Relations of Avian to Human Diphtheria.—Since 1888 diphtheria has sensibly diminished its ravages in Belgium, while measles and whooping-cough have increased; in 1892 the number of cases of diphtheria was less than at any time since 1856. M. Schrevens has studied the etiology of diphtheria for many years and has collected a large number of facts which, to him, demonstrate the necessity of certain prophylactic measures. In a recent issue of the *Presse Médicale Belge* he insists on the important part which the Italian hens and game-cocks take in the pathogeny of human diphtheria and seeks to define exactly the meaning of "avian origin of diphtheria." Diphtheritic germs, he says, preëxist in the avian diphtheria, *nifflet*; this is no more spontaneous than is human diphtheria; the hens and cocks are not creators—they only awake into activity the germs sown on the surface of the ground; the passage of the germs on to the mucous membrane of the fowl renders them more apt for later fixation on the mucous surfaces of human beings. The author then gives the results of an inquiry he made last May into the origin of an epidemic at Marcq, a small hamlet, in which he establishes the fact that the germs were transported by some hens, bought Oct. 11, 1892, in a neighboring market-town; four children died among those attacked. He also cites cases at Rumes, due to a cock affected with *nifflet*; the two children first attacked died, but in the meantime they had infected the school and soon ten or more other scholars presented diphtheritic symptoms. M. Schrevens' observations are confirmed by those of Dr. Bricoult at Res-sac in 1888, and of Dr. de Dinant at Falmagne in 1891. Both these practitioners agree that chickens affected with avian diphtheria were the starting points of the epidemics at these places.

Pandemic of Diphtheria.—Reports from all parts of the country, except the south Atlantic area, indicate a wider diffusion of diphtheria than ever before recorded in the United States. The mortality does not seem to be unusual, with occasional exceptions, and, in the absence of any general system of compulsory notification of the contagious diseases, the number of cases can only be inferred from the death returns, from the indications of popular alarm in the closing of schools, the enforcement of quarantine, etc., and from the overcrowded condition of the isolation hospitals. Importation of the antitoxin serum has been practically suspended, owing to the growing home demand in France and Germany, in which countries are the only establishments for its production on any considerable scale. Thus far the output of the British Institute of Preventive Medicine has been only sufficient to supply one of the London hospitals, and the

product in this country is even less. There is no abatement of the enthusiasm and interest of the profession and the public of the countries of Roux and Behring, and it is especially gratifying to note again the generosity and true scientific spirit with which each of these two eminent savants insists on the recognition of the other in connection with what, up to date, seems to be one of the most brilliant therapeutic and prophylactic advances of the century. The latest occasion of the manifestation of this spirit was the presentation to Dr. Roux of the *Grand Diplôme d'Honneur* by the Sauveteurs de la Seine. In expressing his thanks the Professor said a discovery was attributed to him which he had not made; he had only applied it, and he included in the evolution of the discovery the names of Pasteur, Löffler, Koch and Behring. Considerable dissatisfaction is expressed at the course of the British Institute in withholding the name of the hospital to which is furnished all the serum prepared by the Institute, and which, in turn, surrounds itself and the results of its antitoxin treatment with what is styled an "absurd mystery." It is urged that it is the bounden duty of the Institute—after making a successful appeal to the public for the funds necessary to produce the serum—to see to it that the product is so used as to secure an authoritative verdict upon the merits of the treatment in the shortest possible time, and that the research necessary for such verdict "would have taken little more than six weeks to complete," while with the present policy of secrecy "the medical profession can not obtain a definite opinion for an indefinite period." The situation seems to be similar to that in this country. There, as here, the profession is inclined to be skeptical and demands conclusive proof; and there it will refuse to accept as such proof, results obtained through the action of a non-official volunteer organization operating in a favored hospital whose identity is concealed and whose clinical records are unduly withheld. So far as the profession of this country is concerned, its demand was concisely expressed in last week's issue of the JOURNAL: Pending an adequate supply of the serum with which to make individual tests only an authoritative report, after due investigation by a National commission, composed of members selected for their attainments in the branches of medical science involved in the modern system of serotherapy, will be accepted as conclusive of the merits or demerits and of the scope and limitations of the diphtheria antitoxin.

MISCELLANY.

Change of Address.—Dr. Thomas H. Manley to 115 West Forty-ninth Street.

Medical Sketch by Gladstone in Preparation.—Mr. Gladstone is reported to be engaged in writing a biographical sketch of the late Sir Andrew Clark, his own long-time physician and friend. An American journal is to have the copyright.

A Serous Joke.—Apropos of the record of the antitoxin when used in the early stages of diphtheria, the new medical joke in Berlin is the addition of another clause to the familiar "Resist the beginnings" of Ovid: *Principiis obsta; sero medicina paratur.*

The Word was Cabbage.—Readers of the article on "Medicine in Ancient Rome," published in last week's issue of the JOURNAL, are not compelled to accept, as the English equivalent of the French substantive *chou*, the word printed in said article "callage;" *cabbage* was the basis of Cato's therapeutics—"good, both externally and internally, it cured all diseases," etc.

The New York Lying-in Hospital.—The trustees of this institution have been enabled to get a valuable piece of property on Second Avenue and Seventeenth Street, for \$200,000, of which \$90,000 is to be paid at once. This society is nearly a century old, but it has not hitherto been in the possession of a hospital building.

Cerebral Complications of Gonorrhoea.—Pitres has observed apoplectic symptoms followed by hemiplegia in two patients suffering from acute gonorrhoea. One of these was of an age and general condition which rendered the explanation of the hemiplegia by the usual causes difficult. The author asks (*Revue Névrologique*) if this disease may not give rise to cerebral softening. We know that myelitis is also one of its complications.

Another American Hospital in China.—Members of the Low family, living in New York City and Brooklyn have just built, in Wu-Chang, and presented the same to the Protestant Episcopal Mission, a well-appointed hospital for the use of the mission and of the natives of that city. The motive for the erection of this new institution was the honoring of the memory of the late A. A. Low, father of two of the donors, and for many years a resident of China, at Canton chiefly. The new structure bears the title of the St. Peter's Hospital.

Another Anecdote of Dr. Holmes.—The following, from the *Boston Record*, is an anecdote that may fairly be called "characteristic" of the poet-professor; it is odd, yet doubtless truthful to the very center; it is philosophic, modest and void of selfishness: "I asked Dr. Holmes only a few weeks ago, as he was calmly speaking of the possibility that he might not see another birthday, if he had made any arrangements concerning a literary executor or biographer.

"No," said the old poet; 'I must leave that to others to arrange. All my old friends are gone before me. Some one will be found to attend to it.'

"Perhaps your son will do it," I suggested.

"Oh, no," said Dr. Holmes; 'I do not think that he would care to trouble himself with it; it is not at all in his line. He prefers to devote himself wholly to law.'

Another "Fortuitous Combination."—Dr. Viquerat—whose pretentious claims to the discovery of a "sure cure" for tuberculosis by the serum of asses' blood, were referred to in a recent issue of the JOURNAL (October 20, p. 623)—irresistibly recalls that scriptural hero referred to in Judges xv, 16. Dr. Viquerat recently expounded at great length a new and entirely original theory of the bacterial toxins—in effect, that it is the death and not any living action of the bacteria which is toxic. He talked for nearly an hour, completely exhausting the patience of his auditors, members of the Société Médicale de Suisse Romande, and—according to the report in the *Journal de Genève*—"Full of enthusiasm for his discovery, the lecturer ended with this picturesque exclamation: 'Viquerat's ass has killed the learned Koch!'" Whereat the JOURNAL is moved to remark that *le flot de l'âne* is truly a terrible weapon.

What the Country Editor Knows about Medicine.—Mr. "John Quad" has the following explanation to offer why it is that so much profound wisdom as to medicine can be found in the columns of the country editor's paper: "His knowledge of medicine enables him to distinguish accurately the difference between a gum boil and a felon, when he sees one in the mouth and the other in jail, or to diagnose it as a case of hog cholera when a delinquent subscriber dies. He knows that poll-evil is due to had politics, and that ring-bone and string-halt are accountable to the same bacillus. He recognizes that splints—especially on the brain—are resultant from heavy 'jags,' and that 'jim-jams' are not caused by microbes, like

consumption of the lungs, blood or tissues, but by the consumption of whisky. He is satisfied that one may have an excess of gall without being troubled with gall stone, though he may have to dodge a brick now and then, and that conceit is not a secondary symptom of greatness, nor the tintinnabulating mouth the indice of brains."

A Community Without Vaccination.—Dr. Kerr, writing from Rabat on the westerly shore of Morocco, states some facts that will serve to remind the anti-vaccinationists of England of the condition of their own country before the grand discovery of Jenner. Smallpox makes fearful havoc among the Moors with whom Dr. Kerr has lived seven years. During an epidemic at Rabat, over one thousand persons died from that disease in the course of two months. Rabat is a town on the Atlantic seaboard of Morocco having a population of 26,000. Of the conditions of the town during the epidemic, Dr. Kerr writes the following: "Often we felt it sickening when going through the streets, to see young men and boys sitting at shop doors, flour mills, etc., covered with smallpox eruption, in every way facilitating the spread of the disease. Every one thinks that it is impossible for him to escape smallpox, hence no precautions are taken. It is painfully sad to see so many people who have lost the sight of one eye, while many are blind altogether. One day not long ago, I paid a passing visit to a *douar*, or collection of tents, outside the city, and it was touching to see the mothers bring their children, asking me to put the medicine in their arms to prevent the infection. I vaccinated all the children in the village, and although they were surrounded by smallpox none took it."

These conditions, given by Dr. Kerr as to the Africa of to-day, are a simple repetition of what existed in England and Europe before Jenner's great boon to mankind was made possible.

Unequal Distribution of Cancer.—At the recent Medical and Surgical Congress held at Lyons, France, Dr. Gueillot, of Rheims, presented some statistics showing the unequal distribution of cancerous disease. In Paris and in Rheims there are only 100 cases to 100,000 persons, while in one district of the Department of Aisne there are 1,400 to every 100,000. Dr. Gueillot adduces these figures as further proof of the contagiousness of cancer, and cites also instances where the inhabitants of a particular district of a town or the occupants of a particular group of houses have been especially visited by the disease. He has known of fifteen so-called "cancer houses," in each of which three or four tenants—an aggregate of fifty persons—have successively fallen victims, and of 103 other houses in each of which there were two successive cases of cancerous disease. Of these latter, fourteen were fellow lodgers, relatives, or master and servant, and of the remaining eighty-nine, more than four-fifths were husband and wife. Gueillot believes that, while transmission of the contagion may be direct through personal contact, it is more frequently through wearing apparel or table utensils; in two cases he traced it to the medium of a tobacco pipe used in common by a cancerous subject and his "chum." In sixty-four cases the interval separating the appearance of the disease in the two related persons was less than two years. He cites nine cases of physicians who contracted the disease unmistakably from attendance upon cancerous cases. Finally, Dr. Gueillot discredits the supreme influence of heredity in cancer; his analysis of the history of cases shows that only 12.5 per cent. can be fairly attributed to this source, while if the number of persons born of cancerous parents be taken into account, the proportion is reduced to between 5 and 6 per cent.

A Medical Bill of Fare.—Dr. Thomas Dolan, in the current number of his *Provincial Medical Journal*, re-copies the following "prandial prescription" for a dinner given by the Metropolitan Branch of the British Medical Association—a bill of fare composed, as Dr. Dolan observes, "in Latin choicer than that of the Pharmacopœia:"

Programma.
 Consociationis Medicæ Britannicæ.
 Sectionis Metropolitanæ.
 Convivium.
 Apud Hospitium Navem Grenovicensem dictum.
 A.D., VII. Non. Julii. A.C. MDCCCLXXX.
 Ad canes medicamenta abjice—"Dulce est desipere in loco."
 Schema Epuli.
 "Ab ovo usque ad mala."
 Jura.
 Consummatum Habershonis—Purificatum vernale Woodii.
 Pisces.
 Pleuronectes percotti. Salmo elixus cum jure Humari.
 Minutalia ad Homaros. Soleæ parvulæ frixoria coctæ.
 Merlangi intriti Superlativi.
 Anguilla Griggii Vino Lusitanico adjuvante.
 Trutta craticulata cum jure infernali. Assulæ Salmonis more Indorum.
 Clupeæ infantiles simpliciter modoque diabolica redditæ.
 Introitus.
 Pancreata Vitulina Dicksoni
 Pulluli granarienses more Zingariensium.
 Relevata.
 Sella ovina fuscum cocta. Spinacia Boni Henrici.
 Mensa altera.
 Anaticulæ domesticæ ope pisorum perfectæ.
 Intermissa.
 Jusculum coactum Macedonicum.
 Placentulæ diversæ. Glacialis Nesselrodica.
 Fraga cremore mollita. Aqua Citroni.
 Lactus coagula compressa. Vars (a. Stiltonesis; b. Cestrensis.)
 Acetaria.
 Bellaria.
 Vina Interprandialia.
 Xericum. Rhenicum ad Hoc. Companense Spumans.
 Symposium.
 Veteris Bacchi Libationes. "Deprome quadrimum, O'Thaliarche."
 Vina.
 Lusitanicum—Xericum—cognomine—"Amontillado" et et quod ex ædibus Margaviensibus "Claret."
 Propinationes. Orationes Demosthenicæ.
 Joca. "Risum (ne) tenentis amici."
 Sanctæ Nicotianæ Consolatricis Cultus.

Professional Prospects in South Africa.—For the benefit of any JOURNAL reader affected in his practice by the distressing healthfulness of this country and who may think to better his condition by emigration, the following information concerning medical practice in South Africa is offered. It is the substance of a communication to the *Deutsche Medizinische Zeitung*, by a writer who has practiced in various parts of the country for eight years, and who views the situation mainly from a German standpoint. South Africa, while not thickly settled, has some large towns—Capetown and Johannesburg, 60,000 each, Kimberly 25,000, Port Elizabeth 20,000—and these are well provided with doctors and the situation is similar to that in Europe; calls from 2½ to 5 shillings. The gold mines have attracted a large European population, and the newer towns are rapidly increasing in population; these, also, are nearly as well supplied professionally, it being rare to find a place with less than two physicians. Many of the Boer families' sons have become doctors and have advantages over strangers through acquaintances and familiarity with climate, customs, etc. It is possible, however, to find a good location, especially in combination with a drug store; but, besides drugs, instruments, etc., a capital of from 5,000 to 10,000 marks is necessary for subsistence for the first year or two. The foregoing applies as well to Cape Colony and the Orange Free States. The Transvaal, and especially Johannesburg, the capital, are literally overrun with doctors; the capital in 1888, when only one year old, had 10,000 inhabitants and 24 doctors; in 1889 the population had doubled and the doctors increased to 26; now there are 100 medical men for its 60,000 inhabitants. Living is high; it costs a man with a family from 16,000 to 20,000 marks a year to live comfortably. Pretoria has 18 doctors for its 10,000 inhabitants, and it is no exaggeration to say that, in the Trans-

vaal, there is no hamlet of twenty to thirty houses without a doctor. Most of these live off mining companies which pay about 200 marks a month for a laborious and unpleasant service among hundreds of black and white miners. The climate is agreeable, especially in Cape Colony, though Johannesburg, being elevated, is exposed to winds and the winter is severe. The author adds that the study of the endemic diseases is interesting and that the surgeon has frequent opportunity for his skill owing to the numerous mining accidents. Specialists are obliged to undertake general practice as well, as their fees are not commensurate with those of Europe.

Abandonment of Fort Sully, S. D.—This post was one of those established when the regular troops took possession of the Western country after the close of the civil war. Its construction was begun in 1866. It was situated on the east bank of the Missouri River, twenty miles below the mouth of the Cheyenne River. At that time the nearest posts were Forts Randall and Rice, the one 200 miles below and the other the same distance above the site of the new post. Yankton, the nearest town, was distant 300 miles down stream. The mail wagon ran from Sioux City once a week, taking six days for the journey; by the river route the trip from Sioux City could be made in from eight to sixteen days. Even now, at the time of its abandonment, it still remained somewhat isolated, being twenty-three miles distant by stage from Pierre, the State capital of South Dakota. It was built on a terrace about one hundred and sixty feet above low water, the ground rising behind it to the north and east about one hundred feet to the level of the rolling prairie lands beyond, sloping on the south to a deep ravine and on the west to a second terrace, about one hundred yards wide, on which were built the stables, granary, sawmill, etc. Below this terrace lay the bottom lands subject to overflow. The winters were severely cold, the prevailing winds from the northwest with little snow. The summers were excessively hot, with southerly winds and dust storms. In the spring frequent rains gave promise of a luxuriant vegetation, but a few days of hot weather destroyed everything, and left a brown barren landscape. The extremes of temperature were 37 degrees and 110 degrees F. The barracks for four companies consisted of a building 700 feet long by 17 feet wide, with a sallyport 15 feet wide in the middle of its length. The walls were of cottonwood logs, lathed and plastered. The interior was ceiled and divided by partitions into squad-rooms, mess-rooms, kitchens, etc.; the guard house and prison rooms were next to the sallyport. The dormitories were fitted up with rough wooden bunks, double and in tiers as in the emigrant ship, even as late as 1875, when the air space per man was only 255 cubic feet. The latrines, the earth pits of actual field service, were at the usual distance in rear. There were no lavatories or bath-rooms; the men washed in the open air. The officers' quarters were frame buildings affording nothing but shelter, and not any of that to spare. Two six or eight mule teams were constantly engaged in hauling water from the river, the allowance necessarily scanty and the quality inferior. Post gardens were cultivated in the river bottom, and in favorable seasons these were fairly productive. Improvements were slow in taking place at this post. Water was not introduced until 1890. Time was lost in an unsuccessful attempt to reach deep well water; the effort was given up after boring 977 feet. Ultimately a good supply was obtained from twenty wells in the river bottom. The water was pumped into a reservoir and distributed by gravity through six inch mains and three-fourth inch service pipes. Meanwhile frame buildings were constructed with ridge ventilation and fresh air inflows beneath the flooring, opening under the stoves. A bath-house was built with ten tubs and a plentiful supply of hot and cold water. The men were required to take a bath once a week, and a record was kept at the bath-houses. Earth closets were substituted for the pits formerly used, but the post never attained to the dignity of possessing a sewerage system. The natural drainage was good so far as regards rainfall; but the open ditches for the removal of waste water were a nuisance, foul in summer and useless from frost in winter. The hospital was closed November 19, in accordance with recent orders abandoning the post.

"Doctor Rabelais."—Since the following quaint conceit, from the versatile pen of Mr. Eugene Field, is given to the world through the medium of the *Book-Lover's Almanac*, 1895, in an edition limited to 500 copies only, the JOURNAL must give space for its wider circulation among those who will best appreciate it—members of the profession which the great humorist never quite abandoned even after he had become the immortal chronicler of the wonderful *Gargantua* and his still more marvelous son, *Pantagruel*:

DOCTOR RABELAIS.

By Eugene Field.

Once—it was many years ago,
In early wedded life,
Ere yet my loved one had become
A very knowing wife—
She came to me and said: "My dear,
I think (and do not you?)
That we should have about the house
A doctor's book or two.

"Our little ones have sudden ills
Which I should understand
And cure, myself, if I but had
A doctor's book at hand.
Why not economize, my dear,
In point of doctor's bills
By purchasing the means to treat
Our little household ills?"

Dear, honest, patient little wife!
She did not even guess
She offered me the very prize
I hankered to possess!
"You argue wisely, wife," quoth I.
"Proceed without delay
To find and comprehend the works
Of Doctor Rabelais."

I wrote the title out for her
(She'd never heard the name!),
And presently she bought those books
And home she lugged the same;
I clearly read this taunting boast
On her triumphant brow:
"Aha, ye venal doctors all,
Ye are outwitted now!"

Those volumes stood upon the shelf
A month or two unread,
Save at such times by night I couched
Their precious wit in bed;
But once—it was a wintry time—
I heard my loved one say:
"This child is croupy; I'll consult
My Doctor Rabelais!"

Too soon from her delusive dream
My beauteous bride awoke!
Too soon she grasped the fullness of
My bibliomaniac joke!
There came a sudden, shocking change,
As you may well suppose,
And with her reprehensive voice
The temperature arose!

But that was many years ago,
In early wedded life,
And that dear lady has become
A very knowing wife;
For she hath learned from Rabelais
What elsewhere is agreed:
The plague of bibliomania is
A cureless ill, indeed.

And still at night, when all the rest
Are hushed in sweet repose,
O'er those two interdicted tomes
I laugh and nod and doze,
From worldly ills and business cares
My weary mind is lured,
And by that doctor's magic art
My ailments all are cured.

So my dear, knowing little wife
Is glad that it is so,
And with a smile recalls the trick
I played her years ago:
And whensoe'er dyspeptic pangs
Compel me to their sway
The saucy girl bids me consult
My Doctor Rabelais!

Liability for Delay in Transporting Medicine.—Physicians have frequently to send medicines to patients by what the law terms common carriers. Suppose these public servants are remiss in the performance of their duties, does any one have a legal redress? For example, a Texas doctor prescribed, and directed a druggist to send medicine by express, for a woman lying seriously sick near another railway station, the medicine was delivered by the druggist's clerk to an employe of the railway company, to be carried by express

the latter being informed of the nature of the package and the importance of its being sent on by the next train. The railway employe gave the package to the regular agent of the express company, telling him it was to go on the train that night, but without informing him of the nature of its contents. The package, however, was not sent until the next day evening. The sick woman's sufferings, it was proved, in an action brought to recover damages from the express company, were increased by the failure of arrival of the medicine, and that the medicine would have relieved her; and the testimony tended to show that in consequence of its non-arrival she grew worse, and had a long spell of sickness, requiring medical attention, and expenses for a physician, who attended her afterwards for nearly three months. The case was tried by the court without a jury, and judgment rendered for the woman's husband, who it was that sued the express company, for \$300 for physical pain and mental suffering of his wife, \$25 for his own mental suffering, and \$40 for medical bill, making \$365 in all. Under these circumstances, the Court of Civil Appeals of Texas holds, in a decision rendered Oct. 10, 1894 (*Pacific Express Company v. Black*), that the employe of the railway company was so held out by the express company as its agent as that his agency might be implied by persons dealing with him as such, and that the fact that no receipt was given, and no written contract made to ship the package, would not prevent a recovery, if it was accepted for shipment. There was testimony before the court, in this case, from which it might be implied that the employe of the railway company was the agent of the express company to receive the package for shipment. He was notified of the fact that the package contained medicine for the woman who was sick, and that it was important that it should be sent on the next train. This, it is held, was notice to the company, rendering it liable for the injury occasioned by its neglect in forwarding the package with reasonable dispatch. Injury, both physical and mental, was shown to have resulted to the woman by the neglect of the company in delaying the shipment; and, the court declares, it must be held her husband was entitled to recover for such injury. It was not error to admit evidence showing the physical and mental suffering of the woman as the result of the failure of the express company to forward the medicine in reasonable time. But the sympathetic mental sufferings of the husband on account of the suffering and pain of the wife in prolonged labor, caused by the company's failure to deliver the medicine were too remote and consequential. His wife was the direct sufferer, which caused him anxiety and alarm. Her injuries were the proximate result of the default of the company. To allow a recovery for the mental anxiety of the husband on account of the wife's increased suffering, either mental or physical, would be to allow a double recovery for the same cause of action. The trial court should, therefore, not have allowed the \$25 for the husband's injury. Nor was it correct to allow the amount of the medical bill due to the physician attending the woman in her long sickness. It was too remote, and could not have been in contemplation of the parties. The judgment was, on these grounds, reversed as to the amounts allowed to the husband in his individual account and the medical bill, but affirmed as to the amount allowed for the suffering of his wife.

The English Doctor and the Amir of the Afghans.—Dr. G. A. Gray, who for a time was court practitioner at Kabul, has written in the *Lancet* an account of the bitter-sweet aspects of lofty official rank in Afghanistan. He says: "It is a not uncommon occurrence in Afghanistan for an attempt to be made to poison the King. Amir Shere Ali is reported to have died under somewhat suspicious circumstances. The present Amir's father also died suddenly very soon after he came to the throne. Sirdars or nobles of the Amir's own tribe of Barakzai Durrāni are set to watch over his Highness' food and drink, so that, as almost every Afghan has his price, it is possible that the Amir thought a European might have his price also. It is the custom in Afghanistan for the Hakim who is attending the King to drink some of his own medicine before the King tastes it. This was never required of me, but his Highness, though he called me when he was ill, did not as a rule, ask me to prescribe for him till after he had tried the effect of his own medicines and those of the other Hakim. When, however, he had once placed himself under my care he followed out exactly the instructions I gave him. One slight precaution alone was taken; a Hindostani

hospital assistant, one of the better trained, was set to observe and make a note of every drug I used, and I gave him every facility for doing so. I was not asked to treat the Amir medically until I had been many months in his service. His Highness did not ask to see my diplomas, but he received reports as to the effect of my treatment upon other people. I shall never forget one occasion on which he called me to attend him. It was in Kabul after our return from Turkestan. His Highness was taken ill with gout while I was suffering with the diarrhoea alba that I spoke of, so that he had been ill for two months or more before I saw him. It was 9 o'clock one night (Dec. 2, 1890) that I was called, and I found his Highness lying upon his couch rolling his head from side to side in extreme pain. The princes and the chief officers of the kingdom were there kneeling round the room, for they thought his Highness would not live till morning. He was certainly exceedingly ill, and it struck me at the time that I was in as much danger as he, for should he not recover there was scarcely a possibility of my escaping. Apparently, he had had gout in every one of his joints, but when I saw him the acuteness of the inflammation was confined to the right shoulder, elbow, wrist and knee. There was a large patch of crepitation in the left axillary line. He had inflammation of the tonsils and catarrh of the bladder, so that he was passing a drop or two of scalding urine every minute or two; the urine was albuminous to the extent of one-fifth, and his temperature was 103 degrees. He had had no sleep for several nights. I stayed in his room for five days and nights, applying hot belladonna fomentations and administering the medicines myself. As soon as his condition improved I began to make inquiries as to the line of treatment that had been adopted before I saw him. The Hakim had been attending his Highness. They had begun by administering three or four drastic purges; then they leeches the foot that was inflamed, putting on at one time, I was informed as many as a hundred leeches. Suppose we divide this number by three to allow for Oriental flights of imagination, thirty leeches will do. This was not enough, and they bled him frequently; at one time to such an extent that he was insensible, I was told, for twelve hours. Again allowing for Orientalism, say he fainted and was insensible for a few minutes; this is sufficient. Relief being but temporary, and the pain on return severer than ever, they were at their wits' end to relieve their royal patient. They, therefore, tried the effect of plunging the gouty joint into ice-cold water. How many times this was done I can not say, or what other 'remedies' they made use of; but after two months and a half of this treatment his life was in no little danger, and the Feringhi doctor was sent for.

"In spite of the kindness and courtesy with which I was treated at the court, I did not find the experience an altogether agreeable one until his Highness was out of danger. He finally recovered in the spring; but had he not been an exceptionally robust man he could never have borne the treatment to which he was subjected by his native physicians."

Louisville Notes.

LOUISVILLE CLINICAL SOCIETY.—At the regular meeting of this society, the annual election of officers was held. The following were the choice of the society: Dr. George W. Griffiths, re-elected President; Dr. Philip F. Barbour, re-elected Vice-President; Dr. Louis Frank, Secretary.

KENTUCKY SCHOOL OF MEDICINE.—On the 22nd inst., the Faculty of the Kentucky School occupied for the first time their commodious new hospital and dispensary. The first floor of the new building is used as a dispensary. The rest of it contains an elegant amphitheater, wards, and private rooms, fitted out in the most modern and complete manner—steam heat and natural gas, illuminating gas and electric lights. The dispensary has a large waiting room seating about one hundred patients, and twelve private clinical rooms, and a drug room. There are, also, on this floor a library, a faculty and secretary's room. The part in the adjoining old building formerly occupied as the dispensary is to be remodeled and will be used as a chemical laboratory. With this new building of the Kentucky School, the new buildings of the Louisville Medical and the Hospital Medical Colleges, and the added clinical departments of the University, the city of Louisville is abreast of any city with modern facilities for medical teaching.

DR. DAVID W. YANDELL.—Dr. Yandell is lying critically ill at his residence 706 W. Chestnut Street, this city. The announcement of this fact will cause sorrow among the Doctor's many friends throughout the country. He has not been well since his return from a hunt in the West, and there is no improvement as yet in his condition.

ST. JOSEPH'S INFIRMARY.—This institution is located on Fourth Avenue near the U. S. Custom House. The first section or central portion of the infirmary was erected by the Jesuits for college purposes in 1849. In 1852 it was bought from the Diocese by the Sisters of Charity of Nazareth, and established as an infirmary under the charge of Dr. Appollonia McGill. The building at this time had eighteen rooms and three wards. The first patient was received Nov. 29, 1852. In 1890 the first addition of fifteen rooms was made, fronting Fourth Avenue, and in 1893 the second addition was built, connecting the main house and wing, including the chapel, an operating room, nine private rooms and a dormitory. At present there are forty private rooms, and two wards (male and female) of fourteen beds. The nursing is done by the Sisters of Charity, and there is one Resident Physician appointed after a competitive examination from the graduating class of the Kentucky School of Medicine.

DIPHTHERIA.—At present, Louisville is quite abreast of New York City, in that its physicians are enabled to have cultures made from all suspicious cases of diphtheria free of charge to patient or physician. Dr. J. B. Marvin has obtained from the Health Department of New York, a number of the culture tubes and swabs used in that city, and these can be had from Drs. Frank and H. H. Koehler. The inoculated tubes and the swabs are returned to these doctors, with a few notes on the case; duration of the disease, age and sex of patient, where contracted, etc., and in twenty-four hours a report is made as to the nature of the suspected bacillus. This is entirely conducted by the gentlemen named, but the Health Officer is interesting himself in it, and perhaps before long we may have it conducted by the city authorities. In all the cases examined thus far—some twelve or fifteen in number—the result of the inoculation has been verified by the clinical history of the case; showing how invaluable the examination is to the proper conduct of the case.

PLEURO-PNEUMONIA IN CATTLE.—Dr. J. N. McCormack, Secretary of the State Board of Health, has investigated the report received from England, that Kentucky cattle exported to Liverpool were found to have pleuro-pneumonia. In the first place, he learned that the suspected cattle did not come from Kentucky, as was reported in the Washington despatches. Dr. McCormack is satisfied there is no pleuro-pneumonia in Kentucky and there has been none. The error in attributing the suspected herd to Kentucky is one that is calculated to injure the interests of the many export breeders of the State.

MORTALITY REPORT.—The weekly city mortality report shows a total of sixty-five deaths. There were from phthisis eight deaths; from diphtheria four; typhoid fever two; and from pneumonia sixteen deaths. There were thirty-six male, twenty-nine female, forty-five white and twenty colored.

New Orleans Notes.

TULANE UNIVERSITY.—At a recent meeting of the Faculty of the Medical Department, Tulane University of Louisiana, women were admitted on a parity with men in the Pharmaceutical School, and will be granted degrees. This action allows them to attend the lectures on chemistry, medical jurisprudence and toxicology, hygiene, materia medica and therapeutics, while previous to this they were granted certificates and the privileges of the practical laboratories only.

DIPHTHERIA ANTITOXIN has taken a strong hold. Last week Dr. P. C. Archinard, Bacteriologist of the State Board of Health and Demonstrator of Bacteriology, Medical Department Tulane University, sailed for Europe via New York to personally study the subject. The public have responded nobly with subscriptions for the purchase of this new remedy, and there is considerable talk of establishing a station for the manufacture of the article in this city.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Nov. 17, 1894, to Nov. 23, 1894.

Capt. ADRIAN S. POLHEMUS, Asst. Surgeon, leave of absence granted is changed to leave of absence on account of sickness, and is further extended to include Dec. 26, 1894, on surgeon's certificate of disability.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending Nov. 24, 1894.

Surgeon FRANKLIN ROBERS, ordered to the U. S. R. S. "Wabash." P. A. Surgeon E. P. STONE, detached from the U. S. R. S. "Wabash," and to the Naval Hospital at Boston.

P. A. Surgeon CLEMENT BIDDLE, detached from the Marine Recruiting Rendezvous, Philadelphia, Pa.

Asst. Surgeon T. W. RICHARDS, ordered to Naval Laboratory and Department of Instruction.

Marine-Hospital Changes.—Official list of changes of stations and duties of medical officers of the U. S. Marine-Hospital Service, for the ten days ending Nov. 15, 1894.

Surgeon H. W. AUSTIN, to proceed to Boston, Mass., and assume command of Service, Nov. 10, 1894.

Surgeon FAIRFAX IRWIN, to assume charge of Quarantine Division of the Bureau, Nov. 14, 1894.

P. A. Surgeon W. P. MCINTOSH, granted leave of absence for fourteen days, Nov. 9, 1894.

P. A. Surgeon G. B. YOUNG, granted leave of absence for seven days, Nov. 8, 1894.

Asst. Surgeon EMIL PROCHAZKA, granted leave of absence for thirty days, Nov. 14, 1894.

ORIGINAL ARTICLES.

LEPROSY IN AMERICA BEFORE THE ADVENT OF THE SPANIARDS AND THE NEGROES.

BY ALBERT S. ASHMEAD, M.D.
NEW YORK.

There seems to be some apparent authority for the existence of leprosy in Mexico and Peru, before the arrival of the Spaniards. Sabagan¹ says: "It was the custom in ancient Mexico that once in eight years they danced around the statue of Tlaloc. The performers were masked as animals, birds, laborers and sick men." Among the diseases personated by the latter, syphilis and lepra are named.

We find in the same author, a sentence of much more importance: "Those who have the disease of lepra generally lose their eyebrows and suffer great hunger. To cure them it will be necessary to give them a bath, two or three times, and when they come out of the bath, it will also be advisable to rub them with herbs and roots which have been first ground. Let them drink the water of a root called *texputli*; and if these remedies do no good, they must be cut off from the intercourse of the other people, lest they might infect them." While the symptoms here indicated, the falling eyebrows and the hunger, are common to both leprosy and syphilis, the remedies which are said to have effected the cure, would suggest syphilis rather than leprosy. The fact that the remedies failing to effect a cure, isolation was advised, would apply to both syphilis and leprosy.

At Sabagan's time, the Spaniards in America knew syphilis only as a new epidemic disease in Europe, and likening it to leprosy, must have deemed it contagious, as they thought leprosy was; they therefore isolated syphilitics, just as lepers had been for several centuries isolated in Europe.

Torquemada² speaks of "leprosos bubosos, and sarnosos," distinguishing, it seems, between leprosy and the two other diseases.

The use of the word, lepra, here, is just what proves to me that leprosy is not meant. For the Spaniards were more likely to speak of the disease which we call leprosy, as *mal de san lazaro* and call the lepers, *lazaros*. What they called lepra may have been simply a form of sarna, itch. Leprosy was exceedingly well known to the Spaniards, and if they had met with it in these new countries, would they not have spoken of it as the old scourge known for centuries in Europe?

Brinton³ affirms that lepra does not mean in Spanish or in medical Latin, Oriental leprosy.

Dr. Manuel A. Muniiz in "La Lepra en el Peru"⁴

quotes Parra⁵ as giving the name of the first notable Spaniard who contracted leprosy in Peru, Gonzales Ximenes de Quesada.⁶ He remarks, which was hardly necessary, that the disease of which that Spaniard died, was established in Peru before the Spaniards came. According to this same Parra: "The favorite resort of this disease in America has been Old Columbia. (See note.) It never gained much of a foothold in Peru."

We may understand that the conquerors found here a disease which was not leprosy, the presence of which they would have signaled as that of a well-known European fact (for leprosy had been carried to Spain by the Roman soldiers and was common there in the tenth century), a species of itch new to them.

An important fact is that in those days, the Indians of the Pacific coast were not immune from the disease they called lepra, while they are to-day perfectly immune from leprosy. The Spanish monarchs issued a number of orders to have lepra hospitals founded for Indians, as well as Spaniards, and expressed their earnest wish that no village, either Spanish or Indian, should be without a hospital (see fourth law of the *Recopilacion de Indias*). Edition of Charles III.

Ulloa⁷ who wrote about three hundred years after Columbus, says: "The Indians are vigorous and strong. Syphilis (lues) so common in those countries (Mexico and Peru) did not affect them much, and it is even rare to see any of them suffering from it. The cause of this difference is doubtless to be sought in the difference of their humors, which are but little susceptible of the virus of this disease."

He, then, while stating that the Indians do not catch the disease easily, yet assumes a degree of immunity from syphilis in them. We see here that the Indians, although very little affected by syphilis were yet not wholly immune, while it is known to-day that they are immune from leprosy. It was probably for some kind of bubosos or sarnosos that the Spanish monarchs ordered those hospitals built.

Syphilis is admitted to have existed in America before the arrival of the Spaniards. It is the disease most likely to be confounded with leprosy. In eastern Asia the two diseases are considered as being antagonistic; as one declines in a particular locality, the other prevails. This fact is patent in Europe; as soon as leprosy declined, syphilis prospered, which contributed to the confusion of the two diseases at the end of the fifteenth century.

Syphilis, when first inoculated in Europe, was very violent and widespread; then it gradually weakened

⁵ Ricardo Parra, of Bogota, Republic of Colombia. La Lepra (1850-1860).

⁶ See Father Lucas Piedrahite: History of the Conquest and Discovery of the New Kingdom of Granada. See also Father Simon: Historical Notes of Piedro Firme.

⁷ Voyage Hist. de la Amerique Meridionale, 1752.

NOTE.—It corresponds to the "New Kingdom of Granada," called afterwards the "Vice Kingdom of Santa Fe," which has formed to-day three Republics, Colombia, Venezuela and Ecuador. Cartagena of the Indies was a very ancient focus of lepra.

³ Personal Communication.

⁴ La Cronica Medica, Nos. 28, 29, 31, 32, 1886.

its hold and to-day it is comparatively mild, a circumstance which makes any confusion now with leprosy impossible.

The history of syphilis in eastern Asia is the same. There it has existed for over two thousand years, and it has gradually acquired in those races, by repeated inoculation, a mildness at which Europeans are surprised. When the Spaniards came to America it was at the time when Europeans were first receiving their inoculation of syphilis. If they brought it to America they must have communicated it to the Indians with the same degree of virulence as it had then in Europe. That they did not, that the form of the disease at that time was mild in the native Americans shows that they must have acquired, during a long reign of the disease, a considerable degree of immunity. If they had acquired that immunity, no confusion between leprosy and syphilis could occur in the minds of Spanish writers, who were well acquainted with leprosy in Europe; such a confusion was only possible in the most active stage of the evolution of syphilis in the Indian race. Therefore there can hardly be a doubt that when the Spaniards called something lepra, and not *mal de san lazarus*, they knew perfectly well what they were about. Now these writers have mentioned a disease which they called lepra. The word *teococoliztli*, which Brinton⁸ tells me designated a disease well known in ancient Mexico, is translated in Spanish books as lepra. He states further: "In Maya apparently the same disease was called *uez*; it was contagious, and a species of itch. (See *Perez Diet. Maya*). Torquemada says that the ancient Mexicans sacrificed lepers to the white maize god, *Iztac-centeotl*; this probably refers to progressive albinism."

Now on reference to the ancient dictionaries of the Maya, I find that *uez* is in Spanish, *una especie de sarna o' lepra*, a kind of itch or lepra, showing that the Spaniards understood this species of itch to be something different from leprosy. That they did so understand is shown by the meaning of the other Maya word *ueez*, which, in Spanish is *empeine o' lepra*, that is groin or lepra, showing that syphilis (*bubas*), was also included in the term, lepra. *Nanahuatl* is the ancient Mexican word for syphilis. But the Spanish writers in naming these various diseases, in their own language, use the terms lepra, bubas, sarna, for all of them, sometimes choosing the word lepra, sometimes sarna, at other times bubas.

On the Atlantic coast no confusion between syphilis and leprosy occurs. The authors of the Reports of the Hospital dos Lazaros,⁹ Rio Janeiro, state definitely that the lazarus, who were undoubtedly lepers, date in Brazil from the advent of Europeans and negroes.

We read in the *Annals of Rio de Janeiro*, fifth volume, page 210 e. s., of Silva Lisboa, that "in the seventeenth or end of the sixteenth century, there appeared in Rio a disease called lepra (the word here used in its true sense), but which was commonly known under the name of *morphoea* or *mal de san lazaro*. It was attributed to the scurvy of the imported black, to the bad accommodation and food of the poor, to the immorality of women, and also to the dampness of the dwellings surrounded by marshes." Its appearance was, therefore, much before its ap-

pearance on the Pacific. Brazil had not come into full contact with the Europeans as early as Mexico and Peru.

Dr. Francisco G. Delgado¹⁰ Secretary of the General Archives of the Indies at Seville, Spain, says that syphilis (*venereo*), or bubas, the latter being the most ancient name of the disease appeared at the same time on all the points occupied by the Spaniards in America. He can not say whether "the germ of leprosy and syphilis" (for it must be borne in mind that there was at that time a confusion of the two in Europe) was brought by the Spaniards infected in Italy, (see note), or whether it developed here through their contact with the Indians, or whether it had already been imported from some East Asiatic land. But he knows that in Mexico the bubas (*males venereos*) was known a few years after the Conquest, and that the hospitals (whose foundation was recommended by the kings) were really intended for syphilitics. The disease, bubas, was mentioned at about the same time in South America, that is in Peru and Rio de la Plata, and to it was attributed the death in 1527 of Don Pedro de Mendoza, the first conqueror and colonizer of Rio de la Plata. His death was attributed by the historians to the disease known as the French disease (*galico*). See fourth song of the Argentina, written by Basco de Centenera.

In the book entitled, "Fray Juan de Zerमारagga, First Bishop and Archbishop of Mexico," a biographical and bibliographical study by Don Joaquin Garcia Izcabalzeta (Mexico, 1881), mention is made of a bubas hospital built by the said prelate.

Mention is also made of syphilis and not of lepra, in the Mexican bibliography of the sixteenth century, some details of which are taken from a work by Dr. Cardenas, printed in Mexico, 1591.

In "Diez Frayle," a work written in 1571, much is said about syphilis. In these books no mention is made of leprosy, not even of the disease which went by the name of lepra.

Dr. G. Armauer Hansen, of Bergen, Norway, writes me: "If leprosy had existed in America before the immigration of Spaniards, the disease ought to have been much more spread over the American continent than it really is. Leprosy being a contagious, or if you will, an inoculable disease, and the racial customs of the ancient inhabitants of America most probably not being characterized by cleanliness, the disease ought to have invaded a large part of the population." . . . "I have no clear idea," he says, "and nobody has, I believe, of the earlier intercourse between America and eastern Asia, but if there has been an immigration from Asia to America, I should think that it has taken place in the northern part, where the two countries are nearest each other, and that, in consequence, leprosy ought to have been spread among the North American Indians, to whom the disease, however, never has been known, as far as I know."

Dr. James E. Moore, of Barbadoes, West Indies, writes: "This island has never been inhabited by Spaniards; the Spaniards and Portuguese are said to have frequently visited it with a view of captur-

¹⁰ Personal Communication.

NOTE.—Leprosy came to Italy sixty-two years before Christ, and appeared in Spain in the tenth century. It is not, therefore, easy to see why the disease should not have come directly from Spain with the followers of Columbus and afterwards with Cortez, Pizarro, Bilbao, etc. There were, probably, among the invading crowd a great number of soldiers who had served in the Italian wars, and who may have brought leprosy from Italy.

⁸ Personal Communication.

⁹ Hospital dos Lazaros, Reparticao annexa á Irmandade do Santissimo Sacramento da Freguezia Da Candelaria, Rio de Janeiro, 1893.

ing the Caribs, by whom it was then inhabited. This was previous to the year 1624, in which year it was settled by the English, and since which it has always been in their possession. The earliest account I can stumble over of leprosy in this island, is in a small book written by Wm. Hillary, M.D., 'Observations on the Changes of the Air and the Concomitant Epidemical Diseases in Barbadoes.' He says: 'This dreadful disease was first brought to this and the other sugar islands by the negroes from Africa, and is undoubtedly a native of that quarter of the world and Arabia, and is not originally of this western part. Neither was it ever known here before it was brought hither by the negroes.' This was written by him in 1772."

Dr. Enrique Robelin, who is an authority in Cuba, writes me: "American leprosy is an importation. The Indians did not know it before the arrival of the first conquerors. We may extend this statement to all the Antilles, Cuba included."

Brinton¹¹ never heard of leprosy in America either at or before the time of the Conquest. He also denies the introduction by migration of either arts, words or diseases from eastern Asia into America. "The current," he says, "was in the other direction.

When we study the earliest accounts of the explorers of Behring's Straits, we find they speak of American tribes (Eskimos) on the Asian side, but no Tschutsches on the American side. There was a trade between Siberic and Alaskan peoples, but no hint in historic times of a migration from Asia to America, and no archæologic evidence of it, that I know of, in prehistoric times."

Dr. Brinton further says: "Herrera¹² makes no mention of any such disease until seventy years after the discovery."

Muniz¹³ says: "The first leper hospital in Peru was founded thirty and odd years after the foundation of Lima (Lima was founded by Pizarro in 1535), in the place now occupied by the Quarter of San Lazaro."

Leprosy was unknown in the highlands of Peru which were the abode of the Peruvian Indians. This we learn from Ulloa,¹⁴ who wrote in 1797. Now the Quechuas and Aymaras were the main tribes established on that plateau; they were syphilitic three hundred years before Pizarro entered the empire of the Incas, and had become so probably a thousand years before, through contact between themselves. They had a common name for syphilis, *huanthi*, but none for leprosy. (See Tschudi, "Organismus der Khetsua—Sprache.")

Muniz, however, tells me that: "On the other side of the Andes there are, in Peru, regions truly tropical and mountainous, where lepra may have existed or may exist to-day." As to the occurrence of leprosy among the Incas he thinks that it is "almost sure." He seems to find a proof of this in pieces of pottery ("huacos") or articles of earth, though it is not clear to me in what manner. Leprosy, according to this author, may possibly have existed before the Conquest. He is inclined to believe that it did.

"Leprosy existed in Peru in the lower country," says Ulloa, "but was not rampant on the coast of terra firma." It propagates itself rather freely, and still more so in Habana. In those places they be-

lieve that it is caused by the quality of the pork which is there eaten abundantly, and that the fruit of a certain palm, called Royal, and which is also known as Palmiche, and is a favorite food for swine, aggravates the case. The flesh which has been fed by this food is richer in glandulæ than the normal flesh, these being of a black color, and being perceptible in the whole region of the neck. In spite of the popularity of this theory, we must consider as the chief cause of the origin of leprosy, the introduction of the African negroes, in whose country it is very old and very much at home."

We read in "La Lepra en el Peru," by Muniz¹⁵: "In spite of painstaking investigations, it is impossible to make a statistic study of leprosy in Peru. There is nothing to go upon. There are no registers, and those which we encounter are insufficient to serve as a basis for statistics. One fact, however, is certain. It is the decrease in the number of cases. Leprosy has been very hard on the black; all, or almost all, of the ancient inmates of the Refugio, and those who successively died, were emancipated negroes, the disease affecting the Indians rarely, and the whites still less."¹⁶

"At present all the lepers are Chinese, and their Society of Beneficence has undertaken to offer them an asylum in their hospital at Bellivista."

Dr. A. E. Edwards, of Antigua, West Indies, is of opinion that leprosy was introduced in that island by the African slaves. At any rate it is a fact that leprosy never was seen there outside of the black and colored population, with only one or two exceptions. Dr. Edwards knows of some Chinese cases imported into Antigua ten years ago. There is no history whatever of the Spaniards ever occupying this island. So the disease must be of African origin.

We may safely conclude, ourselves, from all these facts, that there was no leprosy in the native population of America; that that same population has known syphilis for centuries; that Spaniards coming across this new disease supposed it to be akin to leprosy and called it lepra, a word which afterward was wrongly believed to be synonymous with leprosy.

YELLOW FEVER INOCULATION, LIKE BANQUO'S GHOST, WILL NOT DOWN.

BY J. McFADDEN GASTON, M.D.

ATLANTA, GA.

In the *Diario de Noticias*, of October 23, published in Bahia, Brazil, there appears an article touching inoculation as a prophylactic against yellow fever. I have made a literal translation of it, and present it for the consideration of the medical profession in this country, without note or comment, as follows:

"In the International Congress of Hygiene and Demography, of Buda-Pesth, assembled in last September, the question of yellow fever was discussed and Dr. Miranda de Azevedo, a delegate from our government, presented to the distinguished assembly the report of our illustrious citizen, Dr. Domingos Freire, whose investigations upon the etiology and prophylaxis of this disease are well known.

"The Congress formed in this respect, the following conclusions:

¹¹ Loc. cit.

¹² The first negro came with Pizarro and was with "the thirteen" of the *Island Gallo* before the conquest. Already in 1536 there were maroon negroes in Peru. The King granted to Pizarro the privilege to import negroes from Africa.

¹³ Personal Communication.

¹⁴ *Historia general de las Indias*.

¹⁵ Personal Communication.

¹⁶ Secret Memoirs of the Journey to South America.

"1. It is a fact attained for science, thanks to the labors of Prof. Domingos Freire, supported by many physicians of Brazil and by observers of other countries, that a microbe (*cryptococcus xanthogenicus Freire* or *bacteria de le Dantee*) is the active cause of yellow fever.

"This microbe is found in the blood of the patients, principally in the large blood vessels, and also in the parenchymatous tissues of the organs, where they form colonies more or less numerous.

"According to Professor Freire, it measures only one-thousandth part of a millimeter, reaching, however, a larger size in the liquid cultures, principally if they are heated from 37 to 40 degrees Cent., for many days. It executes very rapid movements, as noted by a large number of observers.

"Examined in the fresh state without being heated, this microbe presents a central clear point which is very characteristic. The microbe of yellow fever is readily colored by fuchsin or the methyl blue and violet. After heating, the central spot disappears entirely.

"Gelatin is liquified by it, and according to the experiments of Professor Freire, it is reproduced in spores.

"2. The microbe of yellow fever produces ptomaines which infect the organism. In accordance with the investigations of Prof. Domingos Freire, these alkaloids are formed at the expense of the albuminous matters of the body. He isolates two ptomaines of a liquid form and one gaseous. The sediment of black vomit, the blood of the sick, and the cultures of the microbes, contain these ptomaines.

"3. The experiments and studies, upon the preventive inoculations, of Professor Freire, against the yellow fever should be continued, as the best means of combating the existence and development of this disease.

"4. The therapeutic process which affords the most constant and the most beneficial results, according to the practice of Dr. Miranda de Azevedo, in various epidemics, is that of bichlorid of mercury, the salicylate of soda and naphthol internally. Dr. Angelo Simoes, St. Paulo, has employed chlorin water with good effect. To stop the vomiting, and especially that of blood, the tincture of iodine has been given.

"5. The treatment with quinin should not be used, as it is almost always hurtful, and leads to vomiting.

"6. By employing the means recommended by hygiene, prophylaxis, disinfection and cleanliness of cities, there ought to disappear completely the active germs of yellow fever, as has already been accomplished in the city of Campinas, (State of S. Paulo, in Brazil).

"7. The yellow fever is not endemic in all parts of Brazil. It is only developed there when hygienic laws are not observed; as it can appear everywhere when the active microbe is transmitted and finds means of growth.

"9. The period of incubation does not generally exceed eight days. We should then condemn the vexations and useless quarantine observed in Lisbon against ships coming from Brazil, principally when cases of disease are not verified in this country eight days prior to the departure of the vessels."

THE DISEASE OF INEBRIETY.

ITS STUDY FROM THE STANDPOINT OF THE EXPERIENCE OF AMERICAN PHYSICIANS OF EMINENCE WHO HAVE WORKED IN THIS FIELD OF RESEARCH.

BY EDWARD C. MANN, M.D.
NEW YORK CITY.

(Continued from page 826).

CONFIRMED INEBRIATES.

I shall call the first class confirmed inebriates. I prefer the word, confirmed, to the more common term, habitual, for the reason that one may be in the *habit* of occasional or frequent intoxication, and yet not be so far established in the habit as to warrant the application of the term in its ordinary sense. How to care for this class, more than any other, is the problem that the civilized world is now endeavoring to solve and in which every household is immediately or remotely concerned. Confirmed inebriates constitute a considerable class of the community; they are as a rule, largely unproductive, and a necessary drain upon the resources of the people. What can be done for or with them? The first thought in this connection involves the idea of custody and restraint and this is always offensive to the intuitive love of freedom, which in this country especially, is the fountain impulse in every American breast. All our actions are influenced by this impulse, which is as native to our intellectual being as the capacity to breathe is to our physical nature. Yet the safety of the victim's family, the security of his estate, the peace of society and his own welfare, demand that his downward career must be arrested. How far his personal liberty may be restrained to accomplish this end is a delicate question; but perhaps there is no maxim more pertinent to the case than that of John Stuart Mill, who, when discussing the liberty of the subject says: "As soon as the liberty of the subject interferes with the general interest of the community, the liberty of the subject must be forfeited."

The most democratic government will allow that however sacred may be the rights of men individually, they are no more valuable to the individual than the rights of a community are to those who constitute it. A confirmed inebriate is one whose body is poisoned, and whose moral development is retarded. He is incapable of doing what, in his best moments his will prompts him to do, and hence may be dangerous to his family or neighbors as well as to himself. The interests of the community are thus interfered with, and it becomes the duty of the State to defend itself. Hence penal enactments have been adopted, with a view of protecting the community; but the error has been, as it seems to me, that society has overlooked the interest of the offending class. It deals with them simply as criminals, and offers them no aid to a better life. We need not go beyond our own country for proof to convince us that fines and imprisonment for a few hours or days are utterly useless, either as means of recovery or as a protection to society. On the other hand, the degradation and demoralization which are the essential sequelæ of such a course, lessen the chances for the improvement of the individual, and increase the danger and expense of the community, by increasing the liability to offense and criminal prosecution. Detention in asylums, or sanitariums, with appropriate work for body and mind, under prescription of medical offi-

cers, and a limited probationary trial before being finally discharged, would be the salvation of thousands of inebriates and a source of economy to the State. In many cases the detention might be permanent and it could be made more or less productive by the laboring classes. None would be more ready to accept such an alternative than those who are incurable and helpless, provided the odium and disgrace now attached to commitment and detention are removed, and the appliances for improvement and culture take the form of hospital treatment in place of penal retribution.

Class number two will now be considered :

EMOTIONAL INEBRIATES.

Those who without bad intentions or acute convictions of duty and responsibility, or established principles of right, give themselves to the promptings of impulse, and whom I shall denominate emotional inebriates. Emotion may disturb the processes of nutrition, and all the changes incident to the chemistry of life, while the *will* remains powerless and dismayed. Illustrations of this fact might be drawn from the various erratic displays of hysteria, and the strange effects of grief, joy, fear, etc., upon the visceral functions. We have all seen such cases and our experience must have taught us that the victims of emotional irregularity and excess are frequently the most wayward and difficult subjects we are called upon to treat. The same constitutional conditions which induce hysteria in some cases, induce in others the desire for alcoholic stimulants, and the susceptibility to the poison in such is frequently acute. It would be as wise in the one case as in the other, to attempt restoration by fines and imprisonment. Removal from disturbing associations to new and invigorating influences; restraining excessive development on one hand and stimulating feeble powers on the other, is the end to be sought in either case. It is equally true that in both there may be symptoms of violence, as exhibited in hysterical mania or in delirium tremens when such restraint will be temporarily necessary, as can not be judiciously had at home. Nothing is more common to practitioners of medicine than to witness such cases in private practice.

What are popularly known as nervous diseases interfere with domestic happiness and create discontent by their strange eccentricities which seem, at times, to exhaust the patience and even the sympathy of the fondest friends. The subjects of such disorders are, at times, unfit for the enjoyments and amenities of the social circle as they are disqualified in domestic life for its obligations and pleasures. They are frequently committed to asylums for the insane, as the most available remedy, although they do not strictly belong to the category of insanity. Inebriation is but another form of family sorrow and public annoyance; and as both conditions result from similar constitutional causes and are alike distinguished by eccentric and disturbing conduct, there seems to be no good reason why one should be the subject of scientific care and the other of fine and incarceration. If no such reason exists, it is submitted that special institutions are the best remedy for the emotional form of inebriety, where the enfeebled forces may be strengthened by exercise, and the tendency to excess be suppressed rather than restrained, by preventing as far as may be, the occurrence of emotional excitants.

ACCIDENTAL INEBRIATES.

The third class will be named accidental inebriates. Such are men of good principles and character who know and acknowledge their infirmity and endeavor to overcome it. Students, authors and over-worked business men furnish a considerable percentage of this class. Salesmen, also, of large mercantile houses, in the busy rivalry of trade and hospitable attentions to customers are led into the practice of drinking without being conscious of their weakness, till they discern that they are enticed into inebriety and know not how to escape. They are overcome by drink, as men are often overcome by eating immoderately. Colic, gastritis, apoplexy, death may be the consequence of excessive eating; and intoxication with all its resulting dangers of excess in drinking. And why one should be treated as a disease and the other punished as a crime, is among the anomalies of our civilization. If we would endeavor to study the conduct of men, in its relation to the common law which underlies and controls the vital processes, we would be more ready to see that an over-worked brain which reels from its balance into insanity, is alike responsible for the strain to which it has submitted itself, with another over-worked brain, which vainly seeks relief in the use of alcoholic stimulants, and finds, at last, that while it avoids the one evil it falls into another that is equally alarming, etc.

Whether our institutions are large or small, public or private, seems to me but of little importance, provided the means for classification and distinctive treatment are supplied. What these means should be is an important question.

We have denominated three classes; confirmed, emotional and accidental inebriates. It is fair to assume that a large proportion of the first class are beyond the reach of complete recovery, and that they need constant care and supervision in institutions which should be empowered to restrain and control when necessary.

The second or emotional class require rather an educational process, the end of which, as already stated, should be to equalize a disproportionate system and secure stability of character.

The third or accidental class furnishes a large proportion of cures, and should be provided with institution accommodations that are suitable for thoughtful and serious men. With such men convictions mean something; sorrow is real; effort is earnest; and a quiet persistent struggle with self and temptations is a warfare that must be sustained by associations of an elevated and invigorating character. If society would establish within given districts according to the population, asylums where the confirmed class should be kept under judicious restraint, they would, in my judgment react most favorably upon all other classes of drinking men, to urge them to the use of every available means to avoid in themselves the alternative of commitment and detention. These institutions should not be large but numerous; they should be brought as near to the people as possible, that the people may feel them to be what they really would be, an abiding reproof and warning. In addition, there should be homes or hospitals for the curable, which would be sought for and patronized by a large class of earnest and anxious persons. Economy would be thus insured and public health and morals improved. If crime and disease are as largely the result of intemperance as

is generally believed, it is evident that it is cheaper to detain the confirmed inebriate that he may not be in a position to become a criminal, and to treat the better class in hospitals, where they may have opportunity to recover and become productive with less risk of being burdensome to society and of continuing a diseased posterity.

Statistics seem to prove that crime and intemperance are concomitants of each other, and affect both the social and physical welfare of the people to an extent of which we have yet but an imperfect view. It can not, therefore, be otherwise than safe and economical in the State, to prevent the crime by detaining the confirmed inebriate under proper restraint, and curing the milder form of the disease in suitable and properly endowed institutions, that the effects of this terrible companionship may be modified in this, and largely prevented in the next generation.

The existence of such institutions would afford opportunity of studying the subject of inebriety, as it can be studied in no other way; and they would be instrumental in diminishing the demand for alcoholic and other narcotics, while public sentiment would of necessity become more enlightened, and results could then be secured which would do much to instruct the legislation of the country. As such institutions are multiplied and sustained by judicious legal authority, the public sentiment of the civilized world will approve and foster them.

Light is needed as to the nature of the alcoholic poison and its wonderful power of arresting and destroying vitality; and we should be encouraged to continue, and accumulate and disseminate light concerning this obscure and disastrous evil and the means for its treatment. Society owes much to the inebriate. It recognizes intoxicating beverages as legitimate articles of commerce. Government derives large revenues from their sale, and the law creates a monopoly of the traffic, under a license system, which is more potential for evil than any other adjunct of the government. Society is instrumental, by its defective sentiment and practice on this subject, in creating most of the disability under which the inebriate struggles. It takes from him his property, and in some instances destroys his citizenship, enters the domain of his domestic life, blights the source of family happiness and social prosperity, and then fines him for doing what it entices him to do, and imprisons him for violating a law which entraps his weak virtue, and makes him a victim to the cupidity of the state. To no other class does it mete out such singular inducements to evil, and to no other class does it award such unreasonable and offensive punishment. It may be said that the fault is not in the law or in public opinion, but in the individual. This is true in a large sense, but the fact must be borne in mind that among the results of our abnormal civilization is a generation of people with unusual susceptibilities to evil influences, and that as a consequence they seek abnormal means for supplying the intense demand that is made upon them under such a system. Hence the necessity for a jurisprudence that shall recognize the source of the evil and provide for the protection of those who are weak in will, in judgment or in moral sense.

I desire to call especial attention to the views of the two preceding gentlemen, Dr. Willard Parker and Dr. Joseph Parrish, as they were the pioneers of

the scientific investigation and treatment of inebriety in America, Dr. Parrish having been the originator and master spirit of the "American Association for the Cure of Inebriates." The views of the late Dr. Theodore L. Mason, given below, are of especial interest as he has also passed away, leaving behind him the memory of good deeds, sterling worth and large experience in the field of inebriety. In his anniversary address in 1877 before the American Association for the Cure of Inebriates, of which he was at that time the President, he spoke as follows respecting inebriety as a disease. After stating that the objects of the Association, as set forth in the plan of organization adopted by them, were "to study the *disease* of inebriety, to discuss its proper treatment, and to endeavor to bring about a coöperative public sentiment and jurisprudence;" and that in 1870, at a meeting of the Association, a declaration of principles were unanimously adopted in which these postulates were enunciated: 1, "intemperance is a *disease*;" and 2, "it is curable in the same sense as other diseases are curable," Dr. Mason proceeded as follows: "The first of these principles, viz., 'That inebriety is a *disease*,' is the great fundamental principle upon which the oldest, best established, best known and most successful inebriate asylums in this country are based. The correctness of this principle has, however, in a few instances been denied. I propose to inquire in this paper, What inebriety is? Is it, as some persons affirm, always a *vice*, merely, or is it also a *disease*? May it not be in certain circumstances one of these, *vice*, and in other circumstances *disease*?"

"1. What is the nature of the action of alcohol upon the human system?"

"2. Does alcohol cause acute and chronic constitutional disease in the persons habitually using it?"

"3. Is the diseased constitution thus caused transmissible to the offspring of the drinker?"

"4. Is there evidence that family and national character and constitution may be degraded, by the general use of alcohol?"

"5. And, lastly, are these evils thus caused remediable, and how?"

"A few remarks, may, perhaps, not improperly be here premised as to the character of the active agent, the substance upon the use of which in our own and in the insular and continental countries of Europe, inebriety chiefly depends—alcohol, in some of its varied forms. I do this more readily because of the indefinite and modified manner in which it is sometimes spoken of, even by intelligent physicians. That it is a poison all admit. But immediately upon this admission you will not unfrequently hear this qualifying remark: 'It is a poison when taken to excess;' or, 'it is good for the stomach, but becomes a poison when its effects are felt in the head.' Now this betrays a confusion of ideas, a lingering tendency to hold on to the exploded notions of the past, or an ignorance of the latest teachings of science for which we might find an apology in the jolly monks of the *schola salerniterna*, whose maxim as quoted by Duglinson was: "*Si nocturna tibi, noceat vini; Hoc tu mane vives iterum et fuerit medicina*," but neither of which we think is, at this late day, worthy of intelligent medical men. We do not talk thus about arsenic, opium, atropin, Indian hemp or prussic acid, or any other vegetable or mineral poison. All of these, though poisonous, are of use, and have their places in the *armamenta medica*—

places which the modern practitioner would find it difficult to fill were they removed. They are all of great benefit to man as *remedies for disease*, but they are nevertheless indisputably poisonous. Just so, alcohol has its use in the treatment of disease, but it is a *poison to the normal and healthy man*.

"No intelligent person would say: 'A little arsenic or a little opium, or a little Indian hemp, or aconite, or atropin or prussic acid is a *nutriment*, and is of benefit to man in health and should be taken daily and regularly; but a little too much is a *poison*.' Why, then, suffer ourselves to think or speak thus of alcohol? No. Alcohol is never a *nutriment*, or fit for daily use. Alcohol is a *poison*, inherently, absolutely, essentially; in a drop or in a gill, in a pint or in a gallon, in all quantities and in every quantity it is a poison. Plainly, the quantity can not alter its chemic constitution. The chemic formula, C_2H_6O , expresses the relative proportion of the constituents in a teaspoonful or a gallon of *ethylic, dentilic*, or common alcohol; and Christison and many other authorities in *materia medica* have assigned its place among them as a narcotico-irritant poison."

Alcohol is supposed to have been discovered in the eleventh century of our era by an Arabian alchemist, Casa or Albricasis, a distinguished professor of the mystic art whose adepts were popularly supposed to be helped in their discoveries by the devil, the great enemy of man from the beginning; and verily, were I to judge from the results alone of *this* discovery, I should be strongly inclined to the popular belief, for surely I speak the words of truth and soberness when I declare that, since the transgression of our first parents "brought sin into the world and all our woe" no *single* discovery of man, in his persistent "seeking out of many inventions" has been fraught with such dire results to the moral and physical well-being of our race. The more than seven thousand members of the British Medical Association; the one hundred members of the AMERICAN MEDICAL ASSOCIATION, who met in 1877 in Chicago; the report made before the Section of Medicine of the Centennial Medical Convention in Philadelphia in 1876, composed of representative men from all parts of this country and from Europe, all concur substantially in this one opinion of the noxious effects of alcohol on those who indulge in its habitual use. To this testimony, so clear and full, in justice to our own members and as proof of the views held by them from the organization of this Association I feel constrained to add their evidence.

In a report of Dr. Earle, of the Washingtonian Home in Chicago, I find this description: "Alcoholic mania is the term we apply when, with impaired mental and physical condition, the man seems to have lost all will-power to do as he would. He would do right but he seems to have lost the power to do it. He makes the best of resolutions, calls the Divine Being to his help, but at the first opportunity falls." Is there no disease here? Is this man in a normal healthy condition? "Delirium tremens," he says, "is characterized by insomnia, hallucinations of the special senses, low delirium, with its consequent decreased mental vigor, and with increased digestive derangement." Does no disease exist in this case? Dr. Day, in his paper on "Inebriety and its Cure," read before the Suffolk District Medical Society in December, 1876, propounded this question: "Is there satisfactory proof of the existence of a dis-

ease called dipsomania? If so, can it be cured? I give an unhesitating answer in the affirmative." In his paper on "The Pathological Influence of Alcohol or the Nature of Inebriation," by Dr. N. S. Davis, in answer to the question: "Is inebriation really a crime (vice) or a disease?" and stating certain conditions in which to become inebriated was criminal, he says: "But that the appetite for alcoholic drinks and the state of inebriation are diseased conditions of certain organs or structures is susceptible of clearest demonstration." Dr. Wm. C. Wey, in his paper entitled, "Inebriety by Inheritance," says: "Inebriety being accepted as a physical disorder . . . it becomes us to look back in the train of morbid phenomena by which it has been fostered and developed, and endeavor to analyze its near and remote causes. Conspicuously in this connection comes the consideration of inherited tendency."

The testimony which I have thus brought before you is but a small portion of what is accessible, yet I trust it will be deemed sufficient to establish the proposition with which I began, that alcohol is a *poison*, producing in persons who use it habitually the disease of inebriety—a disease whose forms and features and diagnostic symptoms are quite well understood.

(To be continued.)

CELIO-HERNIOTOMY FOR IRREDUCIBLE INGUINAL OR FEMORAL HERNIA.

BY T. E. SCHUMPERT, M.D.

SHREVEPORT, LA.

There is, perhaps, no operation described within the pages of surgery that ought to be better understood by, or will present itself more certainly and imperatively to the general practitioner, at some time or other, during his professional career than this. An ovariectomy, nephrotomy, gastrotomy, hysterectomy, etc., can be postponed until a more suitable time, but a strangulated hernia demands immediate surgical procedure. I will admit that this operation as generally performed is not at all times easy; that there is danger of doing some vital injury, that the experienced operator, as well as the inexperienced, will at times find himself puzzled to know whether he is contending with the sac or the gut. The theory of cutting down on the hernia and being able to recognize the tissues, layer by layer, is altogether a delusion, and from the fact that it can not be done is calculated to discourage the man who expects to find them.

We do well, after adhesions are formed, to always recognize the sac. I have been at a loss more than once, after I had cut down on the sac, as I supposed, to know if my next stroke was being made in the right direction or not, and have been surprised quite as often to find that I had not reached the sac.

In recent hernia, where the sac is thin, and through some inflammatory process has become adherent to the omentum or gut, it is almost impossible to know positively in all cases when it is reached by any method I have ever seen, *i.e.*, save the one I am now about to describe. For the reason that so many operations have been devised for strangulated or irreducible hernia, and that a great majority of the profession have accepted no particular one, is but an evidence of the fact that none have exactly met the indications, that they are not altogether satisfactory.

Very nearly all operations for hernia are essentially the same; they differ, however, somewhat in detail. The sole object of the operation being: 1, the reduction of the tumor with as little damage to the parts as possible; and 2, a guarantee against its return. Dexterity in this operation is no less important than in all others where an anesthetic is administered, the patient's life, so far as the anesthetic is concerned, being jeopardized in proportion to the time he is kept under the anesthetic. The ordinary operation of herniotomy is begun by making an incision *over* the hernial tumor, and dividing the parts as carefully as possible until the sac is reached, which should be dissected out, cleared of its adhesions to the spermatic cord, emptied of its contents, a ligature thrown around its neck, and the wound sutured. These are the essential features of all the operations, and it requires anywhere from one-half to an hour or more to perform it.

From the first indications above mentioned, the operation which I am now about to detail especially recommends itself, and for the second promises as good results as any, since the closure of the wound and after-treatment is that commonly employed.

The operator, standing at the patient's right, begins his incision in the abdominal parietes about two and one-half or three inches from neck of sac one-third the distance from the anterior superior spine of ilium to spine of pubes one-half inch, above and along the course of Poupart's ligament, and allows it to extend in the line of that usually made in herniotomy, from this given point to one-half inch beyond external abdominal ring, which implies the latter distance over the neck of the tumor. The incision, therefore, for celio-herniotomy must be made about three or three and one-half inches in length, the abdominal portion of this incision or the anterior two-thirds of initial incision is pursued in the same manner as in an oöphorectomy, until the peritoneal cavity is reached, after which the index finger of the left hand is inserted into the abdomen as a guide, with its tip in the ring, in neck of sac, between sac contents and ring; then with a pair of blunt-pointed scissors or a probe-pointed curved bistoury all tissues are divided until the constricting ring is reached, when if a bistoury is used it is inserted between the finger and ring and the cut is made upward; if scissors are used, however, the cut is made in line of the initial incision and in both cases until the constricting ring is felt to relax. The next step is to seize the hernial mass between the fingers, be it gut or omentum, and with a *vis a-fronte* to reduce it, which is easily done and without any danger of rupturing the gut in case it should be threatened with gangrene, as is the case when the force is applied from above.

After the reduction of tumor, the sac is easily and without danger dissected from its contiguous structures and its neck ligated or sutured as in the usual manner. The sac having been removed, the wound is closed by one of the several methods now in vogue, my preference being that employed by Bassini and Marcy, save in dealing with the cord, *i.e.*, after the aponeurosis of transversalis muscle has been sutured to the posterior aspect of Poupart's ligament, and the internal ring closed save just enough space to allow the exit of spermatic cord, using this newly formed wall as a background for the cord; I, instead, gently place the cord in my incision a few centimeters above the internal ring, after buttonholing the incision for

the reception of the cord. Thereby I am allowed to close entirely this ring, which I do with double animal sutures. The cord is now removed entirely from its original habitat in the inguinal canal, save at the external ring, and placed over the aponeurosis of the oblique muscles, where it is incorporated by adipose and connective tissue covered by skin. Some may say there is danger of strangulation by the encroachment of muscular fibers or cicatricial tissue. But this has not proven so in any of my cases, five years having elapsed since the first operation and the patient is without the slightest varicosity or evidence of returning hernia. While this man is too aged to propagate the species, three others by their usual cleverness in this line have testified to the fact that the operation of celio-herniotomy is a complete failure for the production of sterility.

It is asserted by some of the most recent writers on this subject, that their chief object is the restoration of the obliquity of the inguinal canal; mine is the obliteration of this canal, and the formation of another in a locality where the tissues anatomically are better able to resist the etiology of hernia. The locality for the new ring I find to be just within the muscular fibers of the transversalis, a few centimeters above the internal ring. If the component elements of this cord or its anatomic relations have been predisposed to hernia in the first place, statistics go to prove that if left *in situ*, although nature has been greatly augmented by the skill and masterly work of Macewen, Bishop, Czerny, McBurney, Bassini, Marcy, and I might name many other meritorious workers in this field, it will have a tendency to again produce this trouble.

The subcutaneous implantation of the cord is not original with myself, but a product of the ingenious Halstead, however, if the formation of a new ring in a different locality has been used by others, it is without the knowledge of the writer. My operations are performed under the strictest aseptic and antiseptic precautions, realizing, as I do, the proneness of this locality to sepsis. This fact being assured the wound is closed without drainage.

I was called by Dr. D. M., a few days ago to see an old man, 76 years of age who had been suffering from a right oblique inguinal hernia for forty years. His vomit was stercoraceous, his expression excited and anxious, pulse quick and flashy with his arms and legs cold. On further examination, I found an irreducible scrotal hernia that extended half way to his knee, the ring very large and free. Efforts at reduction, by taxis, to my surprise, without avail. On opening the abdomen and reducing the hernia according to my style, I found the hernial mass to be composed entirely of intestine that had assumed a pear shape, the sharp flexions at the base of which were bound firmly by adhesions which extended through the inner ring. The intestine was adherent to the sac, and the sac to the tunica vaginalis which on traction was everted, plainly showing the line of adhesion between intestine and sac, and made dissection easy. The adherent folds of intestine were themselves next severed and the intestine freed.

I am sure this operation was very much facilitated by the combination of celio- with herniotomy. This patient had never in his life worn a truss, but during the entire period had carried this mass in his scrotum. It would have been very difficult in this case, by any of the older methods, for even an experienced operator to have avoided wounding the vaginal tunic or even the gut. I have successfully performed this operation on two patients over 80 years of age, one male, the other female, the latter strangulated; have performed it in all, fourteen times, and twice under

most adverse circumstances. So far it has proven to be all that could be desired. Indeed, the operation is so simple, and the result offered so satisfactory, that when consulted, whether the hernia be reducible or irreducible, I advise an operation. I believe this is the advice of every surgeon of the present day who has given this subject the deserved amount of thought.

• RECAPITULATION.

This operation offers, first, as an advantage over others, its comparative innocence from danger. It also offers the advantage of from several minutes to an hour or more in time, upon which fact, alone, may depend the final good result. It places herniotomy within the reach of the most clumsy and inexperienced operator. The gut or hernial mass falls within a better field for inspection. I close the external ring, save just enough space at its inferior inner angle for the escape of the cord; close the canal after the Bassini-Marcy style, save the internal ring which is closed entirely; buttonhole the transversalis incision just above the inner ring, to form a new ring and prevent the tension of sutures; and place the cord between the integument and the external oblique.

THE TREATMENT OF DOUBLE FRACTURE OF LOWER JAW BY ANGLE'S FRACTURE BANDS, WITH REPORT OF CASE.

BY W. E. GAMBLE, B.S., M.D.

CHICAGO.

Mr. E. N., aged 40, was referred to me by O. A. King, D.D.S., of this city, July 4, 1894, for treatment of double fracture of lower jaw, the line of fracture on right side extending from third molar through angle of jaw (Fig. 1, *x*). Third molar, being loose, was extracted. The fracture on left side was between left lateral incisor and left cuspid (Fig. 1, *y*). The fragment was displaced one-half inch below level of teeth. By direct pressure the fragment was adjusted to its normal place. To keep it there was the problem. A roller bandage was placed the full length of fragment on the under surface of jaw, over which a four-tailed bandage was applied, secured by sewing the bandage carefully.

July 5. Fragment displaced as before. Wiring the jaw was advised, but the patient desired all other means to be tried first. A leather chin cup supported by plaster-of-Paris cast was put on.

July 6. Fragment displaced. I called Dr. A. J. Ochsner who, in addition to chin cup and plaster-of-Paris cast, adjusted a well fitting gutta-percha interdental splint. The Doctor carefully and skillfully applied the dressing.

July 7. Fragment dislocated as before. Further attempt at treatment by splints was abandoned. Dr. Ochsner with my assistance wired the fragment on left side. It seemed unnecessary to wire right fragments. They were not wired. A light plaster-of-Paris dressing was applied to support the jaw.

July 13. Facial erysipelas developed in region of wound, gradually involving face and scalp.

July 21. Fragment slightly dislocated. Region of fracture seat of abscess. Soft tissue swollen to such an extent that the wire suture could not be supported by external splints.

From July 20 to July 31 displacement gradually increased; at the latter date it was two-thirds as great as the original deformity. The wire had evidently cut through the spongy bone a distance equal to the amount of displacement. Had not the process of repair been delayed by the intercurrent disease the wiring would probably have been successful in retaining the displaced fragment. The wiring had not only proved a failure, but it had been a source of injury; the ends of the wire had lacerated the lower lip and tongue. Pus followed the wire, resulting in abscess forming in region of wiring. The lateral incisor (left) and left cuspid became loosened, necessitating the removal of incisor.

Owing to the precarious condition of the patient, resulting from the erysipelas, in addition to the local condition of ends of fragments and the soft tissue about them, a further attempt at wiring was considered not advisable. The frag-

ments must be adjusted and held in place, or a frightful deformity would result. The only fixed surface remaining untried to which this large fragment could be anchored was the upper jaw. The difficulty was to get a fixed point or points on teeth of displaced fragment and opposing teeth of upper jaw to which silk or wire could be attached and the fragment held in place until repair had taken place. At my request, Dr. King kindly visited the Wilmington Dental Manufacturing Company of this city to find, if possible, a band attachment already made to be used in this case. Dr. Angle's fracture bands (Fig. 2) were secured. With Dr. King's assistance a band was placed around the two central incisors of fragment, and to left central incisor of upper jaw (Fig. 1). Little difficulty was encountered in getting bands well adjusted. By burnishing the band accurately to the tooth and tightening the nut until the band is

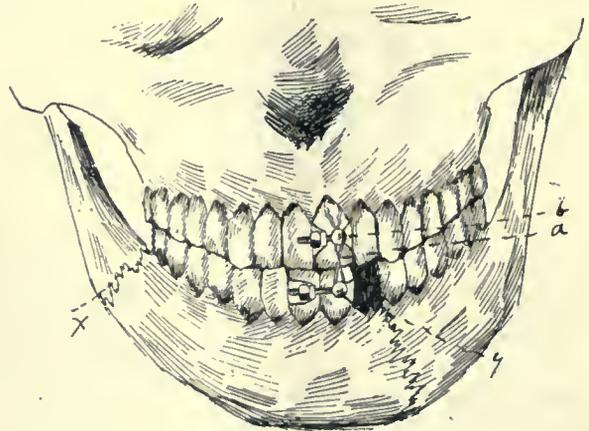

Fig 1

firm, there is but little danger of the band slipping. Floss silk, well waxed, was used about the buttons (Fig. 1, *b*), in the manner of a figure 8. (See Fig. 1, *a*.) The fragments were firmly held in place by this means for six weeks, when repair had taken place with result quite satisfactory.

This case emphasizes the fact that the universal custom of wiring the fragments of a double fracture of the lower jaw where there is much displacement is not the only practical method of treatment. Dr. E. H. Angle has furnished the profession with a perfect instrument for attaching the fragment to upper jaw. These bands are made in different sizes. With care and patience the surgeon can adjust them to the teeth. The teeth can be separated by introducing between them small wedges of orange wood or other hard wood, driven in by a small hammer or handle.

Fig 2

knife, etc. A simpler method is to separate by means of rubber. A piece of rubber of the following dimensions, 15 mm. x 2 mm. x 2 mm., is stretched to such an extent that it can be pushed between the teeth. Its contraction gradually separates them. Fifteen or twenty minutes is required by the method to separate the teeth sufficiently for bands to be applied. The bands may be made doubly secure by cementing.

The simplicity of this method, requiring no anesthetic, no destruction of tissue, no trained assistant, as compared with the bloody, tissue-destroying operation of wiring the fragments, should cause the surgeon to give it consideration in cases in which both

the fragments and the opposing upper jaw are not toothless.

There are no sequelæ as a direct result of treatment, as often follow wiring; abscesses of tissue, loosened teeth and loosened alveolar process.

In fixing opposing molars or bicuspid, Dr. Angle makes use of a rod (Fig. 3, *c*), one end of which is bent to a right angle; this is hooked into an attachment on one band (Fig. 3, *e*). The other end of rod is thrust through a pipe in other band. The rod is held and its length adjusted by a nut (Fig. 3, *d*)

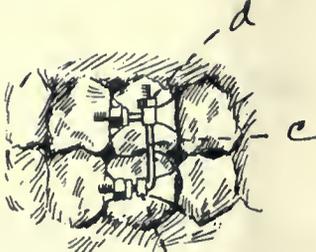

Fig. 3

This rod can be much more easily adjusted in this region than silk or wire, the cheek being in the way.

The articulation of the teeth differs widely in different individuals. The upper cusps and incisors usually project slightly over the lower ones; occasionally the cusps and incisors of lower jaw project farther in front than the upper ones; owing to this diversity in articulation of these teeth, silk floss, well waxed, can better hold them in proper place than the rod or any less flexible material.

264 S. Halsted Street.

MALIGNANT DISEASE OF THE OVARY; REPORT OF CASES.

Read before the Worcester, Mass., Medical Association, Oct. 10, 1894.

BY HOMER GAGE, A.M. M.D.
WORCESTER, MASS.

I trust you will pardon me for asking your attention to a subject which may seem of but little practical importance, and is interesting mainly because it is so rarely met with. I have ventured to report these cases of malignant disease affecting the ovaries, because they present some features of unusual clinical interest and because they will serve very well to introduce the subject of ovarian pathology, about which there seems to be so much confusion.

I think no one who has attempted to do much pelvic surgery himself, or has tried to study pelvic surgery from the medical periodicals or in society transactions, can fail to be impressed with the want of exact knowledge of the various conditions which may be met with in the normal ovary, and with the want of a generally accepted scientific standard, in accordance with which the departures from the normal may be recognized and properly classified. The confusion has been made much worse by the tendency of modern surgery to remove the ovaries upon every slightest pretext, and then to examine them with a determination to find something which should justify the mutilation. The more accurate knowledge which will dispel this confusion must come, step by step, each step perhaps contributed by a different observer.

Can not we, with the increasing clinical opportunities that are being constantly afforded, contribute

something toward the establishment of one of those steps? In the hope, then, of awakening some interest in this subject, I submit these few cases, asking you to remember that nearly all of them occurred among my earliest operations, and that the reports are far from being as full or as accurate as I should like to have them.

The relative frequency of malignant tumors of the ovary is as yet undetermined. Reliable statistics on this point are still too few to furnish any positive data. Cohn's report of 100 cases occurring in Schroeder's clinics, is still the largest number reported, and this list has been reduced by Butlin to 55, by the exclusion of doubtful and unoperated cases. That would be about 8 per cent. of all cases observed during the period covered by his report. Olshausen, grouping all solid tumors together, believes that they represent about 5 per cent. of all new growths of the ovary, and further, characterizes almost all of these as malignant. In Homan's series of 384 laparotomies, there were 7 cases of undoubted malignant disease of the ovaries, but there were 8 other cases in which after removal of the ovarian tumor the patient had died from the appearance of malignant disease elsewhere. The presence of malignant disease at the time of or following the removal of an ovarian cyst, in itself of benign appearance, has also been noted by other observers, and is relatively so common as to make it seem more than a mere coincidence. I have, myself, had one such case which, I think, of sufficient interest to warrant a brief report:

Mrs. H., 53 years old, had been married thirteen years; had never been pregnant; menopause four years ago. Two of her aunts had died of internal cancer, and her father had died of cancer of the face. She had been failing in health for a year; had been suffering from abdominal pain, vomiting and distress after eating, with marked loss of flesh and strength. Five months ago had observed abdominal swelling, which had yielded to medical treatment, but had quickly re-appeared with return of intense pain and constant vomiting. She was entirely confined to the bed. Her abdomen was immensely distended, somewhat tender, transmitted wave of fluctuation readily, was dull over the lower half, resonant in both flanks. I operated on May 6, 1892. On the morning of the operation, her pulse was very small and feeble, 130; extremities cold and moist; had been vomiting all night, a dark greenish fluid in large quantities. She appeared to be *in extremis*, and I certainly expected that she would die during the operation. On opening the abdomen, about three quarts of clear straw-colored fluid of a slightly viscid consistency were evacuated, and a cyst of the right ovary, about eight inches in diameter exposed. It contained a dark thick fluid, was unilocular, and presented only loose adhesions to the rectum and pelvic floor. It was quickly removed, and to my surprise she rallied well from the ether. Pain and vomiting ceased, and at the end of ten days she could be carried to a lounge in the adjoining room and seemed to be gaining steadily. About four weeks after the operation, pain and vomiting and abdominal swelling re-appeared, and on June 22, seven weeks after the operation she died. For the following very careful and accurate account of the tumor and of the conditions presented by the *post-mortem* examination I am indebted to Dr. W. S. Miller, now of the University of Wisconsin:

"The growth was a large cyst, for the most part smooth, but here and there a warty nodule was seen projecting into the cavity of the cyst. About the pedicle the walls were thickened and the nodules were more numerous. I examined portions of all these places, *i.e.*, the thin wall of the cyst, the nodules and the thickened wall about the pedicle. The thin wall of the cyst proved to be that of an ordinary cyst of the ovary; the nodules were simple papillary growths on the wall of the cyst, and the thickened wall of the part about the pedicle showed nothing malignant. The wall was

thickened and the papillary growths more numerous. I remember feeling quite chagrined at the autopsy to find a malignant growth when I had reported on the case as being non-malignant, but I could not then, and I do not now, see anything in the sections to warrant a diagnosis other than papilloma of the ovary.

"At the autopsy a large accumulation of fluid was found in the abdomen, about a pail and a half in all being removed. The entire abdominal cavity was filled with secondary growths of cancer, and in the pelvis all the organs were so firmly matted together that they were almost indistinguishable. This growth in the pelvis seemed to take its origin from the stump of the ovary, but it had none of the appearance of a primary growth. As you noted at the end of your notes, the primary disease was in the pancreas, and the growth in the pelvis seemed to be an implantation on the stump of the cyst."

The tumor was a papillary cystoma, a form of new growth generally classified as non-malignant, except when the papillæ themselves are the seat of cancerous infiltration, and all the cases of this kind are excluded by Butlin from the reports of Cohn and others, in his consideration of the relative frequency and results of malignant disease of the ovary. In the case here presented it would be necessary, to conform to this view, to suppose that the cyst was an accidental complication of the disease of the stomach and pancreas, entirely independent of it, and that the cancerous condition of the stump was not in the nature of a recurrence but was a secondary chance implantation of the disease in this locality. It seems to me that a much simpler and more natural explanation, more in conformity with our knowledge of the history of malignant diseases elsewhere, is to assume that there was something malignant in the cyst itself. These papillary tumors do give rise to metastases, parasitic in their formation to be sure, but very different from anything that we observe in the history of benign tumors. Pozzi, in his late treatise on gynecology, calls attention to the greater degree of malignancy of papillary cystomata, the uncertainty as to what part of the ovary they grow from, and calls for further and more careful investigation of this question. I have not time here to enter into any exhaustive study of the question, but present it to you as one of the unsolved problems of ovarian pathology. Should their malignancy be established, as seems to be conceded by Greig Smith, the proportion of malignant to benign tumors of the ovary must be much larger than is stated by Olshausen.

There is very little in the clinical history or physical examination of ovarian tumors to suggest their malignancy. Ascites is commonly found in connection with both sarcoma and carcinoma, and is relatively infrequent as a complication of benign tumors. Its presence must, therefore, always be regarded with suspicion. This suspicion is further strengthened by the existence of disease in both ovaries at the same time, especially if the tumors are hard, smooth and freely movable; and by a history of rapid growth. It would seem as if, contrary to the general rule, malignancy was relatively more common in tumors appearing in early life. Of seventy-seven cases of carcinoma collected by Leopold, twenty-seven occurred between the ages of 8 and 30, most of them about 20 years, and in thirty-seven cases of ovarian sarcoma collected by Olshausen, fourteen were in patients under 30 years old. It has been suggested therefore, that malignant disease is to be looked for often about the age of puberty and again at the beginning of senile atrophy. Pain in the tumor itself is not often observed; the pain from peritoneal irri-

tation is more common from the solid than from the cystic tumors.

The great majority of all solid tumors of the ovary are malignant. The malignancy of a cystic growth can be determined only after its removal. In the latter states, the presence of a well marked cachexia, of enlarged glands in the groins, or of other visceral metastases is of vital importance.

In connection with this question of diagnosis, allow me to present the history of a case in which the clinical signs are perfectly characteristic of malignancy, while the microscopic appearances seem to point with equal force against it. The case illustrates again, how indefinite and unsatisfactory is our knowledge:

Miss A. S., 30 years old, was referred to me in October, 1891, by Dr. J. R. Lincoln, of Millbury. She had not been well for two years; had complained constantly of pain in her back and hips, more severe in the right, and frequently making it impossible for her to work. It had been growing much worse for the past four months and for eight weeks she had been unable to work at all. Catamenia were regular, of normal amount, and unattended by pain, except on the first day. The abdomen presented neither general nor local distension, was everywhere tympanitic, but was very sensitive to pressure in the right iliac region, which was occupied by a hard irregular mass, apparently beginning at a point one inch above the level of the anterior superior spine, and extending downward into the pelvis, and laterally to the median line. Per vaginam, the uterine body seemed crowded to the left, while on the right and behind could be felt this same hard irregular mass. On opening the abdomen, both ovaries were found very much enlarged, about the size of a small peach, of a hard firm consistency and non-adherent. These were removed as were also two enlarged mesenteric glands. The large mass on the right side was found to consist of a hard bunch occupying the cecum and its mesentery, which rested upon and had moved with the right ovary. The surface of this bunch was smooth, translucent and entirely free from adhesions. Its removal was not attempted. The patient recovered from the operation, but failed gradually in health, became very much emaciated, and although no signs of pulmonary disease were manifested, died in September, 1892, ten months after the operation. The bunch on the right side remained practically unchanged, and a second bunch developed upon the left. Although no autopsy was permitted, there can be no doubt but that she died of malignant disease of the abdomen. I felt very confident that the tumor of the cecum, the bilateral ovarian tumors and the enlarged lymphatic glands would present evidences of the same malignant infection. Upon microscopic examination by Dr. Miller, however, the ovaries and glands were pronounced pure adenoma.

It is unfortunate that in this case the specimens have not been preserved, but they were examined very carefully by Dr. Miller and a typical section was mounted by him, which has been examined by Dr. Baker and Dr. Mallory of the Harvard Medical School, both of whom have confirmed Dr. Miller's report. I can not, however, in any way reconcile the report with the clinical history, and am the more inclined to doubt our correct interpretation of the microscopic appearances, inasmuch as Olshausen and Bland Sutton both state that pure adenoma always appears as a cystoma, and Pozzi fails to notice adenoma as one of the solid tumors of the ovary. Neither of these specimens presented the gross appearances of cystic disease.

There is no treatment applicable to malignant tumors of the ovary except removal, and the operative technique is in no way different from that employed in common forms of cystic disease. The results of operative interference are, however, important and of sufficient interest to warrant a brief review. Butlin has collected ninety-nine cases from the reports of Cohn, Olshausen, Billroth and Thornton. Of these,

thirty-three died from causes directly attributable to the operation, "a very large mortality when compared with the general statistics of ovariectomy." Two of the three cases of sarcoma removed by Homans died from the effects of the operation. It is evident, therefore, that the removal of malignant tumors is attended with far greater risks than the removal of benign ovarian cysts. The subsequent history of those who recover is equally discouraging; only five out of forty-seven patients whose cases could be followed, were alive and well at the end of three years. In the only one of Thornton's cases that remained well three years, the woman had borne a child two years after the operation, and of this he says: "No case could have looked more hopeless than this one did, and the tumor was of a kind in which one would have feared early recurrence." Although there is but little encouragement to be derived from these results, we may, I think, at least go as far as Butlin, in concluding that "the reasons for attempting to remove malignant ovarian tumors are as strong as those which lead surgeons to operate for malignant disease in most other parts of the body."

To this summary, allow me to add two cases from my own series of operations. Both were sarcoma. One is alive and well now, more than five years since the operation. The other died ten months after the operation, and I present her case with the report of the autopsy:

Case 1.—F. S., age 15½ years; works in a shoe shop; came under my observation in March, 1889; maternal grandmother died of cancer of the breast; catamenia appeared at 14, very irregular, not painful, flow considerable in amount, lasting one week; during the winter had noticed that bowels were hard and swollen, and in February accidentally discovered for the first time a hard bunch in the lower part of the abdomen. On February 18, she came home from work with her feet and clothes wet, and complained of not feeling well. The catamenia were due and came on that night with much pain, headache and general malaise. During the next three weeks, she had a temperature ranging from 99 to 102, much local tenderness over the area of the tumor, with abdominal pain; catamenia continued profusely until March 2. She was pale, very thin, had no appetite, could not sleep and felt weak and languid. There was no nausea, no vomiting, and no difficulty about micturition; bowels inclined to be loose.

Filling the right iliac region, extending upward to the level of the umbilicus, and across into and occupying the greater part of the left side, was a hard, elastic, non-fluctuating tumor, slightly movable, with a deep pelvic attachment. It was irregular in outline, and on its anterior surface was a soft sausage-shaped mass freely movable upon it, which felt as if it might be a loop of intestine. The tumor so filled the pelvis that the vagina seemed very small indeed. The cervix could be indistinctly felt high up behind the pubes; the body of the uterus could not be recognized. Although impossible to move it much, the mass could be lifted slightly from below. There was no ascites.

On opening the abdomen on March 16, the movable mass on the anterior surface of the tumor was found to be the uterus, not enlarged, but dragged up out of the pelvis, until the upper border was on the line of the umbilicus. Beneath it and the broad ligaments lay the tumor, irregular in outline, filling the pelvis and everywhere adherent. The adhesions were for the most part soft, friable and easily separated except at the bottom of the pelvis, where they were so tough as to fix the mass firmly, not only to the pelvic floor, but also to the wall of the rectum. Although for the most part of a dense firm consistency, there was an area as large as a 50-cent piece on its upper surface which was semi-fluctuating; no fluid could be withdrawn by trocar, but on enlarging the puncture a small amount of thin fluid and a good deal of soft granular detritus was removed and the size of the mass was sensibly diminished. It proved to have its origin in the right ovary, and a pedicle was secured from the right broad ligament. The patient made a slow, tedious recovery, and suffered from well marked hysterical mani-

festations, convulsions, etc., for several months. Her recovery, however, was finally complete, she became a clerk in a drygoods store and afterwards married. She has remained well up to the present time.

This was my first laparotomy, and had it not been for the skilful and patient assistance of my father, the result, I am sure, would have been far less satisfactory. To his help and encouragement, I owe not only the favorable result in this case, but also whatever measure of success I have obtained in surgery.

The specimen was a somewhat irregularly shaped nodular tumor, of rather firm consistency, weighing about two pounds. On section, it presented numerous small cysts containing clear thin fluid, imbedded in a fibrous stroma which was for the most part dense and firm. Over a considerable area, however, it was much softer and more vascular. The microscopic examination was made by Dr. E. V. Scribner, who was at that time the pathologist to the Memorial Hospital. He reported that it presented the typical appearance of a round-celled sarcoma of the ovary.

Case 2.—Mrs. F., 64 years old, a widow, was referred to me by Dr. D. B. Lovell, in October, 1893. Her mother died of cancer at the age of 78. Her father and two sisters had died of consumption. She was married at 25; and had three children and two miscarriages. Catamenia were always regular and not painful, and had ceased when she was 42 years old. Two years ago she first noticed an abdominal swelling which would, however, at times disappear. Eighteen months ago had considerable pain in the right upper quadrant of abdomen, and soon after was laid up three months with pain across lower part of bowels. Remained well then until last March, when the same trouble returned, and she has not been well since. For two months past has noticed progressive increase in size of abdomen.

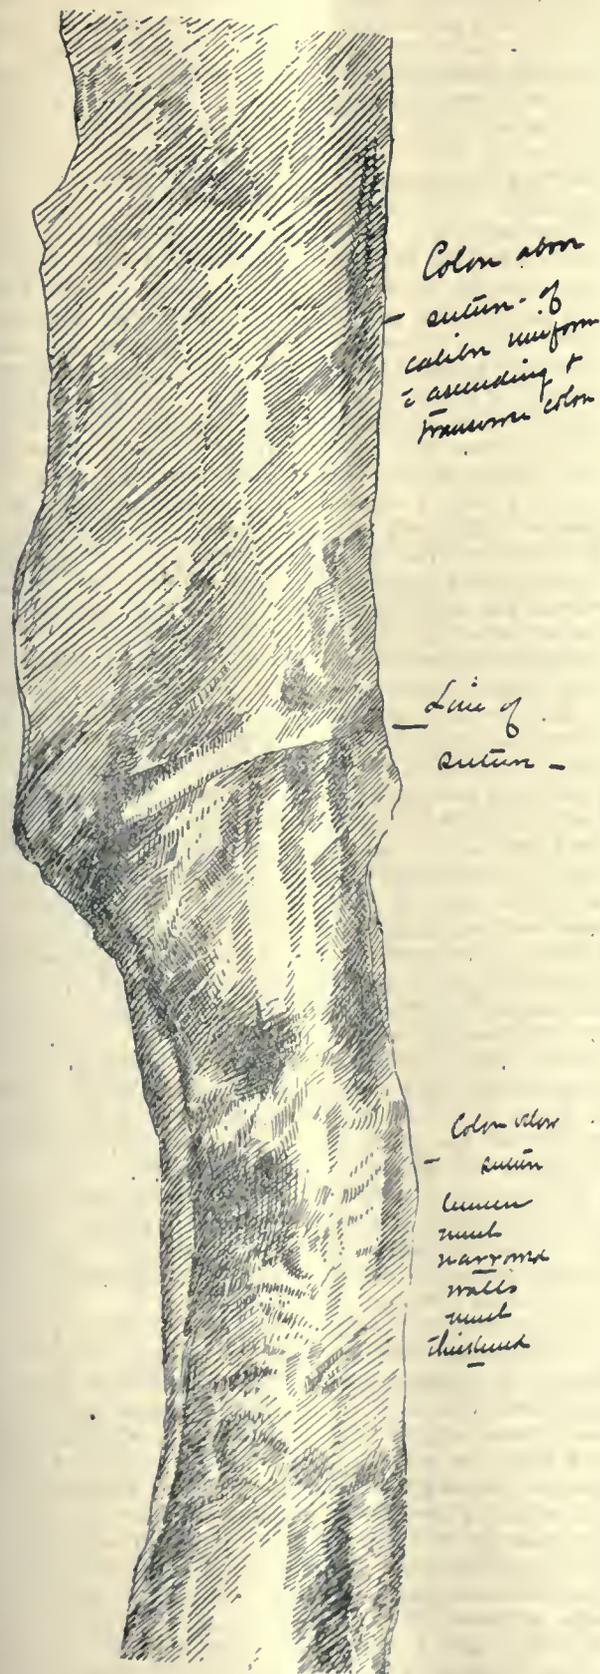

She was well developed and well nourished, weight 160 pounds, girth of chest thirty-seven inches, of abdomen forty-two; heart sounds normal, slight dullness with a few moist râles at both bases behind. The abdomen was evenly distended, tympanitic over the upper part, flat at the side and dull in front from two inches above the umbilicus. Palpation negative at sides, fluctuant in front, and tender everywhere, especially in the left lower quadrant. There was a small umbilical hernia, its contents fluid. Vaginal examination revealed cervix high up behind pubes, posterior vagina wall bulging and fluctuating.

On opening the abdomen, two quarts of pale straw-colored fluid evacuated, revealing a large, solid tumor, occupying nearly one-half the abdominal cavity, with tough fibrous adhesions to the omentum, small intestines and to the descending colon. In separating the adhesions to the small intestines, bits of the peritoneal investment of the tumor were left upon the intestinal walls. In separating it from the descending colon, the colon was accidentally injured so that it was necessary to resect about one and one-half inches just above the sigmoid flexure. The tumor was removed without further difficulty and proved to have originated from the left ovary. The divided ends of the colon were united by three rows of buried silk sutures.

The patient rallied well from the operation, and showed no signs of any general peritoneal infection. On the following day she had some bloody discharge from the rectum, but at the end of a week had a natural movement of the bowels. There was for some time a slight purulent discharge from the abdominal drainage tube which was offensive but at no time feculent in character. When this discharge ceased, there began to be a purulent discharge from the rectum, which continued for two or three weeks. I think there was a localized abscess around the stump of the tumor, which discharged through the rectum, giving rise to the dense pelvic adhesions and to the thickening of the rectal walls, and narrowing of its lumen. The region of the sutured colon seemed to be free from any involvement in this process, as is shown in the accompanying drawing. Mrs. F. gained strength very slowly until in January she became deeply jaundiced, and from that time failed steadily though very gradually. The enlargement of the liver was felt first in July and she died on August 13, ten months after the operation.

The following account of the *post-mortem* appear-

ances is taken from the notes of Dr. Baker, who performed the autopsy, and to it I append his descrip-

stained serous fluid, having a specific gravity of 1021. The intestines were everywhere firmly matted together and distorted, especially near the pelvis. About midway of the descending colon, after much trouble in freeing it from old adhesions, was found the site of an intestinal resection. Below it was a slight dilation of the gut, and at the point of the suturing was a slight ridge of mucous membrane, extending around the lumen. Externally, the point of union could not be recognized. Two silk sutures were discovered, in no way changed during ten months. All the pelvic organs were matted together in one inseparable mass; inguinal glands not enlarged and no recurrence visible in the pelvis.

The liver weighed four pounds and fourteen ounces. It presented numerous nodules from the size of a pea to that of a hen's egg, especially about the lower border of the right lobe, but also scattered over the other lobes. These were reddish white, rather firm and dense. The liver is markedly fatty, and in and across the bile-stained section shows numerous nodules scattered throughout the organ. The gall bladder was not involved. Similar metastatic nodules were, however, found in the lungs, scattered over the parietal peritoneum, and in the mesenteric glands.

The specimen removed was a grayish, opaque tumor, weighing five pounds, of rather soft consistency. On section were found numerous cysts varying in size from that of a hazel-nut to that of one just visible to the unaided eye, filled with a transparent tenacious fluid. Microscopic examination showed it to be made up mainly of small round cells, in places spindle-shaped, imbedded in a homogeneous intercellular substance. It was exceedingly vascular. Sections made from the lung and liver showed the same characteristics, except that they were of firmer consistency. Diagnosis: Sarcoma with metastatic nodules in liver, lungs and peritoneum.

A CASE OF RAYNAUD'S DISEASE.

BY WM. F. BATMAN, M.D.
 LADOGA, IND.

A vascular disorder, probably dependent upon vasomotor influences, characterized by three grades of intensity.

