be brought to bear upon the general government for additional, supplemental, or controlling legislation in everything pertaining to public health or State Medicine.

One of the very first quarantines in the United States was established by the State (then the Province) of Pennsylvania in the year 1700. The title of the act was "An Act to prevent sickly vessels coming into this Government." The following is the text:

"WHEREAS, It hath been found by sad experience, that the coming and arriving of unhealthy vessels at the Ports and Towns of this Province and Territories, and the Landing of their Passengers and Goods before they have lain some time to be purified, hath proved very detrimental to the Health of the Inhabitants of this Province.

"Be it therefore Enacted by the Proprietary and Governor, by and with the Advice and Consent of the Freemen of this Province and Territories in General Assembly met and by the Authority of the same, That from and after the Publication hereof no unhealthy or sickly Vessels coming from any unhealthy or sickly Place whatsoever, shall come nearer than one mile to any of the Towns or Ports of this Province or Territories, without Bills of Health; nor shall presume to bring to shore such Vessels nor to land such passengers or their Goods at any of the said Ports or Places until such time as they shall obtain a License for their Landing at Philadelphia from the Governor and Council or from any two Justices of the Peace of any other Port or County of this Province or Territories under the Penalty of *One Hundred Pounds* for every such unhealthy Vessel so Landing as aforesaid, to the use of the Proprietary and Governor, and that suitable Provision be ordered by the Governor and Council for their Reception if they shall be permitted to Land or come on Shore."

The next year, in 1701, Massachusetts passed a similar act: "An Act providing in case of sickness, That for the better preventing the spreading of Infection, etc.," and in 1723 an additional act was passed "requiring Vessels to anchor near the House (quarantine hospital) on Spectacle Island provided at the Charge of the Province." The penalty for violating the law in this Province was in case of master of vessel fifty pounds; sailors and passengers were fined only ten pounds. This act was in the nature of an experiment and was limited to the end of the session of the court in which it was enacted. It was revived, however, by a later Act, and continued in force until the end of the session of the General Court in May, 1728.

The first National law was passed by the United States Congress in 1799. (R. S. 4792):

"The quarantines and other restraints established by the health laws of any State respecting any Vessels arriving in, or bound to, any port or district thereof, shall be duly observed by the officers of the Customs revenue of the United States, by the Masters and crews in any port or station upon the seacoast; and all such officers of the United States shall faithfully aid in the execution of such quarantine and health laws according to their respective powers and within their respective precincts and as they shall be directed from time to time by the Secretary of the Treasury."

Other Sections of this Act provide: *a*, for the discharge of cargo of vessel in quarantine; *b*, for the erection of quarantine warehouses; *c*, for extending time for entry of vessels, subject to quarantine; *d*, for removal of revenue officers from port when contagious or epidemic disease prevails; *e*, for removal

² Organized in 1873.

³ Dr. Baker, Secretary State Board of Health of Michigan, President's Address, American Public Health Association, 1890.

of public offices from the capital; *f*, for the adjournment of United States courts when contagious or epidemic sickness shall render it hazardous to hold the next stated session of the Court at the seat of Government; *g*, for the removal of prisoners to the next adjacent prison where contagious or epidemic disease does not prevail.

It was under this law nearly one hundred years later, in 1875, that the first circular letter of instructions was issued to United States officers, defining their duties with reference to quarantine and public health. The medical officers of the Marine-Hospital Service were especially directed to inform themselves fully as to the local health laws and regulations based thereon and in force at their respective ports and stations; and strict compliance with such laws and prompt assistance in the enforcement of the same, when requested by competent authority were enjoined.

In 1878 a law was passed establishing a National quarantine. It was entitled, "An Act to prevent the introduction of contagious or infectious diseases into the United States," and it charged the Supervising Surgeon-General of the Marine-Hospital Service, under the direction of the Secretary of the Treasury, "with the execution of the provisions of the Act," and empowered him "to frame all needful rules and regulations," subject to the approval of the President, but "not to conflict with or impair any sanitary or quarantine laws or regulations of any State or municipal authorities."

This was a good law so far as it went, but was incomplete in that no appropriation was made to carry it into effect. Under its provisions, however, medical officers of the Marine-Hospital Service and Customs officers were required to "aid in the enforcement of the National quarantine rules and regulations," and in this manner considerable aid was furnished to municipal and State health officers; and the *Weekly Bulletin of Public Health* was issued from the office of the Supervising Surgeon-General. During this same year (1878) the terrible yellow fever epidemic occurred in the Mississippi Valley and in February following, Congress passed another law (Act approved Feb. 3, 1879) establishing the National Board of Health. The latter act embodied all the essential provisions of the former, but changed the executive authority and carried with it a large appropriation which enabled the several members of the Board and the experts they employed to accomplish a great amount of good work.

But the large appropriation for the support of this Act was limited to a period of four years, and at the expiration of that time the active operations of the Board virtually came to an end. The law of 1878 was then revived and became operative by means of the contingent fund appropriated by Congress to be expended by the President of the United States in his discretion, in preventing the spread of epidemic disease and in maintaining quarantines at points of danger.

The work contemplated by the appropriation act was then continued through the agency of the Marine-Hospital Service in aid of State and local boards of health, and in accordance with the Act of April 29, 1878.

The precedent thus established of requiring the medical officers of the Marine-Hospital Service to perform the active work of quarantine has been fol-

lowed up to this time; and by the recent Act of Congress (approved Feb. 15, 1893) additional quarantine powers have been granted and additional duties imposed on the Service, making it in reality and in addition to its ordinary functions a general maritime quarantine and public health service.

Under the laws of 1878 and 1879, quarantine stations were established at several points on the Atlantic coast, and inspection stations at various times were maintained at points of danger on the frontier. Sanitary inspectors were also stationed at Havana and Vera Cruz to give prompt notification relative to the sailing of vessels bound for the United States so as to aid in the prevention of the introduction of yellow fever. At London and Liverpool, inspectors were appointed to give timely information of the shipment of Egyptian rags or any other articles sent through those ports from infected localities. Inspectors were also appointed at the principal European ports to inspect vessels and emigrants bound for the United States. In 1885 a section for the government of National quarantine was added to the regulations of the Marine-Hospital Service, and the whole was approved by the Secretary of the Treasury and by the President of the United States. In January, 1886, the publication of the *Weekly Abstract of Sanitary Reports*, as required by the Act of 1878 was resumed. In 1888 a law was passed (approved August 1) making the National quarantines⁴ on the Atlantic and Gulf coasts permanent institutions and providing for the establishment of three stations on the Pacific coast. An appropriation of \$500,000 was made to carry out the purpose of this Act. In 1890 an act was passed to prevent the introduction of contagious diseases from one State to another and for the punishment of certain offenses.

The latest and most comprehensive legislation affecting the maritime quarantine, and the nearest approach to legislation contemplating a complete National quarantine service, is contained in the Act (approved Feb. 15, 1893) already referred to, granting additional quarantine powers and imposing additional duties upon the Marine-Hospital Service. The following is the text:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That it shall be unlawful for any merchant ship or other vessel from any foreign port or place to enter any port of the United States except in accordance with the provisions of this act and with such rules and regulations of State and municipal health authorities as may be made in pursuance of, or consistent with, this act; and any such vessel which shall enter, or attempt to enter, a port of the United States in violation thereof shall forfeit to the United States a sum, to be awarded in the discretion of the court, not exceeding five thousand dollars, which shall be a lien upon said vessel, to be recovered by proceedings in the proper district court of the United States. In all such proceedings the United States district attorney for such district shall appear on behalf of the United States; and all such proceedings shall be conducted in accordance with the rules and laws governing cases of seizure of vessels for violation of the revenue laws of the United States.

SEC. 2.—That any vessel at any foreign port clearing for any port or place in the United States shall be required to obtain from the consul, vice-consul, or other consular officer of the United States at the port of departure, or from the medical officer where such officer has been detailed by the President for that purpose, a bill of health, in duplicate, in

⁴ National Maritime Quarantines are located at Tortugas Islands, Fla.; Blackbeard's Island, Ga.; Cape Charles, Va.; Delaware Breakwater, Del.; Reedy Island, Delaware River; Port Townsend, Washington; San Francisco and San Diego, Cal.

The quarantine station at Chandeleur Island in the Gulf was destroyed last season by a hurricane, and in this terrible disaster the steward and several employes lost their lives.

the form prescribed by the Secretary of the Treasury, setting forth the sanitary history and condition of said vessel, and that it has in all respects complied with the rules and regulations in such cases prescribed for securing the best sanitary condition of the said vessel, its cargo, passengers, and crew; and said consular or medical officer is required, before granting such duplicate bill of health, to be satisfied that the matters and things therein stated are true; and for his services in that behalf he shall be entitled to demand and receive such fees as shall by lawful regulation be allowed, to be accounted for as is required in other cases.

The President, in his discretion, is authorized to detail any medical officer of the Government to serve in the office of the consul at any foreign port for the purpose of furnishing information and making the inspection and giving the bills of health hereinbefore mentioned. Any vessel clearing and sailing from any such port without such bill of health, and entering any port of the United States, shall forfeit to the United States not more than five thousand dollars, the amount to be determined by the court, which shall be a lien on the same, to be recovered by proceedings in the proper district court of the United States. In all such proceedings the United States district attorney for such district shall appear on behalf of the United States; and all such proceedings shall be conducted in accordance with the rules and laws governing cases of seizure of vessels for violation of the revenue laws of the United States.

Sec. 3.—That the Supervising Surgeon-General of the Marine-Hospital Service shall, immediately after this act takes effect, examine the quarantine regulations of all State and municipal boards of health, and shall, under the direction of the Secretary of the Treasury, cooperate with and aid State and municipal boards of health in the execution and enforcement of the rules and regulations of such boards and in the execution and enforcement of the rules and regulations made by the Secretary of the Treasury to prevent the introduction of contagious or infectious diseases into the United States from foreign countries, and into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia; and all rules and regulations made by the Secretary of the Treasury shall operate uniformly and in no manner discriminate against any port or place; and at such ports and places within the United States as have no quarantine regulations under State or municipal authority, where such regulations are, in the opinion of the Secretary of the Treasury, necessary to prevent the introduction of contagious or infectious diseases into the United States from foreign countries, or into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia, and at such ports and places within the United States where quarantine regulations exist under the authority of the State or municipality which in the opinion of the Secretary of the Treasury, are not sufficient to prevent the introduction of such diseases into the United States, or into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia, the Secretary of the Treasury shall, if in his judgment it is necessary and proper, make such additional rules and regulations as are necessary to prevent the introduction of such diseases into the United States from foreign countries, or into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia, and when said rules and regulations have been made they shall be promulgated by the Secretary of the Treasury and enforced by the sanitary authorities of the States and municipalities, where the State or municipal health authorities will undertake to execute and enforce them; but if the State or municipal authorities shall fail or refuse to enforce said rules and regulations the President shall execute and enforce the same and adopt such measures as in his judgment shall be necessary to prevent the introduction or spread of such diseases, and may detail or appoint officers for that purpose. The Secretary of the Treasury shall make such rules and regulations as are necessary to be observed by vessels at the port of departure and on the voyage, where such vessels sail from any foreign port or place to any port or place in the United States, to secure the best sanitary condition of such vessel, her cargo, passengers, and crew; which shall be published and communicated to and enforced by the consular officers of the United States. None of the penalties herein imposed shall attach to any vessel or owner or officer thereof until a copy of this act, with the rules and regulations made in pursuance thereof, has been posted up in the office of the consul or other consular officer of the United States for ten days, in the port from which said vessel sailed; and the certificate

of such consul or consular officer over his official signature shall be competent evidence of such posting in any court of the United States.

Sec. 4.—That it shall be the duty of the Supervising Surgeon-General of the Marine-Hospital Service, under the direction of the Secretary of the Treasury, to perform all the duties in respect to quarantine and quarantine regulations which are provided for by this act, and to obtain information of the sanitary condition of foreign ports and places from which contagious and infectious diseases are or may be imported into the United States, and to this end the consular officer of the United States at such ports and places as shall be designated by the Secretary of the Treasury shall make to the Secretary of the Treasury weekly reports of the sanitary condition of the ports and places at which they are respectively stationed, according to such forms as the Secretary of the Treasury shall prescribe; and the Secretary of the Treasury shall also obtain, through all sources accessible, including State and municipal sanitary authorities throughout the United States, weekly reports of the sanitary condition of ports and places within the United States, and shall prepare, publish, and transmit to collectors of customs and municipal health officers and other sanitarians, weekly abstracts of the consular sanitary reports and other pertinent information received by him, and shall also, as far as he may be able, by means of the voluntary cooperation of State and municipal authorities, of public associations and private persons, procure information relating to the climatic and other conditions affecting the public health, and shall make an annual report of his operations to Congress, with such recommendations as he may deem important to the public interest.

Sec. 5.—That the Secretary of the Treasury shall from time to time issue to the consular officers of the United States and to the medical officers serving at any foreign port, and otherwise make publicly known, the rules and regulations made by him, to be used and complied with by vessels in foreign ports, for securing the best sanitary condition of such vessels, their cargoes, passengers, and crew, before their departure for any port in the United States, and in the course of the voyage; and all such other rules and regulations as shall be observed in the inspection of the same on the arrival thereof at any quarantine station at the port of destination and for the disinfection and isolation of the same, and the treatment of cargo and persons on board, so as to prevent the introduction of cholera, yellow fever, or other contagious or infectious diseases; and it shall not be lawful for any vessel to enter said port to discharge its cargo, or land its passengers, except upon a certificate of the health officer at such quarantine station certifying that said rules and regulations have in all respects been observed and complied with, as well on his part as on the part of the said vessel and its master, in respect to the same and to its cargo, passengers and crew; and the master of every such vessel shall produce and deliver to the collector of customs at said port of entry, together with the other papers of the vessel, the said bills of health required to be obtained at the port of departure and the certificate herein required to be obtained from the health officer at the port of entry; and that the bills of health herein prescribed shall be considered as part of the ship's papers, and when duly certified to by the proper consular or other officer of the United States, over his official signature and seal, shall be accepted as evidence of the statements therein contained in any court of the United States.

Sec. 6.—That on the arrival of an infected vessel at any port not provided with proper facilities for treatment of the same, the Secretary of the Treasury may remand said vessel, at its own expense, to the nearest National or other quarantine station, where accommodations and appliances are provided for the necessary disinfection and treatment of the vessel, passengers and cargo; and after treatment of any infected vessel at a National quarantine station, and after certificate shall have been given by the United States quarantine officer at said station that the vessel, cargo, and passengers are each and all free from infectious disease, or danger of conveying the same, said vessel shall be admitted to entry to any port of the United States named within the certificate. But at any ports where sufficient quarantine provision has been made by State or local authorities the Secretary of the Treasury may direct vessels bound for said ports to undergo quarantine at said State or local station.

Sec. 7.—That whenever it shall be shown to the satisfaction of the President that by reason of the existence of cholera or other infectious or contagious diseases in a foreign country there is serious danger of the introduction of

the same into the United States, and that notwithstanding the quarantine defense this danger is so increased by the introduction of persons or property from such country, that a suspension of the right to introduce the same is demanded in the interest of the public health, the President shall have power to prohibit, in whole or in part, the introduction of persons and property from such countries or places as he shall designate and for such period of time as he may deem necessary.

SEC. 8.—That whenever the proper authorities of a State shall surrender to the United States the use of the buildings and disinfecting apparatus at a State quarantine station, the Secretary of the Treasury shall be authorized to receive them and to pay a reasonable compensation to the State for their use, if in his opinion they are necessary to the United States.

SEC. 9.—That the Act entitled, "An Act to prevent the introduction of infectious or contagious diseases into the United States, and to establish a National Board of Health," approved March 3, 1879, be, and the same is hereby, repealed. And the Secretary of the Treasury is directed to obtain possession of any property, furniture, books, papers, or records belonging to the United States which are not in the possession of an officer of the United States under the Treasury Department which were formerly in the use of the National Board of Health or any officer or employé thereof.

New quarantine regulations were framed by a board⁵ of surgeons under the direction of the Supervising Surgeon-General immediately after the law was passed, and the said regulations were promulgated by the Secretary of the Treasury. Under the provisions of the law, medical officers of the Marine-Hospital Service were, last year when cholera threatened, detailed by the President to serve in the office of and in association with the United States consular officers at various foreign ports, and from them all necessary information was received relative to the sanitary condition of vessels, cargo, crew and passengers about to depart for the United States. By this means the consular bill of health was made to be a certificate of actual observation by a responsible medical officer whose sole duty was to prevent, if possible, the introduction of contagious and infectious diseases into the United States.

Under the laws of March 3, 1891 and March 3, 1893, all immigrants arriving in this country are examined and passed upon by medical officers of the Marine-Hospital Service, the object being to detect, and to recommend to the commissioner of immigration for deportation, persons of the excluded class, such as idiotic, insane persons, persons likely to become a public charge and persons suffering from a loathsome or a dangerous contagious disease. The proper performance of this duty must also of necessity result in valuable aid to public health.

These examinations may now be regarded not only as supplementary to the examination and work of the quarantine officer in his efforts to prevent the introduction of the diseases quarantinable at the maritime quarantine, as for example cholera, yellow fever and smallpox, but also such diseases of municipal quarantine as diphtheria, scarlet fever, measles and in some instances tuberculosis, and of what ought to be but unfortunately is not included in the ordinary category of quarantinable diseases, *syphilis*.

If, as a great master has said: "State Medicine does everything necessary to protect the health of communities and States—investigates the air we breathe, the water we drink, the food we eat, the clothes we wear, the fuel we burn, the houses we live in, the soil we cultivate, the habits and industries of life, the origin and nature of endemics and epidemics,

the method of their transmission, and the means of their prevention and of their suppression wherever found." If "its object is to discover the causes, and to prevent the origination of disease, to prevent its spread, to circumvent it, to extinguish it, whether it be zymotic, contagious or specific. In short," if "it is the function of State Medicine to protect the public health, which is the life of the nation," why is it that one of the most contagious (when brought in personal contact) and the most widely distributed and destructive diseases, in its remote effects, of the human race, is not officially and legally placed in the category where it properly belongs? Echo answers why?

Can it be that the seed sown or rather the great tree planted in this ASSOCIATION twenty years ago by the "Nestor of American Surgery,"⁶ and which was so bountifully nourished two years later by the President⁷ of the ASSOCIATION is not to bear any fruit? In looking back along the course of eighteen or twenty years one can see that here and there a vigorous graft was placed upon it, but yet it bears no fruit.

With reference to the destructive character of the disease Dr. Gross said:⁸ "When a pestilence, as for example, that of cholera or smallpox, breaks out in a country and threatens to decimate its population every man's fears are at once aroused, and steps taken to counteract its progress; every citizen is upon the alert, and every newspaper is urgent in its appeals for help; but here is a disease a thousand times worse than the most deadly epidemic, doing its work slowly and, as it were in disguise and darkness, ruining entire families, destroying many of our best men and women, and laying the foundation of untold misery, wretchedness and woe, not unfrequently extending through several generations and literally poisoning the very fountains of life."

Dr. Sims remarked:⁹ "The subject of syphilis is rarely mentioned in polite circles, even by medical men, and then only in whispers. It is our duty to enlighten the public upon all questions of public health, and particularly upon this one. . . . So far as the well-being of the human race is concerned I look upon the subject of syphilis as the great question of the day. . . . A greater scourge than yellow fever and cholera and smallpox combined is quietly installed in our midst, sapping the foundations of society, poisoning the sources of life, rendering existence miserable, and deteriorating the whole human family."

Dr. Ricord, the highest authority in all matters pertaining to specific disease said: "Syphilis is the greatest plague that menaces civilization."

Dr. Albert H. Gibon in his address as chairman of this Section on State Medicine, twelve years ago, said: "It is premature to expect the public to believe that they are in danger, or legislators who spring from the ranks of that public to frame protective laws, until they see demonstrated in figures that the venomous brood of smallpox, diphtheria, scarlet fever and yellow fever has a dread sister in venereal disease whose victims are not, like those of diphtheria, quickly carried to the graveyard but linger on earth, suffering living death."