Depew H., son of a physician; age 34; dark hair; gray eyes; height five feet six inches; weight 120 pounds. He is of a neuro-phlegmatic temperament. By avocation a farmer. His father a hale old man at 70; his mother in good health at 66. Had some uncles on the fraternal side who died with pulmonary tuberculosis, but no other hereditary disease traceable on either side. Had typhoid fever nine years ago, but so far as he knows fully recovered. Had the influenza three successive years, 1890, 1891 and 1892, and had tardy convalescence with each attack.

He first noticed these symptoms three years ago, which have gradually increased and affect the middle or ring finger of the right hand which, with the appearance of winter, is hyper-sensitive to cold, and with slight exposure feels numb and cold and then, when reaction takes place and the whole end of the finger gets congested, looks red and full of blood and tingles for hours. This condition is repeated, in fact; always present on exposure during the winter months. One peculiarity of this disease is the absence of the symptoms in the summer time. The patient did not have any symptoms for two months the past summer. Hare's "System of Therapeutics" and Osler's "Practice of Medicine" both give as a remarkable concomitant symptom, hemoglobinuria, which may develop during an attack or may take the place of an outbreak. This appeared plainly in this patient last

tion of the microscopic appearances of the tumor and its metastases:

The abdomen contained about four quarts of bile-

winter, and promptly with the cold weather of the past two weeks. Professor Osler, one of our greatest clinicians, says he has seen very few cases, and divides the progress of the disease into three stages, viz., local syncope, local asphyxia and local gangrene.

Treatment is, unfortunately, not very favorable, so far as a permanent cure is concerned. A course of nux vomica, iron and quinin greatly benefited my patient and he is able to pursue his work, but if he strikes his finger when cold, the pain is excruciating.

Professor Osler says the pain is so severe at times as to require an anodyne. In the severer forms, when threatened with gangrene, wrap the extremity in wool and elevate it. Carefully applied, systematic massage of the extremities is sometimes of benefit. Barlow advises immersing the affected limb in salt water, and placing one electrode over the spine, and the other in the water.

CHLORATE OF POTASH POISONING, WITH REPORT OF A CASE.

BY J. T. McSHANE, M.D.

INDIANAPOLIS, IND.

At 6 o'clock, P.M., July 31, 1894, I was called to see Marie O'Neal, aged 11 years, whom I found suffering from thirst, nausea, vomiting, pain in the stomach, loins and head. Temperature in the axilla 102 degrees; extremities and face cold; pulse at the wrists imperceptible; heart's action rapid and feeble, and a marked cyanotic condition of the whole surface of the body. The patient had been out with her mother calling on friends until 4 o'clock, when, on account of feeling ill, she returned home. At 8 o'clock P.M. on August 1, the temperature was 102.5 degrees F., pulse 130 and fairly strong, frequent vomiting and insatiable thirst. No evacuation of the bowels or bladder. Cyanosis still present, hands and feet cold, ends of fingers and toes shrunken. The color of the patient was striking, presenting a bluish-ashen hue, very like that of an anemic person whose skin has been discolored with nitrate of silver. At this time the patient was extremely restless and semi-conscious. At 10 o'clock she was again visited, in company with Dr. A. W. Brayton, who saw her several times with me from this time on to the time of her death. Her temperature varied from 101 to 103.5 degrees F., until the morning of the fourth day of the attack, when it was normal, and so continued. Stupor was a constant symptom after the first few hours of her sickness, only varying in degree on different days. She could be aroused sufficiently to answer questions intelligently and recognize her friends any time during her illness, with the exception of the third day.

The history of the case shows that on July 30 the patient had sore throat, for which chlorate of potash had been used, but on inquiry the mother stated that it had been used only as a gargle. On the morning of the third day of her illness, I introduced a catheter and drew off two ounces of fluid which was of an inky blackness. This aroused my suspicion that more of the chlorate of potash had been taken than the mother was aware of. Investigation revealed the fact that eight or ten tablets had been taken on July 30, and a teaspoonful of the solution on the forenoon of the 31st, making not less than two hundred grains in all. On account of inactivity of the kidneys the bowels were kept freely opened by the administration of Rochelle salt. Towels wrung from hot water were applied to her back over the kidneys. Cardiac stimulants and diuretics were administered. The average amount of urine secreted per day did not exceed a half-ounce. The urine, which at first was dark, gradually cleared up. Examination of the blood was negative; the corpuscles were not crenated or otherwise deformed; the number was not counted.

On Sunday morning, August 5, which was the sixth day of illness, the blueness had disappeared and given place to a white, waxy appearance. The whites of her eyes were slightly jaundiced. Light pressure over the hepatic region caused severe pain. Two drachms of urine, containing a large per cent. of albumen, was secured by catheterization. Her condition continued without noticeable change until 2:30 P.M., when she grew worse, and died in a few minutes.

Peculiar interest attaches to this case on account of the rarity of poisoning by this drug, and the freedom with which it is bought and used without the advice of a physician. Tablets are kept in the drug stores and sold for sore throat. They are held in the mouth and swallowed as they dissolve. Crystals of the chlorate of potash are carried in the pocket, and taken in the mouth and swallowed as rapidly as dissolved. The unsuspecting patient takes more of the drug in this way than he is aware of, and may be poisoned.

The death of a saleswoman who took a half-ounce of the crystals during an afternoon, while at work, was recently reported by Dr. Scherer, of this city. His patient died on the following day. Dr. Theodore Potter, also of this city, recently reported the case of a man who had grave symptoms of poisoning from taking "2 cents' worth" (probably less than a half-ounce) of the crystals during the course of two days. Another case was recently reported by Dr. Florence Wier Hays, of this city, of a young lady who dissolved a dime's worth of potassium chlorate in a glass of water and used as a gargle, swallowing portions of the mixture from time to time. There was vomiting and purging; suppression of urine; paralysis of the muscles of vocalization and deglutition; darkening of the urine; blueness of the skin. The patient recovered after a week's illness. The reports of a large number of cases of chlorate of potash poisoning are recorded, and the symptoms are described with remarkable regularity. Hare describes them as follows: "When over-doses of chlorate of potash are taken it produces sickness of the stomach, headache, pain in the loins and belly, dyspnea, cyanosis, heart failure, and great weakness. The blood is dark and chocolate-looking, this change being due to the production of methæmoglobin. The blood corpuscles are crenated and broken down, and the liver, kidneys, spleen and intestines are found softened and filled with disorganized blood." The case of a healthy 15-year-old lad who took 150 grains within six hours, for pharyngitis, is reported in Vol. IV. of *Sajous' Annual*, 1892. This patient had, in addition to the usual symptoms, a number of yellowish-brown maculæ upon the side of the abdomen, back, and anterior portion of the neck, which remained an indefinite time after the blueness had disappeared.

M. Carreau, *Centralblatt für Chirurgie*, gave 150 to 300 grains daily for three days for leprosy. Grave symptoms of poisoning were produced, "but the leprosy tubercles almost entirely disappeared, leaving the skin soft and wrinkled."

The following quotation from H. C. Wood's work on "Materia Medica and Therapeutics" is well worthy of consideration: "It is probable that in diphtheria, deaths attributed to the disease have often really been produced by the chlorate." Quoting further from the same author: "The minimum fatal dose is unknown, but a drachm given in the course of a night has killed an infant under 1 year old, and 3 drachms given during a day, a child 3 years old." Dr. J. von Mering, in 1885, published a brochure ("Chlorsäuer-Kali," Berlin), in which he reported a large number of fatal cases from this drug. Dr. Jacobi, of New York, was the first to call attention to the dangerous action of chlorate of potash. His article was published in the *American Medical Times* in April, 1861. Dr. Fountain reported a case about the same time in which an ounce was taken. Copi-

ous diuresis followed almost immediately, then suppression of urine, and death on the seventh day.

Dr. Stephens and Dr. O'Shaughnessy asserted that chlorate of potash imparts its oxygen to the blood. This was generally accepted as true, and until later investigation proved that chlorate of potash is eliminated as such, and without appreciable loss of weight, it was often prescribed in cases of cyanosis and asphyxia.

Theoretically, chlorate of potash has little just claim as an internal remedy. Practically, it has not been scientifically demonstrated to possess remedial virtues, except as a local stimulant to the mucous membranes.

26 East Ohio Street.

RANDOM THOUGHTS ON OUR SPECIALTY.

Read in the Section on Dental and Oral Surgery, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY A. E. BALDWIN, M.D., D.D.S.

CHICAGO.

Under this heading the writer feels free to wield a free lance, and he also feels that there are many things that may be properly grouped under such a title, thus giving a writer an opportunity to suggest varied lines of thought with possibly not a very logical grouping of them. In taking a retrospective view of our professional work and advancement during the last score of years, one can not help a strong feeling of disappointment, in spite of the very extravagant claims of the average dentist. In such a retrospective glance we must keep in mind that the effort of all truly scientific minds is toward that which is strictly scientific—and all will concede that the nearer we approach that exact position, the more incumbent it becomes us to make our so-called scientific work, truly so, by making it clearly demonstrable. To place our specialty in such a position requires us to develop a class of people in our branch of professional work who will ever and always *think for themselves* on any and all subjects. We can not mix to any extent with our fellows in our society meetings without being impressed with what seems to be a fact, that at least 95 per cent of our fellow workers allow themselves to simply swallow any honeyed or less daintily arranged bolus prepared for them by the other 5 per cent., and presented to them in the name of science in a grandiloquent way by one to whom, perhaps, had not yet been born a single original idea—or who knew not the difference between a "premise" and a "conclusion."

There just now occurs to the mind of the writer an illustration which he asks pardon for narrating. This occurred at a meeting of the American Dental Association a few years ago. One of our brethren, who *assumes* great dignity and profound knowledge, read a paper on "Carbolic Acid." The paper was lengthy and verbose, and was by many of the hearers hailed as a wonderful production; they almost made themselves appear as sycophants in their loudly expressed remarks in adoration of the wonderful ability displayed by the writer in his profound experimental research, as demonstrated by the paper; and doubtless many a young man hearing this paper and the comments of others upon it, went away from the meeting prepared to gulp down anything they might hereafter see emanating from his or his secretary's pen—when to strip this paper from its "ego" and

husks you will find it simply a *compilation* from old authors, good and bad, and containing absolutely nothing of any practical or scientific importance but what was from some work direct; not a thought original with the author. The writer went away humiliated that among the many able men there gathered, there were so few who realized the imposition. Again, at another time, at a meeting of the Chicago Dental Society, the writer heard a so-called leader in our ranks—and this only a few years ago—say that he could always diagnose uterine diseases (presumably of women, though he did not say so) by the condition of the mouth of the patient, and the statement went almost unchallenged. What weight could be put upon anything said by such a "pseudo" scientific physician?

These illustrations are made, not for the purpose of casting slurs, but to call attention to the lack of exercise of discriminating power. What is uppermost in the writer's heart, is that the very small number of our brethren who will think for themselves, and not say "amen" to anything simply because some professor says so—but will weigh with physiologic, anatomic, histologic, pathologic or etiologic scales these so-called facts and then indorse or condemn as the scales may determine, that the number of these may increase and multiply until it will be very dangerous for one to stand up before them in public or private and feed them chaff, calling it wheat, with the hope that the statement will pass unquestioned.

Why should we be blind leaders of the blind, or allow the blind to lead us, though they may *claim* they see. We should be awake and learn to think for ourselves. Probably we, in our busy lives, may not have the time or opportunity for as much original investigation as we would wish, but this does not necessarily imply that we may arrive at the same conclusions that an original investigator arrives at, for we (if he lucidly explains all the processes of the experiments) are in possession of all the "premises" from which he draws his "conclusions," and may view them far differently than he does.

In glancing over our journals the same thing is noticed—the immature thought is stated often as a certain conclusion and accepted as such. Many a specialty journal if put into the retort and subjected to the fire of scientific reasoning would come out wholly ashes, and many more would leave only the microscopic atom of truth.

If we might have some power given us to secure a journal that would contain each issue, nothing but demonstrable truths or plain, honest premises, from which to form our own conclusions, how small and choice such a work would be. Our shelves would never get overloaded, neither our minds overburdened in separating the gold from the dross. Then again we think all observing persons are aware that there are many in our ranks who are oftentimes satisfied to do, under certain circumstances, less than the best they can do. This is a matter that vitally concerns us all, for to slight an operation is to bring reproach upon ourselves as a whole. There is, of necessity, a great deal of difference in the various methods as practiced by different operators, but the rule that should govern in these matters is that we should not vary from well-established rules of operation unless we have well grounded physiologic reasons for believing the experimental method is an advance upon the old.

How few among us know the reason each time for what they do, or even try to solve the problem. How hard we have to drum the idea into the head of the average person, that growth or development of the part is induced by systematic exercise of the part, and if we as specialists expect a healthy and generous growth in mental and physical ability, it must come very largely at least, not only by systematic thought and close study of books, but by training our powers of discrimination, so as to be able to determine the true from the false. Only a few days ago the writer had occasion to extract a tooth for a patient, in which he found that the pulp-chamber had been filled with, apparently, no attempt to clean the *débris* from the root canals or to fill them. Upon learning who the operator was and thinking it was a mistake on his part, he took occasion in the kindest way possible to call upon the dentist and show him the work and call attention to the history of the case; when, surprising as it may seem, the dentist said he knew he did not fill the root canals, and as an excuse said for what he charged he could not afford to do any more work than he did.

Is it any wonder that when such things are done the people are distrustful of the ability or the honor of our workers? No one can afford to do less than the very best that lies in his power, regardless as to whether he gets a large price or does the work for nothing. The rule is called "Golden," that we should follow in this and in all matters; then the world, as well as our profession, would always be the better for our having lived.

DISCUSSION.

DR. TALBOT—There is only one point in this paper I wish to emphasize, and that is the independence of thought which Dr. Baldwin urges. Do not take everything which is said by the voice of authority to be finally settled. Weigh everything and judge it by the best knowledge you have. We, as dentists, labor under one disadvantage. Our professional training is narrow. We are taught one branch of medicine and we do not get the broad, liberal foundation which we ought to have. If we had a thorough training, not only in medicine but in the sciences, we could reason upon all subjects. We could decide for ourselves whether the arguments of a paper were correct or not.

In closing the session, I want to say that I am more than gratified with the papers which have been read and the discussions which have been evoked by them. Taking into consideration all the circumstances, we can congratulate ourselves on having had a very successful meeting of the Section. The sessions have been well attended and the numbers in attendance have been constantly increasing. We never have a large attendance; in fact we do not want mere numbers, unless they enter actively into the work. I was one of the originators of the Section, which was instituted for the purpose of educating the medical profession in dental subjects, and you must admit that they have certainly become interested in us and they read our papers in the medical journals. I believe that we will in fifty or a hundred years be recognized as an important part of the medical profession. The Section then adjourned.

THE PRESENT AND FUTURE STATUS OF THE DENTAL PRACTITIONER.

Read in the Section on Dental and Oral Surgery, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOS. D. HODGEN, D.D.S.

SAN FRANCISCO, CAL.

The dentist of to-day is the doctor of dental surgery, educated and licensed as such. As a practitioner his province embraces the science and art of diagnosing and treating diseased conditions of the organs and contiguous tissues of the oral cavity, of

operating surgically for deformed, injured and wasted conditions, and supplying artificial substitutes in the place of organs and tissues lost in that region.

From such it is to be inferred that the truly proficient practitioner should have, at least, a partial if not a finished medical education; that he is to no slight extent an oral surgeon, and that he is a skilful and scientific mechanic. He is thus at once a physician, a surgeon and a handicraftsman—a dentist. His parallel, to a partial extent, might appear in the oculist, who linked with his own specialty the skill of the manufacturing optician.

In holding that a dentist should have the advantages of a medical education we are well aware that we meet with no inconsiderable opposition. But, while the opponents to such are strong in numbers, they are weak in point of argument to sustain their holding. It is argued that the time and expense necessary to such a course are its greatest hindrances. It is perhaps true that many men who are now enabled to pursue a course in dentistry would be deprived of that privilege if our colleges prolonged their term of pupilage to that extent necessary to embody a medical curriculum. However, we are led to doubt this as a fact when we recognize that only three years ago the course in dentistry was lengthened from two years to three, and that by actual statistics there are more colleges and more students to-day than there has ever been at any time previous. Young men are crowding the colleges and the profession who would do well to stay with the plough and farm. Are we, then, to lower the standard of the profession in order to receive these men to our already overflowing ranks? Is dentistry a refuge for those who are seeking what appears to them an easy and respectable means of gaining a comfortable livelihood? It is also said that dental practitioners burdened with medical education "view their dental work through medical spectacles." What detriment this may be to their judgment as dentists is not clearly explained. Further, it is argued that the majority of dentists who attain a medical education "subsequently abandon dentistry for the practice of medicine." Such a condition does not interest us or fall within our province to consider.

No; the status of the dentist of to-day is—change, preëminently, above all else. He has reached that point at which he must declare himself a handicraftsman, a mechanic, a skilled laborer, or a scientific specialist of the great healing art. He has occupied the disputed position as long as progress will permit. Which shall it be? Back to mechanics and back to charlatanism, empiricism and closed laboratories, or a step towards medicine, a move towards occupying what has been termed the *terra incognita*, that territory of practice which has heretofore been partially claimed by both medicine and dentistry, and preëmpted by neither? It means that we must now decide whether we are to practice tooth restoration or tooth conservation; whether we are henceforth to be satisfied with the slaughter of natural organs and tissues in order to restore and supply, or by scientific investigation aim at the conservation of what remains and prevent the inroads of further destruction.

It has been lately remarked that "dentists are wonderful patchers-up of things half gone, but they do not show how to prevent the going." This is the key-note. And what is the cause of this condition?

Is it because our mechanical skill has been neglected? Should we have had more infirmary and laboratory practice and training at college? Is our metallurgy and physics defective? No; more science and more medical education.

We feel safe in the assurance that conservative dentistry must necessarily be based on an appreciation of the anatomic, physiologic and pathologic relation of the mouth in disease and health, and that until the importance of this kind of knowledge is fully appreciated, a community will fail to receive at the hands of its dentists the benefit which they have a right to expect.

"To be impressed," says one, "with the necessity which these propositions indicate, one has only to remember the various important anatomic and physiologic functions of the mouth; its physical, organic and mental associations, and the corresponding extent of its pathologic relations.

"Anatomically, no portion of the human economy offers a more complex association of structures; physiologically, none whose functions are so diversified, and yet so essential; pathologically, none whose systemic relations are more significant.

"A consideration of the pathologic relations of the mouth includes radiated, reflex or sympathetic disturbances of harmony, or interference with function in contiguous or remote organs, originating in the mouth, as the expression in the oral cavity of lesions or interruption of harmony in other organs. Morbid systemic or constitutional conditions, whether the result of some intermediate primary affection, or of inherited tendency, or perversion, find usually a more or less strongly pronounced expression in the mouth.

"It is supposed that the dentist is entirely unacquainted with the systemic condition of his patient. Indeed, he is not presumed to have any right to meddle with such; while the physician rather complacently ignores the importance of the local lesions which is esteemed the province of the dentist to correct.

"Meanwhile, the patient chafes at the incompetency of the dentist who fails to arrest by mechanical skill the ravages of caries, and perhaps the operator himself fails to recognize in the lesions the expression of the systemic mischief. On the other hand, the physician, ignoring the local causes, tries in vain pills, and plasters, blisters and purgatives; tries in vain the whole round of narcotics, sedatives, stimulants, tonics, anti-spasmodics and anti-periodics; talking learnedly of neuroses and cachexia until pharmacopœia, patience and patients are alike exhausted."

These undeniable facts are illustrative in the necessity that a wider range of knowledge by the dentist is imperatively demanded.

During the year 1881 a considerable agitation of the subject, the status of the dentist, was evoked by the publication of a paper written by Dr. Truman W. Brophy and read before the New York Odontological Society, in which that gentleman advocated the establishment of a Section of Dentistry in the AMERICAN MEDICAL ASSOCIATION. And notwithstanding the somewhat considerable opposition on the part of physicians and dentists, that Section was organized at the thirty-second annual meeting of the ASSOCIATION. The principal objection to the movement at the time was, as many may remember, the condition

upon which dentists were to become members. Since only those practitioners of dentistry who were graduates of regular medical colleges and members of local county societies were held eligible, the opposing members of the dental profession held that dentistry was being represented by representatives who had no constituency.

In the same year the first meeting of the Section on Diseases of the Teeth—a compromise in name—was held at the International Medical Congress in London.

At the thirty-eighth annual meeting of the AMERICAN MEDICAL ASSOCIATION, in 1887, to relieve the embarrassment that existed between the regular profession of medicine and the dental profession, it was argued that the Department of Dental and Oral Surgery was as much a part of the profession of medicine as ophthalmology or otology, or any other 'ology, "because," said our friend, "our teeth are parts of our system, and are used more than any other part," and that since dentistry has owned with humiliation the soil from which it sprang and had since steadily advanced presumably to a decent respectability, that it was only just and proper that the arms of the AMERICAN MEDICAL ASSOCIATION be more widely extended to receive the foster child.

At this meeting the line of demarcation was drawn as per the following resolution:

"Resolved, That the regular graduates of such dental and oral schools and colleges as require of their students a standard of preliminary or general education and a term of professional study equal to the best class of medical colleges in this country, and embrace in their curriculum all the fundamental branches of medicine, differing chiefly by substituting practical and clinical instruction in dental and oral medicine and surgery, instead of clinical medicine and surgery, be recognized as members of the regular profession of medicine, and eligible to membership in this ASSOCIATION on the same conditions and subject to the same regulations as other members."

This is as far as the recognition of dentistry as a medical specialty by medicine has gone. Since 1887 no particular advancement has been made, certainly, on the part of medicine. Thus far we have defined the position of dentistry and shown what has been done on the part of those most active in the advocacy of its being a specialty of medicine.

Medicine, in its broadest sense, is the science and theory of disease and of remedies, the art of preventing, curing or alleviating diseases and lesions of the human body, and its highest form to-day is found in its specialism; in other words, the medical art breaks away at once from the unity of the theory of disease, and while there is but one body of pathologic doctrine for either sex, for every period of life, and for every region and part of the organism, the practical art divides itself into departments and sub-departments, such as surgery, obstetrics, dermatology, ophthalmology, otology, etc. Dentistry, or more properly at this juncture, odontology, being the science or art of preventing, curing or alleviating the diseases of the teeth, which form an important part of the human body, is therefore a department of the healing art.

Such a deduction is but a natural one, and true in the confines of its premises. Why, then, are we still clamoring without the gates for admission? Because to the doctor of medicine this is not strictly true. He is not so liberal. Medicine to him is only medicine when the art of preventing, curing or alleviating diseases of the human body is practiced by medical graduates of medical colleges. When teeth are con-

served from disease or extracted when useless, it is dentistry.

So the status of dentistry to-day, as far as our medical brothers are concerned, is not that of a specialty of medicine, principally because we are not graduates in medicine. Are they right? To those who may believe that they are not, it is comforting to feel that though their maternal acknowledgment is so dear and their association so keenly desired, they shall not be permitted to sit sole judges of our relationship.

Other influences, both external and internal, are doing much to drag us from this fireside of art and science. The first, we are led to believe, is the necessary amount of mechanics our profession is obliged to teach and practice; 2, the distinctive degree and curriculum we are attempting to maintain and enforce; 3, the percentage of our profession who are not graduates—many of whom, though, are our brightest lights; 4, our determination to be recognized.

The forces and influences which are tending to draw us beneath the maternal roof are, however, such that they will eventually overcome all opposing ones. They are:

1. The addition of medical chairs to dental faculties, and the division of dentistry into the operative and the mechanical dentist.

In all large communities men who make a business of doing mechanical work for one or more practitioners are fast becoming a special department of dentistry. These mechanical dentists in many cities do a very large percentage of all the mechanical work, and in some States the law is inclined to wink at the infractions of these unlicensed.

2. The patent dissatisfaction in which the degree is held, and the disinclination of colleges and universities to settle upon the not unusually adopted degree of doctor of dental surgery, together with the tendency to establish a variety of post-graduate degrees for the purpose of advertising those decorated and the college conferring it.

3. The rapid percentage decrease of the body of non-graduates and the tendency of dental and medical graduates who intend to practice dentistry to acquire both medical and dental degrees.

4. The establishment of the Oral Section of the AMERICAN MEDICAL ASSOCIATION.

The elevation of any particular class of men is, however, dependent upon a demand on the part of their constituents; the people. The greatest advancement of any profession or body, the pulpit, the bar, the medical fraternity, or what not, is the result of enlarged conception on the part of their representatives, and that conception has its stimulus in the public demand.

The forces, then, of successful issue lie in the education of our patients, in the establishment of recognition from them, occasioned by scientific efficiency, and an elevated qualification in the average practitioner.

No amount of recognition from a National, State or local medical association given a body of men undeserving, can be made to stand the test of popular opinion.

We therefore believe the future course of those who are so ably leading, to be not only through the channels of education as it may present itself in the education of dentists in the specialty of medicine,

but that theirs is a plea for text-books and for education of the people.

Complete recognition can only, and will result, in the displacement of the dental degree by the medical for all, with special training for special practice.

DISCUSSION.

DR. R. H. COOL—I am interested in the paper, especially in its advocacy of a wider range of knowledge for the dental practitioner. I take the opposite view, that more knowledge of oral and dental surgery and of its resources by medical men is needed. More and more the best surgeons and best physicians are coming to call in the dentist in oral lesions. As an instance of the value of the dentist's knowledge in these cases, there is no known splint for a broken jaw like that made by an experienced dentist. In antral troubles the surgeon also calls in the aid of the dentist. With regard to instruments, those shown by Dr. Talbot for perforating the antrum produced the impression that they would give a great deal of pain, while our dental engine makes a prettier opening much easier. We can almost say that dentistry is now acknowledged among the leading surgeons as a nucleus for dental information, and I think we are being recognized as a professional body by them.

DR. A. F. McLAIN, Santa Rosa—I agree with Dr. Cool as to the advantages of skilled consultation between surgeons and dentists in diseases of the mouth and jaws. A student at the dental college contributed to a successful result in a case in which there was a fracture of the jaw near the ramus, which may have been comminuted. This student took the case in charge, made an interdental splint for it, and I defy any one to say that the result was not everything that it should be.

DR. M. J. SULLIVAN, San Francisco—I heartily indorse the tone of the paper. I have always believed in a liberal medical education for the dentist. The better the foundation the surer the success, both theoretical and practical.

SOME PATHOLOGIC NOTES ON NEOPLASMS OF THE MAXILLÆ.

Read in the Section on Dental and Oral Surgery, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY VIDA A. LATHAM, F.R.M.S., D.D.S.

CHICAGO, ILL.

Among the conditions associated with the pathology of the oral cavity and its contiguous parts, none are perhaps more interesting than those relating to the new formations which may be observed there. A pathologic formation may be simply an excessive production of the normal structure and is a morbid condition only in respect to the amount and arrangement of the ordinary tissues of which it is composed, or of the region in which it is situated. These are known as "homologous" growths and form a large number of all the pathologic formations throughout the body, and include the hyperplasias, exostoses, congenital tumors, and many growths of varying origin, such as the arthritic enlargements, formations following a rheumatic attack, or the chronic inflammatory enlargements due to long continued irritations. The main and most important class of neoplasms are those belonging to the "heterologous" class in which the structural elements are different from the tissues in which they are situated, or with which they are connected. The true distinction is one which depends upon the histologic composition, rather than upon the gross external appearance or upon the clinical peculiarities. The great and only reliable distinction is the microscopic, for upon this depends to a very great extent the correct estimation of the nature and tendency of any pathologic formation, both in relation to its effect upon the tissues with which it lies in direct contact, as well as

its influence upon the well being of the individual. Certain growths are found to consist of a tissue different from any found in the adult body, and therefore, unlike any of the tissues in which they are situated. These are very confusing to the pathologist and they have to be referred to some of the immature forms of the tissues, or to their derivatives. We must, in fact, return to embryologic tissues, for we only find the embryonic types sparingly distributed in adult life or limited to certain parts.

We usually regard growths of mesoblastic origin as of a malignant type, but still the benign forms are found as fibroma and so forth.

Granulation tissue or embryonic connective tissue is not a permanent structure. It only exists in the body of the embryo as a transitory material, the conversion of which produces another and entirely different material. We can easily understand if embryonic tissue re-appears at a time when no process of repair is going on, and accumulates in any great amount, that it may undergo similar changes to those belonging to it in its usual and normal state. It is never a permanent tissue, but is always changing to other and different forms of structure. When a new growth appears it exhibits a tendency to undergo further changes, either extension of disease, or more often a rapid decadence or retrogression of the tissue already formed, and lastly it may be combined with almost any form of tissue in the body.

Text-books on oral surgery and pathology convey erroneous impressions by classifying neoplasms of the oral cavity as ordinary types; but a careful examination with the microscope reveals the fact that they are much more complex and peculiar. It is to this "mixed" class that I find the majority of the tumors of the maxillæ and oral cavity belong, basing this statement on the microscopic examination. These growths are also much more common than is usually thought to be the case, particularly so in the region of the neck, reaching from in front of the submaxillary gland to the parotid, and surrounding the angle of the jaw. Nearly every specimen obtained so far from this region has been of this peculiar type of growth, bearing no resemblance to any fixed type of tissue and having only an ordinary clinical history. The diagnosis made by the operator has in almost every case proved to be erroneous when the growth has been examined microscopically. The commonest varieties perhaps are epithelioma and sarcoma, the latter usually a peculiar mixed form between the round-celled, spindle-celled and osteo-sarcoma. Enchondroma undergoing sarcomatous¹ degeneration is also met with.

Tumors of the salivary glands are almost always confined to the parotid, being very rare in either the submaxillary or sublingual glands.

The commonest type of the parotid tumor is one composed of a mixture of cartilage, myxomatous tissue, a varying quantity of connective tissue and ill-formed glandular acini. Growths of this nature are often called "parotid glandular tumors" or "adenomata," but it is quite rare to find a growth the bulk of which is composed of true gland tissue. The cartilage of these tumors is hyaline and it is by a mucoid degeneration of its stroma, and that of the fibrous tissue of the growth that the myxomatous tissue is produced. Sometimes there is a considerable mixture of sarcomatous tissue; at others the growth is chiefly cartilaginous; and as might be expected

from this variety in structure there is a corresponding difference in the rapidity with which such tumors develop. These growths appear in middle life and are found in either sex. They occur most often in that part which overlaps the lower jaw, are usually encapsulated, and when small adhere but little to surrounding parts. They attain large size if left alone, and may cause death by encroaching upon the pharynx or large vessels. The lymphatic glands are seldom affected, and although the growths may recur locally after removal, they seldom or never become disseminated.

Malignant growths are happily rare in the parotid. About the only growth which occurs in the submaxillary gland is made up of cartilage and even this is rare. According to Bowlby, there are not more than seven or eight cases on record and they are usually enchondromata.

Tumors of the maxillæ possess so many distinct features as to almost require a separate description. These distinct characters depend partly on the proximity of the neighboring mucous cavities, partly also on the presence of the teeth and of the fetal structures from which the latter originate.

Epulis is a loose term often applied to any tumor which appears on the gum, but is best limited to the fibromata. It usually develops from periosteal tissue and is occasionally attached to the periodontium and very often extends into the alveolus. It necessarily compels the extraction of a tooth or teeth and excision of a portion of the alveolar margin. A simple diffuse epulis is usually only a thickening of the gum.

Myeloid sarcomata are often included as myeloid epulides growing within and expanding the jaw bones, presenting rounded, tense and elastic swellings often feeling suspiciously like cysts; and generally found in young people. Other varieties of sarcomata occur within the jaw bones and also within the antrum. The cells are round or oval. The growths being soft and rapid in development, tending to extend all around and to fungate through the skin, affecting the lymph glands and so disseminating.

The distortion of the antrum and its relative structures is too well known to require description. Any tumor growing in this region tends to distend the cavity in this way, but malignant tumors do so in a more typical manner than do the benign growths. Fibro-sarcomata are found in the inferior maxilla (mandible) are not very malignant and when completely removed with the bone seldom recur.

Carcinoma are most often found in the antrum¹ and develop from the epithelioma lining the antral cavity. They are rapid in their course, affect the glands, rapidly disseminate and are usually found in elderly people.

Multilocular cystic tumors, so-called by Mr. Eve,² and known as "cystic epithelioma" stand in the position of a mixed growth—a solid and a true cyst. They are most common in the inferior maxilla and are endosteal or central growths and possibly originate by an ingrowth of the epithelium of the gum and following caries or traumatism of the teeth. They occur at any age but usually between 20 and 40, are slow in growth and may take years to reach any size. The growths are usually not malignant and seem not to affect the glands or disseminate. The

¹ New York Medical Journal, November 10, p. 586, and November 17, p. 612.

² British Medical Journal, Jan. 6, 1883.

bone is usually expanded on its inner side, and is very hard to the touch, sometimes elastic and crepitant. The teeth loosen, fall out, and a sticky discharge comes from the alveoli. Macroscopically the bone shows expansion, the cavities are filled partly with a solid growth of a soft fibrous or fleshy material, partly by fluid, serous or viscid. The septa dividing the cysts are often incomplete and are either fibrous or bony.

Periosteal cysts are situated beneath the periodontium, generally inflammatory in origin and are found in connection with carious teeth or with imperfectly extracted roots. They are very painful.

Antral mucous cysts may also be found and must be differentiated from malignant growths as they produce a similar distension by their slow growth and fungation; and as the bone turns the presence of fluid is soon detected.

Dentigerous cysts and odontomes³ are quite well described in our dental surgeries and pathologies.

Diffuse osseous growths of the antrum are rather peculiar in that they diffuse over the whole area of the antral wall, and do not grow from some definite portion as is the usual mode. Therefore we have no definite tumor, but a general thickening of the whole bone which incloses the antrum and a gradual obliteration of the sinus by the new bony formation. It may be confined to the antral cavity or may extend to the superior maxilla. The growth is slow, occurs in youth and is benign.

Cartilaginous tumors of the superior maxilla are extremely rare and usually combined with sarcomatous elements.

Sarcomata. This group which is mainly due to the exertions of Virchow, includes the fibro-cellular, the mucous tumor, and the myeloid of English surgery. The group, on the whole, nearly corresponds to Paget's recurrent fibroid. The best classification of this group is perhaps a strictly pathologic one after Billroth:

1. Round-celled sarcoma, granulation-sarcoma (including glioma) consists of mesoblastic corpuscles; the inter-cellular substance is homogeneous, striated, reticulate and varies widely in amount.

2. Spindle-celled sarcoma. The cells are usually well-marked, intercellular substance is absent or scanty, homogeneous or fibrous. The most recurrent sarcomata contain this tissue but do not always recur.

3. Giant-celled sarcoma, myeloid. This has the general structural elements of one of the other varieties and has in addition many large multinucleated cells.

4. Net-celled sarcoma—mucous sarcoma. This is not exactly like the myxoma. Myxomata are sarcomata of various kinds and are similar by having a gelatinous appearance. Net-celled sarcomata contain stellate cells with long processes and gelatinous intercellular substance.

5. Alveolar sarcoma are very rare.

6. Melanotic, may be combined with alveolar. Glandular tumors secondary to epithelioma of the lip or tongue become adherent to the lower jaw in the later stages, but must not be confounded with growths originating in the bone itself.

These are, in brief, the most important varieties of neoplasms met with.

With regard to frequency. The superior maxilla seems to be most often involved and usually recovers

itself, on account of its high degree of nutrition. In an article in *Archiv. für Klin. Chirurg.*, (Vol. xviii, 25, 1875) an account is given where the entire jaw was removed fifteen times:

"Twice for carcinoma, five for sarcomatous growths as giant-celled, three as spindle-celled, one as round-celled and one as medullary. Cylindromata twice required partial resection; epitheliomata twice an almost complete resection; enchondroma one, a total resection. Mortality being 15 per cent. According to this proportion carcinoma is more common than medullary sarcoma."

This does not agree with Prof. C. O. Weber's account: "The usual result of carcinoma is a recurrence after about one to three years and usually recurring in the cicatrix."

The diagnostic signs of antral growth are as follows: When springing from the interior of the antrum, the orbital, nasal, palatal and buccal walls of this cavity are expanded, according as the tumor grows upward into the orbit, inward into the nostril, downward into the mouth, or forward upon the cheek, causing a prominence of one side of the face. A tumor of the antrum in many instances grows simultaneously in all these directions, producing exophthalmos, obstruction of the nostril, prominence of the cheek, and bulging of the roof of the mouth. When springing from the anterior surface of the superior maxilla it causes a projection of the cheek, dipping down between the gums and the soft structures of the face. It may extend backward into the interior of the antrum by increase in size, thus secondarily implicating that cavity. When springing from behind the superior maxilla the upper jaw is first pushed bodily forward, but as the antrum becomes secondarily involved, any of the walls of this cavity subsequently become expanded and rendered prominent.

A serious affection of the gums appears in a more innocent garb, apparently a mere ulcer. Dental surgeons are more apt to see it in its earliest stages than are surgeons. A sore appears, perhaps awakened by a carious tooth. It does not heal kindly, but exhibits a tendency to extend. Its borders become hard and thick, its base soon adheres to the bone beneath—this is cancer.

"Bone is never the seat of cancer primarily." This broad statement was first made some years ago by the best German pathologists, and cancers of the superior maxilla were held up as positively disproving any such idea. But now we know there are but two locations in the superior maxilla where cancer is first encountered. The first appears as above—upon the gum; the second in the antrum of Highmore. In each case it starts as an ulcer, eats its way into the bone, and never appears as a distinct tumor. The sore is found upon the gum, its edges thick and firm, base immovable, and this characterizes its malignant infiltrating tendency. Dentists can not have these facts too strongly impressed upon them. It will be noticed that carcinoma of the body of the superior maxilla conceals its true nature at first, and except by a careful person is not recognized until extensive destruction of bone has resulted, possibly an opening made in the oral, nasal or orbital cavity and is soon beyond operative relief.

Butlin has removed the upper jaw within seven weeks of the first signs of the disease, only to find the bone entirely destroyed and sinuses burrowing into all the

³ New York Medical Journal, p. 612, 1894.

surrounding parts. Thus we see the necessity, when malignant disease is suspected, to examine not only the mouth, nose and orbit, but even the throat, and here comes the necessity for broad medical and dental education in the combined efforts of thorough dentists and surgeons. Professor C. Heath gives an excellent suggestion, and a most valuable one, when he says the attachment of any growth to the roots of extracted teeth should excite the suspicion that a serious disease is present in the antrum, and a microscopic examination should be made.

In conclusion, we have seen from the foregoing remarks that neoplastic growths of the maxillæ are then modified forms of the great groups, carcinoma or sarcoma. They are, in fact, more truly complex and diffuse in structure, so much so as to require special grouping; for in structure the histologic-elements are not allied as is usually the case in growths found in other parts of the body. I regret to say that lack of time prevented the subject being brought before you in a more thorough manner, but as their structure is so complex more special study was required. It is hoped this may be completed later and published with photographs and cases. Might I suggest that members of the ASSOCIATION and profession kindly collect such specimens and examine them, or aid by loaning or giving specimens for examination? They would thus enable better and more complete work to be done in this line, and so preserve valuable material. They would confer a great favor upon the essayist, and at the same time help to make understood some of the great questions which occur in oral pathology, especially in the histologic details.

DISCUSSION.

Dr. JACOBS—Some seven or eight years ago I studied the structure of tumors considerably, but I have done very little work in that direction lately. I should not therefore dare to discuss the paper further than to confirm it as far as I know, and to say that Dr. Latham is the hardest worker I ever knew, and I have no doubt of the correctness of everything she says.

SOCIETY PROCEEDINGS.

Medical and Chirurgical Faculty of Maryland.

Semi-Annual Meeting held at Cumberland, Maryland,
 Nov. 21 and 22, 1894.

FIRST DAY.

The Medical and Chirurgical Faculty of Maryland convened in session in the council chamber of the city hall at Cumberland, Nov. 21, at 10 A.M. After the Address of Welcome by Dr. J. M. SPEAR, of Cumberland, and the Address by the President, Dr. R. W. JOHNSON, Dr. H. SALZER read a paper on "Distension of the Stomach," in which he spoke of the methods of diagnosis of diseases of the stomach, and especially distension of that organ, by examination of the gastric secretion. He did not always use the stomach

tube, but let the patient vomit the substance taken, and then made an examination.

Dr. WM. OSLEA thought that the method of Dr. Salzer was more pleasant than the one by the use of the stomach tube. He thought that the examination for movable kidney, as suggested by Dr. Salzer, was important. He generally found signs of dilatation of the stomach in neurasthenic patients, and palpable if not movable kidney, and it may be at times a floating kidney. He believed in the abdominal bandage after pregnancy, and it was important in preventing these troubles.

Dr. GEORGE J. PRESTON thought that all those who saw many cases of neurasthenia would be interested in this paper. It is a question how far the nervous condition affects the distension and how far it should be treated. In many cases that he had treated he had noticed diminished knee jerk.

Dr. E. M. SCHAEFFER would support what he said about the corset and absence of exercise. He thought the use of the tight corset was potent to do much harm, and exercise would correct many troubles, and he approved of the bicycle in certain cases.

Dr. ROBERT L. RANDOLPH read a paper entitled "Some Suggestions as to the Treatment of Wounds Involving at the same time the Lens and the Ciliary Region," and reported two cases in which he did not find it necessary to remove the eye, but took out the lens and one case got well, with some vision.

Dr. HARRY FRIEDENWALD read a paper on "Removal of Particles of Steel from the Interior of the Eye with a Magnet," in which he related several cases successfully treated, showed the steel and the magnet, and explained the manner of using it.

Dr. WILLIAM H. WELCH then made some

REMARKS ON THE DIAGNOSIS AND TREATMENT OF DIPHTHERIA.

The study of the antitoxins is the order of the day. The evidence that the Klebs-Löffler bacillus is the cause of diphtheria is very conclusive; no one can doubt this now. It is constantly present in every case of genuine diphtheria; isolated in pure culture it is productive of the disease and the disease can be produced experimentally in no other way. We are familiar with the toxic principle of this disease and we know its physiologic but not its chemic properties. This substance has been found in the bodies of those dead from diphtheria. There is probably no organism the study of which has led to such practical results as this. It gives us the diagnosis, prognosis and treatment. The diagnosis can be made with certainty by the demonstration of the specific bacillus. There are many diseases which are like diphtheria in their clinical history, such as membranous croup. Then there are the cases where the disease would not have been recognized on account of the slight symptoms if the bacillus had not revealed the diagnosis, and these light cases are the very ones which spread the disease. Then our increased knowledge of this disease allows us better to understand its symptoms and the question whether it is a local or constitutional disease is cleared up. It develops locally; the bacilli are attached to the membrane in the pillars of the fauces and here the toxins find their way into the body, causing the constitutional symptoms. The prognosis hinges to some extent on the demonstration of associated bacteria. Other bacteria may be associated with the Löffler bacillus in the throat; thus the presence of streptococcus gives an unfavorable prognosis and offer fewer chances for successful treatment. An accurate diagnosis is not only important in order to carry out the treatment, but makes it possible to take sanitary precautions. Of those who are exposed to diphtheria not a small number receive the bacillus without getting the disease, especially in crowded districts. The organism has been found in as many as 50 per cent. of the persons exposed whether they took the disease or not, which shows that there must be a susceptibility, which is a very important point. This susceptibility may be local, that is, susceptibility exists for the local effects and not for the toxins, or the reverse may be true; the local effects may be slight and the general systemic poisoning very severe and in some cases there is no susceptibility at all. Some cases show a thick membrane and little poisoning, and *vice versa*. The method of making the bacteriologic diagnosis is a simple one. As little of the membrane as possible is taken, or some of the secretion from the posterior pillar of the fauces near the larynx. First, cover-slip preparations are made. If it is a case of genuine diphtheria the diagnosis can be made in about 50 per cent. of all cases with no further ex-

amination. Still this is not so conclusive, as it is not quite so characteristic as the tubercle bacillus. For culture medium the Löffler blood serum mixture is used. It is usually sterilized now by exposing it to a heat just below the boiling point for a half hour. The mixture is opaque when rapidly heated, and clear when done slowly. When a small piece of the membrane or some of the secretion has been smeared over the surface of the culture medium and put in the incubator at body temperature, the culture appears in eighteen to twenty-four hours. Even if kept at the temperature of the room there will be a feeble growth. Usually the growth takes place rapidly. The difference between the growth of the true and false bacillus may be seen in the beef bouillon. In most beef, of which the culture medium is made, there is usually a little inosite or muscle sugar. This undergoes a change in color when the true diphtheria bacillus is inoculated into it, which does not occur when the false bacillus is inoculated.

The question now is how to make this method of diagnosis available to all physicians. In New York City this problem has been beautifully solved much to the admiration of the whole scientific world. Formerly many cases of ordinary angina and sore throat were called diphtheria and much glory was reaped by the physician who cured the case. Now the bacteriologic diagnosis shows that only about one in four is true diphtheria, and this not only separates the cases and makes a certain diagnosis but it saves those other three cases from exposure to the disease, for in most instances these supposed cases were put at once into the diphtheria wards and if they did not have diphtheria before, they promptly acquired it there. In carrying out the serum-therapy only artificially immune animals can be used; those naturally immune will not do. The animals usually selected are the horse, goat, cow and dog. The manner of procedure is to inoculate the animal selected, with a minute part of a pure culture of the organism. A change takes place in the blood and a new substance is found there. After each injection of the poison there is a diminution of the antitoxins and then they increase and so on until in course of time the antitoxin takes its place in the blood and a large dose of the culture will not affect the animal. It takes from three to four months to immunize an animal. In simple cases where there is no association of the streptococcus a few injections will effect a cure. Roux' experiments showed that in all cases under ordinary treatment about half died whereas in the antitoxin treatment about 26 per cent. died. A mixture of the pure culture of diphtheria and antitoxin in a test tube does not destroy the bacillus but holds its action in abeyance when this mixture is injected into an animal; if the streptococcus be added and then this mixture be injected, poisoning takes place from which it is concluded that the streptococcus keeps the antitoxin from acting and allows the poison to affect the victim. Roux advises against any caustic treatment of the throat as making a cure more difficult.

DR. JAMES A. STEUART said this was a great advance; that health officers had sometimes difficulty in distinguishing dangerous from ordinary cases.

DR. I. E. ATKINSON thought that such practical steps should be taken in Maryland.

DR. JOHN N. MACKENZIE had had great success in treating diphtheria with the dioxide or peroxid of hydrogen.

DR. JOHN MORRIS thought there should be no municipal or State control of this remedy, and referred to the poor vaccine matter furnished by the State of Maryland.

DR. I. E. ATKINSON said it was largely the fault of the profession that we did not get good vaccine matter. State and municipal duties had not been carried out. It is because the profession has not demanded it.

DR. E. T. DUKE defended the vaccine matter of Maryland and said as Health Officer of the city of Cumberland he had used it very successfully, and referred to an institution in which he had vaccinated fifty persons and forty-eight of them took.

After some discussion on the State and municipal control of the antitoxins by Drs. G. H. Carpenter, G. J. Preston, John Morris and Welsh, the subject was closed.

DR. G. H. CARPENTER reported a "Case of Puerpura Hemorrhagica," in which he advocated the use of the tincture of the chlorid of iron in large doses, say 40 drops, every two hours. He also expressed his opinion that the disease was much graver in character than was usually taught.

DR. W. J. CRAIGEN read a paper entitled "Electricity in Gynecology," in which he reported several cases treated by electricity, spoke of the use of high currents and their dangers, and referred to the possibility of resuscitation after a severe electrical shock as was suggested in New York.

DR. RANDOLPH WINSLOW reported "Two Cases of Gastro-tomy for Cicatricial Stenosis of the Pharynx and Esophagus," in which he showed that the operation had saved life so far, and gave some promise in one case of ultimate recovery.

DR. GEORGE J. PRESTON then read a paper entitled "Hysterical Pyrexia" in which he showed that: 1, in hysterical individuals a rise of temperature may occur, due probably to disturbance of the heat regulating centers in the central nervous system; 2, the type of this fever is either continuous or intermittent; 3, the type of fever is characterized by its great irregularity and atypical exacerbations, by the fact that the pulse and respiration frequently remain normal, or nearly so, that the temperature is often different on the two sides of the body, by the temperature not yielding readily to antipyretic measures and by the unaltered urine and the unchanged nutrition; 4, hysteria often complicates existing fevers, changing their types; 5, the hysterical manifestations would be more frequently noted if the temperature were taken in all cases.

DR. WILLIAM H. WELCH thought that the question of fever from central nervous origin was an important one from many points. It most likely comes from diminution of heat loss and there is no evidence of increased heat production. In some cases there are remarkable irregularities in heat distribution. It may be high in the vagina and normal in the axilla and *vice versa*. By taking the surface temperature great differences may be found.

DR. G. J. PRESTON had noticed many of the points above alluded to. There may be the greatest differences between the temperature of the two sides of the body. The fever may be out of all proportion to the organic lesions and may be caused by hysteria.

DR. WILLIAM OSLER then made some remarks on

CHILLS AS A CAUSE OF ERROR IN DIAGNOSIS.

Chills differ very much in their etiology, but they may be divided into two main groups: 1, from some sudden shock to the nervous system; 2, from absorption of the toxic material formed by organisms. In the so-called nervous chill, fever is absent. In the second group, there is always fever. The first group need not detain us. The nervous chill is that met with in gall-stone colic or in the passage of a catheter. This initial chill is without fever, but subsequently there may be chills with fever due to infection. The disease most often associated with chills is malarial fever and here the chill is of a characteristic kind so that the name, "chills and fever," is synonymous with malaria. The two great diagnostic points in malaria are the invariable association of the plasmodium of Laveran and the invariable curative effects of quinin. These are the two special features of the malarial chill. It may be said that within forty-eight hours the chill will cease in genuine malaria if quinin be used. On the other hand, the paroxysms continue and under its use malaria may be excluded, except in a few cases of the autumnal malarial fevers which may resist quinin for a few days, but these have not the same character of ordinary intermittents. He had not met a single instance of genuine malarial fever which quinin had not stopped. Chills cause errors in diagnosis in various affections. In tuberculosis, the error may be made early or late in the disease, for it is at the two extremes of pulmonary tuberculosis that we have chills. These are a special feature of the early stages of tuberculosis. He has had many cases of early phthisis brought to him as malarial fever. Errors occur frequently in regions where paludism is common. Then there is the large group of septic processes with fever, such as abscess of the liver which is a common cause of chills and fever in this latitude. There are very few cases of abscess of the liver which are not at first regarded as malarial fever and thus much valuable time is lost in the treatment. Malignant endocarditis is another disease which is ushered in by chills and which is often treated for malaria. A not frequent source of error is the chill following and associated with pleurisy of a tuberculosis nature form and from empyema following the infectious diseases, as scarlet fever, etc., and following the formation of pus. The chills in typhoid fever are of the greatest importance and have attracted attention for years. They occur in 2 and 3 per cent. of all cases. Very often the chill is due to the doctor's giving powerful antipyretics. He had seen a case in which chills and fever had followed a large dose of antifebrin. In certain affections of the urinary passages and more especially pyelitis, chills occur which are often obscure. In chronic obstruction of the common duct by gall-stones there is the condition called by Charcot, hepatic intermittent fever due

to catarrhal cholangitis. In new growths of various kinds, as in cancer of the stomach, in Hodgkin's disease and lastly in syphilis, errors in the fever may be made. The important points in the diagnosis are in the use of quinin and in the examination of the blood.

Dr. JOHN NEFF reported a case of fever, in the course of typhoid fever, in which there was kidney complication with albumen and casts. The use of nitroglycerin caused much improvement.

Dr. HARRY FRIEDENWALD referred to a case of otorrhoea which had high fever, and which turned out to be due to a thrombosis of the lateral sinuses.

Dr. JOHN MORRIS made some interesting references to the fevers of former days and the manner of treatment.

Dr. G. H. CARPENTER spoke of having seen cases of tuberculosis with fever which he thought was malarial because it occurred in a malarial district. He also said he had seen a certain number of cases of fever in the course of typhoid fever which he called typho-malarial fever.

Dr. I. E. ATKINSON referred to some obscure cases with fever, and said milk fever was a thing of the past as we now know it and was not due to the condition of the milk or the breasts. Septic fever occurred in the course of typhoid fever.

Dr. J. J. WILSON referred to a case of typhoid fever in his practice in which there were several chills and finally an abscess of the parotid gland developed.

Dr. WILLIAM OSLER was glad to hear Dr. Carpenter's remarks about typho-malarial fever. Many physicians treat ordinary cases of typhoid fever as malarial from beginning to end. There is no such disease as typho-malarial fever. The two diseases may exist concurrently. Quinin will cure malarial fever but it will not influence typhoid fever at all. Cases of so-called typho-malarial fever are typhoid and should be treated as such. Too many lives have been lost by neglect of this caution. In nearly four hundred cases of typhoid fever which have been treated at the Johns Hopkins Hospital, in no case had malaria coexisted.

SECOND DAY.

Dr. THOMAS A. ASHBY read a paper entitled "Treatment of Retro-Displacements of the Uterus," in which he reported several cases with the results of his treatment. He considered the subject under four heads: The congenital; the acquired forms without adhesions; the acquired varieties associated with inflammatory conditions of the tubes and ovaries; and those cases in which the tubes and ovaries are not involved to any extent but where the uterus is firmly attached to the pelvic peritoneum by firm bands of adhesions.

Dr. W. J. CRAIGEN asked if he had ever had trouble with a hemorrhage after breaking up adhesions. It is not good to leave the uterus with a partially diseased stump after removal of the tubes and ovaries.

Dr. E. M. SCHAEFFER was glad to hear him speak of massage, and also of the use and abuse of the corset.

Dr. ASHBY had never had any trouble with hemorrhage after the operation if the blood vessels are looked for and tied. He does not believe in removing the uterus unless it is diseased; then tie off the stump and disinfect it and do not remove more tissue than is absolutely necessary. This is a principle of surgery which should be followed in gynecology. Massage should always be tried first. He had seen return of the uterus to its normal position by manipulation. He believes the corset is a cause of trouble, but can Dr. Schaeffer tell us how to avoid it?

Dr. R. W. JOHNSON then read a paper entitled "Wandering Kidney with Report of a Case of Nephrorrhaphy," in which he spoke of the importance of a correct diagnosis, and the ease of making it, and the causes. He related a case which had passed through the gynecologist's hands and had lost both ovaries without feeling better. He found a wandering kidney which he fastened in place and the case recovered.

Dr. OHA referred to cases in his practice, and spoke of the difficulty of making a diagnosis of floating kidney in stout persons.

Dr. R. W. JOHNSON would not advise removal of the kidney unless there was some good reason for it. He is in favor of conservative surgery and referred to removals of the vermiform appendix. He did not advise operation for hernia as long as the truss will retain the hernia and as long as the case is in a civilized region where trusses can be found and operations done in an emergency.

Dr. E. M. SCHAEFFER then made some "Observations on the Use of Food as Medicine," which was a very practical

paper showing the importance of using the proper food both in health and disease and the necessity of cooking it in the right way. He showed charts illustrating the comparative values of food by weight and nourishment and made some strong objections to the dress of woman.

Dr. E. N. BRUSH said that persons should be taught not only what good food is, but how to purchase it and how to cook it.

Dr. S. J. FORT said that he treated epilepsy and imbecility by giving the proper food.

Dr. W. B. CANFIELD said that while it was eminently proper to insist on nourishing food, many persons preferred to eat what they liked rather than what was good for them and in making a diet list, palatability should be considered. Many a person, sick or well, preferred a savory dish even if not so nourishing or digestible, and often its palatability made it more digestible in spite of chemistry and physiology to the contrary. The diet of rice as pointed out by Dr. Schaeffer may be very nourishing, but it was also constipating and not to be borne by many. He noticed that little reference was made to the use of sugar in food. He thought that the craving of children and some adults for candy was a natural one, and he did not think that good candy in moderate amount was injurious.

Dr. G. H. CARPENTER said he knew more about cattle raising than he did about bringing up a healthy race and the former was much easier. He agreed with Dr. Canfield in what he said about palatability. It is important to gratify the appetite when no actual harm is done.

Dr. T. A. ASHBY said that disease in woman was divided into two classes; that in the married and that in the unmarried. In the sterile woman the disease is generally from some defect formed in childhood. Then hygienic measures are important. About 90 per cent. of the diseases in child-bearing women are due to childbirth. Sexual selection is ideal and so are the charts which were here shown.

Dr. SCHAEFFER said in conclusion that rice constipated because it was so thoroughly digested that there was little residue. There is no waste as in other foods. Rice properly cooked formed a very palatable dish. The Chinese recognized the value of rice when they ate rice and butter.

Dr. E. N. BRUSH then read a paper on the "Treatment of Insomnia," in which he deplored the multiplication of hypnotics which had been encouraged by physicians so much of late, and spoke of natural methods as inducing sleep. He referred to baths, proper clothing and attention to general hygiene.

Dr. SCHAEFFER agrees with Dr. Brush and thinks that attention to food and drink will often take the place of drugs as he had already shown in his paper.

Dr. S. J. FORT then read a paper entitled "Pseudarthrosis," in which he related cases of hysterical joint trouble in children, simulating rheumatism.

Dr. WILLIAM B. CANFIELD then read a paper on the "Treatment of Pulmonary Consumption in Large Cities," in which he referred to the great advances in the pathology of that disease and the failure to find a specific remedy. He said that cod-liver oil and tonics were still relied on in most cities. Out-door life, equable climate, good food, comfortable clothing, slight occupation in some cases do more than drugs. With our present light the proper treatment of consumption in large cities, especially the incipient cases, was in small hospitals where each case could be studied.

Dr. H. FRIEDENWALD then read a paper entitled "Spring Catarrh of the Conjunctiva."

Dr. E. M. SCHAEFFER then read a paper on "Dirty Air in Public Places," in which he spoke of the necessity of good ventilation.

The papers by Dr. GEORGE THOMAS, "Illumination of the Accessory Nasal Cavities," and by Dr. J. T. SMITH on "Acute Pericarditis" were read by title. The profession of Cumberland and vicinity were very cordial to the visiting physicians.

Mississippi Valley Medical Association.

Abstract of the Proceedings of the Twentieth Annual Meeting, held at Hot Springs, Ark., Nov. 20-23, 1894.

(Continued from page 854.)

THE IMPORTANCE OF URINALYSIS IN DIAGNOSIS.

By Dr. A. B. WALKER, of Canton, Ohio. If physicians and surgeons would avail themselves of this important aid to diagnosis, much more good could be accomplished to their patients, many a life spared and thousands of dollars saved life insurance companies. As urinalysis requires but a few

moments of time, and the results from it are so positive and true, the author felt that no opinion of a case of any importance should be given without there having been made a careful examination of the urine. Many a case of Bright's disease might be prevented if, when the first symptoms of the disease manifest themselves, a careful examination of the urine be made and the proper treatment and diet prescribed. An interesting case was cited in point.

In every case where ether is to be given as an anesthetic, a careful examination of the urine should first be made to determine the condition of the kidneys, when if they show the least symptom of disease it should not be given, for it is known to exert an unfavorable influence upon them. Many cases of transitory albuminuria are noticed after ether has been administered, proving that it does affect the kidneys. When the kidneys are in an advanced stage of disease, the ether is likely to cause a congestion of the organs and thereby prevent the elimination of urine, when death will surely be the result. The author is surprised that all life insurance companies do not require an examination of the urine even for their small risks. He believes the time is not far distant when they will see the necessity of it and demand it in all cases.

DR. A. M. OWEN, of Evansville, Ind., read a paper entitled "My Experience with Gold as a Therapeutic Agent."

SECOND DAY—AFTERNOON SESSION.

DR. STARLING LOVING, of Columbus, Ohio, read a paper entitled

PHYSICIANS' PRESCRIPTIONS.

He said in but few medical schools of the present day—of this country, at least—is the theory and art of prescribing taught or even mentioned. Hundreds of bright, enthusiastic young men, full of knowledge of other departments of professional learning, and of hope and ambition, are turned out every year without having had even a hint of the difficulties which they must encounter when they essay their first prescription. We seldom read of mishaps from defectively written prescriptions in England, Germany or France, where requirements are larger and more systematically taught. When such occur, the apothecary is usually to blame. The same lack of method and carelessness, notable in the writing of prescriptions is to be found in the combining of medicines in the various forms. Sufficient attention is not always given to compatibilities, chemic and therapeutic, to solubilities, the influences of light, temperature, the air, and of other circumstances affecting the condition of drugs and chemicals. Many failures in treatment and many accidents, some serious in character, result from carelessness or want of accuracy in the directions given to nurses and patients for the administration of medicines after they have been brought ready for use. Why should the medical profession of the United States, in other respects so quick to see their own advantage, so sagacious in diagnosis, so bold in operating and in treatment, neglect so important a branch of knowledge as the theory and art of prescribing? The answer is, carelessness on the part of teachers and pupils.

DR. WILLIAM F. BARCLAY, of Pittsburg, read a paper entitled

TOXICS.

After defining a poison, the author said it may seem strange that almost all toxics are innocent, until they reach the circulation of the blood. Their slow or rapid absorption largely determines their deleterious effects upon the system. In our observation we are reminded, from time to time, of the idiosyncrasies of individuals and we seldom inquire into the causes of these peculiar conditions. It is generally attributed to a perversion of the nervous system, but in truth is caused by a rapid absorption of the poison, and is modified by the power of resistance inherent in the individual. Toxics enter the circulation of the blood, and their action on the normal cells produce toxins, and the multiplication of these products bring on pathologic conditions. Nothing is more easily demonstrated than that the emunctories throw off toxics. We observe at once upon the entrance of a toxic into the circulation of the blood that all the functions of the body are impaired to a greater or less degree, and that definite poisons are quickly formed, such as ptomaines, leucomaines, and others, which is nothing more or less than an altered nutrition. The vital forces are at once disturbed or arrested. Primarily the circulation, and secondarily, the nervous system are impaired, and a condition termed shock is superinduced. In the state of shock, nature seems intent upon relieving herself of all effete matter, by the discharge of the contents of each viscus of

the body. All such efforts should be assisted by artificial means in restoring a healthy condition. Vigorous health and strength are maintained by proper food, perfect digestion with healthful environment.

QUININ IN THE TREATMENT OF CHOREA.

By Drs. FRANK R. FRY and M. A. BLISS, of St. Louis. The writers briefly reviewed Prof. H. C. Wood's theory of the causation of chorea as set forth in a paper on "The Choreic Movement," which was published in the *Journal of Nervous and Mental Diseases*, April, 1893. He therein advanced the suggestion that chorea is due to disturbances in the spinal inhibitory apparatus, which he supported by a highly scientific argument. He made the further practical suggestion that inasmuch as quinin had been found physiologically to stimulate spinal inhibition in animals, the drug be given to dogs, and the human subject affected with chorea. In this direction he had made a few trials with very gratifying results. Although his opportunities for observation had not been many at the time he published his communication, they were of such a nature as to encourage others to use quinin in treating chorea. The writers cited the results of other clinicians who had been using it, wherein it was found that the drug had had a decidedly beneficial effect. They then recited a number of their own cases from clinic and private practice in the treatment of which they have been using quinin. Their results confirm those of Dr. Wood and others. They called attention to the fact that they had not used as large doses as others, yet had very satisfactory results. They raised the question whether the effect of quinin in this disease is due to the *modus operandi* suggested by Dr. Wood, viz., its stimulating effect on the spinal inhibitory apparatus, and not to some other effect. They suggest that this drug has a decided value in the treatment of certain infectious diseases in which class, according to the opinion of some authorities, chorea belongs. They further suggested that drawbacks may be found in giving quinin in large doses to choreic patients, inasmuch as it sometimes produces unpleasant nervous phenomena, and especially in nervous or neurotic individuals. They met with no inconveniences of this kind so far in the choreic patient, to whom they had administered it. In fact, they stated they could confirm an observation made by others to the effect that these patients are not apparently easily cinchonized.

While they have witnessed decided and, as a rule, only beneficial effects from the drug in these cases, they concluded that more data must be collected before its final status may be determined upon. With this end in view they have been keeping and would continue to keep careful notes of all their cases to which quinin was given. An interesting item of the paper was the citation of a severe case of chorea which after resisting other remedies, promptly recovered on full doses of quinin, the notes of which were published by Dr. Fry in the *Weekly Medical Review*, June 15, 1889, five years ago.

REFLEX IRRITATION AS A CAUSE OF DISEASE.

By DR. EDWIN WALKER, of Evansville, Ind. The essayist said that no error in modern times has had such tenacious hold on the professional mind as that of reflex irritation as a cause of nervous disease. In fact, to most of us the explanation of the occurrence of any nervous phenomenon or lesion is satisfactorily accounted for, if some peripheral irritation is found. A long prepulse, some slight version, flexion or laceration of the uterus or other deviation from the picture in our charts, is sufficient to account for hysteria, epilepsy, or other nervous disease. The reflex theory dates back many years. Early in this century it was offered as an explanation for certain neurotic phenomena, but its prominence in the medical mind of to-day is due to the lectures of Brown-Sequard on the "Physiology and Pathology of the Nervous Centers," delivered in London in 1858. The essayist then alluded to the contributions of several other prominent writers in regard to reflex irritation as a cause of disease, and said that for nearly twenty years he had thought much of this question, his attention being first called to the articles of Sayre. He followed his advice and did many circumcisions, and later, mainly through the teachings of Emmet, did operations on the cervix and vagina; he has observed many cases of neuroses in women presenting various lesions of the genital tract, and states that he has never seen a case of epilepsy, insanity, catalepsy, hysteria, or grave neurasthenia, or any organic disease of the nervous system cured or even permanently benefited by any operation on the genital tract, either done by himself or any one else. He has also noticed that a large proportion of patients who consult us for diseases of the genital tract do not suffer from defi-

nite nervous disease; and on the other hand, that of patients who do consult us for nervous diseases, many and perhaps most of them are free from genital disease. In a given case in which we find genital irritation and nervous disease, a careful inquiry into the case will develop other more potent causes. The writer does not deny that lesions of the genital tract may not in some way derange the nervous system, but insists that it does not do so by reflex action. For example, a woman has a bad laceration of the perineum that interferes with her locomotion; it is difficult or painful for her to go about, her life becomes sedentary, she suffers with constipation, later, dyspepsia from her inactivity, then her general system suffers from deficient nutrition as well as the want of healthful exercise. The nerves are not nourished and disease is engendered. Or a patient has some disease of the abdominal viscera, perhaps he has intestinal indigestion and nervous symptoms—a very common thing. Are we now to say that his nervous disease is reflected from his bowels? Certainly not. The lack of proper digestion and assimilation of food starves the system or by auto-infection poisons it.

Dr. HAROLD N. MOYER, of Chicago, read a paper entitled "Accidents and Injuries from Electric Currents of High Potential."

THIRD DAY—MORNING SESSION.

Dr. FRANK P. NORBURY, Jacksonville, Ill., read a paper entitled

THE MENTAL SYMPTOMS OF CEREBRAL SYPHILIS; A CLINICAL STUDY.

He drew the following conclusions:

1. Somnambulism and allied states; lapses of intelligent conceptions with associated loss of memory are mental symptoms of cerebral syphilis.

2. Sudden somnolence with ocular spasm or paralysis point to syphilis, when preceded by headache and monoplegia is almost pathognomonic. Headache, quasi-periodical, as defined by Gray with marked insomnia, suddenly ceasing and followed by psychic disturbance is due to syphilis.

3. Melancholia or mania when following periodical headaches, insomnia, or somnolence; *a.* with ocular spasm or other form of monoplegia or heterogeneous paralysis is due to syphilis; *b.* pseudo-paranoia. By this, he means cases presenting all symptoms of paranoia; systematized delusions depending on hallucinations of sight, hearing, taste or smell with slight impairment of general mental functions are due to syphilis, as we know that syphilis causes isolated local losses of power, and it is noteworthy when the special senses are involved that mental derangement usually results; *c.* pseudo-paresis, characterized by fibrillary tremor of tongue, indistinct speech (partial or complete aphasia), uncertain and trembling gait, with delusions of grandeur, and occasional outbursts of maniacal excitement, papillary involvement—all characteristic symptoms of paresis—but which yield readily to anti-syphilitic treatment, we can say are due to syphilis.

4. Class 4 have epileptiform and apoplectiform attacks. We find cases in which treatment was undertaken too late. The symptoms are those of terminal dementia, only occurring in patients of previous sound mental condition and with no special hereditary history.

Dr. CHAS. B. PARKER, of Cleveland, Ohio, contributed a paper on

THE SURGICAL TREATMENT OF INJURIES OF THE HEAD, in which he presented the following conclusions:

1. In any case of doubt as to the character of a head injury, explore by incision, if necessary.

2. In the case of wounds, especially the smaller and punctured, enlarge them for exploration and cleansing.

3. In all cases of fracture, depressed or fissured, operate, elevating the depression and exploring the fissure for a depression of the inner table which so often occurs.

4. Leave principal fragments of bone after elevation, if surgically clean, even if entirely detached from the dura mater and pericranium, thus averting cerebral hernia, vertigo and other cerebral disturbances.

5. All these operative measures should be conducted under the most rigid aseptic and antiseptic measures.

Dr. GEO. N. LOWE, of Randall, Kan., read a paper entitled

TRAUMATIC LESIONS OF CRANIUM AND BRAIN,

in which he reported four interesting cases. The first case was one of depressed comminuted fracture of the right parietal bone at the junction of the temporal bone, caused by the

kick of a horse. There was also a contused lacerated wound of all the soft tissues along the entire ramus of the left inferior maxillary. In this case the author trephined and elevated the depressed comminuted bone fragments. Recovery.

Dr. B. MERRILL RICKETTS, of Cincinnati, read a paper entitled

(A)—CASTRATION FOR HYPERTROPHIED PROSTATE; (B)—REMOVAL OF HEAD OF FEMUR FOR DISLOCATION INTO LESSER SCIATICA NOTCH; (C)—TREPINE FOR PRESSURE AS A RESULT OF FLUID IN ACUTE CEREBRAL MENINGITIS.

In the case of castration for hypertrophied prostate, the author said he was inclined at first to make a suprapubic operation, possibly combining the suprapubic and perineal. After thoroughly considering the matter and explaining to the patient the probable results of the various operations, he decided to remove the testicles. After having the patient under observation for ten days, he proceeded to operate, removing the testicles. The arteries were torsioned, the wound closed and integument coapted with a continuous silkworm gut suture. The patient rallied well from the chloroform and suffered no inconvenience or pain thereafter. The wound was examined on the fourth day and primary union was found to have taken place. The patient left Dr. Ricketts' private hospital at the end of the sixth day. On the second day after the operation the patient told him that he could urinate with greater ease, and that the pain was slight; that he could sleep four hours at a time during the night, whereas formerly he had been getting up once every hour. This condition continued to improve during the patient's stay in the Doctor's hospital.

Case 2 was reported to show how little is known of what takes place within a mass of muscular and adipose tissue. It has been said that all operations upon the abdomen are exploratory, and it might be well said that positive diagnoses can not be made in cases of fracture or dislocation without an exploration. The question therefore arises, What is our duty to ourselves and our patients in these complicated fractures and dislocations, where doubt exists as to their character? Especially may this question be asked where the results are not what might have been expected.

TUMOR ALBUS OF THE KNEE JOINT.

This paper was read by Dr. WILLIAM E. WIRT, of Cleveland, Ohio. The object of the paper was to present a summary of the points to be observed in the treatment of tumor albus of the knee joint, and to call attention to the fact that most excellent results are obtained by the use of conservative measures. The author classified the treatment under the two headings of constitutional and local measures, and the local under the subdivisions of conservative and operative treatment. The author first considered constitutional treatment, and then the local treatment which he divided into the conservative and operative. The conservative measures to be carried out in the treatment of this affection are counter-irritation and local applications, fixation, protection, extension, rest, and correction of deformity. These were considered under their respective heads. Of sixty cases under the expectant plan, 60 per cent. had motion. Of 145 cases under the fixation plan, 76 per cent. had motion, and of 37 cases under the protective plan, 95 per cent. had motion. Of 227 cases only 15 recovered with a deformity at an angle under 135 degrees, and 141 had an angle of deformity not less than 165 degrees. This enabled them to walk with their limbs practically straight, and with scarcely any appreciable deformity.

Dr. A. H. MEISENBACH, of St. Louis, read a paper entitled

RESECTION OF THE KNEE FOR SEPARATION OF THE LOWER EPIPHYSIS OF THE FEMUR.

The case was of two years' standing in a patient 13 years of age. The author said separation of the epiphysis is a condition that may occur either on account of trauma or disease. There seems to be a difference of opinion by writers as to the frequency of its occurrence, especially as the result of trauma. As the result of disease of the bones—osteomyelitis, it is considered a not infrequent accident. Traumatic separation of the lower end of the femur occurs in about from one-11th to one-third of all the reported cases, and in the majority of instances previous to the sixteenth year, seldom later. The forces that are necessary to produce this separation are various. Thus during child-birth, traction may produce it. Volkmann states that he has produced it when the hip is diseased, when making rotation in seeking for crepitation, or extension in the application of plaster-of-paris dressings. Other forces are indirect external vio-

lence, usually of a twisting character, or lateral, or at right angles to the axis of the limb. The readiness with which the dislocation of the separated diaphysis into the popliteal space occurs can be explained; 1, on account of the anatomic structures of the surrounding parts; 2, the force and position of the patient, the popliteal space being in the direction of least resistance, while on the anterior aspect we have the quadriceps tendon, the patella, and the ligamentum patella. The occurrence of pathologic separation of the epiphyses is regarded by the latest writers on surgical pathology and diseases of the bones as a not infrequent accident in diseases of the bones and joints. It is noted in osteomyelitis of the long bones.

Dr. J. E. LINK, of Terre Haute, Ind., read a paper entitled "Colles' Fracture," which will appear in the JOURNAL at an early day.

THIRD DAY—AFTERNOON SESSION.

Dr. J. H. KELLOGG, of Battle Creek, Mich., demonstrated by diagrams and illustrations the deformities of American women resulting from neglect of physical exercise and the conventional mode of dress.

Dr. C. R. HOLMES, of Cincinnati, read a paper entitled "Diseases of the Accessory Nasal Cavities; their influence upon the Organs of Sight; Modern Surgical Treatment with Report of Cases."

Dr. W. C. WEBER, of Cleveland, Ohio, read a paper on

HYDROCELE.

The author first dwelt upon the anatomy of the testis, and then alluded to congenital hydrocele. He said that this form results from an imperfect closure between the cavities of the tunica vaginalis and the peritoneum. It is most frequently met with in children and can be demonstrated by inverting the child or by elevating and compressing the scrotum. During this manipulation the liquid passes into the abdominal cavity where it can be retained by making pressure over the external rim. Considerable care should be exercised in dealing with this form of hydrocele, as it not infrequently happens that a loop of the intestine has also found its way down and is liable to serious injury from pressure. The treatment of the congenital form is usually simple and satisfactory. Having reduced the tumor by the above manipulation, all that is required in most instances is continuous pressure over the external ring for a time when adhesion soon occurs. Other plans of treatment consist in the use of discutients of various kinds, acupuncture and tapping. Acquired hydrocele occurs in children and most frequently in early adult life. Its cause is not always known, though traumatism is probably the most constant factor in its production. Having diagnosed a hydrocele, how shall it be treated? This depends mainly on the size of the tumor and its age. In a hydrocele of small or ordinary size, and the date of its origin recent, an evacuation by means of a small trocar and canula may be all that is necessary to accomplish a cure. Should this fail in its purpose, it becomes necessary to adopt measures whereby sufficient irritation of the tunica vaginalis may be produced to secure inflammatory adhesion of the opposing surfaces. This end is usually attained by the injection of the tincture of iodine, alcohol, carbolic acid, perchlorid of iron and other substances into the sac after the removal of its adventitious contents. Among other methods of treatment may be mentioned excision, incision and the seton. The seton and incision should rarely or never be employed in the opinion of the author. The author then reported a case in which he used carbolic acid, which illustrated very nicely what can be done in the way of radical treatment in apparently extreme cases. The result was very satisfactory.

TREATMENT OF TRAUMATIC CATARACT ATTENDED WITH RAPID SWELLING OF THE LENS.

By Dr. JAMES M. BALL, of St. Louis, Mo. For years the subject of traumatic cataract has been the *bête noir*. Cases of lenticular opacity caused by a foreign body which remains within the eye are always extremely dangerous, owing to the introduction of pathogenic germs on the one hand, and the danger to the sympathetic ganglia on the other. Such cases must always remain the opprobrium of ophthalmology. There are many cases, however, of traumatic cataract attended by rapid increase of intra-ocular tension, with the production of iritis or irido-cyclitis, and ultimate excavation of the optic nerve head in which the foreign body either lodges in the lens or is withdrawn at the time of the accident. It is concerning such cases that the author desires to speak. For many years the practice of the profession has been to rely upon the use of atropia if the symptoms were not severe and to perform linear extraction if the symptoms

be acute. Linear extraction, the author considered a relic of that barbarous surgical age when antisepsis was unknown. Performed for the purpose of relieving undue tension and evacuating the lenticular fragments, the very nature of the operation has been such as to diminish the first only temporarily and defeat the second frequently. The situation of the corneal incision has been such as to preclude the possibility of removing all the fragments of the swollen lens. The oblique course of the wound has rendered its patency impossible while favoring its closure. Furthermore, the incision made by the ordinary keratome is too short.

The proposition the author desired to advance was this: In cases of traumatic cataract with rapid increase of intra-ocular tension, an operation should be performed, and that operation should not be linear extraction, but an extraction made with the Graefe knife, and with the incision located in the corneo-scleral junction. The knife should cut from one-third to two-fifths of the corneal circumference, according to the extent to which the softening process in the lens has advanced. If glaucomatous symptoms supervene with softening of only a small part of the lens, the corneal incision should be large. If the softening involved the whole of the lens, the incision should be of less extent. The extent of the incision in the cornea, as far as healing is concerned, is of little importance provided we make an aseptic operation. The chief merit of the operation lies in the avoidance of the valve which is produced by the linear methods. In other words, the author's method permits of free evacuation of all the lenticular substance with the least amount of traumatism. An iridectomy is not made. All *debris* is removed at once. This can not be accomplished by the linear method. The author then reported two very instructive and interesting cases.

Dr. LEWIS C. CLINE, of Indianapolis, Ind., read a paper entitled

SOME OBSERVATIONS ON SORE THROAT DUE TO CONCRETIONS IN THE TONSILS,

in which he said every experienced practitioner can recall cases of recurring tonsillitis or sore throat that often develop without any apparent cause, but which were doubtless due to chronic inflammation of the follicles, altered and retained concretions. It was to this class that he invited attention. The symptoms of these cases are not as a rule very prominent, and are not confined to cases where the tonsils are much enlarged, but are often found in patients from whom they have been partially removed or have sloughed away by repeated attacks of inflammation or quinsy. The author's remarks dealt more particularly with the cheesy bodies and not the calculi which are probably the outgrowth of the long retained cheesy deposits acting as a nidus for the deposit of the more solid materials, as phosphate and carbonate of lime, iron, soda and potassa, etc. The soft or cheesy deposits vary in size from that of a pin head to a grain of wheat, and consist of epithelium, pus corpuscles, bacteria and chalk. These troublesome concretions are found more frequently in the small tonsil, or where there is scarcely any tonsil to be seen, for the reason that in the larger tonsils there is more pressure brought to bear on them and they are kept squeezed out. These concretions are doubtless the result of a catarrhal condition of the mucous lining of the follicles, coupled often with a uric acid diathesis. Some writers believe them to be parasitic in origin.

These concretions predispose to attacks of quinsy, and in the author's judgment are the cause of the majority of these cases, and they can be permanently cured by carefully hunting out and destroying all the crypts and pockets in which these bodies are formed. The author reported several interesting cases which emphasized the point that he wished to make, viz, that perverted secretion of the follicles of the tonsils from catarrhal inflammation resulting in cheesy concretions, which remain as a smoldering fire ready to be fanned into a flame by the least exposure, is the cause of more sore throats and quinsy in adults than any or all other causes combined.

Dr. CHAS. H. BEARD, of Chicago, read a paper entitled, "Squint with Especial Reference to an Operation."

(To be continued.)

Bequests to Medical Institutions of Philadelphia.—By the will of the late Dr. William Goodell, of Philadelphia, the sum of \$50,000 is donated to the Medical Department of the University of Pennsylvania. The College of Physicians will from the same source fall heir to \$10,000. Dr. Goodell was the eldest son of a veteran missionary to Turkey, and himself practiced medicine for several years at Constantinople.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, DECEMBER 8, 1894.

THE PRESIDENT'S MESSAGE.

PRESIDENT CLEVELAND'S message makes the following recommendation to Congress concerning a Public Health Establishment:

"I am entirely convinced that we ought not to be longer without a National board of health or National health officer charged with no other duties than such as pertain to the protection of our country from the invasion of pestilence and disease. This would involve the establishment, by such board or officer, of proper quarantine precautions or the necessary aid and counsel to local authorities on the subject, prompt advice and assistance to local boards of health or health officers in the suppression of contagious diseases, and in cases where there are no such local boards or officers, the immediate direction by the National board or officer, of measures of suppression, constant and authentic information concerning the health of foreign countries and all parts of our own country, as related to contagious diseases, and consideration of regulations to be enforced in foreign ports to prevent the introduction of contagion into our cities and the measures which should be adopted to secure their enforcement.

"There seems to be at this time a decided inclination to discuss measures of protection against contagious diseases in international conference with a view of adopting means of mutual assistance. The creation of such a National health establishment would greatly aid our standing in such conferences and improve our opportunities to avail ourselves of their benefits. I earnestly recommend the inauguration of a National board of health or similar National instrumentality, believing the same to be a needed precaution against contagious disease and in the interest of the safety and health of our people."

The PRESIDENT thus compliments the Bureau of Animal Industry of the Agricultural Department, and its accomplished chief, Dr. SALMON:

"The scientific inquiries of the Bureau of Animal Industry have progressed steadily during the year. Much tuberculin and mallein have been furnished to State authorities for use in the agricultural colleges and experiment sta-

tions, for the treatment of tuberculosis and glanders. Quite recently this department has published the results of its investigations of bovine tuberculosis, and its researches will be vigorously continued. Certain herds in the District of Columbia will be thoroughly inspected, and will probably supply adequate scope for the department to intelligently prosecute its scientific work and furnish sufficient material for purposes of illustration, description and definition. The sterilization of milk suspected of containing the bacilli of tuberculosis has been, during the year, very thoroughly explained in a leaflet by Dr. D. E. SALMON, the chief of the Bureau, and given general circulation throughout the country."

It is very apparent from the PRESIDENT'S words that he would lose no time in approving an act establishing a Department of Public Health.

A GREAT WORK ON YELLOW FEVER.

We are pleased to announce that this JOURNAL will soon commence the publication as a serial, of the "Original Investigations on the Natural History of Yellow Fever (Symptoms and Pathology) 1854 to 1894," by PROFESSOR JOSEPH JONES, of New Orleans. The work, as a whole, is devoted to the record and elucidation of carefully conducted observations on the temperature, pulse, respiration, black vomit, *post-mortem* temperature and other phenomena of yellow fever.

In 1859 PROFESSOR JONES presented to the AMERICAN MEDICAL ASSOCIATION an elaborate record of similar investigations in regard to malarial fever. The forthcoming series is more elaborate, and it will be apparent to our readers as the articles appear, that the labor involved in their preparation has been incessant for a period of more than forty years, and has rarely been surpassed by any one. Fragmentary extracts of some of these articles have appeared from time to time in various medical journals, but the ASSOCIATION JOURNAL alone will publish the whole investigation, which is a storehouse of information on the subject. The expense of the laboratory and the necessary library has been borne by the author during all these years, and the American medical profession will be the gainer by his self-sacrificing labors.

It may not be improper to mention in this place that PROFESSOR JONES was himself prostrated by the disease during the great epidemic of 1878, and the attack was followed by a malignant carbuncle which left him much prostrated for a considerable period.

In concluding this advance notice we can only say, and we feel that we simply voice the opinion of the whole ASSOCIATION when we say: Honor to our distinguished fellow member, the learned Doctor JOSEPH JONES, of New Orleans.

"THE VIRCHOW-BEHRING FEUD."

If further argument were needed for the immediate creation of a National Diphtheria Commission for the investigation and report on the antitoxin treat-

ment of MM. ROUX and BEHRING, it is to be found in the results of the unfortunate feud between HERR BEHRING and PROFESSOR VIRCHOW. Stung into a wholly unnecessary access of passion by VIRCHOW's conservative and somewhat critical attitude toward the serum treatment, BEHRING made a bitter attack upon the eminent and popular scientist, and, with singularly poor taste and judgment, selected a pronounced political journal as the medium for the publication of his diatribe. VIRCHOW's half century of scientific work needs no defence and his high character is proof against attack; nevertheless, the Berlin Medical Society deemed it incumbent to formally declare that "it is necessary we show that we feel an indestructible thankfulness and veneration for VIRCHOW and behold him with pride at our head." VIRCHOW thanked the Society, expressing the hope that, for such a cause, such expression would never be called forth again, and it was believed the affair was ended.

A cable dispatch of the 3d inst., however, announces that VIRCHOW's assistant, DR. HAUSEMANN has informed the Berlin Society of his intention to contest PROFESSOR BEHRING's claims of the curative and prophylactic properties of the antitoxin—mentioning several cases in which patients had died, although, as alleged, they had received the injections in the prescribed quantities and within the defined period of the attack; he also challenges the accuracy of the published statistics, averring that no cure of proved diphtheria by the serum treatment has yet been substantiated, while, on the other hand, "there seems reason to believe that the serum causes kidney diseases, pains in the joints, fevers and other ailments." Making due allowance for partizanship, it still remains that HAUSEMANN's notification gains significance from his association with PROFESSOR VIRCHOW; that the Professor has probably sanctioned his assistant's action; and that, therefore, the verdict of the profession on the claims of the new treatment—which seemed to be crystallizing into one of unanimous approval—may be seriously delayed.

For the benefit of the medical profession of this country, as well as for the probable benefit to the public, which is now suffering from an unwonted prevalence of diphtheria, this verdict should be arrived at as speedily as may be, and with all the weight and authority that a National Commission of competent investigators can give.

Let there be created a Department of Public Health!

LOCATION OF CONTAGIOUS DISEASE HOSPITALS.

One of the vexed questions in sanitary administration is the one pertaining to the location of hospitals for contagious diseases. The matter has been recently brought to the surface in Washington City in a most unpleasant way.

As is well known, the unfortunate residents of the

Capital City have no voice in the selection of their rulers, the right of suffrage being denied them. The natural consequence is that the District Commissioners pay little or no attention to the wishes of the people, and like the late Mr. Vanderbilt, when any of their acts meets with popular disapproval they snap their fingers and say with much unction: "The public be d—d." One of the handsomest parts of the city, one having one of the finest views about Washington was chosen by the Commissioners as a site for the new contagious disease hospital. Naturally, the property owners in the vicinity, whose real estate is damaged by this action are indignant, and a public mass meeting has been held to denounce the Commissioners' action. The action of the Commissioners is considered all the more irritating and arbitrary, as there are many acres of equally salubrious land on the brow of the hill between the Bladensburgh road and the Almshouse, not near desirable residence property, and far enough away from the other charitable institutions to prevent conveyance of infection to the inmates, and at far lower prices.

Congress is confidently appealed to by the citizens to prevent the consummation of this scheme.

No municipal government has the right to disregard the welfare and property rights of citizens in selecting sites for these necessary institutions, and as all citizens of the United States are directly interested in all that makes the Capital better and more estimable, we desire to express our opinion on this question, as citizens and sanitarians, to the effect that the proposed site should be abandoned and that right speedily.

Let there be created a Department of Public Health!

CORRESPONDENCE.

Letter from Vienna.

VIENNA, NOV. 18, 1894.

To the Editor:—As the Behring remedy for diphtheria is causing a great commotion in medical circles throughout Europe, and probably also in the United States, it may be of interest to inform your readers of the status of the remedy on this side of the Atlantic, in so far as it is possible to get at the facts.

I made daily visits until a few days ago, for three weeks at Professor Koch's barracks in Berlin where Dr. Kossel is conducting the treatment of diphtheria patients with Behring's blood serum, and am happy to be able to say that, in the main, the treatment of his cases has been followed by satisfactory results while the work there has aroused the interest of European physicians. Every day a number of different foreign physicians are to be met there who have come to investigate the progress of the treatment, and its results. Dr. Kossel asserts positively that nearly every case sent to him thus far before the third day of the disease, has recovered, but with each successive day's delay the chances of recovery are greatly diminished. In other words, to get the full benefit of the treatment the "serum" should be injected within the first three days after the invasion of the

disease. The first case he lost was one that came to him on the seventh day and died of a mixed infection, streptococci having invaded the child's blood.

One day on entering the ward we found three children breathing through tracheotomy tubes, aged respectively 2, 4 and 7 years. The Doctor explained that the 2-year-old child was on the point of suffocating when he entered the barracks; the 4-year-old child came to the hospital on the sixth day. His larynx was involved at the time and before the serum had had an opportunity to retard the progress of the disease, stenosis occurred and tracheotomy became necessary. The 7-year-old child was brought in on the third day with a thick membrane in the larynx; his parotid glands were greatly swollen. In this instance, Dr. Kossel conjectured that the disease was of longer duration than was known. All three recovered.

One of my colleagues expressed surprise that tracheotomy was still necessary with this treatment. The explanation given was that in some cases the laryngeal stenosis comes before the remedy has had time to influence the disease, as in the case above mentioned. In other instances the patients were so profoundly poisoned that the membrane continued to form for hours after the serum was injected and during this time stenosis could occur. This made it necessary in a percentage of cases to use the tube.

The percentage of recoveries in the barracks since August, when the blood serum treatment was introduced was 85; before August 1 recoveries were 40 per cent. Out of twenty-five tracheotomies 55 per cent. recovered. He also mentioned that of fourteen tracheotomies in children who came under treatment before the third day, twelve recovered.

Roux, of Paris, states that the mortality rate in the children's hospital there was reduced from 55 to 26 per cent. since the Behring treatment was introduced.

In Vienna, the serum was used in a case of puerperal fever, although Behring claims that the remedy is only to be relied upon to attack the germs of diphtheria. The patient is recovering. How much the serum influenced the disease one can not tell, although her temperature has steadily descended.

The treatment is simple; Koch's syringe is used for the purpose; ten cubic centimeters of the serum are injected below the axilla, where the connective tissue is quite loose. *Asepsis strictly observed.* The temperature in nearly every case begins to descend in from eight to twenty hours. There is no reaction after the injection. No elevation of temperature or discomfort to the patient occurs.

The injection is repeated after twenty-four hours if no improvement is noticed in the patient, and may be repeated daily if necessary. Usually, however, the first injection is followed by decided improvement within twenty-four hours, and in the milder cases one injection is sufficient to stay the progress of the disease. After twenty-four hours the membrane softens and in many cases comes away in shreds. No other medicines are given, except to weak patients who are supplied with an abundance of wine, milk and beef tea. Behring says the serum is a *specific* for the destruction of the diphtheria germ only, and if complications arise in the case as a result of a *mixed* infection his treatment should not be held responsible for it, as diphtheria is a disease peculiarly liable to be accompanied by a mixed infection; other germs finding an infective atrium in the naso-pharynx, larynx and bronchial tubes. Any complications appearing must be treated by the usual methods, but so long as diphtheria germs are discernible the serum is to be used to *destroy* them.

He also wishes to have it understood that the remedy is not a poison like Koch's tuberculin, but an *antitoxin*, being the blood serum of an animal (horse or sheep) that has suc-

cessfully stood inoculation with the diphtheria culture. He claims to have found small "bodies" in the blood serum of such animals which he says are antagonistic to the diphtheria germ. He calls them "Heil Küfer" and claims to have proved his discovery by repeated experiments upon lower animals. As the remedy is considered an antitoxin, many of the most prominent members of the profession in Berlin, Vienna and Paris say that the remedy can not injure the patient and ought to be thoroughly tried in view of the fact that such remarkable statistics have been presented in its favor by thoroughly competent and well-known physicians of Germany and France.

Yours truly,

F. C. SCHAEFER, M.D.

The Discoverer of Anesthesia.

ATHENS, CLARKE CO., GA., NOV. 26, 1894.

To the Editor:—Dr. Ephraim Cutter, in his note to the *Journal* of November 17, says the rotunda of the Capitol contains a statue of Dr. "J. D. Crawford," the discoverer of ether in 1842. This note is replied to by Dr. W. H. Sharp, of Parkersburg, W. Va. Dr. Sharp's note is on the right track. Dr. Crawford W. Long used ether as an anesthetic in 1842 in Jefferson, Jackson Co., Ga., eighteen miles from Athens, to which fact a number of old citizens of Jackson County will testify. It was first used for surgical purposes on a man named Venable, and a member of this same Venable family lived near Jefferson, Ga., for several years previous to 1842.

Both in Jackson and Clarke Counties the young people at parties would call for volunteers to whom ether should be given for the amusement of the crowd present on these occasions. My own mother was present at a number of these entertainments in Clarke County, one of which was at the old Weir place four miles from Athens, on the Monroe road. At this time ether was given to a negro boy, and when full anesthesia was established, the young men who gave the ether became very much frightened, thinking they had killed the negro. In their fright they sent to Athens for a physician, but when he arrived the negro had come to life as they thought, and so expressed it.

Now as to the statue spoken of by Drs. Cutter and Sharp, I have this to say, which I think will explain the matter fully. A few years after the death of Dr. Crawford W. Long, portraits were made of two of Georgia's most distinguished citizens (two portraits of each one); one to be placed in the State Capitol at Atlanta, Ga., the other in the rotunda of the Capitol in Washington, D. C. The name of Dr. Crawford W. Long was presented as one of the number, being the discoverer of ether as an anesthetic in 1842. This claim has been fully established by abundant proof, and some authors give the honor to Dr. Long. In the "American Text-book of Surgery," by Keen and White, Dr. Long is named as the discoverer, and one or two English authors give the credit to Long. In the East the credit has been given to Dr. Morton, who first used his anesthetic in 1844, and to whom a monument has been erected, and a public demonstration held in his honor as the discoverer. Dr. Morton deserves all this as one of the discoverers, but Long having antedated Morton two years, he should at least share this honor, notwithstanding the fact that Morton did make known first his discovery to the world. The medical profession of the world should take up this subject and ask for a monument fund, to be raised by voluntary subscriptions by the physicians of every nation.

The statue to Sims, at the unveiling of which I had the honor of being present, is an honor worthily bestowed. The noble profession of the healing art deserves much praise for this work, and I hope the good work will go on. The

names of McDowell, Long, Gross, Morton and Sims, as well as others, should be placed on statues, that in this way their names and achievements may be perpetuated in the minds of future generations. I will head the subscription list from Athens (and no doubt every physician in Athens and vicinity will follow) in raising a fund to erect a statue to the memory of Long. Respectfully, ISHAM H. GOSS, M.D.

Report of a Case of Extensive Gunshot Wound.

READING, PA., NOV. 1, 1894.

To the Editor:—On Aug. 2, 1894, I was summoned in great haste to see Mr. G. B., who met with a dangerous accident half an hour previous to my arrival at his residence, by a discharge of a full shell, containing No. 8 shot, from a breech-loading shotgun, into his left side. Upon examination, after anesthetization by the assistant physician, I found the whole contents of the shell, containing about two hundred and fifty shot, had entered three and three-fourth inches to the left of mid-sternum between the seventh and eighth ribs, fracturing the ninth, eighth and part of the seventh ribs to minute pieces, tearing and lacerating the pleura, peritoneum and diaphragm; lung and liver protruding, and impregnated with numerous shot.

At first sight the case was thought and expected to be entirely hopeless. However, I was determined to do all that could be done, so I excised a great deal of lacerated marginal tissue. I extracted all the pieces of bone obtainable, with numerous shots, and shreds of clothing from lower left lobe of lung and liver; washed out the peritoneal and pleural cavities with a warm bichlorid of mercury solution, 1 to 2500, but could hardly control capillary oozing until, as a last resort, I applied hydrozone half diluted with water, which admirably controlled all capillary oozing, and at the same time acted as a strong disinfectant.

After a thorough cleaning and removal of lacerated tissue, I brought the edges together and coaptated with silk sutures, after inserting two drainage tubes; one under the lower lobe of the left lung and the other under the liver from which I ascertained there was absolute drainage. The external dressing was composed of iodoform gauze. I prescribed internally brandy, belladonna and quinin and a bland but nutritious diet.

On the third day, I found my patient restless and coughing, with hematemesis and fever. Upon this I removed the dressing and washed out the abdominal and thoracic cavities with hydrozone in solution through the herein mentioned drainage tubes, and reapplied another antiseptic dressing, from which time the case made a remarkable forward progress until about the fifteenth day, when again the patient began to show some internal disturbance that on the eighteenth day proved to be an abscess on a large scale in left lower lobe of lung; this ruptured spontaneously three days later, leading to profuse purulent expectoration (undoubtedly a result of remaining shots and small fragments of bone) breaking down the patient's vitality very much for a time which, however, was soon repaired with quinin and iron, and now the patient is absolutely well.

I merely report this remarkably unusual case to show what can be and often is done to apparently hopeless cases.

Fraternally,

F. H. BROBST, M.D.

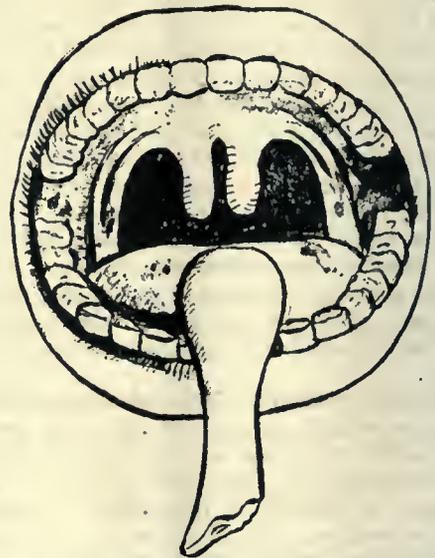

Report of a Case of Bifid, or Double Uvula.

KANSAS CITY, MO., DEC. 3, 1894.

To the Editor:—The patient whom I present is 23 years old, and is a mechanic by occupation. He was born in Ireland, came to the United States three years ago, all of which

time has been spent in Philadelphia, Pa. About four weeks ago he came to Kansas City to enter Park College, the great industrial school at Parkville, Mo., about ten miles from this city. His family history is good, and is of no importance as far as his own case is concerned. He has always been well. None of his relatives have ever had cleft palates, or any trouble with their throats. Several weeks ago he was referred to me by my friend, Dr. Jessie Woodside, of Parkville. He complains of some difficulty of deglutition and articulation. The voice is rather fine, for a man. On attempting to sing he notices a little accumulation in his throat; this is caused by the saliva adhering to the bifid uvulae and sticking them together.

He is a good patient to examine, and has such perfect control of his throat, and opens the mouth so wide, that every one can have a perfect view of this beautiful specimen of double uvula. On looking in his throat, you see two distinct uvulae, side by side, separated all the way to the arch. As you see, there is not the slightest tendency to cleft palate in his case; in other words, his hard palate is perfectly natural. If you will look in his mouth you will see that each uvula is about the normal size. I am under obligations to my friend, Dr. J. C. Steward, who has kindly drawn the perfect sketch of my case which accompanies this article.

The patient insists on having one uvula removed, and I have promised to comply with his wish, thereby hoping to relieve the small amount of difficulty he has in deglutition and articulation. This patient was exhibited to the Kansas City Academy of Medicine Oct. 8, 1894.

HAR FOSTER, A.B., M.D.

“Great Swelling Words.”

CHICAGO, DEC. 3, 1894.

To the Editor:—The man who knows neither Greek or Latin, and at the same time lacks training in English, seems to have a mania for padding out his writings with useless but sonorous phrases of classical derivation. He appears to think that by inflating his language in this way he will make his thoughts more pompous and impressive than if he sets them forth in the crystalline gems of pure English words.

Two of the stilted phrases which have recently gotten into vogue are “etiologic factor” and “etiologic entity,” and they have been rattled about our ears from so many quarters that nobody knows the first sinner who introduced them.

The Greek word, αιτια, means a cause. Αιτιολογια,

from which is derived etiology, is compounded of *αιτια* a cause and *λογος*, which taken in composition signifies a study or science. The whole means the study or science of causes. *Αιτιολογικος*, from which comes etiologic, means a person skilled in the study of causes, and may mean any person or thing pertaining to the science of causation. *Factor* is a Latin word lugged in to mix with the Greek, and signifies a person doing or producing anything. It has also a mathematical use. When two quantities are multiplied together and bring out a product, they are called factors, that is producers. Putting it all together, an "etiologic factor" should be some person or thing producing some other person or thing skilled in, or related to the science of causes; or in other words a causative-science-maker; or a maker of something or of somebody pertaining to the science of causes.

In the name of all the gods of Greece and Rome, what idea are these men trying to express? If they simply mean *cause*, why don't they say *cause*, and be done with it?

As to "etiologic entity," I believe the phrase originated in England and its elucidation may be safely left to the learning and wisdom of our mother country.

Can we not, in some way, induce medical men to reduce their technical terms and classical derivatives to the smallest possible amount and to use the simplest and purest English which will express their meaning? This is the rule among all the best scholars and writers, and only by diligently observing it can medical literature be elevated to its proper dignity.

EDMUND ANDREWS, M.D.

Testimonial to Sir Joseph Lister.

To the Editor:—Sir Joseph Lister having recently retired from active hospital and teaching work, the occasion has been thought appropriate for presenting him with a testimonial of the esteem in which he is held by his former colleagues and pupils, and committees have, therefore, been formed in Glasgow, Edinburgh and London for the purpose of raising the necessary funds.

It is proposed that the testimonial shall take the form of a portrait. Subscriptions have been limited to two guineas, and it is hoped that sufficient funds will be collected to permit of some memento of the occasion being presented to each subscriber of that amount.

As there are probably many surgeons in the United States who may wish to join in the movement, but whose names and exact address it has been difficult to ascertain, I should be glad if you would permit me to state that subscriptions may be sent to me at 29 Weymouth Street, Portland Place, London W. England, or to one or other of the following gentlemen who have kindly consented to act as Treasurers, viz: Dr. James Finlayson, 4 Woodside Place, Glasgow, Scotland; Professor Chiene, 26 Charlotte Square, Edinburgh, Scotland; Prof. William Rose, 17 Harley Street, London, W. England; Dr. Malloch, 124 James Street, South, Hamilton, Ont., or J. Stewart, M.B. 37 South Street, Halifax, Nova Scotia.

I have the honor to remain sir,

Yours faithfully,

J. FREDERICK W. SILK, Honorary Secretary.

P. S. Two guineas are about \$10.23.

Tubercular Abscess of Spine—Incision and Irrigation—Drainage with Iodoform Gauze—Recovery.

MEYERSDALE, PA., NOV. 2, 1894.

To the Editor:—A. M., age 26 years; German-American, applied to me in March, 1894, for relief of rheumatism of the spine and lower extremities. He had been suffering for some years, and at this time was unable to perform any

manual labor. Examination showed carious spine with large lumbar abscess.

March 24. A free lumbar incision was made and the abscess cavity evacuated. The cavity was gently curetted and irrigated with saturated solution of boric acid. It was then injected with a 10 per cent. emulsion of iodoform in sterilized olive oil and packed with iodoform gauze, applying externally the usual antiseptic dressing. The dressing was repeated every third day until July, when the healing was found to be complete. Every effort was made to have and maintain asepsis throughout the entire course of treatment. Some tonics were given to improve the general health which was much depreciated. No anesthetic was used; the patient declining to take any. Since the operation he has gained some twenty pounds in weight and seems entirely well, having been at his work (coal mining) for several months and experiences no inconvenience.

A. C. HARRISON, M.D.

Souvenir of the Mississippi Valley Medical Association.

A CARD FROM MRS. HAY.

HOT SPRINGS, ARK., Nov. 30, 1894.

To the Editor:—On November 23, the wheels and flying sparks took from me the most enthusiastic and charming assembly of people it has ever been my good fortune to know, and after many miles lay between us I received an exquisite token, a circular pin, of richest gold, with a diamond in the center; its rays showed me plainly the brilliancy of the givers. I do not thank them "four or five times," but four or five million times.

Yours appreciatively,

LOTANANNA F. HAY.

The Term Scirrhus.

CHICAGO, ILL., Nov. 29, 1894.

To the Editor:—To settle a dispute, will you kindly inform me of the origin of the term "scirrhus?"

MEDICAL STUDENT.

ANSWER.—The term *σκιρροζ*, from *σκιροζ*, "hard," was first used by Galen to all indurations, but gradually became limited to one form of carcinoma.

ASSOCIATION NEWS.

The Treasurer's Notice.

Many and generous have been the responses to the Treasurer's notification of arrears, but there are many, very many, who forgot to respond. Another notice will, therefore, be mailed this week. The Treasurer would be pleased to present a report to the Association at Baltimore next May, to the effect that every member had paid his annual subscription for the current year. The purchase of the new office plant makes it imperatively necessary that every member who has not already done so, should pay his subscription promptly.

The Baltimore Meeting.—Active preparations for the next annual meeting are being carried forward in Baltimore. Dr. Julian J. Chisolm has been temporarily compelled to rest from his labors on account of illness, and has delegated Dr. Wm. Osler, of Johns Hopkins as acting Chairman. Dr. George H. Rohé is secretary of the committee, and the members may rest assured that the committee's work will be well done. All the signs point to the next meeting as one likely to be the largest ever held in the history of the Association. It is expected that two special trains will be organized west of the Alleghenies.

SOCIETY NEWS.

Trinity Medical Society.—A regular meeting of the Trinity Medical Society of Toronto, Ont., was held November 16.

The New York Society, for the Relief of Widows and Orphans of Medical Men, held its annual meeting November 21. The following officers were elected for the ensuing year: President, Ellsworth Eliot; Vice-Presidents, David Webster, J. H. Emerson, and Charles H. Feale; Treasurer, Henry Tuck. The fund of this Society has been increased nearly \$60,000 during the year.

NECROLOGY.

GEORGE LEONARD BAGLEY, M.D., aged 44 years, died in Des Moines, Iowa, of septicemia caused by a pin prick upon the middle finger of the left hand. He was a member of the Polk County, Capital District, and Iowa State Medical Societies. His death took place in twelve days after the injury.

ALEXANDER F. CARROLL, M.D., of Brooklyn, died November 17, aged 28 years, from anemic coma due to chronic nephritis. He was born in Brooklyn, of Irish parentage, the son of the late Colonel Carroll, formerly County Register and Police Commissioner. He was son-in-law of ex-Register McLaughlin, and was for a time an attache of the Health Department. He was one of the County Hospital staff and a member of the Kings County Medical Society, of the staff of the Columbian Dispensary and of the Conception Nursery. His medical degree was given at the Long Island Medical College in 1888.

H. X. HIXSON, M.D., of Oshkosh, November 23.—C. F. Strecker, M.D., of East St. Louis, who was seriously injured by the overturning of his carriage, died November 26, aged 43.—C. S. Ellis, M.D., of Wabash, Ind.—Charles L. Jones, M.D., of Chicago, November 23.—John B. White, M.D., of Saginaw, Mich., November 21.

PUBLIC HEALTH.

A New Serum.—An Italian physician, Dr. Risso, of Genoa announces that he has discovered a new anti-diphtheritic serum which he claims is much more efficacious than Behring's, whose pupil he was. The successful results of its use are reported by the French journals to be confirmed by the highest Italian authorities.

Cholera in Armenia.—Letters recently received by the American Board of Foreign Missions from its correspondents in Armenia near the scene of the recent atrocities by the Kurds, report that a virulent type of Asiatic cholera has broken out at Moosh, a town in the vicinity of the wholesale slaughter. From twenty-five to thirty-five deaths a day were occurring, death ensuing from five to ten hours after the appearance of the first symptoms and only about 10 per cent. of those attacked recovering. The virulence of the disease is attributed to the effluvia from the bodies of the slain, numbering in the neighborhood of ten thousand.

Conservation of Food by Antiseptics.—M. Nocard, having been commissioned by the Prefect of Police of Paris to investigate the conservation of meats and fish by the use of boric acid, borax, bisulphite of soda, etc., reports that the use of these agents should be proscribed on two grounds—first, their use allows meats to be preserved that have already undergone alterations, possibly not rendering them toxic but modifying their organic elements so as to deprive them of part of their nutritive value; second, the direct action of the conserving agent may modify the nutritive value of the

meat more or less profoundly by causing the formation of organic compounds which do not exist in the fresh state. Furthermore, now that sulphuric acid is made from arsenical pyrites it is not impossible to have the sulphites retain traces of arsenic. For these reasons M. Nocard thinks that borax, boric acid, bisulphite of soda or of potash should not be used in the conservation of alimentary materials of animal origin.

Smallpox.—There is a gratifying paucity of smallpox intelligence. No new centers of importance have been reported since the date of the last issue of the JOURNAL. There were twenty-one new cases and twelve deaths in Milwaukee during the week ended December 3; total cases in the city, ninety; in hospital, thirty-eight, in homes 52. Dr. Wingate, Secretary Wisconsin State Board of Health, says: "Nearly all new cases occur in one section of the city—the south side. Disease not known to exist at present outside of Raymond and Rochester, Racine County, one each, and the city of Milwaukee." In Chicago there were forty-eight deaths from smallpox in the month of November, as against forty in October. On the 3d inst., there were sixty-seven cases remaining in hospital—none in homes. Except the cases at Sandwich, previously reported, and two cases in Aurora, contracted in Sandwich, it is not known that the disease exists elsewhere in Illinois. There is a slight increase in the number of cases in New York, and there have been one or two sensational cases in that city and elsewhere; a member of an English variety company, playing in Harlem, was found to be suffering with the disease and created considerable alarm among the other members of the company on the 1st inst.; a Thanksgiving visitor from New York developed a case of the disease at the house of his host in Paterson, N. J.; another case contracted in New York was taken to the City Hospital in Cincinnati on the 26th—the first it is said, received at that institution in three years; a woman, resident in Dubuque, Iowa, for two months, developed an attack of smallpox on the 24th, and its origin has thus far baffled all investigation.

Diffusion of Diphtheria.—There has been no abatement, but the contrary, of the prevalence of diphtheria during the past week. Estimated on the basis of reports received during September the disease has increased about 50 per cent. during the last sixty days. Public schools continue closed in many localities and isolation hospitals are overcrowded. In Detroit the public and parochial schools, which were closed on November 24 for one week, remain still closed and it has been proposed to convert the new smallpox hospital, just completed, into a hospital for diphtheria; the disease is also reported epidemic at Tyrone and other points in Michigan. In Chicago, while the disease has seriously increased, it has not been found necessary to close the schools; reports of its prevalence among the pupils of one school created considerable alarm and the school was taken charge of by the Health Department, which instituted a domiciliary inspection of the families of all pupils and promptly allayed the excitement by revealing the real extent of the disease. The incident has been utilized for a more thorough notification of cases and the exclusion of scholars from infected families and residences. Elsewhere in Illinois the disease is especially prevalent in the central portion of the State, and schools have been closed in consequence at Earlville, Farina, Lilly, Pontoosuc, Five Points, Brocton and a number of other places. It is also epidemic at several localities in Nebraska, Minnesota, Wisconsin, Indiana, Missouri, Kentucky and Ohio, with the usual results; public funerals of diphtheria victims are rigidly prohibited in Fort Wayne and other precautions against spread are enforced, and schools have been closed in St. Paul and Kansas City. Of the Eastern States the

most numerous reports come from Massachusetts, New York, New Jersey and Pennsylvania. During November there were upward of 100 cases reported at Yonkers, with a mortality of about 40 per cent.; all the public schools, seven in number, were closed on the 25th for an indefinite period, although it was hoped that the disease would be "stamped out" shortly after Thanksgiving. In New York City, in Brooklyn and elsewhere on Long Island the disease is increasing, as well as at Buffalo and points in the interior. The Evelyn Female College, three-quarters of a mile from Princeton College campus, was closed on the 29th ult., and the students sent home on account of a fatal outbreak of diphtheria in the institution; one of two students, kept in quarantine, developed the disease and has since died. There is also an increase in the number of cases in Philadelphia, and schools have been closed for indefinite periods at Doyleston, Exeter, South Williamsport and elsewhere in Pennsylvania. Other isolated reports from points in Canada, Oregon, Louisiana, Texas, Tennessee and West Virginia, indicate the pandemic extension of the disease.

BOOK NOTICES.

Transactions of the Colorado State Medical Society. Twenty-fourth annual convention, Denver, June, 1894. Pp. 486. Cloth.

This is a handsomely printed, well-edited volume, containing the proceedings, papers and discussions of the last meeting of the Society. Many of them have been printed elsewhere, and they are all of general interest, with the exception, perhaps, of the address of the President, which is devoted to matters concerning Colorado. The Transactions as a whole, reflect worthily the high state of professional culture which Colorado has attained.

The Medical News Visiting List for 1895. Weekly (dated, for 30 patients); Monthly (undated, for 126 patients per month); Perpetual (undated, for 30 patients weekly per year); and Perpetual (undated, for 60 patients weekly per year). The first three styles contain 32 pages of data and 160 pages of blanks. The 60-Patient Perpetual consists of 256 pages of blanks. Each style in one wallet-shaped book, with pocket, pencil and rubber. Seal grain leather, \$1.25. Philadelphia: Lea Brothers & Co. 1894.

The Medical News Visiting List for 1895 has been thoroughly revised and brought up to date in every respect. The text portion (thirty-two pages) contains useful data for the physician and surgeon, including an alphabetical Table of Diseases, with the most approved Remedies, and a Table of Doses in both decimal and old systems. It also contains sections on Examination of Urine, Artificial Respiration, Incompatibles, Poisons and Antidotes, Diagnostic Table of Eruptive Fevers, and the Ligation of Arteries. The classified blanks (160 pages) are arranged to hold records of all kinds of professional work, with memoranda and accounts. A thumb letter index is furnished when required. In its several styles the Medical News Visiting List adapts itself to any system of keeping professional accounts.

A Monograph of Diseases of the Breast, Their Pathology and Treatment with Special Reference to Cancer. By W. ROGER WILLIAMS, F.R.C.S. With 76 figures. Cl., 8vo., pp. 571. Price £1.10. London: John Bale & Sons. 1894.

One naturally places this book with those of Sir Astley Cooper and Velpeau, both written a little more than a half century ago, and yet in certain respects they have had no successors. The anatomy of the breast as presented in the magnificent plates of Cooper, representing prepared specimens, are unrivalled to-day, and the immense clinical material at the disposition of Velpeau makes his work still a storehouse of information on the subject. Where the modern work excels is in the histology and in therapeutic statis-

tics, which are based on modern science. The book under consideration is well written and exhaustive. We may not accept the author's view of the origin of cancer, but we may commend his patient research, and the eminently satisfactory character of the work done. One of the most interesting chapters in the work is one that was unknown to the older works, namely, the geographical distribution and topography. Full credit is given Billings and other American statisticians for their labors in this direction. Taken all together it is an extremely valuable addition to the literature of the subject.

The Principles of Surgery and Surgical Pathology. General Rules Governing Operations and the Application of Dressings. By DR. HERMAN TILLMANS. Translated from the third German edition by JOHN ROGEEAS, M.D., and BENJAMIN TILTON, M.D. Edited by Lewis A. Stimson, M.D. With 441 illustrations. Cl., 8vo., pp. 800. New York: D. Appleton & Co. 1894.

As a text-book for students we have nothing but words of praise for this book. It represents the very latest teaching on the principles of surgery and surgical pathology. The fact is now recognized in all medical schools that the surgeon can never be successful, can never take high rank among his fellows unless his practice is built upon the sure foundation of pathology, and in works on surgery, regional or particular surgery grows smaller in bulk. From year to year, yes, from day to day almost, there are changes and alterations made necessary by the advances in medical science, more particularly in bacteriology and chemistry. To keep pace with these changes in surgical pathology we are compelled, although regretfully, to lay aside the favorites, sometimes in the lifetime of the author. Paget and Billroth follow one another in the annual procession to the top shelf in the library; and the text-books of yesterday will soon follow. Our present interest is with those of to-day. The book is divided into three sections. The first, on General Principles Governing Surgical Operations, contains ten chapters; the second, The Methods of Applying Surgical Dressings, contains five chapters; and the third, on Surgical Pathology and Therapy, contains five chapters; these are: I, Inflammation and Injuries, with an appendix on Chronic Mycoses: Tuberculosis, Syphilis, Leprosy, Actinomycosis. II, Injuries and Surgical Diseases of the Soft Parts. III, Injuries and Diseases of Bones. IV, Injuries and Diseases of Joints, with an appendix on Gunshot Injuries. V, Tumors. We can not too highly commend this volume to our surgical readers.

MISCELLANY.

Intra-Uterine Injections by the Ancients.—Dr. Koromilas, a Greek physician, thinks it is evident from their writings that Hippocrates, Oribasius, Paulus Aegineta and Galen knew of the use of intra-uterine injections. Hippocrates divided the female genital organs into three parts: 1, the external organs; 2, the genital canal or vagina; 3, the uterus; and had a separate remedy to inject into each—wine and honey for the external parts, "goose grease" for the vagina, and wine and oil for the uterus. Dr. Koromilas believes that Hippocrates was the first to make intra-uterine injections.

M. Bertillon Outdone.—The various means used by the police in their hunt for criminals appears to be distanced by that employed lately in Germany to capture a fugitive spouse. The wife of a rich manufacturer at Essen abandoned the conjugal roof and it was discovered had taken a train for Pecs, in Hungary; whereupon the husband telegraphed to the chief of police of that town as follows: "Arrest a woman who will be found on the train at Pecs. Description: Weight, 83 kilogrammes—exact." Upon repair-

ing to the train with this "exact description" the chief was somewhat disconcerted at discovering that all the women on the train were rather portly. However, he had them all weighed in the baggage room and only one weighed 83 kilogrammes exactly. This proved to be the fugitive, and the *Journal de Médecine de Paris* adds that this shows the importance of knowing the exact weight of one's wife—especially if she be somewhat "flighty."

Another New Antiseptic—It is said in recent therapeutic reports that the salicylate of cadmium has a more energetic action than other salts of this metal. It gives good results in the treatment of purulent ophthalmia, in vascular engorgement of the cornea, as an astringent in mucous discharges, against syphilides, etc. Chemically pure salicylate of cadmium is a white salt, occurring in splendid tabular crystals with plane faces and rounded sides. It has a sweetish taste at first, then styptic. It melts above 300 degrees, dissolves in 24 parts of water at 100 degrees, in 68 parts at 23 degrees, and in 90 parts at zero. It is soluble in alcohol and ether, more readily in warm; very soluble in hot glycerin, but is insoluble in chloroform and benzin. The salt has the formula $(C_6H_5O_2HCOO)_2Cd$, and has 24 parts per 100 of metallic cadmium. It may be prepared either by acting on hydrated oxid or carbonate of cadmium with salicylic acid, or by precipitating salicylate of barium with sulphate of cadmium; the latter method is more complicated and the product is not so pure.

Thyroid Intoxication.—A French physician, Dr. Beclère, writing on myxœdema in the *Gazette Médicale de Paris*, makes use of the above term to express the sum of the symptoms that follow an overdose of thyroid gland. He reports a case that was successfully treated by sheep's thyroids, in the course of which there was an accidental excessive dose, followed by quite an array of symptoms. The patient was a female, 31 years old. The overdose consisted in the ingestion of three ounces of the thyroid gland in eleven days. The English authors have reported such symptoms as tachycardia, variable pulse, insomnia, agitation, pyrexia, polyuria, glycosuria, albuminuria, the sensation of heat and sweating. The present writer adds an increased frequency of respiration, transitory tremblings of the arms, exophthalmia and a staring expression of the eyes. Hysterical symptoms were also observed in this patient, such as aphasia, monoplegia and anesthesia of the right upper extremity, although the woman had not theretofore exhibited any neuropathic symptoms, and Dr. Beclère suggests that an excessive secretion of the thyroid juice may be one of the exciting causes of hysteria. He believed it would be found that thyroidism, when occurring in hysterical subjects, will arouse hysterical seizures in them, just as other intoxications would. Dr. Beclère thinks that the intercurrent of exophthalmic goitre points to a hypersecretion by the thyroid gland and that the juice acted, like other intoxications, as an exciting cause of hysterical outbreaks.

Abandonment of Fort Marcy, N. M.—This post, situated within the city limits of Santa Fé, has been garrisoned since the occupation of the Territory by the United States; but for many years the troops were kept constantly employed in carrying on active operations against hostile Indians so that the garrison was rather in the field than stationed at a military post. The elevation of Fort Marcy was 7,000 feet above the sea level. Foothills rising abruptly in the vicinity of the post lead up to a succession of mountain ranges in the east and northeast, the highest of which, seventeen miles distant, attains a height of nearly 13,000 feet. To the south and west is a plain, twenty miles in extent, broken only by a few small hills and arroyos until the mountains bor-

dering the Rio Grande are encountered. This plain is susceptible of high cultivation if water is supplied by the natural rainfall or by irrigation. The climate is mild and equable on the whole, although when the direct rays of the sun are withdrawn the lowering of the temperature, as in all mountain regions, is abrupt; and in winter cold winds sweeping down from the snow-covered mountains sometimes gives a thermometric fall of 15 or 30 degrees F. in a few hours. Notwithstanding this, the place has been much lauded as a sanitarium for incipient cases of pulmonary consumption. The post participated in the excellent water supply of the city. A reservoir holding 250,000,000 gallons was built three miles above the city on the line of a mountain stream. The water is delivered by iron service pipes under a pressure of 187 pounds per square inch. A government reservation for National park purposes includes the head waters and course of the stream to within a distance of four miles from the reservoir. No settlement is permitted on these grounds; and as the interval between the reservation and the reservoir is a narrow valley, it can easily be watched and protected by the Water Company so as to prevent any contamination of the supply. The barrack buildings were thick-walled one-story adobe houses, with good roofs, ventilated by skylights and ventilating openings near the eaves. The quarters of the officers were commodious and comfortable. Bathing facilities were ample and complete. Waste water from bathrooms and kitchens was conveyed by open ditches to a sandy arroyo where it was absorbed or dissipated. In some instances old wells were used as cesspools for waste water. Earth closets were used in the absence of water carriage for the removal of excreta. The general health of the garrison was good. The only diseases which could be said to be prevalent were bronchial and rheumatic affections.

Necropsy of the Czar.—Following is the official statement relative to the cause of death of Alexander III. of Russia, made by the court physicians, as well as the protocol of the autopsy:

Diagnosis: Chronic interstitial nephritis followed by cardiac and vascular lesions; hemorrhagic infarct of the left lung, followed by pneumonia.

(Signed) PROFESSOR LEYDEN, PROFESSOR ZAKHARIN, PROFESSOR POPOV, DR. HIRSCH, DR. VELIAMONOW, Honorary Court Physicians.

Livadia, Oct. 21 (Nov. 2) 1894.

Autopsy: In the year 1894, the 22d of October (3d of November), we the undersigned, proceeding to embalm the body of the deceased Emperor, Alexander Alexandrovitch, have found the following alterations: Considerable edema of the sub-cutaneous tissues of the legs and reddish spots on the left knee. The left pleural cavity contained 200 cubic centimeters of reddish serous fluid; in the right side there were 50 cubic centimeters of the same fluid. The apex of the right lung showed an old fibrous cicatrix; the right lung is edematous. The upper lobe of the left lung is slightly edematous and there is an hemorrhagic infarct in the lower lobe filled with blood and containing very little air. The infarct was found in the upper border of the lower lobe of the left lung and presented a triangular area on section—one and one-half by one centimeters. The pericardium contained thirty cubic centimeters of reddish serous fluid.

The volume of the heart is considerably increased. The vertical diameter is seventeen centimeters, the horizontal eighteen. The subserous tissue contains a great quantity of fat. The heart was found in a state of slight diastole. The left cavity is enlarged and the wall of the left ventricle thickened (two and five-tenths centimeters). The muscle in this ventricle is pale and flabby and of a yellowish color. In the right ventricle the muscular wall is thinned (six millimeters) and of the same yellowish hue. The valvular apparatus is perfectly healthy.

The abdominal cavity contained about 200 cubic centimeters of serous fluid. The stomach and intestines were filled with a large quantity of gas. The liver is somewhat increased in volume and this organ is very plethoric. The kidneys have the following dimensions: The left is sixteen centimeters long, seven centimeters wide and four thick; the right, fifteen centimeters long, six and five-tenths centimeters wide and four centimeters thick. The capsule of the kidney peels easily and is of normal thickness. The surface of the kidneys is slightly granular and of a deep red color; the hardness is insignificant. The cortex is lessened (from six to seven millimeters) and of a yellowish color—the medulla of a deep red;

in the left kidney was a serous cyst, three millimeters in diameter.

In virtue of the preceding we are of opinion that H. M., Alexander Alexandrovitch, succumbed to a cardiac paralysis, preceded by a degeneration of the hypertrophied cardiac muscle, and to an interstitial nephritis (granular atrophy of the kidneys).

(Signed) PROF. J. F. KLEIN, D. N. ZERNOW, PROF. M. A. POPOW, DR. N. VALTONKHOW, DR. N. C. BELOUSSOW.
Livadia, Oct. 22 (3d Nov.) 1894.

Proper Care of the Eyes.—Dubuque physicians have issued the following statement to the public: In view of the fact that the advice of the family physician is frequently sought on the subject of the proper care of the eyes, it seems proper and opportune to call attention to the following points:

1. Glasses for the correction of visual defects are demanded for a variety of reasons, some of which pertain to the ordinary changes in the refractive media incident to advancing age or otherwise, and some of which are due to true disease of the eye which from the nature of the case are far more serious, requiring for their proper treatment the services of one properly equipped in that department.

2. We believe that the one intrusted with the care of so important an organ as the eye should understand not only the mechanical methods of adapting glasses to the common refractive errors, but also the far more important and intricate diseased conditions, for the proper appreciation of which a knowledge of anatomy and physiology and the principles of medicine are absolutely essential.

3. We have, as residents of our city, men who in our opinion are exceptionally well fitted not only to recognize and correct the ordinary refractive errors, but also to diagnose and treat properly diseases of the eye.

We think it due to the public not less than to these gentlemen to bear this testimony.

Experiments with Mosquitoes in Mississippi.—Mr. Howard Weed, of the Agricultural College, Mississippi, has had some success in the abatement of mosquitoes by the free use of kerosene upon tanks of water and in other positions which he mentions. His observations are published in the last issue of *Insect Life*. He begins by saying that the use of kerosene, for this purpose, has been known for many years in the French quarter of New Orleans. The citizens of that section have found that the addition of kerosene to their water tanks has materially reduced the pest of insects, but much has been written showing that such is the case, and in this age of advancement we can no longer go by hearsay evidence. Everything must be founded upon known facts, and these facts can only be ascertained by experiment. On the college campus are eleven large water tanks, two of which are used for drinking water and the others for irrigation and fire protection. Not far from the limits of the campus are also four pools of standing water, three of which are used for watering stock and the other for irrigation in the horticultural department. These pools, however, are well stocked with fish, and the larvæ of the mosquito are never found there. "Before the water tanks were built, the college campus had been quite free from mosquitoes, but the evil has been constantly upon the increase, reaching its climax early the present season. I have often advised that a small amount of kerosene be placed in each of the water tanks, and the college proctor several times informed me that he 'had a nigger put kerosene in the tanks every week, but it did no good.' The college physician also stated that he had placed some kerosene in a jar of water containing some of the wiggletails, but that the kerosene had not killed them, thus regarding the remedy recommended as ineffective.

"By June 20 of the present year, mosquitoes had become

so numerous on the college campus as to make life a burden, and sleeping without a mosquito bar was out of the question. Wishing to demonstrate the effectiveness of the remedy which I had recommended, I took a large glass jar and filled it nearly full with water from one of the tanks, which was fairly alive with the mosquito larvæ. The jar contained several hundred of the larvæ and I took it to the college physician, poured a little kerosene into the jar, and asked him to please watch the effect. This was as expected, for within fifteen minutes all the larvæ were dead." Some of the tanks for fire purposes were in dark attics and relatively free from larvæ. Four tanks had them in large numbers. Mr. Weed treated these with a gallon of kerosene, and ten days later the mosquitoes were nearly all gone from the campus and the collegians were able to dispense with the mosquito nets. Three weeks later some of the tanks were again dosed. Upon all the outdoor tanks a thin film of kerosene has remained since the kerosene was put in. The campus is now nearly free from mosquitoes and has been so since ten days after the kerosene treatment. Hereafter during the summer, kerosene will be put in the outdoor tanks, putting in enough to keep a thin film over the top of the water.

Mr. Weed recommends the use of kerosene to moderate the irritations that afflict a mosquito-burdened locality. "I have also found that kerosene is a good article to use to prevent mosquitoes from annoying one when they are numerous. To use it for this purpose a little is smeared upon the back of the hands and also upon the face. At first thought this would seem to be a disagreeable operation, but a trial of it will prove that it is not disagreeable in the least. It is quite effective in keeping the mosquitoes away and is much better than the Florida method, which I have been told is to remain secreted under a large iron kettle and with a hammer clinch the bills of the mosquitoes as they are thrust through the kettle."

Prerogatives of Boards of Examiners.—Cases are constantly arising, in one part of the United States or another, where some holder of a diploma and a State Board come into conflict. The latest decision of this nature, where there has been an authoritative adjudication of the points at issue, is to be found in Tennessee. The holder of a diploma from a certain college for the practice of dentistry, presented same to the State Board of Dental Examiners, asking them to file and register it, and to issue to him a certificate to practice dentistry in that State. This the Board refused to do. Thereupon he sought, by the legal writ of mandamus, to compel the Board to issue to him the desired certificate or license.

The board answered that it was not a reputable college of dentistry which issued the diploma, giving a sufficient course of instruction; that the board was not compelled by law to recognize its diplomas; and that, in the discharge of its duties for the protection of the public, it could not be controlled and coerced in the exercise of its discretion. It appeared from the record that the board had determined to only recognize as "reputable" such schools of dentistry as belonged to the National Association of Dental College Faculties, whose rules it has adopted, and by whose recommendations it was to a great degree governed. The Tennessee statutes prohibit the practice of dentistry, except by persons holding diplomas from reputable dental colleges, the validity of which diplomas the State Board of Dental Examiners is authorized to decide upon. When no diploma is presented, the Board is to make an examination; and this it offered to do in this case. Much was said here as to the scope and meaning of the word "validity" as applied to a diploma, whether it meant simply its genuineness, or in addition, its force and effect as emanating from a reputable college.

Coming now to the decision, the Supreme Court of Tennessee holds, under date of Sept. 13, 1894 (State v. State Board of Dental Examiners), that it is evident from the purpose and tenor of the Act that it was intended that an applicant, having his claim upon a diploma from a dental college, and relying upon that, and declining to pass an examination, must have a diploma from a reputable college, and the Board of Examiners provided for must have power and discretion to determine in cases of applicants with diplomas, whether they come within the provisions of the law, and whether the diplomas tendered by them as the basis of their application emanate from a reputable dental college. The

power to determine this could not be lodged in a more appropriate tribunal, composed, it must be presumed, of men learned and trained in their profession, and competent to pass upon, not only the qualifications of applicants, but also the reputation of schools within the State, engaged in dental education. In performing their duties, the Board is exercising a quasi-judicial function; and, so long as it does not act arbitrarily and illegally, its determinations can not be coerced by the courts through writs of mandamus so far as they involve the exercise of this judicial discretion.

In harmony with this, the court further specifically holds that, the board having, by rules which seemed to it to be altogether proper, fixed a standard by which to determine the standing of dental colleges, and, in so doing, having been guided by the opinions and rules of a National Association, composed of eminent dental men, selected in different States with a view to promoting uniformity of decision and advancing of the profession; and having by these rules tested the diploma presented to them, and determined that it did not emanate from a dental college which at the date of its issuance had brought itself up to the standard, although it might have subsequently done so, the board's finding was warranted by law, and conclusive on the facts. The adoption of the rules of the National Association was in no sense a surrender of the board's power or discretion, but, on the contrary, so far as the court could see, an effort to conform to a system recognized over the United States as conducive to the advancement of the dental science, and promoting the best interests of the profession.

Assistant Medical Inspectors.—The fifteen assistant medical inspectors of Philadelphia have presented the following petition to the city council asking for an increase of salary:

To the Select and Common Councils of the city of Philadelphia—*Gentlemen:* We have the honor to submit for your consideration the following petition:

The Assistant Medical Inspectors are doing their work conscientiously and thoroughly. For more than two years they have labored assiduously for the restriction of contagious diseases in all its details.

The population of the city is great, constantly increasing and spread over a wide expanse of territory.

The Assistant Medical Inspectors have no complaints to make of hard work; neither do they desire any remission or diminution of their labors, however arduous they may be; but take much pleasure in the thought that in the performance of their duties many valuable lives are saved to the citizens of this city.

There are several considerations that the Assistant Medical Inspectors desire to submit to the Councils in support of their request for increased compensation.

1. The nature of the work is such that the Assistant Medical Inspectors are required to be continuously on duty, day and night, Sunday and holidays not even excepted.

2. The list of contagious diseases is increasing, notably consumption has lately been added to the list, and doubtless others will be added in the near future.

3. The small opportunities for private practice must necessarily be sacrificed to their public work.

4. The Assistant Medical Inspectors are required, and stand ready at any time to devote their entire time to the public service, when called upon to do so, as in case of epidemics.

5. The work is so widespread that the expense of transportation from one locality to another requires a very considerable daily outlay of money.

6. There is considerable personal danger to themselves and their families, which justly calls for greater compensation than many other employments.

7. The professional training of the Assistant Medical Inspectors, their medical education and large experience make their work that of experts in sanitation, and yet the compensation of \$3.29 per day is not so great as that paid in mechanical pursuits.

8. The public duties of the Assistant Medical Inspectors cut down and curtail their private practice, for the reason that the public will not knowingly employ physicians whose principal business is with contagious diseases. Practical experience has demonstrated that it is only a matter of a short time before they cease to be regarded by the public as practicing physicians but simply as officials of the Bureau of Health.

9. It is an unquestioned fact that the work of our department has largely decreased the number of contagious diseases in our city. At the present time, in view of the prevalence of smallpox and diphtheria in our city, we are war-

ranted in saying that were it not for the vigilance of the Assistant Medical Inspectors a serious and widespread epidemic would have occurred.

10. The Committee of Fire and Health, recognizing the justice of our claims and the value of our services to the city of Philadelphia, have unanimously recommended an increase in our salary.

Under these circumstances we respectfully request of your honorable bodies that in our efforts as conservators of the public health we be granted an increase in salary commensurate with the character of our work. Very respectfully your obedient servants,

THE ASSISTANT MEDICAL INSPECTORS.

Hospital Notes.

BOARD OF MANAGERS, M. E. HOSPITAL.—The annual dinner of the Board of Managers of the Methodist Episcopal Hospital of Brooklyn, took place November 22. Dr. James M. Buckley presided. The toasts and those who responded were as follows: "Ecclesiastic Fellowship," the Rev. H. C. Farrar; "Brooklyn Journalism," Murat Halsted; "Hospital Experiences," the Rev. J. S. Breckinridge; "Relation of Medicine to Law," G. G. Reynolds; "The Medical Faculty," W. N. Belcher, M.D.; "The Internes," A. D. Bogart; "The ex-Internes," W. X. Campbell.

WOMEN'S HOSPITAL OF NEW YORK.—The annual report of the Women's Hospital of New York, shows the total number of patients treated in the in-door department was 302, of which 262 were free patients. The total number receiving treatment in the out-door department was 5,096; consultations held in the out-door department numbers 10,304.

RESPECTFULLY REFERRED TO THE BOARD OF ASSESSORS.—The Youngstown, Ohio, *Indicator* of November 20 says that the Mahoning County Medical Society have petitioned the County Health Commissioner for a supply of "antitaxin."

THE EPISCOPAL HOSPITAL OF PHILADELPHIA.—The Ingersoll Building of this institution was dedicated November 26. The new building contains the ward intended for the reception and first care of surgical cases. The building is located to the right of the main edifice at the corner of Front Street and Lehigh Avenue; is 55x155 feet, and is three stories high with a basèment and sub-basement. It is made fireproof by all the foundations and division walls being of brick and laid in cement. The walls are of hard brick, with Trenton brown stone trimmings, the whole building costing about \$90,000. The basement is intended for a surgery dispensary. It connects with the main building by an underground vaulted passage. The diet kitchen for the use of the first floor is in the basement. On the left of the entrance hall on the first floor is the men's ward. On the right of the hall a wide corridor connects with the operating-room. On the second floor is a ward for the treatment of patients suffering from burns, a woman's ward and a diet kitchen. The third floor is fitted up in a similar manner with wards for patients, sleeping-rooms for nurses, etc. The new building is complete in every respect for the purposes intended, and will be a great aid to the proper care of accident cases at that institution.

CLEVELAND STATE HOSPITAL.—The annual report of the Superintendent of the Cleveland State Hospital shows the total number of patients under treatment during the year 1,199. At the beginning of the year there were 863 patients in the hospital, 436 males and 427 females, and 176 of the former sex and 160 of the latter were admitted. The average number under treatment was 929; discharged during the year, 263, 131 being males and 132 females. The recoveries were 122. Forty were discharged improved, eighteen unimproved, and eighty-two died. The percentage of recoveries of the number admitted was 36.3.

Louisville Notes.

BOARD OF PUBLIC SAFETY.—The first report of this Board which has been acting under the new city charter for the past year, has been submitted. In it are included a few points of medical interest. It states that the much needed

ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.
NEW ORLEANS, LA.

Yellow fever (vomito; vomito prieto; vomito negro, fièvre matelotte; febris flava; fièvre jaune; gelbes fieber; febbre grilla; febris icterodes; typhus icterodes; typhus tropicus; typhus d'Amérique; fiebre amarilla; coap de banc; febris maligna biliosa Americana flava; bulam fever; hemogastric pestilence; pestilentia hemogastrica; synochus icterodes; causus; febris flava Americanorum, epanetus malignus flavus; typhus jaune; ichwaites erbrechen westendisches fieber; fiebre yialla; black vomit; malignant yellow fever; pestilential fever; epidemic yellow fever; specific yellow fever.)

DEFINITION.

A pestilential fever, of a continuous and specific type, originally developed in tropical and insular America; confined to definite geographical limits, and dependent in its origin and spread upon definite degrees of temperature, and capable of transportation and propagation on ships and in towns and cities in those portions of North and South America which lie between 45° N. latitude and 35° S. latitude. The disease has been limited chiefly to the coast of tropical America, rather from the number and position of the commercial centers, than from any climatic causes adverse to its propagation elsewhere. It has been imported chiefly from the Antilles, and from the cities of tropical America by ships into the Gulf and Atlantic cities of the United States, and into Cadiz, Carthagena, Barcelona, Gibraltar, Lisbon, Saint Nazain in the department of the lower Loire, and into Plymouth and Southampton in Europe; and it has been imported and become epidemic as far south as Montevideo and Buenos Ayres in South America. As a general rule, it has originated and become endemic in cities situated in low, unhealthy malarious districts on the sea or river coasts of insular and tropical America, and has rarely occurred at an elevation of 2,500 feet above the level of the sea; in Jamaica it has prevailed at Stoney Hill, 1,300 feet above the sea, and at Newcastle 4,000 feet above the sea; according to Alexander Humboldt, it has never ascended in Mexico to 3,044 feet above the level of the sea, below which limit the Mexican oaks do not flourish, showing that the constant average temperature below this is of a tropical character.

In the United States the disease has never in its epidemic form reached an elevation of 500 feet, and it has been observed that its epidemic course or limit coincides to a certain extent with the range of the growth of the live-oak, the cypress and the long moss. The inhabitants of the barren rock of Gibraltar, at an elevation of between 1,400 and 1,439 feet above the

level of the sea, have been desolated by this disease upon more than one occasion. It is certain that yellow fever has prevailed in the celebrated table land of Caracas, 3,000 feet above the level of the sea. In the remarkable epidemic of yellow fever which prevailed in Peru in 1855 and 1856, the disease passed over the barrier of the Andes, committing fearful ravages in Andine and trans-Andine regions, at elevations of 14,000 feet above the level of the sea. The stereotyped expressions of systematic writers, as to the limitation of yellow fever to certain elevations and to the sea and river coasts must in the light of the preceding facts be abandoned.

Yellow fever presents two well defined stages; the first characterized by severe pains in the head, confined chiefly to the orbits and forehead, back and lower extremities, a peculiar shining or drunken appearance in the eyes, rapid circulation, elevated temperature, and increase of those constituents as urea, uric acid, phosphoric acid and sulphuric acid which result from the increased chemic changes induced by the febrile poisons; and which stage may extend from 36 to 150 hours, without any distinct remissions, according to the severity of the disease; the second characterized by depression of the nervous and muscular forces, and of the general and capillary circulation, capillary congestion, slow and intermittent pulse, jaundice, a purplish and yellowish mottled appearance of the surface, urinary suppression, albuminous urine loaded with granular casts of the urinary tubes, fatty degeneration of the heart, liver and kidneys, defibrination of the blood, passive hemorrhages from ears, stomach and bowels, nares, tongue, gums, uterus, vagina, gall bladder and anus, and in extreme cases from the eyes, ears and skin, black vomit, interstitial hemorrhages, delirium, convulsions and coma. In its origin and propagation, it appears not to be dependent on those conditions and causes, which generate malarial paroxysmal fever, from which it differs essentially in symptoms and pathology.

One of the prominent symptoms of the first stage is that rapid increase of the pulse, within the first few hours of the febrile excitement, and the progressive diminution of the beats of the heart, even while the temperature progressively rises; and in like manner, the slow and feeble action of the heart constitutes a prominent and striking symptom of the second stage. Yellow fever, in common with such contagious diseases as smallpox, measles and scarlet fever occurs as a general rule, but once during life, and may be propagated by contagion; it differs, however, from the exanthematous diseases, in that it has never been known to propagate beyond 48° N., and 38° S. latitude, nor below a temperature of 65 degrees F. The symptoms of yellow fever may be divided for description and investigation into:

1. Those manifested during the period of incuba-

tion, or that period of time which elapses between the introduction of the poison inducing the disease and the actual manifestation of the febrile phenomena. As this stage is of uncertain duration, the disease sparing neither age nor sex, those only being exempt from its influence who have, at some former time, been subjected to the action of the yellow fever poison, and its attacks being confined neither to the night or the day, nor to any special state of the system, whether of fasting or repletion, of plethora or anemia, of robust health or chronic disease; and as the disease often attacks suddenly those who are apparently in perfect health, who are seized with intense headache, chill, shivering pain in the limbs and back, followed by rapid elevation of temperature, increased action of the circulation, animated congested countenance, red, glistening suffused eyes, intense thirst, anorexia, uneasiness of the epigastrium, nausea and vomiting; the investigation of the phenomena of the stage of incubation is attended with great difficulty and much uncertainty.

While it must be admitted, that during the time which elapses from the moment of the effective action of the cause, to that of the manifestation of the disease, changes are produced in the blood and nervous system and which, although producing no recognized obstacle to the healthy performance of the functions, are not the less real, and increase up to the moment of the final explosion of the disease; but as to the nature of these changes in the system, we know nothing, and the subject is open for investigation. The difficulty of such an inquiry is clearly recognized, when we consider the want of knowledge of the nature of malaria, of the constituents of emanations from the soil, and of other imputed sources of pestilential diseases; the mist of ignorance and prejudice involving these agents, and exaggerating their influence, and their inferred nature and operation, without further proof of their existence than certain effects which have been imputed to them either upon insufficient data, or even without the smallest evidence.

A sure foundation for the investigation will be reached, when the yellow fever poison is isolated; either from the soil, waters, or atmosphere, or from the diseased human body. Our knowledge has not and will not be advanced by hypothetical discussions as to the mineral, vegetable or animal origin and nature of the yellow fever poison; and the time wasted in such arguments would be much better employed by careful physical, chemic, microscopic and physiologic investigation of the waters, atmosphere and soil and of the minute flora and fauna of those regions and places in which the disease is endemic and epidemic.

2. The symptoms manifested during the exhibition of the first disturbances in the nervous and circulatory systems are characterized by chilly sensations, and changes of temperature, and severe pains in the head and loins, restlessness, mental depression and anorexia. The symptoms of this stage, which may be called that of chill or primary depression, are not uniform; in some cases, and even in those of the greatest violence, chill and chilly sensations are entirely absent; in others, the chill amounts only to a sensation of coldness, sometimes slight; at others, deep, penetrating and stupefying, or alternating with flushes of heat and crawling sensations; while in others, the febrile excitement is preceded by chills of

greater or less severity and duration, with a constriction or contraction of the extreme peripheral vessels and a shriveled appearance of the skin; in some cases again, the disease is ushered in by giddiness bearing some analogy to that produced by inebriating liquors; and in others it has been known to have commenced with convulsions.

The presence or absence of chills and chilly sensations can not, therefore, be regarded as characteristic of yellow fever; and the chills, when most strongly marked, appear to differ materially from the chill of paroxysmal malarial fever, in that there is an absence of uniformity in the phenomena, and that the chill or cold stage of yellow fever partakes rather of the aberrated nervous actions and sensations, referable to the action of the causes producing the intense pain in the head and loins, than that marked depression of the temperature of the periphery and elevation of the temperature of the internal organs, even to the degree of 107 degrees F., which I have shown by careful observation to be characteristic of the true malarial paroxysmal chill.

The chill and chilly sensations of the early stages of yellow fever, appear rather to be related to the same manifestations of aberrated nervous action in the early stages of various acute diseases, as pneumonia, pleuritis and smallpox. As these symptoms are often absent in yellow fever, as they occur in the earlier stages, and as they are in most cases of short duration, it is not often that the physician has the opportunity of investigating the phenomena by means of the thermometer and sphygmograph, and by the careful collection and analysis of the urine during this period.

3. The symptoms of the stage of reaction, or active febrile excitement following the chill and chilly sensations, or arising as it were spontaneously, with but few premonitory symptoms beyond uneasiness and pain in the head, loins, and limbs, and general prostration and languor, characterized by rapid elevation of temperature, which is maintained with slight morning and evening oscillations, and with a progressive descent to the normal standard, for periods varying in different cases, from one to six days. During this stage of active febrile excitement, profound changes are induced by the yellow fever poison, by the products to which it gives rise in the blood and organs. The maximum elevation of temperature is rapidly attained, and may range during the first days of the disease, according to its severity, from 102 degrees F. to 110 degrees F. in the axilla, and it is probable that the internal organs attain a still higher temperature. As a general rule, from the third to the fifth day, the temperature steadily falls and sinks to the normal standard and even below; in some fatal cases it rises again toward the end, rarely, however, reaching or exceeding 104 degrees F., and never attaining the high degree of temperature characteristic of the stage of active febrile excitement.

The supervention of an inflammatory disease or the occurrence of an abscess will, in like manner, cause a progressive elevation of temperature, with slight evening exacerbations; but as a general rule, the secondary elevation of temperature thus caused never attains the maximum of the stage of active febrile excitement.

¹ Observations on some of the Physical, Chemical, Physiological and Pathological Phenomena of Malarial Fever, Transactions AMERICAN MEDICAL ASSOCIATION, 1859.

When malarial paroxysmal fever is engrafted on yellow fever in its later stages, or during the period of convalescence, the temperature during this hot stage may even exceed the maximum of the hot stage of yellow fever, but will be characterized by sudden periodic depressions and elevations, recurring at definite intervals. The pulse, at the commencement of the attack, when the period of reaction or active chemic change has fairly set in, is often rapid (ranging from 100 to 140 per minute), strong, tense and full; in other cases it is rapid but feeble and compressible; the increase in the frequency of the pulse does not, however, as a general rule, continue to correspond with the elevation and oscillations of temperature; and in many cases, the remarkable phenomenon is witnessed of the pulse progressively decreasing in frequency, and even descending below the normal standard, while the temperature is maintained at an elevated degree; and in the examination and comparison of these discrepancies between the frequency and character of the pulse, and the oscillations of the temperature the observer is forced to the conclusion that during the hot stage, some poison or depressing agent is acting upon the heart, or upon the nerves which supply its muscular structures and regulate its actions, thus deranging the nutrition and molecular structure of the muscular fibers. On the other hand, the pulse frequently increases in rapidity, but diminishes in force near the fatal issue.

The occurrence of copious hemorrhages from the stomach and bowels may be attended with sudden depressions of temperature and increase in frequency, but diminution in force and fullness of the pulse.

The stage of febrile excitement is not of fixed duration, and may, in some cases of the gravest character, appear to be comparatively mild and unimportant, attracting so little attention, and the pains, wherever seated, may be so mild, and there may be such an absence of agitation and delirium, and the strength of the patient may be diminished to so slight a degree, that both patient and physician may be deceived and the patient may die without taking to his bed, *on foot*, as it were.

Case 1.—Louis² recounts the case of Dr. Mathias, who died after an illness of four or five days, and who experienced no other symptoms but some pains in the calves of the legs and a suppression of urine. He had no nausea; he did not vomit. His mind was clear through the whole course of the disease. He noticed the continuance of the suppression of urine; dictated three or four letters to a friend; begged him to write rapidly, so that he might sign his name, then devoted a little time to an affectionate intercourse with this friend, and soon after, unable to speak, he thanked his friend with a sign, and in a quarter of an hour he was dead.

Case 2.—In the month of October, 1870, a stout Irishman walked up from the gate of the Charity Hospital of New Orleans, and entered one of the wards on the third floor up stairs, presenting to the casual observer no special marks of disease beyond some congestion of the capillaries of the face and extremities, a dusky, livid hue, a slight increase of heat, and restlessness. A few hours after entering this ward, he vomited about one quart of black vomit, and died in convulsions twenty-four hours after his entrance into the ward. The black vomit ejected during life, as well as the portion which filled the stomach after death, presented the appearance and character of dark grumous blood, was of high specific gravity and alkaline reaction, contained both ammonia and urea, and also an immense number of altered, colored blood corpuscles. Careful microscopic examination with lenses of different powers, ranging from one-quarter to one-eighth of an inch, revealed no animalcules or vegetable

organisms (vibrions and fungi are frequently present in black vomit, but as far as my observations extend, they have nothing to do with its causation). The superior portions of the body of this patient, after death, presented a deep golden yellow color, while the dependent portions presented a purplish, mottled, ecchymosed and congested appearance; the heart was pale, yellow and flabby, and contained many oil globules, and the muscular structures or fibers presented an altered appearance under the microscope; the transverse striæ being less distinct, and the interior of the muscular fibrillæ, as well as the connective tissues, being loaded with oil globules. The kidneys were pale and of a yellow color, resembling that of the heart, and the excretory tubes were filled with albuminous and fibroid granular matter, excretory cells, and oil globules. The bladder contained no urine, there having been complete urinary suppression since the entrance of the patient into the hospital. The liver presented the usual yellow color and bloodless appearance of this organ in yellow fever, and the liver cells contained an abnormal amount of oil.

In these changes yellow fever resembles acute phosphorus poisoning.

The gall-bladder, as is usual in this disease, contained only a small quantity of yellow bile, not exceeding one hundred grains in amount; while in malarial fever, on the other hand, the gall-bladder, after death, is almost universally distended with dark, greenish-black bile of high specific gravity, and generally about one thousand grains in amount.

In some cases of yellow fever which I have observed in New Orleans, the symptoms have rapidly changed from active excitement to utter prostration, and the patients have been speedily destroyed by hemorrhage from the bowels, without any vomiting of the altered blood and gastric secretions which constitute black vomit. I have also observed cases, in which hemorrhage of black blood had taken place in the gall-bladder. In such cases the gall-bladder has been distended with a dark grumous liquid, which upon microscopic and chemic examination proved to be defibrinated blood, without any admixture of bile.

As far as my observations extend, *suppression of urine* is a universally fatal symptom, and is the prime cause, not only of the copious hemorrhages from the stomach and bowels, but also of various alterations of the blood and nervous disturbances, and of the sudden and apparently inexplicable deaths.

Suppression of urine in yellow fever is attended with the accumulation of the constituents usually eliminated by the kidneys, as urea in the blood, brain, liver and heart and muscular organs, as I have demonstrated by numerous analyses. Bile also accumulates in such cases. The presence of the coloring matter of the bile in large amounts in the circulatory fluid may be demonstrated by a simple experiment; thus, if a drop of blood be dropped upon a piece of filtering paper, a brilliant red central spot will mark the presence of the colored blood corpuscles, and this will be surrounded by a bright golden border or ring, due to the absorption of the serum deeply tinged with bile.

The peculiar indifference and even intoxication which mark the cases of suppression of urine are referable chiefly to the retention of the constituents of the urine and the bile.

The changes of the blood in such cases of yellow fever are characterized chiefly by great diminution of the fibrin, which, in some cases, I have found to be not one hundredth of the usual amount; and by the abnormal amounts of urea and ammonia and of the sulphates, phosphates and extractive matters.

I have found the stomach and intestines so charged with ammonia, even when examined within three

² Documents Recueillis par MM. Chervin, Louis et Trouseau, Membres de la Commission Médicale Française envoyée à Gibraltar pour observer l'épidémie de 1828, et par M. le Dr. Barry. Two Vols. Paris, 1830. *Researches on the Yellow Fever of Gibraltar*, by Dr. Ch. A. Jones.

hours after death, that a rod dipped in hydrochloric acid, held over the mucous membrane of the stomach and intestines, gave forth dense white fumes (chlorid of ammonium).

It is without doubt, true, that the poison of yellow fever acts as a direct irritant or poisonous agent upon the mucous membrane of the stomach, not only by deranging its nervous supply and capillary circulation, but also by directly altering the nutrition and secretion of its active cellular elements; but at the same time it is also true that the poison acts equally, if not to a more marked degree, upon the liver and kidneys, thus causing in many cases complete suppression of the function of both organs, and the consequent contamination of the blood with bile, urea and extractive matters and ammonia.

The excrementitious matters thus retained in the blood not only exert a depressing action upon the nervous and circulatory systems, and change the important nutritive actions of the colored blood corpuscles, but the urea, eliminated as such, and as carbonate of ammonia by the gastro-intestinal mucous membrane, alters the constitution of the intestinal and gastric juices, and directly the mucous membrane of the stomach and bowels.

Analogous cases to those just described are witnessed in the action of certain violent poisons, which act alike upon the nervous system and the blood.

It is but just for us to view such cases as a febrile action of an infectious character, deriving its peculiar characters and malignity, from the nature of the cause, which produces such profound disturbances in the nervous system, blood and organs that only a feeble and powerless reaction is possible under the action of so violent a poison.

The action of the poison of yellow fever, during the stage of active febrile excitement, is manifested not only by the intense pain in the head and back, and by the florid congestion of the capillaries of the eyes and skin, and by the loss of appetite and nausea, and by the elevation in the temperature and increase in the frequency of the pulse, but also by the appearance of albumen in the urine, which is rarely absent, and may make its appearance upon the first day of the febrile excitement.

While it is true that the excretory cells and casts of the urinary tubes appear simultaneously with the albumen in the urine, I have also shown by careful analyses of the urine, that the presence of this constituent of the blood in the urine, is not to be referred wholly to acute desquamation of the excretory cells and tubes of the kidney, nor to mere capillary congestion similar in all respects to that in other organs, but equally to the chemic change effected by the poison of yellow fever upon the albumen of the blood.

I have shown by continuous observation and analysis, during different stages of the disease, that the albumen appears in large amounts in cases where there is apparently no failure in the excretory action of the kidneys, and in which the urine was abundant and loaded with urea and other constituents of the urine, and also with bile. While the presence of the blood corpuscles and coloring matters of the blood may be determined by chemic and microscopic investigation of the urine in some cases of yellow fever, at the same time the presence of these constituents of the blood are not uniform and characteristic, as in the cases of that form of severe malarial fever,

which, in our Southern States, is now known as malarial hematuria.

In this latter disease the casts and excretory cells of the kidney tubes may be present in considerable numbers, but only that amount of albumen is present which would correspond to the colored blood corpuscles and coloring matters of the blood escaping at the same time.

In yellow fever, on the other hand, even when blood appears in the urine, the albumen is vastly more abundant than the colored blood corpuscles.

The congestion, so marked upon the mucous membrane of the eyes, and upon the breasts and arms, in some cases, a "subcutaneous rash," extends also to the internal organs, and is best observed in the injected nares, crimson lips, scarlet tip and edges of the tongue, and brilliant congested fauces. The fact that the examination of the congested throat causes nausea and retching, when the tongue is pressed down by the finger or spatula, is of importance as a diagnostic sign; and Blair affirmed that when marked congestion is not observed in the eyes and nares and throat in yellow fever, it will be observed by means of the speculum, in the mucous membrane of the anus and vagina. This intense capillary congestion not only characterizes the mucous membrane of the stomach in yellow fever, but it is even manifested in the pericardium after death.

4. The symptoms manifested during the stage of depression and exhaustion, in which the depressing effects of the preceding changes of the blood and organs induced by the action of the febrile poison and its products are manifold. In cases which terminated favorably, the deleterious substances generated during the stage of febrile excitement are gradually eliminated, and the blood purified and relieved of the altered albuminoid and fibrinous elements, and the organs especially affected by the poison, as the heart, liver and kidneys resume their healthy action.

In cases which terminate fatally, in this stage, the issue appears to be determined mainly by the profound alterations of the blood, the failure of the heart, from acute fatty degeneration, and suppression of the action of the liver and kidneys, and the consequent retention in the blood of urea and bile, the poisonous action of the constituents of the urine and bile upon the blood, and nervous and muscular systems and gastro-intestinal mucous membrane.

There appears to be no just ground for the division of the fourth stage, in accordance with the presence or absence of hemorrhage, jaundice, uremic poisoning and convulsions, for these are simply aggravations of the preceding symptoms, and must be regarded as the maximum phenomena of this stage. Neither is this stage to be regarded as similar to, or identical with the intermission or remission of malarial fever, and as an abortive attempt at the repetition of the febrile stage, in which the disease ends or aborts from adynamic incompetency to carry out the phenomena.

These stages are not of uniform duration, and there may be marked diversity in the manifestations of the symptoms in individual cases, some cases presenting, apparently, but the one stage of febrile excitement, while others, overwhelmed as it were by the poison at once, manifest only the symptoms of blood poisoning, arrest of the action of the heart and nervous system and hopeless prostration.

In mild cases, especially in children, the disease may be so slight as scarcely to attract attention, and convalescence may be established in two or three days; in many cases the stage of febrile excitement continues from two to six days, rarely extending beyond three or four days, and the patient may pass almost imperceptibly into convalescence during the stage of depression; in the severest cases the patient may be carried off in two or three days and die with an elevated temperature; while in other severe cases, which end fatally either from hemorrhage from the stomach and bowels, or from urinary suppression, or from both causes, or from general prostration of the system, derangement of the blood and perverted nutrition characterized by a low adynamic fever, and abscess of the parotids, and the revival of old complaints, and the supervention of some other disease, as malarial fever, the fourth stage may be of long duration, extending over weeks and even months.

It is, however, true as a general rule, that convalescence from yellow fever is comparatively rapid, and in striking contrast with the slow and tedious convalescence of malarial fever. In some cases vomiting may be the preëminent symptom, in others, hemorrhage from the stomach and bowels, or from the gums, eyes, and ears, indicating great alteration of the blood, and especially of the fibrinous element; and in others, cerebral symptoms; but all these symptoms may be referred to certain definite results of the action of the poison of yellow fever.

Yellow fever, according to this view, partakes of the nature of a *continued pestilential fever*, presenting two well-defined stages: The first characterized by *active chemic change in the blood and organs*, attended with elevation of temperature, aberration of nervous phenomena, which may constitute the entire malady, and prove fatal in a manner similar to the infectious fever of smallpox; and the other, a *stage of depression induced both by the sedative action of the febrile poison and by the profound changes excited in the constitution of the blood, and in certain organs, as the heart, liver, and kidneys, and by the direct sedative and poisonous action of the excrementitious matters retained in the blood, in consequence of the failure of action in the liver and kidneys, and by the arrest and perversion of digestion in consequence of the direct action of the yellow fever poison, in causing perverted nervous action of capillary congestion and active desquamation of the secretory cells of the stomach, and in consequence of the elimination of certain constituents from the blood, as the urea and carbonate of ammonia.*

While the phenomena of yellow fever are well marked, and different from those of other diseases, at the same time the duration of the disease and the intensity of the symptoms will depend in each case upon the condition of the system at the time of the introduction of the poison, the various agencies to which the system is subjected during the progress of the disease, as the supply of pure air in comfortable, well-constructed and thoroughly ventilated rooms, or of impure air in filthy, damp and crowded habitations, and in filthy and crowded ships, the diet, medical treatment, climate (whether hot and dry or hot and moist, uniform or subject to great and sudden elevations and depressions of temperature, malarious or unmalarious); but the duration of the disease and the character and intensity of the symptoms will especially depend upon the extent to which the blood

and organs have been involved and altered by the changes excited by the poison.

The various manifestations, as the capillary congestion, depression of the action of the heart, delirium, coma, and convulsions, vomiting, hemorrhage, and urinary suppression, uremic poisoning and jaundice, with biliary poisoning, may all be referred to the action of the poison producing the disease, and should not be erected into distinct types of disease. And even in those sudden and appalling cases in which there is such a modification of symptoms between the stage of active febrile excitement and that of active depression as to produce a deceitful sense of security, in both the medical attendant and patient, in which period of apparent calm and convalescence the patient asks for food, proclaims himself entirely restored to health, and insists upon getting up and walking about, the sudden fatal issue which astounds the friends of the patient, as well as his medical attendant, has been silently but surely induced by the failure of the kidneys to eliminate the poisonous materials from the blood, and the fatal mischief may have been working for hours and days, unobserved and unrecorded by the medical attendant, who has neglected to examine carefully, at stated intervals, the amount and character of the urinary excretion, through which the deleterious products of the poison are mainly eliminated.

While it is true, that few cases of yellow fever resemble each other exactly, some cases being characterized throughout by symptoms of excitement, and others by prostration; in some cases the cerebral symptoms being most marked, in others hemorrhage from the stomach and bowels constituting such prominent symptoms as to give a distinctive feature to the disease; at the same time there appears to be no just ground for the division of the disease into such distinctive types as would lead to the supposition that the cause might differ in different cases, and that the phenomena might not all be referred to the action and results of a definite cause.

The action of the yellow fever poison is the same in all cases, whether mild or severe; the progress and termination of each case, as well as the manifestation of the various symptoms depending upon the extent of the action of the poison, the condition of the system at the time of its introduction, the peculiarities of the constitution, and the supervention of other diseases.

In a word, the action of the yellow fever poison is distinct, and the disease is characterized by definite manifestations, just as each species of plants and animals manifests distinctive laws of development and growth and physical organization, which may be the subject of investigation and accurate description; and while the laws may be modified in their manifestation by varied extraneous causes, the grand distinctive characters are maintained, and may be propagated from age to age.

Yellow fever is a self-limited disease; it runs a definite course and then ceases. When once fairly established in the human system, yellow fever can not be arrested by drugs. On the other hand, it is well established that paroxysmal malarial fever may be arrested and cured by bark and its active principle quinia. Yellow fever may be conducted to a successful issue by the attentive and careful physician, but it can not be arrested.

PERIOD OF INCUBATION OF YELLOW FEVER.

The period between the exposure to the "infected atmosphere" and the manifestation of yellow fever is not of fixed duration, but varies with different individuals; some systems resist for long periods the morbid agents, while, on the other hand, healthy individuals coming into an infected city have been attacked within thirty-six hours. A few hours' exposure to the atmosphere of the city in which yellow fever is endemic may be sufficient for the introduction of the poison into the system. This statement is sustained by the following observations:

Case 3.—A stout, healthy young gentleman, of florid complexion, sanguine temperament, and active habits, resided in a healthy locality in Liberty County, Georgia, thirty miles from Savannah. In the month of September, 1854, while the yellow fever was prevailing, he drove in his carriage into the city, and visited the house in which one of his near relatives had died a few days before with well-marked yellow fever accompanied with black vomit. Entering the city at midday, he remained about four hours (just long enough to secure some business papers relating to the estate of his deceased relative), and returned immediately into the country. In the course of one week this stout young man, in the full vigor of health, was seized with yellow fever, and died with black vomit after an illness of four days. After death, the body presented a deep yellow color, and the dependent portions were mottled from the unequal and excessive capillary congestion. The exposure of a few hours to the atmosphere of the city was in this case sufficient for the introduction of the poison. On the other hand, many individuals living in the infected cities, and holding daily intercourse with the sick, do not manifest symptoms of the disease until near the close of the epidemic; while others, equally exposed, pass through many epidemics without even manifesting a sufficient amount of febrile derangement to require medical treatment. This latter remark applies not only to the natives of southern cities, but also to residents of northern latitudes, who remove to those localities where yellow fever prevails after they have attained their full growth. The period of incubation appears to vary in different epidemics, and among different individuals during the same epidemic, and may extend from twenty-four hours to weeks and even months. In this respect yellow fever is allied to those diseases which are supposed to arise from malarial effluvia, and differs from those well-defined contagious diseases in which the period of latency is well-marked and of definite duration.

During the prosecution of my investigations in yellow fever, notwithstanding frequent contact with the sick and dead, and exposure to the exhalations from the bodies of yellow fever subjects and from the black vomit, excretions, and blood and organs subjected to chemic analysis, I have never experienced well-marked symptoms of this disease until the great epidemic of 1878; although at times, when most exposed to such exhalations, I have suffered with slight fever, loss of appetite, and nausea (these symptoms, however, were not of sufficient severity to cause the intermission of my labors); and such observations have led me to the belief that under certain circumstances the poison of yellow fever may pass through the system, producing slight derangement, without inducing the disease itself.

During the prosecution of similar investigations in smallpox, I have in like manner felt the depressing influence of the poison without manifesting well-marked symptoms of this disease; and upon one occasion, after exposure to the smallpox poison in the crowded tents of a Confederate military smallpox hospital, and after performing a protracted *post-mortem* upon the body of a Confederate soldier who had died with confluent smallpox, I suffered with fever, intense pain in the back and head, and injection of the capillaries of the skin. These symptoms

disappeared, however, at the end of three days. It was evident that the protective influence of the vaccine virus introduced into my arm twenty-five years before was sufficient to cause or allow the passage of the smallpox poison in large amount through the system, with only a partial and mild manifestation of some of the symptoms usual in those unprotected either by vaccination or by a previous attack of smallpox.

In the case of the yellow fever poison, there was no known state of the system artificially produced, as in the case of the smallpox poison, which would account for the elimination of the poison; although that such an elimination must have taken place was manifest from the peculiar train of symptoms attending prolonged exposure to the exhalations of the sick and dead.

Of the various students numbering over one hundred, and many of them fresh from the country, who have observed cases of yellow fever in my wards in the Charity Hospital and witnessed *post-mortem* examinations in the dead house, and chemic and microscopic investigations in my laboratory during the autumnal months of 1870, 1871, 1872, 1873, 1874 and 1875 in New Orleans, only two were attacked with yellow fever. In none of the years specified did yellow fever prevail as an epidemic in the section of the city in which the Charity Hospital is situated. In only a few instances in 1873, did the disease originate among the patients in the wards, who had not been exposed to the infected localities in the city.

There are many persons in the city of New Orleans, who have nursed hundreds of yellow fever patients, stood over them, rubbed and bathed them, inhaled the atmosphere of sick rooms for months, and even washed and shrouded the dead, without ever having a day's sickness. The late Mr. Maybin, a native of Philadelphia, who was distinguished for his devotion to the poor, sick and suffering, informed me that he had passed through all the great epidemics of New Orleans, for a period of over fifty years, including the great epidemics of 1839, 1843, 1844, 1848, 1853, 1854, 1855, 1859, and 1867, without having even a symptom of the disease.

In 1853, many nurses in the Charity Hospital, when two hundred or more died per week, escaped the fever. In the same year, Mr. Logez, one of the carpenters in the Charity Hospital, worked hard all summer, within a few feet of the dead-house where fifteen or twenty bodies were often lying at once awaiting burial, and emitting a nauseating stench, and did not take the disease. Six other carpenters who assisted him took the disease and died. Some of them made the very coffins in which they were buried. The physicians of the Charity Hospital who made careful and thorough *post-mortem* examinations of the bodies in the months of July and August, when the epidemic was at its height, and the bodies in a state of rapid decomposition and offensive, escaped infection or contagion. Over two thousand deaths from yellow fever occurred in the Charity Hospital during the fatal epidemic of 1853. (History of Yellow Fever in New Orleans, 1853, p. 38.)

In *La Republica* of Buenos Ayres, a statement occurs that during the epidemic of 1871 when, according to this paper 17,084 deaths occurred, 350 grave-diggers escaped the fever. The cemeteries are situated on the outskirts of the population. Coffins were exposed for many hours before being interred, from

the press of work. (*Medical Times and Gazette*, August 19, 1871, p. 216.)

According to Dr. Daniel Blair, of British Guiana, in some cases the patients had arrived in this colony and in two weeks died of yellow fever, having been attacked within the first twenty-four hours after arrival. Dr. Blair records the following illustrations:

Miss R. left this colony with her mother and sister in one of Booker Brothers' ships, having been exposed to river influence only the one night previous to departure. All were in good health on embarkation. After being at sea fourteen days they all sickened; Miss R., who had been far advanced in phthisis, died of yellow fever.

Mr. Bramisch had been exposed to the malarial locality of Water Street, at Walmsley and Bowes on Friday. He left town the same day, and sickened with yellow fever on Sunday.

Dr. Reid's exposure and interval between exposure and attack was the same.

Mr. Bolton, of the *Rapid*, was only one night in the malarial district, and within twenty-four hours after proceeding to Sand Hills, was seized with the epidemic.

Thus it would appear that the period of incubation varies, and that some systems can for a longer period throw off the morbid agency; while with others, exposure the most casual and temporary produces immediate effects. A case occurred in the Seamans Hospital, wherein the period of incubation seemed extended to four months being kept latent probably by the phthisis under which the patient was suffering.

Patients previously suffering from intermittent fever, dropsy, iodism (coryza from iodid of potassium), and ptialism have had the epidemic disease engrafted thereon; peritonitis and pneumonia failed to exclude the invasion, and the most inveterate lichen tropicus. It has added itself to delirium tremens and lead colic; it has supervened during the flow of the catamenia. Patients under treatment for anemia, and intermittent fever, sarcocele, scald, diabetes and flesh wounds, fractures, rheumatism, erysipelas, ophthalmia, syphilis, strictures, ulcers, eczema, mosquito wounds, whooping cough, and phthisis, have been attacked and often fatally by yellow fever.

When yellow fever became a parasitic disease, the symptoms were considerably modified at first, but the epidemic disease ultimately absorbed all the other symptoms.

In the epidemics observed by Dr. Blair in British Guiana, the invasion sometimes began with malaria of several days duration. Sometimes this formative stage showed itself in diarrhea; in a few cases it began with apoplectic or paralytic symptoms. Sometimes if the treatment was early adopted, or the patient was suffering from another malady, reverberations, repulse and relapse were observed in the first stage, thus abnormally extending its period. About one-half of the normal cases were so sudden and phenomenal in the seizure, that the exact hour of the attack could be precisely ascertained. The hours of 6 A.M. and 6 P.M. when, in the latitude of Georgetown the most violent atmospheric disturbances of the day occur, were most favorable to the seizure.

The average duration of an attack of the epidemics of British Guiana, ending in convalescence, estimated from 1,158 cases of the *graver* form, and 428 cases of the *milder* form, was 6.34 days for the former and 5.35 for the latter. The average duration of a fatal attack, estimated from 404 cases, was 7.08 days. In these estimates, the day of attack and the day of death, or of convalescence, are reckoned each one

day. Although the maximum and minimum days of duration differed widely from this average, those of the *graver* being 23 and 2, and of the *milder* 13 and 2, and those of the 2,472, yet the vast majority of cases fall in closely with the averages. This coincidence happened always more particularly when the disease was persistent, and the epidemic pulsations most intense. The average, therefore may be assumed as the law of duration, of each class respectively.

According to Dr. Blair, intemperance was occasionally a predisposing cause, by recklessness of exposure; but abstinence, as shown on board the American "teetotal" ships, was no protection. It seemed at the time as if those resident in the infected districts circulated the poison habitually through their systems; that old residents had in an eminent degree the power of eliminating it, and keeping its presence latent—had a tolerance of it; but that newcomers, and particularly those of florid complexions and rigid fiber, were constantly, in reference to the presence of the virus, in a state of tottering equilibrium; so that in them the slightest unfavorable impulse to that balance—the lowering of the vital powers by fatigue, the suppression of any of the preparatory secretions, a shock to either of the nervous centers, or the depressing emotions—were sufficient to excite the latent poisons. (Some Account of the Late Yellow Fever Epidemic of British Guiana, Third Edition, 1852, pp. 60, 61, 69, 70, 72, 74.)

According to Alexander Humboldt, the farm of l'Encero, near Vera Cruz, elevated 3,043 feet above the level of the ocean, is the superior limit of the *vomito*. The Mexican oaks descend no farther than that place, being unable to vegetate in a heat sufficient to develop the germ of yellow fever. Individuals born and brought up at Vera Cruz are not subject to this disease; and it is the same with the inhabitants of Havana, who do not quit their country; but merchants born in the island of Cuba, or who have inhabited it for a great number of years are attacked with the *vomito pireto* when their affairs oblige them to visit this part of Vera Cruz during the months of August and September, when the epidemic is at its height. In the same manner, Spanish Mexicans, natives of Vera Cruz, have been seen to fall victims to the *vomito* at Havana, Jamaica or the United States.

The *vomito* is not regarded as contagious at Vera Cruz. In most countries, the common people consider many diseases as contagious which are of a very different character; but popular opinion in Mexico has never interdicted the stranger not seasoned to the climate from approaching the beds of those attacked by the *vomito*.

The whites and mestizoes who inhabit the interior tableland of Mexico, of which the mean temperature is 60.8 degrees and 62.6 degrees F., and where the thermometer sometimes falls below the freezing point are more liable to contract the *vomito* when they descend from l'Encero to the Plan del Rio, and from there to la Antigua and the port of Vera Cruz, than the Europeans or inhabitants of the United States who come by sea; the latter passing by degrees into the southern latitudes are gradually prepared for the great heats which they experience on landing; but the Spanish Mexicans, on the other hand, change suddenly their climate when in the space of a few hours they are transported from the temperate region to the torrid zone. The mortality is very great, especially

among two classes of men very different in their habits and modes of living; the muleteers (*arrieros*) who are exposed to extraordinary fatigues in descending with their beasts of burden, by tortuous roads like those of St. Gothard, and the recruits destined to complete the garrison of Vera Cruz. Every imaginable care has been bestowed on these unfortunate young men, born on the Mexican tableland at Guanajuato, Toluca, or Pueblo, for the purpose of preserving them from the deleterious miasmata of the coast, but without success; they have been left for several weeks at Xalapa, to season them gradually to a higher temperature; they have descended on horseback, or by night to Vera Cruz, that they might not be exposed to the sun in crossing the arid plains of Antigua; they have been lodged at Vera Cruz in well-aired apartments; but it has never yet been observed that they were attacked with the yellow fever with less rapidity and violence than the soldiers for whom these precautions had not been taken.

In the season when the *vomito* rages with great violence the shortest stay at Vera Cruz, or in the atmosphere which surrounds the city, is sufficient to communicate the disease to persons not seasoned to the climate.

The inhabitants of the City of Mexico when they propose to sail for Europe, dreading the insalubrity of the coast, generally remain at Xalapa till the moment of the departure of their vessel. They set out on their journey in the cool of the night or cross Vera Cruz in a litter, to embark in the boat which awaits them at the Mole; and yet these precautions are sometimes useless, and it happens that these very persons are the only passengers who sink under the *vomito*, during the first days of the passage. It might be admitted that in this case, the disease has been contracted on board the vessel, which remained in the port of Vera Cruz, and which contained deleterious miasmata; but the celerity of the infection is more incontestably proved, by the frequent examples of the better class of Europeans, dead of the *vomito* though on arriving at the Mole, they may have found litters ready to begin the journey to Perote.

Such facts may be held by some to sustain the doctrine that yellow fever is contagious, under all the zones; while those who hold that it is not communicable by immediate contact with the sick and dead, admit that the atmosphere of Vera Cruz contains putrid emanations, which if breathed for the shortest space of time, introduce disorder into all the vital functions.

The most part of the Europeans newly landed feel during their stay at Vera Cruz the first symptoms of the *vomito*, which is announced by a pain in the lumbar regions, by the yellow covering of the conjunctiva, and by signs of congestion toward the head. In some individuals it only declares itself when they arrive at Xalapa, or in the mountains of La Pileta, in the region of pines and oaks, at from 5,248 to 5,904 feet above the level of the ocean. Those who have long resided at Xalapa, deem themselves able to foretell from the features of the travelers who ascend from the coast to the tableland of the interior, whether without their being sensible of it themselves, they contain within them the germ of the disease. Dejection and fever increase the predisposition of the organs to receive the impression of the miasmata; and these same causes render the commencement of the yellow fever more violent

when the patient is imprudently informed of the danger of his situation. In illustration of the preceding statement, Alexander Humboldt cites the following interesting instance:

A person with whom he was on terms of intimate friendship, during his stay at Mexico, had passed only a very short time at Vera Cruz, on his first voyage from Europe to America. He arrived at Xalapa without feeling any sensation indicative of the dangerous state in which he was immediately to be. "You will have the *vomito* this evening," said an Indian barber, gravely to him while he lathered his face; "the soap dries as fast as I put it on; that is a never-failing sign, and for the twenty years that I have been in the practice of shaving the *chapetons*, who pass through this town on their way to Mexico, out of every five, three have died." This sentence of death made a strong impression on the traveler. It was in vain to represent to the Indian that his calculation was exaggerated, and that a great heat of the skin does not prove this infection; the barber persisted in his prognostic, and in reality the disease declared itself a few hours afterward, and the traveler already on his way to Perote, was obliged to be transported to Xalapa, where he nearly fell a victim to the violence of the *vomito*. (Political Essay on the Kingdom of New Spain, London, 1811, Vol. IV, pp. 170-178.)

In regard to the epidemic of Gibraltar in 1804, Sir W. Pym³ states that the *fourth* day was generally the time the contagion seemed to require to show itself; and several instances occurred of strangers who were attacked on the second and third day after their landing at Gibraltar. From the fact that persons were seized on the first day of their landing at Gibraltar, while persons who fled from the garrison were taken ill on the coast of Portugal many days after, induced Mr. Amiel to believe that the disease may be excited into action at any time from the first moment of exposure to a period of fifteen or twenty days. The following statement by Wm. Fergusson, in his "Notes and Recollections," would even show that the disease may be developed in less than twenty-four hours after exposure to the infected atmosphere. At Mark's Hill, "it was the duty of the white troops in both forts to take the guard and duties of the dock yards among the marshes below; and so pestiferous was the atmosphere, that it often occurred to a well seasoned soldier mounting the night-guard in perfect health, to be seized with furious delirium while standing sentry, and when carried back to his barracks on Mark's Hill, to expire in all the horrors of the black vomit, within less than thirty-six hours of the first attack."

Drs. Pausit, Bally, and Francois regarded the period of incubation at Barcelona in 1821, as not exceeding twenty-four hours, or three days at the most; Aujula from twenty-four to thirty-six hours, sometimes from two to seven days, and even as late as from thirty to fifty days.⁴ According to Dr. Harrison, persons who arrived in New Orleans during an epidemic, from the healthiest region, even by the ocean, are subject to attack on the third to the sixth day after their arrival; and Dr. Merrill⁵ states that at the Bay St. Louis in 1820, several persons who arrived while the disease was at its height were attacked in twenty-four hours.

The authority of various other observers, as Lind,

³ Observations on the bular fever which has of late prevailed in the West Indies, on the coast of North America. Gibraltar, Cadiz and other parts of Spain, etc. S. tr., London, 1815, p. 24.

⁴ Pausit.—Observations Sur la Fièvre Jaune fales à Cadiz en 1819, etc. New Orleans Medical and Surgical Journal, March, 1847, p. 569.

⁵ Yellow Fever, by R. La Roche-Mer, Vol. I, p. 510.
Dr. D. O. Saunders, of Memphis, placed the incubation period of the fever of 1873, between twenty-four hours and sixteen days, having seen one case where a gentleman who had been absent all summer was attacked in twenty-four hours after his return, and another who was away from the city was attacked in sixteen days after leaving New Orleans. 1874, p. 800.

John Hunter, R. Jackson, Wallace, Riseuno, Moreau de Jennès, Rush, Townsend, Chisholm, Bryson, might be adduced to sustain the proposition already sufficiently illustrated by the authorities quoted, that the period of incubation of yellow fever is of variable duration. From the preceding facts, the following conclusions may be drawn:

1. Yellow fever differs from such contagious diseases as smallpox, measles and scarlet fever, in the variable duration of the period of incubation.

2. The sudden seizure of many cases after a few hours exposure to the infected atmosphere, indicates the existence in the air of a potent and specific poison, which is most probably introduced through the lungs into the blood.

3. The phenomena of yellow fever in those suddenly exposed to the atmosphere of an infected locality can not be referred to any physical changes of the temperature and electrical condition of the surrounding atmosphere, but must be referred to the action of a specific poison.

4. The propagation of yellow fever from the infected atmosphere of an infected vessel in a healthy city; the communication of the yellow fever from person to person; the spread of the disease from an infected point in a city, however large, over extended areas of said city; and the sudden cessation of epidemics of yellow fever by cold sufficient to produce frost and ice. These and similar facts indicate that the poison of yellow fever is a living germ of animal or vegetable nature or origin.

(To be continued.)

CRANIOPLASTIC OPERATIONS.

Thesis: For admission to Chicago Academy of Medicine.

BY CARL BECK, M.D.

CHICAGO.

The purpose of plastic operations is to remedy defects. Cranioplastic operations have, therefore, to remedy defects of the cranium. The cranium is a bony structure, and operations on such are therefore bone-plastic operations and share more or less of the characteristics, difficulties and the fate of such.

Bone-plastic has been studied attentively of late, but osteoplastic on the cranium has not been the subject of very critical research.

Defects of the cranium can be either congenital or acquired. Teratology and pathology enumerate a large number of instances of such congenital defects. From the monster called anencephalus, hemicephalus, down to porencephalus, through all gradations we have mal-development of the cranium, but these extremely high degrees of defects will not easily be the subjects of a plastic. The individuals thus born are doomed to die early, or they are idiots and not worthy of remedy—for such a creature it is better to be dead than alive. But there are defects of the cranium which allow a normal development of the brain. Such are small defects in the bony part, as present in meningo- or encephalocele—small openings in the skull. Such defects are especially concerned in plastic.

A much larger group than the congenital is the acquired. They can be acquired by trauma or disease. This trauma can either be caused by accident or purpose, and the latter furnishes, with the growing number of surgical operations on the skull and brain, the largest amount of defects. Various dis-

eases may destroy the cranium, and not only the size of the defect in a particular case, but the peculiarity of the disease must be taken into consideration.

After thus reviewing the possibilities of defects from the etiologic standpoint, we will divide the defects into:

1. Congenital.
2. Accidental trauma.
3. Surgical.
4. Morbid.

(a) Tubercular.

(b) Syphilitic.

(c) Cancerous or sarcomatous.

I—CONGENITAL DEFECTS.

Osteoplastic operations, would be considered when a small defect allows the development of a hernia cerebri, meningocele, or encephalocele. A defect of this kind might be situated on any place on the cranium; might be quite large; inaccessible; might be very irregular or small, and almost like an opening made by a trephine. Fig. A, which shows such a defect of the skull, is drawn after a specimen of the Musée Dupuytren. The localities where they are most common are the root of the nose, the external and internal angle of the eye, the orbital, nasal and buccal cavities. Furthermore, between the sutures of the cranium. These defects, if not attacked by the surgeon, will never be covered with bone and they form, therefore, one indication for plastic.

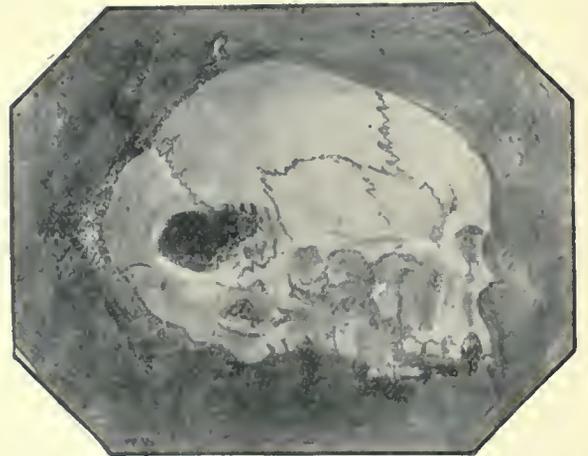

FIG. A.—Defect in skull from encephalocele. (Musée Dupuytren.) Duplay-Réclus. Tr. de Chirurgie.

II—ACCIDENTAL.

All accidents by which complicated comminutive fractures of the skull occur, whereby a part of the bony structure of the skull is lost or is broken out of the continuity, give rise to such a defect. It is not very common that they heal over without being attacked in some way or other by the surgeon; that is, usually, the surgeon removes loose particles, evens edges and corners so as to make the bony wound smooth, so that they would have to be grouped under the third head.

III—SURGICAL.

Defects produced by the surgeon are such as mentioned above. They are very common. All procedures on the skull, whereby parts have been removed, will have, if plastic is not done, a defect. Every opening of the integral cranium for the purpose of dura- or brain-operations or ligature of vessels, if not repaired by plastic leaves a defect.

IV—MORBID.

Tubercular defects are not very common and not

likely to become the subject of a surgical operation. Syphilitic and cancerous defects might be the subjects of quite an extensive plastic.

We now come to the physiology of the parts concerned. The cranium is a bony structure, very much depending on its periosteum. It is not like all bones, having a periosteal covering not only on its outer side, but also on its inner side, for the dura mater certainly acts as a periosteum. We have many proofs of such action. (*Ollier Traité, Exp. et Clin. de la Regeneration des os, etc., Vol. I, page 80,*) says: "The dura mater is a membrane about which the authors have not agreed. Some want to give it the same quality as the periosteum proper, making an internal periosteum of the cranium of it. Others regard it as having no part in the ossification. The study of its development shows, however, that it is united with the bones of the cranium in a very intimate way during the embryonic stage. Furthermore, it is even the seat of pathologic ossifications. In order to decide this question, we proceeded with this membrane in the same way as with the periosteum and have transplanted the same. On young rabbits, we have removed a part of the dura mater of the convexity immediately after death, and we have transplanted this under the skin of the hip. We have obtained bony tissue, mostly in little disseminated granules, sometimes in a mass of the size of a kernel of corn.

This one experimental fact, and another one which I will mention in the report of my cases (Case Chen-sik), and furthermore, the fact that we find hyperostosis of the dura mater during pregnancy, the so-called hyperostosis or osteophytæ gravidarum, prove it to evidence that the dura mater is nothing but a periosteum. From this fact we draw the conclusion that in doing osteoplastic operations on the cranium we have no difference from other osteoplastic operations, but the fact that it is a combination of a very brittle internal bone-plate, tabula vitrea—and a very hard, somewhat elastic external plate with great individual differences and varieties in circulation, thickness and form, give to this bone an exceptional position.

The question whether we can transfer the results of our experimental work on animals directly to the human, is a very important one. It is a well-known fact that a dog will stand almost any operation on the intestine and survive, while in the human being it shows a different refraction. And so it is with the experiment on the cranium and brain. The cranium of the human especially, is so different from that of other animals, that our experiments, as to technique and peculiarities of healing, can not be immediately transferred nor compared to the human. Some plastic operations (autoplastic) especially, will be much easier on the human than on the animal, while others (heteroplastic) will be just the reverse. It is, therefore, hard to decide about the value of some devices and methods which have been used in experiments on dogs, and not yet been employed on patients.

THE METHODS OF PLASTIC.

Plastic has different methods. The ideal of all plastic is to make it as much as is possible, similar to nature, as we are never able to make it equal to nature, even with our best skill and will. To replace a defect or bone by bone again, of similar size and shape, will therefore be the ideal. This may be accomplished in different ways. Either the bone that

has been removed may be replaced right away, with the smallest possible loss of substance, or bone from the same individual, from different parts of his body, may be taken to cover the loss. This procedure is called autoplastic. All the rest of the procedures can be comprised under the name of heteroplastic, and the value of a differentiation between the material—whether from a living subject or whether a dead body—seems to me of little importance, inasmuch as it comes more and more to light that even the transplanted portions from living bodies are not dealt with differently by nature than dead bodies, in the healing process, inasmuch as they all are encysted. It is then only a question, which of those bodies is preferable, and the one that is encysted the quickest and, after encysted, fulfills the purpose of protection the best, is best for transplantation.

We will now go more into the details of these methods.

A—AUTOPLASTY.

1. *Temporary Resection.*—This would be the simplest method of covering a defect, but it is only applicable where we produce the defect temporarily; therefore, in operations for processes in the dura, the vessels, or the brain, where the cranium is healthy. There

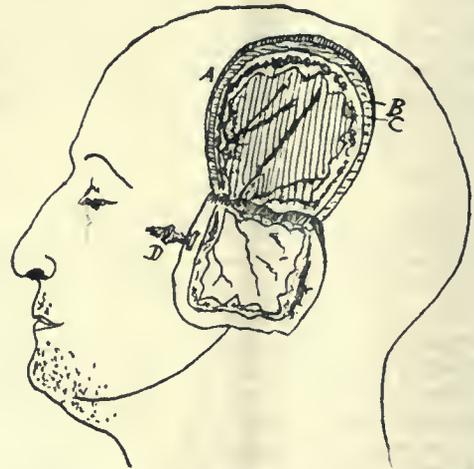

FIG. B.—Temporary resection (Wagner, 1889). A. Incision of the soft parts. B. Space between bony and soft parts. C. Section of bone with both plates. (Chipault.) D. Franck's forceps.

are different methods of temporary resection. One of the first was Wagner's method of skin periosteum bone-flap, in the form of a door of oval shape, with the hinge. It was produced by chisel and mallet.

Usually by this procedure with chisel and mallet (Fig. B.) a great deal of substance of bone is lost, so that the space between the flap and integral bone is left to be filled by cicatrix or a newly formed bone. Modifications of this method are by Müller, Lowenstein, Poirier, Salzer, Bruns, Toison and Chipault. The accompanying figures (Fig C, c, c₂) explain the more important modifications. Of all the methods that have been described, Chipault's seems to be the most appropriate, inasmuch as it does away with one disadvantage—the lack of apposition of flap and integral bone. Without knowledge of Chipault's method, I have used in a special case, a similar procedure for opening of the skull in the case of a brain tumor but I found that the flap, even then, has been moved so violently by the increased pulsation of the dura that it interfered with the healing, and though the periosteum had been very carefully sutured, two weeks after the operation the flap was

as loose as if it had not been in contact with the bone at all. In order to prevent this, I have studied this question and would suggest a modification of the temporary resection, which I will describe in detail as follows (*vide Centralbl. f. Chir.*, 94, No. 44):

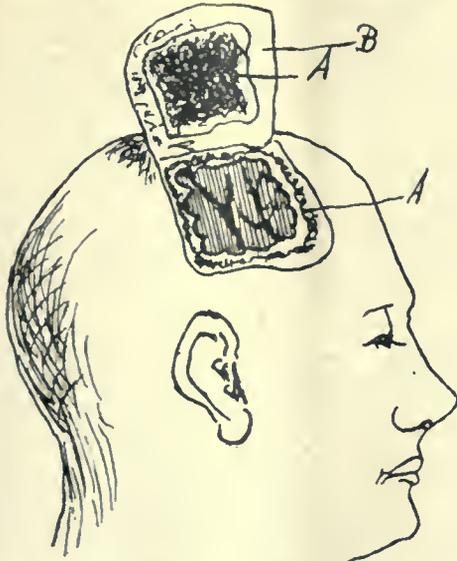

FIG. C.—Temporary resection. (Müller.) A flap with tabula vit. and diploe. B. Soft tissues. The remaining inner table being removed with rougeur.

A more or less rectangular incision with a pedicle in the direction of the larger vessels, is made into the skin and periosteum. The bone is then chiseled in the direction towards the outside, obliquely, through the thickness of the cranium, in the same manner as it is done for Müller-Koönig's osteoplastic, in three directions until the diploë is reached. The edges of the bone, which have been chiseled, are tilted up in

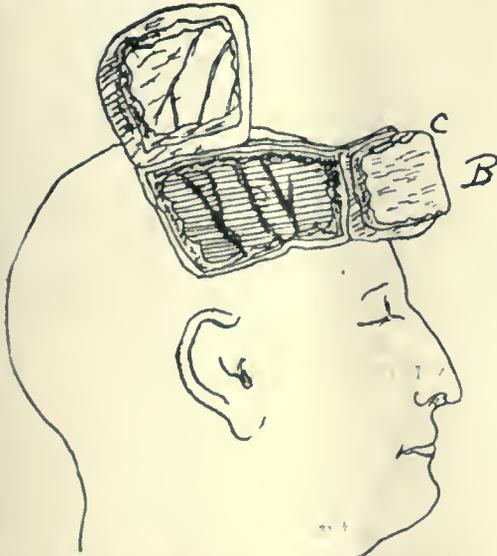

FIG. C 1.—Temporary resection. (Brammaun.) Double flap to enlarge the opening. Flap B must be replaced first on account of its oblique inner border c. (Chipault.)

the manner shown by the accompanying drawing. (Fig. D, D.) In the corners it must be split diagonally a little. When the diploë is reached, a small opening is made by the chisel and hammer down to the dura, and with a narrow gouge a furrow cut out all around, so that the flap is now movable from three sides. This maneuver, complicated as it may appear, is quickly accomplished, if done with some skill. The fourth side of the flap can be simply broken, if

the skull is not very thick, or a chain saw or fret saw may be introduced and the bone sawed through. This procedure has several advantages:

1. It prevents pulsation of the flap.
2. There is, as the transverse cut shows, hardly any

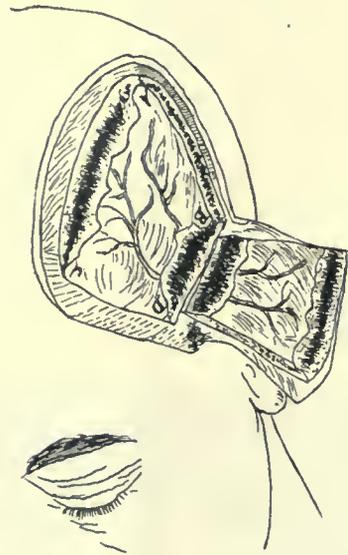

FIG. C 2.—Temporary resection. (Chipault.) On both sides of the replaced osteoplastic flap will remain an open space, A B, C D.

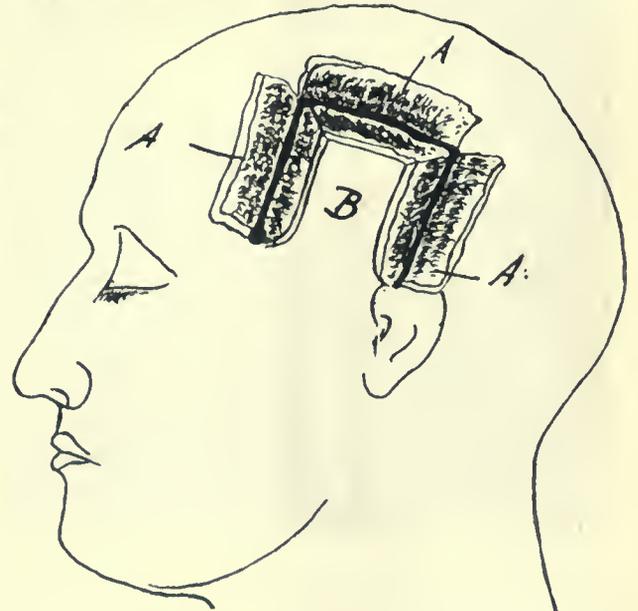

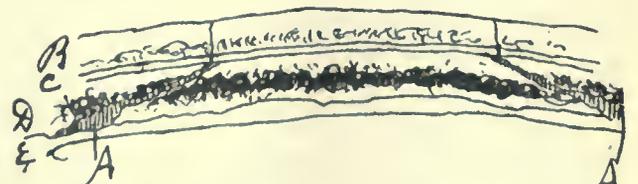

FIG. D.—Temporary resection. (Beck.) A. Obliquely cut and bent up borders containing scalp and skull. B. Flap before turned up.

loss of substance, and therefore the healing, as in the case of a fractured bone, without much cicatrix, is most probable.

3. The chiseling and gouging is done much quicker, and with much more simple instruments than if the trephine is used and saws introduced by forceps and

probes, as in the methods of Toison and Chipault.

Thus far, I have been able to do this method only on cadavers and dogs, but I will give it a trial in the next case of brain operation. In the dog it is a very hard procedure, on account of the perfect impossibility of chiseling obliquely down to the diploë, the bone of the dog being so irregular in its thickness. In this respect the human skull has a great advantage, especially over the convexity, where these temporary resections are usually performed. Temporary resection will be the operation of choice in the future because, once started, the opening can be made as large as needed and without any loss of cranial substance, as in the case of trephining. Two or three such flaps can be formed, and half of the skull—or more even—laid bare if necessary.

2. *Implantation of Cranial Fragments.*—This method comprises trephining with replacing the bone plates, as well as the re-implantation of loose fragments in

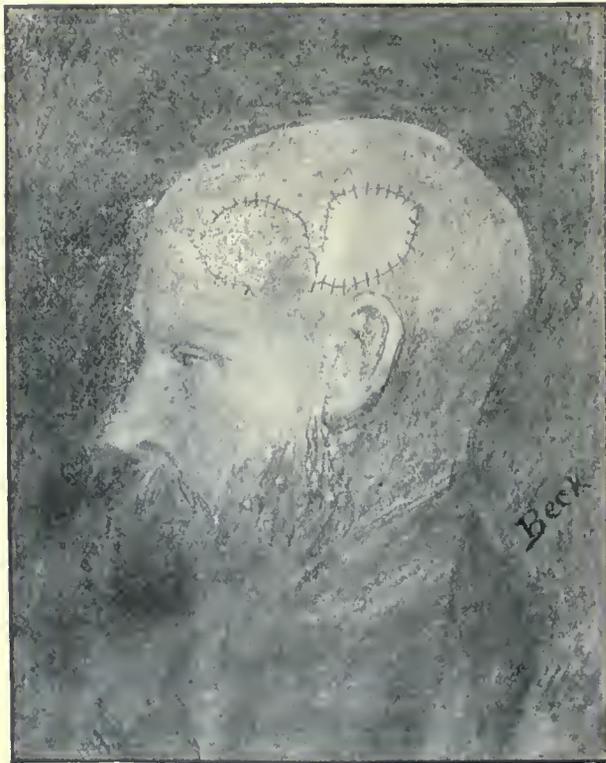

FIG. E.—Bert. Bereman, eight days after operation.

fractures. They both have, physiologically, more or less the same conditions of wound healing. Fragments from fractures, *ceteris paribus*, give even better conditions than the round chips formed by trephine, or the square chips by the chisel and mallet, because the fracture causes a simple breach, while the saw destroys substance between the fragments. The relation between these lesions is the same as between an incised and a ragged wound. The former, if taken under a microscope, will also appear as ragged and lacerated, but the necrosis between the two borders will be much smaller and the substance thrown off much less; the wound healing process, therefore, more simple than in the latter. From this standpoint, I would prefer a chisel and bone-cutting to trephining.

The plastic of this group is done in the following way: The bone is replaced from where it has been

taken, more or less unchanged. In many cases, in fact, these bone fragments, though without periosteum have healed in, and there are numerous observations where they have healed in, not in the manner of foreign bodies—that is, encysted—but with perfect integrity of their substance. They have the great advantage over other foreign bodies which are used in their place, in that they have perfect diploëtic circulation which readily takes in the blood from the neighborhood, as well as many openings in the table for new vessels from the dura. Fragments of fractures have very often some connection with the periosteum, and should therefore not without consideration be torn off or out, but carefully adapted, their periosteum sutured, and the condition rendered as much as possible similar to the condition before. To cut the little fragments into small pieces—little chips—may, at the same time render the nutrition easier, because the plasmatic circulation might get harder through a large chip than through a small one but on the other hand, it might endanger the life of that little bone chip altogether, and the chip might cause an irritation which not only causes this one chip to suppurate out, but also prevents the others from taking good strong hold, as I have observed in a case where I used all bone chips, replacing them as nicely as possible; they suppurated all out.

3. *Transplantation of Bone from other Parts of the Body.*—There are two possibilities again: *a*, transplantation from the neighborhood; *b*, from a distance.

a, Transplantation from the neighborhood, or the so-called autoplasty by the slide of Koënic's which gives so far, splendid results. The method is best described by the following history of a case, whose picture, before and after the operation shows the result:

Bert Bereman; painter; Cook County Hospital, February, 1894. Eighteen years ago this man was struck on his forehead by a rotating crank, and a piece of his skull was chipped out. He was taken to a hospital and a piece of bone, one and one-half inches in diameter removed, and the defect simply left to heal by granulation. A cicatrix which was closely adherent to the dura showing marked depression was the result of this operation. From that time on, the patient had attacks of epilepsy—as frequent as one hundred in a day—and lately so many that he sought refuge in the hospital for surgical cure. The condition before the operation is shown by the photograph. (Fig. D. Photo 3). It was thought that the cicatrix adhering to the dura, and possibly to the brain substance, was the cause of this epilepsy and I decided, therefore, to relieve this scar by dissecting it down to the brain and covering the defect with bone. The scarred tissue was excised at first with the surrounding healthy skin, to the extent shown by the white semi-circular line on the picture. In the center of the free dura mater was a splinter of bone, vertically inserted, which was removed. The incision into the dura was made and the brain underneath inspected. It was found that it was in no place adherent to the dura; that the thin arachnoidæ were whitish and opaque. The blood vessels of the pia mater were somewhat congested but no other pathologic change. The dura mater was therefore, sutured up again, and a flap formed exactly in the manner of Müller-Koënic's suggestion of scalp, periosteum, bone, which was slipped over the defect, implanted carefully, and carefully adapted. A pear-shaped defect with bare diploë was on the place from where the flap was taken. (See Fig. E.) This defect was covered by a free flap which was dissected from the leg of the patient and quickly sutured.

The patient had no attack of epilepsy for a number of days. Müller-Koënic's flap healed by primary union, and so did the free flap, except in its central part, where it sloughed out in the following manner: The borders of the free flap to about one-quarter of an inch, were rose-colored on the second and third day; the central part somewhat paler, but during the following three or four days this central part acquired a pink color. The superficial layers of epidermis

were thrown up by exhalation and a wine-colored fluid formed vesicles; necrosis of the epidermis. While the borders acquired a more and more healthy appearance, the central part grew more and more cyanotic, and after about two weeks, it had all the appearance of necrotic tissue to about one-quarter of the thickness of the flap.

To resume, I would say that the central part of the free flap sloughed out, but not to its whole thickness. Thiersch grafts were used to cover the granulating flap. The epileptic seizures recurred, and the patient left the hospital only slightly improved. The bone flap has grown firmly on its place, and the original depression and defect are filled out with bone.

b. Transplantation from a distance. Such transplantation can be either that of bone, periosteum or cartilage.

Periosteum and bone have been taken from the tibia and transplanted with success. The use of cartilage has been suggested by Sacchi, but so far only done on dogs.

PHOTO. 1.—Josie Chensik, 30 years old. Nekrosis cranii (granuloma supra dur. last?) defectus cranii sxt. Before plastic op.

In the Royal Academy of Genoa, on April 23, 1894, Sacchi reported that he had used cartilage bone plates from the epiphysis of a large young dog, into the defect which had been caused by trephination. The plate is implanted two days after the operation, so that the bony part lies on the dura, while the cartilage is underneath the scalp. In three cases in which this procedure has been used, it held in without fail and a complete firm covering accomplished.

4. *Heteroplasty*.—That means the transplantation of substance from outside of the subject that is operated upon. This substance might be from a living subject (which has been denoted as heterobioplastic), or it might be an inorganic body (heteronekroplastic).

From the experiments and conclusions of later date (Barth and others) we can judge that there is not much difference whether we transplant from a living

subject or an inorganic substance. Both are encysted, and if they heal in aseptically, the only difference that can be noticed is, that the organic from the living subject is encysted with much more difficulty than the inorganic. The reason is very simple. The organic substance has to undergo great changes of nekrobiosis while it is implanted, and it is a much more complicated pathologic process to carry away decaying substance, to assimilate living substance of a different composition and histologic texture, than to surround with a network of proliferating cells an entirely unchangeable foreign body.

The experiments which have been made to ascertain the possibility of healing, appropriate for living substance from a different species into the human, are manifold. During the period of aseptic surgery, bone plates especially have been used to cover defects. McEwen has taken the parietal bone with the center of ossification and periosteum of a six-weeks-old dog to cover a defect of the skull. Ricard and Schmitt, have repeated this experiment. The bone plates of a goose's skull have been used by Jacksch and Kapper to cover defects with, they say, good results. But the instances are too few and besides the cases could not be analyzed afterward, to refute the objection that these plates have been disorganized, re-absorbed, and new bone, calcareous deposits have taken place on the previous defect. Chipault questions the possibility of implanting a living heterobioplastic graft and, I would say, rightfully. The very instructive history of the Case Chensik will prove the impossibility to graft a large living substance;—if we can say *living* for a substance that has been taken away from the organism; we might rather call it organic:

Mrs. Josie Chensik; 30 years old; employed in housework; German; widow; has had one healthy child. Husband, as far as she knows, had been healthy. Up to July, 1883, she enjoyed good health. In July, she noticed a swelling on the right side of her head, which grew considerably and finally broke, discharging a large amount of pus. During the same time an eruption on the skin set in, which disappeared shortly afterward leaving no marks. The swelling caused no pain. The opening where the swelling broke enlarged to the size of a 50-cent piece, leaving the bone bare. The neighborhood of that bare place was discolored, and shortly afterward two other places of the same size had sloughed, so that when I first saw her at the Charity Hospital December, 1893, I noticed three ulcerations on the right side of the parietal region, all of the same size. The skin around them discolored, the bone lying bare, and black from use of bichlorid washes. The bone was apparently necrotic, perforated by a hundred little holes of pin-head size, through which came pus of a very disagreeable odor. This was her condition, and made the patient very offensive, nobody being able to bear her presence. In every other respect she was healthy. There was no trace of syphilis; no tuberculosis in her family. On January 23, she was taken to the Post-Graduate Medical Hospital. Temperature 99.2; pulse 102; the wound discharging considerably; strong odor.