During the same year, 1882, a committee of the American Public Health Association of which Dr.

⁶ The late Dr. Samuel D. Gross.

⁷ The late Dr. J. Marlon-Sims.

⁸ Address in Surgery, American Medical Association, 1874.

⁹ President's Address, American Medical Association, 1876.

Gihon was chairman submitted the draft of a bill having for its object the restriction of syphilis. The bill was carefully prepared and did not differ materially from the laws and municipal regulations governing in the management of other contagious diseases dangerous to the public health. The committee proposed that the bill be referred to the different State and Territorial Legislatures for adoption, but upon this proposition the ASSOCIATION refused to take any action whatever, notwithstanding the fact that only two years before, in 1880, the same ASSOCIATION by a large majority passed a resolution "recommending municipal and State boards of health to urge upon the legislative bodies of this country the enactment of a law for the prevention of venereal diseases."

I do not know how to account for such apparently diametrically opposite action on the part of a great association within so short a period, unless it be on the ground described by Dr. Lomax¹⁰ as "the apathy which at the present day stupefies the mind and conscience of a community in regard to legal interposition as a remedy for this curse, is so unpromising of early beneficial results as almost to preclude it from the prophylactic program of sanitarians. And yet the popular will is so spasmodic in its evolutions and tergiversations, and so plastic in its capabilities, as possibly to bring the benign opportunity within the range of practical accomplishments in an unexpectedly brief period of time. At all events the subject should be constantly paraded before the public gaze, and its importance pressed upon the attention of the people until it receives due consideration at their hands."

It is not my purpose to recite the various methods or avenues through which syphilis may be and is acquired, *innocently* or *otherwise*, nor to discuss that worst of all forms of the disease, *inherited syphilis*. Suffice it to say that according to a late estimate there are now in the United States 6,000,000 of people infected with the disease, and a considerable proportion of this number is made up of persons who have not only acquired the disease innocently, but who are in absolute ignorance as regards the character or cause of the malady from which they are suffering.

An admirable paper on "Syphilis Insontium; A Plea for the Restriction of Syphilis and a Suggestion for the Prevention of its Spread," by Dr. L. Duncan Bulkley, of New York, was read by title in this Section at the last annual meeting at Milwaukee, and published in the JOURNAL under date of Nov. 11, 1893. I trust this paper has been read by every member of the ASSOCIATION. It ought to be read by every physician, sanitarian, philanthropist and legislator in the land. It is brief and to the point on "Syphilis of Innocents"—marital syphilis, syphilis in females, in public and private practice, hereditary syphilis and infant mortality, and lastly but by no means least, the *extra-genital* communication of the disease.

"This," as he says, "is a vast subject, which has been greatly developed of late years, and one which will occupy the serious attention of every physician and sanitarian. . . . The individual with syphilis is not only in danger of communicating the disease in marital relations, and almost sure to do so, and is also most likely to transmit more or less of

the taint to the offspring, if they survive, but is also himself or herself a constant menace to society by virtue of the contagious character of the disease, in some of its manifestations, even for a long period of time."

In referring to the title of his paper, "Syphilis of the Innocents," the author said: "We approach the subject of the restriction of the spread of syphilis solely from this aspect, and argue for the control of the disease by health authorities wholly on behalf of the vast army of innocent sufferers from a disease which is absolutely preventable, provided the absolutely proper measures could be and were absolutely carried out. The proper measures for its restraint will never be instituted until the public is thoroughly alive to the relative frequency and importance of syphilis as a non-venereal disease, and the rights and claims of those who may be innocently infected thereby."

The present widespread discussion and the adoption of measures by different organizations and municipalities for the restriction of tuberculosis, notably the recent action of the health department of the city of New York, ought to, and doubtless will, tend to encourage similar discussion and action with regard to syphilis, not because of any possible or special relationship between these two diseases, but rather on the ground that they are equally widespread and baneful in their effects on mankind; and the measures with few exceptions already recommended for adoption and actually adopted by health authorities for the prevention of the spread of tuberculosis, will be equally effectual, if properly applied, for the restriction of syphilis.

Some encouragement for the workers in the line of progress may also be derived from the decision of the courts in at least two of the States, where it has been decided that syphilis pleaded in answer to an action to recover damages for breach of promise of marriage is a *complete defense*.

But I have reached the limits of the time at my disposal. Thanking you for your kind attention and especially for the high honor you have conferred upon me by calling me to preside over your deliberations, and begging your indulgence and kindly cooperation in the discharge of the duties pertaining to the chair, I now declare the Section of State Medicine open and ready for the transaction of business, and for the reading and discussion of papers as laid down in the program.

NOTE.—Since writing this paper Dr. Bulkley has published a volume of over 300 pages on "Syphilis of the Innocents."

MINUTES OF THE SECTION ON STATE MEDICINE.

FIRST DAY—JUNE 5.

The Section convened in Friendship Hall, Odd Fellows Building, Corner Seventh and Market Streets, Dr. GEORGE W. STONER, U. S. Marine-Hospital Service, in the chair. In the absence of the Secretary, Dr. Charles H. Shepard of Brooklyn, Dr. Liston H. Montgomery, of Chicago, was unanimously elected Secretary *pro tem*. The first session was held at 3 P.M. Tuesday, June 5, and in addition to the above named gentlemen were, among others, the following: Dr. H. S. Orme, Los Angeles, Cal., Ex-President California State Board of Health; Dr. C. A. Ruggles, Stockton, Cal., President California State Board of Health; Dr. W. F. Wiard, Sacramento, Cal., member California State Board of Health; Dr. J. R. Laine, Sacramento, Cal., Secretary California State Board of Health; Dr. Jerome Cochran, Mobile, Ala., President

¹⁰Syphilis; its Prophylaxis. In Annual Report State Board of Health of Indiana, 1883.

Alabama State Board of Health; Dr. H. D. Thomason, Albion, Mich., member Michigan State Board of Health; Dr. John Godfrey, U. S. M. H. S., San Francisco; Dr. J. H. Stallard, M. B., London, Eng.; Dr. Charles E. Winslow, Albuquerque, N. M.; Dr. S. S. Herrick, San Francisco; Dr. J. H. Davisson, Los Angeles, member California State Board of Health; Dr. John W. O'Neill, Chicago; Dr. A. J. Erwin, Mansfield, Ohio; Dr. Gerard Geo. Tyrrell, Sacramento, Cal.; Dr. Thomas Ross, Sacramento, Cal.; Dr. M. M. Chipman, San Jose, Cal.; Dr. M. F. Price, Los Angeles, Cal.; Dr. C. E. Stone, Marysville, Cal.; Dr. Charles N. Cooper, Campbell, Cal.; Dr. Joseph A. Oliver, San Francisco, Cal.; Dr. W. R. Clunoss, San Francisco, Cal.; Dr. Benjamin T. Kierulf, Los Angeles, Cal.

Dr. STONER read his annual address.

The first paper of the session was

ON THE PRINCIPLES OF SANITARY SCIENCE, THE CHIEF OBSTACLES TO THEIR PRACTICAL APPLICATION AND THE MOST EFFICIENT MEANS FOR THE REMOVAL OF SUCH OBSTACLES

by PROF. N. S. DAVIS, of Chicago. As the venerable teacher was unavoidably absent he furnished the Section with an outline of an elaborate paper of which he was preparing the synopsis. This was read by the Chairman and was briefly discussed.

1. The principles of sanitary science or preventive medicine are based on correct knowledge concerning the causes of disease, both specific and predisposing, and the conditions or circumstances that favor or hinder the production or propagation of such causes. The question is discussed whether at the present time the attention of sanitarians is not given too exclusively to the specific causes, more especially of a bacteriologic character and their ptomaines; while much more might be accomplished by giving more attention to the predisposing influences both as regards those pertaining to the individual and to his surroundings. Are not many, if not all, of the pathogenic germs really morphologic deviations from various non-pathogenic germs under morbid conditions either within the body or adversely affecting its surroundings, always present, but harmless, until thus acted upon by unfavorable influences? And would not much greater benefit result by giving more attention directly to personal hygiene and domiciliary conditions than has been given heretofore?

2. It is claimed that the chief obstacles to the practical application of sound principles of sanitation are the deficiency of knowledge on the part of the great majority of the people; their tenacious adherence to established customs, fashions, and modes of living; and the difficulty of procuring the enactment of needed sanitary laws, and the still greater difficulty of securing their honest, persistent and efficient execution.

3. It is stated that the most efficient means for the removal of the foregoing obstacles are, better education of the people on sanitary topics by frequent public meetings under direction of the State and local boards of health; by judicious articles in the daily secular press; by more quiet, though efficient instruction in family circles by practicing physicians during their ordinary professional intercourse, and especially by persistent efforts to impart to the people more correct knowledge concerning the laws governing the production and diffusion of contagion and infection, and the readiness with which they are destroyed by free contact with pure air, good water, and bright sunlight, that their exaggerated fears and prejudices may be removed.

The question how far the present methods of arresting the spread of contagious and infectious diseases by isolation and disinfection are successful is discussed—and continued in an elaborate paper.

Upon motion of Dr. Jerome Cochran, the Secretary was authorized to request DR. DAVIS to furnish a copy of his paper in its entirety for publication in the JOURNAL.

At this juncture a notice was received from Dr. L. Duncan Bulkley, Secretary, requesting the Chairman to appoint three substitutes on the Business Committee for this session, in place of Drs. C. A. Lindsley, Benjamin Lee and R. Harvey Reed, all of whom were absent, resulting in the appointment *pro tem.* of Drs. Jerome Cochran, C. A. Ruggles and W. F. Wiard.

Dr. COCHRAN moved, duly seconded, that we discuss the suggestions or topics in the Chairman's address. Also, those embodied in Dr. Davis' paper. Carried. A protracted and interesting discussion then ensued which was participated in by Drs. Cochran, S. S. Herrick, J. H. Stallard, J. R. Laine, H. D. Thomason, the Chairman and others.

The Secretary then read a biographical sketch of the late Dr. John H. Rauch. A committee was appointed to prepare a suitable preamble and resolution regarding the deceased to be read first before this Section and then submitted to the ASSOCIATION. The following gentlemen constituted the committee: Drs. C. A. Ruggles, H. D. Thomason and Liston H. Montgomery.

The Chairman appointed the following Nominating Committee: Drs. C. A. Ruggles, J. R. Laine and John Godfrey, and at 4:45 P.M. the session adjourned.

SECOND DAY—JUNE 6.

The second day's session convened at 2:30 P.M., with Dr. STONER in the chair. The first business transacted was the report of the Committee on Nominations for officers of the Section for the ensuing year, which was unanimously adopted, resulting in the election of Liston H. Montgomery, Chicago, Chairman; Charles H. Shepard, Brooklyn, N. Y., Secretary.

Executive Committee: John Godfrey, U. S. M. H. S., San Francisco; C. A. Lindsley, New Haven, Conn.; Benjamin Lee, Philadelphia, Pa.

The first paper read was entitled

THE PHYSICIAN AND STATE,

by DR. CHARLES E. WINSLOW, Albuquerque, N. M. The paper was heartily approved. One of the many interesting portions which is quoted at this time is the following: "It is a fact that healthy nations are wealthy nations, proving that public health is of great commercial value. This being true, is it not worthy a place in the Cabinet? If the improvement and preservation of plant and animal life are important enough to need a representative in the Cabinet, vastly more important is that which prevents sickness, prolongs life, protects homes, uplifts humanity, adds wealth to the State and is the life blood of the Nation." Discussion was participated in by Drs. Orme, Ruggles, Godfrey, Stallard and Thomason.

A FEW REMARKS ON LEPROSY

is the title of a short valuable paper read by Dr. HENRY S. ORME, of Los Angeles, Cal. The author thinks there are more cases of leprosy in California than is known. The most important conclusions reached were that leprosy is not kindred to syphilis or tuberculosis; that it is contagious and that it is not diffused by hereditary transmission. There is abundant proof that the plan of segregation will in time cause leprosy to disappear, providing it be rigorously enforced. In Dr. Orme's judgment all lepers should be legally registered and kept under surveillance by the sanitary authorities, so that they may be isolated whenever necessity occurs. The law might provide for periodical inspection, and certificates of the same to those allowed to be at large. The discussion was continued by Drs. Ruggles, Stallard, J. H. Davisson, Ross, Cochran, S. S. Herrick, W. F. Wiard and the author

The next paper for consideration was

RESTRICTION OF TUBERCULOSIS,

by DR. J. H. DAVISSON, of Los Angeles, member of California State Board of Health. The paper was discussed by Drs. Ruggles, Cooper, Stallard, Cochran and Godfrey.

A very carefully prepared paper,

A STUDY OF THE EFFECTS OF POISONED AIR IN THE CAUSATION OF INEBRIETY,

was read by DR. T. D. CROTHERS, Superintendent Walnut Lodge Hospital, Hartford, Conn. Said the author, in part, in his conclusions: A society of aerationists, who would seek to show how disease could be prevented and life lengthened by always breathing pure air, would do some real work for the elevation of humanity. Specific hunters and reformers will find an open field and unlimited scope for research in the air we breathe, and its influence in increasing or diminishing disease. That inebriety is caused by bad air in some cases, and is largely influenced by both good and bad air in all cases is a fact unquestioned. Rational medicine demands a study of all conditions of living and surroundings in the questions of diagnosis; it demands that disease and diseased conditions should be regarded as physical entities. Discussion by Dr. Stallard, of London, who maintained that in that metropolis squalor and poor surroundings increased inebriety, and by Drs. Godfrey, Herrick and Anderson.

The committee appointed to take notice and prepare resolutions of respect upon the death of their late fellow, Dr. J. H. Rauch, submitted the resolutions published in the JOURNAL, page 954, June 23, 1894, which were upon motion unanimously adopted and referred to the ASSOCIATION.

The Section then adjourned.

THIRD DAY—JUNE 7.

Section convened at 2:35 P.M. with DR. GEO. W. STONER in the chair and twenty-two members present. The first paper was presented by DR. S. S. HERRICK, of San Francisco, entitled

COMMON CARRIERS AS DISSEMINATORS OF CONTAGION.

The writer dwelt more particularly on the disposal of the excretions of travelers on inland waters and on railway coaches; that certain communicable diseases whose contagious property is discharged from the alimentary canal is liable to reach the alimentary or respiratory tract of other persons if not intercepted or destroyed, and cholera, typhoid fever, dysentery, intestinal tuberculosis and other filth diseases were named as notable examples in this respect. Companies who provide meager accommodations for passengers were properly censured, and should be held justly responsible if inadequate remedies were provided for their patrons. In Dr. Herrick's judgment the time had arrived for sanitarians to speak plainly and forcibly on the subject, and to demand of legislators a specific remedy which courts will be bound to apply to this class of offenders against health. Discussion by Drs. Ruggles and Cochran, Davison and Stoner, all of whom were in accord with the opinions advanced by Dr. Herrick.

The second paper presented to the Section this afternoon was

STATE MEDICINE; ITS RELATION TO PATENT MEDICINE,

by DR. SAMUEL P. DUFFIELD, of Detroit, Mich. In the absence of the author the paper was read by Dr. Stoner. Cases were cited where patients were beguiled into the belief that they could be benefited (even though it be at \$10) to start with, by advertising itinerants, printed circulars, etc., using the United States mail for these deceptions. Various patent remedies advertised to quiet certain "nervous conditions," to restore "lost vitality," etc., were scored. The attention of the Attorney-General, Postmaster-General and Congress should be called to this matter and have such ma-

terial excluded by the postal authorities. The Patent Office came in for its share of censure, wherein it issues the right to any person or to a firm to manufacture and sell medicines so powerful that they work death to an innocent citizen. Accompanying the paper were various exhibits of advertisements for the members of the Section to read and act upon—not to be reproduced in print, however.

The paper was discussed by Drs. Ross, Stallard, Ruggles, Davison and Price, and upon motion of Dr. Ross as was suggested by the author, a committee of three was appointed by the chair to try and agree upon some method of procedure of investigating the composition of various proprietary medicines that are advertised in medical journals and elsewhere, and to do what else was deemed best in the judgment of the committee, even to bringing the matter before Congress. Dr. Thomas Ross, Dr. J. H. Stallard, and Dr. Liston H. Montgomery were named as the committee. The latter gentleman being appointed instead of Dr. W. F. Wiard, who was unable to serve.

It may be well to state that a committee for a similar purpose was appointed at the annual meeting of the American Pharmaceutical Association last year to report at their annual meeting to be held during the first week of September, 1894, at Asheville, N. C.

The next paper,

CLEANLINESS THE CHIEF ANTISEPTIC,

was read by the acting Secretary, on account of the absence of the author, DR. C. F. ULRICH, of Wheeling, W. Va. Dr. Ulrich thinks preventing bacilli from entering the human body when it can be done, far preferable than bacteriologic investigations afterward; and that the former is more apt to be accomplished by thorough and perfect cleanliness than by the use of so-called antiseptics.

VACCINATION AND RE-VACCINATION

is the title of a carefully prepared essay by DR. EZRA M. HUNT, Secretary of the State Board of Health of New Jersey. This paper had been forwarded by the author to the Section, and as he was unavoidably absent on account of ill health it was read by the chairman. Never was so much loose vaccination done as now. We sound not too soon this note of warning, for we believe that if the present loose methods are permitted to continue, vaccination will become less and less a preventive of smallpox and so its enormous value will be greatly impaired. There must be more thorough work and more exact discipline as to this whole matter of vaccination. Among the tentative answers as indicating lines of direction for inquiry, Dr. Hunt said: *a*, there should be a National vaccine and distributing establishment for bovine vaccine at Washington; *b*, arm to arm vaccination should not be wholly abandoned. In our larger cities, at least, physicians should arrange to have at hand certified humanized lymph of which the sources are local and fully known; *c*, vaccination direct from a charged ivory point used for scratching, or from a needle used but for one case, should be relied on; *d*, re-vaccination should be advised for all who have not been vaccinated within ten years, and oftener where there has been special exposure, or there is any doubt as to marks, or time of first vaccination; *e*, children should not be admitted to public schools until vaccinated. Provision should be made to encourage general vaccination of infants and youth; *f*, a vaccination card or certificate should be given, stating time and place of vaccination or of re-vaccination, whether there was subsequent examination and at how many points the lymph had taken; *g*, while time of quarantine must vary somewhat according to circumstances, persons who have been fully exposed if not quarantined at once should be under quarantine or watch from the ninth to the fifteenth day after exposure.

The discussion was participated in by Drs. Orme, Ruggles, Herrick, Ross, Stone, Chipman, Price, Stoner and Montgomery.

The last paper was read by title as the author was obliged to be absent during a portion of the afternoon session: "Tuberculosis and its Prevention," by Dr. WINSLOW ANDERSON, of the University of California, which was upon motion referred for publication in the JOURNAL.

CHAIRMAN STONER announced that this would close the reading of papers. He closed his official duties by eloquently thanking the members for their attendance at the meetings, which offers good argument for the continuation of this Section.

DRS. RUGGLES and ORME were appointed to escort the chairman-elect to the chair. Upon being inducted into office, Dr. MONTGOMERY said in substance:

It is a well-known fact or maxim that accidents sometimes occur to the best regulated families. When I left my Chicago home two weeks ago, the thought was remote from my mind of being selected either as Secretary *pro tem.* of the Section of State Medicine for this meeting, or chosen chairman of the Section for the ensuing year. Since you have seen fit to confer upon me these double honors, which I am cognizant rightfully belong to others as well, it is but just for me to express to you my heartfelt thanks for this mark of appreciation on your part.

As you are all aware, the officers of the Section have endeavored to secure the names and addresses of all who have attended the Section at this meeting. I trust, therefore, that you will consider yourselves individually or collectively as being personally invited to prepare papers and essays for the annual meeting to be held next year. Again renewing my thanks for the honor of selecting me as chairman of the Section for the coming year, and if by so doing the Section of State Medicine will prove as interesting then as the present meeting has been under the able guidance of my predecessor, your selection of officers for 1895 will not have been a mistake.

A vote of thanks was upon motion of Dr. H. S. ORME tendered to Dr. STONER for his able and dignified parliamentary rulings throughout the sessions of the Section. No further business was presented. The chairman at 5:40 P.M. then declared the Section adjourned, *sine die.*

LISTON H. MONTGOMERY,
Acting Secretary.

ORIGINAL ARTICLES

MEDICO-LEGAL SUPERSTITIONS CONCERNING CRIMINAL INEBRIATES.

Read in the Section on Neurology and Medical Jurisprudence, at the Forty fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY T. D. CROTHERS, M.D.

SUPERINTENDENT WALNUT LODGE HOSPITAL, HARTFORD, CONN.

During the past few months I have examined the facts and circumstances of six different homicides. In all these cases the prisoners were convicted and sentenced to suffer the extreme penalty of the law. In every instance the prisoner was an inebriate, and had been using spirits to excess before and at the time of committing the crime.

The defense in all these cases was insanity, intoxication and incapacity to reason of the nature and consequences of the act, with inability of control. The prosecution denied this, and sought to prove a state of sanity and mental capacity that in no way lessened responsibility. The jury in each in-

stance considered this established and returned a verdict of guilty.

In four cases the judge expressed great approbation of the courage of the jury in their verdicts, and sentenced the prisoner in terms of severity and harshness.

In one instance the judge expressed great confidence in the wisdom of the law and predicted less crime when the punishment was clear and prompt.

In another case the judge urged the prisoner to throw off all disguise and be honest with himself before he died.

In one case the judge gave no opinion, in another he became lachrymose and fell into a religious strain.

I shall refrain from the use of names and dates, because these cases are not unusual or in any way different from many others occurring daily in all the large cities of the country.

The question I propose to examine is: For what reasons and upon what evidence can medical men in the court room swear to the sanity and capacity to reason rationally of men who are under the influence of spirits? The superstitions of the law and the delusions of judges and jurors on matters on which they can not possibly form sound judgment, because they are not acquainted with the facts, are familiar to all.

Why should medical men accept these delusions and act upon them as if they were absolute facts? As an illustration, take any case where the question of insanity comes into the court room, and a certain number of physicians will give testimony in accord with legal conceptions of what should constitute insanity. Medical views of authorities are twisted and turned to suit some legal diction, or ignored altogether. Scientific facts and conclusions are strained down to the level of the law, and previous decisions of the courts, as if they were absolute authority.

Many physicians exhibit scientific demoralization in the court room, and are unable to state clearly or defend the authoritative teachings of those who are in a position to know. Hence the sneers at expert testimony and its supposed unreliability.

The physician should go into the court room as a scientific man, to give facts and opinions irrespective of all conclusions or possible antagonisms to prevailing views.

In Case 1 of these homicides mentioned, the physicians for the prosecution each acknowledged that they knew the law declared that drunkenness was no excuse for crime. Each one seemed to give very careful testimony that should not conflict with this dictum. In this case the prisoner came from a degenerate family, in which insanity, inebriety, pauperism and idiocy had appeared in many members. He had been an inebriate tramp from early life, drinking to excess at all times and places, and had suffered from delirium tremens, sunstroke and typhoid fever. He had been a gambler, barkeeper and hotel runner, and he had lived very irregularly all his lifetime.

He was confined in jail some months suspected of burglary, but was finally released for want of definite evidence. He drank daily to excess from this time, and after an altercation over some trivial matter he threatened to kill a man; the next day he renewed the threats while intoxicated; the third day he met the man and killed him in a personal encounter. He had drunk to excess all day, and while not stupid was clearly intoxicated. These facts were not dis-

puted. On the trial three physicians swore that he had full power of forming conceptions as to his acts and their consequences. That as he had driven a hack and had acted rationally on these days in his business he must have been able to reason on the nature and quality of his acts. Also he could not have been insane or unconscious of what he was doing. On cross-examination, alcohol was called a stimulant, and never a paralyzant except in excessive doses, also persons who used spirits were not in any way affected mentally unless intoxicated.

In Case 2 the prisoner killed his brother under unknown circumstances. He affirmed no recollection of the act. He was a periodical inebriate and had been drinking for two weeks every night to excess. He had begged money on the night of the crime and when refused declared he would have money if he had to kill some one. The next morning he had money and his brother was found murdered. He had drunk at intervals from the time he was in the army in 1864, gradually becoming worse. His father was an inebriate and his mother died insane, and he had lived an irregular life as a pedler. He had been in jail for intoxication and was weak-minded when not drinking.

On the trial two physicians testified that they had examined him and found him of sound mind, and that he was fully capable of knowing what he did even when under the influence of spirits. They also swore that unless stupid or delirious he would be sane and conscious, and act with premeditation. They also believed that alcohol did not destroy normal consciousness, without giving evidence in conduct and appearance.

Case 3 was a man who had previously occupied a prominent position, and was considered to have more than average ability. He came from a consumptive and neurotic family. At 30 he was injured in a railroad accident and his wife was killed. From this time he drank and lived with low society, was a low barkeeper, pawnbroker, and drank steadily, seldom becoming stupid or delirious.

Finally he killed a low woman companion and ran away. The evidence showed his condition before and after the act to be in no way different from that at other times, although he was evidently under the influence of spirits. Two expert physicians swore to his measure of sanity and his ability to have restrained himself, also that he gave no evidence of ever having been insane and unable to reason on the nature of his acts.

Case 4 was a low Italian laborer without any history, except that of spending all his week's earnings drinking Saturday night and Sunday. He never seemed stupid or hilarious, but was rather thoughtful and sedate when drinking. He killed the barkeeper who refused to sell him more spirits. About the same testimony was brought on by the medical witnesses for the prosecution. The prisoner was considered sound and in possession of all his faculties at the time of the homicide.

Case 5 was a wife murder by an inebriate who was possessed when under the influence of spirits, of delusions of his wife's infidelity. When sober he was silent and seemed not to consider this, but after drinking he became morbidly suspicious of every act and word. In all other relations he was unchanged and appeared rational. These drink periods would culminate in attacks of acute gastritis and long free

intervals of sobriety. On the trial the medical testimony denied all possibility of his being unable to realize the nature of his acts, but assumed that his natural jealous disposition was increased by spirits, and he could at any time have checked it.

Case 6 was a farmer who had drunk cider brandy for many years, and in a rage at his brother-in-law, who tried to arrange for the removal of the spirits, shot him. There was no history other than that of excessive drinking for many years and gradual decline of health. He appeared and acted rational to all general observation. The medical testimony on this trial was very emphatic in denying the irresponsibility of the prisoner, and assuming that he was fully competent to understand his acts and know right from wrong. Alcohol was declared to be non-poisonous taken every day.

Such is an outline of the medical testimony on which conviction was secured in each case. Three of the cases were defended by elaborate medical evidence, and the impression created was that it was simply paid testimony.

In two cases medical witnesses offered voluntary testimony in rebuttal to the evidence of the prosecution concerning the sanity of the prisoner. In one case no medical evidence in defense was presented. I assume that the evidence offered to show the mental integrity and responsibility of the prisoner by physicians in these cases is a fair example and is a common experience in all criminal courts of the country. I propose to show that such evidence is theoretical and entirely unverifiable.

The supposition that insanity must always be marked with delirium, idiocy or dementia, and that no insanity is present unless such symptoms are clear, is not true in reality. Many of the most dangerous lunatics and thoroughly insane men exhibit a degree of mental acuteness and vigor not seen among the sane.

The old theories of right and wrong test, and of capacity to do otherwise, and free will to judge and decide of the act, are misleading and unsupported by facts. The same facts obtain in the study of inebriates; intoxication marked by delirium and stupor, are not the only conditions of irresponsibility. Facts within the experience of every one point out states of trances, of delusions, of morbid impulses and imperative ideas, which are veritable insanities, that give no evidence of their presence except in certain lines of conduct, that are not understood.

The assumption of capacity with knowledge and control and the fact that the person was not stupidly and wildly intoxicated is wrong and unverifiable.

To assume sanity in any person who persists in using spirits to excess, a habit destructive to all his personal and pecuniary interests is contrary to facts, and is simply the tenacity of an old delusion of the value of alcohol. The person who uses spirits to excess at intervals or continuously must have a defective mentality, either before spirits were used, and certainly after its use he is more degenerate. Statistics are clear on this point, that in at least one-third of all cases of inebriates the use of alcohol is a symptom and not a cause. A symptom of some brain defect, either congenital or acquired, or some latent tendency to exhaustion which is exploded and made to take on acute conditions which are masked by spirits.

The theory that alcohol is purely a stimulant, and always the sole cause in inebriety is untrue. The theory that excess in the use of spirits is only temporary derangement, of the same class as indigestions, exhaustions from muscular overwork, is also untrue and dangerously misleading.

Recent experiments on healthy men show that in varying doses of from 1 to 2 ounces of spirits after the first hour the temperature and pulse fall, the senses are diminished, the muscular strength is lessened, the memory is more imperfect and all the brain functions are slower and below the normal in acuteness. These are facts which can be measured and seen, and are not observations or theories, and they show that alcohol is a depressant and paralyzant in all cases. That the temporary increase of the heart's action, and circulation of the blood is deceptive and is followed by reaction and depression. The weary horse whipped to greater efforts is not given new strength, but is made weaker and more incapacitated. This depressant action of spirits in the second state is a fact that can be proved in every instance beyond all question by instruments of precision.

It will be obviously impossible to continuously depress all the vital functions of the mental and physical organism and retain health. The man who is intoxicated, stupid or delirious, is in the extreme stage of this depression. The man who at intervals for years becomes intoxicated, or who is obviously under the influence of spirits, can not be in possession, or have full control of his faculties.

In any of these cases of homicide, the history of continuous and excessive use of spirits, or excess at intervals, is almost absolute testimony of incapacity. No appearance of sane acts and reasoning are proof of sanity. Some of the most insane men both think and act rationally on matters outside of their delusions.

The inebriate in most cases acts automatically, following lines of previous thought and action. When forced into new fields of activity his weakness appears. In Case 6 no one suspected the real condition of his brain. Although his general health had greatly declined, yet when his brother sought to remove the spirits which were injuring him, he became delirious and killed him. His insanity had been the growth of years and was not the transient impulse of anger.

In Case 5 the presence of delusions had been recognized when suffering from the drink paroxysm. This, with the fact of having drunk for years, was clear proof of incapacity to reason or to control his acts.

The drinking history of Case 4, spending his wages weekly in spirit excesses was also clear evidence of mental degeneration and unsoundness.

Case 3 was clearly one of marked disease of the brain in which the use of alcohol was not only a symptom but an additional cause of irresponsibility.

Case 2 was evidently a trance state with a history of neurotic inheritance, which in itself would have caused doubts of capacity to reason rationally.

In Case 1 a similar bad inheritance and injury from sunstroke pointed to brain incapacity.

Irrespective of all this history, the fact of using alcohol to excess is evidence of a degree of brain failure that should be unquestioned. From clinical facts and teachings I affirm with confidence that no

one who uses spirits to excess for any length of time has a normal sound brain. That it is rational to assume insanity in any case where the history indicates alcoholic excess for long periods before the commission of the crime. No appearances or sane acts should prove the sanity of a man who has been for years destroying himself with alcohol.

The question of how far he was unconscious of his acts, or unable to control himself, or comprehend right from wrong, opens up another field of inquiry, which can not be determined clearly, but the general question of his mental impairment should be considered established.

A further study of this question will show that the use of alcohol always paralyzes the higher functions of the brain, and is followed by heart feebleness and depression. The senses are disturbed and are less and less capable of transmitting accurate impressions. The higher brain is less able to comprehend the nature of acts and their relation to surroundings. Delusions of strength are common, and events and their consequences, and motives and purposes are exaggerated, misconceived, misinterpreted, and the brain is unable to correct them.

All inebriates have defective brain and nerve power, and every toxic state from alcohol more or less permanently impresses and increases brain degeneration. All such persons have lowered pride of character, less ambition, less fear of consequences. The brain is anesthetized and crippled and unable to realize the nature of acts. Crime committed by inebriates must be under abnormal states. The more prominent the inebriety the more incompetent the brain is to act rationally and soundly.

The effort to find a point or dividing line where sanity and insanity join, or where the person could or could not have controlled his acts or realized their nature, is an impossibility which every advance of science demonstrates. Capital crime by inebriates is always the result of some circumstances or some sudden strains on an enfeebled brain; some morbid delusions or illusions that suddenly dominate the mind, or epileptic explosions masked and concealed in some way. Alcoholic somnambulism or trance conditions may be present in many cases. The mind during these periods is always dulled and largely unconscious of all external or internal considerations, and is subject to strange unknown impulses that may vary suddenly. There are present either states of insanity of inebriety, or the inebriety of insanity or both. Such cases are masked to all superficial observation, and are not subject to the ordinary influences and motives which control the normal mind.

The teachings of modern psychology fail to confirm the commonly accepted theory that states of delirium and dementia from alcohol are harmless, and that recovery from these conditions is complete. Sanity and clear healthy brain consciousness do not alternate with the delirium and stupor of intoxication. The moderate and continuous drinker suffers in the same way only in a lesser degree. The person who from continuous use of spirits develops an attack of acute mania and insanity, with all the classical symptoms, and after a few weeks restraint in an insane asylum is discharged as cured and sane, is a good illustration of the theoretic delusion that all injuries from alcohol are transient. When such persons relapse and commit capital crime the ques-

tion of their former treatment in an asylum is only admitted in court as a general fact bearing on their possible mental state. This is an error and opposed by all teachings of facts. The subsidence of the acute symptoms due to alcoholic excess and the removal of spirits is not the cure or restoration of the disordered cell and nerve tissues.

The apparent sanity of the epileptic in his free intervals is no evidence that the attacks will not return, or that the man has recovered, or that he is fully sane and capable of exercising sound judgment. The periodical and continuous drinker is always unsound and unreliable; like the epileptic he can not be trusted to act normally under all circumstances. Crime by such persons is the natural consequence of a brain that is degenerating. It is unreasonable and unnatural to expect such persons to act rationally as other men who do not, or have not, suffered in this way. The court-room superstitions that overlook this fact, and attempt to measure the degree of consciousness of right and wrong, and the power of discrimination of facts and their relation to each other, is deplorable in this age of scientific inquiry.

The physician who is called to give evidence as to probable states of sanity in the case of an inebriate criminal, where the history of alcoholic excess is associated with the crime, is lending himself to encourage superstition that should rapidly disappear. The effort to formulate certain assumed facts into a position to support a theory that is unverifiable always ends in confusion and injustice. In three of these six cases the testimony of the physicians who swore to the sanity of the prisoner was a sad mixture of confused, disjointed statements, which were open to so many exceptions as to be literally worthless. In all these cases the inquiry should have turned to the drink history of the criminal, its heredity and growth up to the commission of the crime. From these facts some idea of the capacity or incapacity of the mind to act rationally could be found. The exact condition of the criminal at the time the crime was committed, separated from events before and after, gives no clear conception of the man or act.

It is absolutely farcical for a medical man on the witness stand to be drawn into an explanation of metaphysical theories of inebriety. He should refuse to give an opinion on presumptuous cases, which involve half fact, with moral, legal and sentimental theories, that are false. He should refuse to attempt any explanation of motives or capacity to will or otherwise in a person who was under the influence of alcohol at the time of the commission of the act. He should testify clearly to the incompetency of any one drinking spirits to will or to do, at the time, and insist on only giving general conclusions from established facts. The questions should be: 1, was the prisoner an inebriate? Did he drink spirits before, at the time and after the commission of the act? If these questions are answered in the affirmative and on facts, the mental capacity may be doubted, reasonably and naturally; 2, what was the nature of the act, and the conditions under which it was perpetrated? Do they strengthen or disprove the inference of mental unsoundness; 3, what conclusions do the facts point to? If the preponderance of evidence indicates a defective consciousness of conduct and the relation and consequences of acts, the probability of disease of the brain in its broadest sense is almost a certainty.

No scientific study will sustain theories of the degrees of health and disease, or boundary lines of responsibility and irresponsibility. If the prisoner has poisoned himself with alcohol before and at the time of the act, he can not be considered as sound, sane and in possession of normal faculties. Evidently there is here a very wide field for new and exact studies, which will revolutionize and clear up much of the superstition and odium which has grown up about expert medical testimony.

A summary of the facts may be grouped as follows:

The questions of inebriety are becoming more prominent in the legal treatment of crime, and yet to a large extent the theories of centuries ago prevail, and form the working basis from which to judge such cases.

Physicians as expert witnesses make the fatal mistake of attempting to harmonize facts and legal theories of interpretations, with some vague notions of insanity and inebriety.

It is a legal fiction and delusion to suppose that crime committed while under the influence of alcohol is the voluntary act of a conscious brain.

It is a delusion to interpret acts that indicate premeditation by inebriates as evidence of sanity and consciousness of their import.

It is a delusion to consider inebriety a normal condition, and that the victim has full power to poison himself for years, even up to and over into the region of full insanity, but should he commit crime punish him as sane and accountable.

It is a delusion to consider that all inebriates have the power to drink and abstain at will; that intoxication implies a voluntary state *which is under control* of the mind.

It is a *fact* sustained by unmistakable evidence that an inebriate who commits crime is not of a sound mind. That no criminal act by persons who are under the influence of spirits at the time of the commission of the act comes from a sane, healthy brain.

The delusions of the law insist on fixing boundaries of responsibility, and urge medical men to go into this penumbra region of sanity and insanity, and draw lines between vice and disease, and indicate where human justice should punish and where excuse.

The medical man on the witness stand and at the bedside must go beyond the theories of yesterday or the facts on which yesterday's views were based. A clearer, wider range of facts point to broader conclusions to-day and still clearer facts to-morrow.

DISCUSSION.

THE CHAIRMAN—The paper of Dr. Crothers is now before the Section. I for one feel that I owe, and I think the Section generally owes Dr. Crothers a debt of gratitude for the earnestness with which he is presenting to the people the results of this condition of the nervous system and I will be very glad to hear from any person present, whether in the Section or not.

DR. GIVENS, Idaho—Mr. Chairman, I feel and completely agree with the Doctor in all of his propositions, but as he read his paper I thought "that is true, but what are you going to do about it?" Now to the man who has daily experience with the alcoholic insane and with all forms of the disease, there is no question in his mind about the truth of the proposition that the Doctor has laid down. But how are we to get the judges and the courts to believe as the Doctor does? Nay, how are we to get the medical profession to

believe it either? How are we to get them into the attitude of mind the Doctor is in? I don't think we can argue the courts into it; we can not argue the juries into it. I have no hope we can argue the medical profession into it. The only way I know that a man can be convinced of the truth that is in this paper, is to put him among the insane; his daily experience and contact with the insane will convince him of the truth of these things. How are we to do that? By the care of the insane. The tendency has been to take the insane and lock them up in asylums away from the world. We have a few specialists in charge of the insane asylums. We have a few young men who go there for varying periods of from two to ten or fifteen years, and they acquire accurate information in regard to all the facts that are known in regard to insanity, but they are very few, and all the clinical resources and advantages that would accrue to the medical practitioner by contact with the asylums are lost by the present arrangement. I have thought for many years that it would be better if we could have our insane treated more nearly as the sick are treated in hospitals, and that when the young men graduate they should be expected to be received as internes, to treat insane men for a period of two or three years. That kind of a system would very soon cause these facts to permeate the medical profession. That is a practical point that I hope will be reached some time in some kind of a practical way. There is no question but the law, and the conception of the lawyers is wrong in regard to the matter, but it seems to me a herculean task to convince them of their delusion, and impress them with the real facts, as the Doctor has given them to us to-day. Society itself, civilization itself, is halting over this question—is stumbling over it. A great deal of wrong is done, but how are we going to right it?