On January 26, operated; ether narcosis. The assistant was Dr. Marie White. The head prepared as usual for brain operations. The scalp, as far as it was discolored, removed, together with the periosteum. The bone underneath looked yellowish white; apparently necrotic. After chiseling away and gouging away the necrotic bone, which was of different thickness and arched inside, a tumor of the appearance of a granuloma presented itself, extending underneath the necrotic bone in ante-posterior direction about four inches; thick in the center and tapering toward all sides. This could be easily peeled off from the underlying dura, except in its central part, where it was quite coherent with the same so that a part of the thickness of the dura had to be removed together with it. However, it did not go through the whole thickness of the dura mater. The bone was gouged away beyond the borders of this, until it was bleeding freely, which symptom showed that it was living bone. There was no demarkation of living and necrotic bone visible. After

these maneuvers, the defect in the scalp measured five and one-half inches by four inches; the bone defect, about one-half inch smaller. The dura mater showed marked pulsation and threatened at times to break through on the thinned portion. The wound was dressed with iodoform gauze, and the patient put to bed. Operation lasted two hours.

Remarks.—From the appearance of the thickened bone and that granulosomatous mass, I was inclined to believe that I had to deal with a syphilitic process, but the microscopic examination left me in doubt. The specimen showed a large amount of spindle cells and new embryonic cells, and even for the well educated eye of a microscopist it would be hard to decide whether the specimen is spindle-celled sarcoma or granuloma. Clinically, the case seemed a syphilitic process; microscopic examination indicated sarcoma. The decursus for the next twelve days, was that of a normal wound healing. Healthy granulation covered the dura and the patient was doing well. Daily dressing. The question arose, how to cover this large defect. The picture which was taken about this time, shows the sloughs that remained after the use of Esmarch's bandage to save blood. (Photo 1).

On the thirteenth day, a second operation was performed,

PHOTO 2.

and an attempt was made to cover the defect by the method of Müller-Koönig's scalp periosteum bone flap. A large skin flap was formed, periosteum incised, and with the chisel an attempt was made to separate the upper table to the extent of the defect, but after hard work of an hour and a half it was seen that this attempt was fruitless, the bone being as brittle as glass and falling off the periosteum; the bone not of the same condition as a healthy bone through the whole scalp; it seemed porous (hyperplastic osteitis). The flap was sutured therefore on its old place again, and the patient put to bed. The healing was by primary union. Again two weeks passed, and the attempt was made to cover the defect by heteroplasty. A dog's skull was shaved and aseptically prepared. Scalp, periosteum and bone flap, to the size of the defect were removed, but when the trial was made to place the same into the defect—whose granulations were thoroughly scraped—it was seen that the very uneven inner surface of the dog's skull would bring about a very dangerous irritation of the dura and the experiment was abandoned. Two days afterward another attempt was made. At

the suggestion of one of my friends, I tried a more even surface; the same being given by the inside of the ribs of a very young dog. A flap, consisting of skin, muscles, ribs (cartilaginous portion), which were very close together was dissected out, the pleura removed, the dura mater of the patient thoroughly scraped, and a fresh flap of the dog, with the raw surface of the perichondrium of the ribs implanted, and the perfectly approximated borders sutured together. No rise in temperature consequent upon the operation, but on the third day, a very offensive odor indicated that the flap had become partly necrotic, and though some portions of the same seemed to indicate a close coherence and some vitality—bleeding when removed—I was obliged to abandon this experiment, to remove the flap.

The patient, though better, left the hospital on the forty-third day, the defect being protected by a firm dressing, but shortly afterward she returned again, being afraid to do the slightest work from fear of perforating the thin membrane covering her brain. Nothing seemed to remain to be done but to cover the granulomatus dura with Thiersch's grafts, giving to it at least a covering of skin. It had to be scraped again, and the Thiersch grafts took wonderfully. For four

PHOTO 3.—Mr. Bert Bereman. Epilepsia traumatica, typ. irreg. Defect, cranii indent. trepanatis taris. Plastic op. (Müller, Koenig, Wagner) with plastic of a large free flap upon denuded surface.

weeks the patient remained in the hospital, after which she returned home. By so often scraping the dura, as we did, this membrane seemed to acquire such a thickness that it seemed to me to give more protection against insult than ever before. The patient came at regular intervals to my office, giving me the chance of watching the remarkable process of regeneration of bone between the Thiersch grafts and the dura. Each graft looked like a fish scale, and that it was not retracted, connective and hardened tissue which gave this firmness, was shown by an incision in two places within the boundaries of the previous defect where I could remove two particles of bone which had newly formed. These little scales of bone closed together and at present the defect is covered to two-thirds of its extent with true bone. There is yet some movability between these plates, but gradually less and less, and the bone is getting unevenly thicker, too, as can be seen on the photograph which gives the final result. (Photo 2).

Resumé.—We had to deal here with a post-operative defect of the scalp, which had closed by reproduction of bone over the dura mater, which has acted here as true periosteum. This repair of bone might be due to that irritation of the dura which has been caused by the frequent scraping of the same.

a. The only possible, but, as it seems for larger grafts, imaginary change of such grafts seems to be the hypothetical possibility to engage circulation through preëxisting channels and use the preëxisting bone structure for protection. But rarely such a circulation in an efficient manner would be established, and decay of even such a tissue as bone, that does not require very much nutrition, would take place and it would be exfoliated, if not re-absorbed. I would therefore, reject, *a priori*, the use of any animal grafts for covering of bone defects.

b. A transition from the animal graft to the entirely inorganic, is the graft of decalcified bone. Kümmer has used such decalcified bone, the preparation of which for this purpose is well known (1891). The very extensive, very careful researches of Dr. Senn about the use of decalcified bone plates and decalcified chips as filling material for cavities of bone, would suggest this material for plastic processes on the skull if they would not share, more or less, the disadvantage of the previous material—the animal grafts. Decalcified bone is, in some way, a substance that can be re-absorbed. It may leave particles which are furnished with new circulatory vessels and therefore encysted. They might become the seat of calcareous deposits but they might be absorbed entirely, and they might act, by decay, as irritating material.

c. The oldest methods, that of transplanting entirely inorganic metallic plates, have been used in some cases on a human. With best results has been used a material that has been recommended by Fraenkel in 1890, and since that time used by Eisensberg, Hinterstoisser, Berger and Potemski. That is the celluloid plate. But inasmuch as this celluloid plate in some cases has been exfoliated or had to be removed on account of accumulation of pus underneath, and inasmuch as it was rather irksome to form and cut a plate exactly corresponding to the defect, it seemed to me worth while to go into some detailed experiments in this direction, the results of which I will now communicate.

In No. 9 of the *Centralblatt für Chirurgie*, Martin of Köln, has reported some experiments of filling cavities of bone with dead material. He used plaster-of-paris and gutta-percha for filling of bones. I have, according to his experiments, used these two materials and some others to fill out defects of the cranium.

Experiment 1.—Plaster-of-paris powder which has been exposed to dry heat in a test tube was kept ready. At first a plate of about half an inch square, on a dog's parietal bone, was chiseled out. This defect was filled with plaster-of-paris, which soon formed, with that slight moisture of the transudation from the defect, a very hard cover which not only filled out the defect perfectly, but also was immovable from the first start, so that when the periosteum had healed over it, it looked almost as normal as before. There was no reaction of infiltration in the neighborhood of this defect. The experiment was made the end of March, 1894.

Experiment 2.—A dog was operated on in this man-

ner: A one-inch square defect in his parietal bone was chiseled out. Gutta-percha plate, as it is used by dentists, was heated in a watch crystal and pressed in, filling out the defect in every pore of the bone, the periosteum drawn over it and the wound sutured. Three weeks afterward, the dog was killed and the following was found: The dura mater on the inside did not show any difference. When drawn off the bone it was found that the plate of gutta-percha had a smooth surface covered with very fine membrane of connective tissue, through which the color of the gutta-percha was transparent. From the outside through the skin, the place could hardly be felt where the gutta-percha was implanted. Encysting structure of fresh connective tissue seemed to have formed between the periosteum and the plate, the result of the implantation or filling being as satisfactory as possible. The plate had been made aseptic by heating before use.

Experiment 3.—A dog operated in the same manner as the first one; an accident produced a heavy hemorrhage from the sinus longitudinalis, which seemed to be uncontrollable. The dog had lost considerable blood, when I employed the filling of plaster-of-paris, which formed, with the blood, a crust that hardened, and checked the hemorrhage in this way. The periosteum was drawn over and the dog, which seemed to the spectators, almost dead when taken off the operating table, rallied wonderfully and is still living. The plaster-of-paris healed in five weeks after the operation.

Experiment 4.—A dog operated in the same manner as the second one; a large defect of an inch and a half square produced and filled by gutta-percha plate. The result is union, the plate encysted and healed; the dog still living. Details since the operation, same as in Experiment 3.

Experiment 5.—Large dog operated in the same manner as Experiment 3, the defect filled out with sealing wax; primary union. The sealing wax encysted; the dog still living.

From these few experiments which gave so uniformly good results, I am very much encouraged to use the materials just mentioned—plaster-of-paris, gutta-percha, sealing wax, celloidin—for plastic purposes in the human in future. They have the advantage that they can be made perfectly aseptic, can be easily procured and always ready, can fill out the defect perfectly and without leakage, and give strong enough protection. The indications in regard to material and method of plastic on cranium, I would formulate in the following manner:

a. Autoplastic is to be used preferably in all possible cases. There should be removed as little as possible of the cranium, and temporary resection in the most efficient way be preferred to any other proceeding.

b. In case of the impossibility of autoplasty, heteroplasty with gutta-percha or plaster-of-paris might be used to great advantage.

c. In rare cases, bone is formed from the dura mater, but we should not rely on such occasional possibility.

Woodman, Spare that Tree.—The Forestry Association of Wisconsin has taken steps to actively push their bill to save the Wisconsin forests. The proposed bill provides for the withdrawal of all forest lands from sale, and will place certain restrictions on cutting timber.

HYDROPS ARTICULORUM INTERMITTENS— REPORT OF A CASE.

Read before the Shelby County (Ind.) Medical Society, Oct. 8, 1894.

BY SAMUEL KENNEDY, PH.G., M.D.
SHELBYVILLE, IND.

I desire to report to this Society a case of hydrops articulorum intermittens. It is a rare disease, as but thirty-three cases previous to this one have been reported, and of these but three were in America. Thus it will be seen that this is the fourth case so far reported in this country and the thirty-fourth on record. The fact of its great rarity makes it all the more interesting, and consequently I have watched this case for many months with intense interest. It is also interesting from the fact that it had been seen by several physicians and invariably pronounced rheumatism. The usual remedies, such as the salicylates, wine of colchicum and other anti-rheumatics, had been administered, but wholly without beneficial results.

After obtaining a detailed description of the case, and making a careful examination, I concluded that it was at least *not* rheumatism. I was for some time at a loss for a diagnosis, but immediately began to look up the literature on this class of diseases, and at last concluded that it could be nothing but intermittent dropsy of the knee-joint. The symptoms in all the cases so far reported are so remarkably uniform that it precludes the possibility of a mistake in diagnosis to one who has become familiar with them.

Excellent articles appear upon this subject in the "Reference Handbook of Medical Sciences," Supplement, page 484, by William Barnes, and one in the *Medical Record* of June 16, 1888, page 657, by A. H. Fridenberg, of New York. Dr. Fridenberg reports two cases and Dr. Barnes one. These with the case I now report, are the *only ones* reported in this country.

Dr. Barnes says: "There is a remarkable uniformity as regards the symptoms in all the cases, they forming a clinical picture so characteristic and typical as to leave no doubt of the diagnosis in any well developed case. The patient notices a slight swelling in one of the larger joints, usually the knee, and perhaps has his attention drawn to it by a feeling of tension or of discomfort, uneasiness, insecurity, or wobbling in the affected part. This rapidly increases, so that usually, in from twenty-four to thirty-six hours the joint is so swollen as to seriously interfere with, if not to entirely inhibit, the normal functions. In a short time, usually a day or two, the swelling begins to subside and in from twenty-four to thirty-six hours more it is entirely gone, leaving the joint to all appearance in as perfect and healthy a condition as before. After an interval of perfect freedom, the swelling again appears and the same phenomena are repeated, and so on for an indefinite period of time. There are no premonitory symptoms or signs indicative of the disturbance. The patient may be and usually is in his customary good or bad health as the case may be. During the attack there are in most cases no signs of constitutional disturbance; the normal functions of the body remain undisturbed. In two cases, those of Bruns and Pletzer, there was a slight rise in the temperature during the initial attack, but not afterward, while Perrin reports a case in which each attack was preceded by slight chills, followed by slight fever ending in perspira-

tion. Simultaneously with this there was a contraction of all the flexors of the upper extremity, also a painful prickling in all the joints of the same limb. A few hours later the swelling began, and with it the above phenomena gradually disappeared."

Dr. Fridenberg says: "The question as to the nature of this interesting disorder can only be answered in a general manner. We need not hesitate to look upon it as a neurosis of vasomotor origin. But we shall be at a loss to define its exact pathology, and even an approximate idea of the seat of lesion can only be a matter of conjecture, not only on account of the imperfect state of our knowledge of the vasomotor origin and distribution, but because no case has so far reached an autopsy. This much we are justified in concluding: Knee-joint swellings are of vasomotor origin. They must be produced by serous exudation from the capillaries of the synovial membrane. In the absence of any permanent disability or injury to the joint or involvement of the deeper structures, we may assume a non-inflammatory change in the vascular blood-pressure and consequent dilatation of the arterioles, due either to stimulation of the dilating or paralysis of the contracting vasomotor nerve-fibers in the vessel walls. As the vasomotor contraction or tones of the arterioles is the more constant and uniform, this latter is probably interfered with or inhibited. Thus dilatation of the capillaries persists, permitting active transudation. When the lost influence of the nerve function is reëstablished, the vessels resume their normal tones, and the equilibrium between secretion and reabsorption is readjusted. The excess of fluid is absorbed as rapidly as produced. This exudation is not of an inflammatory nature. The pain and disability are due to a rapid mechanical distension of the capsule only. It is therefore a passive dropsy, and its transitory character a clinical reflection of a similar process in the nerve centers.

"We can hardly picture to ourselves pathologic changes in the central nervous system of a transitory nature, otherwise than as the result of a disturbance of the vascular supply of the area involved, leading to exudation, edema, and compression of the surrounding nerve tissue. Vasomotor disturbances are characterized by rapid changes in the caliber of vessels, thus favoring local congestions or ischemias. These central changes must be supposed to subside spontaneously, or be in some manner checked, before developing sufficiently to constitute a permanent lesion.

"Can such central disturbances produce joint swellings? When we consider the intimate connection of arthropathies with certain forms of organic spinal disease, with which we have become familiar through Charcot, Weir-Mitchell, Esmarch, Shaffer and Gibney we need not doubt the occurrence of temporary joint disease as a possible consequence of transitory central disturbances. Long before Charcot's writings, Dr. J. K. Mitchell, of Philadelphia, cured a persistent case of subacute 'rheumatic' synovitis in a woman with an angular curvature, after failure of all the usual remedies, by treatment for spinal inflammation. He subsequently treated three similar cases with the same success. He concluded to regard rheumatism as a spinal neurosis.

My case of this interesting and rare affection was met with in Mr. James B., a day laborer of this city. He is an American, having been born and raised in Indiana, and 33

years of age. I was first called to his house upon Sept. 5, 1892, the person (his wife) coming after me stating that he had a "bad case of rheumatism." Upon catechising both the patient and his wife, I elicited the following history: About four years previously he suffered his first attack in left knee, but not in a very severe form. He recovered entirely in four or five days, but has been having similar attacks every twenty-four days since. He said each attack would last from three to five days, the knee become swollen and very painful. He has always had good health with the exception of this trouble. I have now seen him have twenty-five attacks since the first one. The left knee becomes very much swollen and edematous and he suffers excruciating pain. Upon each and every examination I have found fluid in the joint by fluctuations and a floating patella. During three days of each attack he is compelled to lie in bed, and every movement of the knee causes an exacerbation of pain. The effusion is intra-capsular. Each attack now lasts exactly five days, being worst on the third day and gradually subsiding by the fifth. He has a similar attack just twenty-four days from the last day of the previous attack, and they now recur regularly every twenty-four days. During the twenty-four days' intermission he is absolutely free from any trouble with the knee and attends to his work of ditching regularly, except during his attacks.

During the time I have had charge of the case he has had no trouble with any joint except the one mentioned. He can foretell the approach of an attack to the day and almost to the hour, but he says it is by means of sensations that are impossible to describe.

Regarding treatment, I might say he has taken quinia, iron, strychnia, cod-liver oil, ergotin, carbolic acid, electricity, sodium salicylate, sulphur baths and other remedies too numerous to mention, but all with no apparent benefit. Soon after making my diagnosis, I informed the patient of the nature of the affection, and that it would probably take several years to cure him, if at all, and by this means I have been able to keep the case under close surveillance. So far as I am able to learn, there is no trace of syphilis in this case.

In closing this report, I desire to say that I shall try and keep the case under observation and report to you any progress, if any is noted.

79 East Franklin Street.

A CONTRIBUTION TO THE KNOWLEDGE OF BACTERIOLOGIC CHEMISTRY.

Read in the Section on Materia Medica and Pharmacy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY W. T. WENZELL, M.D.
SAN FRANCISCO, CAL.

In the year 1865 a German chemist named Marquardt made the discovery that during the putrefaction of animal matter, a substance was formed which bore a close resemblance to an organic base or alkaloid known to reside in the leaves of the spotted hemlock (*conium maculatum*) known by the name of coniine.

Schwanert, found very soon after, while pursuing a similar investigation of the intestines, liver and spleen of a child who had died suddenly, an organic base which he separated by the Stas-Otto process, and also by a similar search in the human cadaver, a sufficient amount of the alkaloid to enable him to determine its nature. He found that it possessed strongly basic properties, that it blued reddened litmus paper, that it was neutralized by muriatic acid, and that it was precipitated by alkaloidal reagents such as chlorid of platinum, chlorid of gold, iodo-iodid of potassium, phospho-molybdic acid, etc.

To these organic bases Marquardt gave the name septicines, the name indicating their source, being derived from the Greek, "septicos," the literal meaning of the word being to make putrid. In 1869, Bergmann and Dragendorff conjointly confirmed the discovery of Marquardt, but also announced the existence of a second alkaloid in putrid flesh, which was not volatile as the alkaloid first discovered by Marquardt, but was a solid substance crystallizing in the form of needle-shaped crystals. It also responded to the usual properties and tests for organic bases, and physiologic tests instituted with it demonstrated a decided mydriatic effect on the eye, and when introduced into the circulation an increase in the action of the heart was observed, and also a cessation of the peristaltic action of the bowels was noted.

In 1869 two cases of suspected poisoning occurred in Italy, where chemist experts claimed to have found morphin in the body of a lady and delphinin in that of a man. The authorities not being altogether satisfied with the results of the analysis referred the matter to Professor Selmi, an eminent chemist in Turin, by whom it was shown that the alkaloids in question were neither morphin nor delphinin, but that they were cadaver alkaloids analogous to those announced by Marquardt ten years before. Ignoring the claims of priority by Marquardt, Professor Selmi saw fit to change the name of the bases formed during the decomposition or putrefaction of flesh, to ptomaines, the Greek for a dead body or cadaver, a name which has since been exclusively used, for all organic bases derived from this source.

The relations which are at the present time known to exist between bacteria and cadaver alkaloids may be considered as fully established, much of which is owing to the indefatigable researches of Dr. Brieger, who announced that poisonous ptomaines were generated during the growth of pathogenic bacteria. He divided the ptomaines into two classes, toxins and non-toxins accordingly as he considered them derived from pathogenic or non-pathogenic organisms.

Without entering into the subject of the various ptomaines found by Brieger, Selmi, Gautier and others in decomposing animal tissues and animal fluids, it may be well to say that although the bacilli of anthrax, tetanus, tuberculosis, septicemia, the streptococcus of erysipelas, and the gonococcus of gonorrhoea, etc., have been thoroughly studied by bacteriologists, and propagated, yet ptomaines and other products generated during their growth, have not received the share of investigation which their importance demand.

So far as this subject has come to my knowledge, the isolation of ptomaines, has been effected principally, if not altogether from the animal body and putrefying organic substances, and no attempt has been made to ascertain if an organic base is invariably a concomitant of bacteriologic culture. Not only this, but we should also direct our researches, in order to determine, if possible, whether the product of such culture will always give rise to the same identical ptomaine.

The writer must admit the difficulties by which he is confronted, arising in a great measure from the fact that, according to the present state of our knowledge, it is a difficult matter to distinguish even between the ptomaines obtained from well-known pathogenic bacteria. However, we should not be discouraged by these drawbacks, which are inseparable from all

newly developed sciences; but rather hopefully and trustfully look forward for future success. It has been the good fortune of the writer to enlist the coöperation of Dr. Silas Mouser, of San Francisco, whose superior ability and unswerving enthusiasm as a bacteriologist stand unquestioned, to obtain from him such pure cultures as may be required for these investigations. The products of these cultures as usually obtained from tube-cultures, are exceedingly small as to quantity, therefore the work must necessarily be both microchemic and microscopic in its character.

Tube-culture of the Fungus Actinomyces Pathogenic—found in the animal body and course of analysis.—The culture was carefully removed from the culture medium and macerated in water at a temperature of 50 degrees E., to remove adhering particles of the gelatinous culture medium. This process was repeated until the water ceased to give a precipitate on the addition of tannic acid. To this water which held the spores of this fungus in suspension, some sulphate of barium was added and the mixture passed through a filter. The spores with the sulphate of barium remained on the filter, the barium salt being used to stop up the pores of filter to prevent the spores from passing through. The filtered liquid was then tested with the usual reagents for the detection of alkaloids, but with negative results.

The fungus after its treatment with water, was then macerated in ether-alcohol (2 parts ether and 1 part alcohol) for twenty-four hours. The yellow color of the fungus was mostly taken up by this menstruum communicating to it an orange color. On concentrating this solution by the aid of a gentle heat; on cooling, nearly the entire amount of yellow coloring matter separated as an orange-colored flaky substance which was collected on a filter and washed with a small quantity of alcohol. The yellow coloring matter thus obtained proved insoluble in water, sparingly soluble in alcohol, but very soluble in ether and in chloroform. Attempts to obtain crystals from its ethereal or chloroformic solution met with failure. The substance was insoluble in 10 per cent. solution of caustic potassium. When treated with strong nitric acid the yellow color was changed to a blue; exposure to day-light caused the yellow color to fade in a short time.

The ethereal solution of this coloring principle is yellow, while its chloroformic solution presents an orange color. In all of the above stated properties, this coloring agrees with lutein, the coloring matter of the *yolk of eggs*, and which is also found according to Hahn and Staedeler in the *corpora lutea*. On making a spectroscopic examination of this yellow coloring matter, it was found that its absorption spectrum exceeded that of the lutein of yolk in length, and while the chloroformic solution showed only one absorption band, beginning at the Fraunhofer line *b*, causing the absorption of a part of the green, the blue and the purple rays of the spectrum, the spectrum of lutein will be seen to have three absorption bands, one covering the line F, another band situated nearly midway between the lines F and G, and the third band commencing with the line G, and continuing to the end of the spectrum. However, there is no question but that the yellow coloring principle of the actinomycetes is a physical isomere of lutein. (See accompanying spectroscopic illustration.)

The alcoholic filtrate, separated from the yellow coloring matter, was concentrated, water being added

to replace the evaporated alcohol, acidulated with muriatic acid filtered from the yellow coloring matter which had separated. The colorless solution thus obtained was tested for alkaloids as follows:

Mercuric chlorid gave no precipitate.

Platinic chlorid gave an orange precipitate.

Potassium ferrocyanid gave a whitish precipitate.

Tannic acid gave a whitish solution in alcohol.

Iodo-iodid potassium, a brown precipitate, soluble in an excess of the reagent.

Potassium iodo-hydrargyrate a white precipitate.

Palladium chlorid, no precipitate, but on evaporation a double salt in the form of a Maltese cross and square plates was obtained.

Potassium ferrieyanid with ferric chlorid gave rise to the production of Prussian blue.

The filter which contained the spores of this fungus, together with barium sulphate, was incinerated with nitric acid to get rid of all of the carbonaceous residue and finally heated to a dull red heat. On dissolving the residue in dilute nitric acid, filtering and adding the concentrated solution to the molybdic solution, a comparatively large amount of the yellow precipitate indicating phosphoric acid was obtained.

From the foregoing analysis it will be seen that the fungus actinomyces contains a ptomaine, a yellow coloring principle isomeric with lutein. And that the spores contain a relatively large amount of phosphorus in an undetermined state of combination, a fact which the author desires to place on record, pending future research on phosphorus and its relation to organic life.

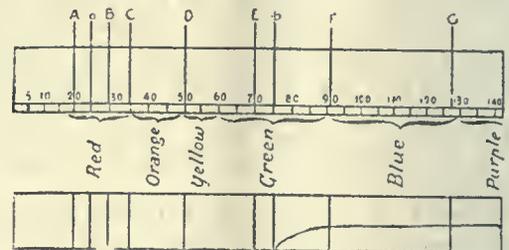

FIG. 1.—Lutein from actinomycosis.

FIG. 2.—Lutein from yolk of eggs.

Bacterium of Green Pus—A Pure Tube Culture.—The culture was carefully removed from the culture medium. On examination the culture was found to consist of a mass of microscopic fibrous crystals, mixed with the bacteria of pus. The crystals were found to be insoluble in water but readily soluble in alcohol. The preliminary examination furnished the means to determine a procedure for conducting the analysis. The entire culture was treated with water in a similar way as the actinomycetes, and for a similar purpose, and aside from testing the filtrates with tannic acid, testing was also made for phosphoric acid by evaporating a portion of filtrate, igniting, re-dissolving in dilute nitric acid and testing with molybdic solution. This last testing was adopted to remove all traces of any substance from the bacteria that might contain phosphorus as a phosphate or in some other organic combination, the ultimate object being a search for phosphorus in the bacteria.

The residue on the filter left after the exhaustion by water of everything soluble in it, was then subjected to the action of ether-alcohol by which a solution was obtained, which when a drop of it was allowed to evaporate on a glass slide and examined with a

microscope was found to leave a residue composed of transparent colorless acicular crystals arranged in stellar aggregations. When platinic chlorid was added to the ether-alcoholic solution, a precipitate appeared, which changed in a short time to yellow octohedral crystals; evidently a double salt of the ptomaine generated during the growth of the bacteria of pus.

The entire bulk of the ether-alcoholic solution was evaporated to dryness and re-dissolved in alcohol for further investigation, when the accidental loss of the solution prevented further work in this direction.

The filter containing the bacteria together with barium sulphate was incinerated and finally ignited and dissolved in dilute nitric acid, the process being conducted similarly as in the case of actinomyces. On applying the molybdic test a sufficient amount of the yellow ammonium molybdic phosphate was obtained to show conclusively that phosphorus in some form is a normal constituent of the bacterium of pus.

THE RELATIONS OF MATTER AND MIND.

Read at the Annual Meeting of the Indiana State Medical Society,
May 16, 1894.

BY JAS. F. HIBBERD, M.D., LL.D.

RICHMOND, IND.

In the near future the most important and useful progress in medicine will be along biologic lines. Biology is the science of living things; in the broader sense covering all vital processes; teaches the phenomena concerning the genesis, the development, decline and death of all vital organisms.

To my mind it is a self-evident proposition that a physician should fully understand the cytogenesis, the morphology, the histology, the anatomy, the physiology and the pathology of man, and as man is a microcosm of animated nature it is but a corollary that a perfect physician must be a thorough biologist.

In the matter of the biology of the human mind there is abroad a great popular misunderstanding, and I am apt to believe that physicians have not given such attention to the relations of matter and mind as to leave no shadow of dubiety in the premises in their own minds.

No student of current mental conditions has failed to recognize the difficulty of accounting for the incongruities of mental manifestations met with in all classes of people, and certainly no physician of experience but has been puzzled in many instances to draw the line between physical disease and so-called mind disorders. Much of the uncertainty in these cases is due to the fact that we have not sufficiently mastered the physics or the functions of the nervous organization in which the mind originates. In this state of knowledge it has been beyond our ability to point out definitely the true relation to hypnotism, to spiritualism, clairvoyance, Christian science, faith cures and a long list of similar disturbances to ordinary normal mental operations. It is my contention that all these are understandable erratic operations of the mind as emanating from the nervous organization, and it is the intent of this dissertation to indicate how I arrive at this conclusion. I beg to premise that in this study the definition of psychology is restricted to its etymologic signification, to-wit, the science of the soul, quite a distinct thing from the somatic mind as herein elucidated, and that in this discussion I do not enter the realm of psychology.

When one attempts the analysis of the relation of matter and mind by a study of it, as it exists in the human adult, one fails of success most signally. The relation here is so involved, its manifestations so diverse, so extensive and apparently so mysterious that its essential nature can not be made out by such a study, and yet this has been almost the exclusive field cultivated by investigators of metaphysics since the time of Aristotle with the constant result of endless disagreements and confounding confusion. Accordingly, for a satisfactory elucidation of this relation we must pass the schoolmen, depart from scholasticism, and make use of modern scientific methods of investigating involved problems, devoting ourselves to seeking the simplest form in which the relation of matter and mind exhibits itself and following its development, step by step, in its ascending scale until it reaches its maximum in enlightened man.

The amœba is the lowest organism that exhibits the essential characteristics of animal life and its genesis is in protoplasm. The amœba is conceded on all hands to be an animal, and I will seek in it the first link of the chain of nervous energy that extends through all forms of animal development up to man, and still continues to extend in man as witnessed in his expanding knowledge and increasing enlightenment. The amœba is a single cell whose habitat is water containing protoplasm, and at rest and not under pressure, is globular. If it desires food it projects from its surface a pseudopod, a finger-like process, from its general substance. If this feeler finds nothing the animal wants, the pseudopod is retracted into the general mass of the amœba. This may be repeated indefinitely and from any part of the cell, and when the pseudopod finds something seemingly suitable to its needs the body of the amœba follows up the pseudopod, and if the something, on examination, turns out to be a morsel of food, laps itself about the morsel, secretes a digestive juice, dissolves and absorbs the nutritious part of it, then unwraps its body and releases the indigestible refuse. When sufficiently developed to procreate its species the amœba divides by fission, making two organisms with identical structure and functions; each of which follows precisely the same career as the parent and has posterity in like manner to continue the family.

Here, then, is an animal of low degree, representing in miniature all the essential phenomena of the most exalted animal creation; *e. g.*, it has volition—it wills to move and at once projects a pseudopod; it has judgment—it meets a morsel of something, seizes and examines it; if found to be food appropriates it, if not food discards it; it has secretion and absorption—it pours out a digestive fluid, dissolves its food into a peptone which it absorbs and assimilates; it has growth and reproduction—it develops by appropriating food, and reaching the procreative stage, divides, creating two amœba. Are not these functions of the amœba all of the essential functions of human beings? Are not the differences between the amœba and man, differences of degree and mode of manifestation and not of kind? Does not the amœba, a single microscopic cell of undifferentiated protoplasm, exhibit in every part of its organism all the attributes that promote the life and perpetuate the species of man who is but a community of untold billions of cells differentiated into departments and organs, such that each function has its assigned cells

to perform every special service? In short, if man is a microcosm of the cosmos, is not the amœba with equal appropriateness a microcosm of the man?

If protoplasm is the blastema of the amœba whence comes protoplasm? To answer this basic query, I must call attention to leading facts in the dynamics of physics operating to fashion the world as we find it, such as will indicate my line of argument. I must, however, confine my rehearsal to some of the more salient points; to recite all that would support my contention would require a volume, while my privileges of time and space will be exhausted in a few paragraphs.

There are about seventy elements that constitute the world, but only a small percentage of them are met with in a simple or uncombined state. These elements the Creator has made up of atoms and has endowed the atoms with ceaseless oscillatory motion. When the atoms of two elements are conjugated under chemic affinity a new substance is formed, wherein each element has lost its distinctive atoms and motions, forming molecules that have their distinctive characteristics. These new substances are subject to the law of chemic affinity and are as ready to conjugate under proper conditions as were their parent elements, and thus these conjugations go on almost *ad infinitum*. These continuing conjugations of atoms and molecules are the effect of a primal law of the Creator impressed upon matter in the beginning, the mandate being that neither atom nor molecule shall ever rest, and by reason of perpetual motion shall work perpetual progress. Every step in this progress modified the environment and every modification of the environment invited phases of the conjugation of molecules not possible under any previous condition. When these progressive conjugations had continued for eons, the face of our globe had reached a condition wherein four of the elements, to-wit, oxygen, hydrogen, nitrogen and carbon combined to form a semi-fluid, slimy mass and this slime was primary protoplasm. The primal law of progress, forcible as ever, wrought modifications in this protoplasm and in time a speck of it segregated and became a cell in which was manifested an advanced phase of matter in motion, known as vital activity, notable in that the cell absorbed surrounding material and converted it into its own substance. This is a point to claim acutest attention. It marks the first step in the operation of the primal law of matter and motion beyond the simple, never-failing conjugation of atoms and molecules whenever conditions favored, and always in definite proportions and with unvarying results limited to the act of union. True, this first step was but a slight departure; the surrounding material from which the new-born cell absorbed its pabulum was the protoplasm from which it was just segregated, which, already cognate, required but slight assimilation to become identical with the cell substance, but, nevertheless, this step was the initial one in the mode of motion in matter that has produced all the marvelous forms and colors and motions of the vegetable kingdom, as well as the still more wondrous developments in the animal kingdom.

The initial cell was without a nucleus and was known as a moner, but the energy creating it continuing, further developments followed, a nucleus was formed, presently more elements were incorporated completing the plasm of the amœba which then appeared. Nor did harmonious progress halt or waver

with the amœba; development continued in it until its congeners were many.

Thus was the amœba born, and further progress of animal organisms to higher classes was by the aggregation of cells in greater and greater numbers and their differentiation into organs and systems for special but associated service. As has been illustrated, the amœba was undifferentiated protoplasm but it had voluntary motion, exercised equally by every part of its body, while in the higher animals motion is the service of the muscular tissue. The amœba had secretion but no glands; in the higher animals are many secretions, each produced by a special glandular structure. It exhibited consentient autonomy in all its parts; this is secured in the higher animals only through the most intricate nervous organization. With the increase of associated cells and differentiation of function in the more than 300,000 species of the animal kingdom, the development of the nervous system progresses *pari passu* with the other systems and, finally, in man it still continues its evolution, at least of function, while all other cognate departments appear to have attained their limits. As a whole, the scale of progress has been uniform—there are no cataclysmic phenomena in biology. There are, however, needs of animals that have caused the cultivation and achievement of special diversions of nervous energy with corresponding development of cells to answer the demand, *e. g.*, the eagle can see its prey from an unknown elevation; the dog can follow a selected scent when mingled with numerous other closely related scents, and so on. Even in different individuals of the same species there are marked divergences from the average normal, illustrated in the arithmetical juvenile prodigy who adds up five columns of four digits each, at the same time, and in the musical monstrosity known as "Blind Tom." All these specialized sense developments are due to the influence of the environment on the direction the primal energy in matter and motion may take when acting through protoplasm.

In the further consideration of the relations of matter and somatic mind, we will abandon the anatomy of the nervous system and study its physiology, adopting the classification of Hulings-Jackson who divides it into lowest, middle and highest levels. The lowest level is the old spinal system of Marshall Hall, composed of centers that preside over the automatic activities of the body. The middle level consists of the motor area of Ferrier and others, in the central cortical region of the hemispheres. The highest level is represented in the anterior and posterior regions of the hemispheres and, like the centers of the other levels is sensori-motor. The centers of the lowest level may act independently of the centers above it. The centers of the middle level can act independently of the highest centers but are necessarily associated with the centers of the lowest level. The highest level is the supreme commandant of the nervous system, but its centers can only exercise physical force through the centers of the levels below it. Its marked distinctness is being the seat of the somatic mind, and the anterior region of the hemispheres is more specialized in this behalf than the posterior, where the mixed motor function predominates.

In this connection it is important to understand that the brains of men differ in form, size and force

one from all others, as the bodies of men differ in form, size and force, one from all others, and in like manner the sundry regions of the brain differ as the sundry organs of the body differ; in short, as there are no two human bodies precisely alike, so there are no two human brains precisely alike, and by the same token no two somatic minds alike.

The mind is made up of departments or sections that usually act in more or less harmonious concert but may, and in truth do often, manifest exalted function in one department and depressed activity in another department, and these varying conditions frequently change under changing environment and stimulation. If we gain a clear concept of these pregnant facts we will have but little trouble in understanding that the occult mental phenomena, claimed as a special endowment of supernal power is simply the unbalanced erratic activity of a perturbed physical brain.

In numerous instances one department of the mind has been exalted, with apparently a corresponding and related depression in another department, and under this condition the functioning of the stimulated center is so intense that it overrides the function of other centers of the highest level, indeed dominates them all to the extent of suppressing all consciousness of every act not under the dominion of the excited center, as *e. g.*, in catalepsy, somnambulism, hypnotism and numerous minor and more transient manifestations during excited passions. In other instances, several centers have undue functioning and together disturb the average normal activity of the mind, inducing hysteria, spiritualism, clairvoyance, Christian science and quite a catalogue of other morbid conditions of varying intensity and duration, covering the superstitions of the world, countless in number and inconceivably discordant in form, extent and direction.

These errors of function of the intellectual nerve cells of the anterior region of the cerebral hemispheres are not always of this gross and distinct character, indeed, generally, they are in the first departure an almost imperceptible step, a mere shading of error, growing deeper and darker in many sad instances, until the somatic mind is entirely obliterated.

The etiology of these erratic phases of the somatic mind is as varied as the manifestations and not constant in any number of them. The physical structure of man is not identical in any two persons and the nervous tissue, both macroscopic and microscopic is morphologically as irregular as other systems; this undoubtedly accounts entirely for some of the defects of function and is a coadjutor more or less potent in many.

The environment is responsible for much that presents in these cases, teaching both by observed example and covert influence. The inmates of a French juvenile institution suffered from an invasion of catalepsy, epileptiform seizures and other neuroses, and the distemper was arrested only by the exhibition of incandescent metal instruments prepared to cauterize the next victim of the disorder. But in no case are such derangements either induced or relieved by the will power of one person over another, except through spoken word or suggestive motion. The greatest misconception touching hypnotism arises from the widely entertained popular belief that a hypnotist can control a hypnotee by will power alone,

whereas it has been abundantly proven that the hypnotist can not influence the hypnotee through the exercise of unassisted will power, but only through present suggestion or previous arrangement.

In the history of the amœba it was shown that the cell exercised the attributes of a living animal by all parts of its protoplasm, and that the development of the higher animals, including man, was by an increase of cells and their association and differentiation into tissues, organs and systems each with special functions. It is, however, important to understand that in the increase of cells and increase of better defined function the individual cells retained something of the original attributes and attitude of the amœba, illustrated in man as in all the higher animals, by the fact that the cells of every tissue select the pabulum for the tissue from the general supply; thus the cells of bone select from the current of blood the material for bone, absorb and convert it into bone; the cells of muscle select the appropriate instrument for muscular tissue and transform it into muscle; and the nerve cells arrest from the circulation only the substances to maintain nervous tissue; and in all these instances this service is performed by virtue of the inherent discriminating energy of the cells independently of the highest, the middle or the lowest levels of the nervous system; this energy being the lineal descendant through protoplasm and the amœba of the primal energy of matter in motion, here, as in all intermediate organisms between moner and man, modified by the surroundings, and harmonized by the higher nervous levels of the system.

In all past time, the origin and nature of consciousness has been the most abstruse problem in metaphysiology. The origin of mental energy in man, inculcated in this dissertation, affords a solution of the problem. Neither the amœba nor the cells of the tissues of man can seize the floating particle of matter, examine it, and decide whether or not it is fit for food without knowing the particle was there and the purpose for which it was examined, and knowing is an act of consciousness. The difference between their consciousness and that arising from the anterior convolutions of the hemispheres is one of degree and not of kind. The former is evanescent, serves its purpose for the occasion and vanishes unregistered; the latter is permanent, always ready for action while the brain is intact and registers its service in the memory.

Do not these converging testimonies focus the truth in the proposition that the somatic mind of man is clearly enough the highest manifestation and legitimate sequence of the operation of the primal law of matter and motion, impressed by the Creator in the beginning on the elements of the earth?

SECTARIANISM IN MEDICINE—DISTINCTIVE FEATURES OF EXISTING MEDICAL SECTS.

Read before the Practitioners' Club, Nov. 26, 1894.

BY EDWIN J. KUII, M.D.
CHICAGO.

The three sects recognized in the community in which we live are the regular profession, the homeopathic and eclectic.

In denoting the regular profession as a sect, I am

conscious of a violation of the meaning of the term, sect. A sect is a body of persons who have separated from others in view of some special doctrine or doctrines. Now, the regular profession has no separate doctrine or doctrines, nor has it separated from anybody.

When you cut off a piece of a dog's tail, you do not cut off the dog from the tail, but the tail from the dog. For it is a fact well recognized by the profoundest experts of natural history, that it is the dog who wags the tail, and not the tail who wags the dog.

The regular profession has been stigmatized by certain apostates as the "old school." The spirit is the same as that of a man who designates the mother who has borne him, and given him life, and nursed him at her breast, and fostered and raised him, as the "old woman."

This idea of decrepitude and senility has been foisted upon the public and is given popular credence.

It appears to me, however, that the old school of medicine is, in spite of its age, rather frisky and vigorous. William Harvey, it must be confessed, has been dead for some time; and John Hunter and Edward Jenner, if they had lived, would unfortunately figure as gentlemen rather advanced in years and with a crick in the back. But, fortunately, the science they have enriched has outlived them.

Science is a mother of unlimited fecundity and vitality. Old as she is, she seems as far from her climacteric as when she was first born. At every age and every year this "old school" breeds new progeny, who bound into the arena and wrest new knowledge from the silence and mystery of the universe. Cruveilhier, Rokitansky and Virchow are her children who stood parent to pathology; Laennec and Skoda to physical diagnosis; Hebra to dermatology; Semmelweiss and Oliver Wendell Holmes to the most appalling menace to maternity; Helmholtz and Albrecht von Graefe, Czernak, Marion Sims, Jackson, Morton and Simpson, Lister, Charcot and Weir Mitchell, Koch and his pupils, each and every one became a leader and builder in his special domain.

The structure of medical knowledge, as that of all knowledge, will never become complete. The infinite vastness of science is its guarantee against stagnation and age. The medical body to which we belong forms a strong and indissoluble brotherhood with the natural sciences. We would defy any body of scientists to lay larger claims than ours upon Helmholtz. He belongs equally to us and to them.

Robert Mayer, the country physician, has given to physics the law of conservation of energy; and it was before a combined body of naturalists and physicians at Heidelberg, in the year 1889, that the much lamented Heinrich Hertz, of Bonn University, proclaimed his wonderful investigations on the unity of the phenomena of light and electricity, thereby giving the most brilliant experimental proof ever recorded in physics of the correctness of the purely mathematical doctrines of Thompson and Maxwell. In this manner does science enrich medicine, and medicine science.

Rational medicine, as we all know, has no dogmatic system and no pope. Whoever gives us knowledge that will bear the test of critical scrutiny is welcome. What we are after is the truth! We do not bow to authority. The rejection of tuberculin was none the less emphatic because Koch fathered it. And Koch, who established a great principle of toxin effect, but

no cure for tuberculosis, took a rest cure in Egypt and sat at the foot of the pyramids and gazed into the eyes of the sphinx.

How different with homeopathy. The stuffed prophet still lives, and his disciples bow before the fetich. Homeopathy stands or falls with its pope. No Hahnemann, no homeopathy! And still, how inconvenient this gentleman has become to his followers. His itch pathology and other paraphernalia have been discarded; his disciples with evasive eyes can be found in drug stores buying ounces of taboed drugs, such as calomel, phenacetin, hypodermic tablets of morphia, etc., etc. The teachings for which their name stands have been renounced, but the name is still carried. And why is this done? Why is it that homeopathy, whose speedy extinction Oliver Wendell Holmes predicted fifty years ago, is still flourishing in this country at least? If homeopathy is a delusion why does it take people so long to find it out? The reasons are manifold but clear. Man is an animal who likes to be deceived. Everybody has a secret love for the marvelous. The marvelous is the most beloved child of faith.

A story is related of a bright young physician who strove for years, honestly but unsuccessfully, to acquire success. He was finally obliged to give up in sheer despair, and to masquerade as a quack. This brought him the success he had failed to acquire by legitimate means.

To most people their medical preference is a sort of physical religion; a religion of the body and of disease. They have the homeopathic creed because their grandmother had it or their neighbors have it. The doctor of their choice may have a lovely complexion or such charming manners, or may be a great light in the church.

"Unfortunately, among the guardians of our morals, the ministers, are to be found the most ardent supporters of quackery in its various forms."

Then most of the calls which physicians receive are for minor ailments, which cure themselves under favorable conditions. Pellets or tinctures of an attenuation, which expressed in figures, exceed the most extravagant vagaries of a demented paralytic, are given under the pretense of effecting a cure. "During the entire course of the sickness, pellets and tinctures are faithfully administered; the attention of the patient is assiduously called to their use and imagined effect, and every improvement in his condition attributed to their influence."

Then there is, as I said before, the surreptitious substitution of rational drugs and doses for the homeopathic ones. The hypodermic syringe, in the hands of the homeopath, requires the same hypodermic tablet for the allaying of pain as we use. The homeopathic surgeon, oculist and obstetrician has, provided he possesses average intelligence, recourse to all the methods used by rational medicine. His affiliation with homeopathy, therefore, can only emanate from dishonest motives. He maligns his parent, disowns his name, but allows the parent to support him. They have been likened to medical highwaymen, who with one hand grasp the throat of the profession and with the other appropriate its possessions. If the theory of "*similia*" were really correct, which it has been abundantly proven not to be, it could be practiced by honest men under an honest name. I can, therefore, not recognize the slightest defense for homeopathy as a sect.

"Hahnemann, driven from the court of science, appealed to the people. His cause has been kept a popular one ever since. His disciples have ever avoided a scientific discussion of their doctrines. In view of these facts, how can an intelligent person or lover of true science countenance homeopathy for a moment? If he does, his conduct is indefensible."

With the riper experience of years of practice I have become convinced, although I once held different views, that such recognition of homeopathy as meeting practitioners of that system in consultation is an indorsement of their absurd doctrines and an inconsistent practice. It is to be supposed, also, that those who thus compromise themselves have some motive other than pure benevolence or tolerance.

It does not bespeak well for the intelligence of the American public in medical matters, that homeopathy has received such general recognition and broad encouragement in our country. In Germany, where the medical profession stands probably on the highest level, a homeopath is so rare a phenomenon as to form a promising nucleus for a dime museum. There are no homeopathic schools in Germany, and but one in Great Britain. In Great Britain and Ireland with their 35,000,000 inhabitants there are but 275 homeopaths. The United States, however, are a perfect hotbed of this quackery. It is computed that one-eighth of our practitioners are homeopaths.

The faith in homeopathy must, therefore, be considered a remarkable anomaly of our century. It is a superstition of equal mental obliquity as the belief in witchcraft, in Perkin's Tractors, in the divine right of kings, in the infallibility of the Pope or in the Democratic party.

We shall now proceed to a consideration of the distinctive features of the last existing medical sect, namely, the eclectic. The very few eclectics with whom I am acquainted wear a long beard and ride down town on a bicycle. An eclectic is, therefore, a gentleman with a long beard, who rides down town on a bicycle. In addition to this he is supposed to treat both by rational medicine and by irrational medicine, namely, homeopathy. Or, in other words, "you pay your money and take your choice."

I can not conclude these remarks without saying some uncomplimentary things about the regular profession. One of the most pernicious practices of the regular profession is excessive medication. Most of us have accustomed the public to consider a prescription the equivalent for a fee. When a patient consults us we are supposed to dive into our pockets for prescription blanks. This absurd practice injures the patient, injures the profession, helps the homeopath and increases the so-called silent majority.

Then there is another point: Those men to whom is intrusted the education of the thousands of young men who are newly created physicians, are not always guided by the highest motives. Our medical colleges are in a large measure responsible for the existence of those medical scalpers who hover around the limbo of our sacred profession under the name of homeopaths and eclectics, or even regular physicians. Our students are graduated with some capacity for good and a great capacity for harm. It was a favorite saying of Billroth's that it was his highest ambition to educate students to such a level that they could not do any harm. "*Non nocere*" is the device which should be inscribed upon the banner of medi-

cine. Raise your standard of medical education and you will crush out medical sects.

NOTE.—I wish to acknowledge my indebtedness to Dr. W. W. Brownling, from whose article, "Modern Homeopathy," I have quoted.

THE DISEASE OF INEBRIETY.

ITS STUDY FROM THE STANDPOINT OF THE EXPERIENCE OF AMERICAN PHYSICIANS OF EMINENCE WHO HAVE WORKED IN THIS FIELD OF RESEARCH.

BY EDWARD C. MANN, M.D.

NEW YORK CITY.

(Continued from page 853.)

HEREDITY.

"In referring to the influence of alcohol," says Prof. Willard Parker, "we must not omit to speak of the condition of the offspring of the inebriate. The inheritance is a sad one. A tendency to the disease of the parent is induced, as strong if not stronger than that of consumption, cancer or gout. The tendency referred to has its origin in the nervous system. The unfortunate children of the inebriate come into the world with a defective organization of the nerves."

There is a class in every community of which we have before spoken, how numerous, it is not easy to say; the inherited mobility of whose nervous organization predisposes them to fall into this diseased condition with an almost positive certainty. "It is a fact," says a recent writer, "that drunkenness or dipsomania is a physical disease, depending on some molecular change in the nerve tissue, the direct effect of alcoholic poisoning; and the 'gemmules' of this tissue, when transmitted, become active factors in the formation of character." "It is important," says another writer, "to keep in view that the person afflicted with a tendency to drunkenness obeys a law of his members more potent than his will."

Heredity, then, is another fruitful cause why the drinking habit continues amid such abundant evidence of its terrible results. In the presence of the facts and statements coming to us from varied and most reliable sources, what appalling dimensions does our subject assume? Well might Dr. Richardson, of London, say in view of them: "The most solemn fact of all, bearing upon the mental aberrations produced by alcohol, and upon the physical, not less than upon the mental, is that the mischief inflicted on man by his own act and deed, can not fail to be transmitted to those who descend from him, and who are thus irresponsibly afflicted. Among the inscrutable designs of nature none is more manifest than this, that physical vice like physical virtue descends in line. It is, I say, a solemn reflection for every man and woman that whatsoever we do to ourselves, so as to modify our own physical conformation and mental type for good or evil, is passed on to generations that are yet to be. Not one of the transmitted wrongs, physical or mental, is more certainly passed on to the yet unborn than the wrongs that are inflicted by alcohol. We, therefore, who live to reform the present age in this respect, are stretching forth our powers to the next, to purify it, to beautify it, and to lead it toward that millennial happiness and blessedness which, in the fullness of time, shall visit this earth making it, under increasing light and knowledge, a garden of human delight, a 'paradise regained.'"

Another cause why drinking habits prevail is found in the ignorance or skepticism of the masses of the people. Notwithstanding the abundant testimony on these points, neither the majority of the medical profession, of the ministers of religion, nor of the public, have hitherto accepted these truths, or regulated their conduct in accordance with them. This ignorance must be dispelled, this skepticism overcome. The experience of man in all ages is that, when the convictions of the intellect are at variance with his habits, desires and appetites, he requires "line upon line and precept upon precept" to move and keep him in the right path. In these views I find my apology for reiterating, as I have done, facts and principles so often and ably stated and demonstrated by others.

Reliable statistics lead to the conclusion that two-thirds of our pauperism, disease and crime have their origin in this prolific source. In the endeavor to form some proper estimate of the far-reaching influences of this agent, we must not forget how nearly the complicated and all-important questions of the prevention and punishment of crime and of individual and social responsibility are related to this subject. They have already attracted the attention of students of medico-legal science, which is doubtless destined to be modified in the future by the study of them. Moreover, in this country, inebriety has already passed into the legislation of numerous States, and the duty of Legislatures in reference to it excites increasing attention. Nor have the annual squandering of six hundred millions of dollars (\$600,000,000), with its harvest of want and woe, and sixty thousand deaths, escaped the notice of statesmen. In the House of Representatives of our Congress, at its session in 1877, an elaborate bill was introduced by a very prominent and influential member, by the provisions of which he hoped to greatly diminish these evils. In Great Britain there has been and now exists, with a quickened activity, an influential association for promoting legislation for the "control of habitual drunkards"—legislation for the aid of institutions based upon the specific views and dogmas upon which our American asylums are founded. In Australia, the Colonial government has already enacted such laws and the home parliament has sanctioned the action. In France, in 1877, *La Temperance* made its appearance, and gives evidence that it will do good work in the cause. These are indications that the minds of the medical profession are taking the true direction and that, relinquishing the errors of the past, many of them are awakening.

The church is awaking to the moral bearing of these questions. Witness the position of the bishop and clergy of Central New York, listening with respectful attention and approval to the teachings of our associate, Dr. Wey. In the city of Buffalo there was a great demonstration, sanctioned and led by the bishop and priests of the Roman Catholic Church, which, if I am not in error, has no precedent in the history of this movement in this country, while Cardinal Satolli is heart and soul for temperance. The vast influence thus exerted we can hardly estimate. In the same city, a few days since, the pastor of a large and influential Protestant church made the following remarks: "In England, where the evil is even more marked than with us, the Established Church, so long indifferent to the danger, has begun to arm herself for the conflict. The clergy are man-

ifesting a zeal never before seen. Canon Duckworth, one of the royal chaplains, and Canon Farrar, among the most brilliant of English writers, have spoken decidedly in favor of total abstinence. For men brought up as they have been, holding the positions to which they have been raised by royal favor, to take this stand, requires an amount of moral heroism which unfortunately but few Christians possess. Never in the history of the great University at Oxford had a temperance lecture been delivered from its pulpit till Canon Farrar preached there a few years ago. When the Church of England is zealous on the subject of temperance we may know that the evil is of gigantic proportions."

Surely, in all these movements, we may find cause for the hope that remedies adequate to the removal of this overshadowing calamity will become universally known and applied. That the American Association for the Cure of Inebriates has already done much to disseminate the knowledge of its vastness and of the methods of its prevention and cure we need not doubt. We may be but one of the forces at work in this cause, but we are far from being an unimportant one. The seed we sow is springing up and must in due time bear an abundant harvest. May we not, then, without the appearance of indecorous self-assertion claim to hold the place—not of "advanced students" only, but also of instructors to those who truly desire to be informed on these engrossing themes; and go on with our appropriate work with renewed diligence, confidence and hope? As certainly as the "good days we look for" shall irradiate the earth, so certainly shall this stupendous obstacle to their advent be taken away; for the era of universal peace and purity can never visit a race debased and embruted by this prolific source of moral and physical degradation. Dr. Mason once said respecting the study of the disease of inebriety: "This is a vast field into which we have entered, and in which we may hope to reap the reward of true laborers; which on high authority, we learn is apportioned in accordance with their sincere purposes and persevering efforts rather than with their success." Dr. Mason was preëminently a "true laborer," and for his zeal, sincerity, philanthropy and perseverance in his efforts for the prevention of the evils of intemperance to his fellow-men we doubt not that he is now reaping a rich reward, and that ere now he has heard the words: "Well done, thou good and faithful servant."

Dr. Geo. Burr, of Binghamton, N. Y., in writing on the "Pathology of Inebriety," thus expressed himself, and his views are worthy of careful consideration and attention: "Inebriety has at length come to be regarded as a disease. Under the names of dipsomania (thirst craziness), or methomania (an irresistible desire to drink), it has found a place in the catalogue of diseases. It is not, however, a new-fangled notion, or a novel idea, to regard the intemperate use of ardent spirits as the result of a morbid condition." Nearly sixty years ago, Dr. Rush referred drunkenness to a morbid state of the will. To effectively treat the subjects of this disease he recommended "the establishment of a hospital in every city and town in the United States for the exclusive reception of hard drinkers." "They are," he remarks, "as much objects of public humanity and charity as mad people." Esquirol distinctly recognizes the existence of a disordered condition of the

system, which leads certain individuals to the abuse of fermented drinks. "There are cases," he continues, "in which drunkenness is the effect of accidental disturbance of the physical and moral sensibility, which no longer leaves to man liberty of action." Dr. Robert Jamieson, of Aberdeen, speaks of the propensity to drunkenness as "a morbid impulse, forming a variety of moral insanity, referred to under the name of dipsomania." In 1833, Dr. Woodward, of the Worcester (Mass.) Insane Asylum, in a series of essays, maintained that intemperance was a disease, and declared, from his own experience in the management of many hundreds of intemperate persons who had committed crimes which rendered confinement necessary, or who were insane in consequence of this habit, that this disease was amenable to treatment, and that "a large proportion of the intemperate in a well-conducted institution would be radically cured, and would again go into society with health reestablished, diseased appetites removed, with principles of temperance well grounded and thoroughly understood, so that they would be afterward safe and sober men." Dr. Isaac Ray, while he was inclined to believe that this condition is the effect of a long-continued voluntary habit, yet affirmed that "there is strong evidence in favor of the idea that they (the pathologic changes) in turn become efficient causes, and act powerfully in maintaining this habit, even in spite of the resistance of the will."

Opinions of a more recent date confirming this view, might be quoted *ad libitum*; but the foregoing are sufficient to establish the proposition laid down that it is no novel or newfangled idea which refers the phenomena of drunkenness to morbid causes and to a diseased state of the system. In considering the subject of inebriety as a disease, we must bear in mind that it is the propensity or desire to indulge in the use of ardent spirits, and not the habit of drinking to excess, or drunkenness, and its subsequent effects upon the economy of the human system that is to be regarded as the morbid condition. A broad distinction must be made between the two. The latter is but the development of the former. The propensity when under the influence of exciting causes arouses the appetite, overcomes the will, blunts the moral sensibilities and makes everything else subservient to its demands. The habit is the natural sequence of the growth and development of the propensity. The one bears the same relation to the other that the eruption of smallpox bears to the contagion of that disease, or the several stages of an intermittent fever, to the poison of malaria. The delusions of the insane are but the morbid phenomena of a mind disordered; so the love of the bowl, and the self-destructive acts of the inebriate are likewise the manifestations of a condition of the organism that may well be regarded as diseased. What is the true pathology of this disease? Where is its seat? Why do men drink? What is the secret of that terrible propensity which impels them to put forth their hand to take the intoxicating cup? To answer these questions fully and satisfactorily requires a degree of knowledge relative to the intricate and complicated operation of his own organism at which man has not yet arrived. That the seat of the disease is much more remote, and that it is more intimately related to the ultimate and more recondite operations of the economy than the opinions which have usually been held would

lead us to believe, we can not but admit; but in what tissue and by what change of structure do we have the first intimation of the morbid propensity to drink? The early stages make no revelations. The unhealthy sensations that first call for alcoholic stimuli make no changes that can be located. As in some forms of insanity, the knife of the anatomist would be unable to reveal the slightest aberration from a normal condition in any of the structures. It is only when the propensity has gained the ascendancy, when the habit of excessive drinking has become established that we begin to find the morbid changes and the anatomic lesions.

A careful study of the phenomena of inebriety, and a just appreciation of its symptoms will enable us, however, to obtain an inkling, at least, of the true pathology of this terrible malady and curse. The more prominent symptoms of inebriety are great nervous irritability or restlessness, unnatural sensations, an uncontrollable desire for strong drink, and a disposition to frequent fits of intoxication from the use of ardent spirits. These all indicate that the nervous tissue is the seat of the morbid influence. The symptoms enumerated are those of morbid sensation, of perverted taste and appetite, of disorder especially in that portion of the nervous mass in which is evolved the desire for alimentary material or hunger and thirst. The disordered sensation and perverted taste are not unlike the emotional and intellectual disturbances that characterize insanity, and more especially are they similar to the hallucinations of the insane, to those impressions made upon the eye and ear, which give rise to sights and sounds entirely imaginary. Disorder of the nerves of taste creates a desire for strong alcoholic beverages which nothing else will satisfy. The same disorder affecting the apparatus of hearing, conveys the impression of supernatural voices or of strange and anomalous sounds. In the morbid manifestations of one we have methomania or drunkenness; in the other we have perversion of the moral sense, homicidal impulse, hallucinations, delusions, etc.

The seat of the abnormal sensations in this disease, according to Professor Reid, is in the encephalon and not in the stomach or in the pneumogastric nerves. This opinion is formed from the fact, which he ascertained, that the sensations of hunger and thirst continued after both these nerves had been divided. . . . In the anatomic structures, then, the seat of the morbid propensity to drink must be referred to that portion of the brain which takes cognizance of the nutritive operations of the body; to the nerves of taste, viz., the third branch of the fifth pair; and to the glosso-pharyngeal, or one of the eighth pair; to the trunks of the pneumogastric nerves, and to their terminal branches upon the mucous membrane of the stomach. It is probable that in the earlier stages, only a part of these structures is involved; but that, as the disease advances and the habit becomes fixed, the healthy operation of the entire apparatus is perverted and changed. In what the morbid condition consists, what molecular changes in the nerve substance are characteristic of this disease, as has already been remarked, has not yet been revealed to us. That there is some such change we have good reason to believe. . . . Of a certain grade of diseased tastes and appetites we have examples in the capricious demands of the stomach in chlorotic females, in certain longings

during the period of gestation, in the voracious appetite often seen in dyspepsia, and in the thirst of diabetes. These conditions are generally transient, or, if persistent they rarely exceed certain limits. Instances have occurred, however, of the grossest excess in devouring slate, clay, chalk and other similar substances by females whose appetites and taste had become perverted by disease. The opium habit, as it is termed, is another instance of morbid appetite, depending upon causes similar to those exciting inebriety; and there are few physicians, I apprehend, who have not witnessed instances of extensive disorder, manifested by excessive fondness for coffee and tea.

There is a natural desire of man for stimulants, which under proper subordination and moderately indulged in, could be a source of enjoyment and pleasure. It is this propensity becoming diseased that causes the uncontrollable desire for strong drink which gives rise to the phenomena, and which entails upon the unfortunate subject of the attack all the evils of inebriety.

Inebriety presents itself under various phases and assumes diverse characteristics. One class of inebriates are termed constant drinkers. In them, the propensity seems to be always present, urging the subject of it to daily indulgence. The use of alcoholic drinks with this class is a continuous habit, and as the disease progresses, in its later stages, every night finds the victim in a state of intoxication. Persons of this class are solitary drinkers. The propensity is not excited by either social or convivial incentives, but the indulgence is caused by an irresistible desire for drink. This form of inebriety is the most obstinate and the prospect of reform or cure is much less than in some others, and it is only by the strongest restraint and the most persistent efforts that any improvement can be made.

Another class of inebriates are subject to paroxysms of drunkenness, with intervals of greater or less duration, when they are entirely free from the habit, and feel no propensity to drink. The attacks are periodical in their character, and in this respect they are not dissimilar to other forms of periodic disease. The intervals vary materially in duration, some lasting only a week, others continue a month, a year, and even longer periods have been noticed. Dr. Van Arden, of Auburn, related to me a case in that city where a period of eight years elapsed before the paroxysm of drunkenness returned. The periodic form is probably the most common. A large proportion of the drunkenness under observation is of this character. The paroxysms appear to be excited by opportunities for gratifying them, such as visits from the country to our larger towns, the frequenting of drinking places, etc.

(To be continued.)

SOCIETY PROCEEDINGS.

Southern Surgical and Gynecological Association.

Seventh Annual Meeting held in Charleston, S. C.,
Nov. 13, 14 and 15, 1894.

FIRST DAY—MORNING SESSION.

The Association was called to order by the President, Dr. C. Kollock, of Cheraw.
Prayer by the Rev. Dr. Campbell, of Charleston.

An Address of Welcome was delivered by the Mayor of Charleston.

Dr. BAODIE, of Charleston, followed with an Address of Welcome on behalf of the local profession, and President Kollock responded in behalf of the Association.

Dr. WM. E. PARKER, of New Orleans, read a

MEMORIAL ADDRESS

On Dr. Warren Stone, which was prepared by the late Dr. A. B. Miles, of New Orleans. He said as Professor of Surgery in the University of Louisiana for thirty-five years, as surgeon to the Charity Hospital for thirty-eight, and as general practitioner from 1832 to 1872, whose experience covered eighteen epidemics of yellow fever and cholera in New Orleans, the name of Warren Stone is impressed indelibly upon the local history of a remarkable period. In his surgical clinics he taught the advanced surgery of the old school. He taught the principles of drainage in suppurative arthritis, in hepatic abscesses and in pyothorax. He advocated resection of the rib to facilitate the drainage in suppurative pleuritis. Whether in operative work or in the liberation of pus he made free incisions. He was among the first in the cure of aneurism of the vertebral artery. In the surgery of the arteries he was an expert. During fourteen years of his work at the Charity Hospital, he labored without an anesthetic. Realizing the difficulties under which he labored, he was ready to welcome the new era in surgery then about to dawn. The lives of many men are mirrored in their books and published papers, but the writings of Dr. Stone give but meager knowledge of his work, or his position as an authority on surgery in the South. No man in the profession of Louisiana was ever so universally beloved as Dr. Stone. In his relations with other physicians he was gentle and considerate; never intrusive or aggressive. Many of the physicians in Louisiana to-day who knew him in life, speak of him affectionately as "Old Stone," and always with some expression of endearment and respect. His position in New Orleans may be compared with that of Physick in Philadelphia, Mott in New York, Lister in London, and Velpeau in Paris.

Dr. J. B. S. HOLMES, of Atlanta, read a paper,

GONORRHEA IN WOMEN.

He said there was no disease that affected women that should engage the serious and thoughtful consideration of the physician more than gonorrhoea. The author then, after quoting Tait and Sinclair on gonorrhoea, said he had no doubt but that many of the chronic diseases of the ovaries and tubes that came under the observation of gynecologists were due to this disease. In the majority of cases the poor woman was ignorant of the fact that she had had or has any specific disease. Indeed, her husband might tell the physician that months or even years before his marriage he was a subject of gonorrhoea, which was cured and had since shown no evidence of a return. The essayist could conceive of nothing more dangerous than curetting the uterus in the presence of immense pus tubes with pelvic adhesions. The drawing down of the organ necessary for curettagge may break up pelvic adhesions and pour out the contents of pus sacs into the peritoneal cavity, which would result in the majority of cases in death to the woman. If her life is saved at all, it will only be done by a prompt abdominal section, with thorough irrigation and drainage of the abdomen. Then why not, in the first instance, when pus is detected, promptly remove it by surgical interference? We then treat the woman rationally and give her the very best and only chance of relief and restoration to health.

Dr. GEORGE J. ENGELMANN, of St. Louis, called attention to the importance of differentiating between latent or chronic gonorrhoea and the acute form of the disease. He does not look upon acute gonorrhoea as a dangerous disease in women, but he does the latent or chronic form. He has not seen serious results from the acute form, but it is the infection which is not observed from a supposedly cured gonorrhoea in the male which produces the suffering in women.

Dr. BEDFORD BROWN, of Alexandria, Va., took exception to the statement made by Dr. Engelmann in regard to the non-danger of acute gonorrhoea in females, and cited the case of a female in which acute gonorrhoea ran its course, terminating finally in fatal nephritis. In this case there was first urethritis, then cystitis, ureteritis, pyelitis, and acute nephritis.

Dr. RICHARD DOUGLAS, of Nashville, thought Dr. Engelmann had sounded the key-note in that there is quite a difference in the infection from acute gonorrhoea and the latent

form of the disease. Infection from the latter was a mixed infection, not only with the gonococcus, but with the streptococcus and staphylococcus also, and that accounts somewhat for the virulence of the trouble. That gonorrhoea is the cause of uterine fibroids, he could scarcely accept, although he thought Dr. Price was the author of that idea.

DR. JOSEPH TABER JOHNSON, of Washington, D. C., said in the treatment of pus tubes the result of gonorrhoeal infection, the very radical suggestion of Dr. Holmes was correct, viz., to resort to abdominal section, as he was satisfied that gonorrhoeal pus tubes were incurable by conservative measures. In addition to the removal of pus tubes, if present on both sides, the uterus should be removed also, because it is through the infected mucous membrane of the uterus that the tubes themselves have become infected.

DR. WILLIAM P. NICOLSON, of Atlanta, said the general surgeon was concerned in the treatment of gonorrhoea as well as the specialist. We are told that a urethra has been inflamed and subsequently restored to its normal condition, and yet years afterwards the man transmits gonorrhoea to his wife. It is hard for him to accept such a doctrine. If a man goes for months and years with a gonorrhoea absolutely producing no effect whatever, if he is not well, how are we to tell him that he is not? We are told by the essayist that gonorrhoea is contracted by the female when there is absolutely no evidence whatever of disturbance in the urethra of the male, or that there is no trouble by which he can propagate disease.

DR. A. M. CARTLEDGE, of Louisville, thought the essayist failed to differentiate between cases of subacute and chronic salpingitis and the cases of acute infection from gonorrhoea. He threw out the suggestion that physicians were not fully conscious of the great prevalence of artificial abortions in young married women of the better as well as lower class, and he believes that in these cases of secondary infection from pathogenic organisms we have a more fertile source for the development of tubular and ovarian disease than from gonorrhoea.

DR. W. E. B. DAVIS, of Birmingham, Ala., considered the disease a dangerous one. The views of Tait, however, in regard to gonorrhoea were extreme. We have a frequent cause of tubal disease in the puerperal state, in delivery at term or in premature deliveries, frequently in artificial abortions, brought about by mechanical means. More or less infection occurs after all cases of abortion, but if the patient is in good condition at the time, she will not be materially affected. If we have a soil that is favorable for the development of septic germs we will get a severe inflammation—a mixed infection.

DR. W. D. HAUGARD, of Nashville, desired to place himself on record as opposed to the removal of the uterus and tubes for pyosalpinx as the result of gonorrhoea, believing that by dilatation and judicious curetting, patients can be relieved of an endometritis produced by gonorrhoea.

DR. JOHN D. S. DAVIS, of Birmingham, Ala., emphasized the importance of using the microscope in connection with gonorrhoea and carefully examining the pus. Experience has demonstrated that the latent effects of gonorrhoea were not always directly due to the gonococcus *per se*, but to a mixed infection; that is, we have an inflammation as a result of the gonococcus, which is fired up by another infection from the streptococcus. When we have a mixed infection we have as a result pus tubes, suppurative peritonitis, and finally death of the patient if surgical interference is not resorted to.

DR. HUNTER MCGUIRE, of Richmond, entered a protest against the doctrine that a man can have gonorrhoea and not get well. As for the idea that a man who has had gonorrhoea should not get married, it is preposterous. He had seen thousands of cases get well and remain so.

DR. HOLMES, in closing, said he was aware that many cases of acute gonorrhoea resulted in no secondary trouble, because they were recognized early and cured by judicious treatment. He wished to be understood as not indorsing the views of Mr. Tait, that gonorrhoea in the male was never cured, but he insisted that general practitioners were often too careless in advising patients to get married who have been the subjects of gonorrhoea.

SOME CASES OF ACUTE INTESTINAL OBSTRUCTION, WITH DEDUCTIONS

was the title of a paper read by DR. A. MORGAN CARTLEDGE, of Louisville, in which he reported six cases, three of which terminated fatally. The author said that the limited number of operated cases reported in his paper, together with an individual observation of probably as many more not

subjected to operation, conform to the accepted belief of the hopeless nature of acute intestinal obstruction unless treated by early laparotomy. While the author does not contend that we can dispense with opium in the treatment of these cases, certainly where obstruction is in the least suspected we should withhold its use until a diagnosis can be made. Certainly the practice of masking every abdominal condition characterized by pain with opium is far too prevalent, and its practice gains additional calamity as surgery advances in knowledge which offers relief of these very conditions concealed by the cloak of opium and ignorance. The practical and cardinal points in avoiding a fatal delay and making an early diagnosis, are to be found in: Sudden abdominal pain; a rapidly accelerating pulse; the vomiting of much more fluid in a given time than is taken by the mouth; the green-tinged character of this fluid; the anxious expression of countenance when no opium has been used, the fact that although enema may be stained by the contents of the colon there is no expulsive movement of the bowels, and the passage of no gas. The burning question now is to educate men to know that action to be successful must be quick; that timely aid depends upon the man who first sees the case; that when a physician from any reason suspects that a patient's bowels will not move, he should drop everything else and center all his time and attention upon that patient. He should not waste his gray matter by trying to determine if it be a probable intussusception, volvulus, band, diverticulum or what not—leave that for the operation to determine; it is the most reliable way to find out.

In the afternoon, the members of the Association were taken on a special train to Professor Shephard's tea plantation and to the Forest Inn.

SECOND DAY—MORNING SESSION.

DR. F. W. McRAY, of Atlanta, Ga., read a paper entitled
HERNIA OF THE DIAPHRAGM WITH REPORT OF A CASE.

The author brought this subject before the Association for consideration, not alone because it offered an inviting field for experiment and investigation, but also because of a recent interesting case where, without warning, he was forced to meet the emergency without time for research into the literature of the subject; and while he was not then sustained by a knowledge of the opinions of the leading authorities, he finds from subsequent investigation that the course pursued was in accord with the recommendations of such eminent authorities as Laennec, Bowditch, Guthrie and Marcy. In the case reported, strangulation had occurred five days prior to the doctor's visit. Had an early diagnosis been made, he feels sure the strangulation could have been relieved and the patient's life prolonged. The opening in the diaphragm was accessible, and he believes it could have been closed with a fair chance of permanent recovery. The case serves to emphasize the necessity for early operation in all cases of acute obstruction of the bowels.

DR. LOUIS McLANE TIFFANY, of Baltimore, Md., read a paper entitled

GUNSHOT WOUND OF THE SPLEEN AND KIDNEY—ABDOMINAL SECTION—HEMOSTASIS BY DEEP SUTURE—RECOVERY.

The patient was a male negro, 20 years of age. Two hours previous to entering the University Hospital, March 21, 1894, he had been shot with a small caliber rifle from a distance of twenty feet, the weapon being directly behind him, and he being erect. His urine was slightly albuminous; the pulse, temperature and respiration normal. There was a bullet wound three inches to the left of the spine just below the last rib, from which blood oozed. After properly cleansing the wound it was enlarged, and it was found that the kidney had been injured and that a bullet had passed onward, presumptively into the peritoneal cavity. The wound was filled lightly with gauze by the resident physician, and Dr. Tiffany was notified. External examination of the abdomen by touch and palpation revealed nothing, not even painfulness. The patient was anesthetized, laid on the belly, and the wound after being enlarged was examined. The upper portion of the left kidney was perforated, and dark blood flowed from the peritoneal cavity beyond. This large wound was filled with gauze, the patient turned on the back, and the abdomen freely opened along the left semilunar line. A moderate amount of blood was free in the peritoneal cavity; no wound of the intestine could be discovered, but the spleen was found perforated, blood flowing freely from the wound of entrance, as well as from the wound of exit; the latter wound, in the concavity of the organ, was slightly the larger of the two. The perforation

through the spleen was about three inches from the free lower border. Unwilling to subject the patient to splenectomy, the essayist attempted to arrest the bleeding in the following manner: A long needle threaded with silk was passed entirely through the spleen, central to and parallel with the bullet track; the long ligature was then tied over the free border of the organ so as to press the surfaces of the wound together tightly enough to arrest bleeding, yet not to tear through the splenic tissue; the ends of the ligature were cut short, the peritoneal cavity cleaned by copious irrigation with hot water and the abdominal wound closed. The kidney was tamponed with gauze through the dorsal wound. Convalescence was uneventful; the anterior wound healed by primary union; urine flowed freely from the dorsal wound for two days only, union by granulation taking place. The patient left the hospital well, April 22. In this case, the wound being small, hemorrhage was not profuse, and no abdominal organ save the spleen was wounded.

DR. WILLIAM PERRIN NICOLSON, of Atlanta, Ga., next presented a paper upon the report of a

SEVERE CASE OF NEVUS

which was cured by the use of galvano-puncture. The case was one of a large growth occupying the groove from the angle of the jaw, up to and covering a portion of the ear, and extending out upon the cheek, the entire tumor being almost the size of a hen's egg. Dr. Nicolson formulated the following conclusions as having been reached in the long period covered in the treatment of this case:

1. That while this treatment may not be applicable to all cases, in many of those that are reached by difficult dissection, and are subject to dangerous hemorrhage, as well as an unsightly looking scar, this is undoubtedly to be preferred to any other surgical proceeding. The time required in a cure is more than balanced by the entire preservation of the skin and the absence of danger from operative work.

2. That as to the quantity and quality of the current to be employed, as many as six cells of a zinc-carbon battery may be sufficient in small growths, while twelve cells of the same is perhaps the maximum to which it should be carried if the current from the positive pole alone should be employed.

3. The method of applying needles. Various forms of needles may be employed, but the ordinary steel needle gives equally satisfactory results, as the eschar produced in the skin at the point of entrance is not sufficient to amount to anything and the needles can thus be changed at each sitting. That only one of them should be inserted into the tumor, while the negative pole should be attached to a sponge electrode moistened with a salt solution, and placed upon some indifferent point, care being taken to remove it from point to point in order to prevent blistering the skin.

4. Method of attacking the tumor. Better results are obtained by passing the needle in from a periphery of the growth on a line horizontal with the skin, and in directions radiating from the circumference towards the center. Several of these punctures should be made at each operation. The length of the entire sitting should not extend to more than twenty minutes or half an hour, while intervals of two to three weeks, or longer, should be left between operations to know whether there may not be a progressive shrinking away of the tumor.

5. As to the method of cure. He thought that several elements entered into attaining the result, of which the coagulum of the blood was one, and perhaps the least. The two remaining elements were the subsequent contractions of the small eschar produced in radiating lines from the tumor, and the effect of the current upon the vasomotor nerve supply. He felt sure that a thorough trial of this method as to the settling of the various points considered, would result in its adoption in the treatment of perhaps a large majority of these cases where we have a large elevated blood tumor with which to deal. He also believed that perhaps pricking the surface with the needle attached to a positive pole of the battery, might result in a series of small scars, which would result in removing the ugly port wine marks so common in this trouble.

OPERATION FOR COMPLETE PERINEAL LACERATION.

This paper was read by DR. JOSEPH PRICE, of Philadelphia, in which he said that there are many men who, essaying to be authorities on the surgical diseases of the major order, have no conception whatever of injuries of the perineum and cervix so far as their intelligent repair is concerned. Indeed, there are many with a large obstetrical practice, who labor under the delusion that they have never ruptured a peritoneum, and that all their patients have entirely normal perineae. This misconception is due to improper

teaching more than to any other cause. Perineal lacerations, unless extending through the skin to or through the sphincter, may escape detection unless by thorough digital examination. All these tears should be approached as distinct surgical lesions to be repaired in the line of their anatomic destruction, and not as cosmetic operations, whose object is to obtain superficial appearances without regard to perfection and utility. Heaping up of tissue outside the lines of resistance and tension, or mere thickening of mucous membrane and skin does not make a true perineum, neither does a set of outside sutures, however much they may draw the parts together, afford any anatomic counterpart of a perineum. From this basis all the so-called outside flap splitting operations for perineal tears are only puckering operations, bringing parts within the sutures that have never been severed, and in many cases taking them out of their proper relations. Big sutures, heavy ligatures, clumsy instruments have no more place here than in other surgery. The ordinary short strong sewing needle, fills the bill exactly in most cases, though the Emmet stryfine short needle for general use is preferable. Silkworm gut or silver wire is the preferable suture. The Emmet operation as originally suggested, and afterwards modified by its distinguished devisor, is the foundation for all successful operations on the lacerated perineum, either with or without sphincter tear. Dr. Price, in closing, said the tears of perineae are often unavoidable, but their restoration is always possible, and their neglect is criminal.

After the reading of Dr. Price's paper, Dr. Engelmann took the Chair and PRESIDENT KOLLOCK delivered his

ANNUAL ADDRESS.

He first thanked the Association for the honor conferred upon him in electing him President. He then alluded to the death of Drs. William T. Briggs, of Nashville, and A. B. Miles, of New Orleans. Dr. Briggs' life had been one of usefulness. He had done excellent and remarkably brilliant work, and had achieved an enviable reputation. Dr. Miles, who had been made Professor of Surgery in Tulane University, was a man full of youthful activity and manly vigor, who by patient study and diligent research, aided by a brilliant intellect, had won for himself a high position in the profession, and in the estimation of his fellow men. "To know him was to admire and love him." His life was gentle and the elements so mixed in him, that Nature might stand up and say to all the world, "This was a man."

While in all branches of gynecology good progress had been made, he noted with pleasure that surgery had had its triumphs. Many reports of cases show enlarged experience and continual improvement in the treatment of appendicitis, hernia, intestinal obstruction, and many other ills that flesh is heir to.

OBSERVATIONS ON THE ACTION OF CHLOROFORM ON THE FUNCTIONS OF THE HUMAN BRAIN AND SPINAL CORD, AS WITNESSED IN EXTENSIVE INJURIES OF THE CRANIUM AND BRAIN.

DR. BEDFORD BROWN, of Alexandria, Va., read a paper on this subject. Dr. Brown cites the history of two cases of extensive compound comminuted fracture of the os frontis and serious injury and destruction of a portion of the frontal lobes of the brain as the basis of his paper. One of these cases of injury was caused by the kick of a newly shod horse, the other by a spent grapeshot in battle. The subjects of both of these injuries retained perfectly their powers of consciousness and sensation. The history of the first case was published in the October number of the *American Journal of Medical Sciences*, 1860, and occurred in the summer of that year. The fracture in that case involved a large portion of the os frontis. The fractured bones were driven back into the substance of the brain quite an inch in depth, lacerating the frontal lobes extensively. There was a loss of about two tablespoonfuls of brain. During the operation, which lasted more than an hour, the patient was placed under a compound of chloroform three parts, ether one part, four different times. Through this large opening in the skull the brain could be seen clearly and its varying changes of action under chloroform could be observed perfectly. The invariable action of the anesthetic was to suppress hemorrhage, to quiet cerebral pulsation and to positively reduce circulation in the brain and arterial tension. These peculiar effects were observed as many as three or four different times. When the patient was threatened with collapse from chloroform, stimulants injected in the rectum produced increased circulation and arterial tension in the brain promptly. Any struggling, mental excitement, or resistance while inhaling

chloroform caused marked increase in cerebral circulation and pulsation with increase of hemorrhage.

The second case was that of a Confederate soldier, who in battle received a spent grapeshot in his forehead, causing an extensive compound comminuted fracture of the os frontis, driving the fractured bones back more than an inch into the frontal lobes. The wound in the skull was quite two inches in diameter, and more than an inch in depth. This patient was subjected to chloroform three times during the operation which lasted an hour. The action of chloroform on the functions of the brain in this was similar to that in the first. When under full anesthesia each time the cerebral hemorrhage ceased, the cerebral pulsations diminished to a mere tremor, and the arterial circulation was markedly reduced. This occurred three different times during the operation. The action of alcoholic stimulants resorted to in this case to prevent collapse from chloroform increased the cerebral pulsations and circulation in a positive manner.

HYDRO-PYONEPHROSIS—SUCCESSFUL REMOVAL OF A FORTY POUND TUMOR OF THE KIDNEY.

By DR. JOSEPH TABER JOHNSON, of Washington, D. C. The patient was 63 years of age, and had inherited and possessed until five years ago a remarkably good constitution. At this time a lump appeared in his right side in the region of the liver and was supposed up to the date of the operation to be caused by enlargement and abscess of that organ. This lump slowly increased in size and the patient had gradually lost flesh and strength until the date of the removal of the lump, when he could not have weighed more than 80 pounds. At no time did he suffer from pain, and only a few weeks with fever. There were several points of interest in this case, viz., failure of a number of good men to make a diagnosis, though the patient was under observation for nearly five years. Failure of repeated examinations of the urine to detect the slightest evidence of disease of the kidney. The only explanation the writer suggests is that the disease at the time of analysis and subsequently had so destroyed the function of the kidney as to prevent the escape of any urine at all, and that the specimen examined came from the other organ, which fortunately was healthy. Failure of such large quantities of foul smelling pus to produce more sepsis. Absence all through the history of pain or fever. The median line incision, the separate ligation of the renal vessels, and the ligation and dropping of the ureter.

The writer is aware that the lumbar incision is preferred by nearly all nephrectomists, and that they frequently bring out the cut end of the ureter and fasten it to the abdomen. While the lumbar incision may be best in small tumors and other disease of the kidneys it certainly could not have succeeded, the author believes, in a case of the magnitude of the one here reported, not only on account of its great size, but also on account of its being so extensively adherent to the omentum and abdominal wall. The colon had to be carefully separated from the anterior surface of the tumor.

Dr. W. L. ROBINSON, of Danville, Va., read a paper entitled

REPORT OF CASES.

He reported two gunshot wounds of the abdomen, lacerating the liver and bowel. In neither case were the symptoms commensurate with the injury; neither shock, hemorrhage, nor pulse portrayed the necessity for operation. Yet in view of the 92 per cent. mortality of gunshot wounds of the abdomen without operation, he did not hesitate. The first case came so near dying on the table, and his light being imperfect (at 12 o'clock at night) he only found the liver wound, failing to find the hole in the posterior border of the hepatic flexure of the colon. The patient died in three days. His second case was operated on promptly, and the injury in the transverse and descending colon was promptly repaired with the Murphy button. The man was on a spree and had had no action from the bowels for three days. He pressed out much fecal matter, but should have taken more time and ruptured the bowel as far as practicable. For two days no unfavorable symptoms presented themselves, but on the night of the second day tympanites and pain began. He suggested to his associates the propriety of reopening the abdomen, but enemata and grain doses of calomel were tried. This, the author considered, was his fatal mistake, for the waiting of ten hours had lost him the chance of a life-saving operation. He reopened and with medium trocar emptied the bowels of gas, but exudative lymph was manifest on bowels, and obstruction of button by feces existed. The button held its tissue firmly, and no leakage had occurred. He washed out the cavity, but patient died in ten hours of shock.

MOVABLE KIDNEY.

This paper was read by DR. GEO. BEN JOHNSTON, of Richmond, Va. At the outset the author emphasized three propositions: 1, movable kidney is extremely common; 2, it is capable of producing very distressing symptoms, and in many instances is a menace to life; 3, it is curable by a simple and safe operation. The author's own experience with movable kidney from a surgical standpoint extends back a little more than three years. Prior to the first nephrorrhaphy, which he performed in May, 1891, those cases he had met with were given little or no thought. Since the date mentioned, he has looked with more interest on his cases, and has come to marvel at the frequency of the malady. He has examined a limited number of persons likely to be the subjects of movable kidney since his first operation for its relief, and in a comparatively small number of subjects he has encountered twenty-seven cases. Edebohls, who has studied 500 cases fixes the rate at 1 for every 5 or 6 women examined. Linder gives about the same rate. Osler makes no statistics, but mentions it as a common occurrence in his hospital wards. The records of these observers and Dr. Johnston's cases justify the assertion that it is a common malady. It occurs more often in women. He had never seen one in a male subject. Age is a factor in its production. His own cases have been in subjects varying in age from 20 to 35 years. In only one instance has he seen it in a woman over 40. Both kidneys may be movable at the same time. The right is the one that is affected in the preponderating majority of the observed cases. This is accounted for by the relation of the kidney to the liver on this side. Two anatomic facts help to explain the preponderance of the right over left kidney displacement: 1, the greater length of the right renal artery; and 2, the firmer attachments of the left kidney. The author has twice seen a movable kidney follow obstruction of the ureter. It happened that both of these cases were on the left side. The increased weight of the kidney due to accumulated urine and congestion must have played an important part in the etiology of the dislocation in these two cases. In many cases of movable kidney, there are no symptoms. In others, the symptoms are extremely distressing, producing great mental disquietude, as well as intense physical suffering. In a proportion of cases the symptoms are grave. Torsion of the ureter is common, partial occlusion by bending is not uncommon, inducing a distension of the pelvis by dammed up urine. Hydronephrosis may follow. Calculus is thus invited by reason of poor drainage. Apart from tumors of the kidney itself, the condition most likely to be mistaken for movable kidney is distended gall bladder.

Nephrorrhaphy is not indicated in every case of dislocated kidney, but only in such cases as manifest distressing or dangerous symptoms. When gastro-intestinal disturbance impairs the general health, when nervous symptoms are severe, when the dragging abdominal pains are constant, when disease of other organs is simulated, when hydronephrosis is threatened, when one or more attacks of torsion have occurred, the operation is imperative. The author then outlined his method of operating on movable kidney, and closed his paper with a report of seventeen cases.

Dr. RICHARD DOUGLAS, of Nashville, followed with a paper entitled

ACUTE PERITONITIS.

Appreciating the condition under which the colon bacillus may escape from its natural habitat and become actively pathogenic, and knowing the supply is unlimited, the dose being governed alone by the integrity of the bowel, naturally we accord to this bacillus the first place in the causation of peritonitis. In obedience to the teachings of experimental work, the surgeon must accept the classification of Pawloski of two forms of peritonitis: 1, that produced by chemic agents with which we are not concerned; 2, that produced by infection. The latter is more tangible. It is fully in accord with our ideas of the genesis of the disease. It harmonizes with clinical work. With Mordecai Price, the author agrees that every case of general peritonitis has a demonstrable cause, and that cause is septic in character. Pathologic manifestations of peritoneal infection are subject to many variations which, in a great measure, indicate the violence of the poison and guide us in forming a prognosis, but to simplify matters, the author considered it under two heads, which illustrated the microscopic and macroscopic changes the result of general peritonitis.

It is an indisputable fact that the type and virulence of the inflammation are largely dependent upon the origin

hence in our bedside work we may consider the subject under the following etiologic classification:

| | | |
|-------------------------|------------|---|
| Infection from without. | Immediate | { This is the direct infection of the peritoneal membrane through penetrating wounds of the abdomen, either accidental or surgical. |
| | Mediate | { This form embraces all cases of contamination of the peritoneum occurring from extension of adjacent infected areas, as leakage from mural abscesses, or puerperal infection. |
| Infection from within. | Immediate. | { Visceral perforation or rupture and direct inoculation of the peritoneal membrane with escaping contents, as in perforating typhoid or gastric ulcer, appendicitis, or rupture of gut or bladder. |
| | Mediate. | { Infection by emigration of micro-organisms through visceral wall of impaired resistance as in incarcerated hernia, intestinal obstruction, ruptured ovarian cyst. |

The author then reported a few illustrated cases. One case was reported of general purulent peritonitis. The patient recovered and the author considers that it was due entirely to free incisions, thorough irrigation and ample drainage.

THIRD DAY—MORNING SESSION.

HISTORY OF VAGINAL EXTIRPATION OF THE UTERUS.

DR. GEO. J. ENOELMANN, of St. Louis, read a paper on this subject, in which he stated that at the New Orleans meeting of the Association he was deeply interested in vaginal hysterectomy, which he presumed was a comparatively new operation with very recent modifications; but Dr. Lewis, of that city called his attention to an old French pamphlet, showing that the operation had been done in the '20's. Since then he had found it was done still earlier precisely as it is done to-day, the operation having developed step by step.

DR. LEWIS, of New Orleans, in the discussion stated that the first vaginal hysterectomy was performed by Dr. Dabourg in the little town of Autell, France.

DR. EDMOND SOUCHON, of New Orleans, read a paper entitled

REMINISCENCES OF DR. J. MARION SIMS IN PARIS.

In 1860, Dr. Souchon had just entered into the study of medicine in Paris, and was attached to the service of Professor Velpeau. In the spring of the following year, he by accident met Dr. Sims who had come to Paris with a letter to Velpeau from Valentine Mott, of New York. At this time Dr. Sims knew nobody in Paris and could not speak a word of French, so that the meeting of young Souchon was a very great help to him in his intercourse with Velpeau and the other surgeons of the French capital. Sim's great object was to get a case on which to demonstrate the success of his operation for vesico-vaginal fistula. Velpeau procured a case which Sims operated successfully before a large audience of students, doctors and professors in the operating theater of the old Charitè. The ovation Dr. Sims received was very great and gave him the start that made him the universal surgeon we all know him to have been. Wherever he traveled and located he had more calls than he could attend to. This success, however, was not without hard moments, for twice he met cases that came very near terminating disastrously from the effects of chloroform. But their final recovery only increased the admiration of all for his fine qualities as a surgeon. Dr. Souchon relates in his paper several instances of Dr. Sims' generosity and gives a graphic account of the generous and sublime manner in which Dr. Sims came to his rescue in a trying moment of great distress. Dr. Souchon's paper ends in words of highest praise, enthusiasm and love for the great and good man, Dr. Sims.

DR. GEO. H. NOBLE, of Atlanta, Ga., read a paper entitled
A CASE OF CARCINOMA OF THE PARTURIENT UTERUS, REMOVED
THREE DAYS AFTER CONFINEMENT—RECOVERY.

The specimen presented was one of carcinoma of the parturient uterus removed by vaginal hysterectomy three days after labor. The woman had previously been confined, sustaining a laceration of the cervix uteri, which perhaps was a factor in the cause of the disease. In the first few months of the last pregnancy the patient was treated locally by her family physician; but there was nothing to cause a suspicion of malignancy. Almost the entire vaginal portion of the cervix was destroyed, less than one-fourth of its circumference remaining intact. The induration extended deep

into the uterine tissue, but could not be felt beyond the limits of that organ. The roughened ulcerated surface was easily traced for a considerable distance within the cervix, the os being dilated to about five centimeters in diameter. Her condition was unpromising, and surgical interference was clearly interdicted, so the os and vagina were cleansed thoroughly and lightly dressed with gauze. She was then placed profoundly under the influence of morphia sulphate with a view to arresting labor, securing rest, and recuperation sufficient to permit evacuation of the uterus, which occurred spontaneously twelve hours later. The child was poorly nourished and lived only a few weeks, finally dying of inanition.

What is the advantage of hysterectomy over Porro's operation, and if hysterectomy is preferable should the vaginal or abdominal method be given precedence over the other? To the first question the author answered that hysterectomy undoubtedly promises more to the mother than a Porro operation in cases where the disease is confined to the uterus, and he asserts that when the cancerous mass can be successfully removed, it is the duty of the surgeon to do it, as Porro's method merely bridges the woman over the puerperal state and leaves her to her fate. In radical removal there is a promise of cure.

In answer to the second question, the author said it is evident that the method of operating must depend largely upon the character of each individual case. Thus the vaginal operation may be done when it is desirable to take advantage of the diminished liability to shock, even though the large size of the uterus may render the operation more tedious. The main point in the paper was to show the feasibility of hysterectomy in the puerperal state for cancer of the uterus, as the case reported clearly demonstrated, even though it is too early to claim immunity from the return of the disease.

LIGATION OF ARTERIES

By DR. JOHN A. WYETH of New York. The author said that in August, 1894, in an operation for the removal of a malignant neoplasm of the left upper jaw, which involved the spheno-maxillary fissure and part of the orbital cavity, it became necessary as a preliminary operation to ligate the external artery. In cutting down upon this vessel by the usual incision—the point of bifurcation of the common carotid artery being, as demonstrated by him in a study of 121 subjects, opposite the upper border of the thyroid cartilage—he found quite a network of veins crossing from the median line of the neck to the internal jugular immediately over the point of ligation, and spreading from one-half an inch above down to the bifurcation of the common carotid. As it would have taken some time to apply a double ligature to each one of these veins, and as the author, on account of the bad general condition of the patient desired to expedite matters as much as possible, he resorted to this expedient: By catching hold of the sheath of the common carotid and at the same time making gentle traction upon the lowermost of these veins with a blunt hook in an upward direction, he found that with his aneurism needle, armed with a good-sized catgut ligature, he could slip this instrument around the artery just in the crotch of bifurcation of the common into the external and internal carotids. Having every confidence in the healing power of arteries ligated under aseptic conditions, especially those tied with animal ligatures—in preference catgut—the ligature was applied at this point, and immediately tightened. It was so close to the common trunk that it also occluded the superior thyroid branch which is given off as a rule just at this point, and which he saw within the grasp of the ligature as he tightened it. The wound was immediately closed without drainage and sealed by iodoformized collodion dressing. The operation on the jaw was completed with an insignificant loss of blood, and on the fifteenth day after the operation the patient left the private infirmary in New York City for his home in the western part of the State. There was no hemorrhage following this deligation. About five years ago, in a similar operation, a ligature was applied at this point with equal success. The speaker did not relate these two cases for any bearing they might have upon the safety of ligation of the external carotid artery, since that question had long been settled. But the reason for narrating these two cases was to bring before the Association a consideration of the inflammatory changes which occur in arteries which have been ligated, and to discuss at length the best methods to pursue in these operations to secure the greatest safety to the patient. In tying arteries, an important point to consider is the selection of a ligature. It seems to the author that in the animal ligatures, and especially in well prepared and

properly aseptized catgut is found the best ligature material. For the last ten years he had used catgut almost without exception, only once or twice using silk, and then in the ligation of the large venous trunk close to the root of the neck, in which he was fearful that the animal ligature might slip, from the blood pressure in the act of vomiting, as the patients came out from under the influence of the anesthetic.

Porta in four hundred experiments, found that in from one to two years, 70 per cent of catgut ligature had become absorbed; 36 per cent., of silk, 66 per cent. of hemp or flax, and 20 per cent. of horse hair. Order of rapidity; catgut, hemp, silk, horse hair.

SIMULTANEOUS APPEARANCE OF CANCER IN BREAST AND UTERUS.

This paper was read by DR. JAMES EVANS, of Florence, S. C. The subject of this interesting manifestation of the disease was a lady 53 years of age, married and the mother of six children. A striking peculiarity in the history of the case, was, that when the disease was most active and destructive in the breast, it rather checked and retarded its tendency in this direction in the uterus. Excision of the cervix and removal of the breast were proposed; but declined. The author closed by saying that although there is a very general consensus of opinion among surgeons that the most successful treatment of cancer affecting the breast and uterus is early and radical removal by the knife, yet it is doubtful in the opinion of the author if operation is advisable when the disease appears in multiple form and in distant organs. When the disease is confined solely to the uterus and recognized at an early stage of its invasion, the prompt removal of the organ is usually followed by permanent recovery; in fact, recurrence less often takes place than removal from any other organ or part of the body.

DR. W. E. PARKER, of New Orleans, reported seven cases of

VARICOCELE

treated by incision, ligation and shortening of the scrotum. An incision, varying in length according to the size of the varicocele is made, and the scrotum shortened by converting the wound from a longitudinal to a transverse one. All cases recovered with union by first intention, and are still doing well, the period since the first operation being seven months. At the conclusion, he gave the following general indications for the treatment of varicocele: The milder forms should be treated with a suspensory bandage with proper attention to diet, exercise and bowels. A varicocele should be operated upon: 1, if it is of large size; 2, if it is painful; 3, if marked nervous symptoms be present; 4, if the testicle is atrophying; 5, if the varicocele is increasing rapidly; 6, if it is an obstacle to entering a public service; 7, if, on account of a patient's occupation, a suspensory is troublesome and he desires an operation.

DR. RUFUS B. HALL, of Cincinnati, Ohio, read a paper entitled

FIBROID TUMOR OF THE UTERUS WITH SUPPURATING OVARY DISCHARGING PER RECTUM.

As a preface to his report, Dr. Hall said the subject of operative treatment for fibroid tumor of the uterus is one in which the keenest interest is manifested by men engaged in abdominal surgery. The main points in the technique of the operation have been practically settled, but certain minor details in operative procedure are capable of improvement. Complications occasionally arise, which tax to the utmost the skill of the operator. The following case was reported in detail, as illustrating a number of these complications: The patient, aged 44, was known to have a fibroid tumor for five years. She had suffered from sepsis for five weeks previous to the operation. In addition to the fibroid tumor was a large suppurating ovary holding about two pints of pus, which was discharged per rectum every eight or ten days. The suppurating ovary was densely adherent, and after its removal disclosed a large opening in the rectum. The operation included total extirpation of the fibroid uterus with the suppurating ovary, and repair of the intestinal rent. There was no leakage of the injured bowel after the operation. The patient recovered.

The Doctor drew the following conclusions: The question of operation during sepsis is one that will admit of discussion both *pro* and *con*, but in the end it must be decided by the merits of the individual case and not by rule. As to technique, total extirpation was given the preference, as it gives the ideal condition both theoretically and practically for after treatment. The Baer method was condemned as it does not give thorough drainage—a thing absolutely neces-

sary where there are extensive raw surfaces which have been bathed in pus, and no peritoneum to close off the general peritoneal cavity. The strengthening of the suture line with a tag of adventitious tissue was advised. The packing of the pelvis with gauze to protect the cavity from intestinal leakage should any occur, and to prevent intestinal adhesions, was recommended. The gauze is usually removed on the fourth day and peroxid of hydrogen used as a wash for the cavity several times daily. Again, forcible dilatation of the sphincter ani muscle to cause incontinence, thus relieving the intra-intestinal pressure from accumulating gases, the Doctor says, adds greatly to the chances for recovery. He first employed it for this purpose on Feb. 6, 1893, in an operation for extra-uterine pregnancy with extensive bowel injury, the patient recovering. He says, so far as he knows, he is the first man to practice forcible dilatation for this purpose.

DR. J. G. EARNEST, of Atlanta, Ga., contributed a short paper in which he reported some complicated cases of pelvic surgery. Two cases were detailed simply to illustrate a method of treatment that under certain circumstances is safer for the patient and just as apt to give relief of symptoms as total extirpation of the tumor; also to emphasize a growing conviction the author has, that intestinal adhesions are frequently tinkered with when it would be best to leave them alone. The essayist was no advocate of timid or imperfect surgery, but in cases where the tumor can be effectually dealt with without disturbing old, thoroughly organized adhesions, which the history and condition of the patient clearly show to be harmless, and in view of the fact that if those adhesions are loosened they will almost certainly anchor at some other point where they may be a source of constant annoyance, or even produce a fatal obstruction of the bowel, he believes it best to leave them undisturbed.

THE REMOVAL OF AN INTRA-UTERINE FIBROID TUMOR BY MORCELLEMENT WITHOUT HEMORRHAGE.

DR. HERBERT M. NASH, of Norfolk, Va., read a short paper on this subject. In September, 1892, he saw in consultation Mrs. A., aged about 42 years, the subject of intractable hemorrhages from the uterus, lasting from two to three weeks of each month, and which had been habitual for several years. The uterus could be plainly felt above the pubes, and by the conjoined method, sound and so forth, the diagnosis of intrauterine fibroid was made. Not wishing at that time any radical procedure, she continued under the care of her physician, whose best efforts to control the hemorrhage proved fruitless. On July 11, 1893, she entered the hospital for surgical treatment. On August 26, the essayist operated under ether. It was found quite impossible to dilate the os to the extent desired, but there was room enough for manipulation without dividing the cervix, and no difficulty was found in seizing the presenting mass—the attachment of which to the uterine walls had been made out to be sessile—with a strong volsellum. Upon making traction with some force, in order to determine the best method of procedure, the tissue gave way, and the withdrawn part of the detached mass was quite large, but no bleeding followed. This fact decided the Doctor to proceed by morcellement, and with the forceps, scissors, and the instrument he exhibited, the whole growth was removed piecemeal, and with only a slightly colored serous discharge. The previous packing had been so effectual that the growth itself, and indeed the uterine walls appeared to have been exsanguinated. The fragments removed, when under strong compression, presented a mass of fibroid tissue nearly as large as an ordinary cocoanut. When the patient left the hospital, the uterus had contracted firmly and measured a fraction over three and one-half inches in depth, occupied its proper position in the pelvis, and the patient is to-day entirely well with perfectly normal functions.

The following officers were elected:

President, Dr. Louis McLane Tiffany, of Baltimore, Md.

First Vice-President, Dr. Ernest S. Lewis, of New Orleans, La.

Second Vice-President, Dr. Manning Simons, of Charleston, S. C.

Treasurer, Dr. Richard Douglas, of Nashville, Tenn.