DR. HEISHOLT—Mr. Chairman, I have been very much impressed with the paper that has been read and entertain the same views on the subject. But perhaps it would be fitting to make some few remarks as to what influence these views might have upon the exercise of justice, as justice is being exercised. Every one of us knows how it is being exercised every day; the principle seems to be rather let many guilty men escape punishment than to let one innocent man be punished. However, I doubt whether the result of having these views believed in by medical men at large, by judges and by juries—I doubt whether the result would be as good as perhaps those who entertain these views think they would be. If courts are managed as they are to-day, or law is exercised as it is to-day, and the methods in court go on as they do to-day, with the hypothetical question that is brought up as the basis for medical witnesses to judge by, there would be more loopholes for guilty men to escape through. However, I must say I believe in alcohol having its effect—this paralyzing effect—often where no marked delusions or other symptoms of insanity are present.

Another point is, the way such people are taken care of after they have committed a crime apparently under the influence of spirits or alcohol. They are sent to asylums and they are there kept for a certain length of time. Then as I know in a number of cases there is no law that enables the superintendent of such an asylum to keep these people; he must let them go again, and as it is well known the inebriate has no control over himself for any length of time—he falls into the same old habit and his crime is generally repeated. Now the question with me then is, if such views should be believed in throughout the land, not only the medical men should hold these views but the judges and juries should know of them and believe in them, that the laws first of all must be changed.

DR. WRIGHT, California—Mr. Chairman, I do not rise to discuss the paper because I am heartily in accord with the

statement made. I only rise to say that sometimes it will take a good deal of courage—a good deal of moral and intellectual courage, if you please—for a physician to go upon the witness stand and present views that have been presented here by the doctor in this paper, knowing the popular feeling, and that the court, that is to say the judge and jury and the attorneys, will all laugh at you for making what they will call, a fool of yourself. This matter has been brought to me in a forcible way. I was asked to state upon the witness stand my opinion—where an individual for a life long had most grossly abused himself by the use of alcoholic substances, and after he had practiced this habit for some thirty years, without any apparent sufficient provocation, and when not directly under the influence of liquor he killed his daughter; and his attorneys while admitting that he was guilty of the murder of the daughter yet hoped to secure for him a lighter sentence than that which would attend a conviction along the line of the prosecution, namely, that he was guilty of murder in the first degree; I went upon the stand and said that this man's excessive use of alcoholic liquor had put him in such a condition that he was not as fully alive to the enormity of his crime as if he had lived a sober life. Well, some of the gray-headed veterans of our profession held a diametrically opposite view, and said that such a view as mine was wrong, and that the man knew what he was doing when he committed the crime and that therefore he was responsible.

DR. CROTHERS—Mr. Chairman, I should like to hear your views in regard to that matter. You have had a long experience which must have brought you into possession of a great many facts for or against the ideas here presented. I should like to hear what you have to say and I could then add a word in closing.

THE CHAIRMAN—I thought when I asked you to discuss the question, that I put myself on record in a few words as fully indorsing the sentiments of the paper, and when I expressed my thanks to Dr. Crothers for the earnestness with which he has to my knowledge for years been endeavoring to bring the effects of alcohol properly before the profession, because as Dr. Crothers says, even to-day some of the gray-haired veterans that Dr. Wright speaks of, speak of alcohol as a stimulant simply, whereas to-day I presume every person in this Section knows that alcohol by a most careful physiologic investigation has been declared to be not a stimulant at all, but an anesthetic, a paralyzing agent; and if a paralyzing agent, and anesthetic, then it certainly must, even if the quantity used would not be regarded as excessive, if it has a paralyzing if it has anesthetic properties, it must to a certain extent diminish the powers of reason and judgment. I agree with the Doctor when he refers to the bit of moral courage necessary to express views that are a little in advance of the people, but it is none the less the duty of the doctor to do it. And the people are being enlightened upon these questions. In my own State, the State of Illinois, we have endeavored to correct the abuse of this medical expert testimony, and I propose tomorrow to present to this Section the resolutions of the bill that has been prepared to be introduced in the Legislature governing it. I am sorry to say we have too many doctors who are willing to go on the stand and declare testimony upon questions about which they know nothing, or questions in which they have not kept pace with the progress of scientific investigation. Certain it is that alcohol is a paralyzing agent, and if it does produce anesthetic effects upon the brain, it certainly must diminish, to a greater or less extent, as I said a moment ago, the power of reason and judgment. I do not care to detain the Society any longer, but I must again express my entire approbation of the proposition the Doctor has made about the necessity

of our being bold in our declaration, let the consequences be what they may. The people who know nothing about it may make such declaration as they please, but it is the doctrine that fifty years hence will be the universal doctrine among scientific people.

DR. CROTHERS—Mr. Chairman, I will just say one word with great thanks to the Chairman for his complimentary words to me, and his thorough recognition of the principles of my paper.

We are on the verge of a great reformation. In the courts all over the United States, we are all making the eternal blunder of sentencing diseased men, the same as they sentence the half insane and the witches and the possessed of the devil—we are doing the same thing in this country with the crazy inebriate. So the same blunder is repeated and we go on. Now regarding a man as insane or incompetent does not take away responsibility at all. Some people fear a great deal that to say because he is an insane man you should let him go loose. Not at all; it only takes away the severity of the punishment. And I can only say that this is the view that is going to obtain in the coming century, and be put into practice; and the physician who adopts it as part of his life and his thought and in his practical application will first become the recognized man.

REPORT OF TWO CASES OF INTRACRANIAL TUMOR.

Read in the Section on Neurology and Medical Jurisprudence, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY ANNE BURNET, M.D.

WAUSAU, WIS.

The following cases of intracranial tumor occurred in patients in the Illinois Eastern Hospital for the Insane.

The clinical history and post-mortem findings are given, not because of any marked peculiarity, so much as because of the growing interest in the subject—an interest which can but be stimulated and widened by reports of the careful observation of such cases.

It is a matter of regret that an accurate diagnosis was not made before the patients reached the post-mortem table, and there is a sort of selfish vindication in the thought that those of wide experience and having at their command the most approved means and methods of diagnosis sometimes fail to arrive at correct conclusions.

As knowledge of the brain and its functions increases improvements in methods of diagnosis may be looked for, until a tumor may be as accurately located in the skull as in the abdominal cavity.

Case 1.—Mary C., American, about 35 years of age. No history accompanied the patient when she was admitted to the hospital, and very little that could be relied upon was obtainable from her. She had lived a life of licentiousness, and the commitment papers gave alcohol as the cause of her mental disease. She was only fairly nourished. The pupillary reflex was normal; the tendon reflex absent. She walked with difficulty, her lower extremities seeming to be paretic. Her mouth was very foul—the gums swollen, spongy and exuding pus—presenting a good illustration of too much mercury. There was a profuse purulent discharge from the vagina and the patient said she had specific disease. Sensation seemed quite good at first but was soon evidently deranged. The patient's mental condition was such, however, that her statements in this regard as indeed in the matter of subjective symptoms in general could not be wholly relied upon. There was a slight hesitation in her speech and her memory was slow. She had hallucinations of sight and hearing accompanied by delusions of grandeur. These mental defects were not pronounced at first, but it is quite possible that change of surroundings may have thrown them into the background for a time as is often the case. Later,

however, these mental symptoms were very marked and she became quite irritable.

She appeared to be weak and unable to get about and seemed to suffer so much from pain in all parts of her body that she was sent to the infirmary and permitted to remain in bed or to sit up as she preferred. She complained of very intense headache, claiming that she could not sleep on account of pain in her head and other parts of her body. The head pains were the only ones definitely located. The others seemed general and were suggestive of multiple neuritis. In a short time she became quite helpless and very untidy. She failed rapidly. Her stomach refused food and she suffered from an obstinate diarrhea. A few days before she died she developed a persistently high temperature and rapid pulse accompanied by copious perspiration. She was in the hospital less than six weeks. Before death for several hours the muscles of the neck became markedly rigid. She was quite deaf and there appeared to be a failure of sight also. The autopsy was made five and one-half hours after death. The head was small and the skull unusually thick. The diploe were nearly obliterated. Exostoses were found on the inner surface of the frontal bone and in the temporal fossa on the left side. The brain weighed forty-one ounces. The dura was somewhat adherent to the skull and was thickened. The pia was thick, tough and unusually vascular. At a point corresponding to the exostosis in the left temporal fossa, the pia was roughened and granular to the touch. This was over the third temporal convolution and a point of red softening was found in this area. Signs of recent inflammation and a spot of red softening three millimeters in diameter were found in the left frontal lobe. A large number of syphilomata were found in different parts of the brain as follows: A gummatous patch in the dura over the paracentral lobule on the left side; two tumors apparently developed from the pia over the occipital lobes causing corresponding depressions in those lobes; another at the top of the second frontal convolution extending into its substance at the expense of the gray matter; a large one at the upper border of the angular gyrus; one in the interparietal sulcus involving the gray matter on both sides of that fissure in the right hemisphere; one in the fissure of Rolando on the left side at about the middle of its extent; another at the tip of the cuneus in each hemisphere; one large and several small ones about the middle of the corpus callosum; one in first frontal sulcus on the right side anteriorly; one large one in the substance of the optic thalamus; several small ones buried in the surface of the cerebellum with others in the substance of its lobes; a large one in the pons showing as a projection in the floor of the fourth ventricle; a second in the pons extending to the crura.

These tumors varied in size from a small pea to a good-sized hazel-nut and in most instances seemed to exist at the expense of the gray matter—appearing to rest directly upon the white substance of the brain. The white matter was in all parts unusually tenacious.

Some of the growths found in the sulci were rolled out on passing the finger tips between the convolutions. No similar growths were found in the lungs, liver, heart nor kidneys—but the spleen seemed to be literally filled with them. The kidneys showed advanced fatty degeneration.

Considering the large number and wide distribution of these tumors it seems strange that there should have been so few marked symptoms. It is probable that the true physical condition was masked by her mental deterioration. The cerebral cortex was seriously pressed upon at several points, but there was nothing in the patient's condition until a few days before death to indicate such pressure. At no time after her admission did she have a convulsion. The persistent vomiting and reeling gait might have suggested cerebellar disease of some sort; and these symptoms together with the severe headache complained of did suggest such a diagnosis. The patient's history, too, left little occasion to question the probable cause of the disease, although there had been no improvement under treatment.

The patient had evidently received a thorough course of mercury at least before she was sent to the hospital, judging from the condition of her mouth. The irritable condition of the stomach and bowels made all internal medication as well as the matter of nutrition very difficult.

It is stated in the books that while gamma occurs more frequently than any other form of intracranial tumor (except perhaps tubercular) it very rarely occurs in the cerebellum. In this case several tumors were found in the cerebellum, although much the larger number were in the cerebrum.

Case 2.—Mrs. O., Swede, 67 years of age, widow, mother of several children. No history pointing to organic brain dis-

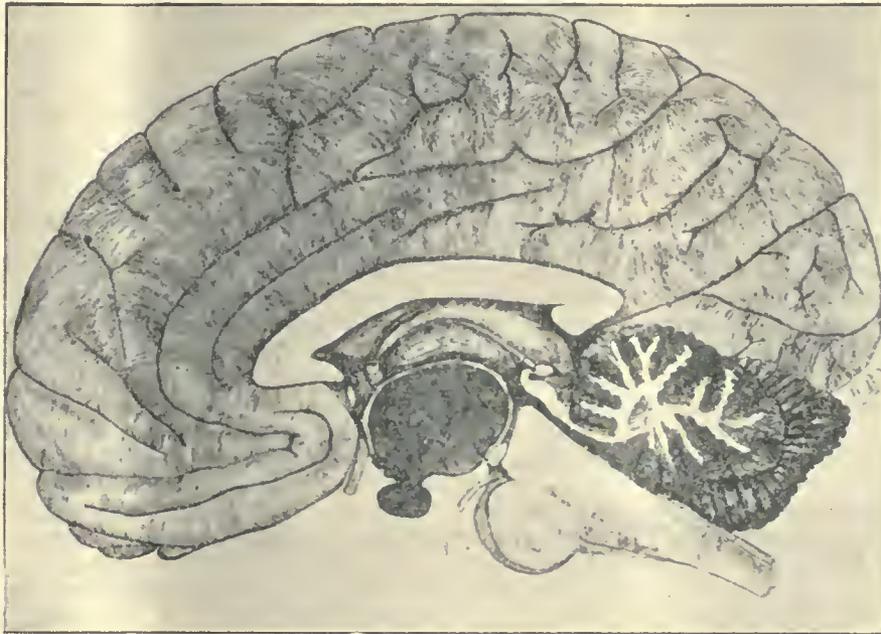

ease. The case appeared to be one of senile dementia. She had been well cared for, but a tendency to wander and very untidy habits made it necessary for her friends to place her in the hospital. On examination she was very well nourished; the reflexes were found to be fairly good, and no disturbance of sensation was noted. Her sight and hearing seemed fair for her time of life. Her weakened mental condition made accurate information impossible. Her gait was her most noticeable defect. She walked very unsteadily with a rolling movement such as a sailor adopts in rough weather at sea. She was weak-minded, childish and affectionate—usually very cheerful, humming softly as she walked about or sat in the ward. She talked very little but seemed to think she expressed her sentiments in pleasant little sounds like a happy child.

One morning not long after her admission Mrs. O. was reported as having fainted at the breakfast table. On going to the ward she was found in bed where her attendant had placed her, looking very pale and as though she might be extremely nauseated. Her pulse was weak and slow, but steady, and she was inclined to sleep. She remained quietly in bed the greater part of that day and next morning was up and about as usual.

These attacks recurred a number of times, the patient seeming to be more helpless after each one. Her gait became more unsteady until she could not walk without assist-

loss of sight and post-mortem findings confirmed that impression.

She died ten and one-half months after admission. The post-mortem was made thirteen hours after death. The body was well nourished. There was nothing unusual in the shape nor dimensions of the skull. The brain weighed forty-three ounces, and there was between five and six ounces of cerebro-spinal fluid. On the internal table of the calvarium in the frontal region were some fungosities. The caliber of the internal carotids at the point of entrance into the skull was greatly enlarged and the arteries at the base of the brain were also enlarged and atheromatous. The dura was very hyperemic and the walls of the longitudinal sinus were thickened. A bony nodule as large as a bean was found in the dura at a point corresponding to the upper end of the fissure of Rolando. On raising the frontal lobe to begin the removal of the brain a large tumor was discovered connected with and seeming to include the pituitary body—resting below on the sella turcica and pressing upward spreading apart all the basilar structures, carrying before it the infundibulum, the walls of which seemed to form a capsule for the growth. The tumor pressed against the anterior commissure anteriorly and greatly widened the optic commissure, against the pons and crura cerebri posteriorly and the anterior portion of the caudate nuclei laterally. On removing the growth (which was nearly spherical

ance. Her mental faculties and powers of perception also failed. It was observed that she never seemed to notice a person unless directly in front of her, then when her attention was called she would smile pleasantly. This suggested the idea that the field of vision was limited but a satisfactory test was not made.

On account of her helpless condition and to prevent her from being injured by falling or by other patients, she was taken to the infirmary and put to bed. For a time she was very noisy and hard to care for. She was extremely untidy and required constant attention. The right leg soon began to contract at the knee and her general helplessness increased. When attempting to sit up in bed the muscles of the back seemed incapable of supporting the body, the tendency being for the body always to fall toward the left. She slept most of the time day and night. It was often necessary to arouse her to give her nourishment, etc. These changes were developed during about ten months. Her deafness increased until it was apparently complete and all other faculties seemed to fail in proportion. A short time before death she developed a temperature of 105 degrees on which baths and antipyretics failed to make any impression. At this time she began to keep her eyes closed continually, even when she took her food and medicine, which she did very well to the last. Her mental condition was such that it was not possible to discover the reason for keeping her eyes thus closed, but it was thought possibly to be due to

and about twenty-eight millimeters in diameter) and its false capsule, large openings into the lateral ventricles were exposed. The third ventricle was greatly enlarged and mostly occupied by the neoplasm. The brain tissue in contact with the tumor, *i. e.*, the anterior half of the third temporal convolution, anterior portion of the caudate nuclei, the optic thalami and crura cerebri were softened from pressure necrosis. The island of Reil was apparently normal. The neoplasm was dark in color and its surface was irregular, almost bilateral. It was freely supplied with blood vessels by branches from the internal carotids.

The pia in all parts was intensely congested, especially at the bottom of the sulci and fissures. The line of demarcation between the white and gray matter was not clear in the portions of the brain near the tumor. The vessels in the floor of the lateral ventricles were enlarged; the choroid plexus was apparently normal. Nothing unusual was noted in the fourth ventricle, and the cerebellum was apparently all right. On section the tumor was grayish in its interior and rather soft. By an oversight there was no microscopic examination made.

Dr. Valin made a drawing of the tumor *in situ* from which the accompanying photograph was taken. It is quite correct except that the pituitary body was not so distinctly separated from the neoplasm as the photograph would indicate.

In another case presenting symptoms similar to

the one described, it was thought that the pituitary body might perhaps be abnormal. This patient died several months after the first, and on post-mortem examination the pituitary body was found to be noticeably enlarged and unusually firm. It could not be said to resemble the first, however.

There was a point of interest in this latter case which you will pardon my mentioning. Along the entire margin of the fold of pia which dipped down into the fissure of Rolando, on the left side, there was a succession of sago-like bodies of various sizes. This patient had several convulsions such as are not unusual in cases of paretic dementia, each attack leaving her more paretic until she was entirely helpless and bed-ridden.

I have found very little literature on tumors of the pituitary body. Gowers, in his latest edition, dismisses the subject in a short paragraph, while others merely mention the fact that tumors of that gland sometimes occur.

The tumor in the case described must have been of slow growth. No symptoms diagnostic of a new growth were noticeable until after the patient became bed-ridden. She never had a convulsion unless the attacks resembling a fainting spell could be so considered. Gowers speaks of a brief loss of consciousness resembling *petit mal* as occurring in some cases, and it is possible such may have been the nature of the attacks this patient had.

Headache and head pains are the most common symptoms of brain tumor, yet this patient never complained of either and never manifested any sign of suffering. She had attacks of vertigo and occasionally of vomiting, but her digestion was good and so was her appetite during her entire illness.

What the character of the growth was, I am sorry not to be able to state definitely. There was no history and no evidence of specific disease and no tubercular tendency. The tumor had not the appearance of a cancerous growth and there was no such growth elsewhere in the body.

Judging from its consistency, color and abundant blood supply and from the frequency of glioma, may it not have been a circumscribed glioma?

ON THE NATURE OF LOCOMOTOR ATAXIA.

Read in the Section on Neurology and Medical Jurisprudence at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY L. HARRISON METTLER, A.M., M.D.

MEDICAL EXAMINER NEDERLAND LIFE INSURANCE COMPANY; CONSULTING NEUROLOGIST TO LAKESIDE HOSPITAL, CHICAGO, ILL.

The intelligent treatment of a disease can only follow a thorough comprehension of its true nature. The management of locomotor ataxia has undergone many modifications until now it is beginning to be recognized that the very best results are obtained from a general constitutional treatment. Cauterizations, stretchings, and suspensions have all been tried and found wanting. Various specifics have been vaunted and quickly forgotten. Antisyphilitics continue still to benefit strictly syphilitic cases. At the present time, however, we rely chiefly on good food, change of scene, tonics, baths and properly regulated exercise. All this to me is very suggestive, and for the past few years I have been suspecting that the disease we call locomotor ataxia is but a manifestation of a general affection or cachexia. This cachexia

is something more than a predisposing cause, and its cure means the cure of the nervous lesions and symptoms.

The etiology and pathology of locomotor ataxia, spastic paraplegia, ataxic paraplegia, amyotrophic lateral sclerosis, the disseminated, diffuse and even secondary scleroses are so similar while their differences are so insignificant that the grouping of them together, as some writers are doing, is entirely rational. When the same morbid process occurs in different parts of the brain, giving rise respectively to motor, sensory or special sense symptoms, we do not speak of them as different diseases. Neuralgia is the same disease in one nerve as it is in another, and the various special nerve palsies when dependent upon the same cause, are only distinguished by their differences of location. This is even more forcibly illustrated by considering together the three affections known as locomotor ataxia, hereditary ataxia and ataxic paraplegia, all of which bear a marvelously close relationship and are but different manifestations, as it were, of the same trouble. In regard to the lesion, Friedreich's disease stands as the connecting link between the other two. Its more limited extent in locomotor ataxia naturally defines more sharply the symptomatology of this disease; while in the more extensive form of the trouble, that known as ataxic paraplegia, the motor paralysis due to implication of the lateral tracts quite alters the ataxia dependent upon disease of the posterior columns. Every one knows that in hereditary ataxia there is more of an equality between the ataxia and paretic symptoms with a slight tendency, however, for the ataxia to predominate.