Secretary, Dr. W. E. B. Davis, of Birmingham, Ala.

After introducing and adopting resolutions of thanks, the Association adjourned to meet in the City of Washington, D. C., the second Tuesday in November, 1895.

Blank Applications for membership in the Association at the JOURNAL office.

Mississippi Valley Medical Association.

Abstract of the Proceedings of the Twentieth Annual Meeting, held at Hot Springs, Ark., Nov. 20-23, 1894.
(Continued from page 872).

FOURTH DAY—MORNING SESSION.

DR. ROBERT C. HEFLEBOWER, of Cincinnati, read a paper on

THE REMOVAL OF THE AUDITORY OSSICLES FOR THE RELIEF OF CHRONIC DEAFNESS AND OTHER ABNORMAL CONDITIONS.

After a thorough and exhaustive review of the history of operations to relieve chronic deafness, from the earliest date to the present time, the author passed to the indications for the operation. He believes that it is indicated in deafness caused by chronic catarrhal processes, as well as headache, vertigo, tinnitus, etc., accompanying this condition, adhesions and chronic suppuration from the middle ear, especially when the ossicles are necrotic. In seven cases reported, where the operation was made to relieve either deafness or tinnitus, or both, there were good results. In closing, the writer says: From my experience with this class of ear cases, I would draw the following conclusions:

1. No bad results attend the excision of the malleus and the incus, but the removal of the stapes is not without the most serious danger, both to life and hearing.
2. That the removal of the malleus and incus alone is far preferable to the removal of the stapes.
3. The operation is of extreme service in chronic suppuration in suitable cases, frequently avoiding mastoid and other serious disturbances of an equally serious nature.
4. It should be performed in cases where there is a high perforation, or where the membrana flaccida is perforated and where the ossicles are necrotic.
5. Tinnitus, headaches of ear origin and vertigo are relieved.
6. In suitable cases it is invaluable for relieving deafness, whether from chronic suppuration or from chronic catarrh and sclerosis.

Dr. H. C. DALTON, formerly Superintendent of the St. Louis City Hospital, read a paper on

STAB WOUND OF PERICARDIUM.

In which he gave the history of a case upon which he operated for that injury. The patient, 22 years of age, entered the hospital Sept. 6, 1891, having been stabbed in the left breast an hour before admission. A wound half an inch in length was found, an inch and a half above the nipple. As there was no hemorrhage from the wound and the patient's general condition was good, an antiseptic dressing was applied and the patient put to bed. Percussion of heart and lung gave normal results. The temperature was 99.5 F., pulse 110; respiration 28. Ten hours after admission to the hospital, his temperature rose to 101, pulse 112, respiration 40, and superficial. Percussion then gave dullness over entire left side. The dressing was removed and blood and air gushed from the wound with each inspiration. The patient was chloroformed and six inches of the fourth rib removed. The bleeding intercostal artery was tied. The pleural cavity was full of clotted and fluid blood, which, together with air, gushed from the wound with alarming force with each inspiration. The patient was turned upon the side and the blood washed from the cavity. A transverse wound of the pericardium, two inches in length, was then seen. At the inner angle of the wound the pericardium was penetrated to the extent of half an inch. By the use of two pairs of long forceps, Dr. Dalton was able to grasp the pericardium a little beyond each angle of the wound and bring it well up to the surgical wound. With a long needle holder, armed with a sharply curved needle and catgut, he succeeded in closing the wound with continuous suture. Great difficulty was experienced in following the up and down movements of the pericardium caused by the heart pulsations. The pleural cavity was then thoroughly irrigated with hot sterilized water and the surgical wound closed without drainage. During the operation the pulse was 140, respiration 60. Several times during the operation the patient appeared to be dying but was revived by hypodermatic injections of whisky and strychnin. One hour after the operation the pulse was 100, temperature 99 and respiration 28. As there did not seem to be an unusual amount of fluid in the pericardium, the Doctor made no extended examination in this direction, the patient's condition being so grave as to necessitate the completion of the operation at the earliest possible moment. The heart itself was not penetrated to any appreciable extent. The patient made a rapid recovery.

The remainder of the Doctor's paper consisted of a discussion of stab wounds of the thorax in general. He insisted that in all penetrating stab wounds of the thorax, in which the wounds were low down anteriorly and laterally, a rib should be resected in order to see if the peritoneum had been penetrated through the diaphragm, in which case he strongly advised that a laparotomy be done. He stated, however, that in case the liver should prove to be cut, the better plan would be to resect a rib, split up the diaphragm and sew up the liver from above. He cited a case which he had reported in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Nov. 15, 1890, in which he had operated successfully in a case of this kind. The same patient also had a wound of the ileum. In order to reach this wound, he made a median incision. The patient recovered. He referred to a case reported in the *Medical Mirror*, in which he adopted this plan. In this case, the knife blade passed through the thorax and diaphragm, penetrating the spleen. He resected a rib and found omentum protruding through the diaphragm. The wound was then closed, and the abdomen opened by an incision four inches long, an inch below the costal border. This revealed a wound of the spleen which he closed by catgut suture. The patient recovered.

THE NEATEST CIRCUMCISION.

By Dr. BRANSFORD LEWIS, of St. Louis. The author detailed a method of doing that operation for which he claimed many advantages in celerity, ease and exactitude of performance, and rapidity of healing. The operation was done with the assistance of two instruments presented by the author, a clamp and prepucator, which enabled the operator to carry out the following steps of procedure: 1, after cleansing the penis and encircling it with a small rubber band, the prepucator is drawn strongly forward, the traction being applied to its inner surface by means of the serrated tractor, mentioned; 2, the glans penis being repressed, the curved, fenestrated clamp is applied; 3, with these as a support and guide, 10 per cent. cocain solution is injected between the two layers of foreskin, anterior to the clamp—no danger of cocain poisoning occurring, since both clamp and rubber constrictor lie between it and the general circulation; 4, after effective anesthesia has been secured, six double length (ten inch) catgut sutures are run clear through the clamp-fenestra and the four layers of foreskin; 5, with strong scissors the latter is cut off at one sweep; 6, tractor and clamp being removed, the double length sutures being divided, and two additional sutures being placed at the dorsal and frenal sites, previously occupied by the tractor; 7, the vessels are secured and sutures tied all around, making a circumcision that is at once symmetrical, precise and admirable, leading to prompt union and a satisfactory result.

This operation does away with inaccuracy, appended cutting of the mucous layer, and slowness or replacing of suturing, etc. Patients read the newspaper while it is being done.

Drawings illustrating the steps of the procedure and of the instruments (made by the A. S. Aloe Co., of St. Louis,) were also presented by the author.

THE TREATMENT AND MANAGEMENT OF CORPOREAL ENDOMETRITIS AND A WORD AS TO PROPHYLAXIS IN TUBAL AND OVARIAN DISEASES

Was the title of a paper read by Dr. WILLIAM H. HUMISTON, of Cleveland, Ohio, in which the author said that nine-tenths of all cases that he treats suffer from some form of endometritis, and its baleful influence on the sympathetic nervous system is marked and manifested by numerous and varied symptoms. Clinically the author recognizes three forms of endometritis—simple, septic and hemorrhagic. These forms were dwelt upon. The first and important principle in treatment is to relieve the passive congestion of the uterus, and this is accomplished by medicated tampons. The first tampon should be medicated with boro-glycerin, iodo-glycerin or ichthyol-glycerin and supported by sterilized, non-absorbent cotton tampons. The depleting effect of the medicated tampon is marked, and a notable relief is felt at once. The septic cases must be treated on modern surgical principles—rest, asepsis, drainage and curetting. When the cases are diagnosed early, and the proper treatment instituted, the author says the abdominal surgeon will not have his belt hanging full of suppurating tubes and ovaries.

Dr. S. E. GANT, of Kansas City, followed with a paper entitled "A Few Remarks on the Early History of Rectal Diseases."

Dr. FRANK WOODBURY, of Philadelphia, contributed a paper entitled

HEADACHES OF EXTRA-CRANIAL ORIGIN,

Which was read by Dr. I. N. Love in the absence of the author.

Dr. E. R. HAUGHTON, of Midland, Texas, read a paper on "Surgical Treatment of Injuries of the Head, Trephining for Blood Clots and Pressure;" and Dr. E. H. McCULLERS, of St. Louis, followed with another paper entitled "Exercise Essential to the Proper Development and Maintenance of Function."

Dr. G. FRANK LYDSTON, of Chicago, contributed a paper entitled

REMARKS ON THE RELATION OF RESIDUAL URINE TO VESICAL IRRITATION, ESPECIALLY IN PROSTATIQUES.

The author said it is generally accepted that most of the symptomatic disturbances incidental to certain chronic bladder diseases, especially in cases of prostatic enlargement, are dependent upon the accumulation of residual urine. The author has long been impressed with the idea that residual urine, *per se*, is not as important a factor in genito-urinary irritation as is ordinarily believed. He is satisfied that in a large proportion of adult males there is always a greater or less residuum of urine remaining in the bladder after micturition. If prostatic enlargement or other obstruction attacking the mouth of the bladder develop, we have the typical accumulation of residual urine characteristic of such cases. It will then be seen that there may be at varying periods of life extreme differences in the degree of accumulation of residual urine. The author believes that the residual urine is simply an incident upon which, if taken alone, the symptoms of vesical irritation in no wise depend. Ideally perfect drainage of the *bas fond* can only be accomplished by thorough drainage from above the tube through the trigone and out of the rectum. There were certain objections to this method which the author said it was not necessary to dilate upon. He simply stated as his opinion that only by some such procedure can the *bas fond* be thoroughly drained.

Dr. HANAU W. LOEB, of St. Louis, reported a very interesting case of

DOUBLE NASAL ATRESIA DUE TO SMALLPOX.

The author said we read with remarkable monotony, of failure after failure in the treatment of webbed fingers and conditions due to the deposit of scar tissue. We realize quite readily the almost futility of the treatment for the permanent relief of cicatricial contractions and adhesions resulting from syphilitic lesions of the pharynx, palate, and larynx, so that while no great skill was claimed in the management of the case reported in the paper, yet the patient's condition after a year and a half of observation merited attention.

LAPAROTOMY FOR PELVIC DISEASES NO LONGER A NECESSITY.

Was read by Dr. R. STANSBURY SUTTON, of Pittsburg. The assertion found in the text of this paper was founded upon the following argument: 1, we have a substitute for laparotomy in total extirpation of the uterus and appendages by the vagina, either with or without morcellement; 2, the operation has already been proven to be effectual and successful by Péan, Segond, Jacobs and others in Europe, and Henrotin, Engelmann, Sutton, Edebohls and others in the United States; 3, total extirpation of the uterus and appendages per vaginam gives a lower mortality than laparotomy for the removal of the appendages alone. Morcellement of small fibroid tumors gives a lower mortality than laparotomy for the removal of similar tumors; 4, these operations by the vagina shorten the convalescence of patients, who are out of bed on the seventh day; 5, in all cases of gonorrhoeal, tubercular or other infectious type of endometritis with chronic salpingitis and chronic ovaritis, a cure is not effected save by total extirpation of the uterus and appendages. The vaginal route is the best; 6, in all cases of fibroid tumors of the uterus, not reaching above or quite to the umbilicus, when the uterus must be sacrificed, total extirpation of the organ, tumor and appendages by morcellement can be best effected per vaginam; 7, small cysts of the ovary or broad ligament, or solid tumors of the ovary can be reached and by morcellement and puncture removed through the vault of the vagina, leaving the uterus and opposite ovary intact; 8, in all cases of pyosalpinx or of multiple pus centers with coexisting solidification of the pelvic roof, total extirpation by morcellement per vaginam is the only feasible operation, and it cures the patient; 9, total extirpation per vaginam is followed by a cure in the greatest majority of cases as compared with laparotomy; 10, the following sequelæ after laparotomy do not occur after total extirpation per vaginam: Cancer of the uterus, adenoma of the uterus,

tuberculosis of the uterus, gonorrhoeal affection, hemorrhages of the uterus, filthy catarrhal discharges from the uterus, ventral hernia, fecal and other fistulas, the mark of a wound on the abdomen. The nerve storms subsequent to total extirpation are not as great as after laparotomy. The patient is restored to perfect health; this is not the case in more than 50 per cent. of laparotomies for pelvic diseases; 11, the bacteriology of infectious diseases demands removal of the uterus with the appendages; 12, total extirpation per vaginam is in strict conformity to anatomic relations; 13, the physiologic results following total extirpation are free from jarrings, and the patient is functionally a smoothly running mechanism; 14, laparotomy for these diseases is followed by all manner of physiologic disturbances which affect the vascular, muscular, nervous and digestive systems; 15, in the face of this argument, laparotomy for pelvic disease is no longer a necessity, but in the author's opinion should be abandoned except in very rare instances indeed.

MODERN SURGICAL TECHNIQUE.

By Dr. HENRY O. MARCY, of Boston. The essayist in his paper first emphasizes the importance of a most careful bacteriologic training on the part of him who would become proficient in surgical practice. In the preparation of the operating room, Dr. Marcy points out the ease and safety with which an ordinary living room, by preference the kitchen, is made comparatively sterile, when from necessity the surgeon is called upon to act promptly and suddenly. In abdominal wounds, where irrigation is not advised, he substitutes for it a slowly flowing stream of oxygen gas from a compressed cylinder. This sterile gas is heavier than atmospheric air which it displaces, and as a consequence renders the wound less likely to infection from the products of respiration and atmospheric contamination. Dr. Marcy reiterates his well-known views upon the value of tendon sutures, buried in all aseptic wounds for the approximation and reinforcement of the structures, emphasizing the importance of abandoning the drainage tube in all aseptic wounds and hermetically sealing the same with iodoform collodion. Aseptic wounds made in aseptic structures, aseptically closed and sealed are always followed by primary union.

The Committee appointed to consider the recommendations contained in the President's Annual Address submitted the following report:

1. While this Association is loyal to the last degree in its affiliations and associations with the members of the regular profession, it still believes that it is not derogatory for a scientific physician to hold a patent on a mechanical or surgical device that proves of benefit to suffering mankind. It sees no reason why the genius and talent of an inventive physician should not be protected by law as well as that of any other man.

2. This Association, if it would demonstrate its usefulness and perpetuity must insist upon the application of business principles in the management of its business department. It therefore insists that every member shall pay his dues annually and with promptitude or else he must be suspended from the exercise of further privileges. To this end the Secretary is directed to drop all names from the roll who decline to pay their dues after two years.

3. The Association for the present will adhere to the plan of general sessions, reserving the right to divide into sections in the future whenever a necessity therefor shall arise.

4. This Association does not believe that the genius of its organization would be attained by reference to a committee, of the papers offered at its annual meetings, with a view to determine which shall be read; but it recommends that authors of papers furnish the Secretary with abstracts of the same, not to contain more than eight hundred words, at least ten days before each meeting.

5. The Association does not feel that a change in the date of its annual meetings is advisable.

6. This Association unites in urging upon the Congress of the United States the propriety of appropriating sufficient funds for the proper maintenance and support of a medical school at Washington, whose purpose shall be the instruction and training of physicians entering the army in regard to requirements of the practice of medicine and surgery in the military service of the United States.

7. This Association believes that in the proper education of physicians by adequate preliminary training and a college curriculum of four years and a final examination for license by the State, lies a true solution of many, if not all, the much controverted questions of ethics; and that in the present day a further agitation of these questions by debate

on the floor of societies met together for scientific advancement is unwise and injudicious.

8. This Association recognizes the fact that it owes to Col. H. C. Townsend and Chas. E. Ware, of the Missouri Pacific Railway, a debt of gratitude for courtesies extended in the preparation for and conduct of this meeting, and as a slight recognition thereof it hereby elects them to honorary membership.

(Signed.) WILLIAM WARREN POTTER, M.D., Chairman,
I. N. LOVE, M.D.,
T. H. STUCKY, M.D.,
A. S. GARNETT, M.D.,
CHAS. B. PARKER.

The Committee on Nominations made the following report: President, Dr. W. N. Wishard, of Indianapolis. First Vice-President, Dr. Thomas E. Holland, of Hot Springs.

Second Vice-President, Dr. Chas. B. Parker, of Cleveland. Secretary, Dr. Frederick C. Woodburn, of Indianapolis. Treasurer, Dr. Harold N. Moyer, of Chicago. Judicial Council, Drs. W. F. Barelay, of Pittsburg, and A. H. Meisenbach, of St. Louis.

Place of meeting, Detroit. Time, September, 1895. Chairman of Committee of Arrangements, Dr. H. O. Walker, of Detroit.

DR. WALKER then offered the following resolutions which were unanimously adopted:

Mr. President:—I take the liberty to assume a pleasant duty. Words can not but fail to express what is now in the minds of all of us, that we have had a glorious time in Hot Springs. The twentieth annual meeting of this Association will ever be remembered as the best in its history, replete with scientific profit, mingled with unstinted hospitality.

I, therefore, move that the thanks and appreciation of this Association be tendered to the profession and citizens of Hot Springs, especially to Dr. Thomas E. Holland, the Chairman of the Committee of Arrangements, for his untiring labors in our behalf. To Col. H. C. Townsend and Mr. Chas. E. Ware, of the Missouri Pacific Railway; Col. and Mrs. Woodhull of the Army and Navy Hospital; Dr. and Mrs. A. H. Garnett, Maj. and Mrs. Alfred Whittington; Mr. and Mrs. S. A. Douglass; Mesdames S. H. Stitt and Bancroft; Mr. and Mrs. I. T. Hay, of the Arlington Hotel, and Mr. R. E. Jackson, of the Park Hotel.

Resolved, That it is the sense of this Committee, that in the future the Chairman of the Committee of Arrangements select a committee of three as censors of program to act as a committee on revision, and that every paper or its abstract to be read before this Association in the future, must be in the hands of said committee twenty days before the time of meeting, and must be approved by said committee before being put on the program.

(Signed.) I. N. LOVE, M.D., Chairman.
H. O. WALKER, M.D., Secretary.

On the adoption of the above resolution of thanks, very timely and appropriate speeches were made by Drs. J. C. Culbertson, of Cincinnati, and Chas. H. Hughes, of St. Louis, in which they referred to the hospitality of the citizens of Hot Springs in beautiful language.

On motion, the Association then adjourned to meet in Detroit in 1895.

NECROLOGY.

JOHN MILLS BROWNE, M.D., ex-Surgeon-General U. S. Navy, Dec. 7, 1894. He was born in Hinsdale, N. H., May 10, 1831, and was graduated from the Medical Department of Harvard University in 1852. In the following year he entered the Navy as an Assistant Surgeon and performed his first duty on board the steamship *Warren*. He was promoted to the rank of Passed Assistant Surgeon in 1858, and was made Surgeon in 1861. While serving as Surgeon of the *Kearsarge*, the famous engagement occurred off the coast of France, which resulted in the sinking of the *Alabama*. Ten years later he advanced to the rank of Medical Inspector, and in October, 1878, was promoted to the rank of Medical Director. He was appointed by President Harrison Surgeon-General of the United States Navy, and on the expiration of his term was reappointed and served until his retirement, one year and a half ago. He took high rank in Masonic

circles, was a thirty-third degree Mason, and succeeded the late Albert Pike as Chief of the Scottish Rite for the Southern jurisdiction of the United States.

He was a genial and companionable man who lived without reproach and died without fear. He was not only one of the ablest of his corps, but one known to be absolutely just in all his dealings with his brother officers and mankind in general.

CHAS. PINCKNEY GAGE, M.D., Concord, N. H. He was born in Hopkinton in 1811 and was graduated at the Cincinnati Medical College in 1837. After graduation he spent considerable time in the hospitals and in clinical study in Cincinnati, remaining until 1838, when he removed to Concord, where he has since resided. He was a delegate to the convention for the formation of the AMERICAN MEDICAL ASSOCIATION in 1846, and attended the Baltimore meeting in 1848.

EZRA SLOCUM CARR, M.D., of Pasadena, Cal.—A. W. Lapham, M.D., of Victoria, Ill., November 29.—John Evans, M.D., of Richmond, Ind., aged 84.—W. H. Hart, M.D., of Pittsburg, Pa.—Wm. J. Hunnicke, M.D., of St. Louis, November 30.

SOCIETY NEWS.

Northumberland County (Pa.) Medical Society.—The annual meeting of the Northumberland County Medical Society was held at Sunbury, Pa. The following officers were elected for the ensuing year: President, G. W. Furey, East Sunbury; Vice-President, T. F. Gilbert, Elysburg; Secretary, Wm. B. Stoner, Sunbury.

The Wayne County (Mich.) Medical Society will hold a special meeting in Detroit December 17.

A Dinner to President Maclean.—A dinner was tendered to Dr. Donald Maclean, of Detroit, at the Russell House in that city, December 4. The toasts and those who responded follow: "The Welcome Guest," Dr. Maclean. Dr. T. A. McGraw, who was scheduled for the subject "Fraternity," was unable to be present and Acting Health Officer Webber was appointed as his substitute, who responded in a fitting manner. Dr. C. T. Newkirk, of Bay City, told all about the friendship that exists in the medical profession, and Dr. C. B. Nancrede responded to the toast, "Fellowcraft." Dr. Cogshall, of Flint, appeared as a substitute for Dr. O. P. Barber, and spoke about "Fellowship," while G. E. Frothingham, Sr., told about the "Fidelity" that exists in the medical profession, and Dr. C. G. Jennings about the "Felicity" of being doctors. The speeches were above the average and the themes apparently to the liking of the doctors. Frederick Mills played several violin solos and other artists furnished excellent music. All in all, it was an occasion that will long be remembered by those who attended. A number of ladies occupied seats near the doors and listened to the responses to the toasts and the musical selections.

Financial Loss from Tuberculosis.—It has been computed—on somewhat the same principle that was applied by Dr. Benjamin Lee to the smallpox epidemic in Philadelphia—that there is a money loss, from consumption alone, in England amounting to \$72,000 for every 1,000,000 children born.

Medical Courage Honored.—Dr. Mary Bradford, an American missionary to Persia, is about to receive the highly complimentary present of a hospital, to be conducted by herself. It is the outcome of her very courageous course during the cholera epidemic of 1892. She remained at her post through the entire epidemic. Some wealthy merchants, who recognize the heroic qualities of the lady's conduct, have undertaken to build and equip this hospital as a kind of reward of merit.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, DECEMBER 15, 1894.

THE FAILURE OF THE ERYSIPELAS TOXINS.

"Every delay is hateful, but it gives wisdom."—PUBLIUS SYRUS.

There is no longer much question of the entire failure of the toxin injections, as a cure for sarcomata and malignant growths. During the last six months the alleged remedy has been faithfully tried by many surgeons, but so far not a single well authenticated case of recovery has been reported, so far as our reading has extended, and the personal experience of surgeons of our acquaintance with whom we have conversed, demonstrates that in all cases in which they tried the erysipelas toxin the result was no improvement.

We can readily understand and sympathize with the great desire to rescue from impending death, sufferers from an incurable disease, but science demands that its truths shall be positively demonstrated before being accepted. The medical profession, for centuries conservative in acceptance of new doctrines, has been startled out of its usual practice by the brilliant discoveries of bacteriology, and it now seems as if any assertion, no matter how absurd, needs only some strong voice or lucid pen, to make the profession swallow it greedily. It is the age of the sensation monger, and the seeker after notoriety may enjoy a temporary celebrity by a very easy process. He has only to announce the sure cure of some hitherto incurable disease by some foreign chemic product, or microbial mystery and the thing is done. The celebrity may be short-lived and suffering humanity deluded by false hopes, but the story was a pleasant one while it lasted.

The plain duty of the profession is clear. We should patiently wait until those having the facili-

ties for investigation complete their work, and bearing in mind the infirmities of poor, weak, human nature, we should not accept as conclusive, reported cures by any single investigator no matter how prominent. We should demand that these cures be corroborated by other observers, making investigations independently.

In the matter of the diphtheria cures, we must remember that while statistics show a relatively large proportion of alleged cases prove to be diphtheria by bacteriologic examination, still of this number many recover by natural processes under ordinary therapeutic measures. It will take much time before the commercial supply of antitoxin is at all adequate to the demand, and before it can be produced in this country. Let us, therefore, wait patiently, as long before our horses are properly immunized, our foreign leaders may have prepared even a greater bolus for us to swallow.

A TIMELY TOPIC.

"Shall the State maintain supervision of the propagation of vaccine virus?" is one of the subjects discussed at the National Conference of State Boards of Health, held in Washington during the current week. At this writing the JOURNAL is not advised of the result of the discussion; but it is safe to assume—the members of the Conference being practical sanitarians and men of at least average intelligence—that the answer has been an emphatic affirmative.

The topic is a timely one. Whatever of doubt exists at the close of the Jennerian century as to the value of vaccination is largely, if not solely, due—first, to the use of inert or impure virus; and, second, to want of care in the performance of the operation. Both these causes have been dwelt upon by every writer on vaccination from the time of JENNER himself. The late DR. RAUCH, especially, attributed to these causes the growing neglect of the practice and the opposition to its compulsory enforcement, and boldly asserted that it was not justifiable to compel vaccination when the supply and quality of vaccine material could not be controlled and guaranteed by competent authority; when many physicians, to say nothing of the laity, treated the operation as a mere scratching of the skin; and when the majority of medical colleges regarded it as too insignificant to require a single lecture, and graduated as physicians men who had never seen a vaccine vesicle.

Leaving the anti-vaccinationists out of the question—as belonging to that category of people who require no cause or reason to be "ag'in the government" except that there is a government—it remains that there is still a doubt of the exact value of vaccination after nearly a hundred years' experience. Within the past few months the Royal Commission on Vaccination has made another report of its labors,

but still without expressing any opinion on the evidence it has accumulated. This Commission, presided over by LORD HERSCHEL and SIR JAMES PAGET, has been holding weekly sessions since 1887, and the perplexing nature of its labors, owing to the conflicting testimony presented, still delays a verdict, notwithstanding the vaccination laws are suspended awaiting it. And within the past few weeks DR. CROOKSHANK, Professor of Comparative Pathology and Bacteriology in King's College, has delivered an address before the Medical Society of his College, in which he denies that vaccination has any value at all to protect against smallpox, or at most that "of 'issues' against the plague."

PROFESSOR CROOKSHANK's disbelief, as well as the deferred verdict of the Royal Commission, is due to failure to define "vaccination." Not everything that is so called is really vaccination, and when CROOKSHANK claims to have found seventy different varieties of cicatrices or "marks," produced by different kinds of virus on different individuals, of different constitutions, ages and nationalities, he reveals the *crux* of the situation. These different "marks" are the sufficient proof that CROOKSHANK was not dealing with properly vaccinated individuals. A perfect vaccination—and nothing short of perfection should be considered—with perfect virus, either humanized or bovine, results, to quote DR. MARTIN, "in the production of a scar as distinct and defined as if stamped by a sharply-cut die, and the scars of a hundred such vaccinations are almost as like each other as the impressions on a hundred coins fresh from the mint." To secure such a scar, which only is evidence of a protective vaccination—the first essential is a perfect vaccine, and experience proves that the unregulated propagation of vaccine virus does not furnish this *sine qua non*.

This Conference of State Boards of Health will not have been held in vain if it shall have devised some method by which the first essential condition of compulsory vaccination, as laid down by DR. ELISHA HARRIS, may be complied with, to-wit: "That the quality of the vaccine lymph shall be absolutely perfect, and that the insuring of this uniform excellence shall not be permitted to be subject to uncertainty or to any kind of capricious judgment."

THE IMMIGRATION SERVICE.

The Superintendent of Immigration HON. HERMAN STUMP, has issued his annual report from which it appears that in the year ended June 30, 1894, 288,020 immigrants arrived in this country, a decrease of 152,173 as compared with the year 1893, and the decrease for the preceding year was 141,044. The total decrease for the two years is 293,807. SUPERINTENDENT STUMP thus accounts for the decrease:

"The decrease in 1893 was caused by the suspension of immigration on account of cholera, and the decrease in 1894

is largely to be attributed to the stagnant condition of our business enterprises, owing to financial causes and the consequent absence of demand for both skilled and unskilled labor; but at the same time it must be borne in mind that much of this decrease is to be attributed to the efficient execution of the immigration laws, by the strict inspection and prompt deportation of the prohibited classes, as each person deported to the country whence he came deters many from making the attempt to land here, and also the refusal of steamship transportation lines to sell tickets or embark undesirable persons in foreign countries.

"The inability to procure transportation prevents hundreds from reaching our shores who now apply for tickets and are refused passage by the steamship agents at the homes of those contemplating immigration; thus demonstrating that the act of March 3, 1893, is both wise and humane, and secures to our country a greatly restricted immigration, and those who succeed in coming are of the better class of European peasantry. There seems to be no doubt that as the present system of inspection (*viz*: First, at the home of the emigrant; second, at the port of embarkation, and third, upon his arrival in this country) becomes better understood and is more vigilantly executed it will be more remedial and far-reaching in its effects and can from time to time be improved by such regulations and Congressional amendments as practical experience demonstrates; consequently the volume of immigration will be restricted upon a wholesome basis and the condition of those arriving will continue to improve.

"To show how the inspection of intended immigrants at their homes is enforced, it is only necessary to recollect that by law the steamship companies are required to transport to the country whence they come all immigrants who on inspection are refused a landing in the United States. So many of late years have been returned, that it has proved a considerable expense to them, and in order to avoid this they have made certain regulations defining the classes who should be refused transportation by their agents, and prescribing penalties for booking immigrants prohibited landing in the United States, of which the following is an extract:

Extract from instructions of the North German Lloyd, White Star Line, Hamburg-American Packet Company, Cunard Line, Netherlands, American, Red Star Line, French Line, and Anchor Line and other steamship companies to their agents.

"Such emigrants as are liable to become a burden to the State, paupers, criminals, consumptives, and those suffering with loathsome and contagious diseases; the blind, lame, deaf and dumb, and crippled persons, women with children without any relatives in this country, single females in pregnant condition, single females with children.

"We beg to advise you that the law will be enforced strictly. In view of this, we request you to use the utmost care in accepting emigrants for transportation, and in doubtful cases to consult us, giving all the details and conditions before you enter into a contract. If we approve the acceptance of a passenger or passengers you will be in no way held responsible, but if you enter into a contract for transportation of emigrants, of whom with a certain degree of attention you could have known beforehand that they would come under that class of emigrants which are refused admittance to America, we will be compelled to charge you 80 marks for every adult for return transportation, and also the transportation costs from the port to the home of the passenger."

"For your further information I append to this report a full circular of one of the above-named companies to its agents in foreign countries.

"The principal steamship lines have endeavored to book only such steerage passengers as should be admitted, and have shown a desire to observe the law in every respect; the results of which are plainly evident in the class of immigrants now arriving. At the same time it is to be expected that they will continue to secure as many passengers as possible. Their steerage business to this country this year was very light, and had it not been for the unusual number returning to their foreign homes it would have proved to them a financial loss.

"When it is considered that each of the above lines has several thousand agents located in every section of Europe from which emigration flows, whose duty it is to inspect each and every one contemplating emigration before selling a passage ticket to the United States under the penalties prescribed in the above regulations, it is evident they will exercise the utmost caution. And this inspection is most valuable, being based upon self-interest and the agent's desire to shield his company from the responsibility imposed upon it

by our laws in embarking persons belonging to the prohibited classes, and is more valuable because he may be, and generally is, personally acquainted with the immigrant and his surroundings."

It is certainly gratifying to see that not only is there a diminution in the number of immigrants, but that there is an actual exportation of this class. The United States has been overburdened for many years past, and this will be a much needed relief. The Commissioner, while not furnishing the statistics, is of opinion that for the past year, more steerage passengers have left our shores than have come in, through our seaports.

The medical inspection at Ellis Island, under the direction of SURGEON WM. A. WHEELER, of the Marine-Hospital Service shows the work of the Medical Examiners as follows:

| | |
|---|---------|
| Steerage passengers inspected upon arrival | 281,662 |
| Physically examined, certified, and sent to hospital | 1,081 |
| Physically examined, certified, and sent before the board of special inquiry for action | 527 |
| Physically examined and recorded (for minor defects). | 1,630 |
| Landed cases applying for relief which were certified and sent to hospital for treatment | 471 |
| Landed cases applying for relief which were physically examined and certified for deportation | 215 |
| Landed cases applying for hospital relief, examined and rejected. | 151 |

That officer's report to the New York Commissioner is published and we here reproduce it:

ELLIS ISLAND, N. Y., July 12, 1894.

SIR:—The following is a report of the work done by the medical department of the immigration service at Ellis Island during the year ending June 30, 1894:

Since our last report there have been no changes in the medical staff either connected with the office or the hospital. Some important and greatly needed changes, however, have been made in the hospital buildings which were recommended last year, in addition to which the hospital has been provided with a complete steam disinfector, fully capable of meeting all requirements. It will be noticed that we have this year treated all of our insane cases at Ellis Island. This we have found to be practicable since they are few in number, and it is very much in the interests of economy. The only cases not treated on the island are those of small-pox, diphtheria, and scarlet fever, and unless a suitable building were provided, well isolated, it would not be possible to properly care for them. During the past year there have been but fifteen of these cases, and, should that number be not increased, it is doubtful if any better arrangement could be made than the one we now have with the Health Department of the city of New York.

My recommendation of last year that a contagious hospital be built at Ellis Island for these very cases was based upon the larger number occurring during the previous years. It is very gratifying to find that for various reasons the number of such cases is annually diminishing and with it the need of a separate contagious hospital on Ellis Island.

Our buildings have been painted and are to-day in a good state of preservation. The roofs of the kitchen, dining rooms, and hospital C have been painted by our attendants, also the inside of the male and female wards. The roof of the executive building needs painting, which our attendants can not do, owing to its high pitch and their lack of experience.

The walls of hospital C will soon need to be sealed with rock plaster, as they are becoming infested with vermin which it is impossible to dislodge. In that respect the plastering of the partitions of the male and female wards has been an unqualified success.

THE COMMISSIONER OF IMMIGRATION,
Port of New York, N. Y.

TO WHOM THANKS ARE DUE.—The HON. SHELBY M. CULLOM, U. S. Senator from Illinois, has kindly sent the JOURNAL a copy of the *Congressional Record* for the last two years, and we are also under obligations to that Senator for various public documents. This

Senator has always been keenly alive to the wants and wishes of the medical profession.

CORRESPONDENCE.

Modern Insanity.

ORAN, Mo., Dec. 4, 1894.

To the Editor:—If an individual shows marked superiority in any line of thought he is pronounced *insane*. The doctor, lawyer, preacher or tradesman who excels all others in his special line is said to be "cranky." The teacher who excels all other teachers is said to be "eccentric." The modern aggressive evangelist is also "insane." The inventor like unto Edison, he too, is "insane." Anything outside of the ordinary is pronounced insanity. The excessive user of narcotics is called a "narcomaniac." The individual who drinks excessive quantities of alcohol is said to be "insane." The individual who appropriates goods which do not belong to him is said to be a "kleptomaniac." In fact, any excess in any line of conduct, whether good or bad, is pronounced insanity.

In olden times, if a man showed any superiority over his fellow-men he was given credit for it. If he was a great scholar he was thought to be more intelligent than others with less knowledge. Men in different callings who showed marked superiority were called great men; some, like Solomon, were called wise men; others, like Christ, were called good men. Men who committed great crimes were called criminals. Men who drank excessive quantities of liquor were called drunkards. Young people were taught to imitate the good and great men and to abhor the criminal and drunkard. These notions are all changed now. We no longer have good or great men. A genius is now defined as a man who has one or more talents highly developed, while his other talents have been neglected. A genius and an insane man now mean one and the same thing. In olden times an insane man was thought to have lost some mental quality once possessed, but this notion seems to have been erroneous. Men do not lose mental power any more; they only allow some sense or talent to be too much developed. This unbalances the fellow and he becomes insane.

Modern insanity is easily diagnosed and is said to be very curable, especially under hospital treatment. A few doses of animal extracts and antitoxins do the work. The antitoxins stop excessive action of all kinds. The animal extracts develop the undeveloped talents or senses, thus producing the ordinary. This modern insanity works a revolution in science, the arts and education. The rising generation will be taught that being wise, good or bad is symptomatic of insanity and a dangerous thing to do. The main thing is to be ordinary. Reading the Bible or hard study of any kind is dangerous. Going to school more than one day in a week would have a tendency to produce literary insanity. Preaching more than one discourse a month would produce Jonesism. Listening to a brass band more than a few moments at a time is extremely dangerous. Do not go to church at all. Religious insanity is the worst form. Attend baseball and football games often; this exercises all the senses equally. Prize fighting never produces insanity. No prize fighter ever went crazy. See to it that you do not go into excess in any line; just continue to be ordinary. Education is a great factor in producing insanity. Curious! What old-time people thought was intelligence turns out to be only modern insanity. Idleness is the thing to look after; especially to keep the mind idle. Do not think. Thinking has caused more insanity than all other things combined. Industry also has a baneful effect. Whatever you do, don't work.

W. P. HOWLE, M.D.

Teaching in Medical Colleges.

WAUKEGAN, ILL., Dec. 9, 1894.

To the Editor:—Allow me to make some suggestions relative to systematic instruction in medical colleges. This matter is forced upon our attention by the criticisms of medical teaching by students from other schools. The time has come when a systematic grouping of subjects to be taught should be adopted by all schools that desire to be known as eminent centers of learning. This system has been adopted by some of the literary and scientific institutions of our country; but it is far from being universal. In medical colleges the plan has scarcely received a serious thought. Only a few schools where medical men are trained have arranged for such united, such systematic work.

The president or dean of a college of medicine should know what is taught in every department, in every chair. This would entail a vast amount of work upon one man, and to aid him in his task the appointment of head professors in the different departments may be made, as is done in some of the universities. The work then can be so systematized that unwarranted repetitions will not occur. Not long ago a gentleman told me that within a short time he had listened to four different teachers in the same institution and each succeeding one was lecturing upon the same subject that he had heard at the first lecture. It has been said by those who do not favor such classified division of work that there is no danger of giving medical students too much of any one subject. That may be true, but there is danger that some important subjects will be omitted; and to avoid these omissions a closer classification and supervision of work is necessary.

The sub-dean or head professor of the department of materia medica and therapeutics should assign the work to be done by the professors of medical botany, materia medica, general therapeutics, electro-therapeutics, pharmacology, et cetera.

The Department of Public Health or Preventive Medicine should be divided into general pathology, general etiology, bacteriology, special animal pathology, practical hygiene, and state medicine, at least. Anatomy, medicine, surgery and other departments should be likewise subdivided and the work so assigned that each subject will be exhaustively presented and needless repetitions prevented.

When such a plan as this is adopted in our medical colleges, we may hope to send out men more competent to deal with the practical work of the physician. The suggestions that have been lately made in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION relative to advanced standing and higher work in the Department of Public Health could then be practically carried out, and the medical profession would take a long stride forward.

J. M. G. CARTER, M.D.

The Antiseptic Treatment of Typhoid.

FREEMONT, ILL., Dec. 4, 1894.

To the Editor:—Dr. John Eliot Woodbridge, of Youngstown, Ohio, has published during the last year, in several medical journals, among them the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, such a glowing and enthusiastic paper on the treatment of typhoid fever, that, contrary to my conservative habits, I have been lately giving it a trial. The treatment, it seems to me, if not beneficial is absolutely harmful. The first part of his prescription containing podophyllin, calomel, guaiacol, thymol, menthol, eucalyptol, if given to the extent that the author recommends, will certainly have a tendency to weaken the patient and lessen his chances of recovery, unless it acts at the same time as a germ killer and thus lessens the virulence of the disease. In my hands, so far, the remedy has failed to produce that marked change in the temperature curve, that Dr. Woodbridge's charts show in his own practice. In fact, in a vig-

orous young woman, after two weeks' trial of the treatment, I have still a temperature of 105 F. under the tongue every afternoon, unless I combat the excessive heat of body with frequent spongings and bathings, which I have done from the outset.

My motive in writing these brief lines, is to solicit a correspondence, from the profession as to their experience with this new treatment of this terrible disease.

I hope, Mr. Editor, you will see the importance of getting the experience of others in this matter, and allow me the space in your JOURNAL for this end.

Hoping I may hear from others of the profession, who have undoubtedly like myself been trying Dr. Woodbridge's treatment,

I am yours very truly,

W. S. CALDWELL, M.D.

The Index Medicus.

PHILADELPHIA, PA., Dec. 3, 1894.

To the Editor:—I have learned that the Index Medicus will cease to be published with the February number, owing to lack of support and the fact that a large number of its subscribers are delinquent, unless an effort is made to continue it.

The value of this publication to those who do any work at all in connection with medical literature is so great that I take the liberty of writing to you to express the hope that you will not only become a subscriber, but will urge other of your professional friends to do so. It is particularly necessary that the Index Medicus should be continued owing to the fact that after the completion of the supplementary volume of the Index Catalogue of the Surgeon-General's Library, there will be no record of contemporary medical literature and he who desires to keep pace with it, or who wishes to study a particular subject will have to resort to the laborious task of seeking in various journals that which he desires if the publication of the Index Medicus ceases.

It will be possible to continue the Index Medicus if 500 new subscribers are obtained. The subscription price is \$10 per annum which should be sent to Mr. George S. Davis, publisher of the Index Medicus, Box 470, Detroit, Mich.

As the Index Medicus can never be made a success from a commercial point of view because of the peculiar scope of its work, I have no hesitancy in making you acquainted with these facts, and I earnestly hope that you will insert a notice emphasizing the importance of this matter in the columns of our journal.

Yours truly,

H. A. HARE, M.D.

Photographs of Members.

DUNKIRK, IND., Dec. 3, 1894.

To the Editor:—Please explain the use of the photographs of members of the ASSOCIATION as requested in the JOURNAL of last week.

Respectfully,

J. B. GARBER, M.D.

ANSWER.—It is proposed to keep them on file in the JOURNAL office, for reproduction in the columns of the JOURNAL from time to time as occasion may require.

No Diphtheria at Brocton.

BROCTON, ILL., Dec. 11, 1894.

To the Editor:—As to the prevalence of diphtheria at Brocton and Five Points, Ill., will say there is not a case at this time that I know of at either place, and I have had charge of most of the cases. Our school at Brocton was closed for three weeks, but has been opened for two weeks since. There were two deaths from diphtheria here, or one physician called it such and the other asserted it was not. I never saw either of these cases. General health good in this location.

Respectfully yours,

H. C. KERRICK, M.D.

PUBLIC HEALTH.

Purity of Antitoxins.—The New York City Board of Health has issued the following circular:

HEALTH DEPARTMENT.

Center, Elm, White and Franklin Streets, (Criminal Court Building.)

NEW YORK, Dec. 7, 1894.

HON. CHARLES G. WILSON, (President).

Sir:—The accompanying report is hereby approved. The grave consequences following fraud in the preparation of this valuable remedial agent necessitate prompt and vigorous action on the part of the Board of Health. Steps should be taken at once to supervise in the most careful manner the sale of diphtheria antitoxin in the city of New York. This can only be accomplished by a systematic inspection and scientific examination of the various preparations of antitoxin offered for sale in this city. In event of fraud in the offering of spurious preparations or preparations of doubtful strength, the Board should institute criminal proceedings against offenders. In order to regulate the sale of diphtheria antitoxin in the city of New York, the following resolution is hereby submitted:

"Resolved, That Dr. T. Mitchell Prudden, Consulting Physician to the Health Department in the Division of Pathology, Bacteriology and Disinfection, and Dr. Hermann M. Biggs, Pathologist and Director of the Bacteriological Laboratory of this Department, be requested to prepare and submit some plan for the determination of the strength and purity of the various preparations of antitoxin which are now or may be hereafter offered for sale in the city of New York, so that the public may have some guarantee that only genuine preparations of antitoxin of proper strength are furnished for sale.

Respectfully submitted,

(Signed)

"CYRUS ENSON,
Chairman Sanitary Committee."

The above report and resolution were adopted at a meeting held on Wednesday, Dec. 5, 1894.

HEALTH DEPARTMENT.

Center, Elm, White and Franklin Streets, (Criminal Court Building.)

HON. CHARLES G. WILSON, (President.)

Sir:—The great practical importance of the new antitoxin treatment for diphtheria, not only in controlling but in curing the disease, has created a demand for the new remedy so universal and urgent, that the occasional small supplies which can be obtained from the European laboratories are wholly inadequate. It is therefore imperative that without unnecessary delay the preparation of the new remedy should be generally undertaken in this country. It has been already begun by the New York City Health Department in a limited way, and we trust that the requisite means and equipment may soon be furnished to the Department for making the antitoxin in sufficient amount at least for local use.

The preparation of this remedy requires considerable outlay for laboratories, for the necessary animals and their safe housing and scrupulous care; and above all for the services of competent and experienced bacteriologists or specially trained experts. The efficiency of the remedy and the security of those to whom it is administered from any possible danger in its use, depends in the most intimate way upon the skill and reliability of those engaged in its manufacture. Careful and delicate tests are required at every stage of its preparation. The strength of each lot of the remedy must, when it is finished, be determined in the most exact way by those in command of the necessary special skill and experience. It is one of the distinguishing characters of this remedial agent, that its greatest efficiency is obtained only when it is administered in the earlier stages of the disease and then in doses possessing a strength absolutely to be relied upon. Should the material used be for any reason deficient in healing power through error, carelessness or fraud in its preparation, time may be lost, so precious to the patient, that it may involve his life.

The antitoxin serum when ready for use is a yellowish fluid without any especially distinguishing or characteriz-

ing appearance; to the eye resembling the clear, yellowish fluid which separates from blood when it clots, from which it can be distinguished only by exact tests of its curative and protective value on animals.

The new remedy will be at the best rather costly, on account of the time required for its preparation—always many weeks at least—the cost of material and animals and of expert services. At present the market price of the antitoxin is unduly great, and probably will be so for some time to come on account of its scarcity and the great demand for it. It follows from what has been said that it is of the utmost importance to those who use this remedy that there should be some reliable guarantee for every preparation placed upon the market that it has been prepared by competent persons, and that in every case it possesses the requisite purity and power. The preparations now occasionally furnished in this country in small quantity by the German pharmaceutical houses, Schering and the Farbwerke (Hochst-am-Main), have specific guarantees as to strength and purity by bacteriologists of universally recognized skill and experience. Unless some such security is afforded, it would be quite easy for unscrupulous persons willing to commit such a crime to place on the market small bottles of yellowish fluid labelled "antitoxin," containing an inefficient amount of the healing agent, or even none at all, and for a time at least profit by the extraordinary demand for it, perhaps at the cost of life and at the risk of discrediting a most potent and beneficent remedy.

That this is not a merely fancied and only possible menace to the welfare of those stricken with this dreaded disease, and so often the wards of the Department of Health, is shown by the fact that already in the city of New York several different preparations of alleged diphtheria antitoxin, said to have been prepared in this country, and wholly, so far as we can learn, without proper guarantee of efficiency, have been furnished and used for the treatment of diphtheria. One of these preparations has been already subjected to the necessary crucial tests by the Department and found wholly inefficient and inert.

While we suggest its importance, we are not prepared at the moment to recommend in detail a definite form of guarantee of purity and adequate strength in this remedy, such as would be practicable and desirable for the protection of the public against carelessness or fraud. But we call your attention to the matter at this early period in the use of diphtheria antitoxin in the hope that at least a warning of the medical profession and the public against spurious and unguaranteed preparations of this remedy, if not more drastic measures, may seem to you wise and useful, and appropriate to the functions of this Department as a guardian of the public health.

Respectfully submitted,

(Signed) HERMANN M. BIGGS, M.D.,
Pathologist and Director of the Bacteriological Laboratory.
T. MITCHELL PRUDDEN, M.D.,
Consulting Physician to the Health Department in the
Division of Pathology, Bacteriology and Disinfection.

Contagious Diseases.—Judging from the meager reports received from JOURNAL correspondents there is a remarkable diminution of the principal contagious diseases. The pandemic of diphtheria seems to have subsided as suddenly as it appeared; smallpox is, apparently, stationary—the only report received up to the 12th inst., being from Chicago, where there were, at that date, 63 cases in hospital, as against 67 one week previous. The outbreak at Sandwich, Ill., (population, 2,516, last census), resulted in 15 cases with 5 deaths, with 2 fatal cases at Aurora contracted at Sandwich; on the 12th there was but 1 (suspected) case remaining at Sandwich.

Diphtheria and the Antitoxin.—The commercial exploitation of the diphtheria antitoxin has been begun in this country. This was to be expected from the furor which has been created abroad over the discovery and from the prices charged for the foreign product—prices which would seem to afford an enormous profit. Thus, it is estimated in Belgium that a suitable horse can be bought for, say, \$40; that it takes three months to render him immune, during which his keep and care, in that country, will cost \$35 more; that he may then be bled three times, furnishing 9,000 grammes of the serum (or 450 doses of the strength prescribed by Dr. Roux), worth,

at quoted prices, 20 francs for 10 grammes, or \$3,474—counting the franc at 19.3 cents American—for what cost \$75 to produce. It is not to be wondered at that, at the suggestion of Dr. Jules Felix, of Brussels, delegate to the last International Congress of Hygiene, a resolution has been unanimously adopted calling upon the Belgian government to establish a State institute for the production, preservation and distribution of the antitoxin, with all possible guarantee to insure its purity and standard quality, and also to secure its gratuitous supply to all medical men in Belgium for the free treatment of the poor, and its supply at a reasonable price to those able to pay. In the absence of the possibility of any such safeguard in this country lies one of the chief dangers of the antitoxin treatment here, and that this danger is a serious one is shown by the rancorous dispute now raging between the rival manufacturers in Europe. In which connection, by the way, it is worth while noting that shares in the Höchst establishment—one of the chief antitoxin producers and with which Professor Behring's name is closely associated—went up several points on the Frankfort Stock Exchange recently, on a rumor that the works would soon put on the market a typhoid antitoxin of Behring's discovery. Surely Behring can not already have forgotten the blow to Robert Koch's scientific reputation through a similar commercial manipulation of his name by the adventurer Levy in connection with the "tuberculin cure."

National Diphtheria Commission.—Prompted thereto, doubtless, by the suggestion and arguments of the JOURNAL, Representative Goldzier, of Illinois, has prepared and will endeavor to secure the prompt adoption of the following preamble and joint resolution for the creation of a National Commission for the investigation of the antitoxin treatment of diphtheria:

WHEREAS, The following propositions are believed to be true, to-wit: That the disease known as diphtheria is one of the most destructive of human life in this country—ranking in this respect only after consumption, pneumonia and the diarrheal diseases; that it is steadily increasing in prevalence and in the number of its victims; that its mortality, under the usual methods of treatment, is equal to, or greater than, that of unmodified smallpox; that recent scientific developments in Europe seem to have evolved a method of treatment by which the mortality of the disease is reduced more than one-half, with promise of still better results; and that the details of this new method and the claims made for it should be thoroughly investigated and authoritatively reported upon for the information of the medical profession in the interests of the public health; therefore, be it

Resolved, By the House of Representatives, the Senate concurring, That the Secretary of the Treasury, the Secretary of War and the Secretary of the Navy be, and they are hereby, authorized and directed to create a commission for the investigation of the antitoxin treatment of diphtheria, said commission to be composed of not more than three officers of the medical services of each of the respective Departments, which officers shall be selected for their special qualifications for such investigation and shall serve without extra pay or emolument; that said commission shall immediately proceed to the proper localities for the necessary study and research and shall prepare, with as much promptness as is consistent with thoroughness, a report embodying the results of their investigation, which report, upon the joint approval of the Surgeons-General of the Army and Navy, and of the Supervising Surgeon-General of the Marine-Hospital Service, shall be published in a special edition of the Abstract of Sanitary Reports now published by the Treasury Department in accordance with the Act of Congress of Feb. 15, 1893.

Credit Side of the Cholera Account.—A reduction of more than 15 per cent. in the general death rate is, grossly stated, the claim made for the sanitary administration of Great Britain initiated by Sir John Simon in 1865, when he undertook the defense of that country against Asiatic cholera. Abandoning *in toto* the system of defense by quarantine restrictions, as against that individual disease, a vast machinery of notification, isolation and disinfection with reference to the infectious and contagious diseases generally, has been organized, the efficiency of which may be measured, with substantial accuracy, by the statistics of one group of diseases—the typhoid or enteric and other continued fevers. Thorne

has recently shown that, whereas the mean annual death rate of this group was 567 per million living in the five years 1869-73, it was only 179 in the five years 1888-92; that if, during this latter quinquennium, people had died of these fevers at the rate at which they died in the former five-year period, there would have been during 1888-92 no fewer than 55,808 more deaths than actually occurred; and that had the same mortality obtained in 1892 that prevailed in 1869 no less than 14,232 persons who, at the end of 1892, had escaped death from these causes, would have died during that year. "In short," he says, "even if cholera had recurred in England and Wales between 1867 and 1892—a period during which that disease was practically absent from our midst—on the same scale as between 1849 and 1866, we should still be the gainer by several hundreds of thousands of human lives. And our gain in this respect is largely due to the incentive given by reason of cholera prospects and of the knowledge that the disease would have to be met by improved sanitary administration."

MISCELLANY.

Personal.—Gen. R. G. Dyrenfurth, an ex-Commissioner of Patents and well known from his experiments at "rain-making," is a graduate in medicine, his *alma mater* being the Baltimore College of Physicians and Surgeons.

Indiana Insane Asylum Report.—The annual report of the superintendent of the Northern Indiana Insane Hospital at Long Cliff, shows 508 inmates at present, with a total of 1,478 admitted. The hospital was opened in 1888. The capacity of the hospital has been increased by the construction of a new hall, and it is recommended that a further addition be erected with a capacity of eighty.

A New Food Supply.—According to *Das Schiff* two new industries have been created in Germany, owing to the development of the sea fisheries—the manufacture of sausages and of guano from fish. The sausages are made by stuffing skins with the prepared fish, as in ordinary meat sausages, and may be sold very cheap, not exceeding 1 franc per kilogram. The guano is made by adding chalk to the *debris* from the fish; it is then dried, reduced to powder and is highly appreciated as a fertilizer.

Thermometers for High Temperatures.—Mercurial thermometers give no exact indications beyond 250 degrees C., but when the tube is filled with nitrogen under pressure, temperatures up to 450 degrees C. may be registered. M. Niehl, at the Institute of Technical Physics in Berlin, has constructed thermometers which register up to 550 degrees, by substituting gaseous carbonic acid for nitrogen. The tubes are made of the boro-silicate glass from Jena, which does not melt below 600 degrees C.

Craig Colony for Epileptics.—Dr. William P. Spratling, of New York City, has been elected Superintendent of Craig Colony for Epileptics in that State. This institution was created by the last Legislature and embraces 1,800 acres of land in the famous Genesee Valley. There are now fifty-four buildings on the site, and the coming Legislature will be asked to appropriate \$300,000 for the construction of an administration building, hospitals and observation cottages. The colony will be modeled largely after the celebrated German colony at Bielefeld.

New Institutions for the Sick in Maryland.—A new home for epileptics has been established at Port Deposit, Md., to be known as the Silver Cross House for Epileptics. The educated colored physicians of Baltimore purpose to inaugurate a hospital and dispensary, for people of color, and a building has been procured. There is said to be a colored population in that city amounting to 75,000, abundantly able to give support to an undertaking of this nature.

An additional State Hospital for the Insane will be built in 1895. The sum of \$75,000 was appropriated by the last Legislature to that object.

Medallion of the late Professor Knox.—A memorial medallion of the late Prof. James Suydam Knox was presented to Rush Medical College by his widow, Mrs. Elizabeth H. Knox, December 5. The medallion is of bronze and was

ORIGINAL ARTICLES.

A SERIES OF APPARENTLY WELL ESTABLISHED FACTS IN THERAPEUTICS ON WHICH ARE BASED SOME QUESTIONS OF GREAT PRACTICAL IMPORTANCE.

BY N. S. DAVIS, M.D., LL.D.
CHICAGO.

1. The three well-known anesthetics in common use—ether, chloroform and alcohol each and all, when received into the blood, either by inhalation, hypodermic injection, or by the stomach, first suspend the sensibility of the cerebral hemispheres (unconsciousness or anesthesia), and next they suspend in succession or simultaneously the functions of the respiratory, vasomotor and cardiac nerve centers or ganglia, thereby suspending life. It is hardly necessary to adduce proof of this proposition, as it is familiar to every practitioner of medicine and surgery.

2. Each of these three anesthetics act on the nervous centers in the same direction, and consequently each intensifies the action of the others, whether given together by inhalation as in the A. C. E. mixture, or separately by different methods, provided they are present in the blood at the same time. The correctness of this proposition is demonstrated by the experiments of Dubois in 1883, and still more fully by those of H. C. Wood as detailed in his "Address on Anesthesia" to the Tenth International Medical Congress, Berlin, 1890, and by many carefully observed clinical facts.

3. The action of these three anesthetics—alcohol, chloroform and ether, on the cerebral, respiratory, vasomotor and cardiac nerve centers, is not only in the same direction, but that direction is one of *diminished sensibility* or paralyzant in direct proportion to the quantity used. This has been so perfectly demonstrated by the well-known experiments of Sidney Ringer and Sainsbury; Professors Martin and H. C. Wood; David Cernay, J. H. Kellogg and others, particularly in regard to the action of alcohol, that it must be admitted as an established fact, or we must deny the value of all experimental therapeutics.

4. These anesthetics not only directly diminish nerve sensibility and force, but their presence in the blood so modifies the action of the hemoglobin, corpuscular elements and albumen, as to diminish the reception and internal distribution of oxygen and to lessen the activity of the cell nuclein and leucocytes; and consequently they lessen all metabolic and natural excretory processes. The correctness of this proposition is sustained by an amount of both experimental research and clinical observation sufficient to fill a fair-sized octavo volume. So far as relates to the action of alcohol, the reader will find these proofs alluded to more in detail in a paper

prepared by me for the World's Temperance Congress in Chicago, 1893, and published in the second volume of "Temperance in all Nations," 58 Reade Street, New York, and also in an interesting volume "On the Effects of Alcohol," by Dr. J. E. Usher, London.

5. When alcohol or either of the anesthetics named, is retained in the blood but a few hours, as is usually the case when administered for strictly anesthetic purposes, the effects mentioned in the four preceding propositions soon disappear. But when the dose is repeated sufficiently often to keep it pretty constantly present in the blood and tissues for weeks, or months, or even years, as when alcohol is administered liberally from the beginning to the end of many of the acute general fevers and some chronic affections, or drunk in the form of beer, wine or distilled spirits as a beverage, the constant impairment of nerve sensibility and force and the coincident impairment of oxidation processes necessary for healthy tissue metabolism and excretion, directly encourage fatty or atheromatous degenerations in almost every tissue in the body, and especially in the stomach, liver, lungs, heart and kidneys, as may be seen illustrated in every case of chronic alcoholism. It is this effect of alcohol in diminishing the internal distribution of oxygen and also the activity of the nuclein and leucocytes of the blood, that makes the individual using it more liable to attacks of almost every variety of acute disease, whether epidemic or endemic, and lessens his vital resistance when attacked. So true is this, that every modern writer of note on practical medicine tells us that even habitual *moderate* drinkers of alcoholic liquor give a much higher ratio of mortality when attacked with cholera, continued fever, pneumonia, influenza or almost any other acute disease, than the total abstainers. Even the more intelligent part of the non-professional public have come to quite generally recognize this inherent and inevitable power of alcohol to impair man's physical power and activity, and hence they prohibit its use in all circumstances requiring the highest degree of activity and endurance, whether mental or physical. Having stated as plainly as possible the five foregoing propositions, and believing their correctness to be capable of abundant proof, I will ask a few questions of very great practical importance both to the profession and the public:

1. If alcohol when taken into the living body directly diminishes nerve sensibility, muscular force, and so alters the constituents of the blood as to retard both the internal distribution of oxygen and natural tissue metabolism in direct proportion to the quantity taken, why do we continue to speak or write concerning it, or to use it, as a *stimulant*, *heart tonic* or *restorative agent*? Is not such designation untrue, and directly calculated to perpetuate errors of the most destructive character, both as regards its use as a medicine and as a beverage? Why not give it its

true designation, *i. e.*, an anesthetic and organic sedative; and to be used only as such?

2. If the presence of alcohol in the blood directly diminishes respiratory, vasomotor and cardiac nerve force, and retards the reception and internal distribution of oxygen, what possible indication can there be for its use in such diseases as pneumonia, diphtheria, typhoid fever, etc., in which all the functions just named are already below the natural standard? Would not its presence not only still further depress the respiratory and vasomotor functions, but also by retarding the internal oxidation and metabolic processes, help to retain in the system both the specific toxic agents and the natural products of tissue changes, and thereby increase both the duration of the disease and the danger of final exhaustion?

3. Does not an accurate study of the history of the therapeutics show that, the greater the amount of alcohol or other anesthetics used in the treatment of the general acute diseases, especially those named under the preceding head, the higher has been the average ratio of mortality?

4. If alcohol and other anesthetics actually diminish cerebral; respiratory and vasomotor functions in proportion to the quantity used, why administer them to any patient coincidentally with strychnin, digitalis, strophanthus, convallaria, cactus, or other direct cerebro-spinal, respiratory and vasomotor tonics? As both direct experiment and clinical observation have proved that strychnin, digitalis, etc., most reliably antagonize the effects of alcohol and chloroform, is it not the climax of therapeutic inconsistency to give a patient a hypodermic injection of strychnin and at the same time fill his stomach or rectum with whisky or brandy?

5. How is it possible to determine the real value of the antitoxin serum in the treatment of diphtheria, if the patient is given at the same time liberal doses of a toxic bacterial product in the form of wine, whisky or brandy? And if these latter are omitted or their quantity greatly reduced, how shall we know whether the increased ratio of recoveries is owing to the virtues of the antitoxin serum or to the omission of the toxin, alcohol? Having carefully noted the published results of the treatment of diphtheria by antitoxin serum, as given in the best medical periodicals, I find a very large proportion of the cases so imperfectly described as to render them of no value in determining practical results. In many cases, nothing is said about any coincident use of other remedies; in other cases it is simply said that stimulants and nourishment were given, but what kind or amount is not stated; in still other cases the administration of quinin, iron, etc., is mentioned in addition to stimulants and nourishment; and in one case reported in the *British Medical Journal*, the child, 6½ years old, presenting symptoms of an average case of diphtheria without laryngeal obstruction, was treated with antitoxin and was represented as progressing very favorably until the fifth or sixth day, when a moderate antitoxin injection was given and six ounces of brandy ordered to be given the succeeding twenty-four hours. The next day the child was cyanosed and soon died. Can any one be quite certain whether this last case died from the toxin of diphtheria, the antitoxin, or the torula cerevisæ toxin in the six ounces of brandy?

Is it not practicable to have three or four hospitals admitting diphtheria patients supplied with a suffi-

cient quantity of some one of the reliable antitoxin preparations and then make a fair test of its efficacy by treating in parallel beds with good air, rigid cleanliness, and good milk for nourishment but no alcoholic stimulants, two series of cases as nearly alike in severity as possible. To one series of cases, let the antitoxin or antitoxin serum, be given in strict accordance with the most approved rules, and no other internal remedies. To the other series, let just enough calomel be given during the first or second day of the attack to procure one or two intestinal evacuations, and let this be followed by small but frequently repeated doses of a solution of bichlorid of mercury and belladonna until the diphtheritic membrane begins to break up, which is generally between the fourth and sixth days, then substitute suitable doses of tincture of chlorid of iron and quinin until the case is terminated. Let the most complete record possible be made in both series of cases, and then we shall have data that are parallel or comparable, and from which the most reliable practical conclusions can be deduced. If, in cases in either series, the disease invades the larynx sufficiently to demand it, intubation or tracheotomy should be performed as in other cases. The results of the two series of parallel cases thus managed would not only be comparable with each other, but both would be comparable with the results of the liberal alcoholic, and all other methods of treatment in vogue.

AN INSTRUCTIVE CASE OF APPENDICITIS NECESSITATING AN UNUSUAL METHOD OF OPERATION.

BY JOHN A. WYETH, M.D.

NEW YORK, N. Y.

On Sept. 29, 1894, I saw, in consultation with Dr. Herri-man, of Long Island City, New York, a young lady, 16 years of age, who, from the history given me at the time, evidently had an attack of appendicitis beginning ten days before this time. There was a large well-recognized tumor in the right iliac fossa, and although deeply seated, fluctuation was evident by palpation through the abdominal wall and the intervening viscera.

Operation was advised, and undertaken at once. The anesthetic used was chloroform. Upon opening into the peritoneal cavity through the usual incision, a large mass was discovered, in no place adherent to the abdominal wall. It was evidently an abscess due to perforation of the appendix, the walls of this abscess being made up of plastic lymph thrown out in advance of the inflammatory process, and agglutination of the neighboring intestines.

I recognized that any attempt at the removal of such a large mass by dissection, would lead to its rupture, escape of pus into, and general infection of, the peritoneal cavity.

The whole mass was lifted over to the patient's right side, a contiguous surface of omentum was stitched to the wall of the incision in the abdomen in such a way that it shut off from the general peritoneal cavity the proposed opening into the abscess. Sutures were applied upon the outer side of the wall of the abscess, and this was also stitched to the incision. Iodoformed gauze was carefully packed into the wound, which was left open, and further operation deferred for forty-eight hours in order to secure firm adhesion of the abscess wall to the margins of the incision. Forty-eight hours later, the abscess was easily opened without an anesthetic, was freely drained and the patient made a perfect recovery.

There was present at the operation, in consultation, a medical practitioner of New York City, of large experience, who informed me that he had seen a patient of his perish from the rupture of an abscess in connection with appendicitis, which was in every respect similar to the one we had just operated upon; that

the surgeon had made an effort to dissect the abscess out, it had ruptured and caused a general infectious peritonitis, from which the patient died. I, myself, had seen one other case in which a fatal termination was scarcely averted by leaving the wound open, and general packing, and had determined then that I would never again undertake to dissect out a large well-recognized abscess of the appendix until I had secured adhesions sufficiently strong to hold the abscess wall in contact with the abdominal parietes.

It not infrequently happens that when the abdominal cavity is entered in operations for appendix abscesses of long standing (six or twelve days), there are no adhesions between the wall of the abscess and the anterior abdominal wall, but adhesions have formed posteriorly in the iliac fossa, or the abdominal wall immediately over the crest of the ilium. Under such circumstances, it is the proper practice to use the anterior incision as a guide to the abscess cavity through a posterior incision made along the crest of the ilium, or over the point of firm adhesions.

In this manner the abscess is opened and drainage secured without danger of infecting the peritoneal cavity.

MINERAL SPRINGS OF CALIFORNIA.

BY WINSLOW ANDERSON, A.M., M.D., M.R.C.P., LOND.
SAN FRANCISCO, CAL.

From the earliest dawn of history, mineral waters have been highly extolled for their medicinal properties. The ancient Egyptians and Arabians used mineral waters in the treatment of many diseases. The hot sulphurous springs of Tiberias (now called Tabareah) have been in extensive use for the past 3,000 years, as they are at the present day, by patients from all parts of Syria. The thermal baths of Calirrhoe near the Dead Sea, made famous by Herod are still in use. The ancient Greek and Roman physicians prescribed mineral waters extensively, as may be seen from the writings of Hippocrates, Aristotle and Herodotus. Homer speaks of using mineral waters for bathing, for the preparation of sacrifice, for the reception of oracles and for holy marriages. Josephus and Pliny refer to the marvelous curative powers of mineral waters. The thermal springs of Thermopylae, immortalized by the heroic Spartans, have been in use for over twenty centuries and many are the remarkable cures accredited to their waters. The ancients erected magnificent temples in proximity to these fountains of health and dedicated them to their god, Æsculapius. Costly tablets were inscribed and placed in the temples, commemorative of the patients' gratitude. (Some of these tablets may be seen even to this day in the museums of Europe.)

The popularity of these mineral fountains of health has not been decreased by the discoveries of new worlds. Indeed, we find that our own aborigines in America have been using mineral waters for centuries, often traveling hundreds of miles to drink and bask in their smiling waters. Nor have the modern discoveries in medical science decreased the use of mineral waters; on the contrary, mineral water bathing and the internal use of mineral waters have increased enormously in America, as well as all over Europe. Balneotherapy and the internal use of mineral waters have become recognized branches of medicine to such an extent that many European universities have established chairs which are filled by

some of the ablest men of the period, for the purpose of teaching the effects of the external, as well as the internal, use of mineral waters on the human economy.

CALIFORNIA SPRINGS.

In California, on the golden shores of the Pacific, we have over two hundred mineral springs of all known varieties from the cool, delicious effervescent soda and sparkling Vichy, to the hot sulphurous wells direct from Pluto's realm, ever ready and ever flowing to alleviate suffering mortals. In 1890 I wrote: "When our California mineral springs become more generally known and their similarity to the famous European spas better understood, our invalids will not find it necessary, nor indeed expedient, to undertake the long, tedious, expensive and in many instances hazardous journey abroad, when

THE GOLDEN WEST.

they can find right here in California almost the identical mineral waters they have in Europe, besides all the conveniences of luxurious accommodations, a greater variety of food products and a pure, dry and balmy atmosphere—an invigorating and stimulating winter climate not equaled in any other country on earth.

USES OF MINERAL WATERS.

The *sine qua non* of the use of any mineral water is that it be thoroughly analyzed by a competent chemist, that its mineral ingredients be vouched for, and that as the internal administration and external application of natural mineral waters have been reduced to a scientific basis, it is quite important that the rules regulating their administration should be followed.

¹ See Anderson's Mineral Springs and Health Resorts of California

Thousands of invalids, ill-advised or perhaps wholly unadvised, seek the different springs and health resorts annually. During my travels among the springs of California, I frequently found people whose cases were actually aggravated and a fatal termination hastened by the use of *the wrong mineral water*.

Mineral springs are not "cure-alls." As a rule, too much is claimed for them. The many marvelous cures cited and the many improbable and ridiculous statements seen on printed circulars do more harm than good. Sensible people are not going to believe that a "magnetic" mineral water can cure a "bad case of consumption," or that any "mineral water" cures heart disease, etc. On the other hand, it would be quite as flagrant an error to suppose that all the

CALIFORNIA PALMS.

reputed beneficial effects of mineral waters were the result only of extravagant or interested imaginings.

To obtain the greatest possible benefit from the springs, it is absolutely essential that the patient first consults his regular family physician who makes a careful diagnosis, then if a change of scene and a course of treatment at some spring be truly advantageous to the patient, let the physician, who is certainly the most competent to advise in such matters, recommend the resort best suited to the case, or send the patient to consult some physician who has paid special attention to mineral waters and their uses. In this connection I have found that if mineral waters and the hygienic *régime* recommended be used as

auxiliaries to the regular internal treatment, the best results may be hoped for. Once at the springs the patient should follow implicitly the directions of the resident physician, who, if armed with a personal letter from the patient's regular physician can prescribe wisely and at once.

The indiscriminate use of mineral waters, either for drinking or bathing purposes can not be too strongly condemned, for while they look bland and harmless, they are potent therapeutic agents which may accomplish much good if judiciously employed, but may also do much harm and may be followed by serious if not fatal results in careless hands.

The climate in California is conducive to the highest excellence in mental activity and physical strength. When an individual contracts a disease—rheumatism for instance—which requires several weeks for a complete cure, he becomes restless and eager to follow his vocation. The result in many cases is, that as soon as the patient is able to walk at all he begins the continuous rush of business and neglects his disease, which gradually lapses into a subacute or chronic state. In this condition, perhaps, he goes to the springs. Here the same restlessness characterizes the average Californian, and, indeed, the majority of American patients. He will "rush" the treatment. If one glass of water be prescribed three times daily, he will take half a dozen glasses as many times a day. If one sulphur-water or mud-bath be prescribed, once in three, or once in two days, he will want to take it two or three times daily in order to hurry up the treatment. This is not an overdrawn or an individual instance. Resident physicians have repeatedly informed me of the difficulty experienced in keeping patients within due bounds, and in more than one case this rushing and unauthorized self-treatment has resulted fatally in less than one week's time. Therefore, let patients who go to the springs, be thoroughly examined and their diseases carefully diagnosticated. Let the intelligent physician send his patient to the springs best suited to the individual case, and while there let him drink the waters, use the baths, and follow the *régime* directed by the resident or supervising physician. This plan, with judicious internal medication promises the best results.

THERAPEUTIC ACTION OF MINERAL WATER.

The specific action of mineral waters must depend upon the chemic ingredients they contain. Mineral waters, as a rule, are well borne by the stomach. They are readily and rapidly absorbed, carrying the ingredients which they hold in solution in the most minute form of subdivision into the circulation. By the use of mineral waters much larger quantities of fluid also are taken which assist in distending the minute ramifications of the capillaries, thereby assisting the removal of morbid products of chronic congestion or inflammation. Mineral waters act on the peripheral nervous system stimulating the circulation. They also act as simple diluents, flushing out the renal and chylo-poetic viscera, diluting the fluids of the body and assisting elimination. The carbonic acid gas which nearly all of the mineral waters contain, is very grateful to the gastro-intestinal mucous membranes. It enters the system charged with mineral particles and presents them to the mouths of the absorbents in a highly diluted condition. The gas promotes absorption by its tonic

and stimulating action on the nervous and vascular systems. This would seem to explain why the fractional part of a grain of peroxid or carbonate of iron, finely subdivided and largely diluted with water, and an abundance of gaseous acid may exercise a greater influence on the system on account of its rapid absorption by the stomach and intestinal absorbents than many times more of the pharmaceutical product which has first to be dissolved, diluted and subdivided by the gastric juice previous to absorption. It is of common observation that the stools rapidly become dark after the exhibition of ferruginous salts because the iron is not absorbed. One-tenth of a grain of iron in solution in a carbonated mineral water will accomplish as much good as ten grains taken without a suitable vehicle, simply because very little of it is absorbed.

SUMMARY.

1. Carbonated and chalybeate mineral waters are, as a rule, easily borne by the stomach.
2. They stimulate digestion.
3. Accelerate absorption.
4. Improve capillary circulation.
5. Assist in the elimination of morbid and waste material.
6. Act as diluents.
7. Besides exerting a more or less specific action on different diseases according to the mineral ingredients of the water.

The diseases which I have found to be most benefited by mineral waters are: Atonic and catarrhal dyspepsia, hepatic and splenic engorgement, atony of the bowels, flatulence and chronic constipation, inactivity and congestion of the kidneys, irritability and chronic inflammation of the bladder, chronic malaria, hydremic conditions of the blood and weak circulation, chronic articular diseases such as rheumatism, rheumatoid arthritis, gout, synovitis, glandular enlargement, blood-glandular diseases, scrofulous, syphilitic and cutaneous contaminations, etc.

It is needless to remark that each disease requires a different régime, different mineral waters and different internal and external medication. (The consideration of mineral water and mud-bathing has been omitted for a future article.)

With the caution given relative to a careful diagnosis, proper internal medication and the selection of the special springs or mineral water which is suitable for the individual case, a patient sojourning for a few weeks or months at some of our California springs will accomplish much toward the alleviation and eradication of his disease. The entire change of his habit of living, the pure wholesome food with plenty of fresh, pure, ozonized California air are auxiliaries which, with our California mineral springs have restored many broken-down, overworked and diseased individuals to health, strength and future usefulness.

608 Sutter Street.

THE IDENTIFICATION OF THE TYPHOID FEVER BACILLUS.

BY EDWIN O. JORDAN, Ph.D.*

CHICAGO.

Few points are of more fundamental importance to the practical bacteriologist than the ability to identify quickly and with unfailing certainty a given

pathogenic organism. In the early days of pure cultures the work of describing accurately and exhaustively the different "species" of bacteria was entered upon with a confidence perhaps unwarranted. There was a general, if not fully expressed feeling, that certain characters sufficed to distinguish unmistakably a particular species, and that these characters when once determined were safe recognition marks. From this comfortable initial position we have in several instances been forced to recede. This withdrawal of our reliance on characters once believed to be "diagnostic" has been most marked, perhaps, in the case of the specific organism of typhoid fever.

The Eberth-Gaffky bacillus, as is well known, has been found to bear so close a resemblance to bacillus coli communis, a common saprophyte and a normal inhabitant of the intestine of many animals, that several investigators (Rodet and Roux, Arloing, Malvoz) have been led to conclude that the two organisms are substantially identical. The considerable variability of the typhoid bacillus, together with the existence of numerous intermediate "varieties" have helped to give color to this view and have certainly augmented the difficulty of identifying the typhoid fever germ.

The morphology of the typhoid fever organism is far from distinctive, all the salient morphologic characters being repeated more or less closely by the colon bacillus or by some of the intermediate varieties. The typhoid bacillus, for example, when grown in bouillon, shows a tendency to form long threads, a trait that is not ordinarily shared by the bacillus coli. I have, however, through the kindness of Dr. A. P. Ohlmacher, recently come into possession of a culture of the latter obtained from an old peritonitis, which is not only actively motile, but grows out into long threads precisely simulating the typhoid growth. Some investigators¹ have considered that the larger number of flagella borne by the bacillus typhi suffice to distinguish it from the bacillus coli group, but this view is by no means generally accepted. Most investigators have been unable to recognize a constant difference in this respect. My own observations on this point have not led to any constant result. The age of the culture and character of the culture medium, as well as certain undetermined causes, bring about considerable variation in the number of flagella. It is interesting to compare the statements made by those who regard the number of flagella as diagnostic. According to Luksch, bacillus coli possesses from one to at most three flagella, while the bacillus typhi has from eight to ten. Nicolle and Morax² state that the maximum in the bacillus coli is ordinarily six, but may be "exceptionally eight to ten," while in the bacillus typhi ten to twelve are frequently found. Moore³ in his careful study of the character of the flagella borne by certain members of this group has reached a negative conclusion: ". . . the number of flagella on the individual bacteria vary in the different fields in the preparations from the same species as much as in those from different species, excepting in the maximum numbers; this is also true of the length of the flagella." ". . . Until further facts are determined, the character of the flagella will not furnish a means for specific differentiation."

The typhoid bacillus itself exhibits great varia-

² Annales de l'Inst. Pasteur, 1893, p. 554.

³ Wilder Quarter-Century Book, 1893, p. 330.

* Instructor in Biology in the University of Chicago.

bility in form under changing conditions. Slight fluctuations of temperature, culture media of varying composition and of different degrees of alkalinity give rise to considerable variations in shape and size, while one and the same culture, examined at different ages, is sure to afford a wide range in form and dimensions. Gasser⁴ is so impressed by its variability in form, that he declares that no organism is so polymorphous as the typhoid bacillus, even when it is grown in the same culture medium. The changes in structure induced by change of habitat, food supply, etc., are familiar to all students of the higher organisms and are phenomena coming under the daily observation of bacteriologists.⁵

It is to-day, therefore, generally admitted that the morphologic characters of the typhoid fever organism are not of diagnostic value, and do not permit us to separate it surely from the common colon bacillus.⁶ In all the higher organisms, both plant and animal, differences in structure are the generally recognized basis for classifying organisms into such groups as species and varieties. Physiologic traits can not with safety be utilized for this purpose, since they are more likely to undergo sudden and radical change. Changes in function usually precede and in large measure determine changes in structure. Examples of the diversion of physiologic activity from one channel into quite a different one will occur to every one. Such being the case, the fact that we are at present forced to base our diagnosis upon the physiologic characters of the typhoid bacillus does not at the outset inspire us with great confidence in the soundness of our method. Since morphologic characters, whether from the inadequacy of our microscopes or the low structural differentiation of the bacteria, fail to afford us means of diagnosis, we are compelled to fall back upon functional characters confessedly liable to great and sudden change.

If we examine, for example, the question of motility, a physiologic character of considerable importance, we find ourselves beset with difficulties. The nature of the culture medium and the age of the culture have here full play as disturbing influences and may lead to very discordant results. The typical typhoid bacillus is actively motile, while the colon bacillus is usually described as non-motile. Under certain circumstances, however,—at present imperfectly understood—the typhoid bacillus does not exhibit movements of translation. According to Germano and Maurea, the presence of acid in the culture medium is one of these perturbing factors. Furthermore, it is well known that the power of motion is one of the characters frequently parted with by many bacteria during a long-continued series of transfers. Every one who has had occasion to isolate species from water and soil has observed species which are motile when first examined, but which lose the power of movement under prolonged artificial cultivation.

The lack of motility alleged of the bacillus coli rests upon a similarly inadequate basis. Escherich, indeed, to whom we owe the first description of the

bacillus coli, describes this form as possessed of slow movement. I have not been able to satisfy myself as to the occurrence of really "slow" or "sluggish" movements among the members of this group. The difference seems rather to consist in the proportion of individuals exhibiting any movement at all. Most coli-like varieties show in the hanging drop a whole field of motionless individuals, but, with continued observation, two or three active individuals may occasionally be detected. In *kind* of movement I have not been able to discover a difference between these forms and the typhoid organism. There are undoubtedly some "intermediate" forms, like the one I have noticed above, which are actively motile. We are not at present in position to assert confidently that a motile typhoid-like bacillus can not be a variety of bacillus coli any more than we are able to deny that a non-motile coli-like bacillus may after all be a modified typhoid germ.

It is to the existence of these "varieties" or "intermediate" forms, these *coli-ähnliche* and *typhus-ähnliche* bacilli, that the difficulties of diagnosis are due. Broadly speaking, these "varieties" of the typhoid bacillus resemble the latter in morphology and in their growth upon plates of nutrient gelatin; they form no spores and do not stain by Gram's method. The true typhoid bacillus has, however, been considered as separated from these varieties by its possession of certain well-marked peculiarities. The growth of this organism on potato was for long regarded as of diagnostic value, but confidence in this test was shattered by the work of Pfuhl and Kitasato. The failure of the "invisible film" as a final test has, however, never been more clearly demonstrated than in the recent discovery made during Kruse and Pasquale's studies on dysentery⁷ of a *typhus-ähnliche* bacillus in pure culture from the liver. The bacillus grew upon potato exactly as the "typical" typhoid bacillus should do, and proved itself in other respects similar to the typhoid germ. Upon the other half of the potato, the real typhoid bacillus grew atypically. The newly discovered variety was more "typical" than the typhoid bacillus itself. Upon another slice of potato, however, on which the typhoid bacillus grew typically, the "variety" grew atypically.

Other physiologic attributes have, one by one, met with a similar fate. The negative-indol reaction put forward by Kitasato, the cultures in colored media,⁸ the production of acid or alkali,⁹ the coagulation of milk have all failed as definite and final criteria. A coli-like bacillus that forms indol in a peptone solution containing no sugar may indeed be definitely excluded from the typhoid group, but the inability of a *typhus-ähnliche* bacillus to produce indol in no way assures us that we are dealing with the genuine typhoid organism. Similarly, inability to coagulate milk is not diagnostic. Coli-like bacteria that produce indol and coagulate milk are certainly not typhoid bacilli, but typhoid-like bacteria that are unable to bring about either reaction can not, on this ground alone, be unmistakably identified as true typhoid germs.

Few bacteriologists who have studied the bacteria of this group have failed to meet with these intermediate varieties. J. M. Flint in some yet unpublished

⁴ Archives de Méd. expt. Jan. 1891.

⁵ The changes induced in lowland plants by removal to higher altitudes is a case in point. The aerial shoot-axis becomes dwarfed and the subterranean parts, on the other hand, undergo an exaggerated development, while plants of an annual habit in the plains become perennial at the higher elevation. Goebel adds significantly: "These transitory changes answer in general to the characteristic hereditary peculiarities of Alpine plants."

studies upon the distribution of bacillus coli, has discovered in the feces of the moose a bacillus resembling the typical bacillus coli in all points, except that it is unable to produce indol. I have recently obtained from the spleen of an individual, dead from typhoid fever, a pure culture of a bacillus which agrees with the colon bacillus in all respects, save that it does not coagulate milk even after prolonged growth, and does not grow in formalin bouillon.¹⁰

There is one test of this character, however, which has for some time stood on quite a different footing from the others and has been generally regarded as making it possible to exclude definitively these troublesome varieties. This physiologic character is the ability to ferment grape-sugar in a peptone medium. The typical typhoid bacillus is unable to perform this feat, but the typical colon bacillus invariably ferments the sugar with abundant production of gas. It has of late been pretty universally held that the "varieties" also could always be distinguished from the typhoid bacillus by the power they possessed of fermenting sugar. To the work of Theobald Smith is due our knowledge of this valuable characteristic. The most recent and thorough-going comparative investigations upon the typhoid bacillus and its allies—those of Germano and Maurea—support the position taken by Smith. These authors consider this test to be unfailingly diagnostic, and assert that, "*Dieser Charakter ist beständig und führt also sicher und schnell zur Unterscheidung des Typhus bacillus von den typhus-ähnlichen Bakterien.*"¹¹

Fuller,¹² after frequent water examinations covering more than a year and involving more than twenty-four hundred species determinations, comes to the conclusion, "that there appear to be no other non-liquifying bacteria in the water of the Merrimac River which do not coagulate milk and also produce a turbidity without gas, in the Smith test." Notwithstanding this weighty testimony, it appears that the glucose-fermentation test must now share the fate of the other "diagnostic" characters. Kruse and Pasquale, in their paper already referred to, find that three out of the twenty-five cultures of *typhus-ähnliche* bacteria examined by them, comport themselves like the typhoid bacillus, *i. e.*, produce no gas in glucose-agar. A similar but less satisfactory statement has been made by Roux and Rodet. There is little reason to doubt that the fermentation of glucose, although a very valuable aid in diagnosis, is no more a final criterion than the other physiologic attributes that have, one by one, been advanced as "characteristic," only to be overthrown by subsequent discoveries of intermediate forms. It might almost be anticipated on purely *a priori* grounds that further research will bring to light other *coli-ähnliche* bacteria unable to ferment glucose when put to the test.

One of the most recent attempts to establish a diagnostic character for the typhoid germ is that of Schild,¹³ who uses formalin bouillon (1 to 7000) and finds that with pure cultures of the typhoid bacillus the bouillon remains perfectly clear, whereas with bacillus coli and its allies the fluid soon becomes turbid. My experience with this differential test inclines me to think that at best it will not rank higher than the negative indol reaction. I have referred

above to one intermediate form I have studied which, in most of its physiologic attributes, is far removed from the typhoid organism, and yet which refuses to grow in 1 to 7000 formalin bouillon. I see no reason for regarding this as an isolated example.

At this point, I may be allowed to digress so far as to note the parallel afforded by the present condition of the means for diagnosis of the cholera vibrio. Here, as in the case of the typhoid bacillus, morphologic characters are not distinctive and the only recognition marks of the cholera germ are physiologic. There exist not only "varieties" of the cholera vibrio which have been found in outbreaks of cholera in certain localities, *e.g.*, the Massanah vibrio described by Pasquale, but also, precisely as in the case of the typhoid bacillus, there exist confusing water vibrios which simulate more or less closely the typical cholera vibrio. Bacteriologists have now to reckon with a vibrio danubicus, a vibrio berlinensis, and other cholera-like organisms. Furthermore, in the light of recent research, the "cholera reaction" can no longer be regarded as characteristic of the cholera germ, and it is widely admitted that this much relied upon nitroso-indol color test is not a final criterion. The inoculation of animals is declared, in a recent interesting discussion of the question,¹⁴ to possess even slighter diagnostic value than the nitroso-indol test. The single attribute of the true cholera vibrio which may at present be regarded as "characteristic" is the growth in gelatin, and this only when carefully controlled under certain definite and constant conditions.

The difficulties met with in identifying the typhoid bacillus are not, therefore, singular or unique; we have, however, for the moment, come to closer quarters with them than we have yet reached in the case of cholera.

The close similarity of the products of the common colon bacillus and the typhoid bacillus has justly attracted much attention. Cesaris-Demel and Orlandi¹⁵ have studied in detail the highly remarkable correspondence between the metabolic products of these two organisms. These authors assert that in therapeutic and immunizing power the products show thorough-going biologic equivalence. They assert, moreover, that the serum of animals rendered immune against bacillus coli has both immunizing and therapeutic power against infection with the typhoid bacillus; the converse also being true. The recent revolutionary conclusions reached by Sanarelli¹⁶ must lead to a suspension of judgment on this point. Sanarelli's prolonged studies upon experimental typhoid fever lead him to maintain that the intestinal disturbances in this disease are due to the action of the toxin and not to the local action of the typhoid bacteria. He finds that the intestinal glands can be protected against the action of the typhoid toxin without in the least impairing the general susceptibility of the animal. He asserts, moreover, that the alleged identity of lesions produced by bacillus coli and bacillus typhi does not in reality exist; that the lesions of the latter are invariably far graver, while those of the former are of a septic nature. Sanarelli is unable to establish the biologic equivalence of the two poisons but finds, on the contrary, that the toxins of the Eberth bacillus exert upon the mucous

glands an action incomparably more energetic and severe than the toxins of the bacillus of Escherich.

While the close similarity of the colon bacillus and the typhoid bacillus is necessarily recognized by every one, and while it is admitted that there is no single criterion that absolutely distinguishes the latter from all of the perplexing "varieties" and "related forms," it is nevertheless maintained by many that the sum total of the morphologic and physiologic characters presents a true and unmistakable picture of the specific organism of typhoid fever. These investigators hold that, although the varieties may approach more or less closely to the typical typhoid germ, they may always be distinguished from it by at least some one character which is not shared by the genuine typhoid organism. One "variety," it is held, may differ from the typhoid organism only in its ability to produce indol, another solely in the glucose fermentation test, while still another differentiates itself from the "true" typhoid organism only in parallel cultures upon potato. It is said that it is the "true" typhoid organism alone, however, that is actively motile, produces no indol, is unable to ferment glucose, refuses to grow in 1 to 7000 formalin bouillon, and agrees in every other respect with the bacilli found in the spleen of a typhoid fever victim.

It will be observed that those who take this stand elude in a measure the very questions at issue. There is no doubt whatever that an organism is usually found in the spleen, mesenteric glands and other organs of an individual dead with typhoid fever, which may be distinguished from similar organisms by the methods above indicated. The question arises, however, as to whether this particular bacillus is the cause and the sole cause of typhoid fever. Can the "varieties" cause typhoid fever in favorable soil? Or, indeed, can harmless "varieties" be transformed under natural conditions into the "typical" pathogenic form? Neither of these questions has been satisfactorily answered. The fundamental point as to the invariable occurrence of the typical organism in the spleen of a typhoid fever victim can not as yet be regarded as definitely settled. The earlier investigators did not reckon with the then undiscovered varieties, and even the more recent work has not been of a very extended or rigorously comparative character. The fact must be kept in mind, moreover, that in the mesenteric glands, the liver, and the kidneys, the "varieties" are frequently found, while in the dejecta the "varieties," and even the typical colon bacillus appear frequently to far outnumber the typical typhoid organism. It might, indeed, be reasonably urged that the conditions environing the bacteria in the spleen tend towards a certain uniformity of type, that members of the coli-typhoid group under like conditions are forced into a like mold, and that the "varieties" may be as truly the cause of typhoid fever as the typical form. This argument is entitled to some consideration, but must be regarded as suggestive rather than convincing. Further research on this point is necessary.

In this connection, one aspect of the transformation question may be considered. It has not escaped notice that the typhoid bacillus differs from the colon bacillus chiefly in that it possesses the characters of a weaker organism. The former does not, as a rule, grow so luxuriantly upon gelatin and agar as the latter, is unable to produce indol or ferment glucose, does not live so long in water, and is prevented from

growing by a 1 to 7000 formalin solution. Some observers¹⁷ have gone so far as to assert that the typhoid bacteria isolated from corpses are in all cases weakened organisms, and to declare that many of the most "typical" reactions result from the physiologic incapacity of the enfeebled germs.¹⁸ It is interesting to note that one author (Blachstein) finds that healthy and virulent typhoid bacteria—isolated from dejecta—are able to produce in sugar-containing fluids a considerable quantity of gas and large quantities of lactic acid! I regard it as a fatal objection to the enfeeblement theory, however, that the typhoid bacillus is actively motile. I have observed active movement in a typhoid culture after nine months of artificial cultivation. This is the more remarkable since, as is well known, many bacteria speedily lose all power of movement under artificial conditions. The fact that the typhoid bacillus so tenaciously exhibits movement appears to me an insurmountable obstacle in the way of regarding it simply as a "weakened" variety of the ordinary non-motile colon bacillus.

By far the most important aspect of the question is that bearing on the direct transformation, and it is unfortunate that the evidence at our command fails here both in abundance and cogency. The position taken by Roux and Rodet is well known. These observers¹⁹ claim to have succeeded not only in so modifying bacillus coli that it lost the power of fermenting lactose, but also in imparting to a typical typhoid culture the ability to ferment lactose. A similar result is claimed by Vivaldi²⁰ who cultivated bacillus coli in gelatin mixed with filtered bouillon cultures of different water bacteria—*e.g.*, *proteus vulgaris*—and believes that under these circumstances bacillus coli can assume the characteristics of the Eberth-Gaffky bacillus. This transformation, however, was not permanent. One of the most interesting statements upon the transformation question is that by Malvoz as quoted by Chéron.²¹ By passing the colon bacillus through successive cultures in bouillon to which a little carbolic acid had been added, Malvoz obtained a form showing the characteristics of the Eberth bacillus.²² In all these reports of transformation experiments, however, the details are meager and unsatisfactory, and the conclusions reached by the authors are far from carrying conviction. The fact that bacillus coli can be made to lose such a property as that of indol production does not necessarily imply a nearer approach to the typhoid bacillus. The totality of the characters of the altered form may, it is possible, diverge more widely from that of the typhoid bacillus than does that of the normal colon bacillus.

There is a certain kind of evidence that bears more or less relevantly upon the questions considered. Such, for instance, is the statement by Denys and Martin²³ that their old cultures of the pneumobacilli show a striking approximation towards the typhoid bacillus, in that the pneumobacilli had lost the power of developing gas from glucose and lactose, while the growth on potato was hardly visible. It is unnecessary to dwell upon the suspicious association of bacillus coli and its varieties with certain disorders of the alimentary tract,²⁴ or to point out the frequent presence of these bacteria in the cadaver.²⁵ Agro²⁶ has

discovered the very interesting fact that the mixture of the cultures of bacillus coli and bacillus typhi abdominalis has greater toxic power than a similar quantity of either in pure culture, seeming to show that a symbiotic relation may exist between the two organisms. The mixture of sterilized cultures also possesses a greater toxicity than the sterilized cultures taken separately, but only up to a certain point. These facts, while bearing perhaps rather remotely upon the transmutation and substitution problems, are certainly suggestive.

We may summarize the situation in the following way:

1. There is usually found in the spleen and other organs of an individual dying with typhoid fever, a bacillus which possesses certain definite morphologic and physiologic characters.

2. This bacillus, when viewed in the light of all its characters can be distinguished from the other members of the coli-typhoid group. No single character, however, is "characteristic" and nothing short of an enumeration of all the known morphologic and physiologic properties of the bacillus is a sufficient basis for diagnosis.

3. There exists a well-nigh complete chain of varieties between the typical colon bacillus and the typical typhoid bacillus. Whether this represents ontogenetic as well as phylogenetic possibilities is still an open question.

4. The intermediate varieties, of which there appear to be many, resemble the typhoid organism very closely. It is still uncertain whether they are able to cause typhoid fever, or a disease resembling it, in man.

5. The cases of alleged conversion of one "species" or "variety" into another do not carry conviction and are susceptible of other interpretations than those advanced regarding them.

FADS AND FOLLIES I HAVE KNOWN.

BY ROBERT H. DALTON, M.D.

ST. LOUIS, MO.

The present state of medicine is the result of a grand evolution and, like all achievements of the human mind, claims but an humble origin. Its progression has been marked by error and superstition from time to time, and even now, when it justly demands the highest rank, it is probably liable to the same change; for while we are certain that superstition must be eliminated, we are not so sure that grave errors may not be exposed by time and more patient investigation.

I propose to indulge in a temperate consideration of facts that fell under my personal observation in the early part of my career, eschewing those which seemed to have a basis of merit, but really, may have tended to retard the progress of scientific medicine, some of which, even at this enlightened period, are seriously agitating our profession, and may hereafter be ridiculed and laughed at, like those I witnessed long ago.

In 1826-27 I had the privilege of attending a course of medical lectures at the Transylvania University,

Lexington, Ky., where Dudley, Drake, Caldwell and others were holding forth to a class of 205 students from all parts of the South and West. It was remarkable that the school at Lexington, then only a first-class village, should rival the great institution at Philadelphia; but there was a fair reason for it—the fame of Drake, Dudley and Caldwell. Of these three champions, Drake, though indomitable, was the lesser light illuminating the sphere. He might have been greater had he been less peripatetic, for he was ever restless and inclined to change his base. He was a bold and generally successful practitioner, skilled in diagnosis, and well patronized by the people wherever he lived. Like many other doctors, he had hobbies, one of which I mounted and rode as long as I was in the field—in cases of dropsy, to give every other day in small but repeated doses, a combination of elaterium and jalap until active purgation was produced. Usually the fluid passed off in a few days, and then strong tonics were immediately employed. I confess, however, that the plan sometimes failed. Believing that all western people complaining of any disorder, were bilious, the Doctor seldom failed to unload the liver by a dose of comp. extract of colocynth and calomel; and of this I had some experimental knowledge, having once employed him to treat me for a headache induced by sitting up late at night reading by a tallow candle.

Drake's oratory was fervid but not eloquent, and as he rose to a climax the blood would mount to his face and forehead seeming ready to burst forth to relieve the tension, though ordinarily he was thin and pallid. Ten years afterwards he published a massive book chiefly interesting to Western practitioners, which I bought and read with little edification.

Caldwell having paid his debt of ingratitude to Dr. Rush at Philadelphia, his preceptor and early patron, by assailing his doctrines on every hand and all occasions for several years, and beginning to recognize the verdict of the physicians and people of that city against him, was easily persuaded to transfer himself to a distant region, to quiet his nerves and afford an opportunity of displaying his wonderful eloquence and erudition; hence the popularity of Transylvania in 1826.

Caldwell was born and reared in the brave and good old State of North Carolina in the mountainous western region near King's Mountain, where Tarleton's troopers bled. He belonged to a family distinguished for learning at that time and, if I mistake not, he was a nephew of the celebrated Caldwell so long President of the University of North Carolina at Chapel Hill, the alma mater of so many eminent men who went forth to dignify the councils of their State, while many emigrated to the West and South to build up democratic institutions there. His eloquence was much enhanced by the magnificent appearance of his person. Stalwart and gracefully proportioned, with handsome features beaming with intelligence, his splendid presence could not fail to prepossess any kind of an audience before a word was uttered; and even now, after the lapse of three score years and nine, a pleasing sense of admiration seems to thrill me, as my mind reverts to that old lecture room at Lexington, Ky. True it is that "music hath charms," but true it is also that it pales before the fiery waves of eloquence, the very witchery of language.

The legend in North Carolina of how Caldwell appened to become a physician at Philadelphia

runs thus: His father was a large stock-raiser, who annually drove cattle to either Charleston, Richmond or Philadelphia; and when Charles had graduated and returned home, he was on the eve of starting off with a large drove to Philadelphia; but falling unwell, he was compelled to substitute Charles in his place, who was more than willing to engage in such a spree. At that early time (1795) the Piedmont hills and valleys from Alabama to New York were covered thickly with wild pea vines, the best of food for cattle, so that the long trip cost nothing but time, as there was no food to buy nor rivers to cross. Having sold the beeves, Charles fobbed \$1,500 of the proceeds and sent home the drivers, with the balance inclosed in an affectionate letter to the old gentleman, advising him to will his property to the other children, which doubtless he did. In the meantime he became a private pupil of Dr. Rush, to lay the foundation of his career, I might have said his brilliant career, for it was brilliant, indeed, until green-eyed envy wreaked its vengeance upon him in old age.

Benjamin Winslow Dudley, the great Western surgeon of that day was not over-estimated. Such a man would have been famous in London or Paris. Among physicians of the time, his fame seemed to rest on his remarkable success in lithotomy, but that was a mistake, for he was truly great in everything pertaining to medicine or surgery. He was so notorious for the treatment of chronic diseases, that patients came to him from all parts of the South and West; some living in quarters in the village and others boarding in the country, whom he visited on horseback, for he was never seen in a vehicle. I saw much of his practice through the favor of his principal private student, who had been my classmate in North Carolina. In the treatment of chronic diseases, his general plan was by diet and alteratives, following Abernethy, the patients being usually confined to skimmed milk and corn-bread entirely. His lectures were delivered in a conversational tone, but always interesting, as evidenced by the profound attention of the class. He went to Paris and London for his education, where he remained for several years as a private pupil of Abernethy.

Dudley was a small man of middle age, about five feet six inches high, having a large round head and ample forehead, with auburn hair encircling a bald crown; a gray eye stern and indicative of determination. His nose was not large, and his upper lip, being thin and slightly drawn, gave him a cynical look not in accord with his true character. When about to perform a capital operation, he would always appear ghastly pale as he followed the men bearing the patient into the amphitheater; but when operating, he was as firm as an Irishman carving a hog, and his work was quickly done. He firmly believed that his successful lithotomy was owing to dietetic preparation of patients—skimmed milk and corn-bread for a week before operating, and nothing else.

Drake having resigned in 1827, Cook from Western New York was installed in his place and soon became notorious by propagating a pill called "Cook's Pill," and the startling theory of giving enormous doses of calomel for the relief of all bilious affections; and as everybody in the West and South at that time was supposed to be bilious, the pill had a marvelous run for years. For some reason, perhaps the dignity of

his professorship, he failed to take out a patent for the pill, and allowed its ingredients to be known—aloes, rhubarb and calomel! The calomel administered was in doses of 40, 60, 100, or 150 grains according to the biliousness! But it had a run of only two or three years in such large doses. While the fad continued, little else was relied upon in the treatment of remittent fever by those who fell into the rage. The liver and portal circle bore the brunt of many a siege and could not be reduced effectually by anything but heroism. Milder modes of treatment went sneeringly by the name of "pop-gun practice." And what was the consequence of this terrible hallucination that went forth from Transylvania?

We all know how prone young graduates are to adopt the theories and practice of favorite teachers, especially when urged with captivating diction. Perhaps all young doctors are thus trammelled until their minds are enlarged by experience. For my part, I remember that, whenever a sleek, beautiful hobby came along I was apt to mount him, and away we went in a canter, but would not go far until he would kick up and throw me off; then I would have to swap him for a gentler nag, and so on, until finally I found myself trotting along on an old Conestoga that neither kicked nor dodged, and never flew the track.

Swarms of these young graduates galloped away from Lexington every spring, with glaring sheepskins in their saddle-bags, printed in a dead language which perhaps many could not read, to settle down at every cross-road in the great West and South, armed with a quart bottle of calomel and a gallon or two of Cook's pills to cleanse the liver and scour out the bowels of their trustful friends. And what was the result? Collapse and death, or constitutions broken down by horrible salivation, and loss of teeth for mastication. And yet this medical epidemic continued to rage for a number of years; but thanks to the Nestor of our profession at Chicago for his happy thought of establishing the AMERICAN MEDICAL ASSOCIATION the renaissance has come.

The furore of that practice was, however, a god-send to the homeopaths, for they soon sprang up everywhere, laughing in their sleeves and fooling the people with their infinitesimals. The people actually seemed to be afraid of regular physicians, and in despair turned to the nearest and only help for relief, thus pinching the pockets of regular physicians and swelling the purses of the homeopaths. This seemed to be a timely retribution, serving to arrest careless and extravagant practice and promoting many ingenious and agreeable modes of administering nauseous drugs, indispensable in treatment.

In the meantime, some sharp fellow whose name, if I ever knew it, I have forgotten, witnessing the good luck of the homeopaths, conceived the idea of supplanting both parties by establishing what he called eclecticism, thereby hoping to fill the pockets of himself and comrades; but the success of that sect has not been material, nor do the homeopaths seem to be holding any sway under the shadow of vast improvements lately made by the regular profession; neither does it appear that medical art or science has ever been advanced by their boastful efforts while looking for dimes.

It has been only a few years since we began to hear of Legislatures regulating the practice of medicine. Many efforts were made from time to time, but the

bills were uniformly rejected because the people were not ready for the innovation and, therefore, unwilling to protect themselves; so every man was a doctor if it suited his fancy. If the patient got well in spite of remedies, the doctor was regarded as a savior by patient, friends and himself, but if he died, then—everybody dies. From 1830 to 1840, the South and West were entirely overrun by a gang of steam doctors calling themselves Thompsonians, a doctor of that name living in Western New York, being the founder of the humbug. His disciples were furnished with a little primer containing twenty or thirty pages, and not more than three by four inches in size, containing directions for administration of the roots and preparations recommended; and any farmer or business man in the country was at liberty to invest \$10 for one of these primers and become a full-fledged doctor. Many embraced the opportunity, for there was one or more in every neighborhood. The armamentaria consisted of herbs, but was chiefly confined to powders numbered from 1 up to 6; No. 6 being the remedy mostly employed, and containing pepper of the most fiery kind. The great remedy, however, was lobelia to break up intermittent fever and root out all obstinate diseases that resisted the powders. If the emeto-cathartic of lobelia failed, then it was to be heroically repeated till what they called "alarm" came on, which was really a true collapse. The weaker powders were principally used in chronic disorders.

And here I must risk violating the proprieties by relating an anecdote by way of illustration: In 1835, and afterward, I was a citizen of South Alabama, where saloons prevailed, but then they went by another name, doggeries, on account of their dinginess, odor and other unkempt qualities. A young man, Keloo, was tapster in one of these. He lived on the margin of his income so as to lay up money for a rainy day, and when the steam system began to fascinate the population he too, fell a victim to its charms. Suddenly he retired from the doggery, took quarters at the Arrington House dressed up in broadcloth, silk hat and boots, and purchased a fine horse and equipments; then he rode out of town and back again, like any other gentleman; after a few weeks, his card appeared in *The Voice of Sumter*, emblazoned with "Doctor Keloo" at the top. In less than a week after that, a negro man came galloping into town inquiring for Dr. Keloo, and soon the Doctor was mounted and riding around the public square, followed by the negro, for the purpose of asking for his mail, buying a few cigars, leaving orders, etc., exciting every one's curiosity as to where he was going. Capt. Paine, the sick man, was a very respectable planter living eight miles up the Sucarnoochee, who had been infatuated with the steam-fad, and reading Keloo's card, had sent his man for him. Next day the Doctor returned at 12 o'clock, and rode around, chatting as he had done the preceding day. On being asked how Paine was, he replied: "Oh, I fixed his flint;" and so he did, for at 5 o'clock P.M. a white man came in to buy a winding sheet for poor Paine. The jeering and laughter was more than Keloo could endure, so he disappeared, but where he went is yet a mystery.

I will venture another tale of woe: A year or two after Keloo's extinguishment, Dr. P—— appeared. He seemed to be a gentleman and I called on him, not suspecting heresy, but I soon discovered my mis-

take, for I saw lying on his table a large book lately published by Thompson on the steam system, so-called. However, my visit led to further acquaintance, as he was a respectable man, and had respectable friends in the community, preaching occasionally in the Methodist church. One morning in September, on going to the country, I rode by his door as he sat basking in the sun on the steps, looking quite pale, and I halted to ask what was the matter. "Oh, I've had a couple of chills," said he, "and another will try to tackle me at 10 o'clock to-day, but I'll be ready for it this time." "I suppose you will head it off with quinin," said I. "Quinin!" he exclaimed derisively. "No, I'll take lobelia and a plenty of it, and not fool with it as I did yesterday;" and so he did, for in passing by on my return at sundown I learned that he was in collapse and nearly dead. The "alarm" happened to be in earnest that time. These and many other similar cases came under my immediate observation, but such were constantly occurring all over the country.

Regular practice, at and before that time, in some respects was equally culpable with that of the steamers. Venesection ad *deliquium animi* in fevers was one practiced by some of our craft, drawing off the pabulum of life when most needed. But a majority were opposed to that heroic measure. Although the *vis medicatrix* was acknowledged and frequently discussed, no such inherent force was trusted, for the doctors took the whole responsibility in treating a case; hence strong revulsions of every kind characterized the practice. Even Europe, with its ages of culture and refinement, seemed to fall into these errors. Rasario, a celebrated professor at Milan, I believe, conceived the idea of curing all violent inflammations by heroic doses of tart. emetic repeated until tolerance is established, the whole amount given sometimes reaching twenty-eight or thirty grains. About 1830, the *American Journal of the Medical Sciences* was ventilating the plan over here, and I began to look out for an opportunity to give it a trial; I soon met with a suitable case. A youth, 17 years old, living in the country fifteen miles from town, had a violent attack of pleurisy, which was neglected for several days until the parenchyma of the lungs was involved, and he seemed to be in the last stage of pneumonia. His physician had given him up and I was called. Believing the case hopeless, I concurred with the doctor and was about to leave, when the father implored me to resort to any means, however desperate. I alluded to and explained the Italian practice, and then he cleared me of all responsibility. I gave three grains every forty minutes, until he had taken twenty-one grains and fallen into collapse. Then I ceased, resorting to sinapisms, bottles of hot water around his body, etc. After several hours he finally reacted, with scarcely a vestige of pneumonia left. After that I treated another case of rheumatism attacking the dura mater with complete success, and one more of pneumonia, which I lost. That mode of practice, founded on repulsion, which is a legitimate principle of therapeutics, should not be entirely condemned, for there may be cases curable in no other way.

In viewing the past, we observe that there was a reason for that long-continued war upon the portal circulation by regular physicians; the ridiculous practices of steam doctors and the like absurdities of the age. The fact that medicine was not an exact sci-

ence gave license to wild theoretic speculation, leading to the adoption of empirical means to ends, and palliating most absurd errors of practice. But while all that confusion was in progress, Brown-Sequard, Bell, Marshall Hall and a few other savants of our profession were busily engaged in prying into the mysteries of the nervous system and laying a firm foundation for physiologic medicine, by which our art was made sure, and methods of practice simplified and placed on a scientific foundation. All these worthy pioneers in the field of neurology have passed away now, leaving their names already budding in fame to blossom out and reach remotest posterity.

In regard to the antitoxin theory now agitating the public mind and denounced by some physicians as a fad, we should be lenient in criticising the microbe theory of disease, for the reason that it seems to be proving its legitimacy as it goes on. If the Jennerian theory in regard to the antitoxin power of vaccine has been amply sustained in smallpox, how can we deny the sound efficacy of other similarly modified forces in relation to other constitutional diseases? Certainly, it seems equally plausible. And what is more, the inference leads to the conclusion that all constitutional diseases may be probably placed in the same category; and if so, the art of medicine is bordering on a revolution beyond anything of the kind in all the past. Let us wait and see.

ENLARGEMENT OF THE HEART WITHOUT VALVULAR DISEASE—WITH SPECIAL REFERENCE TO TREATMENT.

Read at the meeting of the Mississippi Valley Medical Association, held at Hot Springs, Ark., Nov. 20-23, 1894.

BY ROBERT H. BABCOCK, A.M., M.D.
CHICAGO, ILL.

If any excuse be needed for the presentation of this paper, it is found in the frequency with which individuals have consulted me of late, suffering from enlargement of the heart without valvular lesion. In looking over my record of cases for the twelve months ending Nov. 1, 1894, I find, that of the cases of heart disease there entered, 15.4 per cent. are under the diagnosis of idiopathic enlargement of the heart. Although open to the objection of vagueness and implied ignorance of the nature of the disease this term is, nevertheless, employed by Fraentzel because it embraces in concise form all those cases of hypertrophy and dilatation of the heart, unassociated with chronic endocarditis. On account of its conciseness, therefore, I shall make use of Fraentzel's term interchangeably, with that stated in the title of this paper.

Hypertrophy and dilatation are combined, the former predominating so long as compensation is adequate; but so soon as this becomes impaired, the hypertrophy begins to yield to dilatation until at length the latter assumes the chief rôle.

Post-mortem, these hearts are found to have greatly thickened walls, while the ventricles are dilated and the papillary muscles flattened. Fatty degeneration of the heart muscle is generally present, but in variable proportions and of too limited extent to make this the primary and main condition. Indeed, Fraentzel is of the opinion, that we shall have to abandon the notion of fatty heart as an independent and original

affection. There is, he says, no direct or constant relation existing between the extent of fatty degeneration and the gravity of the clinical appearances. In the very cases under consideration, demonstrable degenerative changes are by no means always so extensive as to explain the progressive cardiac failure. If sclerosis of the aorta and coronary arteries be absent or but slight, the heart muscle may present very insignificant evidences of fatty or other degeneration. In cases in which the cardiac enlargement is associated with general arterio-sclerosis or chronic interstitial nephritis, there may be microscopic, if not macroscopic, evidence of degeneration. In most instances, however, particularly those due to excess in food and alcohol (*Luxus consumption*) or to overwork, one is often astonished at the meager *post-mortem* findings, and also at a loss to explain the cardiac weakness.

This form of cardiac enlargement affects individuals of both sexes but more commonly males. They are usually men of large frames with capacious chests. Indeed, the amplitude of the thorax is a characteristic upon which Fraentzel lays great stress. The great predisposing cause of ventricular enlargement is prolonged high arterial tension. If this exist in the lesser circulation of chronic pulmonary disease, the right ventricle will become enlarged; but the cases, commonly presented to the physician, manifest enlargement of the left ventricle with secondary increase in the size of the right. Prolonged arterial tension in the systemic circulation results from a variety of conditions; such as 1, chronic interstitial and parenchymatous nephritis; 2, arterio-sclerosis; 3, excessive consumption of food or drink; that is, excessive with relation to the amount of exercise taken; 4, severe manual labor together with abuse of alcohol; 5, prolonged overstrain of the heart, as in soldiers, particularly, associated with abnormally small arteries. Other factors also concerned in the production of idiopathic enlargement of the heart, are too uncommon to be considered here.

Whatever the condition, it is essential that it produce and maintain, for a long time, abnormal blood pressure within the arterial system.

Let us consider a little more in detail the third factor of *Luxus consumption*. In this condition more food and drink are habitually taken than are required for the needs of the system, moreover these individuals generally follow a sedentary pursuit and, as a consequence of their physical indolence, often take on a large amount of adipose tissue as they pass their fortieth year. This is one type of the individuals described by Fraenkel as very apt to develop arterio-sclerosis. Through the circulation in the blood of toxins, resulting from their mode of life or some other reason, there is abnormally high arterial tension for years. Whether associated or not, with degenerative changes in blood vessels or kidneys, this abnormal blood pressure increases the work of the left ventricle. To overcome the peripheral resistance the left ventricle becomes hypertrophied. Compensation is thus established. After a time, peripheral resistance becomes too great for the enlarged ventricle and dilatation sets in. But the enlargement is not confined to the left side of the heart. Increased blood pressure also exists within the pulmonary vessels and occasions corresponding enlargement of the right ventricle. So long as the nutrition of the cardiac muscle is adequate to the increased demands made upon it there are no symp-

toms and the cardiac enlargement escapes recognition.

In the case of laborers or other individuals performing severe manual toil, abnormal blood pressure results from the frequent repetition of muscular contractions. If to this be added the injurious effects upon the circulatory organs of the habitual consumption of alcohol and tobacco, there is sufficient explanation of cardiac enlargement and ultimate loss of compensation.

Time forbids a detailed description of the symptomatology of this disease. The patient first becomes conscious of something wrong in his chest, through either dyspnea or a feeling of fullness and oppression in the præcordium. The dyspnea, which in the beginning generally consists of breathlessness on ordinary exertion may increase to habitual shortness of breath or in the severer cases to attacks of cardiac asthma. A sense of fullness or oppression in the heart is very common and like the dyspnea, occasioned by exertion. Cardiac pain is rare, but when present, usually dull and associated with a feeling of weight. In only one of my cases was angina pectoris complained of and in this one this symptom was so frequent and violent, as to render sclerosis of the coronary arteries highly probable. The pulse is always tense and accelerated, often small, and regular or irregular, as the case may be. The arrhythmia so frequently mentioned by Fraentzel was present in but a small proportion of my cases and only those in which cardiac dilatation had been present for so long a time as to be a chronic condition. The urine is usually diminished in amount, of high specific gravity and contains a small percentage of albumen; hyaline and granular casts may or may not be found. The liver is generally somewhat enlarged from passive congestion. The peripheral arteries often feel a little thickened, in some instances slightly tortuous but do not usually present marked sclerosis. Edema is generally absent in the earlier stages or perchance confined to slight puffiness of the ankles.

As the malady progresses, edema and other symptoms increase, until at length the disease presents all the phenomena of cardiac asystole from whatever cause. In the latter stages, cardiac asthma is apt to be particularly distressing.

These patients die, either from pulmonary edema or hypostatic congestion, due to progressive cardiac failure. Sudden diastolic arrest of the heart is not common, unless brought on by unwonted exertion.

The diagnosis does not usually offer much difficulty, and yet there are certain conditions that can easily prevent the recognition of the cardiac enlargement. The individuals most frequently presenting this disease are men with large, often round chests and correspondingly voluminous lungs. The left nipple is situated much further from the sternum than in those of average size, my records of measurements often showing it to be from four to four and one-half inches from the left sternal border. Ordinary methods of percussion show superficial cardiac dullness to lie between the left margin of the sternum and the left nipple. The capacious lungs conceal the deep limits of heart dullness, while the apex beat is neither visible nor palpable, partly because of intervening lung tissue and partly on account of the feeble impulse of the heart. For these reasons the practitioner is very likely to pronounce the heart of normal size. Fraentzel thinks, however, that the

very fact of superficial dullness reaching to the nipple in these broad chests is sufficient to indicate an abnormally large heart and that this consideration, in connection with high arterial tension and perhaps thickened arteries, justifies the diagnosis of idiopathic enlargement. Although believing this theoretically correct, I am personally in the habit of depending on auscultatory percussion to corroborate the results of percussion after the ordinary method. By this means and the auscultation of the heart's sounds, I have frequently determined great general enlargement and located the apex beat far to the left of its normal site.

The heart sounds are usually free from murmur, the first at the apex being weak and valvular. The second aortic sound is usually accentuated in consequence of the increased blood pressure in the arterial system. The normal rhythm of the sounds may assume more or less that of the fetal heart sounds. In one of my cases, a female, a distinct jogging sensation was transmitted through the monoral stethoscope.

Finally, the abnormal pulse tension, the pulse rate, and the symptoms are of great diagnostic significance.

In the early stages, appropriate treatment may do much to stay progress, nay, even to remove much of the cardiac insufficiency. When compensation has once been fairly lost, the physician is powerless to do more than mitigate symptoms. In my opinion the first condition of successful treatment, and one which I always follow is to explain to the patient the injurious effects of persistent high blood pressure, and the importance of lessening it so far as possible. He is warned against still further dilating his heart through too great muscular efforts. Stair climbing, hurried walking, carrying of heavy packages are absolutely forbidden. Moderate walks upon the level ground and for distances too short to produce fatigue are encouraged. The feeling of oppression and fullness in the præcordium is found to be a good gauge of the patient's endurance; since he is cautioned against ever walking so fast or far as to produce this uncomfortable sensation. As a matter of fact, more than one patient has told me he found a slow walk in the open air relieved the discomfort in his chest. Patients are also instructed to avoid distending the stomach by too hearty meals and beer or other effervescing drinks. For the same reason, the diet is regulated so as to prevent fermentation and consequent distension of the digestive tract by flatus. Most saccharin and amylicious articles are forbidden, therefore, as well as most uncooked fruits such as apples. Coffee and tea are allowed sparingly. The chief meal is at mid-day and if milk does not disagree, it must constitute the main portion of the evening meal. Alcoholic beverages, excepting malt liquors and champagne, which are absolutely interdicted, may be permitted sparingly or forbidden altogether according to circumstances in each case. My belief is that whisky in small amounts with the meals serves as a beneficial stimulus to both digestion and circulation. If the individual be corpulent, reduction of his weight is desirable but must be done cautiously.

Only woolen underclothing should be worn and all the clothing should be loose and comfortable, so as not to constrict chest and abdomen. Warmth of the body during cold weather is imperative lest the vasomotor constriction, produced by cold, increase

peripheral resistance and thereby also intra-cardiac blood pressure to an injurious extent. These patients should not attempt walking in the face of a strong cold wind. If possible, they should pass the inclement seasons in a mild equable climate. Massage and Swedish movements given skilfully and carefully, often prove highly beneficial. The immoderate use of tobacco and alcohol, sexual excess, fits of anger or emotional excitement of other kinds, too close and prolonged application to business are all injurious and should be explained as such to the patient.

As gentle exercise is beneficial, so on the other hand, prolonged rest in bed, so useful in certain valvular lesions, is injurious in idiopathic enlargement of the heart. Fraentzel explains this on the hypothesis that the heart muscle, being striated, degenerates under prolonged rest in the same way as does voluntary striped muscle after a long period of inaction. As I have stated elsewhere, this seems to me incorrect, since the cardiac muscle can never during life be subjected to complete repose. The injury resulting from absolute rest in these cases is explicable, I think on the following hypothesis:

In consequence of feeble contractions of the left ventricle, blood pressure in the aorta sinks, with corresponding rise of pressure in the two venæ cavæ. Moreover, absolute physical rest deprives the venous circulation of the aid derived from muscular contractions and deepened respiration. The work of maintaining the circulation is, consequently, thrown upon the already weakened left ventricle, which speedily succumbs under its increased labor.

This hypothesis is not at variance with the clinical observation of high pulse tension, since this is due to obstruction to capillary outflow and not to powerful contractions of the left ventricle. It is better, therefore, that these patients take rest for short periods, and for the purpose of recovering from fatigue occasioned by exercise.

We now come to the consideration of the medicinal treatment. Our first indication is to lessen the abnormal arterial tension which has led to the cardiac enlargement. This is best and most speedily accomplished by free catharsis. It makes but slight difference what purgatives are used, although they should not be highly drastic. I generally administer a full dose of calomel on account of the power possessed by mercurial preparations of diminishing arterial tension, even before producing alvine discharges. The calomel is generally followed in six or eight hours by a saline such as epsom salts or one of the laxative waters, Rubinat Condal, Hunyadi Janos or Franz Joseph. I not infrequently prescribe 4 ounces of the compound infusion of senna to be taken in one draught, which occasions profuse but painless watery stools. This remedy is specially recommended by Fraentzel. The effect on the pulse is often very remarkable, shown by greater regularity and volume. The sphygmographic tracings before and after the purge often exhibit striking diminution of tension. But this is not all; the dyspnea and sense of precordial oppression are usually lessened and sometimes wholly removed temporarily. It is well to keep down tension by the daily administration of a saline cathartic, but of less than the initial dose. The omission of the cathartic for even two or three days is generally followed by appreciable increase of arterial tension and of symptoms.

Digitalis and its congeners have no place in the therapeutics of this affection, unless weakness be confined to the left ventricle, the integrity of the right being preserved when moderate doses are useful. But if there be general weakness with dilatation of both ventricles these drugs are harmful. I have used them, and I have repeatedly seen them followed by increase of symptoms and arrhythmia or by irregularity of the pulse that previously had been regular. Why this is, I can not now attempt to explain, as it would require a lengthy discussion, both of the action of digitalis based on experiments of Openchowsky, and of the conditions of the circulation in this form of heart disease. The inutility, nay the harmfulness of digitalis in these cases is an empirical fact, the recognition of which has rendered my results far more satisfactory. Fraentzel employs cardiac stimulants, musk, castoreum and valerian, which not only spur on the jaded organ but favorably influence arterial tension. I have administered elixir of the valeriate of ammonia, nitroglycerin, whisky, tincture of castor, and in one instance even sulphate of atropia in doses sufficient to produce its physiologic effect upon the throat and pupils. Camphor and compound spirits of ether might be added to this list. The action of these stimulants is fugacious and therefore they must be exhibited frequently. Improvement is necessarily slow, and when any stimulant or combination of stimulants has demonstrated its ability to sustain or reinvigorate the heart's action its employment must be continued so long as required by the exigencies of the case. Nitrate of strychnia is also a powerful heart tonic, but must be given in full doses and when possible subcutaneously. Another useful and I believe positive heart tonic is the hourly inhalation of at least a gallon of pure oxygen.

Unfortunately there are many cases beyond the possibility of more than temporary relief. A most valuable stimulant in these, particularly if nightly attacks of cardiac asthma are distressing, is the hypodermic injection each evening of $\frac{1}{4}$, still better, $\frac{1}{10}$ of a grain of morphin combined with atropin, as in the ordinary hypodermic tablets. The dose must be small so as to secure the stimulant and not the depressing effect of the morphin. Given in this way, as Fraentzel says, a patient can often be carried along for weeks or even months after all hope of permanent improvement has been abandoned. Should dropsy finally set in and resist the use of cathartics and diuretics, such as calomel and perhaps also diuretin-knoll, it may be drained away by small incisions of the ankles or the use of appropriate drainage tubes.

The time limit of the papers necessarily forbids a more detailed discussion of the treatment, as well as the consideration of many questions that are suggested. I feel that I have been able to only outline what I believe to be the correct principles in the management of idiopathic enlargement of the heart.

Finally, three of my cases in which compensation was either threatened or not irretrievably lost, were treated by the Schott method of baths and gymnastics. The results were most gratifying and in one case truly surprising. The apex beat, previously neither visible or palpable, became fairly well defined, while appreciable retraction in the size of the heart took place and the patient regained ability to walk without much discomfort. This mode of treatment seems to me particularly adapted to this class of cases. It

unloads the over-distended heart, strengthens its contractions and dilates the arterial system; the very effects so desirable to produce in cases in which the heart is unequal to the abnormal blood pressure.

Appended are four sphygmographic tracings, of which Nos. 1 and 2 are from a man of 49, weight 260 pounds, suffering from general cardiac dilatation and chronic interstitial nephritis. The urine analysis showed in addition to abundant albumen and granular casts, blood, bile and indican. The first tracing was taken before treatment was instituted. The second was taken two days later after the administration of a vigorous purge and shows the beneficial effect of the same in this class of cases.

The third and fourth tracings are from a man of 60, who was beginning to manifest loss of compensa-

2. The primary condition is not fatty degeneration, which bears no definite relation to the clinical phenomena.

3. The disease results from prolonged high arterial tension and is observed most frequently in men with large chests and a tendency to corpulence.

4. Abnormal arterial tension may arise from excess in food and drink (*Luxus consumption*) and from severe labor, combined with immoderate use of alcohol and tobacco.

5. The diagnosis is not difficult, if one remembers that in these large chests actual cardiac enlargement may coëxist with a superficial precordial dullness, confined within the so-called normal limits.

6. The first indication for treatment is the lessening of the abnormal arterial tension, which is most

FIGURE 1.

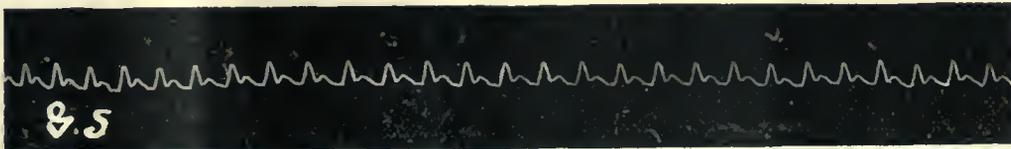

FIGURE 2.

FIGURE 3.

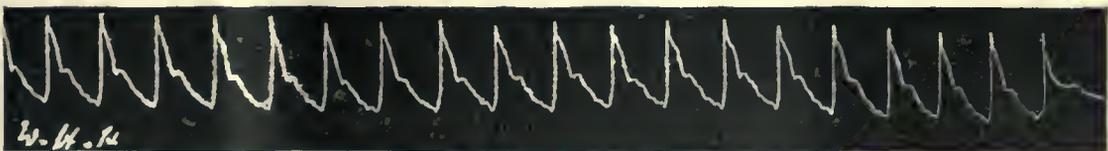

FIGURE 4.

tion of an idiopathic enlargement of the heart. His chief symptom was precordial oppression. There was no apparent arterio-sclerosis and urinalysis revealed nothing more than chronic renal congestion. No. 3 was taken before beginning treatment and No. 4, five weeks later, shows the benefit derived from the management of this case, based on the principles laid down in this paper. It consisted, in brief, of gentle exercise by walking, daily catharsis, stimulants and regulation of the diet.

CONCLUSIONS.

1. By idiopathic enlargement of the heart is meant: combined hypertrophy and dilatation, without valvular disease.

readily done by means of cathartics and regulation of diet and exercise.

7. Digitalis is harmful, except in cases in which the weakness is confined to the left ventricle.

8. In cases of general cardiac enlargement and weakness, stimulants are called for, such as ammonia, nitro-glycerin, ether, valerian, etc.

9. The hypodermic injection of $\frac{1}{10}$ of a grain of morphia combined with $\frac{1}{200}$ of atropin is the most efficient stimulant in cases suffering from nightly attacks of cardiac asthma.

10. The Schott treatment, by baths and gymnastics, seems specially serviceable in this affection before compensation has become irretrievably lost.

ORIGINAL INVESTIGATIONS ON THE
NATURAL HISTORY, (SYMPTOMS
AND PATHOLOGY) OF YELLOW
FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 893.)

CHAPTER II.

COMMUNICATION OF YELLOW FEVER THROUGH THE
MOTHER TO THE FETUS IN UTERO; WITH OBSER-
VATIONS UPON THE COMMUNICATION OF
SMALLPOX TO THE FETUS.

It is possible for yellow fever to be communicated through the mother to the fetus in utero.

I have had opportunity of illustrating this proposition by the following observation:

Case 4.—Illustrating the communication of yellow fever through the mother to the fetus in utero. Mary Heitman entered Charity Hospital, New Orleans, Louisiana, Oct. 1, 1871, with fever, and intense pain in head and back. On October 4 (third day of disease) patient presents all the symptoms of yellow fever; conjunctiva jaundiced, eyes injected, capillaries of mouth and gums congested, capillary circulation sluggish, surfaces of extremities mottled, nausea and vomiting. Patient suffering with uterine hemorrhage.

October 5 (fourth day of disease) the patient gave birth to a still-born fetus, apparently about four months old. The skin of the fetus presented a jaundiced yellow hue, and, upon dissection, the liver of the fetus presented the usual appearance of this organ in yellow fever. On October 6 this woman died, apparently from the immediate depressing effects of hemorrhage from the uterus and stomach. The pathologic lesions were those of yellow fever. The serum from the blood of the cavities of the heart presented the usual golden color, and contained bile. The colored blood corpuscles were altered in their outlines, some being swollen and others crenated. The muscular structures of the heart were yellow and brownish-yellow, softened and loaded with oil globules. The liver presented the characteristic yellow color of this disease, and liver cells were loaded with oil. The kidneys presented a yellow and yellowish-red color, resembling that of the liver and heart. Sections of the kidney, by Valentine's knife, carefully examined under the microscope, revealed the tubuli uriniferi, filled with granular fibroid matter, epithelial cells and oil globules. The urine taken from the bladder after death contained albumen in large amount, and urea in comparatively small amount. Under the microscope the urine was found to contain numerous oil globules, casts of the tubuli uriniferi, filled with yellow granular albuminoid and fibroid matter, and in addition to these, numerous free cells from the tubuli uriniferi.

Louis, in his "Anatomical, Pathological and Therapeutical Remarks on the Yellow Fever of Gibraltar of 1828," records the observation that the uterus of a woman, the wife of a soldier of the Fifty-third Regiment, who died with well-marked yellow fever, contained a five or six months' fetus, about whose neck were ecchymoses and whose skin was of a universal wine-lees color. The amniotic fluid appeared to have been colored by bile. In this respect the poison of yellow fever resembles that of certain contagious diseases, as smallpox. Thus instances have been recorded in which the fetus in utero has been attacked with smallpox, in consequence of the mother having been exposed to the contagion, without herself having the disease.

It was long held as a popular opinion, that if persons were insusceptible to the smallpox, either from infection in consequence of repeated exposure, or from inoculation with variolous matter, that they must have undergone the disease previous to their birth. Some medical men, on the contrary, have held that the want of susceptibility in such persons to

the infection of the smallpox was owing to a peculiarity of constitution, which resisted the influence of the disease.

In support of the latter opinion, Mr. William Forbes⁶ recorded the following case:

Case 5.—Mrs. Tagg, 22 years of age, when in the seventh month of her first pregnancy, had the confluent smallpox; from which, contrary to expectation, she recovered, went her full time, and was delivered of a fine child. Frequent solicitations were made for permission to inoculate the child, which was refused by its parents, from a supposition of its having had the smallpox previously to its birth. However, at the age of 12, the child was inoculated, and had the smallpox in the most satisfactory manner.

The two following cases, recorded by Mr. Forbes, on the contrary, tend to prove that those persons who have resisted the variolous infection, in every form, must have undergone the disease when in the fetal state:

Case 6.—Mrs. Alexander, of New Cross, had the smallpox when near the termination of her pregnancy; but the type was so mild that she was capable of pursuing her occupation as a washerwoman, although in daily expectation of being confined. The infant was born with the smallpox upon it.

Case 7.—Margaret, wife of William Crawby, residing at Camberwell, in her infancy had the smallpox severely, to which her countenance bore ample testimony. In March, 1788, she nursed her son Thomas, a child, under the confluent smallpox. She was at that time pregnant of her fifth child, and very near the end of her reckoning. These people being in low circumstances, had but one room, in which the whole family lived and slept. On April 1, at 3 o'clock in the morning, she was delivered of a girl. Three days afterwards the boy Thomas died, and on the same day Mr. Forbes was desired to look at some pimples upon the infant, which proved to be the smallpox, the marks of which she bore upon her face, even after attaining womanhood, and although frequently exposed to the smallpox, never contracted the disease.

The latter case proved that the fetus in utero is liable to the smallpox, from the influence of surrounding infection, although the mother was herself protected by a previous attack of the disease.

Mr. William Rait⁷ recorded the following case, similar in some respects, and even more remarkable than that of Margaret's, just quoted:

Case 8.—During the prevalence of smallpox, and while Mr. Rait was attending such cases, a lady, who manifested no symptoms of smallpox, was delivered of a male child, upon whom the smallpox eruption appeared two days after its birth. The disease went through the course of genuine smallpox. Upon inquiry Mr. Rait ascertained from the mother of the lady (grandmother to the child) that the mother was born with the smallpox.

Dr. Laird⁸ has described the following case of a pregnant woman, who was seized with smallpox:

Case 9.—About the end of August, 1805, she felt the motion of the child till the month of October, and on October 28 she was delivered of a dead child, which was thought to be of six months' growth. On the back, shoulders and side, particularly upon the upper parts of the thigh, where the integuments were perfectly sound, there were several pustular eruptions, with central depressions, strikingly characteristic of the appearances which distinguish smallpox. The fetus was placed in the museum of George's Hospital, and distinctly exhibited the characters of the eruption.

This history confirms the observation that the fetus partakes in many of the diseases of its parent.

Mr. Lynn published in August, 1786, the following decisive instance of smallpox in the womb:

Case 10.—In November, 1785, the wife of Mr. Ere, a coachmaker in Oxford Street, being then in the eighth month of her pregnancy, was seized with vigorous pain in the back, and other febrile symptoms. In two days' time the disease showed

⁶ Cases of Smallpox In the Fetus, by William Forbes, Edinburgh Medical and Surgical Journal, Vol. III, p. 307, 1807.

⁷ Medical Commentaries, by Andrew Duncan Vol. III, p. 318, 1789.

⁸ Edinburgh Medical and Surgical Journal, Vol. III, p. 155, 1807.

itself to be the smallpox, and though the pustules were of the distinct sort, yet they were uncommonly numerous. On the eleventh day they began to turn, and on the twenty-second day her labor took place, which, according to her reckoning, was a fortnight before the regular period; that is, when she was advanced in her pregnancy eight months and two weeks. The child, at the time of its birth, was covered with distinct pustules, all over its body. They did not appear to be full of matter till three days after, at which time I took some of the pus upon a lancet from one of the pustules on the face. With this lancet Dr. Lynn afterwards inoculated, on Dec. 2, 1785, a child of Mr. Charters, in Church Street, in both arms. On the 7th, the inflammation began to appear in each arm, and continued daily increasing, till December 11, when the child sickened, and was affected with all the symptoms which usually precede the eruption. On the 12th the sickness and fever abated, the pustules of the distinct sort of smallpox made their appearance, and the child having regularly gone through the several stages of the distemper, was perfectly well in three weeks.

Dr. Edward Jenner⁹ entertained the opinion that the susceptibility to receive the variolous contagion always remains through life, but under various modifications and gradations from that point, when it passes silently and imperceptibly through the constitution (as is frequently the case with cowpox), up to that where it appears in a confluent state, and with such violence as to destroy life.

It is only under particular circumstances that any proof of the presence of smallpox can be adduced in those cases, in which it passes through the frame without producing eruption, or in any perceptible degree deranging the animal functions.

Such proof, however, as Dr. Jenner clearly exemplified by the following remarkable cases, is afforded by the obvious infection of the fetus before birth, communicated through the mother, herself being already secure from any visible occurrence of the disorder:

Case 11.—Dr. Edward Jenner was requested by Dr. Croft to vaccinate the infant of Mrs. W., a lady in Portland Place. The vaccine fluid, which was inserted fresh from the arm of another infant, produced scarcely any effect, beyond a little efflorescence in the part, which in a few days disappeared. When Dr. Jenner expressed his surprise at this, such an occurrence happening very rarely, Mrs. W. removed his embarrassment by the following narrative:

A few days previous to her confinement she met a very disgusting object, whose face was covered with smallpox. The smell and appearance of the poor creature affected her much at the time, and though she mentioned the circumstance on her return home, she had no idea that her infant could suffer from it, having had the smallpox herself when a child.

During a few days after its birth, the little one seemed quite well, but on the fifth day, it became indisposed, and on the seventh the smallpox appeared.

The pustules, which were few in number, matured completely. Dr. Croft, who attended her, being curious to know the effect of inoculation from one of the pustules, put some of the matter taken from one of them into the hands of a gentleman eminently versed in the practice, which produced the disease correctly. Mrs. W. was not sensible of any indisposition from the exposure, nor had she any appearance of the smallpox.

Another case, similar in its general character to the above, was communicated to Dr. Edward Jenner, by Mr. Henry Gervis, a surgeon of eminence at Ashburton, in Devonshire.

Case 12.—Mr. Gervis says: "The smallpox having appeared in the village of Woolson Green, about three miles from Ashburton, on May 6, 1808, I vaccinated a poor woman, the wife of James Barkwell, who was in the last month of her pregnancy. Her three children had been inoculated the preceding day with variolous matter, by the surgeon who attended the poor of the parish, and who had very properly

declined inoculating her also, from her particular situation. I made two punctures in each arm, each of which fortunately succeeded, and she regularly passed the disorder, complaining only on the tenth and eleventh days, when the areola was most extended, as usual. I saw her very frequently during the progress of the disorder, and once or twice after its complete termination. I therefore can speak positively, that during that time she labored under no symptoms but what are connected with the cowpox. From this period she continued perfectly well, and on Saturday the 11th inst., she was delivered of a female child, having at the time of its birth many eruptions on it, bearing much the appearance of smallpox, in the early stages of the disease. This event happened five weeks after her vaccination, and one month after she had been exposed to the variolous infection of her own three children, and that of several other persons in the same village. On the 14th I visited the child again, when I found the eruptions had increased to some thousands, perfectly distinct, and their character well marked. . . . To put the matter beyond all doubt, I armed some lancets with virus, and produced the smallpox, by inoculating with it. In addition to the circumstance of the mother conveying the variolous infection to her unborn child, without feeling any indisposition from its action in her own constitution, I must remark, that there can not be a stronger proof of the efficacy of vaccination than this case afforded."

Dr. Jenner, without producing more examples, of a similar description, though he affirmed that many were before him, observes that a fact, not unlike the preceding, fell under the observation of Dr. Mead, who, in his discourse on the smallpox (Chap. iv., p. 337, 1772), relates the following case:

Case 13.—A certain woman who had formerly had smallpox, and was near her reckoning, attended her husband in the distemper. She went her full time, and was delivered of a dead child. It may be needless to observe that she did not catch it upon this occasion; but the dead body of the infant was a horrid sight, being all covered with the pustules, a manifest sign that it died of the disease before it came into the world.

From such examples, Dr. Jenner¹⁰ concludes that the smallpox virus may affect the human frame, even to its inmost recesses, although apparently secured from its effects, and yet give no evidence of its presence, by exciting any perceptible disorder.

In 1749, Sir William Watson¹¹ published the following case:

Case 14.—A woman far advanced in pregnancy, who had labored under the smallpox a long time before, who, during this pregnancy, performed the duty of a nurse to her servant in the natural smallpox; and in a month after this attendance, was brought to bed of a child that had about forty scars upon its body like those from the smallpox. This child (a girl), and her brother, were afterward inoculated at the same time. The brother had inflammation of the parts inoculated, eruptive fever and eruptions, as in the most ordinary smallpox; and the girl, born with the pits on her skin, had inflammation and suppuration in the parts inoculated, in the same manner as her brother, and a general indisposition, as in the undoubted cases of smallpox, but no eruptions.

Sir William Watson concluded that this girl had gone through the smallpox before her birth, and Camper and Van Swieten coincided with him in this conclusion.

It was established by actual experiment, that pregnant women were not fit subjects for inoculation, as the smallpox often caused miscarriage, and what is remarkable, when the disease proved mild to the mother, it was sometimes fatal to the child.

The preceding facts, illustrating the communication of smallpox to the fetus in utero, might be greatly enlarged by other observations, as those of Bartholini, 1657; Mr. Durham, 1713 (Phi. Trans., Vol. xxviii., p. 165); Dr. Mortimer, 1749 (Phil. Trans., Vol. xlvi., p. 233); Dr. Mead, 1747, in his Treatise de Variolis;

⁹ Medico-Chirurgical Transactions, Vol. 1, London, 1815, Third Ed., pp. 271-277.

¹⁰ Medico-Chirurgical Transactions, Vol. 1, London, Third Ed., pp. 271-277, 1805.

¹¹ Philosophical Transactions, Vol. xlvi., p. 239.

Dr. Rosen von Rosenstein, 1756; Baron Dimsdale, 1766, Treatise on Inoculation; Mr. Wastall, 1776 (Phil. Trans., Vol. lxx., p. 128); Dr. Wright, 1781 (Phil. Trans., Vol. lxxi., p. 372); Dr. Bland, 1781 (*London Medical Journal*, Vol. ii., p. 205); Mr. Roberts, 1784 (*Medical Journal*, Vol. v., p. 399); Dr. Hagarth, Dr. Woodville, Dr. Ford, Mr. Jones, Dr. Hossack; Dr. George Pearson, 1794 (Medical Commentaries, by Andrew Duncan, Vol. ix., Edinburgh, 1795, p. 213); Dr. George Pearson gives some important cases of equal interest with those recorded above; Alexander Munro (Observations on the Different Kinds of Smallpox, Edinburgh, 1818, p. 626).

We have thus brought together a number of important observations, scattered through various medical and scientific periodicals, bearing upon the transmission of the poison of smallpox, through systems entirely protected from its influence and demonstrating the existence of the poison in a potential active state, as shown by the excitation of genuine smallpox in the fetus, resting in the womb of the mother, protected by previous inoculation, vaccination and smallpox, *in the hope that the attention of physicians may be directed to analogous inquiries in yellow fever.*

If, therefore, the poison of yellow fever is capable of affecting the fetus in utero, in an analogous manner to the poison of smallpox, we may arrive at the following conclusions, which, if more extended investigation should clearly establish, will explain one mode in which the natives of those cities and localities, as New Orleans, where yellow fever often prevails, obtain an immunity from its attacks:

1. The poison of yellow fever is capable of affecting the fetus in utero.
2. It is probable that the yellow fever poison is capable of affecting the fetus in utero, without inducing the disease in the mother, who has had the disease at some period preceding pregnancy.
3. It is thus rendered probable that a certain number of natives are in this manner rendered insusceptible to the action of the yellow fever poison after birth.

MODIFICATIONS OF THE PHENOMENA OF YELLOW FEVER BY PRECEDING DISEASED STATES OF THE SYSTEM.

The most potent cause of derangement of those who reside within the yellow fever zone is the action of malaria, which not only manifests its effects in the causation of the various forms of intermittents, remittents, pernicious and hemorrhagic paroxysmal fevers, which differ materially in their origin, symptoms and pathology from yellow fever, but also, without the active manifestation of these forms of fever, in the slow destruction of the colored corpuscles, derangement of the liver, enlargement of the spleen, attended with a pale, sallow, sickly hue, infiltration of the cellular tissue, dyspnea, palpitations, derangements of the blood and nervous system, and depressions of the muscular and nervous forces.

While those who have been subjected for long periods to the action of malaria appear to be less liable to yellow fever, it is, however, true that the progress of this disease is modified by the changes induced in the blood and organs by the preceding action of the malarial poison; and the lesions after death from yellow fever differ to a certain extent from those observed in subjects freshly arrived from cold climates without being previously subjected to

the action of the marsh miasm. And in every epidemic of yellow fever the malarial influence is so powerful in most of the cities of the tropical, subtropical and temperate regions of North and South America that it is never entirely suspended, and not only in many cases induces characteristic changes before the specific action of the yellow fever poison, but also is frequently engrafted upon the weakened convalescents from yellow fever, thus altering the farther progress of such cases, and inducing changes in the organs entirely different from those characteristic of yellow fever.

In this continuous and preceding action of the malarial or paludal poison, and in the frequent intermingling of the two diseases, we have an explanation of the apparently contradictory statements of observers as to the characteristic symptoms and lesions of yellow fever. It is evident therefore, that no observer is competent to the elucidation of the pathology of yellow fever who is not at the same time familiar with the changes induced by the various forms of paludal fever and malarial poisoning.

If we accept without reserve the doctrine advocated by John Hunter,¹² and ably supported by Joseph Adams,¹³—that “No two actions can take place in the same constitution, or in the same part, or at one and the same time; no two different fevers can exist in the same constitution, no two local diseases in the same part at the same time,”—then the question of the modification of malarial fever by yellow fever, and of the engrafting of the one upon the other, must be definitely settled in the negative.

We have elsewhere shown by an extended discussion¹⁴ of this question that while, when two poisons representing two distinct exanthemic diseases act simultaneously upon the human being, the most obvious pathologic phenomena excited by the poisons will not occur simultaneously, but in succession—the one poison retarding the action of the other; the one producing its cycle of changes, while the other remains *dormant*, as it were, during the action of the first, and immediately after the changes induced by this cease, causing in turn its own distinctive effects—at the same time, it must be admitted that the character and cause of the specific eruptive diseases are greatly modified by such altered states of the constitution as exist in scurvy, scrofula and secondary syphilis. In that class of diseases represented by constitutional syphilis, scurvy and malarial poisoning, the blood is at fault, the nutrition is perverted and the course and products of diseased actions are correspondingly modified.

During the recent war, I embraced an opportunity for observing the effects of engrafting smallpox upon patients broken down by exposure, privation and the exhausting effect of hospital gangrene and pyemia.

In the month of September, 1864, smallpox spread from the ward devoted to the treatment of this disease to the Empire Hospital, which had been filled with cases of hospital gangrene and pyemia gathered from the general hospitals attached to the Confederate Army operating in and around Atlanta. The

¹⁴ Researches in Spurious Vaccination, or the Abnormal Phenomena accompanying and following Vaccination, in the Confederate Army during the recent American Civil War, 1861-65, pp. 38-59, by Joseph Jones, M.D., formerly Surgeon in the Provisional Army of the Confederate States.

smallpox ward was situated in a pine grove about three hundred yards in the rear of the gangrene hospital; and without doubt communication was kept up between the different wards. Several of the nurses of the gangrene hospital were first attacked, and the disease appeared to have been communicated from them to the patients under their charge who were suffering with hospital gangrene and pyemia.

The following case arrested my attention as clearly illustrating the engrafting of smallpox upon a system reduced by hospital gangrene:

Case 15.—J. S. J., Company K, Nineteenth Alabama Regiment, age 21, wounded at the siege of Atlanta on July 22, 1864. Gunshot wound of right leg, which was amputated on the field of battle at the lower third of the thigh. Hospital gangrene attacked the stump, and the patient was admitted into the Empire Hospital on September 22. Nitric acid arrested the progress of the gangrene for a time, but it returned again, and the strength of the patient was gradually reduced by the absorption of the gangrenous matter and from an exhausting diarrhea. On November 2, while the patient was exceedingly feeble and nervous, and manifesting the symptoms of pyemia—viz., chills, icterus and vomiting of dark green matters—the eruption of varioloid made its appearance. The pustules, which were in considerable numbers, but small in size, progressed regularly, and on November 6 presented all the characteristics of the true variolous eruption, with the round form and umbilicated center. This patient had a good vaccination scar, and the smallness of the pustules appeared to be due to the fact that the system was partially protected by vaccination. The patient died during the night of the 6th, apparently from the effects of the gangrene, pyemia and exhausting diarrhea.

None of the pustules in the preceding case presented any appearance of hospital gangrene; and, so far as I was able to learn, both during my investigation and subsequently, no case occurred in the gangrene hospital in which moist gangrene attacked the eruption of smallpox or varioloid.

It was clearly established that smallpox would attack patients suffering with gangrene, and even pyemia.

Case 16.—In an interesting case which occurred in my private practice immediately after the close of the recent struggle for the rights of self-government in the Southern States, acute dysentery of a severe form was superseded by typhoid fever, which was well marked in its symptoms and progress by low muttering delirium, diarrhea, tympanites, lenticular rose-colored spots, and painful enlargements of the parotid glands. As soon as well-marked typhoid symptoms were manifested, all the symptoms of acute dysentery vanished, and the patient passed without pain or straining the ordinary bilious stools of typhoid fever, and the smallest doses of purgative medicine, either mercurial or saline, acted with great and dangerous violence, producing copious "pea-soup" stools.

The patient passed safely through the typhoid fever, and even the parotid glands subsided without suppuration; but in the third week after the appearance of the typhoid fever, when the patient was apparently doing well, the dysentery returned with severe straining, and the bloody and mucoid discharges of acute dysentery, and the patient died in consequence of the return of the original disease.

I have also observed that typhoid fever was often engrafted upon malarial fever among the Confederate troops serving in malarious districts, and that during its active stages it presented the usual continuous fever, with cerebral disturbance, agitation of the muscles, tympanites, diarrhea, and lenticular rose-colored spots. As soon as the typhoid fever was established, all signs of periodicity disappeared, and the torpid liver of malarial fever became active, the sallow hue of malarial fever became clear from the increased action of the liver, the torpid bowels loose and tympanitic; and after the disappearance of the symptoms characteristic of typhoid fever, the original

malarious periodic fever reappeared, with its cold and hot stages recurring at regular intervals, and inducing torpor of the liver and bowels, and the sallow malarial hue.

As far as my observation extends, in like manner, when yellow fever is engrafted upon a system previously under the influence of the malarial poison, it establishes its own peculiar train of symptoms, distinct from those of malarial fever, and may be clearly recognized. When, however, the cycle of changes excited by the yellow fever poison has been completed, then the malarial poison may excite its characteristic recurring paroxysms, and change the yellow fatty liver of yellow fever into the dark slate-and-bronze liver of malarial fever, loaded with dark pigment granules.

While we know but little with reference to the concurrent action of the poisons of these two diseases upon the same system, and know nothing whatever of the state and mode of existence of that poison which "lies dormant" while the other is acting, at the same time we shall endeavor to illustrate the differences and relations of the symptoms and lesions by actual observations.

RELATIONS OF YELLOW FEVER, MALARIAL FEVER, AND MALARIAL HEMATURIA.

I have endeavored by careful observation of the various symptoms, by analysis of the blood secretions and excretions, and by careful examination of the pathologic lesions after death, to unravel the complicated chain of phenomena characteristic of yellow fever and other diseases; and while many facts are unexplained, and much remains to be investigated, we feel assured that the labors which we have pursued unremittingly during the past twenty-two years have been at least in the right direction.

The malarial poison induces profound alterations in the constituents of the blood. Under its action, as I have demonstrated by the first series of investigations (*Trans. AMERICAN MEDICAL ASSOCIATION, 1859*), colored blood corpuscles are more rapidly and to a greater extent destroyed than in any other disease; the fibrin is diminished and altered in quantity and quality; the albumen is in like manner diminished; the extractive and coloring matters of the blood are frequently increased. The unhealthy hue of the complexion in malarial fever appears to be due to the destruction of the colored blood corpuscles and the presence of coloring matter in the blood; the deposit of pigmentary matter, and the failure of the liver to separate fully the coloring matter of the bile.

In yellow fever there is no marked or uniform destruction of the colored blood corpuscles. The fibrin is diminished, and to a much greater extent than in malarial fever. There is no tendency to the formation of fibrinous concretions in the cavities of the heart in yellow fever, while the formation of such laminated fibrinous clots is common in malarial fever, and in some cases is the manifest cause of death.

Malaria, by its effects in inducing sudden congestions, and by its depressing effects upon the heart and upon the general and capillary circulation, and by its potent action on both the sympathetic and cerebro-spinal system of nerves, tends to promote the formation of heart clots, although there is an actual diminution of the fibrin in the blood during malarial

fever. In view of the rapid, feeble, intermittent pulse; disturbed, panting respiration; feeble, rapid, fluttering action of the heart; cold extremities, exhaustion of the muscular forces, stupor, wandering of the intellect, inability to control the muscles and acts of excretion; in view of the sudden onset of all the symptoms in malarial fever; in view of the observations which we have carefully recorded heretofore upon the lesions characteristic of malarial fever, we are justified in asserting that the fibrinous elements of the blood may be deposited in the heart and blood vessels during life in malarial fever, and not only give rise to distinct phenomena, but cause death in cases which otherwise would not have terminated fatally.

It is worthy of observation that in pyemia and in malarial fever, in both of which diseases there is a more rapid destruction of the colored blood corpuscles than in any other class of diseases, *chills* should characterize both affections, and form the most marked symptom. If such facts do not point out the nature of the cause of malarial fever, they at least sustain the belief that this disease, like pyemia and yellow fever, is due to the action of a special poison, and not to mere variations of climate and changes of moisture and temperature.

The rapid destruction of the colored blood corpuscles in malarial fever is evident, not only by a comparison of the constitution of the blood in this disease with that of yellow fever, but also by the presence of a larger amount of coloring matter in the urine. As a general rule, the graver the case of malarial fever the more deeply colored is the urine; while on the other hand, the reverse is the case with yellow fever. The coloring matter of the urine in yellow fever is due to a great extent to the retention of the biliary matters in the blood and the failure of the action of the liver; while on the other hand, the deep red and reddish-brown and orange-colored pigments of the urine of malarial fever appear to be derived chiefly from the colored blood corpuscles,

While the presence of the coloring matter in large amount in the urine of malarial fever may be dependent in part upon some imperfection in the excretion of carbon by those organs whose special function it is to eliminate this element from the blood, as the liver and lungs, and may, as has been observed by Golding Bird, be connected with some functional or organic mischief of the liver and spleen, or some other organ connected with the portal circulation; at the same time, from a careful consideration of the accompanying symptoms and subsequent *post-mortem* revelations, we have been led to the belief that in malarial fever the pigment is derived chiefly from the coloring matter of the blood cells, and that its amount may be taken as an index or measure of their destruction. This would be true, whether it comes at once from the blood corpuscles by changes taking place in the mass of the circulating fluid, or by the destruction of the blood corpuscles in the liver and spleen. Certain it is that this pigment is not found in the kidneys, and does not accompany diseases of the kidneys; nor is it thrown off under the action of organic medicines and compounds, drastics and purgative salts, which irritate and even cause disease of the intestines and kidneys. Even tincture of cantharides, when given in such large doses as to cause albuminuria and even blood to appear in the urine, does not cause such pigments as purpurine (Bird),

uroerythrin (Heller), or urohematin urophæin to appear in the urine. In those cases of yellow fever in which we have the greatest irritation of the kidneys, or rather in which there is the greatest structural alteration of these organs, will be found, as a general rule, the lightest colored urine. On the other hand, poisonous metallic salts, which derange the constitution of the colored blood corpuscles, and interfere with the blood-making or blood-regulating functions of the liver, and spleen, as the compounds of lead, copper, mercury, arsenic, and antimony, cause even in small doses the appearance of this substance in the urine; and when taken in doses sufficiently large to produce poisonous effects the quantity is greatly increased.

In malarial fever the constituent of the blood which suffers to the greatest and most essential degree is the colored blood corpuscle.

In yellow fever the constituent of the blood which suffers to the greatest and most essential degree is the albumen and its modification, fibrin.

The peculiar action of the poison in the former upon the colored blood corpuscles induces a distinct train of symptoms, and establishes distinct recognizable lesions, characterized chiefly by the deposit of pigment matter in certain organs; while in the latter the poison causes such changes in the albumen and fibrin as lead to the formation of non-nitrogenous and nitrogenous materials, some of which, as the oil and modified fibrin, are arrested or accumulated in certain organs, as the heart, liver and kidneys.

During the active stages of both yellow and malarial fever, phosphorus and the compounds of phosphorus in the nervous structures, as well as sulphur and the compounds of sulphur in the muscular structures, undergo more rapid changes than in the normal state; and phosphoric acid and the phosphates, and sulphuric acid and the sulphates, appear in increased quantities in the urine when the kidneys perform their offices. The waste of phosphorus and of its compounds in the nervous structures during the active stages of the disease is greater than the supply of these materials through the food. The nervous disturbances and debility characteristic of these fevers, as well as of others, are in a measure due to those rapid changes in the phosphorescent materials of the nervous structures, and especially of the central ganglionic cells.

In many cases of yellow fever, and in that form of paroxysmal fever called malarial hematuria, the function of the kidneys is impaired, and neither the urea nor the mineral acids are increased in the urine; while at the same time they accumulate in the blood, and exert deleterious effects upon the nervous system and blood. The increase of the urea and of phosphoric and sulphuric acids during the active stages of these diseases should not, therefore, be considered as anything peculiar and as at all distinguishing them from other fevers. It is only the tendency to congestion and alteration of the excretory structures of the kidneys that characterize yellow fever. The peculiar intoxication and nervous symptoms, as well as the black vomit of yellow fever, are intimately associated with suppression of the urinary excretion. In many cases I have found the black vomit of yellow fever to give strong alkaline reaction from the presence of ammonia resulting from the urea eliminated by the gastric mucous membrane. I have also detected by repeated analysis, urea in large amount

in the brain, heart, liver, spleen, muscles, and blood in yellow fever. In this disease, suppression of the action of the kidneys is more to be dreaded than black vomit, which it often precedes and induces.

The increase of these constituents of the urine is referable to the same cause—that is, increased chemic change—in both fevers, although it is evident that the nature of these chemic changes, and the special constituents involved may differ in each disease.

During the slow action of the malarial poison, as well as during the active stage of the paroxysm, important changes take place in the liver and spleen which are wholly different from the changes of these organs in yellow fever. In malarial fever, in both the liver and spleen, the colored blood corpuscles are destroyed in large numbers, and the coloring matter resulting from the disintegration of the colored corpuscles accumulates in them, and in conjunction with other changes in the nutritive processes of these organs produce those characteristic alterations of the normal color. In fatal cases, cellulose is found both in the liver and spleen, while grape-sugar is absent from the liver. The bile is also altered, both in chemic constitution and physical properties.

In yellow fever there is no destruction of colored blood corpuscles either in the spleen or liver, and no deposit of pigment matter, while *oil* is deposited in large amount in the liver, which together with the bile, impart to this organ a yellow color far different from the dark slate or bronze color of the malarial liver. The spleen is comparatively unaltered in yellow fever. Both cellulose and grape-sugar are found in the liver of yellow fever.

That the chemistry of the body is deranged in a definite manner in malarial fever is evident from the changes of the excretions. During the chill, and at the commencement of the hot stage, phosphoric acid disappears almost entirely from the urine. As the hot stage progresses, and the febrile action and the heat begin to decline, there is an augmentation of phosphoric acid. The uric acid is either increased or remains at the normal standard during the chill, disappears almost entirely during the fever, and then increases rapidly and rises to a high figure after the subsidence of the febrile excitement, and often continues for days, two, three, or even six times more abundant than in the normal state, as I have shown by a large number of observations published twelve years ago.

The sudden variations in the physical and nervous phenomena of malarial fever are accompanied by equally sudden and marked anatomic lesions and changes in the excretions. No such variations in the phosphoric or uric acids are observed in yellow fever. The poison inducing malarial fever acts in a definite manner, and is governed by definite affinities and relationships, and produces a type of diseased distinct from yellow fever. The malaria of the swamps and marshes can only generate paroxysmal fever.

In the vast majority of cases of malarial fever, albumen does not appear in the urine. This constituent of the blood may, however, be present in the urine in malarial fever under certain circumstances.

1. Its presence in the urine of malarial fever may be due to preceding disease of the kidneys, of the liver, or heart.

2. To the prolonged action of the malarial poison, and the structural alterations induced by it in the spleen, liver, and kidneys.

3. To the congestion of the kidneys from cold, or from the impaction in the capillaries of pigment matter, or from the irritant action of the malarial poison upon the excretory structures in cases which have suffered with repeated attacks of intermittents.

It is the exception to the rule to find albumen in the urine in malarial fever; it is the exception to the rule to find albumen absent from the urine of yellow fever.

Even in those cases where the prolonged action of the malaria has produced profound structural alterations of the liver, consisting in the extensive deposit of black pigment granules within and around the capillaries of the liver, obliteration of many of the branches of the portal system within the lobules, and in the hardening and contraction of the entire organ, albumen is rarely present in the urine. I have examined the urine carefully without detecting albumen in a number of cases of ascites and extreme dropsical infiltration of the lower extremities, produced by the hardening and contraction of the liver in chronic malarial poisoning. I have observed cases, however, in which the kidneys were structurally altered by the malarial poison in a manner somewhat similar to the liver, in which albumen was a constituent of the urine.

A certain proportion of such cases may be referred to the causes which ordinarily lead to structural alterations of the kidneys, as the excessive use or abuse of ardent spirits, and the effects of exposure to wet and cold and extreme temperature; but there are cases of albuminuria which can be explained only upon the supposition that they are due to the structural alterations of the kidneys induced by the prolonged action of the malarial poison. And this condition of the urine is not to be referred to the watery condition of the blood induced by the destruction of the colored corpuscles and diminution of the albumen and fibrin; for the state of extreme anemia frequently induced by the action of the malarial poison is never attended by albuminuria, unless there be some structural alteration of the kidneys.

In that form of malarial fever characterized by complete jaundice, intense vomiting and nausea, and hemorrhage from the kidneys, which has received different names at different times and in different countries, and which is no "new disease" even in these Southern States, the hemorrhage from the kidneys is preceded by congestion of these organs, and is attended with desquamation of the excretory cells, and tubuli uriniferi of these organs.

Malarial hematuria (hemorrhagic malarial fever—new disease—up-country yellow fever,) as a general rule, occurs only in those who have suffered from repeated attacks of intermittent fever, or who have been exhausted by a prolonged attack of remittent fever; and while some of the symptoms, as the nausea, incessant vomiting (and in extreme cases black vomit,) deep jaundice, and impaired capillary circulation, resemble those of yellow fever, yet there are marked differences, similar to those already indicated, as distinguishing malarial and yellow fever.

The presence of the albumen in the urine of this so-called "malarial hematuria" is attended also with the presence of colored blood corpuscles, excretory cells of the kidneys, and the tubuli uriniferi, impacted oftentimes with altered blood corpuscles. I

have even detected the Malpighian corpuscles containing altered blood corpuscles, and deeply stained by the coloring matter of the blood. As a general rule in yellow fever, the tubuli uriniferi are loaded with yellow granular, albuminoid, and fibroid matter.

In those cases of malarial hematuria which have come under my observation there was evident congestion of the kidneys, attended with desquamation of the excretory cells and coats of the tubuli uriniferi and active hemorrhage. In some of these cases immense quantities of green biliary fluid were vomited, and the patients died in a state of apparent collapse. As a general rule, suppression of the functions of the kidney is a fatal sign, and, as in yellow fever, may be attended with convulsions, coma and delirium. A careful examination of the blood in malarial hematuria reveals great diminution of the colored corpuscles and fibrin.

The pathologic changes observed after death are characteristic of malarial fever: enlarged slate-and-bronze liver, with pigment granules; enlarged and softened spleen, filled with disorganized colored corpuscles and pigment granules; gall-bladder distended with thick, ropy bile, presenting when seen *en masse* a greenish-black color, and in thin layers a deep yellow. As much as one thousand grains of bile of high sp. gr. (1036) have been obtained from the gall-bladder, while in yellow fever not more than one hundred and twenty grains of bile are, as a general rule, contained in the relaxed gall-bladder.

I have thus clearly demonstrated that malarial hematuria is related to the various forms of true malarial fever (intermittent, remittent, and congestive,) and in fact is only one of the phases of this fever which may at any time be assumed after the alterations of the blood, liver, and spleen induced by the prolonged action of malaria. I have also clearly shown that it is distinct from yellow fever, although it may have some symptoms in common, as jaundice, black vomit, and albuminuria.

The treatment of malarial hematuria should be conducted upon the same general principles which should guide us in the treatment of pernicious intermittent, remittent, or malarial fever; with this addition, that attention should be paid to the condition of the kidneys, and they should be relieved by cut cups and counter-irritation. The bowels should be freely opened by a mercurial (calomel is the best preparation) combined with quinin. Ten grains of calomel and ten grains of quinin is a useful combination. Quinin should be freely given. The strength should be supported by nutritious diet (beef-tea and milk punch,) given by the rectum if the stomach will not bear it. Alcoholic stimulants should be used without any fear of injury. The action of the skin should be promoted by the hot-air bath and steam bath.

In brief, the *strength must be supported and the paroxysm arrested by quinin; the liver and bowels and portal system must be unloaded; the congestion of the kidneys must be relieved; and during convalescence the blood must be enriched with pure and nutritious diet, and iron, and a gentle action of quinin maintained.*

(To be continued.)

A NEW METHOD FOR ANCHORING THE KIDNEY.

Read before the Columbus (Ohio) Academy of Medicine, Nov. 19, 1894.

BY R. HARVEY REED, M.D.

COLUMBUS, OHIO.

Since Hahn, in 1881 anchored the kidney, operations for this purpose have gradually grown in favor until at the present time there are few surgeons who do not recognize it as a justifiable procedure. Prior to that time, in cases where a floating or movable kidney required operative interference, surgeons only considered the question of nephrectomy—a most formidable and dangerous operation without the protection of asepsis or antisepsis.

ANATOMIC MEMORANDA.

In anchoring the kidney, there are a few anatomic landmarks it is always well to keep clearly in mind and especially so in performing the operation which we are about to describe. Clinical experience teaches us that movable and floating kidneys occur more frequently on the right side than on the left. In this connection it is well to remember that the right kidney, when in its normal position is usually located a little lower than its fellow and, on the average, measures about four inches in length. The left kidney is usually longer and narrower than the right kidney. The upper margin of the right kidney when in its normal position is on a level with the twelfth dorsal vertebra. This throws its margin slightly above the upper border of the twelfth rib, which is an important point to remember in the operation I am about to describe. The left kidney being located a little higher than the right, its upper margin not infrequently is on a level with the lower border of the eleventh rib and sometimes even reaches a point slightly higher.

The right kidney is usually about two and a half inches in width, while the left kidney seldom exceeds two inches, but makes up for its reduction in width by increase in length. They are each about one inch in thickness, which is also an important factor in considering the question of anchoring. By keeping these few anatomic landmarks in view, the operator will be able to comprehend the mechanical conditions that are present, and which he must meet in anchoring a floating or movable kidney in its normal position.

PATHOLOGIC CONDITIONS.

In a brief paper of this character we shall not attempt to enter into the details in considering the pathology. Only a few salient points will be noticed. If we have a true floating kidney to deal with we have a mesonephron or, in other words, the kidney is enveloped in a peritoneal sac with a pedicle, the base of which usually corresponds with the natural position of the kidney. The length of this pedicle varies in different cases while the size of the sac depends on the size of the kidney. The pedicle contains the nerve, artery, vein and ureter which are more or less displaced and imposed upon, often giving rise to severe congestion on the one hand or hydronephrosis on the other, and associated with frequent attacks of excruciating pain.

It will be observed that in this condition you have a tumor resembling that of a long-necked gourd hanging with the large end of the gourd down, the neck representing the pedicle and the large end of

the gourd the kidney. As a rule this tumor is free to move and changes its position with the movements of the patient, or by manual manipulations, the peritoneal surfaces being free to glide upon each other.

In the movable kidney there is no mesonephron, but the kidney is jarred loose from its attachments and is free to move behind the peritoneum. In changing its position it drags with it the artery, vein, nerve and ureter which form the pedicle. In a movable kidney you will observe the peritoneum is dissected up from its posterior attachments and the kidney is free to move behind it. It will, therefore, be observed that the only practical difference between a floating kidney and a movable kidney is that the one is enveloped in a peritoneal sac, while the other moves behind the peritoneum and has no sac. In either condition, however, there is danger of obstructing the artery, vein or ureter, or any two of these vessels, or all of them. They may become occluded by pressure or torsion, producing congestion or hydronephrosis, or both, as the case may be. At the same time the nerves are liable to be implicated, producing severe neuralgic pains with or without the presence of either congestion or hydronephrosis.

SURGICAL RELIEF.

Prior to 1881, when surgical relief was attempted under these conditions, nephrectomy was the only operation considered. At that time, Hahn, of Berlin, made a lumbar incision and fixed the kidney in its normal position by suturing it to the lumbar muscles. Ashhurst shortly afterward made the same operation successfully. Subsequently, the operation was performed by Kuster, Esmarch, Bassini, Newman and others with satisfactory results. The object in making *this* operation was to avoid entering the peritoneal cavity which was a very necessary precaution prior to the introduction of aseptic surgery. The difficulty, however, in performing this operation was in manipulating the kidney (and especially so in fleshy persons) and holding it in place until it could be fixed by sutures to the lumbar muscles. These operators did not close the incision but packed it with iodoform gauze and allowed it to heal by granulation. Those of us who have performed either the extra- or intra-peritoneal operation will readily appreciate the difficulty of holding the kidney in its place. In my experience I find it about as difficult to manipulate a floating kidney and hold it in a fixed position as it is to manipulate a cake of wet soap on a wet soap dish with soapy hands, and hold it firmly in one place. I have seen good operators attempt this operation (both extra- and intra-peritoneal) who were absolutely unable to manipulate the kidney so as to hold it in its place long enough to securely suture it. This difficulty, together with the advancement of aseptic surgery, has led to opening the peritoneal cavity with a view of getting at the kidney more readily and by manual manipulation hold it to its place until it can be securely anchored. In fixing the kidney in this way, it was necessary to use a curved needle which was sufficiently long to pass through the kidney (which you will remember is an inch in thickness) the fascia, and into the muscle of the back sufficiently deep to insure a firm attachment. This requires a half-curved needle not less than two and a half to three inches in length. In making this operation it was not only a difficult task to hold the kidney in position until the first

suture could be inserted, but it also necessitated great care on the part of the operator to avoid wounding the liver, gall-bladder and even the intestines with the point of the needle, or tearing the parenchyma of the kidney with its heel in making the short curve necessary in completing the suture. I have seen hemorrhage from tears of this kind so profuse that it became necessary to open the posterior wall of the peritoneum and control it by the use of hot compresses which not only delayed the operation, but increased the danger to the peritoneum. I never anchored the kidney, either intra- or extra-peritoneal, without feeling that the various operations heretofore employed should be simplified and the operation performed in less time, with less danger and much less trouble, and equally good or better results obtained. The consequence is that I have devised the operation which I now perform, and from the limited experience I have had with this operation and the successful results following it, I feel that I am justified in presenting it to the profession for their consideration.

In view of the minimum amount of danger in opening the peritoneal cavity under aseptic precautions, together with the decided advantage it gives to the operator in manipulating the kidney, and assuring himself that the vessels and ureter are not incarcerated in any way, I have arrived at the conclusion that the intra-peritoneal operation is to be preferred over that of the extra-peritoneal.

My operation consists in making the ordinary perpendicular abdominal incision over the median line of the kidney. As a rule, it need not exceed two and a half to three inches in length, depending largely on the thickness of the abdominal walls. Having made the incision sufficiently large to get the fingers in and bring the kidney to its normal place, I then use a long needle which I have had made on purpose, varying from five to seven inches in length. Two of these needles are threaded with aseptic silkworm gut or aseptic silk, using but one ligature, armed with one of these long needles at each end. Having placed the kidney in its normal position (and in the case of a floating kidney scored the peritoneum so as to favor adhesions), I now insert my first needle through the upper and inner part of the cortical substance of the kidney, directly through the muscles of the back, coming out between the eleventh and twelfth ribs. The second needle which is on the other end of the ligature is also passed through in a similar manner, about an inch from its fellow, through the upper and outer cortical substance of the kidney making, as you will recognize, a staple stitch. These ligatures are tied on the integument of the patient's back by an assistant. If necessary, another suture is inserted in a similar manner through the outer margin of the kidney, the first needle of the second suture being passed about an inch below the last needle of the first suture, and the second needle of the second suture about an inch below the first needle of the second suture through the cortical substance of the outer portion of the kidney. By anchoring the kidney in this manner, the entire operation can be performed in not to exceed fifteen minutes unless there are some annoying complications to contend with, for, as you will observe, all that is necessary is to open the abdominal cavity, place the kidney in its normal position and with the use of these long needles the suture can be

placed in position quickly without any fear of injuring the abdominal viscera, or unnecessarily tearing the cortical substance of the kidney. In tying the sutures, care should be taken to draw them sufficiently tight to not only hold the kidney in place, but to produce sufficient irritation to excite inflammatory adhesions, which are intended to hold the kidney in place, and which are so essential to make the operation a permanent success. It is also necessary to be guarded against tying the sutures so tight as to cut through the peritoneum and the substance of the kidney. Either of these conditions, however, can be avoided by care on the part of the operator. After properly tying the sutures the abdominal wound is closed in the ordinary manner. The anchor is allowed to remain from ten days to two weeks. At the expiration of this time, adhesions are formed sufficiently strong to hold the kidney in place when the anchor is removed, and in two weeks more the patient will be able to leave the hospital.

The advantages we claim for this operation are:

1. Simplicity.
2. Rapidity.
3. Efficiency.

The operation is practically bloodless. There is no danger of injuring the abdominal viscera. It is easily performed and the results so far are certainly very satisfactory as illustrated by the following case:

Miss E. E. B., age 28; single; occupation a stenographer; family history and previous health good. In February, 1894, while lifting a large piece of coal, felt something give way in the abdomen, and from that time had suffered from pain principally located on the left side of the abdominal cavity. Living in Chicago, she consulted several physicians in that city who differed in opinion as to the nature of the case. One pronounced it ulceration of the os uteri and treated her accordingly; another announced that it was a floating left kidney. The patient in the meantime gradually grew worse and returned to this city, her former home, when she consulted her family physician, Dr. E. Frazier Wilson, who called the writer in counsel. Upon examination a wandering right kidney was readily discernible, which could be moved from its normal position to a point as low down as the brim of the pelvis, and could be easily shot up until it was lost behind the lobe of the liver. This manipulation was not painful. On further examination, a displacement of the left kidney was discovered, which was found fixed in an abnormal position. The exact condition of the left kidney could not be satisfactorily diagnosed prior to operation, and patient so informed.

She was admitted to the Protestant Hospital, July 21, 1894. Assisted by Dr. Wilson, I operated on her July 22, and found the wandering kidney, which we anchored according to the method I have already described, using but one silkworm gut suture. This part of the operation was rapidly accomplished and was practically bloodless. Had it not been for other complications the operation could have been completed in a few minutes. On further examination, it was discovered that the left kidney was congenitally malplaced, and was located much below, and very much closer to, the vertebral column than it should be normally. The peritoneum covering the lower margin of the kidney was adherent to the left ovary. The latter was found to be about the size of a walnut and very much inflamed. The adhesions were broken up, the ovary removed and the abdominal incision, which in this case was made through the linea alba on account of the suspected complications, closed in the usual manner. There were no unfavorable symptoms. The temperature and pulse ranged from 98.6 to 101.7 and from 72 to 108 respectively.

The patient was discharged from the hospital August 14, and in a few weeks returned to her position at Chicago, where she has been working ever since. It was my fortune to see her, when in Chicago recently, at which time I was permitted to make a careful examination. I found the right kidney firmly anchored in its normal position and free from all tenderness.

The patient's health has improved ever since the operation. She has gained several pounds in weight and to all appearances has obtained permanent relief.

After reading the paper, the author exhibited the needles he has had made for this purpose.

150 East Broad Street.

TWO CASES OF BRAIN SURGERY WITH REMARKS.

Read before the Northern Tri-State Medical Association at Hillsdale, Mich., Dec. 11, 1894.

BY HAL C. WYMAN, M. Sc., M.D.

DETROIT, MICH.

Case 1.—A young woman, 23 years old, a teacher, had an attack of facial erysipelas, which started from a crack or cold sore in the alar aspect of the left nostril. Her face swelled and closed her eyes. The left ear became greatly swollen. The scalp of the forehead and left side of head was swollen and edematous to the crown. She suffered great pain, but no pus appeared in the parts, although she had a temperature ranging from 104 to 105 degrees F., for seven days. She took quinin and tincture of iron in doses of 2 grains and 7 drops respectively, during that time. The inflamed area was brushed with tr. iodine, reduced one-half with dilute alcohol, once a day. The left nostril was obstructed by swollen mucous membrane for three days, but it gave way under the daily use of an ointment made by rubbing 20 grains of citrin ointment with 1 ounce of white vaselin. The swelling then left the face and scalp; and delirium, which had been so violent that the constant service of a nurse was required to keep her in bed, now disappeared. Convalescence apparently began on the ninth day of her illness, but in reality, another train of symptoms began. Fever of less degree and indifference to her surroundings became a feature of the case and she had cold spells, during which her lips were quite purple and bodily temperature rose from 99 to 102 degrees and declined again to 99 degrees, when the lividity disappeared. Respiration was hurried during the cold stage and profuse sweating accompanied the return of normal respiration. Delirium re-appeared. The whole right side became paretic. The left pupil enlarged and would not respond to light. She became more stupid and, after three days was profoundly comatose. Neither shaking nor loud calls would awaken her. Water placed in her mouth was not swallowed, unless it was placed well back in the fauces. The bowels moved incontinently and the urine was removed with a catheter. Reflexes were nearly abolished. The prognosis of several physicians who consulted on the case was, death, the converse of the maxim that life is governed by probabilities, unless an operation, which had already been proposed for several days, relieved the intracranial pressure.

I need not recite the theories that were advanced during the consultation to account for the symptoms. We have all seen such cases and are familiar with the phenomena of meningitis, thrombosis of lateral and sigmoid sinuses and cerebral degenerations.

The friends consented to an operation. I washed the head with soft soap and warm water, shaved the left side of it and again washed it with alcohol. I then made an incision through the soft parts to the skull, beginning one inch above the external auditory meatus, half an inch behind the ear, two inches long, parallel with the long axis of the mastoid. In the center of this wound, the soft parts being held asunder with retractors, I placed the crown of a trephine, and, by alternately boring and using the elevator, removed a button of bone, half an inch in diameter. From the diploë, a small quantity of sanious fluid oozed. With the strong oval-pointed tip of a dressing forceps, I chiseled through the remaining thickness of the skull and reached the cranial cavity, and a quantity of watery pus discharged. With rouguer forceps the opening was enlarged to the full size of the trephine opening and pus discharged more freely. This was done without anesthetic, the patient being profoundly insensible, in consequence of the disease. In a few minutes, while I was washing the abscess cavity with weak carbolic solution, she moaned and exhibited signs of consciousness. With each respiratory movement, the fluid would well freely from the skull. A probe, with one end resting in the pus cavity, pulsated synchronously with the

heart. A gauze drain was placed in the abscess and covered with absorbent gauze. An antiseptic dressing completed the operation. Complete consciousness returned during the next three or four hours. Convalescence began at once and continued without interruption. For three weeks, pus discharged from the wound in quantities sufficient to soil a handful of gauze, but gradually granulations closed the wound and the patient is now well and sound.

Case 2.—A Canadian farmer, 34 years old, had earache. After several days of suffering, pus discharged from his left ear. He did not, however, recover his full vigor, as he had in several similar attacks he had suffered during the preceding ten years. Instead, his appetite was poor, he was dizzy and had pain in the left side of his head, about the suppurating ear. A soft swelling appeared over the mastoid. His hearing in the left ear was gone. He had chills and fever, and, at intervals of every hour or two, terrible shooting pains would run through his head, starting from the suppurating ear, the discharge from which had diminished. His doctor incised the swelling back of the ear and removed a small quantity of watery fluid, which he did not think was pus. The operation gave a temporary relief from his pain. The wound healed. Fever, however, continued, but it did not rise above 101 degrees F. His general condition did not improve. He had been able to sit about the house half the time, but was now too feeble to get out of bed. His left eye would not close, nor could he see well with it. It was turned outward; the left side of his face was paralyzed; the left conjunctiva was edematous and the left pupil was contracted. In sleep, which came only when he was under the influence of chloral, morphin and bromid of potash, the muscles of his right upper and lower extremities would jerk and twitch. When awake he was very restless, all the muscles of his extremities being irritable. When spoken to loudly, he would briefly quiet down and apparently compose himself for sleep, but would soon sigh and moan and toss about. He was not unconscious and tried to arrange his affairs for death. He had been in this miserable condition four weeks, when I saw him and told his physician that I thought an operation, which would remove the diseased mastoid and drain the skull, would give a chance for recovery. The patient and his friends were pleased to submit to anything that offered any hope of relief. His head was prepared antiseptically, as in the preceding case. He was anesthetized with chloroform and an incision was made back of the ear, exposing the mastoid and a part of the squamous of the temporal bone. Several arteries required to be held with forceps, until sutures were introduced to close the wound. The outer wall of the mastoid was carious and rough. It was easily chiseled away with the point of a dressing forceps, so that the rougeur could be used to open the skull. The mastoid was filled with soft, purulent granulation tissue, which extended to the dura mater. Watery pus discharged in small quantity. I neglected to state that the parotid gland and other glands and tissues of the neck, beneath the angle of the left jaw, were swollen and indurated, indicating that the inflammatory process had extended from the skull to the neck, since the second week of his illness.

This condition, with the absence of a free discharge from the epidural space, convinced me that the membranes contained the offending fluids. With the rougeur, the bone and granulation were further cut away, until my finger could be applied to the dura mater. Bleeding was quite free, but was easily controlled by packing the margin of the bone with iodoform gauze. The pulsation could be felt through the dura mater, which bulged into the opening in the skull. An indistinct sense of slightly movable hardness could be felt in the region of the lateral sinus—probably a thrombus. A small opening was made above the area of hardness, through the dura mater. A bistoury was used for this purpose. At once, a quantity of watery pus discharged. A forceps was passed through this wound to dilate it and the fluid discharged in jets, like the pulsation of an artery. Some of the fluid was dark, like thin dead blood and the remainder of it was like thin pus. The quantity was not measured, but I think two ounces discharged. When it ceased running, a small rubber drainage tube, one inch long, was passed through the dura mater and was fixed with a small sterilized safety pin, to prevent slipping within the cavity of the membrane. Absorbent gauze and antiseptic dressing were applied after the scalp had been partially closed by sutures over the opening in the bone. The patient was ordered to have no more anodynes and to take alternately calomel and sulphate of magnesia, until his bowels were freely open. Then he was given 10 drops of

tincture of iron, in a tumblerful of corn-meal gruel, once in four hours. On this treatment he steadily improved. The drainage was taken from the dura mater at the end of a week, no more fluid discharging from the tube at that time, but the mastoid continued to discharge for a few weeks and the granulations protruded from the wound exuberantly. They were dusted with calomel and dressed with plain gauze twice daily. The bone healed slowly, but his physician tells me that the opening is now, nine months after the operation, entirely closed. His hearing is much impaired on that side. The auditory fistula was not painful, though quite offensive. The squint has not disappeared, although the ptosis can scarcely be noticed. The expression is otherwise normal.

These cases are related to call attention to a department of pathology that, I fear is sometimes neglected in surgery. We are in the habit of leaving all cases of inflammatory disease of the ear to aural specialists, and these gentlemen treat the cases as long as they can apply remedies through the Eustachian tube, external ear or an opening into the mastoid cells. When the symptoms indicate an extension of the inflammatory processes to the parts within the cranium the case is commonly left without surgical interference and terminates fatally. The reason for this is found in the neglect of anatomy by physicians. The anatomy of the temporal bone is made to appear so hard to learn that few students ever get more than a superficial knowledge of it, and graduates commonly think it contains little useful knowledge. In the search for purely practical information it is commonly overlooked and passed by as of no use. But modern aggressive surgery is exploring the *terra incognita* of anatomy as modern geographers are exploring the Congo River and African lakes. Neglect to make careful autopsies and idolatrous devotion to the microscope as a means of revealing the mechanism of disease are also blamable for the absence of a sound pathology on which to base a more active surgical treatment in a large class of inflammatory diseases affecting the brain.

I have brought with me two skulls, which have been prepared so as to show the relations existing between the mastoid and petrous cavities, cells, spaces, fissures and foramina of the temporal bone and the cranial cavity. You will observe that the situation of the lateral, sigmoid, petrous and cavernous sinuses are indicated by red colors. The external wall of the mastoid has been chiseled away, leaving the mastoid cells. The anterior aspect of the petrous portion of the temporal bone has been chiseled away to show the internal and middle ear and their relations to the cranial cavity. The posterior part of the petrous portion of the temporal bone has likewise been in part chiseled away, to show the relations existing between the various cavities of the petrous portions of the temporal bone, the mastoid cells and the middle ear. I need not tell you that there is a direct channel of communication between all of these cavities, by way of the Eustachian tube or perforated drum membrane, and all cases of inflammatory disease affecting the throat or middle ear. By direct continuity of mucous and vascular channels, inflammation may gain access to the cranial cavity, the membranes of the brain and the brain itself.

I am sorry that the distance from Detroit prevented me from bringing more skulls with me. I could have shown you numbers of them in which normally almost direct communication between these cavities and the brain existed, the separation being simply membranous. Let me state that all fora-

mina nearly, that I have mentioned, contain venous and lymph channels, which pass directly from the mucous membranes lining these various cavities and cells to the large sinuses and cerebral membranes; in view of these facts, I do not think it at all strange that simple inflammatory disease of the throat and malignant inflammatory diseases like diphtheria may readily extend to the cranial cavity. We can further see how a disease extending through these bone spaces to the cranial cavity may, by the accumulation of inflammatory products cause disturbance of the function of the brain and spinal cord, not unlike that which we frequently see after diphtheria and are in the habit of attributing to the direct effect of toxins upon the nervous system. These channels in the bone at the base of the skull are the only means of conveying away the materies morbi and their products. The apparatus is so complicated that nature drains away with difficulty the products of inflammation. Therefore, surgery must provide a means of drainage or fatal results will follow. What the appendix vermiformis and the Fallopian tubes are to peritonitis, the mucous cavities in the petrous and mastoid portions of the temporal bone are to meningitis and compression of the brain.

A CASE OF CEREBRAL CLOT; LOSS OF VISION FOLLOWING INJURY; TREPHINING; RECOVERY.

BY JOHN B. HAMILTON, M.D., LL.D.
CHICAGO.

In November, 1893, Dr. Julia Holmes Smith, of Chicago, brought a patient to my service at the Chicago Polyclinic with the following history:

Sister Adele, of the Benedictine order, aged 20, strong and healthy, was injured in Canon City, Colorado, June 18, 1893. At the time of injury was on a step ladder unscrewing one of the fastenings of a chandelier in the Academy St. Scholastica. A staple or hook fell, striking her on the top of the head, just posterior to the Rolandic fissure on the right side. Had great pain, but no wound of the scalp; severe

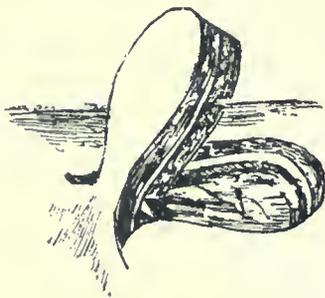

Fig. 1.—Temporary resection of bone flap from cranium. (From Es-march, after Wagner.)

headache which has never entirely disappeared. Vision in right eye gradually failed, and could not see; totally blind in right eye. Deafness of right ear began almost immediately after the accident and continued. There was no motor paralysis, no loss of sense of taste or of smell. Vision and hearing apparently normal on the left side. Ophthalmoscopic examination by Prof. J. Elliott Colburn: "O. S. normal, O. D. slightly vascular; no evidences of past or present neuritis. Must have pressure in region of optic commissure on right side. Diagnosis: Pressure from injury in region of fissure of Rolando."

I trephined the patient November 15 at the Benedictine Convent, Dr. E. J. Senn assisting and Dr. J. H. Smith present. Temporary resection of cranial wall with chisel. Dura mater healthy; incised it and passed a silver wire loop downward and forward toward optic commissure. On withdrawal a firm round coagulum about three centimeters in length

was found attached to the wire. A second time the wire was passed, but this time the result was negative. The wire was then gently passed in a posterior direction following the posterior surface of the petrous portion of the temporal bone, without result. The bone was replaced after suture of dura, and the wound was then closed, three silkworm gut threads being left in the angle of the wound for drainage. The wound was dressed in the usual manner. The patient rallied well after the operation, but on the second day there were con-

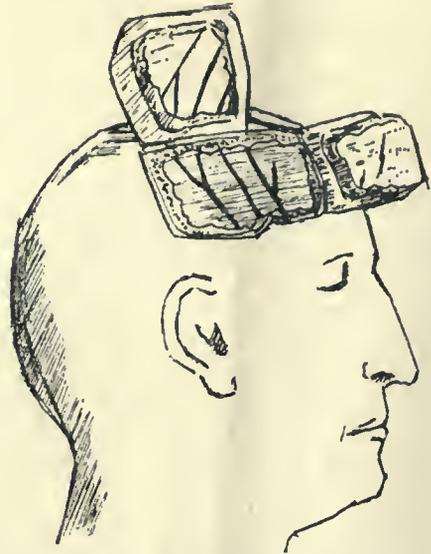

Fig. 2.—Double section of Wagner. (After Chipault.)

vulsions with total loss of consciousness and spasmodic contraction of the muscles of the left arm and hand. I inferred there must have been an oozing causing pressure, and as I was confined to my room with a severe cold, Dr. C. P. Wertebaker, of the Marine-Hospital Service, was requested to reopen the wound. He did so, and removed coagula pressing upon the dura. The wound was again closed after care-

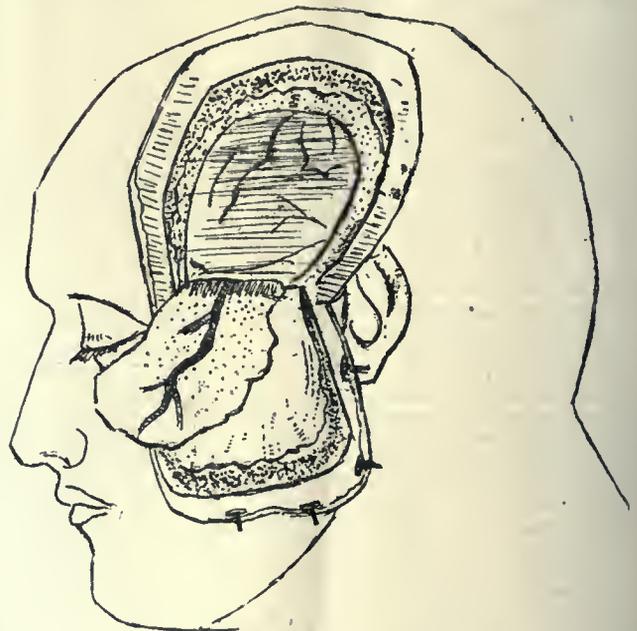

Fig. 3.—Temporary resection of cranial wall with dural flap. (After Chipault.)

ful cleansing, and the patient recovered without untoward symptom. The temperature remained normal.

June 18, 1894, Professor Colburn again examined the eyes and found the field normal in both eyes. Vision had been restored from the date of the operation. Nov. 18, 1894, I again saw the patient and found her with normal hearing and vision, and in good health.

In regard to the technique of trephining, it is

proper to add a few words in explanation. For the last three years, I have used the "corner" chisel and mallet. I think favorably of the circular saw propelled by the dental engine, but I have not used it. Before becoming acquainted with the merits of the temporary resections, I used the large conical trephine, preserved the bone button with great care during the operation, keeping it in a warm towel previously wrung out of a hot antiseptic solution, and replaced it afterwards, but with the method introduced by Wagner, we need no longer fear non-union of the bony flap when replaced, and here as elsewhere, the most rigid asepsis must be maintained during the operation and at the subsequent dressings.

SOCIETY PROCEEDINGS.

Proceedings of the First Meeting of the American Academy of Railway Surgeons.

Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.

FIRST DAY—MORNING SESSION.

The Academy convened in Room 44 of the Grand Pacific Hotel, and was called to order by the Chairman of the Committee on Organization, DR. R. HARVEY REED, Consulting Surgeon, B. & O. R. R., Columbus, Ohio.

On motion, DR. H. J. MAYNARD, Division Surgeon, U. P. D. & G. R. R., Cheyenne, Wyo., was called to the chair.

DR. WEBB J. KELLY, Division Surgeon, Erie R. R., Galion, Ohio, was selected as temporary Secretary.

Inasmuch as the minutes of the previous meeting were nearly, if not all, contained in the report of the Committee on Permanent Organization, the reading of the same was dispensed with.

On the roll call of Charter Fellows the following surgeons who had filed written applications for fellowship were found to be present: Drs. W. W. Appley, Surgeon, N. Y. L. E. & W. R. R., Cohecton, N. Y.; W. W. Barnett, Ass't Surgeon, N. Y. C. & St. L. R. R., Fort Wayne, Ind.; W. R. Blakeslee, Surgeon, N. Y. L. E. & W. R. R., Forest City, Pa.; D. C. Bryant, Oculist, U. P. R. R., Omaha, Neb.; W. L. Buechner, Surgeon, N. Y. L. E. & W. R. R., Youngstown, Ohio; F. H. Caldwell, Chief Surgeon, S. F. & W. R. R., Sanford, Fla.; E. C. Carr, Surgeon, P. C. & St. L. R. R., Coshocton, Ohio; C. K. Cole, Chief Surgeon, Montana Central R. R., Helena, Mont.; J. Homer Coulter, Surgeon, C. B. & Q. R. R., Chicago, Ill.; C. M. Daniels, Chief Surgeon, W. N. Y. & P. R. R., Buffalo, N. Y.; J. I. Barby, Chief Surgeon A. & M. R. R., Americus, Ga.; N. F. Donaldson, Ass't Surgeon, U. P. R. R., North Platte, Neb.; C. D. Evans, Surgeon, U. P. & B. & M. R. R., Columbus, Neb.; A. E. Evans, Surgeon, B. & O. R. R., Columbus, Ohio; Chas. B. Fry, Surgeon, Big Four R. R., Mattoon, Ill.; W. J. Galbraith, Chief Surgeon, U. P. R. R., Omaha, Neb.; David Gildner, Surgeon, B. & O. R. R., Rockwood, Pa.; R. S. Harnden, Surgeon, Erie R. R., Waverly, N. Y.; Milton Jay, Chief Surgeon, C & E. I. R. R., Chicago, Ill.; T. C. Kennedy, Surgeon, Big Four R. R., Shelbyville, Ind.; Webb J. Kelly, Division Surgeon, Erie R. R., Galion, Ohio; C. B. Kibler, Surgeon, N. Y. P. & O. R. R., Corry, Pa.; L. E. Lemen, Division Surgeon, U. P. R. R., Denver, Col.; H. J. Maynard, Division Surgeon, U. P. D. & G. R. R., Cheyenne, Wyo.; W. H. Meyers, Surgeon, B. & O. R. R., Meyersdale, Pa.; R. D. Mussey, Chief Surgeon, C. H. & D. R. R., Cincinnati, Ohio; J. P. Kirkpatrick, Surgeon, P. C. & St. L. R. R., London, Ohio; John E. Owens, Chief Surgeon, C. & N. W. R. R., Chicago, Ill.; F. H. Peck, Surgeon, N. Y. P. & O. R. R., Clinton, N. Y.; J. K. Perkins, Surgeon, U. P. R. R., Kansas City, Mo.; R. Harvey Reed, Consulting Surgeon, B. & O. R. R., Columbus, Ohio; A. Rhu, Surgeon, Big Four R. R., Marion, Ohio; A. C. Scott, Chief Surgeon, C. & S. F. R. R., Temple, Texas; Howard J. Williams, Surgeon, Central R. R. of Ga., Macon, Ga.; S. G. Worley, Chief Surgeon, J. St. A. & I. R. R., St. Augustine, Fla. Chas. H. Merz, Surgeon, C. S. & H. R. R., Sandusky, Ohio, was present before roll call but was called home by telegram.

The Committee on Permanent Organization, through its chairman, Dr. R. Harvey Reed, made the following report:

REPORT OF THE COMMITTEE ON PERMANENT ORGANIZATION.

"History.—The idea of an association of railway surgeons of some kind or character that should have a limited number of members is not a new one. As early as May, 1892, at Old Point Comfort this subject was discussed by many of the prominent railway surgeons of this country, who recognized the fact that such an organization was in the interest of railway surgery, as well as of the railway surgeon and the company.

"In June, 1893, this same question was again talked of by chief surgeons and others at Omaha, and not a few letters were exchanged, subsequently, between railway surgeons relative to this important move. In December, 1893, an editorial was published in the surgical department of the *Railway Age* in reference to this subject. By this brief résumé, it will be observed that an organization, similar to the one we expect to christen here to-day, is not of recent origin, but, on the contrary, is the result of mature consideration that dates back for years. In Galveston on May 9, 1894, an informal meeting was held by those interested in an organization of this character at the Beach Hotel, of which Dr. C. K. Cole, of Helena, Mont., acted as chairman and Dr. J. M. Dinnen, of Fort Wayne, Ind., acted as secretary. On May 10 a similar meeting was held at the Tremont House, of which the following are the minutes:

"In pursuance of the meeting held in the Beach Hotel on the evening of May 9, the following surgeons met in the parlors of the Tremont House and were called to order by Chairman Cole, of Helena, Mont.:

"Drs. A. D. Bevan, Chief Surgeon, Iowa Central R. R., Chicago, Ill.; W. A. Adams, Chief Surgeon, Ft. W. & D. R. R., Ft. Worth, Tex.; W. H. Elliott, Chief Surgeon, Central R. R. of Ga., Savannah, Ga.; John E. Owens, Chief Surgeon, C. & N. W. R. R., Chicago, Ill.; C. W. P. Brock, Chief Surgeon, C. & O. R. R., Richmond, Va.; N. Y. Leet, Chief Surgeon, D. L. & W. R. R., Scranton, Pa.; Geo. Ross, Chief Surgeon, Southern R. R. Co., Richmond, Va.; W. G. Galbraith, Chief Surgeon, U. P. R. R., Omaha, Neb.; Jas. Carter, Surgeon, U. P. R. R., Carbon, Wyo.; H. J. Williams, Chief Surgeon, Central R. R. of Ga., Macon, Ga.; R. Harvey Reed, Consulting Surgeon, B. & O. R. R., Columbus, Ohio; N. V. B. Newcomer, Surgeon, L. E. & W. R. R., Tipton, Ind.; C. D. Evans, Surgeon, B. & M. R. R., Columbus, Neb.

"In the absence of the Secretary, DR. R. HARVEY REED, of Columbus, Ohio, was requested to act in his place. An informal talk was held in which the surgeons present took part, and freely discussed the question and propriety of organizing a new association, to be named hereafter, to be composed of a limited number of members and to have for its object the advancement and improvement of railway surgery.

"It was unanimously conceded that the railways were very much opposed to transporting such a large number of surgeons and their wives to each annual meeting. It was also believed that an organization of active workers would meet with approval among the managers of the railroads and accomplish better results with less expense.

"It was therefore moved by Dr. C. W. P. Brock, of Richmond, Va., that a committee on permanent organization be appointed consisting of Drs. R. Harvey Reed, Columbus, Ohio, Chairman; Dr. W. H. Elliott, Savannah, Ga., and Dr. C. K. Cole, Helena, Mont.; said committee was authorized to proceed and take up the plans for the new organization and prepare a constitution and by-laws for the same, to be reported at a meeting to be held at a subsequent date.

"It was suggested by Dr. W. H. Elliott, of Savannah, Ga., that we request the National Association to become a delegatory body. This was favored by Dr. Brock and others.

It was believed if this could be done it would not be necessary to organize a new association. After considerable discussion which was participated in by Dr. Owens, of Chicago, Dr. Galbraith, of Omaha, Dr. Ross, of Richmond, Dr. Cole, of Helena and others, a motion was finally made by Dr. Elliott, which prevailed, to appoint a committee of three to bring this matter before the National Association through its newly elected President, Dr. Thorne, of Toledo, Ohio, and get an expression from the Association. The motion was carried unanimously and the following committee appointed: Drs. Geo. Ross, Richmond, Va.; W. H. Elliott, Savannah, Ga., and Dr. N. Y. Leet, Scranton, Pa.

"On motion of Dr. W. J. Galbraith, of Omaha, Neb., the chairman of the Committee on Permanent Organization was authorized to call a meeting on or before Nov. 1, 1894, at a place to be hereafter selected for the purpose of perfecting the organization. He was also instructed to take such steps, in the meantime, as would be deemed proper and wise and which would be of assistance in enabling the committee and the charter members to secure the best organization possible.

"On motion, the meeting adjourned to re-assemble at the call of the Chairman of the Committee on Permanent Organization.

"C. K. COLE, M.D., Chairman of meeting.
"R. HARVEY REED, M.D., Secretary."

It is a matter of record that the question of resolving the National Association of Railway Surgeons into a delegatory body was duly brought before the members of the National Association by its President, Dr. S. S. Thorne, in a strong speech favoring the same, which was duly opposed by Drs. Willis P. King and W. B. Outten and the motion to make such a change defeated.

With the instructions given your committee, its members felt that their duty to the railway companies and the members on permanent organization was to proceed to carry out the instructions given them at the meeting held in the Tremont House, which they proceeded to do in the following manner:

1. The members of the committee proceeded at once to interview the presidents and managers of quite a number of the leading railroad companies, in person, in order that they might obtain from them their candid opinion relative to such an organization which should be their guide as to the propriety of attempting to complete the organization. An interview of these officials soon convinced them of the fact that an organization of this character would meet with their hearty approval and support.

Whereupon the following circular was issued, accompanied by a suitable blank, whereby those surgeons favorable to such an organization and who desired to enter it could signify the same in writing which was returned to the chairman of your committee, who has on file in the archives of this proposed Academy ninety-one formal applications and seven informal written applications, making a total of ninety eight applications from all sources, from which must be deducted six who requested to withdraw their names as charter members, leaving a balance of eighty-five formal applications and seven informal applications or a net total of ninety-two.

AMERICAN ACADEMY OF RAILWAY SURGEONS.

Office of Chairman of the Committee on the Permanent Organization.

COLUMBUS, OHIO, Sept. 10, 1894.

MY DEAR DOCTOR:—In pursuance of the instructions given at the meeting held at the Tremont House, Galveston, Texas, the committee on permanent organization begs leave to submit the following synoptical report:

After diligent investigation, both by letter and personal interviews, of a great many of the leading active railway surgeons, and eminent contributors to the literature of railway surgery in this country and the Dominion of Canada, the committee has received, practically, universal encouragement, favoring the organization of an American Academy of Railway Surgery which shall have in view, among

other laudable objects, the elevation and improvement of the science of railway surgery and the study of allied medico-legal questions.

The committee is pleased to inform you that they have presented the subject, pertaining to the organization of an Academy, which shall have for its object, "the higher order of railway surgery," with a limited number of permanent members, who shall be "worthy and well qualified" for membership in this proposed organization, to a large number of railway officials, and so far have only met with the most cordial encouragement.

Having received such enthusiastic encouragement from each of these sources, we have decided to call a meeting of the charter members, in Chicago, at a date to be fixed hereafter, during the latter part of October, for the purpose of effecting a permanent organization.

In addition to the executive sessions, the committee has arranged an excellent program of scientific work, which will be announced later.

With this brief preliminary explanation, the committee will be pleased to have you signify your desire of becoming a charter member by signing the inclosed blank and returning the same to the chairman of the committee, at your earliest convenience, and thus facilitate the work of completing the arrangements for the coming meeting.

Very respectfully submitted,

R. HARVEY REED, M.D., Chairman, Columbus, Ohio.
W. H. ELLIOTT, M.D., Savannah, Ga.
C. K. COLE, M.D., Helena, Mont.

Committee on Permanent Organization.

In no instance has your committee persuaded any surgeon to enter the proposed Academy. Its members adopted the policy of laying the proposed plan of organization and its objects before those railway surgeons who, in their judgment, would make desirable members of such an organization and allow them to judge for themselves of the merits of the same.

The committee recognized the fact that there are many railway surgeons in the United States, Canada and Mexico who would make desirable members of the Academy in addition to those invited and, whom we trust, will at no far distant day be recommended to fellowship in the same.

2. Having received such unquestionable encouragement from so many leading railway surgeons throughout the United States, the Dominion of Canada, and the Republic of Mexico, your committee decided to present the matter to the management of the leading railroads of this country in a formal circular letter, of which the following is a copy, and from which it received a great many replies, all of which were favorable to the proposed organization:

COLUMBUS, OHIO, Sept. 27, 1894.

DEAR SIR:—Realizing the great burden which, for years has been imposed upon the railway companies of this continent, by the yearly transportation of thousands of surgeons for the purpose of attending their annual meeting, it has become evident to many of the leading railway surgeons that it is in the interest of their respective companies to organize an association, with a limited number of representative members, consisting only of active and experienced railway surgeons.

The committee appointed for the consideration of this very important question would be pleased to have you give your views and advice regarding the proposed organization.

If, after a careful and candid consideration of the subject it is deemed advisable, and in the interest of the railway companies of this continent, to put into operation such an organization, with a limited number of members, that shall have for its object the scientific study of the many perplexing problems that are constantly arising in railway surgery, will your company be willing to encourage such an organization in this work, by granting a limited amount of transportation, in the usual manner, for the purpose of enabling its members to attend their annual meetings?

As arrangements are being made to hold a meeting in Chicago at an early date for the purpose of taking final action on this matter, we will consider it a great favor to receive an early and frank reply from you in regard to this organization.

Very respectfully submitted,

R. HARVEY REED, M.D., Chairman,
Consulting Surgeon B. & O. R. R., Columbus, Ohio.
W. H. ELLIOTT, M.D.,

Chief Surgeon Cent. R. R., of Ga., Savannah, Ga.
C. K. COLE, M.D.,
Chief Surgeon Montana Central R. R., Helena, Mont.

THE
Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE. \$5.00

SINGLE COPIES. 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, DECEMBER 22, 1894.

SOME CHRISTMAS REFLECTIONS.

"Without the door let sorrow lie;
As if for cold it hap to die,
We'll bury't in a ChrI-stmas pie
And evermore be merry."

In this season when "the Christmas bells, from hill to hill answer each other in the mist," the festival of the Nativity appeals to all alike.

The ancient pagans, and as well the old Germanic tribes, celebrated the winter solstice, and the return of the fiery sun wheel, long before the Christians adopted the 25th of December as the date of their great celebration, and thus for ages, festal usage has set apart this time for good fellowship and jollity.