In all three diseases the congenital predisposition is more or less marked. It is probable that the hereditary influence is the same in all, but that sometimes, as in Friedreich's disease, it is so overwhelming as to institute a degeneration, or, perhaps more properly speaking, a prevention of development from the very beginning of embryonic life, while in the other two affections it remains milder or latent until awakened into activity by some special cause.

In accordance with the most recent physiology of the cord, we must materially alter our conceptions of the limitations of the lesion and the nature of the anesthesia that give rise to the ataxia of *tabes dorsalis*. The spinal tracts are far more complicated than we have hitherto been led to suppose. The posterior parts of the cord are not entirely sensory in function, nor are the anterior motor. Indeed, the most important centrifugal tract lies wholly behind a line drawn transversely through its center, while according to Gowers the chief centripetal fibers are to be found in front of this same line. Such able investigators as Lücke, Flechsig, and Bouchard have demonstrated the fact that in the posterior columns are systems of fibers endowed with most elaborate and complex functions. And as a realization almost of Reynolds' prophetic words, Charcot, Schultze and Strumpell have shown that the lesion of locomotor ataxia is not uniformly extended, but is most marked in particular sites and areas and that these same areas are affected with remarkable constancy and regularity. Westphal's discovery of the so-called pre-ataxic symptoms, most of which are to be attributed to the involvement of the reflex centers and functions of the cord, long ago intimated a wider extent and profounder state of disease than that of

a mere centripetal system of nerve fibers. This was still more forcibly shown by the various trophic symptoms, arthropathies, etc., which reveal a concomitant involvement of the vasomotor and trophic centers. The association of a peripheral degenerative neuritis added still further to a broader conception of the nature of the disease. The tendency in all forms of spinal degeneration is for the morbid process to extend to other tracts and areas than those in which it originated. This, as Gowers admits, "can not always be explained by contiguity." In advanced stages and in severe cases the extension almost invariably and ultimately involves the motor and trophic centers so as to cause a true paralysis with muscular atrophy. Paralysis of the external ocular muscles is not an uncommon feature of the disease in any of its stages. This paralysis may be transient or permanent, complete or incomplete, of the whole or part of the nerve. In his well-known paper on "Ophthalmoplegia Externa," Hutchinson declares that "there can be no doubt that ophthalmoplegia externa is sometimes a part of the general malady known as progressive locomotor ataxia."¹ Both Gowers and Buzzard also recognize that "external ophthalmoplegia" occasionally accompanies locomotor ataxia. Baedeker,² Fridenburg,³ Peterson⁴ and Seguin have reported confirmatory cases. As these ocular symptoms are sometimes the earliest to appear, it can not be said that they are always due to an extension of the morbid process in the cord.

Dr. Shaw,⁵ of Brooklyn, has reported some cases with cerebral complications and cited others from literature, many of them exhibiting the typical symptoms of locomotor ataxia while at the same time denying syphilis, which inclined him to regard the disease as a diffuse lesion of the cerebro-spinal axis rather than of the posterior columns. Grasset's well-known view therefore seems not entirely without foundation, namely, that tabes instead of being a disease of the spinal cord solely, may prove to have a much more extensive lesion, involving, in fact, the entire cerebro-spinal system.

Many of the so-called complications appear with sufficient constancy and prominence to be regarded as symptoms. Of these paralytic dementia can not at times be differentiated as a complication or additional symptom. Jendrassik⁶ has put upon record two cases of locomotor ataxia with typical symptoms, in which an examination of the cords and brains led him to believe in the cerebral origin of the disease. The autopsy revealed certain alterations in the cortex which resembled in character but not in location those usually found in the general paralysis of the insane. He regarded the sclerosis of the posterior columns as secondary to that of the cortex. One of my private cases, which I may report in full in the near future, is one of mild paralytic dementia which is beginning to show some of the typical symptoms of locomotor ataxia. As Gowers remarks, "dementia paralytica and tabes are so closely related that the name is given to the disease merely in accordance with the preponderance of the one or the other special set of symptoms."

The etiologic relationship of syphilis to locomotor ataxia is still a matter of dispute. Many of the

arguments opposed to the view that the disease is dependent upon syphilis in the majority of cases are rapidly being overwhelmed by accumulating facts. Erb goes even so far as to say that "tabes dorsalis is probably a syphilitic disease whose outbreak is determined by certain accessory provocations." Strumpell⁷ is almost as dogmatic in the same belief. He assumes that the degenerative changes of tabes which he insists are no longer regarded as limited exclusively to the posterior column, must be the result of a poisonous product of syphilitic origin. He maintains that mercury may modify the syphilitic lesions so as to render the tabetic trouble milder and therefore it should always be tried, but we can not expect it to affect the tabetic degenerations already in existence. In connection with this statement it is suggestive to recall that Charcot⁸ declared that a long experience had convinced him of the inutility of antisiphilitic treatment for tabes.

Gowers calculates that in the consideration of all cases we are safe in attributing about two-thirds of them to syphilis. It is not intended by this that the degeneration of the nervous elements is strictly a syphilitic lesion, but rather as this author expressed it in 1881, that the "effect of constitutional syphilis may be to induce a neuropathic state in which certain degenerative diseases of the nervous system readily occur." In the light of all this it is difficult to understand how one of so large an experience as Benedikt,⁹ of Vienna "maintains that the majority of patients afflicted with locomotor ataxia and progressive general paralysis have never been the subjects of syphilis." Tabes, I am convinced, is a frequent accompaniment of syphilis and may be ameliorated by treatment directed against the specific infection which is a secondary, not a primary treatment of the tabetic disease.

Other disease poisons seem to show a similar selective action as syphilis and probably operate in the same way. Pernicious anemia according to Lightheim¹⁰ led in a number of cases observed by him to a rapid degeneration of the spinal cord, especially of the posterior columns. Fürstner records that centrifugal rotation produced such an abnormal condition of the blood as to induce a degeneration of the lateral columns and pyramidal tracts. Tizzoni noted the same results from extirpation of the supra-renal capsules and cases have been reported in which the posterior columns were degenerated in association with Addison's disease. Minnich found spinal changes in cases of chronic jaundice. It was long supposed that ergot caused locomotor ataxia in some special way, but posterior spinal sclerosis could not be obtained by Grünfeld¹¹ as a result of the administration of the drug experimentally. Brunton, therefore, suggested that the bad hygienic surroundings of the ergot-eating peasantry must have been the etiologic factor in the production of the disease.

Dr. Morton Prince¹² has carefully analyzed six cases of locomotor ataxia occurring in persons suffering from malaria. The relationship of the two affections is of such a character as to be highly suggestive of something more than a mere coincidence.

The etiologic importance of malarial poisoning can not be positively asserted from so small a number of observations. Gowers, Ross, Charcot, Hamilton, Spitzka and Strumpell fail entirely to mention it as a cause of tabes or disseminated sclerosis. "It is difficult," says Dr. Prince, "to show that these chronic spinal diseases develop immediately after a malarial attack. The secondary changes which are known to occur in other organs as sequelæ of malaria are not limited to the primary attack. On the contrary they are more apt to be found where malaria is chronic in the system. The connection between tabes dorsalis and syphilis is well recognized. Now it is a noteworthy fact that syphilis and malaria resemble each other in one particular, namely, they are constitutional diseases in so far as the poison or germs may remain in the system for a long period of time and only show signs of its presence by volcanic like outbreaks from time to time. Our knowledge of the effect of poisons upon the nervous system is very fragmentary and we may find that more diseases than we now imagine are due to unsuspected poisoning, zymotic or chemical, of one kind or another. Tabes has been attributed to absinthe, illuminating gas and other chemical poisons. As to malaria, it is known that intermittent paralysis such as hemiplegia, anesthesia, neuralgia resembling the crises of tabes, tremor, choreiform spasms, aphonia, insanity, amblyopia, and other disturbances of the nervous system occur in persons afflicted with the poison, showing that the latter does have a direct effect upon the nervous system."

It is generally believed that the nervous centers are the first to experience the deleterious action of these constitutional poisons by reason of their more delicate organization. The question as to how they are affected is still an open one. The lowered vitality of the entire organism together with a faulty action in the processes of nutrition is being adopted as the true explanation. This coupled with an inherited neuropathic state of the general constitution will quite suffice to explain the particular forms of nervous degeneration caused by these diathetic conditions.

In regard to the action of even the chemic poisons upon the spinal marrow, Spitzka says: "It is supposed that most of the poisons acting on the cord in this or a similar way, such as arsenic, cyanogen, barium and chloral do not produce a spinal lesion directly, but through the medium of a secondary cachexia." On the other hand, malnutrition may be present and to an extreme degree, without the spinal cord undergoing any changes. We can not call the disease, therefore, one of simple exhaustion; nor are we to ascribe the process always to a general or local malnutrition, as both conditions do not invariably obtain. It must be regarded as the expression of a constitutional taint, possibly not always of the same nature, but nevertheless always the same in its deadly action upon the nervous elements.

Some pertinent suggestions tending to demonstrate the constitutional nature of locomotor ataxia are to be found in a report by Dr. James J. Putnam,¹³ of Boston, of a group of cases of system sclerosis of the spinal cord, associated with diffuse collateral degeneration occurring in enfeebled persons past middle life and especially in women. Four of the cases

were subjected to a rigid post-mortem microscopic examination. The entire eight were studied with particular reference to the etiology. "In most of the cases," the writer says, "the pathologic and clinical signs indicated a greater disease of the posterior than of the lateral columns. Yet neither their cause nor the symptoms were characteristic of locomotor ataxia." In this negative evidence there is a manifest hint that locomotor ataxia is not solely a disease of the posterior columns. While some of its more pronounced symptoms may depend upon implication of these tracts, others are caused by minute—almost undiscoverable—lesions in other parts of the cord and general nervous system. How are we to explain the cases of so-called pseudo-tabes, such as reported by Prof. Pitres, of Bordeaux, in the *Arch. de Neurologie*, in which all the classical symptoms of posterior spinal sclerosis were exhibited, but in which an autopsy revealed no discoverable lesion whatever in the cord, medulla, spinal nerve-roots, or peripheral nerves? They are as unaccountable and yet quite as suggestive as that opposite class, of which the famous case of Schultze¹⁴ is a typical example, in which there was a complete disappearance of all symptoms with a persistent lesion of the spinal cord as shown at the autopsy. Dr. Putnam aptly suggests that "one can not fail to be struck with the fact that the causes which play the most important part are a strain of constitutional weakness, such as is preëminently seen in Friedreich's disease, both family and sporadic forms and specific toxic influences of which syphilis is the chief."

The degenerations of the spinal cord, then, are apparently the expression of a general cachexia. But, why, it may be asked, does this latent constitutional force exert itself as it does in locomotor ataxia, upon certain special parts of the spinal cord and nervous apparatus? That will remain a difficult question to answer until we have learned more of the physiology and histology of the nervous elements, the nature of the diathesis which gives rise to these degenerations and the particular action of the constitutional poison, zymotic or chemical, upon the various tissues of the body. Can any one satisfactorily explain why tuberculosis manifests a predisposition to attack the lungs, alcoholism the cerebral cortex, cancer the uterus and breast, and scrofulosis the lymphatic system?

The most ingenious and plausible theories offered to account for the prominence of the lesion in the posterior columns have had for their basis a disturbance of the vascular system. In one of the cases of general sclerosis reported by Putnam "the remarkably large size of the vessels, not only the finer arteries of the sclerotic area but to an even greater degree the larger vessels of the gray matter," was especially noteworthy. The walls of these vessels were thickened and hyaline and were surrounded by numerous leucocytes.

Buzzard has put upon record a case of locomotor ataxia in which similar vascular dilatations were found. Bevan Lewis attributes the spinal sclerosis which accompanies many cases of parietic dementia to dilatations dependent upon a disordered vasomotor action of cerebral origin. This condition of the blood vessels disturbs the nutrition of the parts with which they lie in contact. A hyperplasia of the neuroglia takes place followed by a compression-

¹³ Journal of Nervous and Mental Disease. New York, February, 1891.

¹⁴ Arch. of Psychiat. 1882.

atrophy of the nerve cells and fibers. Dejerine and Letulle¹⁵ hold that Friedreich's disease is a congenital neuroglial sclerosis while all other medullary scleroses, including tabes are acquired forms of mixed sclerosis and belong to the vascular connective tissue variety. Achard,¹⁶ on the other hand maintains that all varieties of medullary sclerosis are of the neuroglial type. It must be admitted that in some cases the process apparently begins in the nerve elements (parenchymatous degeneration) and that the hyperplasia of the neuroglia (interstitial degeneration) is purely secondary. Spitzka believes that the process is interstitial in the syphilitic cases, parenchymatous in the non-syphilitic thus making, it seems to me, two distinct diseases of it. Not a few hold that the lesion is parenchymatous in the peripheral nerves and interstitial in the cord. Whatever be the correct solution, the influence of the vascular disturbance is doubtless the same in all, and this disturbance is primarily the result of a constitutional defect.

Without stopping to discuss the question whether the process is one of degeneration or inflammation, let me ask you to note that it is not limited solely to the spinal cord. It extends into the medulla, the pons, the corpora quadrigemina and in some cases the cerebral cortex. In one case the sympathetic was affected. Involvement of the cranial nerves and of special centers of the brain, such as of sight and hearing, are occasionally indicated by some of the earliest pre-ataxic symptoms. In the cord itself other columns than those of Burdach and Goll undergo the degenerative process, as, for instance, the cerebellar tracts and the vesicular columns of Clarke. Many regard the degeneration of the columns of Goll as merely the result of contiguity, while others consider it as purely secondary to that of Burdach's column. Both views, however, dispense with the necessity of supposing that the disease of Goll's column begins in the same way as that of Burdach's, which, as we have seen, is a nutritional trouble.

The peripheral nerves are found to be affected almost constantly from the very beginning of the disease. The bilateral character of this feature of the disease is difficult to explain except upon the basis of an underlying diathetic condition. Dejerine¹⁷ is radical enough to believe that tabes presents more and more the appearance not of a spinal cord disease, but of a peripheral disease of the sensory and motor nerves and the nerves of special sensation. The parenchymatous character of the peripheral nerve-degeneration as opposed to the interstitial degeneration of the cord, added to the fact that the portion of the nerve trunks lying between the cord and their diseased extremities is usually healthy; and furthermore, that there is no proportionate relationship either in regard to severity or extent, between the cord and nerve lesions, renders still more pressing the necessity for supposing an underlying constitutional diathetic cause. Simple contiguity or trophic influence will not answer as an explanation for such dissimilar and widely separated tissue changes. It is true that Mayer found always some degenerated fibers in the nerves of healthy mammals and man; but Oppenheim and Siemerling¹⁸ have carefully examined the peripheral nerve lesions in fourteen cases

of progressive locomotor ataxia and found more degenerated fibers than was allowed by Mayer to be normal. Yet, in many of these same cases, there were no symptoms indicative of the condition during life. In a case of "typical locomotor ataxia," Dr. Shaw,¹⁹ of Brooklyn, found the changes in the peripheral nerves, sciatic, popliteal and plantar, to be different from those of the Wallerian degeneration, but resembling those accompanying chronic lead poisoning as described by Mayer, and diphtheritic paralysis as described by Pitres and Vaillard.

As yet there is no satisfactory explanation of the optic nerve atrophy. There is no direct continuity between the optic and spinal sclerosis. Of the two theories advanced, the one attributing it to a deleterious influence exercised upon the nerve by the diseased cord is far more difficult to comprehend, and less in harmony with similar observations in regard to other nerve trunks, than is the other theory, which makes both the cord and nerve lesions to depend upon the same general morbid influences. In a number of cases with laryngeal crises, Oppenheim, Eisenlohr and others found a lesion in the floor of the fourth ventricle with atrophy of the pneumogastric and disease of its nucleus. One of Spitzka's cases with gastric crises revealed sclerotic changes of the arteries in the *ala cinerea*. There is no uniform and regular succession through which these widely scattered lesions follow one another. Sometimes one, sometimes another will be the first to appear. Tabes is visibly a degenerative disease of the sensory system, peripheral, spinal and cerebral. It can not be a disease of any one of these parts alone, with that of the others merely secondary to it, since all these parts are often affected at the same time. The operative cause must be the same for all, as there is no evidence of a direct extension of the morbid process from one part to another. The parts are not directly united either by neural or vasomotor connection. Indeed, the sensory distribution of the lesion is not so rigid in its central localization, as many of the cranial nerves involved are entirely motor.

Spitzka, in opposition to Strumpell, asserts that the granular degeneration is like that of ergotin poisoning, is due simply to a vasomotor disturbance and should be compared more to that of a continued disseminated sclerosis than to a Wallerian degeneration. Likewise Babinski²⁰ with most modern pathologists finds that locomotor ataxia resembles disseminated sclerosis more closely than it does any of the systemic scleroses with which Strumpell and Westphal were inclined to classify it. Hence he does not consider the disease in any phase of its pathology as a secondary process. Zacher²¹ agrees with Babinski in not regarding tabes dorsalis as a systemic disease. The whole morbid process is secondary only to a constitutional cachexia and is not the result of any mere extension from diseased structures of like nature. This distinction is of immense importance for the maintenance of my thesis.

It seems to me, therefore, that when we consider the wide distribution of these pathologic changes, the confusion among observers as to whether the process is one of inflammation or degeneration, the peculiar state of the membranes, and the associated vascular condition, we are justified in looking upon

locomotor ataxia as the expression of a general disease. It is an affection of the spinal cord in about the same way and to about the same extent that consumption is a disease of the lungs, scrofula of the lymphatics, and scorbutus of the skin and mucous membranes. The pathologic findings are far from being commensurate with the number and diversity of the symptoms. It is not unreasonable to suppose that a disease of so slow, insidious and varied a character should at times be the result of pathologic changes quite beyond the powers of chemistry and microscopy to explore. In fact, it is admitted by some of the most authoritative observers that the lesions of locomotor ataxia must in every case be very gross before they can be recognized histologically.

In conclusion, then, let me repeat that the history, etiology, pathology, symptoms, complications and treatment of locomotor ataxia point to it as a constitutional malady, with its most prominent manifestations in certain vulnerable parts of the whole nervous apparatus. Our knowledge of the disease is not yet complete enough for us to affirm or deny this positively, but from what we already know of it, I am inclined to regard favorably this constitutional hypothesis and to continue the study of the disease still more closely from this particular standpoint.

THE INTERRELATION OF SOME OF THE LOCAL SPASMS OF EARLY LIFE.

Read in the Section on Neurology and Medical Jurisprudence, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

ROSA ENGELMANN, B.A., M.D.

FELLOW OF THE CHICAGO ACADEMY OF MEDICINE, CHICAGO, ILL.

The reciprocal anatomico-physiologic bases, etiological factors and clinical data of idiopathic torticollis, spasmus nutans and laryngismus stridulus are conspicuously interwoven. The convulsions are local, and whether or not their origin be central, peripheral or reflex, the neuro-muscular territories implicated have an important bearing upon this subject.

The nerves that control the mechanism of these regions are the vagus, the spinal accessory, the cervical spinal and the cervical sympathetic. Not alone are their nervous centers contiguous and correlated, but their conduction paths and terminations inosculate and communicate with branches to distant organs. Thus the exhibition of sympathetic interchangeability and reflex phenomena is interpreted.

Another common factor in the determination of these pathologic states is the immaturity of youthful tissues and organs. The muscles are undeveloped and untrained; the larynx is small and narrow; the nervous system is unstable; consequently, responds forcibly to the slightest stimulus. Let there be a morbid irritation, there results an overflow of nerve force along accustomed channels: For instance, compare the long drawn-out inspiratory sound when the babe begins to cry, to the aspiratory sound at the commencement of an attack of laryngismus. Or contrast the incoördinated infantile head motions to the nodding and turning of spasmus nutans.