Physicians are so accustomed in their daily life to perform acts of charity, that the profession, as a whole, may be said to live in perpetual Christmas time, and in many lives the singing of the Yule log fire is constant. The doctor on his rounds of mercy, sees the holly buds and the Christmas wreaths in the windows of the wealthy, and that the abodes of the wretched are made more tidy, in harmony with the softer spirit that pervades the multitude.

He often wonders if patients are not more tractable and their ills less grievous at this season than any other, when even death seems robbed of its terrors as it approaches its victim, whose otherwise happy surroundings have quieted his mind and tranquilized his feeble frame. Even those doomed to support through life a deformed body, or crippled limb, seem to have forgotten their suffering, amid the general generosity and gladness.

The beautiful story of VOLKMAN's about the folded angel's wings which lie hidden beneath the unsightly hump of the hunchback, have lightened the sorrows of many a little sufferer, and made his burden easier, and noting the effect on the patients of the soothing

influence of such stories and of the Christmas tide, every physician must wish that it were always Christmas with his patients. With this object lesson before his eyes, that doctor would indeed be a strange being, if his voice did not grow more gentle, his hand more delicate in its touch, his sympathy more deep, his pity for suffering more profound, and his humanitarianism more tender, and in this holiday season looking at the profession itself, again the lover of his art and its personnel would say: "Would that it were always Christmas with our profession."

THE ANTITOXIN PRODUCTION.

Already there have been put on the market one or more fraudulent antitoxins for diphtheria. The German preparations that have found their way to this country, a few small packages, here and there, are the only ones that are known to be reliable and guaranteed. Inasmuch as the time necessary to grow the first crop of antitoxin can not, under the methods generally adopted, be less than six months, it will readily be seen that some of the rapidly matured plants must be throwing off an immature and worthless article. After a little while there will be an increased number of producers, and there will be an improvement of methods—there is one such improvement already in use in this country, namely the use of oxygen as a means of "forcing" the cultures—and there will be an abundance of good and relatively cheap product. Two boards of health, those of New York City and Brooklyn, have taken up the work of producing the antitoxin, but their stocks can not become available to the public for four or five months.

DRS. PRUDDEN and BIGGS, of the New York City Board, have already pointed out the necessity of great care in the housing of the animals that are used, and of experienced bacteriologists to conduct the experiments. They themselves are giving no small portion of their attention to conducting the test experiments by which the merits of the various preparations now offered for sale must be determined.

SANITARY SCIENCE VS. MEDICAL PRACTICE.

From time to time the JOURNAL has essayed to give expression to a fact which forces itself with constantly increasing pressure upon the attention of every medical man—to-wit, that the struggle for medical existence is, year by year, growing sharper and more strenuous; and to a thought born of that fact—to-wit, that the rapid development and practical results of preventive medicine, due entirely to the volunteer and gratuitous efforts of the medical profession itself, may be a potent cause of this increasing strenuousness, by warding off disease which, otherwise, the doctor would be called upon to treat to the benefit of his professional income.¹ We have

taken as cheerful a view of the situation as "Mark Tapley" himself could have done, and have suggested one method by which the public, kept well by improved sanitary conditions and the efforts of preventive medicine, may be made to pay in part for the benefits it receives. But we recall the first aphorism of HIPPOCRATES—*Ars longa, vita brevis est*—and are forced to admit that a good many of us will die off long before the adequately paid D.P.H. will be numerous enough to relieve our overcrowded ranks.

Our medical "kin beyond the sea" are confronted with the same condition, and it has given rise to some interesting correspondence recently. One writer speculates as to what would be ABERNETHY'S reflections if he could see the crowded theater of one of the medical schools of the period, filled with young men "beginning the study of the profession whose ranks are already so overstocked," and proceeds to moralize in a strain which the *Lancet* characterizes as "an argument against all medical science which aims at preventing disease, inasmuch as disease is the *raison d'etre* of the medical profession." The logic of our contemporary is not clear and the foundation for the charge can only be surmised, since the text of the letter is suppressed on the ground that it is "too long for insertion;" but in a rejoinder to the editorial comment, the writer, MR. M. H. FEENY, insists that he has been misconstrued—that he had merely "maintained that the advance in sanitary science and that in machinery were alike in their results;" each had reduced the number of men who could be furnished profitable employment. And this does not imply that either the advance in sanitary science or that in machinery is not a social and scientific blessing; "it merely goes to explain a fact—namely, the 'unemployed.'"

A more optimistic view of the situation is that taken by "Pepsin," who reviews MR. FEENY in a late number of the same periodical, and affects to believe that sanitary science, while shielding the public from such scourges as cholera and other epidemics, "provides us, by so doing, with an ever-increasing number of ill-developed and delicate patients who would otherwise be swept out of existence. In short, does it not promote the survival of the 'unfit,' the charge of whom largely develops upon us, whose care and skill are so constantly in requisition, and are the means so often of enabling them to reach the adult age, and in many cases their three-score years and ten, at the same time with much less risk to ourselves?" The gentleman begs the question. Where medical "care and skill are so constantly in requisition" there is nothing of which to complain.

"Pepsin's" digestion is evidently of the most eupeptic character; no one whose stomach was not in good working order and fully supplied with the

best of material upon which to work, could take so roseate a view of the situation.

COLONY FOR EPILEPTICS IN ILLINOIS.

At the last session of the Illinois State Medical Society, a resolution referring to the establishment of a State epileptic colony or institution was introduced and referred to the Committee on Legislation, with instructions to take such action as might lead to the introduction of a measure at the coming session of the Legislature for the founding of such an establishment. The committee has already had a meeting, and the preliminaries for the proposed legislation have been instituted.

At the present time a considerable number of epileptics are provided for in our State asylums, but these are largely those who by their acts and tendencies have shown themselves dangerous to society by reason of the mental aberration induced by their disease. They require restraint and absolute separation from society, and in the insane hospital are often considered the most troublesome and difficult of all the inmates. An epileptic colony of the kind proposed, on the plan of the successful establishment at Bielefeld, in Westphalia, and others in France, Germany, Switzerland and Sweden, could hardly care for such, without special provisions that would approximate it to an asylum in many of its more important and conspicuous features. This, it is presumed, is not the idea of those active in this movement in Illinois. The plan is rather to make a refuge for those who are simply incapacitated by their disorder from properly helping themselves, to put them under conditions most favorable to their moral and physical welfare, and, so far as possible, to prevent their becoming a burden to society, by enabling them to work for their own support. There is no reason why, with the class referred to, this last desideratum should not be largely attained; epileptics are not less industrious than other individuals, and when relieved from the necessity of active competition with those not similarly disabled, and under sympathetic and judicious direction, there is no reason why they should not be to a large extent, at least, self-supporting.

It would take time to completely organize the institution and secure the plant required for this purpose, and some aid might be obtained by requiring some payment for board and care from those who, while availing themselves of the advantages of the institution, were able to contribute, but this would not be considered an essential feature of the plan. It is in every way desirable, however, that the self-respect of the beneficiaries should be promoted, and this can be done by making the establishment, as far as practicable, different from an almshouse, by encouraging them to feel that they are doing some good

¹ Vide "A New Field for the Medical College;" "Activity among Health Authorities," etc.

and may become of some use to society, even under their peculiar disadvantages. The functions of such an institution should be partly those of a hospital and partly those of an industrial establishment, and the latter would with this particular class largely include the former. The training of juvenile epileptics would also come within its scope and form an important portion of its work. Whether or not it could relieve the insane asylums of the insane epileptics, often less dangerous under proper management than they are supposed to be, is a question that time and experience will have to solve; at present it may not seem advisable to include this among the objects of the institution. At Bielefeld this class is also provided for, to a certain extent at least, and this may have been necessitated by the conditions.

There are several important questions to be considered in connection with the plan, such as the conditions of admission and discharge, the legal status of inmates, the relations of the sexes, etc., etc., but none that should stand in the way of the successful inauguration of the project, or that ought to be considered as difficult or insolvable. The State of Illinois, the third in the Union in population, has a duty in this regard and should not be behind any of its sister commonwealths. It has the unfortunates to be cared for and the advantage of the experience of other communities to enlighten its efforts to provide for them.

It will be understood that only a certain proportion of the whole number of epileptics are in actual and pressing need of the benefits of such an institution. In Illinois, however, with its 4,000,000 of inhabitants, there will be no difficulty in finding a sufficient number for whom such an institution is a necessity; who without such a refuge are daily becoming vagabonds, paupers and even criminals. Epileptics, with their irritable weakness from their disease, often need moral control, and while in no way a reformatory, the establishment will have a useful function in preventing some of these unfortunates from being or becoming bad citizens.

It is to be hoped that every proper consideration will be brought before the Legislature in favor of this project, and that the incorporating act will be so drawn as to insure its usefulness in every possible way. The Craig colony at Mt. Morris, New York, affords a good example of a plan which might well be followed in the proposed Illinois colony.

THE ASSOCIATION LIBRARY.

Seventy-four boxes of books were this week received in Chicago, by the NEWBERRY Library from the Smithsonian Institution, where the volumes have been stored for several years. There has never been any catalogue of these books, and the exact nature is to-day somewhat conjectural. Under the terms of a docu-

ment which by euphemism is called a deposit or loan, but a document which is in reality a deed of gift, the Library trustees agree to bind and catalogue these waifs at the earliest possible date. One thing is definitely known about this collection, and that is that it is rich in the possession of very many volumes of transactions of various foreign scientific societies, which are contained in few other collections.

With this Christmas addition from our ASSOCIATION, and the donation of the SENN collection last year, the NEWBERRY LIBRARY MEDICAL DEPARTMENT takes rank with the best medical libraries in the United States.

THE JOURNAL IS NOW COPYRIGHTED.

At the last meeting of the Committee on Management of the Board of Trustees, PRESIDENT GARCELON presiding, a resolution was passed directing the Editor hereafter to have the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION copyrighted each week. The Trustees directed that all journals should have full and complete permission to reprint any article appearing in the JOURNAL, or part thereof, provided due credit is given to this journal when the article or item is reproduced.

CORRESPONDENCE.

Electrocuted Horse—Post-Mortem Examination.

PANA, ILL., Dec. 14, 1894.

To the Editor:—I send you herewith some printed notes of the *post-mortem* appearance of a horse killed by electricity. As the subject of whether or not a man can be killed by electricity is agitating the public mind through the press at present, I thought perhaps this incident might be of general interest.

In looking up the literature of the subject, I find scarcely any mention made of the *post-mortem* appearance of a body killed by electricity. In the *Annual of the Universal Medical Sciences* for 1891, Vol. v., Section C, page 30, Dr. Rockwell says: "The reported autopsies on patients killed by currents of high potentials are few. In such the blood is usually fluid; the viscera are congested; small hemorrhages are frequent. Peterson thinks there are no pathognomonic signs of death by electricity, but that it divides and disarranges the fine molecular structure of the body." Hence, as confirmatory of the above statement, I send you this. To make the matter more intelligible, I also send a newspaper account of how it all happened:

POST-MORTEM APPEARANCE OF A HORSE KILLED BY ELECTRICITY.

The following is an account of the condition of the two horses belonging to D. M. Pence, that were electrocuted near the Union depot, as found by Dr. Conner, who held a *post-mortem* examination:

"I arrived on the site of the accident in a very few minutes after it occurred. The animals were perfectly limber in all joints. There was not the slightest tremor in a solitary muscle. Their eyes were glazed. It was a wet, foggy morning about 8:30 A. M. The bodies were steaming hot from their recent drive. In about six hours after the electrocution the carcasses were put upon a dray and hauled over a mile and dumped.

"The left shoulder was removed and three ribs sawed across thereby entering the thorax. The first thing to attract attention was the fluid state of the blood and the fullness of the blood vessels. All the peripheral blood vessels, arterioles and veinlets were filled with dark blood. The blood was very dark and without its characteristic odor. The lungs were peculiar. The larger bronchial tubes were slightly filled with a pinkish froth. The lung substance was congested with black blood which made it resemble liver in its gross appearance; only a small portion of the border of the lungs had anything like the natural appearance of lung tissue. The lungs had the appearance of the *post-mortem* conditions of a late, or at least the second stage of pneumonia, "hepatization." A piece of a lung was cut off and dropped into water and readily sank.

"The heart was soft in texture, but neither dilated or contracted. There were no clots in or about it nor in any of the larger blood vessels. I was surprised at the size of the heart, for it was fully as large as that of an ox which would weigh sixteen or eighteen hundred pounds. Neither the brain or spinal cord were examined.

"Conclusions: From the above I should say:

- "1. That the horses were killed instantaneously.
- "2. That when a man is thoroughly electrocuted he is beyond any human power to resuscitate him. Just the same as he would be if he had been killed by lightning.
- "3. That a person may be only stunned by electricity the same as by lightning, and that if proper means are resorted to early enough there are great hopes of reviving him.
- "4. That it is our bounden duty to make every legitimate effort to resuscitate, or better, revive a person stunned or partially killed by electricity or lightning, for we may never be certain as to whether a person is dead or only stunned when so struck.

"I desire hereby to thank Dr. Trinder, veterinary surgeon of this city, for his kindness in assisting me so well in the above operation."—(From the *Pana Palladium*, Dec. 6, 1894.)
J. J. CONNER, M.D.

City Hospital in Wheeling.

WHEELING, W. VA., Dec. 14, 1894.

To the Editor:—For many years, Wheeling had but one hospital, the Wheeling Hospital, which is owned and controlled by the Catholic church. It has never had a regular medical and surgical staff, nor any special provision for charity cases, although at times such cases are received, especially in emergencies. For many years the late Dr. John Frissell did most of the work, both medical and surgical at this institution, of which he was really the founder. His son, Dr. C. M. Frissell, and Dr. G. Ackermann, are his successors, although any physician may attend his own private cases there. About three years ago another hospital was opened under Protestant auspices, in the hope of providing still more liberally for the treatment of the sick poor. A large building formerly used as a female seminary was purchased, and with some changes was made to serve admirably its new purpose. It stands on an acre of ground, on a high plateau away from the noise of the busy streets. The halls are large, and the wards and private rooms well lighted and ventilated, and neatly furnished. The building contains more than fifty rooms and can accommodate over a hundred patients.

This institution, although named the City Hospital, is in no way connected with the city government and receives no aid from it. It has no endowment, but depends for its support upon the receipts from pay patients and the contributions of the benevolent. The board of directors is composed of twelve prominent business men. This board is ably assisted by the Woman's Hospital Association, of which Mrs. W. F. Butler, daughter of the late Dr. W. J. Bates, is the efficient President. The hospital is superintended by Mrs. Johnson, formerly matron of the West Penn. Hospital, Pittsburgh. A training school for nurses has been established in the institution, lectures being delivered systematically and practical instruction given as well, by the members of the medical and surgical staff, which was originally constituted as follows:

Physicians: Drs. S. L. Jepson, E. Hoge, H. B. Baguley, R. M. Baird, R. H. Bullard, Eugene Hildreth. Surgeons: L. D. Wilson, J. L. Dickey, E. C. Myers, A. F. Stifel, R. J. Reed, J. Schwinn.

Of the above, Dr. Hoge resigned and was succeeded by Dr. W. E. Stathers, and Dr. Stifel, deceased, by Dr. F. J. L. Hipp.

What other city the size of Wheeling can boast of nine externes among its staff? We have also two private hospitals and a third in course of construction. There is no demand for so many, and as the City Hospital is unselfishly organized and conducted solely for the public good, it should be liberally supported.

If this should meet the eye of any former citizen of West Virginia, who has met with abundant prosperity in the great West, and feels like testifying to his appreciation of his early home, he can not do so in a better way than by extending aid to our young and very needy City Hospital.

S. L. JEPSON, M.D.

Treatment of Typhoid Fever.

HASELTON, OHIO, Dec. 17, 1894.

To the Editor:—In reply to Dr. A. S. Caldwell, of Freeport, Ill., who has published a letter in the *JOURNAL* of December 15, in which he says Dr. Woodbridge's treatment of typhoid fever has failed in his hands to show the marked change in the temperature curve, which Dr. Woodbridge's charts show in his own practice, I wish to say I have had some experience with Dr. Woodbridge's treatment, and having followed cases with him, I can say the treatment will do all that Dr. Woodbridge claims for it, if it is intelligently carried out. If the treatment is harmful in Dr. Caldwell's opinion, will he please state which he considers the most dangerous; the gr. one-sixth calomel, the gr. one-sixtieth podophyllin, or the non-toxic eucalyptol or guaiacol.

I have treated, and seen Dr. Woodbridge treat, the most severe cases of typhoid fever with better results than I have ever known him to claim. The treatment far exceeds in value any other treatment I have ever seen published or heard advised.

Truly yours,

J. O. YOST, M.D.

A Rabid Dog Bites Seventeen Persons.

MOUNT VERNON, OHIO, Dec. 15, 1894.

To the Editor:—We have had an experience here for a few days past with what was supposed to be a rabid dog and the victims of his work (eleven in number) are now at a Pasteur institute in your city, conducted by Dr. Lagorio (if I remember rightly). The so-called rabid dog was sent after the killing to Dr. Probst, Secretary of the State Board of Health, and a presumptuous diagnosis of rabies was made, and also inoculations have been instituted upon some guinea pigs and rabbits, for the purpose of making a conclusive diagnosis. The dog attacked seventeen persons (from about 6 P.M., to 10 P.M., when he was finally killed); eleven of whom had the flesh broken to a greater or less degree. The scare here has not abated and the destruction of canines is progressing steadily. Feeling that the subject is one of general interest, I am prompted to call attention to these cases so that you may, if possible, give us some special information in our *JOURNAL*.

Respectfully and fraternally,

BALDWIN B. SCOTT, M.D.

Cleft Uvula—(Case of Dr. Foster).

LOS ANGELES, CAL., Dec. 13, 1894.

To the Editor:—The *JOURNAL* of December 8 contains the report of an interesting case of cleft uvula, by Dr. Hal Foster, of Kansas City. I say, cleft uvula, because it is a case of cleft uvula rather than double uvula. I have a similar, if not identical case, in a boy of 12 years, a native Cal-

ifornian. There is nothing in his voice to indicate the anomaly, neither is there any interference with deglutition.

I can not believe the cleft in Dr. Foster's case has anything in particular to do with phonation, as the "fine" voice of his patient is in contrast with a rather coarse voice in my patient. The cleft is also complete in my case and does not involve other tissues or organs. The two rather long appendages frequently adhere but oftener separate and are carried outward and upward, until they are applied to the lower border of the soft palate on either side. Excision, or amputation of both appendages in each case will probably be best on account of titillation.

It has been suggested that the vermiform appendix was made for the benefit of the doctors, and the same may be said (with our existing knowledge of its office) of the uvula, though I can not quite agree with many in the complete ablation of the uvula for slight causes or elongation. Remove the elongated portion and if it elongates operate as often as indicated. While cleft palate is quite common, complete cleft of the uvula is comparatively rare,

Very truly yours

J. H. DAVISSON, M.D.

PUBLIC HEALTH.

Decreasing Death Rate of Stockholm.—Dr. Klas Linroth, of Stockholm, has recently published some interesting demographic tables of that city, the most remarkable of which is that showing the following diminution of mortality during the last thirty-four years:

| Years. | Deaths. | Population. | Deaths per 1,000. |
|--------|---------|-------------|-------------------|
| 1860 | 3,390 | 112,391 | 30.16 |
| 1870 | 4,037 | 135,598 | 30.22 |
| 1880 | 4,697 | 162,436 | 28.79 |
| 1890 | 4,699 | 228,218 | 20.60 |
| 1893 | 4,840 | 249,246 | 19.42 |

Incredible Mortality Rate of "Croup."—St. Louis is not the only American city in which vital statistics are made a farce by the carelessness, indifference, or worse, of physicians in certifying to the causes of death. But just now the Health Commissioner, Dr. George Homan, is reported to be indignant over what is styled "the persistent efforts of doctors to conceal the true cause of death when it is diphtheria." Added to this is a laxity in notifying the Department of existing cases of the disease. This is common in all large cities, and will probably remain so until there is some common-sense, equitable provision for securing the notification of contagious diseases. How farcical vital statistics, based upon the present system of returns, may be made, is shown by some of the tables in Dr. Homan's last report—that for the year ended March 31, 1894. Thus, in "Table 1. Record of Communicable Diseases," the total number of cases of diphtheria reported to the Department is 509; total number of deaths, 198—giving a mortality rate of 38.9 per cent. In the adjoining columns are given the total number of cases of "croup" reported—216, with 133 deaths, a mortality rate of 61.5 per cent! Dr. Homan wisely omits to state the mortality rates of these diseases, but gives the naked figures and leaves the reader to draw his own conclusions, which, certainly, can not be flattering to the diagnostic ability of the profession except at the expense of its therapeutic skill.

Shall Membranous Croup be made Reportable to Boards of Health?—The New York City Board of Health has for some months past required the reporting of cases of true croup. Dr. Emery the Commissioner of Health of Brooklyn, has recently, December 1, issued an order making the same requirement. Before taking this step all the larger medical societies were addressed regarding this subject, and he received from those societies replies sufficiently favorable to make him feel safe in making a regulation, as indicated in the following:

"By virtue of the authority conferred on me by Section 5 of the Sanitary Ordinances of the City of Brooklyn, and in conformity with the unanimous expression of the principal medical organizations of this city, I hereby notify you that true or membranous croup has been added to the list of diseases to be reported to this Department. I take this occasion to call your attention once more to the culture stations established in various parts of the city, and to request that in all cases of diphtheria and croup, you will either make cultures yourself or allow an Inspector of this Department to do so. When bacteriologic examinations of these cultures demonstrate the absence of Klebs-Löffler bacilli, school permits will be issued previous to the expiration of the ordinary period of exclusion. In order to limit as far as possible the spread of diphtheria, it is urgently recommended that the very poor, who can not afford to pay for medical attention and are unable properly to isolate patients, should be advised to take advantage of the desire of this Department to care for all such cases at the Kingston Avenue (or City Contagious Disease) Hospital. Free transportation will be furnished and in the immediate future the antitoxin treatment will be employed. For the latter reason it is important that the cases should reach the hospital at the earliest possible period of the disease."

Sanitary Observations during a Voyage to Arabia.—Dr. Justyn Karlinsky, a government physician of Bosnia and Herzegovina, detailed to visit Arabia, furnishes a summary of his sanitary observations to *Annales d'Hygiene*. A large number of pilgrims from these quasi-Turkish provinces yearly visit Mecca and, consequently, can easily bring back infectious diseases from the extreme Orient—to prevent which the authorities have taken energetic measures. Dr. Karlinsky arrived in Jeddah at the end of June. The city, surrounded by a high wall, has no aqueduct or other water supply save that brought in on camels' backs and stored in small cisterns. The climate is very hot and dangerous to Europeans. Part of the port has become a marsh through seepage from the canal. The pariah dogs are relied upon to act as scavengers, devouring offal, carcasses of animals, etc. The number of pilgrims annually varies between 80,000 and 500,000. According to Dr. Chaffy, the Egyptian delegate, the deaths from cholera during the last invasion were 10,000, which Karlinsky believes below the reality. There was not enough assistance to carry the sick to the hospitals or bury the dead. In one week there were 60,000 pilgrims in Jeddah. Heaps of corpses were left lying on the sand for days before being buried in it. One of the most crying evils was the embarkation, the ship agents speculating on the throng until the Turkish Government was forced to step in and fix the price of passage. The author embarked with fifty-seven others on an old vessel which already had 1,100 pilgrims on board. Before sailing there had been seven deaths and thirty-three more occurred on the voyage, twenty-seven of them due to cholera. The ship's papers were garbled, so that on their arrival at El-Cor, in spite of the yellow flag, synonymous with quarantine and epidemics, these papers mentioned only seven deaths, all due to natural causes. Another defect is the absence of baths; in the ritual ablutions the pilgrims bathe only their faces, hands and feet; during their sojourn in Jeddah they have no occasion to bathe, and the scarcity of water on shipboard renders a complete cleansing impossible. Many of the pilgrims are covered with abscesses, boils and sores. During their stay in quarantine they sleep on the sand, the temperature of which is much lowered at night; hence chills, rheumatism and bronchial catarrh are rife among them. Dr. Karlinsky thinks that the international measures taken to prevent the introduction of cholera into Europe still leave much to be desired.

Demography of Japan.—The following synopsis of a report made by Dr. Nagayo Sensai, Director of the Central Sanitary Bureau at Tokio, to the Minister of the Interior, possesses a timely interest. This report, which is published in full in the *Journal d'Hygiene*, covers the year 1890—the twenty-third year of the Meigi—but has only recently been made public. Under the heading, "Movement of the Population," the following figures are given: Births, 1,145,174

(61,536 less than in 1889), a natality rate of 28.15 per 1,000, or, on the total population of 40,688,000, one birth to 35.53 inhabitants; the natality rate for the decade 1881-1890 was 26.17. Deaths, 821,043, a rate of 20.18 per 1,000; the highest rate, 28.07, was in Osaka Fu, the lowest, 16.35, in Hakodadi; among the causes of death, affections of the digestive tract lead the list, with 193,690 deaths; diseases of the respiratory apparatus rank next, with 137,699 deaths, and infectious and contagious diseases third, with 78,583 deaths.

Physicians, midwives and druggists: The number of physicians in 1890 was 40,215, or a little over 1,000 of population to each physician; of these, 5,593 were authorized to practice upon passing examination, 1,340 upon the diploma of the Imperial University, 1,356 upon the diplomas of local medical schools, 19 upon foreign medical diplomas, and the remainder were engaged in practice before the reform of the laws on the practice of medicine. The number of licensed midwives in 1890 was 828, of whom 218 were licensed during the year; in 1880 there were only 274 midwives and 457 in 1888. There were 2,689 pharmacists in 1890, of whom 142 were graduates of the University, and the remainder had passed the old examinations; there were also 10,390 druggists and 1,201 manufacturers of chemic and pharmaceutical products.

Surveillance of prostitution: The total number of domiciliary visits in 1890 was 1,401,226, as appears from the following table:

| Years. | No. of Places. | Daily Average of Prostitutes. | Number of Visits and Examinations. | | | | Proportion of Diseased and Healthy. Per cent. | |
|--------|----------------|-------------------------------|------------------------------------|----------------|--------------------|--------|---|----------|
| | | | Total Number Visits. | Found Healthy. | Cases of Syphilis. | | Diseased. | Healthy. |
| | | | | | True. | False. | | |
| 1886 | 469 | 21,462 | 1,101,278 | 1,064,271 | 6,254 | 30,748 | 3.36 | 96.64 |
| 1888 | 464 | 32,465 | 1,247,269 | 1,199,767 | 10,857 | 37,145 | 3.81 | 96.19 |
| 1890 | 469 | 31,091 | 1,401,226 | 1,356,526 | 7,769 | 36,931 | 3.19 | 96.81 |

The cases of true syphilis diminished in 1890; the average daily number of prostitutes showed an increase of 1,394 over the year 1889; in two provinces, Wakayama and Okinawa, there were no visits, as no women of this class were found there.

Diphtheria and the Antitoxin.—During the recent Conference of State Boards of Health in Washington, the delegates visited, by invitation, the laboratory of the Marine-Hospital Service where Passed Assistant Surgeon J. J. Kinyoun, U. S. M.-H. S., gave an interesting and instructive *résumé* of the development of the blood-serum therapy of the infectious diseases, with especial reference to the antitoxin treatment of diphtheria. The demonstration was fully illustrated by an exhibit of the appliances in use at the Pasteur Institute in Paris under Professor Roux and a description of the technique there employed in the preparation of the toxin, the immunization of the animal and development in its blood of the antitoxin, and the subsequent clinical application of the remedy, together with the results of his own observations of the treatment of cases in the Paris Hospital for Sick Children. He had been enabled to watch these cases from the time they entered the hospital until their death or recovery; had noted everything that had been done; had maintained a critical attitude and sought sedulously for any flaws in the statistics. At the end of a month of assiduous study, he had arrived at the conclusion that the claims made for the antitoxin treatment of diphtheria were abundantly justified and that "we have in the serum the almost absolute preventive of epidemics of diphtheria"—that "the treatment was past the experimental stage and will in the future be reckoned in value for diphtheria as vaccine is for the prevention of smallpox."

In recounting the origin and development of the discovery of the bactericidal properties of the blood, Surgeon Kinyoun took occasion to refer to the claims of Dr. Nutall to an important share in the honors. Dr. G. H. F. Nutall, now assistant in the Hygienic Institute of Berlin, is an American

to whom the Harvard Medical School awarded the Boylston prize for original research while at the Johns Hopkins University; subsequently, while studying under Professor Flügge at Breslau and Gottingen in 1887-8, he made certain laboratory researches which enabled him to demonstrate that the normal blood of various animals possesses bactericidal properties and he made the results of these researches the subject of a thesis, published, it is said, in 1889.

It is announced that the laboratory of the Marine-Hospital Service is now open to a limited number of duly accredited representatives of State or local boards of health who may wish to familiarize themselves with the subject of the diphtheria antitoxin as demonstrated by Passed Assistant Surgeon Kinyoun.

ASSOCIATION NEWS.

The Baltimore Meeting.—The Committee of Arrangements met on December 14, at the new Hotel Stafford which has been selected by the committee as the headquarters of the Association. In the absence of Dr. Chisolm, Dr. Wm. Osler occupied the chair. The organization was completed by electing Dr. T. A. Ashby, Treasurer of the committee.

The Secretary read the following appointments to subcommittees which had been made by the Acting Chairman:

On Ways and Means, Drs. T. A. Ashby, H. P. C. Wilson, Thos. Opie.

On Places of Meeting, Drs. I. E. Atkinson, J. N. Mackenzie, Jno. G. Jay.

On Entertainment, Drs. Rob't W. Johnson, Henry M. Hurd.

On Registration, Drs. J. Edwin Michael, J. Fussell Martenet.

On Hotel Accommodation, Drs. Wm. A. Moale, M. W. Foster.

On Transportation, Drs. T. S. Latimer, L. McLane Tiffany.

On Reception, Drs. S. C. Chew, W. H. Welch, John Morris, Alan P. Smith.

On Printing, Drs. W. A. B. Sellman, B. Merrill Hopkinson.

Appointments for the Committee on Exhibits have not yet been made. For the present, applications for space can be made to the Secretary at Hotel Stafford, Baltimore. It is requested that all official communications to the committee be made to the Secretary as above. Secretaries of sections are requested to send as early as practicable a copy of the titles of papers to be read before their sections. Preliminary reports from the chairmen of the various subcommittees indicate a widespread interest in the coming meeting on the part of the profession of the city. The Committee on Entertainment expects to be able soon to announce the preparations for entertaining the visiting members of the Association. It is hoped that the various section dinners be given on the evening of the first day of the meeting, in order not to conflict with arrangements for the general entertainments.

GEORGE H. ROHÉ, Secretary.

SOCIETY NEWS.

Peoria (Ill.) Medical Society.—A regular meeting of the Peoria, (Ill.) Medical Society was held December 4.

Appointments.—Dr. H. C. Emerson, of Springfield, Mass., has been appointed assistant physician in the New Hampshire Hospital for the Insane at Concord.

The Eastern Shore Medical Society, Va., met at Eastville, Va., December 7. Dr. E. W. Robertson, of Onancock, Va., presided. The meeting was one of interest and the attendance was large.

The Syracuse Academy of Medicine held its annual meeting for the election of officers December 4, as follows: President, Dr. Alfred Mercer; Vice-Presidents, Drs. John Van Duyn and Ely Vandewarker; Secretary, Dr. T. E. Halstead.

Higher Medical Education.—At a meeting of the Faculty of the Barnes Medical College, held December 3, the following resolution was adopted:

WHEREAS, It is the announced purpose of the Faculty of the Barnes Medical College, to aid in advancing the standard of medical education; therefore be it

Resolved, That the Barnes Medical College declines to recognize the degrees of Ph. G., D. D. S. or V. S., as the equivalent of any part of the requirements for graduation adopted by said College.

Banquet of the College of Physicians and Surgeons.—The Faculty of the College of Physicians and Surgeons, of Chicago, held a banquet at the Grand Pacific Hotel, December 13. Dr. D. A. K. Steele was toast-master in the absence of Dr. J. A. Benson. Dr. Binkley responded to the toast of "The Spring Faculty," and Dr. T. A. Davis to "The West Side Free Dispensary." Dr. Wm. E. Quine, "Our College." In the course of his speech, Dr. Quine made the announcement that the committee appointed by the Trustees of the University of Illinois to investigate and report upon the expediency of having a medical department of the University, had reported in favor of having such a department, and recommended the College of Physicians and Surgeons as that department, provided that institution could be obtained at a reasonable price. It is said that the appropriation to be asked for is \$160,000.

At a joint banquet held at the Union League Club, Dec. 18, the arrangement is said to have been consummated, so far as can be done without legislative enactment.

The Chicago Ophthalmological and Otological Society.—Regular meeting held at Saratoga Hotel, November 13, Dr. Hotz in chair. There were thirty members and visitors in attendance.

The minutes of the last meeting were read and approved. Dr. THOS. FAITH was elected a member.

The Secretary read the applications of Drs. Mary Hollister, Paul Guilford and E. F. Garvin for membership, and the same were referred to the Committee on Membership.

Dr. OAKS showed a case of ulcer of the upper lid. The patient was a boy of 15, who had been struck with a stick in left eye about three months ago. Since that time the eye has been red, but there is no pain or irritation; slight mucopurulent discharge. On everting the upper lid, an ulcer about fifteen millimeters in diameter is seen near the outer canthus. There are no symptoms or history of syphilis. Dr. Starkey suggested it might be syphilis, but Dr. Holmes thought that the absence of any other syphilitic symptoms was against the diagnosis, and suggested tubercle.

Dr. BETTMAN showed a case of pterygium operated upon two weeks ago by "subvoluton" method. He also showed a man of 47 who three months ago could only count fingers in each eye at ten feet. The right lens was triturated and became opaque. It was removed three weeks ago. V. now equals 20-25.

Dr. WILDER showed a case of recurrent iritis with opaque membrane over pupil. Large blood vessels could be seen running over the iris and the membrane was covered with loops of small vessels.

Dr. STARKEY showed an opaque metal cylinder for argand burner. A movable outside cylinder containing different-sized holes fitted over this, and the amount of light could be regulated by moving the outer cylinder.

Dr. MEYER, of Kankakee, read an essay on "Modern Views of the Architecture of the Nervous System," showing many drawings of nerve tissue.

The Society adjourned by limitation.

C. P. PINCKARD, Secretary.

103 State Street.

NECROLOGY.

JOHN W. PINKHAM, M.D., died December 7, at Montclair, New Jersey, at which place had been passed his entire professional life. He was a native of Gardiner, Maine, and a graduate in arts at the Haverford College. He studied medicine at the Bellevue Hospital Medical College, graduating in 1866. He was one of the founders of Mountinside Hospital, opened in 1891, of which he was the sole consulting

physician at the time of his decease. He was a busy practitioner but found time to use his pen, oftentimes his subject being of a sanitary trend; such was his contribution to the "Household Practice of Medicine," and his address in 1884, before the New Jersey Sanitary Association. His subject at that time was the introduction of subsoil drainage of excreta, as a method of sewerage for suburban places. His death took place unexpectedly from cerebral hemorrhage.

EDWARD H. VAN WINKLE, M.D., of New York City, died December 7, nearly 80 years of age. He had been fifty-eight years in the profession.—William A. Morton, M.D., of Liberty, Mo., December 10, aged 72.—O. P. Geer, M.D., of Alloway, N. Y., December 7, aged 84.—Warren A. Knapp, M.D., of Pottstown, Pa., December 8, aged 30.—C. H. Butler, M.D., of Columbus, Ind., December 12, aged 78.

I. BERNARD BRINTON, M.D., died in Philadelphia December 6. He was born in New Hope, Pa., August 16, 1835, and was appointed a surgeon in the regular army at the outbreak of the war, and was Medical Purveyor of the Army of the Potomac under General Meade. He founded the Botanical Club of Philadelphia, and was a member of the Academy of Natural Sciences, of that city.

MISCELLANY.

License Fee for Transients.—By a recent act of the city council of Muscatine, Iowa, transient physicians attempting to practice in that city will be charged a license fee of \$25 per day.

Bacteriology at St. Petersburg.—A professorship of infectious diseases and bacteriology, with an infectious disease clinic attached thereto, is to be established at the Military Medical Academy of St. Petersburg. The clinic will be equivalent to a small hospital, since fifty beds will be put at the command of the professor.

Changes of Address.—Dr. Chas. G. Cannady to 112½ S. Jefferson Street, Roanoke, Va.—Dr. Walter Lindley to 524 South Main Street, Los Angeles, Cal. He has been elected to the chair of gynecology in the Medical College of the University of Southern California.—*American Journal of Insanity.* The office of publication of this journal has been changed from Utica, N. Y., to Chicago, 34 Washington Street.

Intestinal Antiseptic.—Paraform, according to Aronsohn (*Jour. der Pharm. v. Elsass-Loth.*) is a very strong intestinal antiseptic, superior to B-naphthol, iodoform, salol, dermatol and benzonaphthol, and having a marked inhibitory action on the propagation of bacilli. Paraform is a solid, white crystalline polymer, produced by heating formaldehyde in watery solution. One grain is said to be capable of completely sterilizing 200 grammes of urine.

Tuberculosis in a Lioness.—Strauss reports (*Archiv. Med. Exper.*) the necropsy of a lioness, 5 years old, which had been progressively emaciating for seven months. Both lungs were strewn with nodules, apparently fibrous; on section these proved to be small cavities, varying from the size of a pea to that of a large nut; the inner walls of these cavities were very smooth and studded here and there with grayish granulations; these lesions were developed in a surrounding interstitial sclerosis. The lungs presented a type of fibroid phthisis. Bacilli were found on the surfaces of the cavities. The localization in the lungs exclusively proved inoculation by the air passages.

Inter-State Commerce Commission.—The annual report of the Inter-State Commerce Commission has the following in regard to safety appliances on railway equipment: The "Commission calls further attention to the legislative enactment requiring the application of automatic couplers and other appliances on the locomotives and cars of the railways, and gives figures showing to what extent equipment had been fitted with such appliances up to June 30, 1893. It is stated that all new cars ordered by the railways are being supplied with automatic couplers, and a large proportion with air-

brakes. The accidents of the year show little decrease on account of the use of automatic couplers, and such a result is not expected until more uniformity in such appliances has been attained."

The Holy Coat of Argenteuil.—At the request of Monseigneur Goux, Bishop of Versailles, the famous seamless Coat, preserved as a relic in the church of Argenteuil, has been examined by MM. Lafon and Roussel, scientific experts, for the purpose of determining the exact nature of the spots on the garment, which, according to tradition, are the blood of Christ. The experts report, after describing the tests employed, that—"From the portion of the Coat marked with rust-colored spots we obtained: 1, a faint green coloration with tincture of guaiacum and essence of turpentine; 2, the revival of the red globules of blood with the artificial serum; 3, the formation of crystals of hemin or of chlorohydrate of hematin. These indications are sufficient to enable us to affirm that the spots examined are actually due to blood—and to human blood. Judging by the whole of our analysis we presume that this blood is very old."

An American Physician at the Korean Battlefields.—Dr. Wm. J. Hall, with two other Americans, was enabled to visit the battlefield of Pyong-Yang, in Korea. In this fight about twenty-four thousand troops were engaged, and the Chinese loss was very heavy. These Americans were too late for the battle, but rendered services to the wounded in the hospitals. Dr. Hall was also called upon to visit, in consultation with the Japanese surgeons, one of the generals of the Japanese army, who had been wounded. Dr. Hall is 35 years old, and a native of Canada. He was educated at the Queen's University at Toronto, Ontario, after which time he took up his residence in New York City with the design of fitting himself for work as a medical missionary in the far East. He identified himself with the work among the poor, as carried on by the International Medical Mission School, and in the year 1889 took his medical degree at Bellevue Hospital College. He has been in Korea since the winter of 1891, part of the time at Seoul and part at Pyong-Yang, near the place where the battle was recently fought.

Skiascopic Examination of School-Children's Eyes.—Nels and Diederichs (*Leipzig, Archiv. für Angenh.*, xxix, 1) have examined the eyes of 1,875 scholars aged from six to fourteen years. Ametropia was determined by the right image. The average of emmetropia was from 30 to 34 per cent.; of myopia from 18 to 21 per cent.; of astigmatism 12 to 13 and of hypermetropia 13 per cent. The number of myopes progressively increased from the lower to the higher classes; the number of hypermetropes, on the contrary, diminished, and in less considerable proportions; thus, while myopia increased from 15 per cent. to 26, hypermetropia decreased only from 51 to 39 per cent. The number of anisometropes was considerable; of 422 myopes 241 were anisometropic, and in these the right eye showed a marked degree of myopia in 55.1 per cent. of the cases. These figures seem to confirm the opinion of Sulzer, who found that in myopia of unequal degrees in the two eyes the right eye is the most affected, because children habitually turn the head to the right. But if the same inquiry be pursued in hypermetropia it is found that the right eye is the shorter in 51 per cent. Evidently there is no relation here to the inclination of the head.

Deep Well Pollution.—The useful lesson that the mere depth of a well does not necessarily afford evidence of the purity of its water, is furnished in the history of a well near Edinburgh, bored to a depth of 294 feet from the surface. The well was sunk at the site of a spring, 800 feet from a quarry which received the sewage of some twenty-five individuals—the sewage disappearing, as is believed, into fissures in the rock. At a depth of 114 feet the water was found to be

pure, but when the well was subsequently bored to an additional depth of 180 feet it was found to contain organic impurity. This additional boring had pierced an impermeable bed above which the water was pure, but below it the sewage had found its way through rock fissures from the quarry 800 feet distant and 60 feet higher. The source of pollution of the deeper water supply was made clear by bacteriologic examination; the cracks and fissures had allowed the sewage to pass in an almost unaltered condition, so that the bacteria discovered were not materially modified in their morphologic and biologic characters, as would have been the case had the sewage been subjected to the usual processes of filtration and aeration. The case is, also, cited by Dr. Houston, in the *Edinburgh Medical Journal*, as another argument for the necessity of combining the bacteriologic with the chemic examination of suspected water supplies.

New Theory of Seasickness.—The most generally accepted theory of the causation of seasickness is that which attributes it to an influence on the circulation of the cerebral cortex produced by the oscillation of the ship, thus accounting for the gastric symptoms. This will not, however, explain all cases of naupathia. Rubenstein has often observed that symptoms of *mal de mer*—for instance, paleness of the face, and especially of the lips—develop in some persons when the sea is calm and the vessel moves without oscillation. In these cases he concludes that the cause of the malady is the irritation of the retina caused by the solar rays reflected from the water. This irritation, transmitted to the brain, provokes the well-known symptoms. It is, therefore, well not to look at the water. *Mal de mer* is observed also on snow fields, on the sands of the desert and of the seashore. Under these conditions, gray or blue spectacles afford relief. The author (*Rev. Int. Med. et Chir.*) observed a hysterical female who had retinal hyperesthesia and on sunny days experienced scintillations, photophobia, nausea and vomiting. These symptoms were not produced if the back was turned to the sun. This hypothesis explains why the most nervous and hysterical women are most subject to naupathia. Rubenstein calls the attention of ships' surgeons to this observation and concludes with a play of words: "*Die Seekrankheit reducirt sich für manche Fälle auf eine Sehkrankheit.*"

Pathologic Relations between the Teeth and the Eyes.—Led thereto by his observation of a number of patients, with obstinate ocular affections which rapidly disappeared when a coexistent dental affection was treated, Courtaix concludes (*Rev. Int. de Med. et Chir. Prat.*), after a consideration of the anatomic and physiologic relations between the eyes and the teeth, that there exists a genuine pathologic relation between these organs. Some affections of the eye provoke such violent odontalgia as to lead to suspicion of caries, and thus to a useless sacrifice. Dental troubles may, on the other hand, cause varied symptoms in the eyes; among these are caries, alveolo-dental periostitis, alveolar suppuration, inflammation of the maxillary sinus or of the orbital cellular tissue, malposition of the wisdom tooth, foreign bodies in carious cavities, or poorly-fitted prosthetic appliances. Whenever painful or inflammatory conditions of the eye from unknown causes occur and resist usual treatment, when there is suppression or diminution of visual acuity which can not be explained by ophthalmoscopic examination, by changes in intra-ocular tension or by cerebral complications—in all these cases the teeth should be carefully examined and if any lesions are discovered appropriate treatment at once instituted. These ocular symptoms are usually transient and disappear when their cause is removed. In some cases, however, especially if the causes have been too long neglected, grave consequences ensue.

Abandonment of Fort Mackinac, Mich.—Fort Mackinac, one of the recently abandoned military posts, was so isolated that probably few medical officers of the Army will regret being deprived of the possibility of serving a four years' term of duty within its walls. It is true that of late one could reach a railroad station on the mainland at St. Ignace on

ORIGINAL ARTICLES.

EXPLANATION AND DEMONSTRATION OF THE INFILTRATION (SCHLEICH) METHOD OF ANESTHESIA—PRE- LIMINARY PAPER—WITH TEN ILLUSTRATIONS.

Read before the Milwaukee Medical Society, Nov. 27, 1894.

BY H. V. WÜRDEMANN, M.D.

MILWAUKEE, WIS.

[Your attention is invited to a subject which from the humanitarian standpoint is of the greatest importance and of practical value to us as surgeons. Much of the effort of our profession is directed toward the relief or prevention of pain. Distinct advances in our art followed the introduction of the various narcotics, and the science of surgery took a long step forward when the use of sulphuric ether for anesthesia was discovered Sept. 30, 1846, by Dr. Wm. T. G. Morton, of Wellesley, Mass., and chloroform by Sir James Simpson, of Edinburgh, on Nov. 4, 1847; and these names will ever live in our memory.

But the great boon of narcosis is not unalloyed. Thousands have died from the effects of the volatile anesthetics, and every time we administer them we take upon ourselves the responsibility of a human life. Ether kills once in 15,000 administrations; chloroform once in 3,000.¹ In November, 1894, Dr. Karl Koller, a student in Arlt's clinic of Vienna, first demonstrated the practical value of cocaine,² and we hailed with gladness the promises made by subsequent investigators that the hypodermatic injection of this remedy would do away with the administration of ether or chloroform for all external surgery at least. The cases of intoxication and the fatalities attendant upon the hypodermatic injection of this drug have so discredited the method that many of its former advocates have practically given it up. A personal experience of several hundred cases has been unattended by fatalities although it has not been entirely satisfactory. Administered in this manner it is even four times as fatal as chloroform.

The local anesthesia produced by the application of this drug in ophthalmic and nasal surgery has revolutionized these branches and will probably never be superseded by other modes. The freezing methods are applicable to but a limited number of surface operations, and the plastic healing is not always so good as is desirable. The application of ether, ethylchlorid or rhigolene in spray is somewhat painful and their effect is evanescent. Dread of the pain to be inflicted by the surgeon's knife or of the dangers attendant upon general narcosis or cocaine injection keeps many a patient from a necessary operation until absolutely forced to consult a surgeon; as we daily have occasion to observe, he frequently waits so long that a primarily minor affair needs at last a formidable operation.

Within the last year the results of experiments and operations done in Germany have developed the surprising fact that endermatic injections and infiltration of the various tissues of the human body with water alone or with solutions of indifferent substances afford a practical anesthesia. In the early part of this year my friend, Dr. Casey A. Wood, of Chicago, called my attention to a letter he had received from Dr. Cholewa, of Berlin, who was enthusiastic over a new method of anesthesia, and had been personally operated upon by its discoverer, Dr. Schleich, who had then done 521 operations. Shortly afterward Dr. Wood published portions of this letter in the form of an article in the

OF THE AMERICAN MEDICAL ASSOCIATION, May 26, 1894;³ but as the directions therein were not explicit it has apparently not yet been used in this country.

In July, 1894, at the German Congress of Surgeons, Schleich presented the results of his labors (some three thousand operations) which shortly afterward appeared in book form. I ran across this monograph on "Schmerzlose Operationen,"⁴ and with some little diffidence began his line of experiments, the results of which I will detail later. The opportunities afforded me in special practice are not sufficiently great to permit of the corroboration of all his statements as regards general surgical procedures, so I bring the subject before you in the hope that you will try it in your work and further develop the usefulness of the method.

Schleich presents his claims so well that I have concluded to give them in the form of a translation, from parts of his brochure, which I am enabled to afford you by the aid of Dr. Gustave Kautzheim and which I have abridged for the purposes of this article.]

WHAT DO WE UNDERSTAND BY "INFILTRATION" AND
"ARTIFICIAL" EDEMA?

"Liebrieck's experiments in the production of local anesthesia have proven that subcutaneous injections of various substances will produce a loss of conduction of the sensitive nerves after a transient irritation, without allowing us to class them as anesthetics in the sense of producing a regional, purely narcotic and local anesthesia. In spite of the fact that anesthesia could be produced by destruction, colliquation, necrosis, or corrosion of the tissues infiltrated by chemically active substances, the prodromal pain was such that nobody conceived the idea of using this method for practical use in anesthesia. The greater number of these experiments was made subcutaneously on the skin and mucous membranes of animals. The problems to be unriddled were, however, of such a nature that only experiments on man would solve them, although Liebrieck strongly discountenanced such trials by one of his pupils. In fact, one such experiment (with ammonia) was attended by dire effect.

"In order to obtain positive results in the production of physiologic anesthesia, which could only be produced by injection experiments upon man, I (Schleich) tried them upon myself and my assistants. First of all we had to abandon the method (usually followed in cocaine injections—H.V.W.) of obtaining regional anesthesia by formation of a depot in the subcutaneous tissue, and having the effect carried thence outward to the cutis and inward to the deeper tissues. The subcutaneous cellular tissue is of itself not very sensitive and there was the possibility that the drug employed acted as an anesthetic without this action spreading along the nerve trunks. We might have subcutaneous without cutaneous anesthesia. Consequently we chose our own skin for the trials, particularly the very sensitive portion of the left fore-arm. I am greatly indebted to my colleagues for freely granted opportunities to repeat and

NOTE.—The illustrations accompanying this article are reproduced from Schleich's "Schmerzlose Operationen."

verify my results upon their arms. We first tested the sensibility of an endermatic wheal produced by the injection of a few drops of fluid.

"If we inserted a Pravaz needle flatly under the epidermis, so to speak under the papillæ, and pass it intra-cutaneously until the lumen is fully inserted and then inject a few drops, we produce a white, strongly elevated wheal. (See Figs. 1 and 2.)

"This wheal, which can be increased in extent as far as we wish by renewed punctures within the raised area, is the test object for the anesthesia, paresthesia and hyperesthesia which may be produced by the contact of the fluid. By means of these wheals, we are able to measure exactly the alteration of sensibility produced. This manner of testing has the advantage that we are able to transfer the results obtained to all other tissues, as the skin, with its highly developed sensory organs furnishes a field for particularly accurate observations. The results were certainly applicable to other tissues, as the periosteum, fascias, muscles, the mucous and serous membranes.

"Our first attempt was to determine the lower limit of activity of cocain, as it was desirable to be able to dilute the usual 4 per cent. to 5 per cent. solutions without abolishing the anesthetic action. As with solutions of 5 per cent. we would administer the maximum dose in one to five syringes full we would be compelled to exceed the maximum dose and

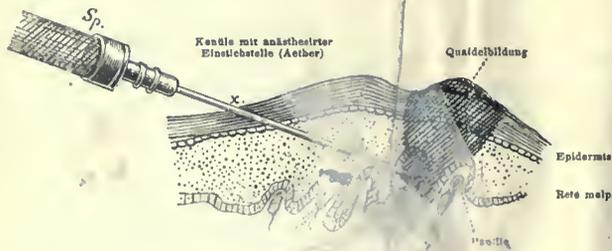

FIG. 1.—Diagram of a section of the skin, showing formation of the first wheal.

thus impress upon the method the objection of great danger, or restrict its use to a small number of trivial operations. The testing of the wheals by the use of cocain solutions below 1 per cent. gave the surprising result that 0.02 per cent. solution produced a complete anesthesia of the infiltrated area without the production of pain during the injection.^{4A}

"Immediately beside the white raised wheal which resembles a mosquito bite, complete sensibility with no reduction of sensation was found; 0.02 cocain to 100 parts aq. dest. is the weakest solution by which we can produce anesthesia without prodromal hyperesthesia. This infinitely small quantity of cocain (0.0002^{4B} to a syringeful, 0.000.001 to a single puncture) suggested the use of distilled water. It was found that this produced quite severe pain during the formation of the wheal, but later caused complete anesthesia throughout the extent of the infiltration. This proved that aq. dest. belonged to the class of *anesthetica dolorosa*, as surmised by Liebrich from experiments on animals. Water causes the same phenomenon not only in animals, as stated by Liebrich, but also in men as we have seen. Practically, this was of no importance, as the pain of injection is so severe that it can hardly be controlled by accessory methods such as the use of the ether spray. (Deep injections of cold water have been used for several years in sci-

atica as a local anesthetic with alleged benefit.—H. V. W.) With the aid of the ether spray, I performed several small operations by this method, but my experiments soon took a different direction.

"We soon found that physiologic salt solution of 0.6 per cent. caused a wheal without changing the sensibility of the skin. *There was no pain during or after the injection but there was no anesthesia.* We surmised that between pure water and 0.6 per cent., NaCl solution we would find a concentration which would admit of painless infiltration and later on account of its resemblance to pure water produce anesthesia. In fact, an 0.2 per cent. solution of salt produces during infiltration but a very trivial feeling of tension, with perhaps a little itching (paresthesia) but after a short time the area of the wheal is anesthetic, as if the solution had contained cocain. This solution is a practical anesthetic, and by its use I excised from the neck of Dr. Bergmann a nævus of the size of a 50-cent piece and united the skin with five stitches without producing the least pain. This solution of 0.2 per cent. salt is the vehicle of all my anesthetic fluids. It is the essential new basis of my method. To my great surprise I found that the lower limit of activity of cocain (0.02 to 100) could be reduced one-half if the salt were dissolved in this solution and in this concentration (0.01 to 100) it was perfectly active. Further trials with stronger salt solutions (over 3 per cent. or 4 per cent., showed that such liquids caused considerable burning and even hyperesthesia in the infiltrated tissues. Even stronger solutions of cocain (4 per cent. to 5 per cent.) will produce burning at first, followed later by anesthesia.

"Thus we find for cocain as for salt, three distinct zones of activity. With salt we find that in a concentration of 0.2 per cent. very slight paresthesia with succeeding anesthesia is produced; a concentration of 0.6 per cent. produces neither paresthesia or anesthesia but in the strength of 3 per cent. or 4 per cent. it produces distinct paresthesia. With cocain we find that a solution containing 0.01 per cent. causes, at first, paresthesia and then anesthesia; one containing from .02 per cent. to 2 per cent. is purely anesthetic, while above this its action resembles that of the *anesthetica dolorosa*. Similar results were obtained with numerous other remedies; thus morphin in the strength of 0.1 per cent. is an excellent pure anesthetic without paresthetic action. This, in spite of the dictum of the text-books that morphin has no local action, a statement which would not have been made if its endermatic action had been tried before. *In fact, the discovery of these truths, so valuable for the questions of local anesthesia, is due simply to a slight change of method, the application of the drug within and not under the skin.* In the strength of 1 to 1000 in water or 0.2 per cent. salt solution, morphin is a very useful anesthetic. Below this strength its action is irritative; in stronger solutions of 3 per cent. to 4 per cent. it causes burning and then anesthesia. Solutions of sugar (3 per cent.); bromid of potassium (8 per cent.); methyl-violet (1 per cent.) and caffeine (2 per cent.) are also pure anesthetics; above and below this strength they have an irritative action on the nerve elements. Carbolic solutions of 0.2 per cent. to 1 per cent. have a purely anesthetic action with the wheals. Two per cent. to 5 per cent. solutions cause smarting. We are convinced that a number of other bodies will be found to have an anesthetic action and possibly future discoveries

^{4A} In this abridged translation I have taken the liberty of italicizing certain important statements.

^{4B} Continental Pravaz syringe.

may have a great influence upon the method. However, the facts already demonstrated have enabled us to develop the method of local anesthesia to a considerable degree and to forever remove the objection of possible danger. With this achievement the method has reached a stage in which it enters into direct rivalry to general narcosis. The use of cocain, morphin, or carbolic acid in such great dilutions that a very large number of syringesful (100, 250, 500) would be required to reach the maximum dose permits us to perform extensive operations without using a dangerous quantity of these drugs. It is incontrovertibly proven that anesthesia can be produced by solutions of cocain of the proportion of 1 to 5 grams in 1 liter of water or of 1 to 5 grams in 10 liters of a two-tenths of 1 per cent. salt solution.

"We must not lose sight of the cardinal fact that the anesthesia exists only within the area infiltrated by these solutions and that outside of that, normal sensation exists. So that our method rests mainly on the principle of a complete artificial edema of the field of operation. The experimental facts teach us that the anesthetic action is not wholly due to the narcotic properties of the drug employed. The physiologic salt solution is too similar to the tissue juices to produce any alteration within the tissues. But a slight change in its concentration is needed to cause its anesthetic action. Even pathologic edema would produce anesthesia if instead of 0.6 per cent. it contained but 0.3 per cent. or 0.2 per cent. of salt. Conversely, by the use of 0.2 per cent. solution of salt I am able to produce an artificial edema which causes anesthesia of the edematous part. The variation of the quantity of salt contained in the liquid is not the only factor.

"Experiments have shown that in this and in all other anesthetics, other factors besides a chemic difference are at work. If the skin and cellular tissue be edematized under considerable pressure the entire area becomes ischemic. Not a drop of blood exudes from the cut surface. This of itself has a tendency to obtund sensibility. Besides this the tissues are under a much greater pressure than normally, by means of which a direct compression of the nervous elements is obtained. In the third place the difference in temperature, if the solution be of the temperature of the room, assists in reducing sensibility. All our dilute solutions lost their anesthetic power wholly or in part, at or above body heat, and showed decidedly increased activity when used cold. (0. degree Cent., or 32 degrees Fah.) To these predisposing and accessory factors the direct chemic alteration of the nerve elements by the narcotic drug is superadded.

"It has been asked why we use the narcotic drugs at all; why the 0.2 per cent. salt solution is not used alone, if it will produce anesthesia as we claim. The salt solution is sufficient for all those cases in which we operate wholly within healthy tissues, although this is but rarely the case in operation. We have always to deal with pathologic changes by which the normal sensibilities are more or less increased. Even if the one-third strength physiologic salt solution will cause anesthesia of normal tissues it will not do so in hyperesthetic areas. The tenderness is occasionally so intense over inflamed tissues that the symptoms evince the presence of mechanical pressure; anemia and difference in temperature will not suffice to abolish the increased nervous function. Here we require the direct coöperation of the narcotic poisons

and for this reason I believe that it will be difficult to use physiologically-indifferent remedies alone. However, as I have proven that cocain, morphin and carbolic acid are active in solutions *which are several hundred times weaker than those in common use*, it is possible to keep the doses necessary for the compensation of hyperesthetic nervous action absolutely below the poisonous limit. The strongest solutions which are used, and then only in the severest cases, contain only 0.2 per cent. cocain and 0.025 per cent. morphin, so that fully thirty syringesful of this absolutely anesthetizing solution is the maximum dose. We will see, however, that (for any operation?) at most ten syringesful of this solution are required (doses of 0.02 and 0.01) and in a manner radically different from their administration in a single dose. We shall further see that hardly one-third of this liquid is absorbed and we will prove by the history of our cases that among three thousand patients operated upon, not one showed the least symptom of intoxication. For the most cases a solution of 0.01 per cent. of cocain or morphin is required and in extremely rare cases as much as one hundred syringesful of this solution might be administered without evil effect. There is always a possibility that we may be able to reduce the dose to one-half or even one-fifth, long before this number is reached. The manner in which this is to be done will be detailed further on.

"The reasons why I combine morphin with cocain in my solutions and why I add a few drops of 5 per cent. carbolic solution to the 0.2 per cent. solution are these: I have found that infiltration of pure cocain solution in inflamed tissues in some cases causes pain before the occurrence of the anesthesia, especially in phlegmonous tissues where there is considerable hyperesthesia of the parts. This circumstance renders the method useless in the few cases in which it might be used if this drawback could be abolished. It must be remarked that this occurred in cases which owing to the size and extent of the operation lay well toward the limit of its availability. This trouble was, to our great surprise, almost entirely obviated by the addition of morphin to the cocain-salt solution.

"In the second place it could not be denied that occasionally the pain occurring after operation in inflamed tissues seemed to be stronger when pure cocain was used than after chloroform. Although a small dose of morphin removed the sequelæ of the operation very promptly, I was for a long time afraid that this circumstance would seriously interfere with the popularity of the method. To my great satisfaction I found that this combination thoroughly removed the objection. In many hundred cases I have found that the pain after operation with the use of the combined cocain-morphin-NaCl anesthetic is decidedly less than that after chloroform. On this account the solution I now use contains 0.025 per cent. morphin.

"The objection to the former methods of local anesthesia, the painfulness of the puncture, is obviated by the use of the ether spray upon the skin. (The ether spray need not be pushed to absolute freezing, as a moderate degree of chilling sufficiently diminishes the sensibility.—H. V. W.) or the application of a drop of carbolic acid or strong cocain solution upon the mucous membranes, and the use of a very fine needle. Then follows infiltration of the tissues; at first of the skin or mucous membrane by the formation of a line of adjoining wheals which

corresponds to the direction of the incision; deeper down everything is infiltrated that we wish to reach by operation. No part is to be operated upon until the artificial edema is complete.

“Only the edematous region is anesthetic. The anesthesia is caused by the anemia, the compression, and the cooling. The pain of the infiltration of indifferent solutions is abolished by the minute doses of narcotic drugs (morphin, cocain and carbolic acid.) Anesthesia occurs at the moment of the completion of the artificial edema. The action need not be waited for. It occurs at once.”

“This method of combined infiltration-anesthesia has great advantages over the old methods of cocain anesthesia. I refer to this particularly, as it has been frequently stated that my method was nothing absolutely new. Even if this be so, it is a matter of indifference whether a method be old or new, so long as it be good, but there is certainly a difference between using a 2 to 5 per cent. solution of a drug or solutions containing from 1 to 5 parts per 1000 and the latter of which show vastly greater eligibility and usefulness. The injection methods in use up to this time were even theoretically dangerous and very limited in application; numerous cases of intoxication discredited them; deaths have been recorded, and on this account the old injection methods could not be substituted for general narcosis, as they share its gravest objection.”

FORMULÆ, ETC.

The formulæ advocated by Dr. Schleich are as follows:

- | | | | |
|----|--|-----|-----------|
| R. | Cocain mur. | 20 | gr. iiij. |
| | Morph. mur. | 025 | gr. ¼. |
| | Natr. chlor. | 20 | gr. iiij. |
| | Aq. dest. ad. | 100 | ʒ iij. |
| M. | Sterilisat. adde. sol. ac. carbol. 5 per cent., gtt. ij. | | |
| S. | Solution No. 1, strong. For operation upon highly inflamed or hyperesthetic areas. | | |
| R. | Cocain mur. | 10 | gr. jss. |
| | Morph. mur. | 025 | gr. ¼. |
| | Natr. chlor. | 20 | gr. iiij. |
| | Aq. dest. ad. | 100 | ʒ iij. |
| M. | Sterilisat. adde. sol. ac. carbol. 5 per cent., gtt. ij. | | |
| S. | Solution No. 2, medium. For most operations. | | |
| R. | Cocain mur. | 01 | gr. 1-6 |
| | Morph. mur. | 005 | gr. 1-12 |
| | Natr. chlor. | 20 | gr. iiij. |
| | Aq. dest. ad. | 100 | ʒ iij. |
| M. | Sterilisat. adde sol. ac. carbol. 5 per cent., gtt. ij. | | |
| S. | Solution No. 3, weak. For superficial operations upon nearly normal tissues. | | |

All are to be kept strictly sterile; scorched cotton stoppers such as are used in bacteriologic experiments for the bottles; small quantities to be poured out in a smaller vessel for each operation. Just before operation the solution should be cooled by laying the bottle containing it on ice, and kept cold during the operation. The syringe should likewise be cooled. The common form of hypodermatic syringe with the finest of needles is all that is usually needed, although Schleich depicts in one place (see Fig. 8) a long curved needle. The former is kept in good order by being frequently soaked in a 5 per cent. carbolic solution, and the needles sterilized after each operation.

TECHNIQUE OF OPERATION UNDER INFILTRATION ANESTHESIA—INCISION OF THE SKIN.

“After thoroughly scrubbing, shaving and otherwise preparing the field of operation, we begin with the induction of anesthesia for the first puncture of the needle. (By use of the very fine needles of American make this preliminary procedure is practically un-

called for, as a fine sharp needle is scarcely felt when introduced even through the whole thickness of the skin of very hyperesthetic persons.—H. V. W.) Upon the skin this is done by means of a spray of ether, ethyl-chlorid (rhigolene, etc.) Upon mucous membranes we must apply a drop of 10 per cent. carbolic solution or cocain. The spray is directed to the point at which we desire to begin the anesthesia (it being, as a general rule, more convenient to proceed in a direction from the operator), until a slight discoloration of the skin appears. The needle is then inserted and pushed in parallel to the surface, until its beveled edge is covered. A slight pressure is then made upon the piston. A white wheal, the beginning cutaneous edema, appears at the puncture of the needle. (See Figs. 1 and 2.) This is increased to the size of a dime by continued pressure on the piston.

“The needle is moved and re-inserted at the periphery of the wheal, but still within it, and a new wheal raised. In this way the line of incision is marked out to any length desired. As soon as the line has reached the required length, we may use the knife, or we may prefer to infiltrate the deeper tissues through the skin. If the operation is to be a short one (not over twenty minutes) we may make the infiltration broad enough to include the line of sutures. In anesthetizing the subcutaneous tissue, I

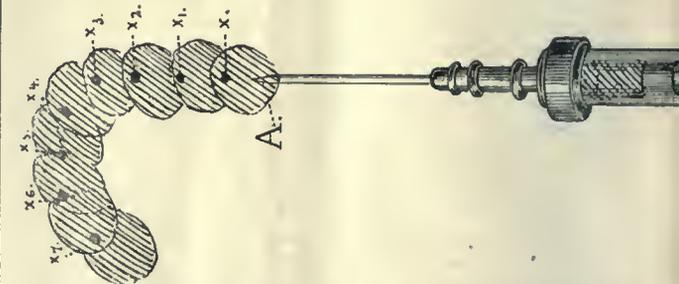

FIG. 2.—Formation of the cutaneous wheals. A. Spot made anesthetic by ether spray for the first injection.

allow a syringe full to three to four centimeters of length, so that the syringe may be at once emptied; even the fasciæ and muscles may be edematized through the skin. The entire field of operation appears as a high, tense, circumscribed edema projecting beyond the level of the skin. Whenever we wish to operate with exact anesthesia, the field of operation must be tensely filled with the solutions, so that it exudes from the cut surface.

INFILTRATION OF THE DEEPER TISSUES.

“Wherever the subcutaneous tissue is loose and easily distensible, infiltration is easy and requires but little pressure; as over the malleoli and condyles, in the scrotum, labia, eyelids, on the backs of the hands; in short, in the regions where pathologic edema first shows itself. Stronger pressure is required where the parts are dense and hard, as in the sole and palm, in cicatricial tissue, the matrix of the nails, and in the hard palate. It is advisable not to anesthetize deeper than into the superficial muscles through the skin, except in cases where the deepest tissue sought for lies superficially, as over bony projections, in the scalp, over the clavicle and sternum. By slowly pushing in the needle until we feel the bone in these cases, we may even anesthetize the periosteum.

“No tissue offers any deviation from the dictum:

Every tissue is anesthetic that can be artificially edematized by our solutions. This holds good for skin and mucous membrane, periosteum, synovial membrane, fascia, muscle, lymph glands, nerves, viscera, and even bone. The latter becomes anesthetic as far as its periosteum is infiltrated because its nerve supply is derived from the periosteum, and because we can infiltrate the medulla by subperiosteal injection. Of this we have been able to convince ourselves many times. The bone whose periosteum has been infiltrated in its whole circumference may be divided by saw or forceps without causing any sensation. Within the area of the periosteal infiltration we may hammer, chisel, break or burn; the patient notices nothing but the noises caused thereby (except vibration? H. V. W.) and if we close his ears, he knows nothing of it. This will be better understood when we find, as we did in every case, that the marrow was infiltrated. As all the nervous elements are surrounded by the anesthetizing fluid, they must be anesthetic. In inflammatory bone diseases (osteomyelitis) it is often advisable to chisel a small hole into the compact layer and through this to infiltrate the marrow.

"If, during the operation, we reach larger nerve trunks, they may be anesthetized for a short time by touching them with 5 per cent. carbolic acid, or by injecting them with the same if we do not care to

included. In longer operations we may form wheals from below the cut edge of the skin, at the places in which we wish to insert the needle. (See Fig. 4b.) For deep sutures the same rule is applicable.

HEMOSTASIS.

"In general, it may be remarked that hemorrhage in fully infiltrated tissues is minimal; bleeding points are caught with forceps and tied as usual. It occasionally happens that nerve twigs accompanying arteries cause pain during the moment of compression. In such cases the spot should be touched with a 5 per cent. carbolic solution before cleansing the forceps. This will usually cause enough superficial anesthesia. If not we will have to produce a circumscribed infiltration in the neighborhood. In operations upon mucous membranes in which the technique is identical with that described, the primary anesthesia is produced by touching the selected

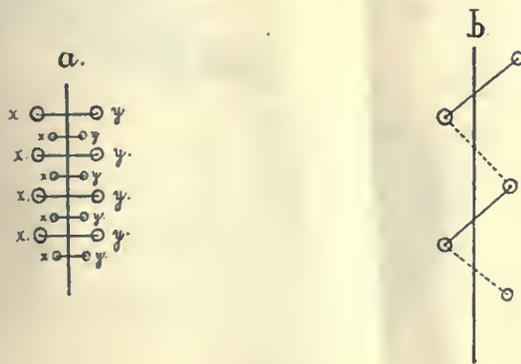

FIG. 3.—Sutures.

infiltrate the surroundings. After incision, in all cases, the incision should be kept open by gentle and steady traction and the infiltration cautiously pushed into the depths of the wound. In amputations the nerve trunks must be anesthetized separately. Operation in non-anesthetic areas is due to personal want of skill or a lack of understanding of the principle of the method which, if properly used, in regions where it can be technically executed can not fail but must lead to an often astoundingly brilliant result. The operator must ever keep in mind that when pain occurs it is a sign of insufficient edematization. It is a personal error to cause a patient pain with this method, wherever infiltration is technically possible.

SUTURES.

"It must be especially noted that the anesthetization of a given point lasts ten to twenty minutes. If during an operation we come to a tissue which was anesthetized more than twenty minutes before, the infiltration must be repeated. In this way we can operate for hours. For instance, new wheals will have to be produced at the point of entrance and exit of the sutures if the operation has lasted more than twenty minutes. (See Fig. 3.)

"For short operations it is advantageous to anesthetize the skin so broadly that the suture line is

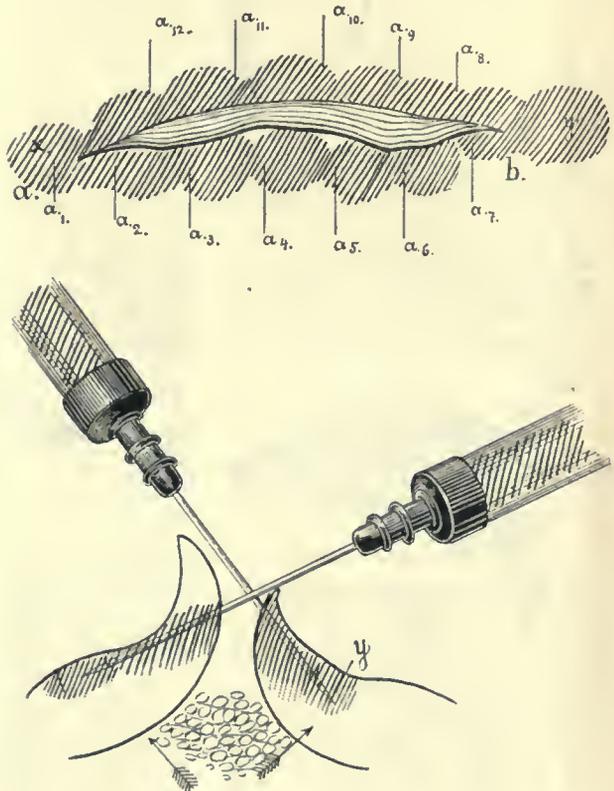

FIG. 4 A. FIG. 4 B. Secondary anesthetization of cut surfaces.

spot with a concentrated solution of carbolic acid or cocain. This is very readily done as it is much easier to insert a fine needle under the epithelium than into the skin. As soon as the first wheal is formed the rest is simple.

INFLAMED PARTS.

"There is, *a priori*, a very great difference between the anesthetization of a part with normal sensation and one with pathologically increased sensibility. In the latter case, the inflammatory hyperesthesia requires some deviation from the general rules of technique given. It is, however, indubitable that even the extreme hyperesthesia of inflammation is abolished by the artificial edema in our methods. As soon as infiltration is complete, pain during operation is excluded. But it is indispensable for the attainment of this object that the infiltration be begun in sound tissues at a distance from the inflamed

focus. (See Fig. 5.) We begin as far from it as practicable (several centimeters) with the ordinary cutaneous anesthesia (ether spray and skin puncture) and then push the needle obliquely through the skin, into the subcutaneous tissue, toward the inflamed focus, injecting slowly a syringeful of solution, being careful to keep the fluid outside of the inflamed area. In this manner, four or more depots of infiltration are placed about the inflamed part and then the cutis may be infiltrated completely around it. (See Fig. 6.)

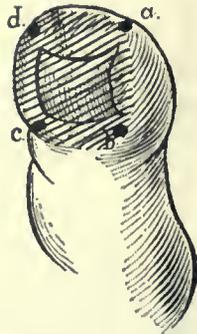

FIG. 5.—Infiltration for ingrowing toe-nail.

The inflamed skin with its dilated blood and lymph channels may be much easier and more widely infiltrated than sound skin. Especially in highly inflamed and swollen skin are we enabled to anesthetize quite a large spot from one puncture, and we may clearly observe the red color recede before the white zone of infiltration. At the same time we find

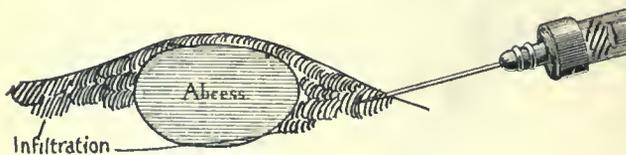

FIG. 6.—Infiltration of abscess.

that the fluid spreads easier in some directions than in others, especially between the spots of infiltration first made. The patient will be able to inform us exactly when the pain is still felt. The injection must be done at first very slowly. When, however, the point has been reached where the infiltration is only felt by its tension, we may rapidly flood the part to the required extent. In this way I usually

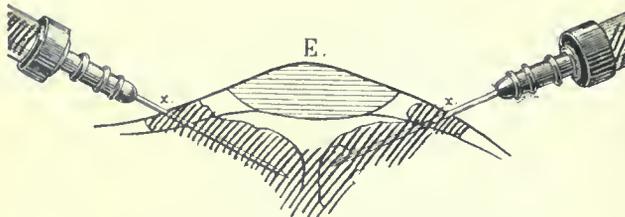

FIG. 7.—Infiltration of inflamed surfaces.

treat furuncles and carbuncles. If incision only is required, matters are much simpler. A straight or crucial line of infiltration is made and the knife used. If desired, the deeper parts can then be anesthetized.

“Under no circumstances must fluid ever be primarily injected into an abscess, an exudation or a pathologic focus. The only result is increased tension, which may be quite painful. Where an ab-

cess (deep?) exists or is suspected, it is better to first anesthetize the skin, incise it, to infiltrate further and make a minute incision to evacuate the pus and after this to complete the infiltration and operation. The most important rule in inflammatory cases is: Never begin the infiltration in an inflamed area or abscess, but surround it and advance upon it from all sides *via* the sound skin. (See Fig. 7.) In these cases we first use Solution 1, and when the infiltration causes no more pain, Solutions 2 and 3.

“In chronically inflamed tissues, especially when sclerosed or cicatrized, Solution 1 is needed, if the formation of neuromata renders the tissues more sensitive. In such tissues considerable pressure is necessary; in one case of mammary scirrhus, I was unable to inject a single drop into the tissue. Here the usefulness of the method reaches its limits, as in all cases where infiltration can not be done anesthesia does not result. These cases are extremely rare, even, compared to the cases in which narcosis is contra-indicated or in which it fails.”

In looking up the literature⁵ of the subject, by reference to the Index Medicus, I can find but the one article by Cholewa before mentioned. It is safe to surmise that this method has not yet been taken

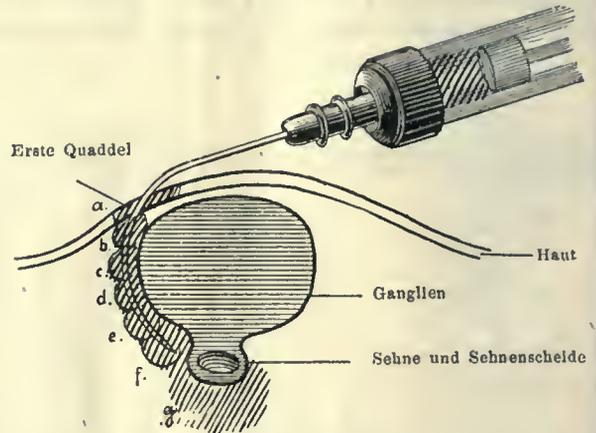

FIG. 8.—Tumors.

up in this country and that we are first in the field of American surgery to present our views in corroboration of his statements.

I began following out Schleich's line of experiments; at first trying his stronger solution (No. 1) and following directions carefully, was surprised to find that the second prick of the needle was not felt and after building the line of wheals along my forearm, I pricked and cut the skin afterward, weaving a suture needle in and out without the slightest sensation. I injected the various fluids into my own flesh many times before trying them on others. The thanks of the author are due to Drs. Barnes, Hitz, Hosmer and others together with some of my patients, for the use of their bodies in proving the anesthetic nature of these fluids.

My first operation was done upon my children's governess who had a deep felon on the index finger of the right hand, in which I made a free incision down to the bone without the slightest pain from the knife after the injection of the solution of medium strength (No. 2). After the anesthetic effect had passed away, the after-pain was less than would be expected and healing was perfect. I next evacuated an

⁵ In the Med. Record, Nov. 24, 1884, there is a brief note, the author of which is apparently not conversant with the subject.

abscess of the lid without pain, removed a papilloma from the inner canthus, opened another abscess of the upper eyelid which was extremely sensitive to palpation, without the patient perceiving the cut of the knife, and feeling the curettement as but a sensation of scratching; opened a painful stye and a number of other minor operations of like nature.

On detailing my experience to Dr. A. J. Burgess he was much interested in the method and desired to have a small growth removed from his own axilla, which Dr. F. E. Walbridge and I did, putting in four stitches without causing our patient a twinge. He then went about his usual work, using the arm freely. This was a sebaceous cyst, about the size of the first joint of a man's thumb. A circumstance which may militate against the method, should it happen in any proportion of cases was that, when the stitches were removed one week afterward, it was found that the wound had not yet healed, although there was no sign of infection. If I remember rightly, healing in the neighborhood of the armpit sometimes goes on very slowly. The demonstration to these surgeons was sufficient to warrant them in trying the procedure in their own practice and, accordingly, the next day Dr. Burgess called me in consultation at the Presbyterian Hospital, over a circumcision in an old man (with cardiac lesion) a former patient of mine. After I made the injections Dr. Burgess proceeded

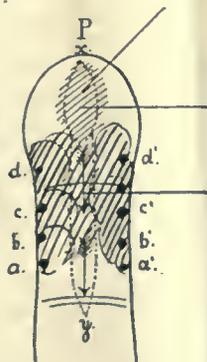

FIG. 9.—Infiltration of foreskin.

with the operation, Dr. Stanton Allen being present. The patient being talkative, was conversing about another subject while Dr. Burgess cut off his foreskin and sewed up the divided edges of mucous membrane and skin. Not the least twinge of pain occurred during the whole operation, which lasted fully twenty minutes. The effect on us was certainly conclusive, and we thought that we should not hesitate to try the method on an amputation or other major operation.

Later, Dr. Burgess excised an epithelioma with local anesthesia by this method from the face of an old lady who had been once before operated upon under cocain-anesthesia and who had refused further operation if it was to be used, as she had suffered from pain during the previous operation. The effect was here favorable and I understood that she remarked, when told that if it recurred, the growth should be removed: "If you don't hurt me any more than you did this time, Doctor, you may come up every day and operate if necessary."

Dr. Burgess did a clamp and Paquelin cauterization operation on a patient of mine, after I had infiltrated the parts with the solution of medium strength. The patient felt the heat on the surrounding parts and

only once during the operation when the third pile was seared away did he complain of any amount of pain. What did occur, I think could have been avoided by first cutting off the piles and then searing the stumps with the cautery instead of burning it all away.

Dr. Thos. Hay removed an epithelioma of the nose of the size of a quarter of a dollar, and put in three stitches after I had injected the No. 2 fluid, in an old man in whom general anesthesia would have been contra-indicated. Dr. K. Morris was present at the operation. When the man was asked in regard to his sensations he remarked during the curetting of the base, "that it felt as if one were scratching on the outside of his old leather boot." Only recently I took a patient of Dr. Thos. Hay, with a crushed toe, the result of a football injury. After injection with Solution No. 2, a knife was passed under the nail to the root and pus evacuated without sensation. I understand that Dr. Shimonek has done a couple of operations by this or a similar method.

I have done other cutting operations that would have caused pain which was entirely prevented and healing has properly progressed in all. Schleich claims that he and his colleagues have made 3,000 operations by this method, and it seems to me that it will certainly not only drive the hypodermatic injection of cocain and the freezing methods of anesthe-

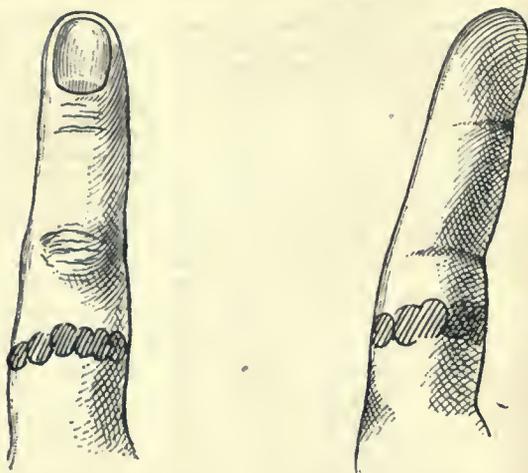

FIG. 10.—Infiltration for amputation of the finger.

sia from the field, but replace general narcosis for at least 75 per cent. of the operations for which it is now given.

There are, certainly, cases in which edematization of the tissues is impossible as heretofore noted, as in some cases where much handling or tension of the parts is necessary, as in most abdominal or pelvic operations, and in others it may not be advisable to have the patient consulting with the surgeon during the operation. Likewise when edematization would interfere with the nicety of the surgeon's work, as in some plastic operations, in ophthalmic surgery as relates to the eyeball, nasal surgery, etc., it is not to be recommended.

But the vast majority of cutting operations for which the surgeon is consulted, some gynecologic and rectal work, the greater number of plastic operations, abscesses, tumors and minor amputations, may be done by the method. According to Schleich, all operations should be done in this manner and he has given up general anesthesia entirely.

If by further trial, his statements be fully verified and the method becomes generally known, the fear of

the knife will go and the deaths from anesthesia will be fewer, as general narcosis will be employed for only the most formidable operations.

805 Grand Avenue.

DISCUSSION.

DR. WÜRDEMANN then demonstrated the technique of the method and the existence of absolute anesthesia therefrom, by injecting the skin of the fore-arm with the weaker solutions (Nos. 2 and 3), on several of the members of the society. A line of wheals was first made in the skin and then a large spear-pointed needle woven in and out of the whole thickness. This demonstration satisfactorily proved the painlessness of the procedure.

DR. BURGESS opened the discussion by saying that he had felt absolutely no pain during the operation on himself and that he could not account for the slow healing in his own case, except that the solution might not have been sterile although he said that now the stitches had been removed the wound was entirely healed. He described the operation for piles and attributed the pain that was felt to the heat on the surrounding parts. In the case of epithelioma and the circumcision, the operation and healing had been in every way satisfactory.

DR. SHIMONEK spoke of reading the article by Cholewa, in the JOURNAL, and of trying the method afterward. As the directions in the article were not explicit, he had mixed up a solution containing a fraction of a grain of cocain to the ounce and had operated upon an epithelioma of the face and upon a case of external piles (cutting operation) without causing pain, and healing had gone on normally. He asked Dr. Würdemann why it was that the skin just outside of the areas injected was in these cases apparently anesthetic.

DR. NOLTE desired to know if the solutions could be sterilized after being made up.

DR. KAUMHEIMER stated that on reading Schleich's brochure he found that Merck's cocain and morphin were stated to be perfectly sterile, and that he was much impressed with this method of anesthesia, although he had not yet an opportunity to try it in his practice. He stated that the pile clamp used in the operation done by Dr. Burgess reduced the edema of the tissues, allowing the return of some sensation.

DR. MERENESS wished to know if the application of a rubber ligature in amputations done by anesthesia of this method, would prove of service, as if ischemic, the tissues would more readily be edematized and the resultant enema would have a tendency to diminish sensation.

DR. WÜRDEMANN, in closing, said: That our experience was not yet sufficient to make a final judgment as to the application of the method or its disadvantages, and that he had brought the subject before the society on account of its novelty and promise of usefulness, in order to interest the many surgeons present to make a trial of the same in their own practice, beginning with minor operations and applying the same to more serious cases as they acquired confidence.

DR. SHIMONEK had apparently used a stronger solution of cocain than any advocated by Schleich, and had thus established narcotic depots in the site of his injections from which the surrounding tissues had been rendered anesthetic. Dr. Kaumheimer's reasons for the pain in the operation done by Dr. Burgess were substantial, as the clamp certainly squeezed the solution out of the tissues. Dr. Burgess had used a metal clamp from which for some reason the non-conducting plate had been removed and which had become quite hot, necessitating its cooling during the operation. He had also burnt away the whole substance of the piles without cutting. A change in the technique of the operation by which the instruments and surrounding tissues would not become heated would obviate this disadvantage. As much care should be taken of the solutions as is used in bacteriologic work and they should be sterilized by heat each time the bottles are opened. The slight amount of extra care involved would save many septic operations. The liability of sepsis would be the principal objection to the method by unskilful hands, as it was evident that this condition would be more likely to result if an impure fluid was infiltrated into the tissues than if only brought in contact with their cut surface by unclean hands, etc. He had brought the subject up as a statement of fact and had left it in the hands of the society with the recommendation for trial of the same in their own practice.

DR. FRIEND then moved that a vote of thanks be tendered the author and assistant for the preparation of the paper, which was carried.

ADDENDA.

Since writing the foregoing, our experience of in-

filtration anesthesia has been widened by a number of operations. While in Chicago December 2, through the kindness of Dr. J. B. Hamilton I was enabled to demonstrate this method upon several trying cases at the U. S. Marine Hospital. These were three cases of phimosis, the results of chancre and chancroid in which the foreskins could not be retracted sufficiently to expose the glans and permit of proper injection of the mucous membrane. After infiltration of the skin the dorsum was slit by scissors and the foreskin held by forceps and then cut off by the scissors, a number of stitches being afterwards taken. In the first case, the slitting of the foreskin was painful, as the mucous membrane had not been anesthetized and as I had unwittingly made several subcutaneous injections there was too much edema of the tissues which interfered with proper placing of the stitches. In the second case the surgeon endeavored to make the injections himself, but owing to inexperience with the technique of endermatic injection did not succeed in properly infiltrating the parts. He then determined to complete the operation without anesthesia "for contrast" and to get rid of the element of suggestion. This operation was done amid the yells of our patient. On the third case we were able to properly inject the structures; the only time that the patient showed that he experienced pain was when the dorsum was cut and at the first prick of the injection needle. In this case, the resultant edema did not interfere with the proper placing of the stitches. On the whole, the superior efficacy of this form of anesthesia over that given by general narcosis, was satisfactorily demonstrated. Since, I have used the method in one operation for ectropion and in several minor procedures. December 20, I assisted Dr. John McDill in excising a chancre of dorsum of the penis, using infiltration anesthesia. The patient watched the operation and said that he had absolutely no sensation of pain. December 10, I received a letter from Dr. Hosmer, of Ashland, in which he mentioned that he had operated upon a tumor, an abscess and a case of hemorrhoids with satisfaction to both the patient and himself. Drs. Wm. and P. H. Jobse removed necrosed bone from the leg by this form of anesthesia and a number of our colleagues have had experience with the method since my exposition before the Milwaukee Medical Society Nov. 20, 1894. Dr. Casey A. Wood, of Chicago, recently demonstrated the method at the Cook County Hospital. Dr. Rumpel and others in that city have since operated by this manner.

Too great stress can not be laid upon perfection of technique, as any spots which have not been infiltrated retain their sensibility. Although I have acquired a certain degree of skill in making these injections, my own experience is not sufficient to make me perfect in this procedure. Endermatic injection is somewhat difficult and until its technique is acquired the surgeon will not have satisfaction. Even those of wide experience, like the eminent surgeon before mentioned, will have to master the details by careful application. This may be raised as an objection by some. Again, the surgeon must become accustomed to working in edematized tissues and in certain localities the resultant swelling of the parts may decidedly interfere with the delicacy of the operation. When working on mucous membranes as in circumcision it would be better to combine the infiltration of the tissues with brushing over the mucous membrane by a solution of cocain of the

ordinary strength. I trust that the profession generally will test the method upon a wider range of operations than here described and that some will soon report their experience.

TOPICAL TREATMENT OF THE AIR PASSAGES, WITH EXHIBITION OF A NEW ATOMIZING VAPORIZER.

Read at the Chicago Medical Society.

BY HOMER M. THOMAS, A.M., M.D.
CHICAGO.

The topical treatment of diseases of the air passages is a subject of much interest to the medical profession. It is fortunate that such is the case when we consider that in the disease of pulmonary consumption alone, the death rate is one in six or seven of all deaths in the United States, not even counting those which result from other diseases of the respiratory organs. This statement is not true of any other disease or diseases. Probably the mortality is due to two facts: 1, that this class of diseases is very difficult to prevent or cure; and 2; that medical research has given less attention to these specific diseases.

In presenting the subject of topical treatment of the air passages, there is no intention of claiming

that a new method or remedy has been discovered, but rather a wish to emphasize the importance of thorough local application of drugs to the affected passages. For some ten years it has seemed to me that the most rational treatment consisted in the local application of drugs to the affected part as one media of cure, not neglecting, and recognizing the importance as well, of the great value of general constitutional treatment. One difficulty which has appeared to lie in the way of the thorough application of drugs to the affected air passages has been in the unsatisfactory action and hence imperfect construction of the various atomizing inhalers furnished the profession. These instruments have either been too delicate in construction to permit the use of sufficient pressure to make a possible deep penetration of the vaporized medicament into the air passages, or become so easily clogged up with the medicament used as to create great annoyance in their use.

The instrument which I am now able to present (made for me by Truax, Greene & Company) is the result of some little time and effort spent in striving to secure an atomizing vaporizer which would

overcome the objections mentioned, and make it useful for the purpose desired. It consists of a heavy glass bottle, ten inches in length and twelve in circumference at its widest portion, narrowing at the top to a circumference of three and one-half inches. The bottle part is of very heavy glass and is tested to withstand a pressure of one hundred and twenty pounds to the square inch. The atomized vapor is produced through a tube made of German silver and heavily nickel-plated, which is nine inches in length. Three inches from the lower end are two tubes, the ends of which approximate to within one-eighth of an inch of each other. The opening of the inner tube is one-third that of the outer tube, which is one-half inch in circumference. When in use, the motive power being compressed air, varying in pressure from five to fifteen pounds to the square inch, enters the main tube, and two-thirds of it is ejected at the mouth of the inner tube, the remaining one-third passing down into the medicinal menstruum, from which it assists in forcing a solid column of the medicament to the mouth of the outer tube. The whole mass is then projected in an atomized form against the inner side of the bottle near the top, from whence it falls in rivulets to the bottom of the bottle, the residue escaping from the top through an outlet opening in the form of a very fine smoke-like vapor. A screw cap, within which is a screw thread three-quarters of an inch in length, securely anchors the top to the bottle. I have found this instrument to be strong, durable, easily cleaned, perfectly antiseptic, and to meet the requirements of this special form of medication.

The uses to which this atomizing vaporizer can be put in the topical treatment of the air passages are many. I have found it of value in the treatment of acute Schneiderianitis where there is a marked swelling of the turbinated bodies, that is, in the intumescent states without true hypertrophy. It is also valuable as a protective to the inflamed nasal surfaces after the use of strong astringent applications. As a palliative to be used after deep linear galvanocauterizations it affords marked relief. The periodical attacks of acute influenza from which so many suffer in this climate are to quite a degree alleviated by the use of topical treatment with the atomizing vaporizer. It is of slight value in the treatment of hay fever, but its use in this affection is very limited.

In follicular pharyngitis, after the diseased follicles have been punctured or removed, the covering of the inflamed surface with an oily menstruum through the media of the vaporizer affords much comfort and relief.

In acute and subacute laryngitis, where you wish to secure an alterative, astringent, or soothing application over the entire inner surface of the larynx, it will be found useful for this purpose. The most striking benefits in the use of the atomizing vaporizer are to be found in the severest cases of acute, subacute, capillary and chronic bronchitis. In those cases, where there is a tenacious, thick, yellowish, and often greenish bronchial discharge accompanied with or without dyspnea, it is quite astonishing with what success old cases of bronchitis, even complicated with emphysema, will be benefited. Beginning the inhalation in these cases, you usually have explosive coughs accompanied by the expectoration of a large amount of phlegm, the vaporized medicament appearing to loosen the secretion from its membran-

ous attachment. The phlegm, as treatment progresses, usually loses its muco-purulent character and is decreased in quantity. As a general rule you will get the most marked benefits within the first ten days or two weeks of treatment. After that the improvement is slower and finally reaches its maximum effect. This treatment will not cure completely a large proportion of cases of chronic bronchitis, but affords very marked relief, and the incurable cases appear to me to be due to the reaction following the severe and sudden changes in temperature which we so frequently have.

I see no reason why, in cases of pertussis this form of medication should not be valuable, but my experience is limited in these cases. I have found in cases of fibroid phthisis, where no bacilli could be detected in the sputa, that the deep and prolonged efforts at inspiration assist greatly in enlarging the respiratory area; that is, a vaporized medicament carried into the lungs, under a pressure of some fifteen pounds to the square inch and assisted in its ingress by the voluntary deep inspirations of the patient, assists in opening many of the closed air vesicles. The greatest success in this method of treatment will depend upon the ability of patients to inhale the medicaments deeply. It is astonishing how few patients really know how to take a deep inspiration. As a rule the inspiratory effort is limited to the supra-clavicular and infra-clavicular regions, hence the necessity of the intelligent coöperation of the patients in inspiring the inhalants. Necessarily a vapor which is principally suspended in the mouth and throat is imperfect because of the lack of inhalation. Patients describe the sensation of the vapors as extending down into the lower and deeper portions of the lungs. Occasionally, there will be experienced a sensation as of the presence of the vapors as low as the diaphragmatic line.* In my experience there can be no possible danger to the patient from the persistent, prolonged and deep inspiration of the vaporized medicaments, the manner in which I use the apparatus making it entirely voluntary, and optional with the patient how deep and prolonged the inspiratory effort is. This I consider of marked advantage, as the sensations experienced can, as a rule, be relied upon as to the desirability of prolonging or discontinuing the treatment. Laying aside for the present any considerations of the therapeutic action of the medicaments inhaled upon the air passages, I believe the chest expansion of a patient can be increased from one-half to two and one-half inches by the daily use of the inhaler. My method of using the inhaler is to take for the nasal passage a tube like this (here the speaker exhibited a tube) if it is desired to treat only one nasal passage at a time. Where you wish to treat two at the same time I make use of the double bulb, and in giving the inhalations directly through the mouth, use is made of this tube. I now desire to present for your consideration a series of experiments with the atomizing vaporizer, which were undertaken to determine how deep the vapors penetrate into the air passages.

August 12, a kitten was placed in a pine box, twenty-one inches in length, eleven inches in width, twelve inches in height, with dove-tailed seams. A half inch hole, two inches from the bottom in the lower end was made for the entrance of vapor. A half inch hole at the top of the further end of the box, two inches from the top end was allowed for the

exit of vapors. A vapor consisting of 5 per cents pure iodine in a 2 ounce solution of blandin which I believe to be simply a neutral oil, was used for the experiment. A pressure of compressed air, about nine pounds to the square inch, was used to pass through the inhaler to generate the vapor. The vapor was introduced continuously for twenty minutes; at the end of this time the kitten was removed from the box and immediately killed by an injection of 60 minims of a 3 per cent. solution of prussic acid per rectum. The respiratory tract was then removed. The starch test for the presence of iodine was then applied to the air passages with the following result: Iodine was found to be present in the mucus from the mouth, on the tongue, in the pharynx and larynx. A typical reaction was obtained of the iodine the entire length of the trachea to just below the bifurcation into the bronchial tubes. A slight iodine reaction was also found in the upper part of the larger bronchi. No presence of iodine could be found in the smaller bronchial tubes or in the air cells.

A second experiment conducted on the same day consisted of placing a dog, weight ten pounds, in the same box. A solution of 5 per cent. methyl blue in glycerin and water, equal parts, in a 2 ounce mixture of blandin failed to vaporize sufficiently to make a satisfactory experiment, as viewed upon the nasal and throat passages of the dog. Then there was substituted 5 per cent. solution of methyl blue in blandin to the former methyl blue, glycerin and water solution, which produced a better vapor, but was too liquid to vaporize satisfactorily. However, this latter solution was introduced into the box for twenty-three minutes under the same air pressure as the former experiment, at the end of which time no evidence of methyl blue could be found in the nasal passages, the throat or tongue by inspection, and it was deemed a failure as a test. I was assisted in these experiments by Dr. Adolph Gehrmann, and Dr. E. F. Wells, to whom I am under many obligations.

August 14, a third experiment was made with a kitten. A 10 per cent. solution of the trichlorid of iron in blandin was vaporized in a box for twenty minutes. The kitten was then killed by a 3 per cent. prussic acid solution introduced per rectum. A solution of ammonium sulphocyanide was then used, to determine the presence of iron salts. The result showed a marked reaction in the mouth, tongue, pharynx and larynx. No test visible on the epiglottis, trachea, bronchi or air cells. Dr. Adolph Gehrmann assisted me with this experiment.

August 14 a fourth experiment was made under the same conditions as the former ones and a ten pound dog was used. A 7½ per cent. solution of pure iodine used with blandin as a base was introduced into the box for twenty minutes. During the course of the experiment this dog was very much excited and made strenuous efforts to escape from the box, and as a consequence his respiratory efforts were greatly accelerated. At the end of twenty minutes the dog was killed with a 3 per cent. solution of prussic acid injected per rectum, and the starch solution used upon the air passages to determine the existence of iodine. This test was a very satisfactory one. There was a hypersecretion of mucus which upon test with starch showed the existence of iodine on the tongue, pharynx, larynx, trachea and larger bronchial tubes down to the medium sized bronchial tubes.

Dr. Adolph Gehrmann made a microscopic exami-

nation of the mucus which was found to contain iodine, and demonstrated its existence down to the openings of the smaller bronchial tubes.

This experiment positively demonstrated that the starch test solution was colored by iodine to the mouths of the smaller bronchial tubes. There was no evidence of iodine to be found in the pulmonary alveoli.

On August 16, I secured a dog, weighing some twelve pounds, and placed him in a box of the following dimensions: Twenty-seven and three-quarter inches long, eighteen and three-quarter inches high and twelve inches wide, inside measurement. This would make the capacity of the box equal to 6,243 $\frac{3}{4}$ cubic inches. A one-quarter inch opening was made in the middle of the top of the box for the entrance of vapor, and a one-half inch opening two inches from the bottom of each end of the box for the exit of vapors. For fifteen minutes a vapor consisting of a solution of equal parts of blandin and a saturated solution of starch was vaporized continuously in the box. During the whole progress of this experiment the dog remained very passive and quiet in the box without the slightest resistance, and in fact appeared to rather enjoy what must have been to him a novel proceeding. At the end of fifteen minutes the dog was removed, and as there was found no evidences of starch upon the air passages easy of inspection without killing the dog, it was concluded that the starch had not penetrated any considerable distance, and hence a new vaporized solution consisting of 20 per cent. solution of iodine in blandin was substituted in the vaporizer. This same dog was allowed to remain in the box twenty-three minutes, at the end of which time he was killed with a 20 per cent. solution of the cyanide of potassium introduced per rectum, 6 drachms of the solution being required to produce death, which occurred in three minutes. Upon removing the air passages, the starch test failed to show the presence of iodine anywhere except in the mouth. Also a microscopic examination of the air passages failed in showing the evidences of any penetration of the iodine. I was assisted in this experiment by Dr. C. D. Wescott and Dr. Adolph Gehrmann.

I am unable to explain the failure of this test to demonstrate the existence of the vaporized inhalant in the air passages, and I believe both Dr. Wescott and Dr. Gehrmann were equally at a loss to understand its failure, as the conditions under which the test was made appeared to be favorable for a successful demonstration. Possibly the inertness of the animal used had something to do with it, as he appeared to make no effort at deep breathing whatever.

In conclusion, it seems to me as a result of quite an extensive experience in the use of vaporized inhalants among patients, as well as in the light of the experiments upon animals quoted, that we are justified in claiming that it is possible for vaporized medicaments to penetrate the air passages as far down as the openings of the mouths of the minute bronchial tubes, and that we may reasonably expect in cases where the inhalants are used that the benefit to be derived is in proportion to the therapeutic relation that the vaporized medicaments bear to the diseased condition. I have purposely avoided any suggestions as to the use of any particular combination of drugs to be used for any given condition in the inhaler. In a general way, I would advise the selection of such combinations as are but slightly irritat-

ing to the air passages to begin with, and then as the patients become more tolerant to the action of the medicaments their strength can be increased as necessary. I have thought that in cases of pulmonary tuberculosis considerable benefit was derived by the inhalation of a 1 to 3 per cent. solution of beechwood creasote, used in solution with some neutral oil, as blandin or albolene.

The paper, as presented, I hope to be but a preliminary one to a series of more extended and extensive experiments, which will have for their purpose the demonstration of the extent and permanency to which vaporized inhalants may penetrate the air passages.

DISCUSSION.

DR. E. FLETCHER INGALS said that experiments showed that the vapor occasionally penetrates to the larger bronchial tubes, in rare instances to the finer tubes, and in the rarest instances to the smallest tubes. The topical treatment in diseases of the air passages must be confined largely to the larynx and trachea, and perhaps to some extent to the bronchial tubes. The suggestion that the remedy should be non-irritating is very important for physicians who desired to medicate patients in this way. Some benefit might be derived from the inhalation of the vapor in tuberculosis. The instrument exhibited was an excellent one, but there was a possibility of the tubes becoming clogged. This was largely true of all other instruments that had been invented.