The laryngo-spasmodic explosions upon crying, swallowing, etc., can be further accounted for, granted that an abnormal activity of the laryngeal center renders them more susceptible to the normal blood stimulus.

The localization, by Semon and Horsley, of the expiratory centers at the base of the third frontal convolution is also significant in this connection; for intellection and inhibition are not attributes of infancy and childhood.

Deducting from the above, the kindredship of wry-neck, nodding spasm and laryngo-spasm seems to be established. It is begging the question to call them functional neuroses. It were better to acknowledge ignorance of their pathology, as does the nomenclature, a cognizant expression of symptoms. Some exception may be taken to the recognition of wry-neck as a neurosis. Its manifestations are distinctly neurotic and confined to a disturbance of one or more affiliated nerves.

In chronic torticollis, either disease of the centers exists, or there is such impairment of the nerves that resection and extirpation proves salutary. From the very nature and course of the acute disorder, no lesion can be demonstrated, but the occurrence of the same morbid change is not an unreasonable inference. Nodding spasm is, as compared to torticollis, a more intense and greater neurographic derangement. Its conjunction with nystagmus indicates a central lesion.

The etiology of these maladies is ascribed to season, heredity, age, emotional disturbances, gastro-intestinal irritation, acute infectious diseases and last, but not least, rickets. These are unquestionably, predisposing causes, and rickets probably bears the same relation to laryngismus that scrofula does to the tubercular infection. But it is not fairer to accept the absolute etiologic relation of rickets to laryngismus, than it is to proclaim pneumonia an unconditionally pneumococcus infection, debarring a streptococcus or tubercular pneumonia.

Dunkin, in speaking of torticollis says: "I question whether the affection is ever directly caused by rheumatism properly so called."

Recently, in some of my own cases, I have noted the co-existence of influenza and wry-neck. Drs. Watson and Curtin describe "stiffness and pain in the back of the neck" accompanying a number of cases of influenza. Lyman reports a case of post-influenzal torticollis and head jerking. The literature occasionally refers to this alliance of such supposedly different disease processes. W. B. Hadden mentions a patient suffering from head-nodding in whom no sign of rickets nor neurotic history was obtainable.

The same is true of an 11 months old nursingling who came to my clinic a month ago. The fontanelle was about closed and dentition regular, and all other signs of rickets were wanting. There was no history of previous illness and with the exception of the head-nodding, the babe appeared perfectly healthy. The movements were intermittent and rotatory and ensued upon a fall from the child's chair. An intercurrent attack of measles aggravated the initial trouble. Nodding motions are now added to the original ones and are continuous except during sleep.

This patient, and the only case of laryngismus stridulus that I have seen in a five years dispensary experience came from a practically foreign (Hebrew-Russian), unhygienic settlement.

Comprehensive statistics by able native and foreign pediatricians disclose similar environment; a fact pointing to a possible infectious origin of the disease. In America, where better living obtains, spasmus

nutans and laryngismus are so rare that my previous admission will be pardoned. Likewise the words of Drs. Adams and Blackraeder are not irrelevant. The former says: "There may be a few, like myself, that have never seen laryngismus stridulus complicating rickets." The latter says: "In Montreal I may say that the cases of laryngismus complicating rickets are comparatively few in English hospitals, and a very infrequent symptom in this country."

In Europe, this disease associated with tetany occurs isolatedly and in epidemics and epidemics. Gangenhofer, Escherich and Loos, call tetany an infectious disease; possibly the other local spasms under discussion belong to the same category. Clinical facts indicate protean etiologic derivatives, rather than any one or few causative agencies for torticollis, spasmus nutans and laryngismus stridulus.

The dissentient views of able teachers is in part responsible for this confusion and uncertainty. Escherich, Loos, Kassowitz, Gangenhofer, Gay and Soltman are a few of those giving earnest attention to the relation of season, age, heredity, unhygienic surroundings, infection, etc., to laryngismus and tetany. The two first named pronounce laryngismus but a symptom of tetany that does not stand in any causal relation to rachitis. This brings a storm of protest from Kassowitz who is the declared exponent of the rachitic genesis of laryngismus.

The craniotabic theory of Elässer does not seem tenable. Nor are Kassowitz's pathologic findings in the skull-cap, membranes and cerebral lesions in rickets, proof positive of their kinship to the dangerous respiratory symptoms of laryngismus.

"The latter," says Gay, "does not necessarily fall upon those who have the most marked signs of rickets." Again, laryngismus is present where rickets can not be demonstrated.

On the other hand, laryngismus is wanting in cases of most marked rachitic deformity where excessive weight and size of the head, and muscular weakness, or irregular and diminished thoracic capacity might lead to sudden serious respiratory disturbance.

Thus, we see, the question is yet an open one. Escherich and Loos, in their study of the relationship of tetany to laryngismus, are clearing the field for a broader and more impartial view of the entire subject. Their work is supported by the clinical investigations of Gangenhofer, Hoffman, Neusser and Jasch, Gay, Abercrombie, and Smith, who describe cases of tetany either associated with laryngismus, or of laryngismus alone in which contractures of the extremities are present, but which is marked by the three cardinal signs of tetany, viz.: Trousseau's phenomenon, the facial phenomenon, and general neuromuscular hyperkinesis.

Gay, in dwelling upon the importance of the facial irritability says: "It is not limited to the seventh nerve, but is significant of an increased excitability, probably of all the motor nerves of the body." "It seems to bridge over and connect laryngismus with tetany as it occurs in children."

To sum up:

1. Torticollis, spasmus nutans, laryngismus stridulus, and possibly tetany are closely allied neuroses, consequent upon their common anatomico-physiologic characteristics.

2. Their relation to commonly accepted causes, such as heredity, environment, rickets, etc., is admitted.

3. Their etiology is undetermined.

4. They may be of an infectious origin and, as it were, the common, the comparative and superlative degrees of one and the same affection.

CAUSATION AND EARLY TREATMENT OF MENTAL DISEASE IN CHILDREN.

Read in the Section on Neurology and Medical Jurisprudence, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY ALFRED W. WILMARTH, M.D.

ASSISTANT PHYSICIAN NORRISTOWN HOSPITAL FOR THE INSANE; FORMERLY ASSISTANT SUPERINTENDENT PENNSYLVANIA INSTITUTION FOR FEEBLE-MINDED CHILDREN.

When I state that this paper is intended to deal with the physical causes which underlie the mental defects of the young, it may appear to you that it could be more fittingly read before specialists in their care and treatment. I hope to demonstrate to you, however, that a very large responsibility antedates their admission into institutions for the feeble-minded, and rests on no one as heavily as on the family physician. It has long been held that mental enfeeblement in children, in the vast majority of cases, was purely non-development of the nervous centers; and this view has been quietly accepted by the general profession and the public at large. Many a family with a clean history of mental health, when a bright child has suddenly changed and mental growth has ceased, perhaps after some slight illness, or perhaps after no noticeable physical dis-

turbance, can not view the misfortune in the same way as they would look on an injury to a limb or any bodily organ; but feel it as a reproach.

Year by year, as opportunities for studying the clinic and pathologic history of these unfortunates increase, it is more apparent how largely their infirmity results, as the residual effect of acute disease. It is to such cases; the diseases which most frequently leave such lasting and serious effects, and the brain changes they induce—with some suggestions regarding their early treatment, that I ask your attention for a few minutes.

The various forms of agenesis, though interesting, we may pass without comment. The laws of heredity are entirely beyond our control; and the marriage of the unfit, with offspring certainly destined to become a burden, is scarcely less so under our present social conditions. The census of 1890 showed over 95,000 feeble-minded in our country, and their number at present will approximate and probably pass the 100,000 mark. This great number may be roughly divided into cases of primary imperfect development, and into what may be looked upon as a juvenile dementia, the result of destructive change in the brain tissue. The development of the brain may be retarded by disease in early years. The growth of the organ in the first years of life is exceedingly rapid. Tuzcek, basing his statements on investigations by Huschke and Bischoff, estimates the daily increase in the size of the brain, during the first year of life, as more than one cubic centimeter. Dr. Robert Boyd estimates the brain weight at birth, ten ounces to eleven and one-half ounces. In thirty-four children between one year and two years, it averaged thirty-two and twenty-five one-hundredths ounces. Between two years and four years thirty-eight and seventy-one one-hundredths ounces. It will be readily understood that any interference with nutrition in this period, if continued for some weeks, as it might be by any disease, would be apt to leave its permanent mark on the growth and full development of the organ. This theory is borne out in fact. In seventy-five brains taken from all classes of feeble-minded children, I found the average weight only thirty-eight and three-tenths ounces. It is rare to find their brain above forty-five ounces in weight, and when it is so found it is generally in cases where the mental defect developed in the later years of childhood; in children when the mental trouble is very slight, or in low grade cases with cerebral hypertrophy. In only eight of my cases was the patient under 10 years old. Such cases are not to be classed with cases of congenital non-development, which, being an inherent fault in the brain, can not be combated as can the condition just described. With congenital or prenatal arrested development, we may class victims of convulsive attacks, which appear before the beginning of dentition. Also cases of injury from prolonged labor or forceps pressure; and they are by no means few. No intelligent physician would apply injudicious pressure on the thin skull and soft brain of the infant except to avoid still greater danger; on the careless or unscrupulous operator all warnings are wasted. It would be unwise to pass over all forms of imperfect development as beyond the reach of medical skill, without some allusion to craniectomy for the relief of microcephalus from premature ossification of the bones of the skull. This operation has, of late, been performed several

times; and from a surgical point of view, successfully. From my own observations, I am strongly of the opinion that the small skull is the result of the small brain rather than the cause. Evidence of pressure I have never seen except in one case. The true value of the operation can only be determined when a sufficient number of operations have been performed to make an intelligent comparison with cases who owe their improvement to school training alone, which is often very successful in such cases, unless sclerosis accompanies, (or perhaps causes) the retarded growth.

With all these omissions, the number of cases where brain lesion and consequent mental enfeeblement appear and originate in easily recognizable disease, at an age when medical treatment may be intelligently pursued, will be found to be very large.

Through the courtesy of authorities at the Elwyn School for the Feeble-Minded, I have been able to examine 1,000 histories from their records, choosing those series of cases which contained the most cases under my own care during my eight years residence in that institution; which, by knowledge of the children and their friends, I had excellent opportunity for verifying.

I have omitted all cases where direct heredity could be traced, when the infirmity appeared to be congenital or the result of accident at birth, or where spasms occurred or lack of ordinary intelligence was noticed before the age of 6 months, and when the patient was too young to decide as to his intelligence at the onset of the alleged causative disease; regarding such cases as possibly congenital. I have declined to count any case said to be due to traumatism, unless spasms, paralysis, or other symptoms of nervous shock directly followed the accident.

Notwithstanding this careful pruning, no less than 322 cases out of the 1,000, appear to have been the direct result of disease which would ordinarily need and receive the physician's care. Quoting figures like these at the International Conference of Charities at Chicago last summer, a foreign representative asked: "What are the doctors doing in these cases?" A question I did not attempt to answer.

The following table will show the relative frequency of the diseases in which the cerebral mischief appears to originate, and the age of onset:

| | 6 months. | 6 to 12 months. | 12 to 18 months. | 18 to 24 months. | 2 to 5 years. | 5 to 10 years. | 10 to 15 years. | Unknown. | Total. |
|--|-----------|-----------------|------------------|------------------|---------------|----------------|-----------------|----------|--------|
| Spasms of dentition | 2 | 29 | 25 | 19 | | | | | 75 |
| Traumatism | 3 | 10 | 2 | 4 | 20 | 6 | | 3 | 51 |
| Cerebral inflammations | 3 | 3 | 3 | 3 | 14 | 2 | 4 | 3 | 42 |
| Scarlet fever | 2 | 2 | 3 | 3 | 15 | 9 | 1 | 7 | 42 |
| Epilepsy of unknown origin | | | | | 10 | 3 | 5 | 2 | 20 |
| Mental shock (fright) | 1 | 1 | 1 | 1 | 5 | 1 | 2 | 1 | 11 |
| Gastric and typhoid fever | | 1 | 1 | 1 | 4 | 1 | 1 | | 9 |

1 While the age is not given, in these cases, the history shows that the child was beyond early infancy.

It will be seen that convulsions, occurring within the period of dentition, heads the list. Then comes traumatism, which includes all injuries from blows or falls on the head. Among the specific fevers, scarlet fever takes the lead for its destructive effects on the nervous system; although the cerebral inflammations claim an equal number. Fright occasions an unexpectedly high number, but in each case counted, the history seemed completely to substantiate this as the active cause.

Let us compare with this table the result of 300 autopsies collected from many sources:

| Hemisphere diseased. | Right. | Left. | Both. | Not stated. | Totals. |
|---|--------|-------|-------|-------------|---------|
| Atrophic sclerosis | 21 | 14 | 38 | 23 | 96 |
| Porencephalus | 14 | 9 | 15 | 9 | 47 |
| Porencephalus and atrophy | 3 | 6 | 4 | 1 | 14 |
| Ageneals | 1 | 6 | 9 | 6 | 22 |
| Tuberous sclerosis | 1 | 1 | 11 | 0 | 13 |
| Atrophy with internal hydrocephalus | 0 | 0 | 2 | 0 | 2 |
| Atrophy with cyst | 1 | 0 | 1 | 0 | 2 |
| Atrophy with hypertrophic skull | 0 | 1 | 2 | 0 | 3 |
| Hydrocephalus | 0 | 0 | 17 | 0 | 17 |
| Thickened membranes | 0 | 0 | 14 | 0 | 14 |
| Thickened membranes and vessels | 0 | 0 | 2 | 0 | 2 |
| Defective corpus callosum | 0 | 0 | 29 | 0 | 29 |
| Microcephalus | 0 | 0 | 10 | 0 | 10 |
| Hypertrophy | 0 | 0 | 15 | 0 | 15 |
| Hypertrophy with sclerosis | 0 | 0 | 1 | 0 | 1 |
| Cyst | 3 | 0 | 0 | 2 | 5 |
| Primary disease in cells, fibers, or both | 2 | 0 | 3 | 3 | 8 |

It will be seen at a glance how relatively few are the cases, when conditions of non-development alone are the dominant defect in this table. It may be justly said that in such a large number, collected from every possible source, many of them intended to illustrate the cause of *physical* defect rather than *mental*, that the true proportion may not be here represented. I beg leave therefore to quote from 100 consecutive autopsies made at the Elwyn institution, in which in 54 per cent. conditions were found constituting the residual effects of former disease or traumatism. The initial stage of some of these, no doubt, occurred so early in life that their nature, and possibly even their existence, might not be determined. Many others probably occurred at an age when there was good opportunity for careful study and perhaps helpful treatment.

Glancing at the table, the large number of cases of sclerosis and porencephalus will be at once noticed. These are both terminal conditions; and when fully established, it is doubtful if they can be relieved by any means within our present knowledge. Closely allied to these changes, we find the thickened and adherent membranes which follow meningeal inflammation, and which must necessarily interfere with the large blood supply so essential to the perfect functional life of the cerebral cortex. Of their early medical treatment we will speak a little later.

An interesting disease, fortunately quite rare, is tuberous sclerosis (*sciérose tubéreuse* of the French writers). From a study of the histories of these cases, which I have been able to verify by autopsy, I should describe its clinical history as follows: Its onset is sudden, and demonstrates itself by spasms of only moderate severity, but nearly continuous. They last always several hours, and sometimes for days, and are generally localized in certain groups of muscles, rather than extending to general spasm. The rise in temperature is moderate. Stupor is continuous but may not be profound. The spasms are intractable under every form of treatment I have

ever tried, and only ceased when the areas involved are functionally dead. If the child survives, it will be found that certain cerebral functions, corresponding to the areas attacked, are entirely and permanently obliterated. In no form of brain disease with which I am acquainted is the loss so sudden, complete and lasting as in this form. Post-mortem, we find rarely single, generally several areas in the cortex, quite sharply defined to the eye, gray white in color and slightly elevated. Microscopically it appears to be due to a finely granular effused material, which presses on the normal elements of the cortex, obliterating the lymph spaces. The functional activity of the cells is first destroyed from pressure, and they soon atrophy. A little boy at Elwyn was found to have several areas of this disease, but his mother insisted that he had never had either a fit or any severe illness. That certain faculties (articulate speech for one) had never shown the slightest tendency to develop. This has led me to suspect that this condition might form in utero, as his mother was subject to spasms during her pregnancy. Though only eight years old, he had a well formed brain weighing forty-eight and one-quarter ounces. The diagnosis of this disease is not difficult, its prognosis is distressingly easy, and I know of nothing which can greatly relieve it. I have dwelt on it to this length, because it is not generally mentioned in text-books, and it is desirable to eliminate in diagnosis of more tractable affections.

From our examination of the pathologic conditions underlying mental enfeeblement, it is evident that medical treatment, at the time they are placed in institutions, is liable to arrive too late to be of much service. By the time the child has reached the age of seven years, the brain has finished its period of most active growth. The hypertrophied brain has its bulk of interstitial tissue usurping the space and nourishment needed by the true brain cells and fibers for their own proper development; and the brain which has suffered from violence or destructive inflammatory process, has its mass of sclerotic scar tissue, whose influence on the healthy portion of the organ is that of a local irritant, tending to induce spasm or an increasing area of disease. However refractory such cases may be at their maturity, it is by no means true that they are equally so at the beginning. Let us take up some of the clinical causes of mental enfeeblement in the order of their frequency.

First among them is spasm occurring during the period of dentition. We find no less than 72 of our 322 cases have no other assignable cause for the subsequent mental decadence. Although in a large number of cases the convulsions ultimately cease, mental development is found to have been interfered with. All infantile disease which places any special strain on the system during this critical period, is liable to cause the same danger, and it will be generally found that the brains of the imbecile weigh less than those of normal children, and we have acquired imperfect development as a complication. The spasms of dentition is a subject deserving the most careful study and treatment.

It is a grave mistake to forget that the spasm by itself is but a symptom. That, however alarming it may be to the friends, it rarely does permanent harm. It is not scientific practice in such cases to numb the brain with large doses of bromid, and take

no means of strengthening its inhibitory power by exercising every known means of building up the nervous system. Plenty of fresh air is an essential. Moderate exercise, tonics, especially the phosphates, long continued. Delay all attempts at school education until assured of recovery, and above all other things guard the child's diet. It is my opinion, formed by years of study of large numbers of epileptics, that there is no more potent factor in the production of spasm in children than irritation of the gastro-intestinal tract. In a recent study of 566 cases of juvenile convulsion, in which the histories appeared full and reliable, in 52½ per cent. the convulsions had ceased although mental enfeeblement had in some degree persisted. I believe as many would have recovered without so many cases of mental impairment, had the cause shared the treatment with the symptom.

Next in order comes traumatism, including blows, falls and all other injuries to the head, from which I have excluded all cases which were not followed by spasms, paralysis or other symptoms of severe nervous shock. It is comparatively rare for operative procedure to be made in these cases, partly, no doubt, because friends will not allow them. It is a very doubtful matter how much good operation would do, except where fracture occurs; for post mortem examination demonstrates that the injury from blows is apt to be diffuse rather than local. Complete rest for some time after the accident should be insisted upon, and the appearance of a spasm after the primary irritation has had time to subside, should awaken the gravest apprehension. Secondary mischief has almost certainly been awakened and such cases are most obstinate. The treatment recommended for early convulsions should be begun as early as possible. I would not discourage operative measures for such cases in these days when such operations can be done with relative safety.

It is difficult to believe that large doses of bromids should accomplish anything in these cases, except to smother the spasms and blind both physician and friends as to the progress of the disease. Of the medical treatment I will speak later. The specific fevers are seen to be a very fertile cause of subsequent cerebral mischief, especially scarlet fever. It is not at all uncommon for convulsions to occur at some period of its course. In measles, if the nervous system is weak, meningeal symptoms are very apt to complicate the case. At the Pennsylvania Institute for Feeble-Minded Children, three epidemics of measles occurred, covering 397 cases. In the school department, when the children were of more healthy growth, catarrhal complications predominated; but in the asylum department, cerebral complications were the rule in the many cases where complications occurred, in some cases so severe as to kill the child in two or three days. When pneumonia would fatally attack a measles case, meningeal congestion would also be found post-mortem. In all such cases, as soon as indications of intercranial irritation are seen, prompt derivative measures should be employed to relieve cerebral congestion before the foundation be laid for permanent changes. Bromids may enter freely in the treatment at this stage but should not be long continued. The general remedies for this purpose are too well known to need mention. The number of imbeciles left in the wake of acute inflammatory cerebral disease is well known. Only

the comparative infrequency of this class of affections prevents this number from being frightful.

In all these diseases which I have described it is the residual products which cause the dreaded after effects. The remedies which are known to be of service are not numerous. Among those on which I have learned to look with favor is chlorid of gold. My use of it has been limited, but occasionally it has proved very effective. Much more can I commend a combination of iodid of potash with iodid of iron. In children where there has seemed to be a reawakening of cerebral change, and extension of old trouble has threatened, the symptoms have abated and the children have gained flesh and strength under its use. Arsenic, though less certain, has occasionally done good service.

The most satisfactory treatment is for the physician to follow his case through convalescence to complete health. To advise regular habits, sufficient rest, and above all things, and before all things, to provide rest and food for the rapidly growing brain, whose needs in the very young dominate all other organs, and the retardation of whose growth may be lifelong.

Lastly, I will refer to those obscure cases of epilepsy which arise in the years between dentition and the advent of puberty without any cause that we can demonstrate, merely to confess my inability to understand their origin or to recommend special method of treatment. They will occasionally recover under almost any treatment. Bromids will best diminish the frequency of their spasms, and, I believe, shortens the period during which they are fated to suffer.

THE FUNCTIONS AND THE FORM OF THE OBSTETRIC FORCEPS.

Read in the Section on Obstetrics and Diseases of Women at the Forty-fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1894.

BY WALLACE A. BRIGGS, M.D.
SACRAMENTO, CAL.

The functions of the obstetric forceps may be divided into constant, occasional, extraordinary and incidental. Its sole constant function is traction—the reënforcement of the natural *vis-a-tergo* by an artificial *vis-a-fronte*. As traction is intended to supplement the natural forces of labor, it should imitate them in so far as an artificial process may imitate a natural one—it should be intermittent, it should be moderate, it should urge the presenting part by its smallest circumference along the line of least resistance which in a general way will coincide with the axis of the parturient canal, at whatever point the presenting part may be engaged, and as nearly as may be with the axis of the blades of the forceps. Minor exceptions, however, are not infrequent. When the head impinges too strongly on the pelvic walls, either laterally or anteriorly, the line of least resistance will traverse the pelvic axis towards the opposite wall. When the forceps is applied before rotation takes place, the axis of the blades will depart from the axis of the pelvis proportionately to the obliquity of the application; at the outlet the interests of the perineum require that traction be anterior to this axis. Traction by the ordinary forceps as usually employed is neither moderate nor in the line of least resistance, and it is likewise neither in the axis of the blades nor in that of the pelvic

canal. The axis of the handles being set at a considerable angle anteriorly to the axis of the blades, and the grasp being at a right angle with the former axis, the direction of the tractive force exerted is always indefinite, not to say problematical, and generally deviates greatly either anteriorly or laterally from the normal line. Traction must be injurious and excessive in ratio to its misdirection.

The forceps of Morales, Hubert and Tarnier, while avowedly designed for traction in the axis of the pelvic canal, are really adapted to traction in the axis of the blades only. They are all alike incapable of adaptation to the varying requirements of individual cases. They embody a distinct advance in the direction of the principle which should guide us in traction, but they do not fully realize it. This principle is traction in the line of least resistance. It should not be departed from except for some well-defined and rational purpose—to promote rotation, for instance, or to protect the perineum. It may be objected that the line of least resistance, like the mathematical axis of the pelvis in the living subject, is incapable of demonstration, but it can not be denied that an empirical approximation to this line should be attempted in every case of forceps delivery.

Leverage, the occasional function of the forceps, may be either axial or transverse. Axial leverage is employed to promote rotation and transverse leverage to produce flexion and extension and, by some operators, in the form of lateral leverage, to “pry” the fetus out of the maternal passages. Lateral leverage should be rejected absolutely because, as Smith has demonstrated, it is mathematically absurd and, as experience has shown, it is extremely damaging to the maternal tissues. Transverse leverage, in promoting flexion and extension, may be applied equally well with any of the modern forceps, but axial leverage as applied by the ordinary forceps is indefinite and inefficient. It is made in the axis of the handles and at a considerable angle with the axis of the blades, and therefore instead of sweeping the head about its own axis tends to sweep it about an axis altogether external to itself and at a marked angle with its axis of presentation.

Compression, the extraordinary function of the forceps, may be made with the greatest exactitude with the shovel-handled forceps which I presented to the profession about a year ago. Among other forceps, however, when compression is exercised designedly there is little choice, but incidentally the ordinary forceps exerts a compression immensely greater than that required for secure prehension of the fetal head. This, it must in all candor be admitted, is a serious objection to this instrument. If compression as an independent function of the forceps is of doubtful propriety and always to be exercised with the greatest caution, compression as an incident of traction should be reduced to a minimum compatible with a solid grasp of the presenting part of the fetus. This is accomplished by axis-traction forceps and by no other.

Uterine excitation, the incidental function of the forceps, its so-called dynamic influence, is exerted by the ordinary forceps probably in a greater degree than by any other, but solely because of its defects, and not because of its perfection as an instrument of precision. In efforts to make axis-traction the handles are crowded against the perineum and the blades against the anterior walls of the uterus and vagina

while, in leverage, the blades are forced laterally against the latter structures. The pressure and friction thus produced, by reflex action, often materially strengthen uterine and abdominal contractions, but always at the expense of the maternal tissues.

The function of the obstetric forceps must determine its form. The blades should conform to the contour of the fetal head, and to the curve of the pelvis, and afford a secure and harmless grasp of the former without materially enlarging either of its diameters; the lock, on the one hand, should be easily adjusted and, on the other, should entirely prevent rocking of the blades; the handles should enable the operator to exercise all of the functions of the forceps with the greatest ease, safety and efficiency.

In accordance with these views, Messrs. Tiemann & Co. have constructed for me two forceps, a long

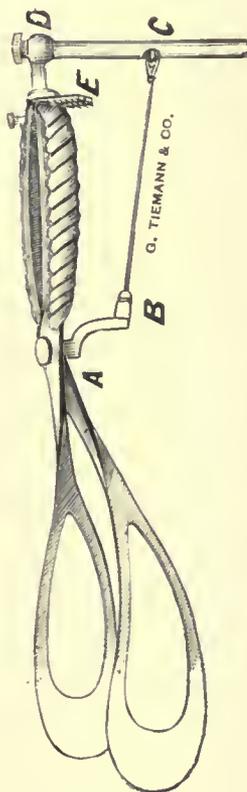

Fig. 1.

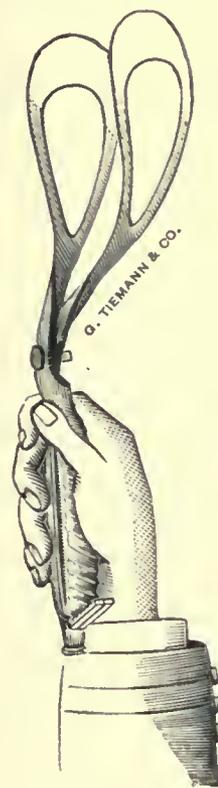

Fig. 2.

and a short which, in form, differ from previous forceps in several important particulars: The distal end of the fenestrum is filled in for a full inch or more; the axis of the handles is parallel with the axis of the blades; the axis-traction rod is connected with the lock of the male blade by a ball and socket joint; the axis-traction bar drops perpendicularly from the right handle about whose axis it moves for nearly 180 degrees; the catch for fixing the blades is in the form of a ratchet placed at the end of the handles, operates automatically and, when not in use, drops between the handles entirely out of the way.

The advantages of this forceps are:

1. Harmless grasp of the fetal head. The danger from compression varies in direct geometrical ratio with the amount of pressure applied, and in inverse geometrical ratio with the area over which the pressure is distributed. Undue compression is exercised

by the ordinary forceps for three reasons—viz, *a*, the extractive force not being exerted in the line of least resistance must be greater than with axis-traction instruments, and the compression correspondingly greater in order to obviate slipping of the blades; *b*, the grasp of the handles is maintained by lateral pressure which increases, particularly when the handles approach parallelism, as it were in parabolic ratio with the increase of extractive force; *c*, traction altogether and compression chiefly are exerted by the distal half of the blades—by the half lying beyond the point of greatest divergence. This pressure, whether of traction or of compression, is made by the ordinary forceps on a narrow surface, that underlying the bars of the blades and rarely exceeding five-sixteenths or three-eighths of an inch in width on either side. This undue pressure, this pressure in excess of what is required for a secure prehension of the presenting part, applied by the narrow bars of the distal half of the blades, it is that so often proves disastrous to the child.

Pressure when applied to the lateral surfaces of the head is by no means so dangerous as when applied obliquely or antero-posteriorly but, with a living child, it may be laid down as a rule absolutely without exception that compression should be reduced to a minimum compatible with a firm grasp of the presenting part and a safe delivery of the mother.

Not only should the pressure be minimized in the aggregate, but it should also be minimized at every point by distribution over the largest possible surface—thus greatly diminishing its injurious results. By the forceps I present to you, total pressure is minimized by axis traction applied by a handle that exercises no leverage whatever, and pressure on any given surface is minimized by filling in the distal or further end of the fenestrum for a full inch and thus nearly doubling the pressure area.

2. Secure grasp of the presenting part of the fetus. Traction with the ordinary forceps is usually made at an angle and frequently at a considerable angle anteriorly to the axis of the blades and has a proportionate tendency to promote slipping. Traction with this new forceps, however, is always quite or very nearly in the exact axis of the blades and slipping, if it occur at all, will not be attributable to any misdirection of the tractive force.

3. Avoidance of injurious pressure on the maternal tissues. The ordinary forceps endangers the maternal tissues in three ways: *a*, by misdirected traction dragging the head upward against the anterior vaginal wall; *b*, by crowding the blades too far forward in efforts to make axis-traction at the superior strait; and *c*, by pinching the intervening tissues between the forceps and the lateral walls of the pelvis in leverage and pendulum traction. These dangers are wholly obviated by the new forceps.

4. Easy application. Comparison here is made particularly with the Tarnier forceps and its numerous modifications.

5. Firm and comfortable grasp in traction. These are possessed by the Tarnier forceps also, but, in protracted and difficult cases, the handles of the ordinary forceps are a source of not inconsiderable annoyance from both discomfort and insecurity of the grasp.

6. Convenient catch for holding and for releasing the blades. The nut and screw of the Tarnier forceps

require some time for their adjustment both in fixing and in releasing the blades, while the catch of this instrument is operated instantly for either purpose and, when not in use, drops between the handles out of the way.

7. Freedom of one hand in traction. The force applied in axis-traction need rarely exceed 20 or 30 pounds and probably should never exceed 50 or 60, although some authorities place the limit as high as 80 or 100 pounds. This force can be easily and comfortably applied with one hand, either the right or the left, leaving the other perfectly free for such uses as constantly present themselves in instrumental delivery.

8. Axis-traction wherever and however the forceps may be applied. The Tarnier forceps and its numerous modifications when applied to the sides of the pelvis enable us to make traction in the pelvic axis as nearly as any forceps can—no more nearly, however, than the forceps under consideration; but when applied obliquely, when applied before rotation has been accomplished, the line of traction departs more or less and sometimes considerably from this axis—it is displaced laterally and superiorly. Not so, however, with the new forceps. When it is applied obliquely the axis-traction handle drops down by gravity into a perpendicular position. Grasping this handle well down below the connecting rod, traction may be still be made in the pelvic axis.

9. Lateral traction whenever indicated. In the living subject it is impossible to determine the exact mathematical axis of the pelvis. Approximation is all that is aimed at even in so-called axis-traction but, as was hinted at the outset, it is the line of least resistance and not the exact pelvic axis that should be sought—this is the method of nature. In a general way, the line of least resistance will correspond with the axis of the pelvis, but at any given point it may or may not. In every case of instrumental delivery the line of most efficient traction, the line of least resistance must be determined empirically—a general law we have, it is true, which must, however, be interpreted by the conditions peculiar to each individual case. Leverage and pendulum traction, are a blind effort to discover this line of most efficient traction, or in other words the line of least resistance. Their efficiency does not depend on leverage but on alternate lateral traction. By carrying the head to one side, pressure is relieved on the opposite side where friction is so reduced that progression takes place; traction is then made on the other side with a like result. This, to my mind, is the solution of the undoubted efficiency of pendulum traction.

But lateral traction is often indicated independently of oscillatory leverage. When the head impinges strongly on either wall of the pelvis, friction will be diminished and the line of least resistance approximated by bearing away to the opposite wall. When, for instance, the forceps is applied obliquely, either at the superior strait or in the pelvic canal, the line of traction may now and then be profitably carried somewhat to the side opposite to that of the presentation. On the contrary, however, traction in the pelvic axis or slightly toward the side of the presentation will sometimes materially assist in producing rotation; for now the force is applied below and to the side of the axis of the blades, while the resistance is made above it and to the same side—the leverage is obvious. This combination of force and re-

sistance is an exact imitation of the process of nature, and conforms perfectly to the dictum enunciated at the beginning of this paper—traction should imitate the forces of labor in so far as an artificial process may imitate a natural one.

10. Index for the direction of traction. The small ring in the axis-traction rod when in normal position marks a point within the axis of the blades. Traction at right angles to the axis-traction bar, with two fingers above the ring and two below, will be in the exact axis of the blades, and approximately in both the axis of the pelvis and the line of least resistance. This ring then furnishes a guide quite as trustworthy as the obsolescent handles or so-called indicatory needles of the Tarnier forceps.

11. Effective leverage. Transverse leverage, either antero-posterior or lateral, may be just as easily and effectually applied by this forceps as by the ordinary one, and axial leverage much more effectually, so that Pajot's criticism of the Tarnier forceps in this respect does not apply to the forceps under discussion. By reversing the axis-traction ring, the nipple is made to catch in a slot at the end of the male blade, and to fix the axis-traction rod. Axial leverage may now be applied by a pronative or supinative movement of the forearm.

12. Freedom of the head to rotate. The ordinary forceps unless very skilfully used materially hinders rotation. The Tarnier forceps allows the head far greater but not perfect freedom. The forceps under consideration may be employed so as to permit the head absolute freedom in this respect, to assist rotation by a combination of force and resistance or, if desired, to act as a powerful axial lever. Freedom of the head is assured in a far wider range of traction by this forceps than by the Tarnier.

13. Exactitude in the application of force and consequent economy in its expenditure. The ordinary forceps is a wasteful instrument. Traction, as usually employed, demands an extravagant expenditure of force which is largely consumed in useless and even injurious pressure on the maternal tissues. Traction by the methods of Smith and Pajot, as Lusk observes, requires both strength and skill. Traction with this forceps, on the contrary, can be made almost wholly in the line of least resistance and therefore with the least possible waste. This must be conceded to be a point of importance when we reflect that in these cases useless force is injurious force.

14. Reserve force and consequent control. In difficult cases the ordinary forceps demands an extravagant expenditure of force and attention. In consequence little reserve, either of force or of attention, remains for the exercise of proper control. As I have elsewhere said, delicacy in any operation implies the existence of a reserve force commensurate with the force employed; with this the greatest force may be conservative; without it the slightest force destructive. With this forceps the various forces are economically applied and intuitively regulated. Power, therefore, is obtained with a modicum of force and regulated with a minimum of attention. In consequence there remains a large residue of force and attention for the exercise of the most perfect control. Not only are the necessary force and attention reduced to a minimum, but also one hand is left free to perform any manipulation that may be indicated in the interest either of mother or of child, and to watch every step of progress or aberration in delivery.

15. Parallelism of the axis of the handles with that of the blades. The forceps is frequently indicated when traction of from three to five pounds or even the mere correction of the cephalic axis is sufficient to complete delivery; strict axis-traction may then be unnecessary. If, for this or any other reason, it is determined not to use the axis-traction attachment it is still possible with this forceps to make traction approximately in the pelvic axis without the adoption of any difficult maneuver. By grasping the handles from below, the forearm is readily placed almost in the exact axis of the blades and makes traction accordingly.

16. Wide range in the line of traction, without axial movement of the blades and consequent friction and abrasion of fetal and maternal tissues. In changing the line of traction with the ordinary forceps the axis of the blades follows that of the handles. The results of this swaying of the blades of the forceps are often observed in abrasions of the fetal tissues, especially near the end of the blades. The line of traction with this forceps, however, is regulated by swinging the axis-traction bar about the end of the handles, and without in the least displacing the axis, either of the handles or of the blades, and consequently without friction or abrasion or injurious pressure of the tissues either of mother or of child.

DISCUSSION.

DR. E. S. MEAD, San Jose, Cal.—It seems to me that however excellent the forceps may be in some respects in helping the traction, they have one anatomic defect. The curve of that forceps is altogether wanting. A forceps to work with facility in my hands must have this curve, especially when you are going to apply them in the interior strait. This curve of the forceps wants to be a great deal more marked.

I do not think it is necessary that we should make such heavy traction, but we should make the traction gradual. Every time the pain comes and every time there is a coming down of the head, the forceps should be re-adjusted. If we do not have an instrument with more curve we wound, necessarily, the maternal tissue. If you can have a forcep made so that the curve exactly corresponds to the curve under the pubis there is no necessity that I see to wound the maternal part. If the forceps are in unskilful hands—I have asked people to assist me in delivery (not me, my patients in delivery), and they put on a pair of forceps, and with great strong muscles that could lift probably two hundred pound dumb-bells, they pull. They seem to think that the only thing to be done is to deliver the child; if they cut off its circulation or bruise the mother, that is a matter of minor importance. That to me is all wrong. It is not brute force that we want; we don't want to make this too strong. I am wonderfully interested in the delivery of children and in the protection of the mother.

Some of the members present have had the fortune, or the misfortune, to see my delivery. I put on a pair of forceps, and they say: "Ain't you going to deliver?" I said: "I am going to wait until there is pain." There is more pain in half an hour, and the child comes. Sometimes the mother is torn, but oftentimes not at all.

I don't like the idea of fixing the handles, as in this instrument exhibited here. When I want to make traction I bring the handles together. I am not a strong woman, but I am strong enough for all the child or woman can bear. It seems to me that it is a lack of anatomic knowledge that destroys so many and makes so many failures.

DR. OSCAR J. MAYER, San Francisco—I think the mechanism as applied to these forceps is directly in opposition to

modern practice and principles of obstetrics. The most improved principle is asepsis. How it can be applied to forceps with so much machinery as this I can not understand.

Another objection to the forceps is their weight. Forceps should be as light as possible. These remind me of some of the older forceps in use. And this handle control I think is entirely unnecessary. Our aim should be not to use brutal force, but intelligent manipulation in expanding, and in rotation of the head in the delivery of the child. I think this forcep will not find much favor with the profession at large.

DR. W. WINTERBERG.—In talking about making that instrument aseptic, my friend Dr. Mayer, evidently forgot that we have sterilizers, and I think it would be very easy to make an instrument like that aseptic. I am in possession of an instrument which will hold that forcep and a whole obstetrical outfit, and all that is necessary to make the total outfit aseptic is to put it in the sterilizer and leave it for a few hours at a certain temperature. I think this is a very nice forcep. I do not object to complication in an instrument, but simplicity is always certainly desirable.

DR. BROWN, California.—I have had considerable experience in obstetrics for the last eighteen years, and I have observed the same objections that Dr. Mead has mentioned. It has not the curve that I like. I have found better success with the old Eclectic or old Philadelphia forceps than any others. I have never had any difficulty with it. I believe that it will fulfil all indications better than any instrument I ever handled.

As far as the complication is concerned of this instrument exhibited here, I can hardly see any objection against that, provided it has all the utilities. But I do think the mechanical shape of the instrument is objectionable.

DR. W. A. BRIGGS.—I will say in regard to the curve of this instrument, that it is really greater than it seems, for the reason that we are all used to the ordinary forceps where the handles instead of being parallel to the axis of the blade are set at quite an angle. This angle makes the blade seem to possess a greater curve than they really have. In these forceps I have measured the curve. I ordered it to be made the same as in the classical forceps; the curve is half an inch less than that of the classical forceps. But it is a condition more in appearance than in reality.

In the second place, in regard to asepsis, that is not, as Dr. Winterberg has said, dependent upon the instrument itself, but upon the care you take of it and the interest you take in making it aseptic. We do not keep an instrument aseptic, but we make it aseptic. This instrument as easily as any other can be made aseptic by heat. What I believe to be the advantage of this instrument is, the greater area for pressure, and the regulation of the direction of traction, so as to make it come within the line of least resistance in any possible application of the forceps.

ABDOMINAL PREGNANCY—FULL TERM, COMPLICATED WITH FIBROID OF UTERUS—CELIOTOMY AND REMOVAL OF THE CHILD AND PLACENTA AND ABDOMINAL HYSTERECTOMY.

Read by title in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the American Medical Association, held in San Francisco, June 5-8, 1894.

BY W. F. McNUTT, M.D., M.R.C.S. ED., ETC.

PROFESSOR PRINCIPLES AND PRACTICE OF MEDICINE, UNIVERSITY OF CALIFORNIA.

It is not the object of this communication to discuss the various views of abdominal pregnancy—whether it is a primary or secondary condition, that is, as to how the fecundated ovum found itself in the abdominal cavity, nor to discuss the formation of a capsule about the ovum and the development of the

blood vessels, nor to refer to the different methods of treatment as to the fetus or to the management of the placenta. This case is reported in the belief that abdominal pregnancy (as distinct from all other extra-uterine pregnancies) is sufficiently rare to justify its being recorded, especially as a living child was removed at full term, and the diseased uterus removed as well.

On August 24, 1893, I was called across the bay by Drs. Payne and Hirshiser, to see Mrs. D., age 34; she had gone to nearly or quite her full term, when she was taken with abdominal pains similar to those of labor pains, with active delirium. Mrs. D. had been delivered of a child seventeen years before, had not been pregnant since till now. Had been in fairly good health while carrying the child and had spent most of the summer at the World's Fair, Chicago. I saw her late in the afternoon; she had then been delirious for thirty-six hours, with a good deal of abdominal pain. The bed had been quite saturated with water which was supposed to have been due to the rupture of the membranes. The child's head was thought to have been felt at the brim of the pelvis; the cervix while soft was as long as an unimpregnated cervix, though the abdominal walls were contracted. The child could be felt very distinctly by abdominal examination. This was then late in the evening; I advised giving the woman rest for the night, and that I would return in the morning. Not being able to go over in the morning, I sent Dr. Winslow Anderson, and asked him to carefully examine her per rectum, with the view of ascertaining if what was thought to be the child's head, might not be uterine fibroid, and the case was probably one of abdominal pregnancy. Dr. Anderson examined her carefully, with Dr. Payne and Hirshiser, and telephoned me to come over with instruments, feeling quite sure it was a case for operation. On my arrival we chloroformed her and opened the abdominal cavity, where I found a living ten pound child, loose in the cavity, not encased in membranes. Lifting the child out and having tied the cord I found the placenta a large one, attached along the margin of the right broad ligament and to the peritoneum, and over the ascending colon nearly to the liver. I detached it rapidly; the hemorrhage was profuse, and would have been greater, had not Dr. Anderson controlled the ovarian circulation. It soon ceased after the placenta was detached and a couple of ligatures used, one included in the ovarian artery. We found a large fibroid of the uterus, which had been taken for the child's head at the brim of the pelvis. Thinking it best not to close the abdominal cavity with such a fibroid, I removed the uterus. As the fibroid involved the lower portion of the body and the upper portion of the cervix it was not possible to make a Porro and the whole uterus was removed. When coming out from under the influence of the chloroform, the woman resumed her delirium, showed no evidence of shock, but died forty-eight hours after.

The cause of the delirium was a question of great interest, as the membranes had ruptured, the child escaped from the sac and there was no fluid in the abdominal cavity. Had the absorption of the amniotic fluid by the peritoneum been the cause of the delirium, or had the fluid escaped by the tube, or had the fluid that had wet the sheets been from the bladder?

POMPOUS WORDS IN MEDICAL LITERATURE.

BY EDMUND ANDREWS, A.M., M.D.
SENIOR SURGEON OF MERCY HOSPITAL, CHICAGO.

A good literary style is as important in medicine as in any other kind of writing.

One feature of good style demanded by all standard critics, is that the sentences shall be expressed in simple, pure, crystalline English, and consist mainly of short Anglo-Saxon words, loaded as little as possible with pompous polysyllables of Latin and Greek derivation.

James Russell Lowell laments our inferiority to English writers in this respect. He says: "It has long seemed to me that the great vice of American writing and speaking is a studied want of simplicity." Whether it be for want of culture—for the highest outcome of culture is simplicity, or for whatever reason, it is certain that very few American writers or speakers wield their native language with the directness, force and precision that are common as the day in the mother country. While the school-master has been busy 'starching' our language and smoothing it flat, the newspaper reporter has been doing even more harm by stretching and swelling it to suit his occasions."

Short Anglo-Saxon words of common, daily use are to be preferred wherever they will express our meaning. It is this choice of short words, resulting in a condensed style of singular force, which gave the plays of Shakespeare and the English translation of the Bible much of their irresistible power.

Generally English medical men have kept much nearer to this strong style than Americans.

It is amusing, but vexing, to find a worthy medical gentleman, who talks in a pure and simple style among his friends but who, on taking up his pen to write a book or an article, changes his whole dialect, and fills his pages with a jangle of harsh technical terms, two-thirds of which are not needed to express his meaning.

Technical terms can not be altogether avoided, but they are a necessary evil, and should be reduced to a minimum and never lugged in without necessity. If employed in the least excess they make the sentences obscure, harsh and weak, and give them an intolerable air of pompous stiffness.

After examining an injured gentleman, the surgeon perhaps announces to his family that he was thrown sidewise from his carriage, breaking both bones of his leg and putting his ankle out of joint. This is a simple, clear and dignified statement. Now if he reports the case in a medical journal, why should he get up on his stilts and say: "The patient being suddenly projected transversely from his vehicle, fractured the tibia and the fibula, and luxated the tibio-tarsal articulation?" Perhaps he thinks he has made his statement in a high-toned, or at least a high-flown literary style.

Akin to the literary sin of too much technicality of language, is the error of overloading the speech with Greek and Latin derivatives. Not that they are forbidden, but good style requires them to be used as sparingly as possible.

These languages being of a very different type from our own, their derivatives rarely work in harmoniously with pure English sentences, and their harshness and their polysyllabic complexity make them serious blemishes in our style. For some curi-

ous reason, it is the half educated man who dotes most on these big words, whenever he displays himself in writing.

His old catheter never has an eye nor a hole in it, but a fenestrum. He does not have instruments but an armamentarium. He does not disinfect them by boiling, but by immersion in water elevated to the temperature of ebullition. He never distinguishes diseases from each other, but he differentiates or diagnosticates them. His patient's mouth is an oral cavity and his jaw a maxilla. If the eye-lids are adherent, it is a case of ankylosymbblepharon, and if there is a stone in the bladder it is an intra-vesical calculus. He never sees any bleeding, but only hemorrhage, or sanguineous effusion.

In sewing up a wound he makes, not a seam, but a suture, and often he blunders, as some good authors do, by calling each separate stitch a suture.

If he discovers wrinkles on the skin, they are corrugations. He never examines a limb by touch, but always by palpation. If he finds it hopelessly diseased, he deems it far beneath his dignity to cut it off, but is quite ready to amputate it.

There is something admirable in the sturdy contempt of our English brethren for all mere word pomp and prudishness. In London the most fashionable avenue for horseback exercise is still called "Rotten Row" from decayed houses anciently there, but long since gone.

The English surgeon has the same spirit in him. He cares for the thing to be done, and not for its phraseology. He takes his trochar and taps a dropsical belly, while the American blushes up to the roots of his hair to hear such plain speech from his British brother. He will not imitate him—not he, but he goes out straightway and performs paracentesis abdominis for intra-peritoneal effusion.

However, the pompousness is not all on our side of the ocean, and it is refreshing to see an occasional touch of it beyond the seas, just to show that we are not the only sinners in this matter.

An eminent British surgeon explains himself as follows:

"Septic peritonitis, save where definable from evidence wholly extrinsic to the condition of the peritoneum, is an etiologic entity which exists only in the mind of the pathologic metaphysician."

This is about as bad as anything ever written on our side of the water.

Our American authors have from time to time brought out many valuable researches and discoveries, but usually in a very defective style. Let us hope that the time is near when they will learn to wield our native language with that purity, simplicity and force which always commands the respect of the world.

2520 Prairie Avenue Chicago.

BOOK NOTICES.

A System of Genito-Urinary Diseases, Syphilology and Dermatology, by various authors. Edited by PRINCE A. MORROW, A.M., M.D. Illustrated in three volumes. 8vo, cloth. Vol. iii, Dermatology. New York: D. Appleton & Co. 1894.

In our review of the second volume of this "System" (JOURNAL AMERICAN MEDICAL ASSOCIATION, Vol. xxi, p. 782) we took occasion to say that it surpassed any recent work on the subject; we can also compliment the author on this handsome volume. The illustrations are excellent, and the

typography good. There is some unevenness in the work of the different writers and some lack of uniformity, but the book as it stands is a valuable contribution to dermatology. Twenty-seven well-known authors have contributed. The volume begins very appropriately with a section on the anatomy and physiology of the skin by Dr. Heitzman, of New York. This chapter, which in truth should be studied more carefully than any other, is—alas for the weakness of human nature—likely to be glanced at instead of read, but much confusion of mind would be obviated, concerning all branches of medicine, if more attention were paid by practitioners to anatomy and physiology. We note with pleasure that the decimal system of prescription writing has been followed by some of the writers, and many prescriptions are given in both the old style and the metric. In classification Dr. Morrow has followed with few changes Crocker's modification of Hebra's system. The placing of the exanthemata (scarlet fever, smallpox, chickenpox and measles) among the skin diseases seems to us of questionable propriety.

One of the chapters in the work which will be found of general interest as well as to the specialist, is the one by Dr. Morrow on leprosy. The author is a firm believer in the inoculability of the disease and he cites many cases to prove it. The well-known case in point of Father Damien (of whom a photograph is given) is cited in full. He recognizes, however, that leprosy is communicated mainly through the respiratory and intestinal tract, with secondary infection through the lymphatic system.

We commend this volume as a fitting companion to its two predecessors, and a creditable addition to the literature of American medicine.

Micro-Organisms In Water. Their significance, identification and removal, together with an account of the bacteriologic methods employed in their investigation. Specially designed for the use of those connected with the sanitary aspects of water supply. By PERCY FRANKLAND, Ph. D., B. Sc. (Lond.), F. R. S., Associate of the Royal School of Mines, Fellow of the Institute of Chemistry, etc., etc., and Mrs. PERCY FRANKLAND. 8vo. Cl., pp. 532. London: Longmans, Green & Co. 1894.

Anything written by a Frankland is authoritative on the subject of which it treats, and this book will doubtless take rank in the same class with Edward Frankland's "Water Analysis." The book gives in detail those methods of bacteriologic study, which are applicable to the examination of water, in which both engineers and health officers are practically interested, not less than students of bacteriology.

The work is divided into nine chapters. Chapter I. On sterilizations and preparations of culture media; II. Staining and microscopic examination of microorganisms; III. Examination of water for microorganisms; IV. Bacterial contents of various waters; V. Purification of water for drinking purposes; VI. On multiplication of microorganisms; VII. Detection of pathogenic bacteria in water; VIII. Vitality of particular pathogenic bacteria in water; IX. Action of light on microorganisms in water and culture media.

The appendix contains a valuable descriptive table of the various microorganisms found in water.

No more valuable contribution to bacteriology has been made for a long time, and pathologists will therefore find the book very instructive to them, not less than to those pursuing other branches of the profession.

Saint Bartholomew's Hospital Reports. Edited by W. S. CHURCH, M.D., and W. J. WALSHAM, F.R.C.S., Vol. xxix. 8 vo. Cloth. Pp. 410, and appendix 108. London: Smith, Elder & Co. 1893.

The volume opens with an account of the "Martha" Ward, by Harrison Cripps, and there are several noteworthy contributions among many excellent ones. Mr. W. Marrant Baker proposes the removal of contiguous teeth, to relieve the pain in the tongue in certain cases of cancer. Sir Dyce Duckworth dissents from the common view that the "*Taches blâtres*" observed in fever cases are due to pediculi. Mr. Chas. A. Parker has an interesting article with a statistical

table, on "Nasal Breathing in Nasal Obstruction." There is an instructive paper by Dr. Edmund Cautley on "Irregularity of the Heart." There is a complete index and a full statistical report of cases treated in the Hospital; altogether the volume is fully equal in value to those of the series which have preceded it.

Charaka-Samhita. Translated into English. Published by Avinash Chandra Kaviratna. Calcutta. Part ix.

We have heretofore commented on the value to the history of medicine of this wonderful book, (See JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Sept. 23, 1893, and April 21, 1894) probably the oldest medical book in existence. The following is an abstract of the contents of the Ninth Fasciculus:

In Lesson XXIII are explained the incidents relating to Santarpana or indulgence in food and acts that is both sedative and nutritive. The diseases that arise from such indulgence are enumerated, such as diabetes, itches, etc. The treatment is then laid down that it is advisable for persons afflicted with diseases due to such indulgence. The remedies in the form of indulgence, in excess, in food and practices which are the reverse of Santarpana, are called Apatarpana. The diseases due to Apatarpana are then enumerated, together with the remedies that are advisable to be administered.

Lesson XXIV treats of the nature and characteristics of the blood. What generates pure blood is explained. It is pure blood that brings about strength and complexion and the happiness of health. How the blood becomes impure. The diseases that are due to impure blood are enumerated. The treatment is expounded of diseases due to impure or vitiated blood. The respective indications of blood when it is vitiated by wind, bile, and phlegm, separately or in combination. The indications of pure blood. Vitiated blood leads to insanity, swoon, and apoplexy. The indications of these diseases are set forth in detail. The treatment to be followed in these respective diseases.

Lesson XXV is devoted to the discussion of the various theories of the creation of man. This discussion contains the essence of the different systems of Hindu philosophy in respect to the cosmogony of the world and living creatures. The objections to each system are also explained. The unutility of such discussion is shown. The use of beneficial food is the cause of the growth of a person; while that of food that is injurious is the cause of disease. What constitutes beneficial food and what constitutes food that is injurious. The regulations about diet are set forth in detail. The different classifications of food depending upon different considerations. A detailed enumeration of the qualities of those substances are used as food. The observations on diet, it will be seen, are extremely interesting.

International Clinics. A Quarterly of clinical lectures on Medicine, Neurology, Pediatrics, Surgery, Genito-Urinary Surgery, Gynecology, Obstetrics, Ophthalmology, Laryngology, Otology and Dermatology. By professors and lecturers in the leading medical colleges of the United States, France, Great Britain and Canada. Edited by JUDSON DALAND, M.D., Philadelphia; J. MITCHELL BRUCE, F.R.C.P., London, England; DAVID W. FINLAY, M.D., F.R.C.P., Aberdeen, Scotland. Volume xi. Fourth series. 8vo. Cl. Philadelphia: J. B. Lippincott & Co. 1894.

This volume is a continuation of the interesting series. There are forty-four separate articles, but as many of the clinics are reproductions of what was said and done at college clinic amphitheatres, they represent a great variety of cases.

These clinics, then, not only represent what the authors say about cases, but it represents what they did in all cases where manual procedures were required. The work is fairly illustrated, but much more might be done in this direction to make the book more useful to those of its readers engaged in active practice.

Practitioners desirous of keeping pace with the methods of our clinical teachers can not well afford to do without this serial, which in the course of a year, covers most of the diseases and injuries to which mortal flesh is heir.

One Hundred Years of Business Life—1794—1894. New York: W. H. Schieffelin & Co.

The story of the rise and progress of a great commercial house must always interest the historical student for it throws a sidelight on passing events, many of which would otherwise escape notice. To the medical profession this book will have a double interest, for not only will it have for it the historic motive, but as well the acquaintance of a firm with whom three generations of medical men have had pleasant business relations. The appendix consists of a scholarly review, "one hundred years of chemistry and pharmacy." And as well known, in the progress of the pharmacy of this country, this firm has long borne an honorable and prominent part. The book is handsomely illustrated.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

SATURDAY, AUGUST 18, 1894.

WORK OF THE ANTI-VACCINISTS.

Among other trials and afflictions which delay the advent of the municipal millennium in the city of Milwaukee, is to be numbered an Anti-Vaccination Society, which has been manifesting a most pernicious activity for the past two years.

The usual results have followed.

Its efforts among the ignorant and easily deluded elements of the population have aroused a determined opposition to the measures of protection sought to be enforced by the City Health Department in the presence of a threatened invasion of smallpox. The Society has preached its regulation doctrine of the terrible results of vaccination and the comparative beneficence of smallpox; that compulsory vaccination is a violation of the sacred rights of the person; that the exclusion of unvaccinated children from the public schools is an invasion of parental authority; and has counseled physical resistance to health officers and aided and abetted legal proceedings against school directors in furtherance of its propaganda of free smallpox.

In common with many other large cities of the country, Milwaukee has recently had its share of smallpox cases; but, except in the localities where the anti-vaccinists have secured a following, the Health Department has been able to control the disease. In such localities the people—mainly aliens unable to distinguish between liberty and license and resentful of any exercise of constituted authority—have not only resisted vaccination but, taught to ignore the infectious character of smallpox, have gone freely among those suffering with the disease, in defiance of quarantine and isolation, and have thus caused such an increase and extension of the outbreak as to lead the State at large to demand that

the State Board of Health shall declare Milwaukee dangerously infected and order quarantine against communication with the city.

Still another feature of the labors of the "antis" in the interest of unrestricted smallpox has been the fomenting and fostering of a sentiment hostile to the hospital treatment of the disease. Gross misrepresentation of the hospital administration, exaggeration of defective conditions and vilification of officers and employes culminated recently in a riot, in which it is alleged a mob of 3,000 excited men and women resisted the attempted removal of patients, and a score of rioters and half a dozen policemen were injured. Mass meetings have been held at which the Health Department has been bitterly denounced and a demand made that the Mayor interfere to prevent further removals to the hospital, and cause the hospital itself to be abolished—a demand which was timidly yielded to so far as to cause a temporary suspension of removals.

All of which has redounded to the disgrace of the fair name of the city and to the serious injury of her commercial interests, and all of which is to be charged to the anti-vaccinists and their work.

Fortunately, the health administration of the city is in good hands; DRs. WINGATE and KEMPSTER—the former until recently, and the latter the present Health Commissioner—have proved themselves to be well-equipped sanitary executives, prudent and conservative but courageous and firm in the discharge of duty. They possess the confidence of the health authorities of neighboring cities and States, and have thus been able to avert unnecessary restrictions upon the travel and traffic of the city. DR. WINGATE, as Secretary of the State Board of Health, has secured the coöperation of the railroads with the Milwaukee Health Department and with local health boards, in a system of inspection and supervision of railway travel to prevent the dissemination of the disease throughout the State or beyond its borders. Health Commissioner KEMPSTER, who estimates that one-third the children of the city are unvaccinated as a result of the efforts of the Anti-Vaccination Society, is pushing vaccination vigorously and extending hospital facilities—as well to meet future contingencies as to remove ground for present opposition.