DR. MOREAU R. BROWN had the pleasure of seeing some experiments made on dogs and other animals similar to those reported by the essayist, and the results were that the vapor did not penetrate very deeply into the bronchi. He was inclined to believe that in the human subject we can get a solution deeper into the air passages than in animals, because in man there was the power of deep inhalation and the attempt to draw the solution deep into the air passages. The ipecac treatment penetrated well into the tubes. He thought iodoform dissolved in either, deeply inhaled, would penetrate further than an iodine solution, if carried in by the globe inhaler. The only objection to the instrument exhibited was that it does not properly vaporize watery or oily solutions. This could be accomplished by the globe nebulizer.

DR. WILLIAM E. CASSELBERRY directed attention to the proper position of the head and tongue when an attempt is made to give a spray for inhalation into the air passages. This might explain the diversity in the results obtained from the numerous remedies used. Some penetrate deeply, while others did not. He was satisfied that the spray could be made to penetrate a considerable distance into the bronchial tract.

DR. NORVAL H. PIERCE directed attention to the closure of the nose. If a tube is inserted in the mouth and the patient told to breathe through it, he used the nose instead; therefore in the use of any inhaler the nose should be closed and respiration carried on through the tube. He had used the globe atomizer in forcing vapor into the middle ear in a case of otitis media, after having performed paracentesis, and there was no doubt but that the vapor had penetrated the middle ear.

THE TEETH OF OUR SCHOOL CHILDREN; WHAT CAN BE DONE TO SAVE THEM?

Read in the Section on Dental and Oral Surgery, at the Forty-fifth Annual Meeting of the American Medical Association held at San Francisco, June 5-8, 1894.

BY J. C. McCOY, M.D.

SANTA ANA, CAL.

No doubt this question has been asked by every intelligent practitioner, as day by day he looks into the oral cavities of Young America, seeing there the almost universal dissolution of the masticatory organs. Those who live in small cities or towns and practice for all classes of society, have a better opportunity to know the condition of the teeth of the masses than does our city brother with his aristocratic patients.

A large majority of the people can not pay for

skilful operations, and their teeth must be saved in an inexpensive manner or be gradually lost before middle age, to be replaced by miserably fitting rubber dentures, with the accompanying shrunken alveola and uvula-like appendages called gums, condemned to worry through the remainder of their earthly existence feeling that nature did a poor job on their masticatory organs, or they would have lasted till old age, irrespective of ignorance and neglect from their earliest childhood. Ignorance and neglect go hand in hand, and are the cause of more diseases and of the loss of more teeth than all other causes combined.

For the past ten years my practice has been in a community that numbers among its citizens many persons of culture and refinement. Others whose exterior apportionments of life are all that could be desired, and whose children are being trained in all the arts and sciences of the day except that of cleanliness of the mouth. We have thousands of this class. I have examined and worked for hundreds of them in the past ten years. The ignorance on the part of the parents, and neglect on the part of the children who know better, is one of the wonders of the nineteenth century.

In one school of 700 pupils, 500 from 10 to 18 years of age, I distributed printed slips with the following questions: Do you cleanse your teeth with a brush every day? Do you cleanse your teeth with a brush twice a day? The teachers requested the pupils to answer the questions by writing the word yes, or no, to each question. The slips were immediately gathered up. On summing up it was ascertained that out of 500 pupils, 50 cleaned their teeth twice a day; 275 used a brush sometimes; while 175 did not own a brush. Notice, the ages were from 10 to 18. In the primary department of 200 pupils, from 6 to 10 years of age, the teachers said they did not think there were 10 children in the department who used a toothbrush.

This school is not an exceptional one in this matter, as further inquiry and investigation demonstrated. In fact its graduates take high rank at our universities, and if there is any difference, it is in advance of most schools in percentage of those who have clean mouths, as well as neat clothes and bright faces.

When there is so much neglect, and so little real care of the mouth, it is not at all strange that the sixth year molars have to be sacrificed daily, because the parents can not go to the expense of treatment to have them preserved, thinking all the time that this most valuable tooth is deciduous, and soon to be replaced by one that is bacteria proof and will last forever, in a mouth that has never been properly cleaned.

The school of 700 pupils mentioned, where only 50 made any pretense to regularly care for the teeth, shows what a field for instruction and training every teacher has. What an opportunity for philanthropy and missionary work!

Our children's teeth must be saved. Experience has taught us that it is impossible to repair the ravages of decay, except in a limited degree. Prevention through cleanliness and proper care of the teeth is the only way possible and practicable, to limit the wholesale destruction. Yes, I say limit, for even when ordinary care is used there is still room for the work of the skilful dentist.

The question before us is, What can we do to save the teeth of our school children?

American dentistry leads the world to-day, and the world justly honors us for the great advances we have made in the preservation of teeth; but the fact still confronts us that millions of teeth are annually lost in America, that need not have been sacrificed if proper care and cleanliness of the mouth had been begun in childhood and continued to manhood and womanhood.

The dentists of America, a noble and philanthropic band of 20,000, have done much to educate and train our citizens in the care of their teeth. We must do more. And at the same time in order to multiply our usefulness, we must solicit the aid of our public school teachers. With their coöperation we can reach and train millions of children.

A majority of the children of our land are in our public schools. They are under the teacher's instructions from 5 to 17 years of age. If the teachers were required to instruct and train the children in the proper care of their teeth, and to insist upon their carrying out such instructions practically at home, we would have accomplished—or at least begun—a great work. If such pupils could be trained from infancy up through all the grades to the high school, I am very sure we would see men and women with better teeth than the average American of to-day. The teachers are the only ones who can do this work. The parents of a large per cent. of the pupils are ignorant and careless almost beyond belief, and their children will follow in their footsteps, unless we dentists of America come to the rescue.

How can we bring this matter prominently before the educators of our land and secure their hearty coöperation?

I hope this ASSOCIATION will pass resolutions on the subject, indorsing the plan, and by its sanction give prominence to its importance.

Let the dental and medical press advocate it. Let each State dental association not only pass resolutions on the subject, but appoint a competent committee to arrange a manual on the subject of the care of the teeth. Let the same committee induce the State board of education to adopt such manual as a text-book to be used by teachers, and taught in our normal schools, requiring teachers to be able to pass an examination upon the contents of such manual, and then require them to carry out such instructions in their respective schools. May each one of us constitute ourselves into a special committee, to see that the spirit of this paper is carried out practically in the schools of our neighborhood.

It is not necessary for me to give more than a few hints on the subject to this body of intelligent dentists before whom I have the honor to speak. I hope to gain not only your hearty approval to this plan, but your enthusiastic coöperation, so that inside of twelve months every public school in our broad land will have begun the much needed reform of cleanliness of the teeth and mouth. So that in the future examinations of schools on the subject of oral hygiene, instead of there being only 50 out of 700 who clean their teeth regularly, we will not find 50 careless ones in 1,000.

This is a great work. We alone can do it. Let each one of us resolve to do our full share and prove ourselves philanthropists to the rising generation.

ORIGINAL INVESTIGATIONS ON THE
NATURAL HISTORY, (SYMPTOMS
AND PATHOLOGY) OF YELLOW
FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 948.)

CHAPTER II.

The following cases will serve to illustrate the effects of a preceding attack of malarial paroxysmal fever, upon the progress of the symptoms and pathology of yellow fever:

PATHOLOGY OF YELLOW FEVER RELATIONS TO
MALARIAL FEVER.

Case 17.—Remittent fever followed by yellow fever; patient reduced in strength and anemic before the attack of yellow fever; fatal issue; liver presented the marks of both yellow fever and malarial fever. Mark Curtis; age 22; native of Germaoy. Entered Charity Hospital, Oct. 18, 1873. Patient states that on October 3 he was seized with vomiting followed by high fever; the vomiting and fever returned every alternate day, until his entrance into the hospital. Previous to this time had been exposed to the malaria of the swamps; came to New Orleans on October 3, 1873. Has resided in America five years, and in Louisiana since October 1 of the present year.

October 18. Patient very anemic and sallow; lips bloodless; gums pale; tongue very pale and flabby, with edges indented by the teeth; pulse 92; respiration 26; temperature of axilla 101.5 degrees.

October 19, 8 A.M. Patient complains of pain in upper and lower extremities. Tongue pale, flabby and furred at the center. Patient anemic, feeble, lethargic and without appetite. Urine abundant and without albumen. Bowels not constipated. Pulse 66; respiration 22; temperature 99.5 degrees. 7 P.M., pulse 72; respiration 20; temperature 100 degrees. Tongue pale, almost as colorless as his face, and furred in the center; gums pale and bloodless; conjunctiva a light yellow, not congested. Patient complains of dizziness in his head. Has been placed under the influence of quinin and has taken about 20 grains during the day.

October 20, 8 A.M. Complains of pain in head, back and lower extremities. Presents the appearance of great anemia about the lips and face, although the surface is now somewhat congested, and the patient has high fever. Pulse 104; respiration 22; temperature of axilla 104.5 degrees; 7 P.M. Patient complains of pains in all his bones. Urine contains no albumen. Pulse 112; respiration 26; temperature of axilla 105.4 degrees. Has taken 10 grains of sulphate of quinia at 10 A.M. and at 12 M. (20 grains in all) without any apparent effect upon the fever. Ordered 20 grains of sulph. carbolate of sodium, every three hours during the night, until 60 grains are taken. Ice, brandy and carbonic acid water and iced milk.

October 21, 8 A.M. Complains of pain in head, back and extremities; capillaries of eyes and surface congested; conjunctiva and surface generally present a yellow jaundiced hue. Urine contains no albumen, light colored and abundant. Pulse 80; respiration 16; temperature of axilla 100 degrees. As there appeared to be a remission in the fever, ordered 3 grains of sulphate of quinia, every three hours, until 24 grains are taken. Continue fragments of ice, carbonic acid water and brandy and iced milk. 7 P.M., the quinin has not prevented the rise of the fever. Pain in the head and bones continues. Pulse 90; respiration 22; temperature of axilla 103.7 degrees. Continue sulpho-carbolate of sodium, ice, brandy and carbonic acid water and iced milk.

October 22, 8 A.M. Patient restless; slept not at all during the night. Complains of pain in right side in region of liver. Capillaries of surface congested, but tongue and gums anemic, great prostration, patient desponding, depressed and restless. Pulse 96; respiration 22; temperature of axilla 103 degrees. Continue sulpho-carbolate of sodium. 7 P.M. Pains in bones and extremities continue. Pulse 86; respiration 24; temperature of axilla 104 degrees.

October 23, 8 A.M., capillary congestion increasing. Complains of pain in right side; loss of appetite, nausea and restlessness. Pulse 94; respiration 23; temperature 100.9 degrees. 7 P.M., pulse 80; respiration 26; temperature 104.5 degrees.

R Quinia sulph gr. xx.

Divide into four powders; one powder every three hours October 24, 8 A. M. Capillary circulation very imperfect. When fingers are pressed upon the purplish congested surface a white mark is left into which the blood slowly returns. Conjunctiva yellow and congested. Intense jaundice. Spirits greatly depressed; restless; complains of pain in right side. Pulse, 94; respiration, 21; temperature, 100.4.

R Sulpho-carbolate of sodium 5i

Divide into three powders; one powder every three hours R Quinia sulph.; pulv. rhei ññ ʒi

Mix; divide into two powders; one powder every two hours.

7 P.M., pulse 70; respiration, 20; temperature of axilla, 102. Breath very offensive. Body emits a foul odor.

October 25, 8 A. M. Bowels constipated, breath and odor of body very foul. Complains of pain in both sides and abdomen. Epigastrium and abdomen generally very tender on pressure. Tongue, gums and lips anemic. Surface of face, trunk and extremities purplish yellow. Conjunctiva congested and very yellow. Tongue white and furred at center; large with edges indented by the teeth; this condition of the tongue is attributed to the preceding action of malaria. Urine loaded with albumen and biliary matters. Pulse 78; respiration 22; temperature of axilla 101 degrees.

R Quinia sulph.; pulv. rhei, ññ ʒi

Mix; divide into four powders. Take one powder every three hours.

Continue sulpho-carbolate of sodium with milk, brandy and ice as before.

At 7 P.M. the rhubarb has caused small action in the bowels, and the patient says that the pain in the side and bowels is much less and that he feels better. Pulse 70; respiration 19; temperature of axilla 101 degrees.

October 26, 8 A. M. Pulse 93; respiration 24; temperature of axilla 100.5 degrees. The quinin appears to have reduced the temperature, and the action on the bowels caused by the rhubarb appears to have afforded much relief. Continue sulpho-carbolate of sodium, 20 grains every four hours. 6 P. M., pulse 71; respiration 25; temperature of axilla 99.2 degrees. The patient vomited his food about 4 P. M. Continue brandy and iced milk.

October 27, 8 A.M. Pulse 72; respiration 20; temperature of the axilla 99.6 degrees. Great capillary congestion; deep jaundice, nausea and vomiting. Continue sulpho-carbolate of sodium, 7 P. M., pulse 62; respiration 18; temperature of axilla 99.2 degrees. Urine scanty and loaded with albumen casts, granular matter, excretory cell and biliary matter.

October 28, 8 A. M. Patient presents a fearful appearance; great capillary congestion, with yellow and purple surface. Yellow congested eyes, urinary excretion scant and loaded with albumen and casts. Has vomited curdled milk streaked with dark flakes. Pulse 60; respiration 16; temperature of axilla 97.2 degrees. The pulse, respiration and temperature give no indication of the extreme danger of this case. Continue sulpho-carbolate of sodium, 20 grains every three hours; ice water injection to rectum; iced milk; brandy and carbonic acid water; ice bag to epigastrium. Black vomit. Notwithstanding the occurrence of black vomit and the great capillary congestion of the surface, the tongue and gums still continue pale. 7 A. M., pulse 58; temperature 99.1 degrees. Vomiting of black vomit continues. The ice-cold enema appeared to restore the action of the kidneys temporarily. Continued to throw up black vomit during the night.

October 29. Died at 6:30 A.M.

The following table presents the relations of the pulse, respiration and temperature:

| Date. 1893. | Pulse. | | Respiration. | | Temperature. | |
|-----------------|--------|-----|--------------|----|--------------|--------|
| | M. | E. | M. | E. | M. | E. |
| Oct. 18 | | 92 | | 26 | | 101.5° |
| " 19 | 66 | 72 | 22 | 20 | 99.5° | 100.0 |
| " 20 | 104 | 112 | 22 | 26 | 104.5 | 105.4 |
| " 21 | 80 | 90 | 16 | 22 | 100.0 | 103.7 |
| " 22 | 96 | 86 | 22 | 24 | 103.0 | 101.0 |
| " 23 | 94 | 80 | 23 | 26 | 100.9 | 104.5 |
| " 24 | 94 | 70 | 21 | 20 | 100.4 | 102.0 |
| " 25 | 78 | 70 | 22 | 19 | 101.0 | 101.0 |
| " 26 | 93 | 71 | 21 | 25 | 100.5 | 99.2 |
| " 27 | 72 | 62 | 20 | 18 | 99.6 | 99.2 |
| " 28 | 60 | 68 | 16 | 20 | 97.2 | 99.1 |

Necropsy.—Three hours after death. Body still warm; weather cold and frosty; temperature of cavities of heart 97.0 degrees. There had evidently been no rise of temperature after death in this case. Ex-

terior: Deep yellow color. Conjunctiva of eyes yellow. Dependent portions of body mottled. Surface presents the appearance of great capillary congestion. Lips and gums pale and of the same color as the skin of the face. Tongue also pale and bloodless. Throughout the illness of this patient the tongue has been very pale, and I called the attention of my medical students to the effects of the preceding malarial disease, in rendering the blood watery, and in affecting the color of the tongue. The appearance of the tongue in this case was decidedly different from that of uncomplicated yellow fever.

Thorax: Recent pleuritic adhesions in the lobes of the right lung; the patient during life had complained of pain in right side, as well as in abdomen. Dependent portions of both lungs much congested. We have in this pleuritic inflammation, proof that inflammation may arise, in a system depressed by the action of the poisons of malarial and yellow fever. Heart: Cavities distended with dark fluid blood. When abstracted, the blood from the heart formed a loose voluminous soft coagulum which did not completely gather up the colored blood corpuscles. Reaction of blood neutral. Red blood corpuscles greatly diminished; colorless corpuscles very abundant. Under the microscope some of the colored corpuscles presented a crenate stellate appearance, but the vast majority were normal in appearance. After prolonged and careful microscopic examination with magnifying powers ranging from 420 to 1050 diameters, I was unable to discern any bacteria, or living animalculæ in the blood of the heart. Blood thin and watery. Serum golden colored. Muscular fibers of heart, pale and of a yellow color. Upon microscopic examination, the transverse striæ of the muscular fibrilla are to me indistinct, and granular matter and oil globules were numerous; but the amount of oil and granular matter appeared to be less than in uncomplicated cases of yellow fever. The patient was anemic and emaciated before the attack of yellow fever.

Abdominal cavity: Liver. This organ presented on the exterior a bronzed and mottled color, resembling a liver of malarial fever, which was in the early stages of fatty degeneration. The general appearance of this liver would lead the superficial observer to repeat the assertion which unfortunately has been too often made by those who have enjoyed every opportunity to crush the error, "*that there is no characteristic lesion of the liver in yellow fever, and that this disease has no pathology.*" The surface of the liver presented a mottled color of bronze and deep yellow. Many of the lobuli presented a deep yellow color, like the liver of uncomplicated yellow fever. When sections of the liver were carefully washed, the distinct deposit of yellow fever was everywhere discernible and the more deeply colored portions were chiefly in the peripheral capillary network of each lobule. Under the microscope the liver was found to be loaded with oil globules and yellow granular matter, and also with numerous masses of hematin, deposited chiefly in the peripheral system of portal capillaries. The peculiar color of the liver, therefore was clearly referable to the combined action of yellow fever and malarial fever. The presence of the pigment particles revealed the previous action of the malarial poison. Gall bladder flaccid; contained no bile, and only a small quantity, about twenty drops of a thick cream-like semi-liquid substance; which also filled and ob-

structed the gall ducts under the microscope. This was found to consist chiefly of desquamated epithelium from the mucous membrane of the gall bladder. Mucous membrane of gall bladder, thickened and intensely congested, presenting a deep red and purple color. Spleen enlarged and softer than in uncomplicated yellow fever. This organ contained much pigmentary matter.

Kidneys: Congested. When sections were made and washed, the kidney structure presented the characteristic yellow color of yellow fever. Sections with Valentine's double-bladed knife, under the microscope, presented the usual appearance of Malpighian corpuscles and tubuli uriniferi impacted with oil globules, granular matters and detached cells.

The urinary bladder: Contained about one fluid drachm of turbid yellow urine, loaded with colorless corpuscles, casts of the tubuli uriniferi, detached excretory cells from tubuli and pavement epithelium from pelvis of kidney, ureter and urinary bladder.

Spermatozoa: The urine contained albumen. I have observed spermatozoa in the urine of several cases of yellow fever after death.

Stomach and intestinal canal: The stomach contained about one pint of a mixture composed of milk and black vomit. A portion of this milk soon coagulated. Under the microscope the contents of the stomach consisted of the oil globules of the milk, masses of hematin, detached cells from the mucous membrane of the stomach and also the spirules and matters of a delicate fungus resembling the torula, which is very common in the black vomit of yellow fever. I have frequently observed the same fungus in the urine of yellow fever, after it has been allowed to stand for a certain time. The sulpho-carbolate of sodium did not prevent the formation of this fungus. The mucous membrane of the stomach congested and ecchymose. The mucous membrane of the ileum and colon greatly congested, presenting a brilliant injected appearance. In portions the mucous membrane was softened, eroded and covered with effusive blood.

The peritoneum exhibited evidences of recent inflammation. The omentum was intensely injected. Coagulable lymph of a yellow color and in some places of a red color was thrown out in small amounts upon the surface of the peritoneum. The inflammation of the pleura and peritoneum in this case may have been excited by the cold weather and the sudden changes of the temperature of the ward, in which the stoves had not been erected.

In the preceding case, we have a complication of diseases, namely, malarial fever, yellow fever, pleuritis and peritonitis.

It is a matter of great moment to determine whether the malarial poison under any circumstances induces fatty degeneration of the heart, liver and kidneys. If the malarial poison acted in a manner similar to that of yellow fever in producing fatty degeneration of these organs, a strong argument could be established for the identity of these two diseases in their origin and manifestations. I have endeavored to investigate this question thoroughly, by carefully observing the individual cases and noting the chemic and microscopic changes after death, in the blood and different organs, and especially in the liver, spleen, kidneys and heart. In no instance have I observed the production of fatty degeneration of the heart, liver and kidneys in malarial fever. All

the various forms of malarial fever have been subjected to critical investigation, including remittent fever, pernicious, malarial or congestive fever, malarial hematuria, quotidian, tertian and quartan intermittents and chronic malarial poisoning.

If in any condition, fatty degeneration of the heart, liver and kidneys results from the action of the malarial poison, it should be most clearly shown in prolonged cases of malarial poison. I selected the following from a large number of similar cases:

Case 1.—Chronic malarial poisoning, anemia, destruction of colored blood corpuscles, high temperature, fatal issue. Samuel Erhart; age 35; native of Germany; entered ward 13 Nov. 22, 1873, in a feeble depressed condition, with continued fever and sallow greenish-yellow complexion. Has been in America about eight months. In Europe his profession was that of an architect, but during his residence in America he has worked as a laborer in the low swamp lands of Louisiana. About eight weeks before entrance into the Charity Hospital, had a chill followed by fever, which has remitted occasionally, but has never been entirely absent. During his sickness has had scant supplies of food, and has had little or no medical attendance. The effects of the action of the malarial poison are manifest in his pale, sallow, greenish-yellow surface, pale lips and gums, muscular and nervous prostration, continuous febrile excitement, bloated countenance and swollen extremities. His present condition Nov. 22, 1873, is clearly referable to the action of the paludal poison of the swamps, bad diet and neglect.

November 23, patient pale, anemic, rapid pulse, high temperature. Nausea and vomiting of bilious matter. Quinin is retained with difficulty on the stomach and the patient takes little or no nourishment. November 24, A.M., temperature of axilla 105 degrees; pulse 112; respiration 21. Urine high-colored, but free from colored blood corpuscles and albumen. Chlorids greatly diminished. Nausea and jaundice. Great nervous and muscular prostration. 8 P.M., temperature of axilla 104.7 degrees. November 25, A.M., temperature of axilla 103 degrees, pulse 116. 8 P.M., temperature 104 degrees; delirious. Strength failing. November 26, A.M., temperature 102 degrees; P.M., temperature 103 degrees. Notwithstanding the great prostration of the patient, the fever still continues. We observe in the record of temperature no decided decline of the fever, but only fluctuations which correspond with those of the so-called bilious remittent fever. The disease has evidently run into this continued stage from the absence of all remedial agencies. It was impossible to produce any impression upon this patient by means of quinin, administered either by the mouth or rectum. November 27, patient died at 6 A.M.

Post-mortem, three hours after death. Body warm, limbs flaccid. Exterior, of dingy greenish-yellow color. Lower extremities edematous.

Thorax: The pericardium contained about two fluid ounces of golden yellow serum. Heart presented a deep color and firm texture. Under the microscope, no textural changes were observed in the muscular fibrillæ of the heart, and the microscopic characters, as well as the chemic constituents, were wholly different from those of yellow fever. Examination of the blood from the cavities of the heart: Light yellow fibrinous concretions were observed in both cavities. The fluid blood from the cavities of the heart, when viewed by the microscope was found to contain a large number of dark masses of hematin of various sizes, from one three-thousandth of an inch to one seventy-five hundredth of an inch in diameter. These masses were similar in all respects to those observed in the spleen and liver. Specific gravity of blood from cavities of the heart, 1021; solid residue in 1,000 parts of blood, 73.00. Specific gravity of serum of blood, 1015; solid residue in 1,000 parts of serum, 58.00. The fluid blood from the cavities of the heart coagulated after abstraction, and numerous oil globules were observed upon the surface of the coagulum. Coagulum large and soft;

fibrin diminished in amount. Lungs normal; hypostatic congestion of dependent portions of lungs. Stomach distended with gas; mucous membrane pale and anemic. Stomach contained partially digested food discolored by bile. Liver enlarged and hardened; deep slate color on the exterior and bronze within, and contained numerous black pigmentary particles, deposited chiefly in the peripheral network of the portal capillaries. Spleen enlarged and softened and loaded with altered blood corpuscles and dark masses of hematin. Gall bladder flaccid and contained about fifty grains of thick mucus, which was loaded with the desquamated cells of the mucous membrane of the gall bladder. Kidneys normal, with the exception of slate-colored spots, about one and one-half inches in diameter, on the surface of each kidney; and when thin sections of the discolored portions were examined under the microscope, the discoloration was found to be due to the deposit of black pigmentary particles in the capillaries.

(To be continued.)

THROMBOSIS.

Remarks made at the Opening Exercises of the College of Physicians and Surgeons, Boston, Sept. 19, 1894.

BY E. CUTTER, M.D.

NEW YORK.

HEART CLOTS OR THROMBOSIS.

Practically this subject is in my line of genealogy, as my father, Dr. Benjamin Cutter, died of thrombosis; in my line of clinical morphology, as it includes the detection of the pre-thrombic or embolic state, and in the line of applied medicine, which teaches that thrombosis is caused by soured food and is curable by diet, mainly, an American idea practically proved.

The subject has been studied much and well. I own a Latin essay on the polypi of the heart, published in 1729, at Jena, and read before a critical audience, including Dr. Hermann Frederick Teichermeyer, President of the Medical College, by Dr. John Christian de Winterbach, as his inaugural thesis for the doctorate of medicine. Not a bad custom for to-day! The essay is short, but deep and creditable now. It shows that fibrinous concretions in the heart and blood vessels have been observed from Galen down. By Altinus, Antipater, Andreas, Bonetus, Lithias, Malpighius, Mangetus, Morgagni, Pacchionius, Pichlius, Peyer, Smith and others; that some deny this, *i. e.*, that they are formed in life; that Malpighius admits that the fibrin of the blood is the substance of the polypi, "*Polyporum origo est coagulatio sanguinis*;" that acid is the prime cause of the coagulation, "*Causa coagulationis primaria acidum est*," and that the diet must be attended to in the cure.

In 1862, Sir B. W. Richardson, in London, gave me his monograph on fibrinous concretions of the heart. Going to Washington I found that the Army Medical Museum was destitute of such works and I delighted the Librarian, my friend, Surgeon J. J. Woodward, by the gift of my copy to the library. Sir B. W. Richardson wrote learnedly, exhaustively and originally, made many vivisections and *post-mortem* experiments. He thus found that clots were formed during life. He actually drew them from the beating hearts of dogs just before death! Says this distinguished

author: "I am not without hope that the day may come when science shall show us how the dissolution of these concretions may in some cases be effected, for I have seen them partly dissolved as an effect of alkaline treatment."

Later, in the admirable "Medical and Surgical Memoirs of Prof. Joseph Jones, M.D., L.L.D.," of New Orleans—which ought to be in every American medical library, as they are comprehensive, encyclopedic, intensely graphic and unprovincial—we find this subject treated at length, two cases given where Professor Jones diagnosed cardiac thrombosis before death and verified by autopsy. If this is a fair sample of his clinical teaching the New Orleans medical students have had fine instruction from this prince of clinicians.

Dr. Jones quotes the following authors who affirm the existence of thrombosis in life: Altinus, Andral, Baillie, Cloquet, Sir Astley Cooper, Crewell, Crompton, Dessault, Duncan, Gaspard, Graham, Hewson, Hodgson, Jones, Kirkes, Langstaff, Lee, Lobstein, Louis, Meckel, Martel, O'Halleran, Otto, Paget, Petit, Rokitsky, Richardson, Stengel, Mackra, Tiedmann, Virchow and Wardrup. Dr. Jones italicizes Dr. Richardson's words that "the diagnosis must rest upon the general symptoms rather than the physical."

Dr. Woolridge, a late English author on coagulation of the blood, comes down to 1890. His experiments are not clinical and mostly refer to *post-mortem* blood. He does not take into account the morphology of the blood in the pre-thrombic stage. He throws no light on the cure. His work is rather that of the physiologic laboratory chemist; careful, ingenious, strictly original, but gives no aid to those who treat thrombosis.

From what has been said about acid clotting blood, is it not strange that none of those gentlemen named, thought of feeding animals on acidulated foods, to see if thrombosis did not result? But it happens that thousands, if not millions, of American animals are fed on acidulated food, and that the diseased action of such foods has been studied in America.

In 1858 Dr. Salisbury (see "Alimentation and Disease," J. H. Vail & Co., New York, 1888) worked up this subject. Some of his results were briefly as follows: Of 104 swine fed on rum distillery swill till they died, 104 had thrombosis, embolism and vinegar yeast in the blood as shown by microscope. Vinegar and alcoholic yeast were found in the digestive organs; 103 had thrombi of the heart before death; 15 of these had them dislodged as emboli. The speaker testified that he had seen cases of swine fed on swill with like *post-mortem* concretions, and confirms these statements.

Where there is thrombosis, skeins of fibrin filaments, massive and large as compared with the normal fibrin filaments—are found in the blood before death and during life. They are single, double, multiple, straight, twisted, in bunches like skeins, like balls of twine, sometimes in balls of fibrin inclosing gravel like plums in a pudding. I once saw a lady just before confinement whose blood was quite full of skein-like silk threads—thus diagnosing the pre-embolic state. By dieting these were removed before her labor, which her attending physician said was the most normal one he ever attended!

The treatment consists in withdrawing foods that are undergoing or will undergo vinegar fermenta-

tion, and substituting foods which do not undergo this acetic acid fermentation. Beef and mutton are such foods.

It will not do to deny these facts as some deny, for example, the existence of the one seventy-fifth inch objective. The only way to disprove is by like observations conducted under like circumstances.

It is my hope in the coming season to develop the clinical morphologies as applied to these diseases of the heart and blood vessels, and to make these statements clearer by means of solar projections direct from typical cases, than they can be in these few brief, hurried practical remarks.

A CASE OF SARCOMA OF THE RIGHT SUPRARENAL BODY CAUSING OBSTRUCTIVE JAUNDICE IN AN INFANT.

Read before the Chicago Pathological Society, Oct. 8, 1894.

BY FRANK B. EARLE, M.D.,

AND

GEORGE H. WEAVER, M.D.

CHICAGO.

CLINICAL HISTORY.

Georgie L., born Jan. 9, 1891, the only child of robust parents free from disease of all kinds. From birth the patient was extremely anemic; never grew strong but was exceptionally free from the disorders of babyhood and was regarded a healthy child until he was past 2 years old. In February, 1893, he became jaundiced, which increased rapidly, accompanied by clay-colored offensive stools, increased anemia, emaciation and rapid loss of strength. In less than a month, the liver was enlarged to such an extent that it reached below the umbilicus, one-half the distance to the pubes. The gall bladder, greatly distended, was easily felt as a firm body. Pressure on the adjacent organs was so great that vomiting continued incessantly and almost no food was retained. The dyspnea was so troublesome that the recumbent posture was almost impossible.

At this time the patient was seen, separately, by Drs. C. W. Earle, Christopher and Fenger, and each made a diagnosis of malignant disease of the liver or behind the liver. The child was placed on increased doses of pot. iod., and iron was given in full doses.

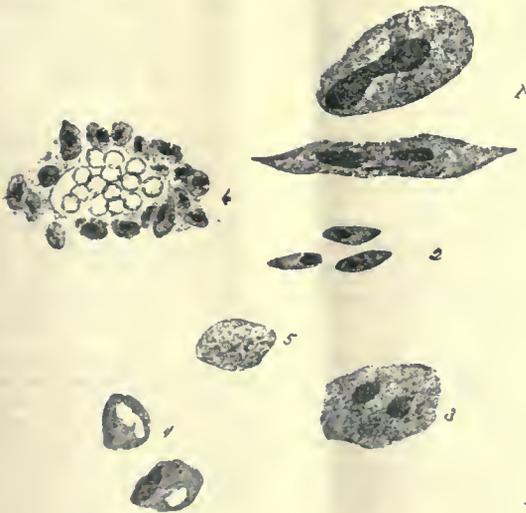

Much to the surprise of all he gradually improved, so that in May he was able to go into the country. Frequent reports of continued improvement were received, notwithstanding the fact that the patient suffered from several severe attacks of epistaxis. When he returned in the latter part of October he had gained in flesh, improved in color, and was playing about with almost as much vigor as a perfectly healthy child. The liver had decreased to one-half its former size, and the jaundice was scarcely perceptible. General improvement continued until December, when the urine became scanty and a condition of general edema developed. It was the most extensive edema I have ever seen, but lasted only a couple of weeks. By the middle of January the child appeared as well as before the attack. He was seen occasionally at the office during February, March and the early part of April and had good appetite, was digesting his food; feces normal in color and consistency. He was again gaining flesh and making blood. On April 18 he again became rapidly edematous, was unable to sleep, developed a typhoid state—temperature 103—and expired suddenly on April 23. The treatment was tonic and alterative; pot. iod. was taken for a long time and tonics all the time. Dr. Weaver will speak of the *post-mortem*.

AUTOPSY.

Nine hours after death. Body emaciated, skin pale yellow, rigor mortis fairly developed. The examination was limited to the abdomen. The peritoneal cavity contained one pint of clear serous fluid. Surface smooth. The stomach was small and the intestines macroscopically normal. The mesenteric lymph glands were slightly enlarged. The spleen was about the size of a normal organ in an adult; dark purple

surface and fairly tense capsule. The section showed a dark-red color, with a distinct increase in the fibrous tissue. The follicles were not distinct. Pancreas about normal in appearance. The kidneys were larger than normal, pyramids red, cortex yellowish with very indistinct markings. The liver reached from the second interspace on the right side, and the third rib on the left, to two inches below the costal arch on the right side, and one and one-half to two inches below the ensiform cartilage in the median line, causing a displacement and compression of the stomach. The surface was olive-green in color and finely granular. The edges were rounded. Both lobes were alike. The organ cut with difficulty, grating under the knife like dense fibrous tissue. The section was olive-green in color, the periphery of the lobules being paler than the center.

The gall bladder (*f*) measured three inches by one and one-half inches. It was tensely distended with clear, colorless watery fluid. The fundus projected one inch beyond the border of the liver *in situ*. The cystic duct was completely obliterated except

Examples of the different varieties of cells in the tumor and a small blood vessel.

one-fourth of an inch at its upper end (*d*), becoming lost in a dense firm mass at its lower portion (*b*). The lining of the remaining portion of the duct was slightly rough. The hepatic duct (*c*) was pervious throughout. At its lower portion it was much compressed and only possessed a fine caliber. On this part where compressed by the surrounding dense mass, the wall of the duct appeared thin and fibrous with its inner surface uneven. The portal vein was surrounded by the same dense mass but, while compressed, was patent. The mass above referred to (*a*) was found to consist of the altered suprarenal body. It lay behind the vessels and ducts in the portal fissure and they were fitted into it. The upper portion was three-fourths of an inch to an inch in diameter; dense, white, and fibrous on section. The cystic duct at its lower portion was lost in it. The lower portion of the gland was flattened, resembling a little more a normal adrenal. On section of this portion the tissue was yellowish-brown with a small central soft portion of darker color. The whole gland was three inches long. A few enlarged lymph glands were seen in the fissure above the adrenal.

MICROSCOPIC EXAMINATION.

The liver was cirrhotic, corresponding to the condition brought about by chronic obstruction to the outflow of bile. The portal lymph glands were the seat of old hemorrhages. No tumor growth was found in them. Sections were made from various parts of the adrenal body. Those from the parts not occupied by the firm, dense formation were as follows: At the outer part of the section was a zone which consisted of small round cells with numerous well preserved red blood corpuscles scattered among them. In a few places the cells were more of a fibrous character and formed fine meshes. There were few blood vessels in this portion of the section and they were filled with blood. The central portion of the section was unstained by hematoxylin. It contained abundant granular blood pigment in the most central part with very much deformed red corpuscles. Between this central area and the outer zone of stained tissue, above described, was an unstained zone, in which were seen red blood corpuscles variously disintegrated making up most of the picture, and among them a few large unstained cells with faintly visible nuclei. These large polygonal cells were probably necrotic suprarenal cells in an area of hemorrhage.

Section from tumor of the supra-renal body.

The section through the dense fibrous portion of the suprarenal body presented every appearance of a mixed-celled sarcoma. The cellular elements seemed to be entirely spindle-formed or only slightly varying from that, the apparent varieties of shape in the cells being due to the direction of the section through them. The cells were arranged in imperfectly defined bundles and were consequently cut in various directions and at various distances from the center, giving the appearance of oblong, polygonal, and larger and smaller round cells. The nuclei were also on this account at times cut so as to present a larger or smaller round form. When cut parallel to the long diameter, the cells were always spindle-shaped, and had oval or oblong or spindle-shaped nuclei. The size of the cells varied from that of cells found in ordinary small-celled sarcomata, to very large ones (Fig. 1) with a length equal to the diameter of ten to twelve red blood corpuscles. The most were about midway in size between the two extremes (Fig. 2). The varieties were quite uniformly mixed, but the large cells were more numerous in some areas, and in some portions of the sections only the smaller cells were seen. The smaller and medium-sized cells

had a single elongated nucleus located in the center of the cell. The nuclei of the large cells were oblong, being about of the diameter of a leucocyte in thickness and three times as long as thick. They stained deeply with hematoxylin and usually lay to the side or at the end of the cell. They were usually single, but some cells contained from two (Fig. 3) to four nuclei. The body of the large cells was usually homogeneous, but in a few was slightly granular, and in a very few there was the appearance of vacuoles (Fig. 4) of various sizes. In cross sections there was sometimes produced the appearance of large oval or round cells without nuclei (Fig. 5), dependent upon the location of the nuclei in the side or at the end of the cells. The intercellular material was homogeneous, transparent and highly refractile. It was present in only very small quantity, and was continuous with the cells at their ends. There were numerous small blood vessels scattered through the tissue, having their walls entirely made up of a single layer (Fig. 6) of cells. Also a smaller number of larger vessels with a similar thin wall were found.

Sections were made to include the dense tissue and the remains of the cystic duct, and the hepatic duct at the point of greatest pressure. The ducts had lost the normal lining, only showing a few irregularly arranged cells in places. The inner surface of the hepatic duct was very irregular and not possessed of a lining mucous membrane. The tumor passed gradually into the duct walls. As the duct was approached, the tissue became more fibrous and there was a layer of mature fibrous tissue making up the duct wall, which was not infiltrated by tumor or inflammatory cells. From a morphologic standpoint the dense structure in the upper part of the suprarenal body corresponds to a mixed-celled sarcoma.

Sections from this portion were kindly examined by Prof. W. H. Welch, and he says that it is not certain that the tissue is a sarcoma, but he should be inclined to so regard it. The long duration of the clinical course of the obstruction and the outflow of bile is not what would be expected in a sarcoma, as a tumor of a larger size would usually be reached in so long a time. The complete destruction of the lower portion of the cystic duct is, however, an evidence of malignancy.

I am under great obligation to Dr. E. R. Le Count for the very accurate drawings he kindly made for me to illustrate the sections.

A CONTRIBUTION TO THE STUDY OF MALIGNANT GROWTHS IN THE LOWER ANIMALS.

Presented before the American Microscopical Society, 1894 meeting, and read by V. A. Latham, D.D.S., before the Chicago Pathological Society, Oct. 8, 1894.

BY EVA H. FIELD, M.D.
CHICAGO, ILL.

The study of disease among the animals used for food has occupied much of the time of our most earnest investigators; the horse, probably on account of his great value as a carrier, has received his share of attention, but I find that "the children's playmates," the cats and dogs, have been in a measure neglected.

There is, I think, no little danger in this fact, inasmuch as enough cases have been reported to prove that these animals are subject to diphtheria, pneumonia, asthma, tuberculosis, cancer, etc.

Historical Sketch.—Osler¹ says: "Cats are subject to a pseudo-membranous disease, and there are many cases on record in which children appear to have caught diphtheria from them." "On the other hand," he says, "I know of one case in which a cat died of angina and intense pseudo-membranous colitis and the children who nursed it did not take the disease; and of a second case in which a pet cat had coryza, difficult breathing, fever, and enlarged cervical glands and here too the children were not affected."

A case of asthma in a cat² was mentioned in the *British Medical Journal* in 1891.

Dr. C. Creighton³ records a case of tumor of the mammary glands of a bitch. The double chain of glands was affected with nodular enlargements at several points, and one of the tumors was large with evidences of malignancy. He found that the micro-characteristics were identical with those of mammary cancer in the human subject. The same author⁴ reports also several other cases of tumors in dogs, viz.: 1, a sero-sanguinous cyst of the neck; 2, a mucous sarcoma of the neck with a cystic interior; 3, a fluctuating tumor from the subcutaneous tissue of the hip of a dog of precisely the same structure as number 2; 4, a spindle-celled sarcoma from the head of a dog, with its center excavated into a cystic cavity crossed by a close network of cystic trabeculae.

A very interesting paper⁵ on "Cancer in Domestic Animals" by W. H. Birchmore, M.D., reports a number of cases of both carcinoma and sarcoma.

Case 1—was a chicken who sustained a fracture of the humerus which did not unite. A lump the size of an egg formed about the ununited ends of the bone. The animal died of exhaustion and on examining the tumor, which weighed 64 grms. it was found to be a large round-celled sarcoma.

Case 2—Another, an old hen whose feet had been frost-bitten and sore, developed an encephaloid cancer as large as a pigeon's egg on the sole of the left foot. The hen died marasmic. Lymphatic glands were found to be enlarged and the tarso-metatarsal bone a mass of encephaloid disease.

Case 3—was a capon. Glands removed by the usual operation. Three months later the capon died of acute peritonitis which was caused by the bursting of a cyst containing an irritant fluid. This cyst formed part of a tumor as large as an egg occupying the place of the right testicle. The tumor was an adenoid sarcoma.

A typical osteo-sarcoma developed from an ulcerated tooth-socket of a fine setter which had been wounded in the mouth by the discharge of a gun. He reported in the same paper the case of a cow supposed to be suffering from snake-bite. There was found on the udder an ulcerated mass which proved both macro- and microscopically to be a nodular mammary cancer. He also mentioned the following cases: A large mixed spindle- and round-celled sarcoma from the lower lip of a mule, caused by the irritation of the bit. A papilloma irritated by rubbing of the bridle behind the ear of a horse, became ulcerated, and when removed was found to be a connective tissue tumor, containing nests of pseudo-epithelial cells. The same author reported⁶ an account of a morbid growth in a pig's stomach. This growth was about two centimeters in length and raised one centimeter above the surrounding tissue. He does not give the form of cancer. An interesting description of a case of carcinoma of all the mammary glands of a cat was reported in the proceedings of the London Pathological Society by W. G. Spencer.⁷ These tumors measured from one-half to one and one-half

inches in diameter. He says in summarizing: "This specimen illustrates two points:

1. A carcinoma of all the mammary glands most marked in the hinder ones, has grown apparently from the ducts, and secreted by the nipples an irritating fluid. At the same time the new growth had a great tendency to undergo degeneration, both in the mammæ and lymph glands. The degeneration is seen to have progressed by the breaking down cells, the nuclei of which still appear at the margin, shrivelled but staining. It is open to conjecture whether the degeneration was not a perverted production of milk by the cells of the cancer and therefore whether the term, 'caseous,' is not in this case the correct term.

2. Extension has taken place by the lymphatic leading directly to the thoracic and right lymphatic ducts. In this way the disease gained the pulmonary circulation, but it had advanced no farther. Therefore the emboli were large enough to stick in the capillaries of the lung. It would have extended to the general circulation without doubt in a short time, by the communication of the nodules in the lung with the pulmonary veins."

J. Jackson Clarke⁸ mentions a case of a tumor found on a cat's lip. These are the only cases I have found recorded.

Transmissibility.—It has been stated⁹ that the lower animals can not be infected with carcinoma or sarcoma from the human subject or from any animal except it be of their own kind.

Among successful experiments, we find that Dr. Hanan, of Zurich, has transferred a squamous-celled carcinoma from a rat with such a growth on the vulva, to a series of other rats. Wehr has transferred a vaginal carcinoma from one dog into the subcutaneous tissue of the abdomen of another. Eiselberg has also successfully grafted fibro-sarcoma from one rat to another. Moran reports a female white mouse inoculated with a piece of cylindrical epithelioma taken from an animal of the same species. A tumor resulted which was retarded during pregnancy but began again immediately after delivery. It will be noticed, however, that in these cases, pieces of tissue from the cancers were transplanted and the usual method of inoculation was not resorted to.

Some little discussion has taken place concerning the endemic nature of the disease, and the conditions under which it arises.

Williams says: "The augmented cancer mortality coincides with progressive population, increased national wealth and marked improvement in the general well being. In Ireland where there has been a decrease of population and wide-spread poverty, the cancer death rate has been much lower than in England or Scotland. Also, the decline in the death rate in phthisis and other tubercular diseases in Great Britain has coincided with the great increase in the cancer mortality."

At a meeting of the London Pathological Society, Mr. Shattuck cited one case in which, in a particular house in a certain spot in South Devon, four cases of cancer had occurred in different families in a few years. Haviland, from his extensive statistics has shown that those countries were particularly the seat of cancer which were traversed by rivers that frequently overflowed their banks. Piessinger has pub-

lished a paper in the *Revue de Médecine* in 1892 on this subject. He has observed a series of cases occurring in villages sometimes consecutively, at others simultaneously. He believes that such groups of cases are particularly liable to occur on the banks of rivers and in their immediate vicinity.

As a further contribution to the subject I wish to report the following recent cases:

Case 1. Cystic Round-celled Sarcoma.—The first case to which I wish to call your attention is that of a supposed abscess below the ear of a cat. A swelling appeared close to the ear and in a short time began discharging a foul-smelling purulent material. Aside from this, the animal was to all appearances healthy. The cat was chloroformed and a portion of the diseased tissue was cut out and brought to the laboratory for examination. There was a space about five centimeters in diameter where the hair had fallen out, and in the center of this space was the spot where the tumor had opened. The tissue on section, had a honey-combed appearance. No examination of the viscera was made. Viewed with the microscope this growth was found to be a cystic round-celled sarcoma.

Case 2. Scirrhous Carcinoma of the Mammary Gland.—A cat between 15 or 16 years of age was noticed to have a hard lump on one of the mammary glands, which grew steadily for about six months. The animal became very much emaciated and was noticed to cough. One evening she was found apparently suffocating, and her mistress hastened her death by giving chloroform, after which she cut out the growth including the axillary glands and brought the specimen to the laboratory for examination. On making section and examining them it was found to be a carcinoma of the scirrhous variety. As none of the organs could be obtained the case is necessarily incomplete, but from the fact that the cat coughed much of the time and finally nearly died of suffocation I think it highly probable that there were metastases in the lungs and possibly in other organs.

It is a noteworthy fact that this cat's age was equivalent to about 70 years in the human subject, and that pregnancy had not occurred for three years prior to death. The history in this case as well as in the following one is perfectly reliable, as the lady who owned them is quite a cat fancier, having from six to ten all the time, giving them their close attention.

Case 3. Primary Mammary Cancer with Metastases.—A few months after the death of the cat in Case 2, a lump was noticed on the breast of another one. The animal had been picked up as a stray kitten eight years before, hence the idea of heredity can be excluded. Knowing that the other cat had had cancer, the lady allowed me to examine this one and gave me the following history: After first noticing the lump, it increased in size and remained hard for a period covering five months when she, thinking it was an abscess, poulticed it and after this it ulcerated and for ten weeks discharged a purulent substance. During this time the cat became much emaciated and after ulceration had begun, seemed to have considerable fever and thirst. Incontinence of urine was present and micturition painful, causing an outcry. The bowels were regular and paroxysms of coughing were noticed. To end her suffering, chloroform was administered. On making an autopsy, I found a hard tumor, the size of a hen's egg, in the left posterior mammary gland lying to the anterior border of the nipple which was not involved. The other mammary glands were somewhat enlarged and hard, as were also the axillary and inguinal glands. A few nodules were found on the peritoneum; the mesenteric glands were enlarged and hard; one nodule the size of a pea was found on the serous surface of the stomach, and numerous nodules on the serous surface of the intestines throughout their entire length. These growths macroscopically, do not seem to extend through to the mucous membrane of the stomach or intestines. The spleen was much enlarged and contained, besides, a number of small nodules, three white masses three centimeters in diameter and about one centimeter in thickness, over which the capsule was tense and glistening. The kidneys were somewhat enlarged and studded with numerous white nodules from five to ten millimeters in diameter to which the capsule was adherent, though otherwise it was free. The cut surface shows also, some white areas in the cortex which

NOTE.—A resumé of the theories regarding the etiology of tumors has here been omitted for lack of space.—[EDITOR.]

do not extend to the capsule. The connective tissue between the kidneys contained a bunch of enlarged glands. The ovaries were examined and found to be diseased; the right containing a small cyst and the left being firm and hard to the touch. The uterus' right horn apparently was normal, but the left contained in the center a lump about the size of a filbert. On opening the thorax, the anterior mediastinal glands were found enlarged and hard. The parietal pericardium contained several small nodules. The heart on the cut surface revealed a nodule three millimeters in diameter in the apex. The lungs were enlarged, completely filling the cavity, but were removed with ease, there being no adhesions. There was scarcely any of the normal lung tissue to be seen on the external surfaces, they being completely filled and covered over with nodules ranging in size from one to ten millimeters. A small area at the apex on each side was free from nodules and was markedly emphysematous. The lungs had, if examined apart from the other viscera, the appearance of miliary tuberculosis, the nodules being hard and shot-like to the touch. They were all under the pleura which showed no signs of inflammation. An examination of the brain was not allowed. However, from what I can learn there were no apparent symptoms of motor or sensory disturbance, the animal retaining its intelligence to the last.

Microscopic Examination.—As the specimens were not obtained until a number of hours after death, the material was only hardened in alcohol and Miller's fluid and was cut by freezing.

Primary Growth.—Sections stained with logwood and examined with low power, showed over the surface a very thin layer of epithelial cells much flattened in appearance and taking a very deep stain, in some places only a fine dark line being visible. Running down from the superficial epithelium are a few hair follicles, sebaceous and sweat glands, the greater number of which are surrounded by a zone of rounded infiltration. Other evidences of inflammation are present, for in the connective tissue lying immediately beneath the epidermis, a large area of granulation tissue occurs in which we see connective tissue fibers and cells, the latter being for the most part fibroblasts and may be seen varying in shape, from round and oval to elongated cells with prolongations. A large number of blood vessels are also found in this area, one being cut lengthwise so it can be traced for about four inches. The capillaries may be easily distinguished from the newly forming vessels by the former containing blood as do nearly all the larger vessels. Below this area we have the fibers forming themselves into a stroma, in some places very delicate with very small alveoli, in others much thicker and the alveoli larger. These all contain epithelial cells of the glandular variety, and many of them are seen to communicate with each other through openings into the stroma which is exceedingly vascular.

The cancer cells present a variety of appearances, some of them being round, others oval and still others cubical in shape; in size many of them might be mistaken for leucocytes, while others are as large as the cells of a squamous epithelioma; in fact, in several places collections of cells are to be seen which, both in shape and arrangement resemble the "bird's nests" of that growth.

The arrangement of the cancerous cells throughout the growth presents as great a variety of appearances, as may be seen in their size and shape. In some parts are found a single layer of cells cubical in shape, nucleated, arranged around an alveolus, and in such a place we find the central portion filled with a delicate homogeneous substance taking a very light stain; in other places the alveoli are packed with cells which seem to have lost their well-defined shape and are round or oval in appearance, some small,

others very large and multinucleated, some presenting the appearance of endogenous cell division.

The blood vessels, instead of being confined to the fibrous stroma, in many places are seen to penetrate it and run in direct contact with the cells. This, our text-books on pathology say, is seldom if ever seen in the carcinomata, they even going so far as to give that as a means of differentiating alveolar sarcoma from carcinoma. Another thing noticeable about the blood vessels is their contents, the white blood corpuscles in some nearly equalling the red in number. One large vessel near the center of the growth contains both red and white corpuscles; outside this vessel wall in the connective tissue are two well-marked areas of infiltration of leucocytes, closely packed together and deeply stained, while red blood corpuscles and a few leucocytes may be seen passing from the vessel to the areas mentioned. In another vessel I find a blood clot which probably was a thrombus. Red and white blood corpuscles are present inside the lumen, the latter massed into the center; among these are some spindle-shaped cells, probably fibroblasts, and the whole is held together by a network of fibrin well seen at the periphery of the clot and attached to one side of the vessel wall. Here there are a few large cells, evidently cancer cells which seem to have invaded the wall and are passing through. In about the center of the specimen, and in all specimens examined in comparatively the same position, we find a large area of degeneration including both the stroma and cancer cells, the former seeming to have been first affected. The connective tissue fibers first assume a swollen cloudy appearance, next the corpuscles are missed, and ultimately the whole framework is lost sight of and we have, in its place, a granular homogeneous material, the exact appearance of granular cloudy swelling.

Where we find the cancer cells just beginning to degenerate, there will be occasionally a nucleus missing; the cells become swollen and cloudy and like the fibers lose their outline and we see the same appearance as in the degenerated stroma. This degeneration very closely resembles hyaline. It does not stain well with logwood but stains much better with aurantia. A number of cysts are present, varying in size, some containing cystic material, others not, and some with a little of the cystic material clinging to the wall. Some of the cysts are round, while others are very irregular in outline.

Lymphatic Glands.—The first examined was the left inguinal glands and as the other present the same appearance only the one will be described. The capsule, for the greater part of the circumference of the gland is not increased in thickness, however, in one portion the fibers seem to have separated and inclose in their network a large number of cancer cells. We also find congestion of the blood vessels in the capsule and in some places clots and well-defined fibrin are present. There is also proliferation of the spindle-shaped fibroblasts. In the gland substance we find the lymph sinuses everywhere invaded by the cancerous stroma containing the same variety of epithelial cells as are met with in the primary growth. In the center of the gland, we here met with the same degeneration as has already been described.

The Lungs.—Beginning at the pleural surface, we find the pleura neither thickened or congested, but immediately under it are numerous cancer nodules which differ but slightly from those already de-

scribed, the main difference lying in the relative amount of stroma and cancer cells; the latter being much more abundant than the former and very densely packed together. A granular *débris* similar to the degeneration described is found here and is not confined to the cancer nodules, but may frequently be seen in the alveoli, in some places entirely filling them. Aside from the cancer nodules, the lungs are found to be in a state of chronic venous congestion. The capillaries are filled with blood, the interalveolar septa thickened, the alveoli here and there containing a few scattered epithelial cells and detritus, in others being entirely filled. Some of these cells are unusually large and lie singly in the middle of an alveolus, while others are small and closely massed together.

Heart.—The heart muscle shows but little change although there is some cloudiness in places. Cancer nodules are found in the apex which are mostly microscopic in size only one being visible to the naked eye while fifteen can be counted in the specimen under examination. These nodules are without doubt the result of a recent invasion. The stroma is delicate, cells stain deeply and may be seen in large numbers infiltrating the heart muscle, the fibers of which are pushed to one side, and in some cases are replaced by cancerous stroma. Another reason for considering this a recent invasion is that there is no sign of degeneration present, but instead a rapid proliferation of tissue.

The question arises, How did this infection of the heart take place? There are three possible ways: 1, from the blood as it passed through the ventricle; 2, by the coronary or nutrient arteries; 3, by the lymph spaces in the serous covering.

The last, I think, is the most probable, as it will be noticed the growths in all the viscera lie immediately under their serous covering.

Intestines.—In the intestines we find the growth in some places directly under the serous coat, and in others between the longitudinal and circular muscle layers, the two having apparently separated to allow the cancer nodule to form there. The description need not be repeated for this specimen is microscopically the same as those already described, the position being the point most worthy of attention. The cancer does not penetrate the circular coat of muscle fibers, however, we find the mucosa considerably altered, possibly from pressure. The villi in some places are absent, in others much diminished in size.

Kidneys.—Nodules are found, for the most part, immediately under the capsule, although microscopic nodules are seen as far as the medullary portion. No description of the cancerous tissue is necessary. The epithelium of the uriniferous tubules is cloudy and so swollen as to nearly fill the lumen. Nuclei are plainly visible. There is some glomerulitis present and Bowman's capsule is in many places thickened.

The Spleen only differed in that the degeneration was more advanced, as might have been expected from the size of the nodules.

The other organs, viz., uterus, pancreas, suprarenals and ovaries will not need description, inasmuch as they are identical with those already described.

The means by which this growth became so generally disseminated was probably by the lymphatics to the nearest lymphatic glands, from them it is easily traced through the thoracic duct to the circulatory

system. It is somewhat strange that the liver entirely escaped inasmuch as it is generally the first one of the viscera to become involved in a carcinoma with remote metastases.

CONCLUSIONS.

1. That the malignant tumors of the human species have their homologue in the lower animals.

2. That we have in Case 3 a scirrhus cancer of the mammary gland, followed by metastatic deposits in the lymphatic glands, lungs, heart, stomach, intestines, uterus, ovaries, kidneys and suprarenal capsules.

3. Inasmuch as inoculation experiments have when practiced on animals of the same species been in a large measure successful, it seems to me that the cat will furnish us a good opportunity of studying and experimenting. If another cat having a cancer can be found, it will be an easy matter to find others to complete the experiments, and inasmuch as the three cases here reported came under observation during a little less than a year's time, one may certainly consider it as not exceedingly rare but that those animals suffering from the disease have simply passed unnoticed.

4. Greater care should be taken by parents and those who have children in charge to see that the animals they play with are free from disease. True, it is said that infection only obtains between those of the same species, still because experiments in this direction have thus far failed, we must not make up our minds that it has been absolutely demonstrated that there is no danger. It certainly is more rational to be on the safe side, at least until it has been actually proven that there is no possibility of infection.

To Dr. Vida A. Latham and Dr. Bertha E. Bush I wish to return most grateful thanks for permission to work in the laboratory and also for their kindly words of suggestion.

SOCIETY PROCEEDINGS.

Chicago Pathological Society.

Regular Monthly Meeting, Oct. 8, 1894.

RANDOLPH N. HALL, President, in the Chair.

DEMONSTRATION OF SPECIMENS.

DR. E. R. LECOUNT—These are some specimens that have been collected from the County Hospital morgue. This specimen of amyloid liver and kidney came from a patient who was very much deformed by some spinal trouble and also had deformed tibiae. The only fact in the clinical history that seemed to have any bearing upon the amyloid disease was a possible rachitis in infancy and this resulting deformity in the bones; there was no tuberculosis in the lungs, no dysentery, and as far as the history showed no syphilis.

This is a slice through the spleen of a patient who died from diffuse tuberculosis. The spleen was very large, weighing about eight hundred and fifty grammes and measuring twenty-one centimeters in its longest diameter. Examina-

tion in the morgue and subsequent microscopic examination of the tissues showed tuberculosis of the lungs, kidneys, spleen and liver, and intestinal tuberculosis as well. This spleen was very interesting, as in the morgue it showed no tuberculosis to the naked eye, but on section there was noticed minute pin-point nodules, the nature of which could not be positively stated, but from the fact that the spleen was so much enlarged and tuberculosis was present in the other organs, being visible to the naked eye in the liver and kidney, it was thought that this might be minute miliary or sub-miliary tuberculosis, and this was confirmed by the microscope.

The section of the liver showing carcinomatous nodules came from a patient who had carcinoma in the stomach and secondary infiltration by direct extension to the pancreas and also this regional metastasis in the liver. In favor of the view that the primary tumor was in the mucous membrane of the stomach, was the fact that adhesions had taken place between the stomach and pancreas at points where the pancreas was not carcinomatous, while the mucous membrane of the stomach was involved at this point, and the mucous membrane was involved to a greater extent than any of the coats of the stomach.

From the patient who was the victim of such a diffuse tuberculosis there was removed this fibroid tumor from the neck. It was perfectly encapsulated, not attached to the trachea or in any way connected with the thyroid gland, lying on the right side of the neck below the ear and easily removed by dissection. Sections were taken from different portions of the tumor because it was supposed that it might prove to be a mixed tumor on account of the varying appearance; certain parts appearing hard, almost cartilaginous in consistency, others soft and apparently edematous, but much to our surprise microscopic examination showed the same histologic structure throughout. The examination of this clinically benign tumor was interesting from the fact that as far as the histologic appearance of the specimens went, one could not say whether the sections were cut from a benign tumor or a malignant tumor of the spindle-celled sarcomatous group. The tumor was lying between the muscles entirely free, that is there was not sufficient attachment to afford any clew as to its originating from surrounding structures. My thanks are due Drs. Walker and McGrew of the house-staff for the privilege of presenting these specimens.

DISCUSSION OF PAPER OF EVA FIELD.

(See page 982.)

DR. G. H. WEAVER.—When I first saw these specimens with Dr. Latham, she spoke to me of the fact of there being more than one case of malignant disease among the cats in the house. The first case proved upon microscopic examination to be sarcoma, this case carcinoma, and there was a third suspicious case in which a hard indurated mass was located in the mammary gland. A number of cats are kept in the house. The rarity of malignant growths in animals has been explained by the fact that they die at an early age as compared to human beings, and on that account the tendency to diseases which occur during or after middle life is not marked. Experiments made so far, do not prove that cancer is contagious or even infectious. Everything done so far has been the transferring of portions of the tumor from one animal to another of the same species, with the result that they have grown. But this is a transplantation of tissue and not necessarily an infection of the animal. These cases on account of several cats being affected in the same house are interesting as suggesting a contagious element.

DR. V. A. LATHAM.—We had another cat from the same house affected by carcinoma of the mammary gland, but we did not get so complete a *post-mortem* as in the case reported. A third case was sarcoma. I have also had a case of epithelioma, with hare-lip in a cat when in the Michigan University. Miss Field looked up the bibliography but she found no recorded case of carcinoma in the cat. Bland Sutton takes up the subject of pigs, fowls and almost every one of the lower animals except the cat. The case here presented, I believe, is the first one of its kind placed on record in this country.

DISCUSSION OF PAPER OF DRS. EARLE AND WEAVER.

(See page 980.)

DR. J. M. DODSON.—I would ask Dr. Weaver if there was anything in the symptoms which might throw light upon the functions of the suprarenal body? Physiologically it seems probable that the suprarenal body is one of the blood-elaborating structures like the thymus gland, and therefore of great physiologic importance, especially in the young. I wondered whether or not in this case, with a tumor

involving that structure, any symptoms appeared which seem indicative of interference with the special function of hematogenesis.

DR. G. H. WEAVER.—So far as I know there was nothing to indicate anything of the kind, but the obstruction to the outflow of bile causing disturbance of the hepatic function was sufficient to mask anything else that might possibly have occurred without that complication. An examination of the blood was made but without anything being found.

MUCINURIA SIMULATING ALBUMINURIA.

DR. J. H. SALISBURY—exhibited a specimen of mucinuria simulating albuminuria, and said: This was the case of the wife of a physician who during pregnancy had edema. An examination of the urine undoubtedly showed albuminuria with a few hyaline and some granular casts. Delivery was made with forceps, and the patient did well, except that there was more or less prostration after delivery. Before delivery there was almost complete loss of sight. I do not know whether there was an ophthalmoscopic examination, but it was understood that there was some affection of the retina. After delivery I examined the urine, and at first I assumed that there was albuminuria, as it responded to all the ordinary tests for albumen, but I noticed a cloud somewhat above the contact line of nitric acid with the urine, that is the cloud reached up higher in the urine than it should for albumen, and I concluded there was also mucin present. I therefore precipitated the mucin with acetic acid and to my surprise found that the clear filtrate gave no reaction for albumen. It is well known that mucin may simulate albumen to the extent of misleading incautious observers, but the cloud is higher up than the one produced by nitric acid and albumen and it does not, so far as I know, give any reaction upon boiling; in fact it is stated in some works that mucin does not react upon boiling. I found, however, that this specimen reacted with nitric acid close to the contact line, and also reacted upon boiling, and yet upon precipitating it with acetic acid and allowing it to stand for twenty-four hours and filtering, I then found no reaction with nitric acid. Recently, attention has been called to the fact that mucin gives this reaction and it has been suggested that it is this mucin reaction which has given rise to the assertion that there is a normal presence of albumen in the urine, and that the numerous cases in which minute quantities of albumen are found in the urine may be due to mistaking mucin for albumen.

DISCUSSION.

DR. J. M. DODSON.—This question of mistaking mucin for albumen is of a good deal of interest to me, for I have known a number of blunders to be made in this matter in life-insurance examinations. I would call especial attention to the value of the under-laying method of using nitric acid as contrasted with the over-laying method. Professor Haines lays especial stress upon this. He called my attention to it not long since, and illustrated it very beautifully in a specimen of urine I was examining. The urine is placed in the test-tube and then the nitric acid is allowed to flow very slowly down the side of the tube. A sufficient degree of acidity is given to the urine above, to dissolve small traces of mucin; then too, after the contact line is formed, as the nitric acid disseminates in the urine, the mucin cloud gradually recedes toward the top of the fluid and disappears. In the specimen of which I speak there were both mucin and albumen. When the nitric acid was first introduced there was the distinct line of the white albumen cloud, which is more opaque in appearance than mucin, and above, at first blending with it, was the more opalescent cloud of mucin. Gradually that opalescent cloud receded toward the top of the liquid, the clearer line of albumen remaining distinct.

DR. J. H. SALISBURY—in closing the discussion, said: The sight has been improved but not completely restored. I should judge that the mucin must be in solution, because I get the reaction after careful filtration and this liquid seems to be entirely clear, so I doubt if the centrifugal machine would remove the mucin that complicates this case. It seems to me the principal point of importance in this case, is that, in case mucin is present if we do not precipitate it by acetic acid and so separate it, we may be in danger of assuming that there is albumen present when there is not. It seems to me that this would be especially important in life-insurance examinations.

DR. DODSON.—Does not that interfere with examination by nitric acid?

DR. SALISBURY.—I think not. Two or three years ago when I was examining a specimen and could not certainly decide whether it was albumin or mucin, Professor Haines advised me to precipitate with acetic acid, let it stand twenty-four

hours, filter and test the filtrate. In that case the cloud was not well marked but in this it was, and I am sure would have deceived nine out of ten observers.

Dr. HALL—Is it not the instruction of Professor Haines in every examination for albumen to add acetic acid to the specimen to be sure that it has an acid reaction?

Dr. SALISBURY—Yes, that is the direction in testing the urine by the heat test, unless it is already acid. If it is, the acetic acid need not be added, and may sometimes be even prejudicial. But in case it is not acid, acetic and not nitric acid should be added before boiling. A subsequent examination of another specimen of urine from this case shows the presence of a small quantity of albumen and of some epithelial and hyaline casts.

DEMONSTRATION OF SURGICAL SPECIMENS.

Dr. J. L. McCULLOM—The first case I have to report is one of intestinal end-to-end approximation. The patient, Mrs. G., 32 years of age, a French Canadian; I was called to see her June 4 by Dr. Hyleman. The history as I obtained it from the Doctor and the family was that the woman while urinating about 5 o'clock in the morning, was taken with severe pain and became unconscious. Her husband found her some time afterward lying upon the floor entirely unconscious. When she came to she began to vomit, and this continued with slight interruptions until the operation. Dr. Hyleman was called in the morning and undertook to give an enema. He introduced a rectal tube about eight inches into the rectum and succeeded in introducing a quart of water, but she continued to vomit. He gave her cathartics and I believe a hypodermic of morphia and some morphia by the mouth. I saw her a week afterward and learned that she had been operated upon two months before by Dr. Newman. Upon examination there was no tympanitis of any consequence, no marked tenderness that would attract attention to any definite locality as the seat of trouble. The diagnosis lay between intestinal obstruction and appendicitis, and we excluded the latter as there was no marked tenderness in McBurney's point. I advised immediate operation as the only possible hope of recovery, consent to which was readily given. We sent her to St. Elizabeth's Hospital and at 7 o'clock were ready to begin the operation. In opening the abdomen I followed the median line of incision. The omentum was everywhere adherent to the peritoneum and very much thickened. I incised the omentum and peritoneum with the scissors in one cut. Immediately upon opening the abdomen a very decided odor of decomposing flesh could be detected, even by those who were not very near the patient. The light was poor and everything had to be done by touch. I found in the left side of the small pelvis a tumor which appeared to fluctuate and was bound down by firm adhesions. By careful manipulation I brought to the surface, after cautiously separating it from its adhesions, a portion of the gut of a dead black color. Although I had not brought a Murphy button, fortunately Dr. Frank had provided the hospital with a set of them, and they were sterilized and ready for use. A ligature was passed at either extremity of the necrosed portion of gut and the necessary omentum quilted off with a double row of lock stitches and eleven and three-fourths inches of gut, together with the omentum included between the two rows of lock stitches excised, and the button inserted and hastily approximated, care being taken that the omental portions should come together. The gut was dropped back into place and a glass drainage tube introduced at the site of the button. The wound was then closed with silk-worm-gut sutures. The next morning the patient was calling for something to eat. We put her on a liquid diet, giving her no morphia until it was time for the button to pass. She occasionally vomited lightly and these attacks grew less and less frequent. On the fifth day she passed wind by the rectum, and on the morning of the seventh day had colicky pains and a slight evacuation of the bowels. We had not expected the button to pass so soon, and an under nurse had been put in attendance on her, but the patient tells me that this seventh morning there were hard masses which she had to get rid of by introducing her finger into the vagina and forcing it out through the rectum. We watched for the button during the three weeks she was in the hospital, but none made its appearance. After forty-eight hours I removed the drainage tube and inserted gauze drainage. After twelve days the sutures were removed. Upon removing the suture at the upper angle of the wound there was a gush of greenish fluid through the opening of the drainage tube. I immediately surmised that we had a fecal fistula and was fearful of the outcome. This continued to discharge for about twelve days, and once or twice some solid feces came through this open-

ing. But finally it ceased to discharge and the opening gradually filled up. On the twenty-second day after the operation the patient went home. In a couple of days I was sent for and found that this fecal fistula had reopened; but after ten days it healed and the woman made an uninterrupted recovery from that time on.

The next case is one of pylorotomy with gastro-enterotomy. In July I was called to see a German, 52 years of age, who had been under the care of different physicians for about a year. He first consulted a physician because he could not retain food but vomited continually. There was a history of more or less pain in the region of the pylorus for more than two or three years. Upon physical examination a well-defined tumor could be made out in the region of the pylorus. I could not get any history of hemorrhage, no coffee ground discharges by the mouth and no tarry evacuation from the bowels. I told him he might get some relief and his life might be prolonged by an operation, but it was questionable. September 1, I received word that he had made arrangements to go to the hospital for an operation. Edema had set in, in his hands and legs, and been gradually increasing for three or four months. I was not positive as to the diagnosis, there not being any hemorrhage, and the pains being rather obscure. The man was anxious for an operation, and after preparing him for several days I performed the operation on September 11, assisted by Drs. Luken, Effa Davis and the internes of the hospital. An incision was made directly over the tumor, which was found to be adherent to the abdominal wall, to the transverse colon, and to the duodenum. It was my opinion that the disturbance was very largely due to pressure upon the portal vein. The man had been reduced from a weight of 170 pounds to a mere skeleton. His pulse was 160 and sometimes even higher. By means of an artery forceps, I succeeded in freeing the tumor from all its adhesions without rupturing the stomach or intestine, Dr. Luken's fingers being used as a clamp to compress the vessels. I removed the tumor and the pyloric end of the stomach and closed the wound with running Czerny-Lembert sutures, making three layers; one for the mucous membrane, one for the muscular layer and one for the peritoneal coat. Having a long Murphy button I had expected to make an approximation without closing the duodenum, but the button was too large for the opening in the bowel, so I closed this and made an anastomosis. The patient died two hours after the operation.

The next specimen is a femur with an exostosis upon the extremity. The patient, Miss S., 16 years of age, a Canadian by birth, gave a history of having been kicked upon the knee a year previously. Some months afterward she thought she had rheumatism and was treated for three months for articular rheumatism by a prominent homeopathist, but failing to benefit her he told the family he did not know what was the matter. Dr. Newman was called in and after seeing the case a few times with him, it came under my care. I advised operation as the patient's life was in jeopardy, and she was sent to St. Elizabeth's Hospital. I cut down upon the tumor at the head of the tibia and found a large mass of sarcomatous tissue. An incision was made two inches above the knee, and the limb amputated; after checking the hemorrhage with hot water the flap contracted so that it was necessary to cut off two more inches from the femur. This operation was done on May 22, and two months afterward she began to have a burning sensation in the angles of the wound. Upon examination I found adhesions to the end of the femur. A month later a sharp protuberance could be felt and I advised another operation, when the remaining portion of the femur was removed. The patient rallied promptly from the operation and was in good spirits for a couple of months, when I was called upon to prescribe for what they considered to be a cold. She was very anemic, and upon examining the chest I found the respiration very shallow and every evidence of an invasion of the lungs by the sarcomatous disease. The symptoms continued to increase until she died of suffocation on January 30, three months after the last operation.

PRIMARY CARCINOMA OF THE PANCREAS.

Dr. D. W. BISHOP—I have here some specimens of primary carcinoma of the head of the pancreas, with secondary metastasis in the duodenum and liver. The specimens were sent to the college by Dr. John B. Hamilton; they were removed by autopsy from a patient at the U. S. Marine-Hospital. The specimen is quite fresh and the sections show remarkably well. They are shown simply as examples of carcinoma of the pancreas with secondary involvement of the other organs. The liver was considerably enlarged, but no measurements were made.

Proceedings of the First Meeting of the American Academy of Railway Surgeons.

Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.

(Continued from page 954.)

During this time a skeleton program was projected and invitations extended to charter applicants in addition to a few others, to participate in the scientific work of the meeting and, with three exceptions, written replies were received and all but two surgeons in their replies, accepted the invitation. But in each instance the replies were received too late to change the program, as it was assumed on the part of the committee that where no objections were raised silence meant consent. Fortunately, however, our program as you will see is so large that the omission of a few from the same will still leave abundance of scientific work.

A galley proof of the program was sent by your committee to the leading medical journals of the United States, the majority of which either published it in full or made a suitable announcement of the meeting.

3. In addition to that, a program was prepared a copy of which, we take it for granted, is in the hands of each applicant for fellowship at this time. A copy of the program together with the following circular was sent to the presidents and managers of the railroads which, up to this time had not responded to the former circular, while a copy of the program without the circular was sent to those who had, in order that those who had replied might see that the committee was carrying out its work in good faith, and those who had not replied could see that the committee was in earnest and working conscientiously in the line proposed by the original circular:

AMERICAN ACADEMY OF RAILWAY SURGEONS.

Office of Chairman Committee on Permanent Organization.

COLUMBUS, OHIO, Oct. 20, 1894.

DEAR SIR:—Please find herewith inclosed the program of the meeting of the American Academy of Railway Surgeons, to be held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.

If you find the program of sufficient merit to warrant your recognition, we will be pleased to have you indicate the same by a letter to the Chairman of this Committee, informing him whether your company will agree to give a limited amount of transportation, provided such is requested through the proper officers of the company by which the surgeon is employed. The amount of transportation necessary for the coming meeting will be very small, as the entire fellowship is limited to not exceed a total of 200 in the United States, Canada and Mexico. An early reply will be greatly appreciated. Very respectfully submitted,

R. HARVEY REED, M.D., Chairman,
Consulting Surgeon B. & O. R. R., Columbus, Ohio.
W. H. ELLIOTT, M. D.,
Chief Surgeon Cent. R. R. of Ga., of Savannah, Ga.
C. K. COLE, M.D.,

Chief Surgeon Montana Central R. R., Helena, Mont.

As a result of these formal interviews with the management we are pleased to report to you that the following railroad companies controlling over 84,000 miles, out of a possible 130,000 miles having railway surgeons in their employ, responded favorably many of whom, as you will see by the letters placed on file elsewhere for your inspection are quite enthusiastic in their support of the proposed organization, provided it is controlled in the manner set forth by the original circular.

List of railway companies from which replies were received together with the mileage of their road:

| Name. | No. of Miles. | Name. | No. of Miles. |
|------------------------------------|---------------|--------------------------------|---------------|
| Allegheny Valley | 259 | K. C. St. J. & C. B. | 314 |
| A. T. & S. F. | 9,320 | Kanawha & Mich. | 167 |
| Baltimore & Ohio | 2,136 | Lake Erie & Western | 720 |
| Boston & Albany | 389 | M. St. P. & S. S. SM. | 1,170 |
| Boston & Maine | 1,294 | New York & New Eng. | 534 |
| B. & M. R. R. in Neb. | 3,421 | N. Y. C. & St. L. | 513 |
| Cent. R. R. of Ga. | 1,384 | N. Y. N. H. & H. | 1,473 |
| Chicago & Alton | 843 | N. Y. O. & W. | 477 |
| Chicago & East. Ill. | 503 | Northern Pacific | 4,494 |
| Chicago & Northwestern | 5,066 | Ore. Ry. & Nav. Co. | 1,066 |
| Chicago B. & C. C. | 195 | Phil. & Reading | 891 |
| C. B. & Q. | 2,175 | Phil. Read. & New Eng. | 181 |
| Chicago & Great Western | 922 | Pitts. Shen. & L. E. | 182 |
| C. R. I. & P. | 3,570 | Plant System | 1,492 |
| C. St. P. M. & Omaha | 1,492 | Queen & Crescent | 1,145 |
| C. A. & C. | 177 | Rio Grande Western | 530 |
| C. C. C. & St. L. | 2,305 | St. A. & T. H. | 240 |
| Cleve. Lorain & Wheel. | 165 | St. L. C. & St. P. | 96 |
| Col. Hock. Val. & Toledo | 326 | St. L. K. & N. W. | 276 |

| | | | |
|--------------------------------|-------|----------------------------------|-------|
| Col. San. & Hocking | 271 | St. Louis Southwestern | 1,227 |
| Del. Lack. & Western | 882 | S. P. Atlantic System | 1,742 |
| Denver & Rio Grande | 1,687 | Southern Ry. Co. | 4,399 |

| K. C. F. S. & M. | 1,192 | West Shore | 512 |
| Mex. Cent. | 1,847 | Wisconsin Cent. | 765 |

84,143

While there are quite a number of railway companies of no mean importance which have not answered to either circular, it is certainly very gratifying to note that without a single instance those who did reply were favorable to the proposed organization, and we are certainly not justified in assuming that those who did not reply were unfavorable.

4. To further assist in the permanent organization and to avoid unnecessary loss of time, Dr. C. K. Cole was requested to draw up a skeleton constitution and by-laws which was submitted to the various members of the committee, as well as others who were interested in this work, from which the Doctor has prepared a constitution which will be submitted to the Fellows of the Academy for adoption, with such alterations or modifications as in the judgment of the majority may be thought wise and prudent.

In entering into a permanent organization of this character, your committee recognized the necessity of allowing every applicant for fellowship the inalienable right of every American citizen to express his views by ballot as to who should be a fellow-member and associate with him in this organization. It was, therefore, thought wise to have the name of every applicant for fellowship placed on a separate slip which may be designated as a ticket, on which are two blanks opposite each name; one for "yes," and one for "no."

It is, therefore, recommended that one of these tickets be given to each formal applicant for fellowship in the proposed Academy, and at the appointed time a ballot be had whereby each applicant will be enabled to vote on every other applicant proposed for the Academy on said ticket. It is further recommended that each member write the word "yes," in the proper column, opposite each name proposed for fellowship, provided he is favorable to the same; and to write the word "no" in the proper column opposite each name of an applicant he is unfavorable to, and that it shall require at least three negative votes to reject an applicant for fellowship in the proposed Academy.

It is also recommended that the ballot be kept as secret as possible, so that no conference be held that will in any way hurt the feelings of any one who may be an honest applicant for admission, and that each ticket be placed in an envelope provided for the same and handed to the tellers whose duty it shall be to open and report the same to the Fellows in session, being careful to keep every ballot on file for reference should such be necessary.

You will observe that we have left it to the applicants for fellowship in the proposed Academy to settle how many negative votes shall be necessary to reject a member, and we would respectfully request you as members of the Association to take proper action upon the same before the ballot is taken. We would also recommend that this ballot be taken immediately following this report, in order that the fellowship of the proposed Academy may be definitely settled and those who have and who have not a right to vote in its proceedings be determined at the earliest possible moment.

It is also recommended by your committee that only those holding charter fellowship certificates, duly signed and numbered, should be entitled to a vote on permanent fellowship in the Academy, that each applicant holding such certificate should be entitled to one vote, and further, that no applicant should be permitted to vote by proxy, but must be in attendance, and when he casts his vote demonstrate his right to cast the same by exhibiting his charter fellowship certificate, which has been furnished every formal applicant for admission to the proposed Academy. If, however, a formal applicant has failed to bring his certificate with him, or has lost it, he can be identified by the roll of formal applications in the hands of the chairman of your committee. But without such identification, it has been thought wise and prudent not to permit such parties to cast a vote. It is also recommended by your committee that immediately after the election of the temporary secretary a roll call of charter members be had, as provided for in the program, and that the said secretary satisfy himself beyond a question that no one is admitted to the executive sessions except those who are formal applicants in the proposed Academy, as it is the firm belief of the committee that this is in the

best interest of the Academy and for the maintenance and promotion of harmony and good fellowship with all concerned.

In closing, the members of your committee beg leave to express their regret at not being able to complete their work more satisfactorily, but at the same time they can assure you that under the circumstances they have tried to do their duty carefully, impartially, conscientiously, and in the interest of the promotion of railway surgery and the railway companies of this continent.

Very respectfully submitted.

R. HARVEY REED, Chairman,

Consulting Surgeon B & O. R. R., Columbus, Ohio.

C. K. COLE, M.D.,

Chief Surgeon Montana Cent. R. R., Helena, Mont.

W. H. ELLIOTT, M.D.,

Chief Surgeon Georgia Cent. R. R., Savannah, Ga.

On motion of Dr. W. H. MEYERS, the report of the Committee on Permanent Organization was received and referred to the Committee on Publication, and the committee discharged.

On motion of Dr. F. H. PECK, Dr. C. K. Cole, Dr. R. Harvey Reed and Dr. F. H. Caldwell, were appointed a Committee on Constitution and By-Laws.

(To be continued.)

CORRESPONDENCE.

Minutes of Ophthalmic Section—A Correction.

DENVER, COL., Dec. 19, 1894.

To the Editor:—In the number of the JOURNAL for September 15, in a report of remarks made by me before the Section on Ophthalmology, which report was published without my knowledge or revision, occurs a passage (page 419, foot of first column) so worded as to be capable of interpretation as a personal reflection on a fellow member of the ASSOCIATION. No such reflection was intended; and I am not aware that any one who heard my remarks so misunderstood them.

My argument would have been better reported thus: "The Congress is not a representative body at all. It does not invite delegates from other associations. It has a different basis of membership. Others prominent in the work of this section intend to be present at the Congress, but it has not occurred to them that delegates should be appointed from this body. Dr. Savage might be as good a delegate as we could find, but we should not appoint delegates merely because it has been suggested to us to do so. To appoint delegates where delegates were not invited would be undignified."

If possible, I should like this correction published in the current volume.

Cordially yours,

EDWARD JACKSON, M.D.

Treatment of Typhoid Fever.

HASELTON, OHIO, Dec. 19, 1894.

To the Editor:—In answer to Dr. A. S. Caldwell, of Freeport, Ill., I should like to report my experience with Dr. Woodbridge's treatment of typhoid fever. I called him in consultation on October 27, last, to see the wife of a brother physician, who had been sick ten days with typhoid fever. The pulse was 120; her temperature was 104.5; rose spots abundant, marked tenderness in right iliac fossa, with enormous tympanitic distension. Her nervous symptoms were very bad; in fact, it was a typical and severe case of typhoid fever, with a feeble breath and a pulse which became dicrotic. I heard Dr. Woodbridge say in answer to the husband's anxious inquiries that he did not consider her in as much danger as he would a well person, taking the ordinary risks of out-door life. Her temperature went to normal on the tenth day of treatment and never rose above normal after that day.

I heard Dr. Woodbridge give equally remarkable prognoses in two other cases in the same family, both of which were verified by the results, both cases being cured in less than ten days.

I have since treated cases of typhoid fever by this method, without consultation, with equally wonderful results. It seems to me that the most remarkable thing about Dr. Woodbridge's treatment is the rapidity with which patients regain their strength and vigor after the temperature touches normal.

J. H. BENNETT, M.D.

BOOK NOTICES.

Weekly Medical Review, Pocket Reference Book and Visiting List. Perpetual. St. Louis: J. H. Chambers & Co. 1895.

A useful annual, handy and convenient.

The Sympathetic Nervous System. A Chart. By BYRON ROBINSON, M.D. Chicago: E. H. Colegrove & Co.

This useful chart represents the careful and accurate dissection of the ganglia and trunks of the great sympathetic nerves. A numbered index in the margin gives the names of the parts displayed. The pelvic plexus has been very carefully dissected and deserves especial commendation.

Obstetric Surgery. By EGBERT H. GRANDIN, M.D., Obstetric Surgeon to the New York Maternity Hospital, Gynecologist to the French Hospital, etc.; and GEORGE W. JARMAN, M.D., Obstetric Surgeon to the New York Maternity Hospital, Gynecologist to the Cancer Hospital, etc.; with 85 illustrations in the Text and Fifteen full-page Photographic Plates. Royal octavo, 220 pages. Extra cloth, \$2.50, net. Philadelphia: The F. A. Davis Co., Publishers, 1914 and 1916 Cherry Street.

This timely volume is elaborately illustrated, and gives a clear description of the modern obstetric operations. The titles are as follows:

Obstetric Asepsis and Antisepsis (Introduction). Chapter I, Obstetric Dystocia and Its Determination; II, Artificial Abortion and the Induction of Premature Labor; III, The Forceps; IV, Version; V, Symphyseotomy; VI, Cæsarean Section; VII, Embryotomy; VIII, Surgery of the Puerperium; IX, Ectopic Gestation.

This book gives in moderate compass the details of applied principles of aseptic obstetric surgery. It is carefully written and we commend its perusal to our readers.

A System of Legal Medicine. By ALLAN McLANE HAMILTON, M.D., and LAWRENCE GODKIN, Esq. With the Collaboration of James F. Babcock, Esq.; Lewis Balch, M.D.; Judge S. E. Baldwin; Louis E. Binsse, Esq.; C. F. Bishop, Esq.; N. T. Bristow, M.D.; B. F. Cardozo, Esq.; C. G. Chaddock, M.D.; A. F. Currier, M.D.; C. L. Dana, M.D.; G. R. Fowler, M.D.; W. T. Gibb, M.D.; W. S. Haines, M.D.; F. A. Harris, M.D.; W. A. Hornblower, Esq.; Chas. Jewett, M.D.; P. C. Knapp, M.D.; R. C. McMurtrie, Esq.; C. K. Mills, M.D.; J. E. Parsons, Esq.; C. E. Pellew; E. M. Judge; C. E. Pratt; W. A. Purrington, Esq.; B. Sachs, M.D.; F. R. Sturgis, M.D.; Brandreth Symonds, M.D.; V. C. Vaughan, M.D. Illustrated. Pp. 738. Vol. II. New York: E. B. Treat (5 Cooper Union). 1894.

We have already expressed our high estimate of the first volume of this work, and we can only reiterate what we then said, as applying equally to the volume under consideration.

The volume opens with a paper by Mr. Hornblower on the Duties and Responsibilities of Medical Experts; then follow II, Insanity in its Medico-Legal Bearings, by Allen McLane Hamilton; III, Mental Responsibility of the Insane in Civil Cases, by Judge Pratt; IV, Insanity and Crime, by B. Sachs; V, On the Relations of Mental Defect and Disease to Criminal Responsibility, by L. E. Binsse; VI, Aphasia and other Affections of Speech, by C. K. Mills; VII, The Effects of Electric Currents of High Power upon the Human Body, by Allan McLane Hamilton and G. DeF. Smith; VIII

Accident Cases, by Lawrence Godkin; IX, Mental Distress as an Element of Damage in Cases to Recover for Personal Injuries, by Jno. E. Parsons; X, Feigned Diseases of the Mind and Nervous System, by Philip C. Knapp; XI, Birth, Sex, Pregnancy and Delivery, by A. F. Currier; XII, Abortion and Infanticide, by Chas. Jewett; XIII, Genito-Urinary and Venereal Affections in their Medico-Legal Relations, by F. R. Sturgis; XIV, Marriage and Divorce, by S. E. Baldwin; XV, Sexual Crimes, by C. G. Chaddock; and XVI, Surgical Malpractice, by G. R. Fowler. There is also an appendix giving extracts from the laws of the different States and Territories of the United States which relate to the care of the insane.

One of the most interesting of the many instructive chapters is that on the effects of electric currents. The cases are cited of the criminals electrocuted in New York, and Hamilton says:

"This case and another quite recently reported in France by Arsonval, raise a grave question of how electricity kills; and whether the production of asphyxia is not what really takes place. The subject of the French case was a workman who received 5,000 volts (!) in some way and was restored to life by artificial respiration and other means. Again and again, cases 'struck' by lightning have, though apparently some time dead, been resuscitated, and it certainly is a grave question whether *post-mortem* examinations should not always be delayed until the matter of death is indisputably settled."—The article on surgical malpractice should be read by every surgeon.

Higher Medical Education; the True Interest of the Public and the Profession. By WILLIAM PEPPER, M.D., LL.D. Philadelphia: J. B. Lippincott & Co. 1894. Price \$1.

In this volume of one hundred closely printed pages, are included two addresses by Professor Pepper. The first was delivered in 1877, at the opening of the one hundred and twelfth course of lectures in the medical department of the University of Pennsylvania. It presented the position of medical teaching in America at that time, pointed out its chief defects and indicated the causes which led to them and the evils to which they in turn gave rise. In the appendix to this lecture, a statement was made giving the requirements of the systems of medical education in foreign countries.

The second address was delivered sixteen years later, in October, 1893, and the occasion was again at the opening of the annual course of lectures. This time the course had been extended to four years, Professor Pepper mentioning with just pride the great advances that have taken place in the system of teaching since his previous lecture. He has the right to feel proud of its accomplishments. He justly concludes as follows:

"I have told you at great length the story of the recent changes in medical education; of the way in which we have tried to secure the reforms recognized as necessary, of the admirable results already secured in the increased renown and prosperity brought to the University, and in the gratifying success and position of our graduates. When we reflect that not at the University of Pennsylvania alone, to which I have limited my remarks, but in many other institutions, the same righteous effort for sound learning and higher education is being made and is meeting with a like encouraging appreciation, it is a proud thought that in this Columbian year we may invite attention, not only to our vast material prosperity, but to the splendid development of our educational resources; to the rapid elevation of our standards, and to the pure intellectual life so strongly fostered in many great centers as it is in this venerable University.

"We have stood on that bridge that spans the lagoon in Jackson Park and have realized, as we gazed to the right, to the left, or ahead through the stately peristyle to the great lake beyond, that we were surrounded by such triumphs of art as not even Athens, in the golden age of Pericles and Phidias, could display. That one scene will pass, its purpose having been effected; but the impression it has produced will never pass away. It has introduced a new

standard; it has furnished a new inspiration; it has shown the astonished world that the fifth act of the world's great drama of empire, as sung by Berkeley, opens on no sordid scene, but on one whose noble ideals and noble opportunities await Time's noblest offspring. And to us who labor here in the departments of this great University, consecrated by the memories of the good and the wise who have lived here, consecrated also by the thousands of pure, high-minded youth who throng her halls, to us this year more clearly than before a vision arises of what she shall come to be, a vision as of temples not built with hands, where Truth shall dwell forever, and from whose glittering portals shall go out to all parts of the world knowledge for the healing of the nations."

NECROLOGY.

DR. OERTEL.—The death of Dr. Oergel, an assistant in the Hamburg Institute of Hygiene, is reported in the *Deutsche Medicinische Wochenschrift*, October 15, and was briefly noticed at the time in this journal. This was a sad case, the cause having been Asiatic cholera probably from laboratory infection. There is no positive evidence as to the manner in which the infection was accomplished, but he was daily engaged in cholera work. This is sufficient in the view of some to account for the event, but others have pointed out that Dr. Oergel may have gone counter to the rules of the laboratory. For example, some time before his death it was reported that he had been experimenting on himself with certain cholera-like vibrios from the water of the River Elbe. When he became ill he was asked whether he had to his own knowledge experimented with cholera germs also. His reply was not determinate; he said he would not have ventured to do anything of that kind, during the absence of Professor Dunbar, whose duties he, Dr. Oergel, had been detailed to perform. The attack was an excessively severe one, as judged by the very complete history of symptoms and treatment, so that there can be little doubt but that the disease was cholera asiatica, most likely contracted accidentally while handling the cultures of the bacillus of that disease in the laboratory.

The victim was yet a young man, having been born in 1864. He was for a time at Greifswald, as an assistant to Professor Löffler, but in June of last year he accepted an appointment at the Hamburg Institute. He was a man of marked ability, admirably adapted to the work of his choice, and highly esteemed by his colleagues.

DR. GEORGE A. PETERS, of New York City, who died December 6, was one of the consulting surgeons to the New York and St. Luke's Hospitals, positions that mark their holder as being of senatorial rank in his profession. Dr. Peters was the son of a clergyman. He took his degree in 1846 at the College of Physicians and Surgeons, N. Y., so that he was not far from entering upon his fiftieth year of practice in upper New York. He was not a frequent writer, but he has left behind him a valuable essay on acupuncture. He had been long connected with the Academy of Medicine, and an office-bearer therein. He was a member of numerous societies and a valued consultant to several other institutions besides the two above mentioned.

C. A. Brooks, M.D., of Americus, Ga., December 17.—W. A. Morton, M.D., of Liberty, Mo., December 10, aged 82.—J. T. McPherson, of Cambridge, Ohio, December 15, aged 70. A. B. Smith, of Geneva, N. Y., December 18, aged 75.—Dr. Foster, of Iowa Falls, Iowa, December 14.

The Manhattan Dispensary of New York.—The will of the late Mr. Hood Wright, of the old banking house of Drexel, Morgan & Co., gives to that institution the residue after certain specific bequests have been paid, and of this residue, the sum of \$100,000 is to be set apart as a building fund.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, DECEMBER 29, 1894.

THE SANITARY INQUIRY AS TO TENEMENT-
HOUSES IN NEW YORK CITY.

A Commission, appointed by the Governor of the State at the instance of the last Legislature, has been engaged on an investigation of the evils of the tenement-house system in New York City. Public hearings have been had, from time to time, for several months. At a recent meeting it was shown that money-taking—proved conclusively to have been the order of the day in other departments—was not foreign to certain Tammany-appointed officers of the Department of Health. It was stated that one officer, concerned in the inspection of tenement-houses, stooped to take blackmail from a little boy who wanted to keep a few pigeons at his place of residence. Another case, lately brought to light, showed the "tenderloin instincts;" it was that of a poor woman, who was keeping a cow under conditions contrary to the sanitary ordinances. Her testimony showed that she had thrice paid money to an alleged officer or officers of the Board of Health, to induce him or them to shield her from complaints against the cow; and her money had, in fact, bought "protection" for quite a while.

Testimony has been received by this Commission to the effect that the tenement-house rentals in New York are about twice as high as those of London. For example, on the "East Side" of New York, the average monthly rent paid for three rooms is \$11.43; for two rooms \$7.86 and for one room \$5.04. Another set of figures, deduced from a canvass of six hundred families, also on the "East Side," places the weekly wage earned by those families that occupy four rooms at \$16.50; three rooms, \$11.99; two rooms, \$10.90; the occupiers of single rooms receive about \$8.50 per

week. So that it may be roughly stated that a fourth or a fifth part of such wages goes to the landlord. Not a few of the landlords are wofully remiss as to taking care of this class of property. In fact, a large percentage of them resist all orders for sanitary repairs until after prosecution in the courts puts a compulsion upon them. It is a felt want in New York to obtain by legislation larger powers for the municipal authorities in order to a condemnation and vacation of tenements, whose owners are wilfully neglectful of their tenants' sanitary needs. Report, to this effect, will be made by the Tenement-House Commission to the Legislature, soon to convene.

The work that has been accomplished for Dublin, in respect of a material reduction of its death rate, is claimed by SIR CHARLES CAMERON, M.D., to have been the result, in no small measure, of the systematic condemnations and vacations of fever-nests and tenement rookeries, many of which are ancient and dishonorable, dilapidated beyond redemption. The power to distenant these Dublin domiciles was obtained through special dispensation by the Local Government Board, in order to enable DR. CAMERON to make the attempt to stamp out the endemic typhus fever of Ireland's capital. The recently published experience of Dublin¹ will be ammunition for our American cities, which have unwholesome old structures that are too old and frail to warrant a bill for repairs.

One of the witnesses before the New York Commission, SANITARY ENGINEER WINGATE, testified to his belief that there should be more frequent and systematic inspection of tenement-houses, that the corps of inspectors should be much more numerous than it is, and that this corps should be composed of a higher grade of intelligence. The most desirable men can not get appointments under a Board that has been Tammanized for years. Political misrule has compelled some of the best employés to resign, and has tainted, with a few exceptions, the system of appointments, promotions and removals. Tammany Hall has, it is true, been "downed" this year, but it may be many years before its baleful influence in sanitary affairs can be nullified. One of the reforms that needs instant proposition is that which will make it possible for a medical man to be placed at the head of the New York Health Department. A plumber or a stock-broker may, under existing laws, be its president, but the medical man is specifically ostracized in that regard.

One of the proposed amendments to the tenement-house laws is one that will forbid the construction of houses, arranged for four families on a floor, on lots that are not more than twenty-five feet wide. Another means of relief in overcrowded sections will be advanced, namely, the tearing down of buildings

¹ See page 562 of this JOURNAL for Oct. 6, 1894.

that are unfit for human habitation, and the creation of small parks in their stead; it has been recommended also that these small parks should be laid out around the public schools, for the double benefit to both neighborhoods and schools.

So rapidly as the clutch of the ward heeler can be loosed from the neck of New York City, in that proportion may be expected a purification of the tenements; and this purification will redound to the perpetuity of our American government. For, as some one has said: "Scratch a tenement-house dweller and you find an Anarchist," or the material for one. The houses that have little light and impure air are the recruiting ground "for the ranks of the socialists and anarchists. Social discontent is bred in overcrowded tenements, and these stifling places may become the incubators of mobocracy. Give the people a chance to breathe, and they will gain in tone, both physical, psychical and political." And the REV. DR. PARKHURST has recently pointed out that the polyglot populations of lower New York are not so blind to their true interests as many have believed. He says that "one of the most interesting and surprising lessons of the recent upheaval is the impression that has been made on the masses; the change of sentiment in this respect in the eastern and southeastern portions of the town during the last year is simply phenomenal." These people are poor citizens, not because they are vicious, but because they have had no opportunity to learn where their higher interests lay, and because they have seen corruption and perjury, during the rule of the bosses, "take all the honors," especially among the police and the courts of justice, so-called. Now it should not be forgotten, in this connection, that the president of the police force is an ex-officio member of the Board of Health, and appointed in the old partisan way.

INCREASE OF THE MEDICAL STUDENT CLASS.

Through the courtesy of the Deans and Registrars of 98 out of the 117 existing regular medical colleges in the United States and Canada, the JOURNAL is enabled to present some interesting data concerning the growth of medical colleges in general, and especially concerning their increasing classes. Since many of the returns were made early in November and before the enrollment was completed, the figures herewith given are below rather than above the exact numbers. Another source of incompleteness also exists in the fact that no note has been taken of newly-organized institutions; in order to institute comparisons, the colleges invited to furnish returns were limited to those listed in the last Report on Medical Education of the Illinois State Board of Health—that dated Jan. 1, 1893, and dealing with 117 institutions which gave graduating courses in 1892.

As already indicated, ninety-eight of these institu-

tions have transmitted to the JOURNAL returns of the total number of students and of the numbers in each grade in attendance upon the current sessions and upon previous sessions covering a period, in many cases, of five years. These returns, with the comments of the reporters, will be published *in extenso* in a future number of the JOURNAL; meanwhile, the following summary statement should serve to drive the iron still deeper into the collective soul of our British brethren, who are bitterly bewailing the decadence of the medical student class, and the consequent diminishing output of medical practitioners, in the United Kingdom.

In 1892 these 98 colleges reported a total of 15,330 students out of a grand total of 18,340 in attendance at the entire 117 colleges; that is, the 98 colleges now reporting for 1893 and 1894 had 83.5 per cent. of the total attendance of 1892. For 1893 they report an attendance of 16,267, and for 1894 an attendance of 17,701. On the same basis of 83.5 per cent., the total attendance in 1893 was 19,481, and for the current sessions the total attendance is 21,186. As before remarked, this latter number will be increased on the completion of the enrollment. The percentages of increase are 6.2 for 1893 and 8.7 for 1894, and the average annual increase since 1881 has been 8 per cent., or an aggregate increase of 104 per cent. in thirteen years.

It is a little difficult to compare these figures with those of the medical schools of the United Kingdom, since the only data at hand are those contained in SIR RICHARD QUAIN'S address as President of the General Council of Medical Education and Registration at the beginning of its winter session, Nov. 27, 1894. In a table, compiled by DR. QUAIN, showing the number of medical students registered in the three divisions of the United Kingdom in the four last quinquennial periods, the following figures are given: 1874-78, total 7,540; 1879-83, total 9,931; 1884-88, total 9,604; 1889-93, total 8,696. If it be assumed that one-fifth of any one of these quinquennial totals were in attendance during any given year of the respective quinquennium, then there were only 1,739 registered students in 1893 and there had been a loss of 14.2 per cent. during the preceding ten years. But the stars and stripes—*pace* OLIVER WENDELL HOLMES—waved over a 99 per cent. increase in the same period, and the American eagle screams with delight to see an aggregate of more than 20,000 neophytes in the Temples of Esculapius during the current year.

Nor do our French *confrères* make a much better showing than the English. According to PROFESSOR BROUARDEL, Dean of the Paris Faculty of Medicine, made at the November meeting of the Council of the Academy, the total number of students inscribed on the books for 1894 is only 5,144—and of this number

1,002 are foreigners; largely, no doubt, from this country. Paris is, in effect, France; but even Greater New York is not the United States. And yet the New York medical schools to-day have an enrollment of more than 2,500 regulars and some 300 irregulars, as against the enrollment of Paris with one-fourth more population.

Congress may put tariffs up or down, or abolish them entirely; may threaten currency legislation, or railroad-pooling bills, or any other device for or against the industrial prosperity of the nation. But here is one American infant industry that thrives apace and asks for no protection. What the struggling practitioner in the already over-crowded ranks thinks of it belongs in another category.

THE ANTITOXIN OF DIPHTHERIA AT NEW YORK CITY—COST OF PLANT.

It is reported that the young medical men attached to the Board of Health of New York are bearing the expenses of the present antitoxin experiments from their own purses. They, some months ago, duly made application for an appropriation of the city's funds for the purpose, but they were denied. It is possible that money may be voted by the authorities after New Year's Day. The sum asked for and refused was \$27,000; it is computed to be none too much to enable any Department of Health to maintain a station with fifty horses for one year. The first half-year mainly is preparatory, and non-productive of the remedy; although this period of delay may be reduced by certain proposed changes in the maturing of the product. The following is an estimate that has been published in New York. It may be interesting to readers in other places, where it is proposed to establish antitoxin stables. The average monthly cost for a stable, having fifty horses under cultivation, will be during the first year about \$2,300. The average cost per horse, during the first non-productive half-year, will not be far from \$290; in the second half-year about \$250. This shows an expense account that will deter some from rushing into the field. It is already apparent that certain people are offering an immature and hurtful (because valueless) product. *Caveat emptor* must be the motto of the profession, just now.

This statement is intended to show: 1, the approximate cost of preparing fifty horses so as to render the latter available for the production of antitoxin. The period which will be necessary to effect this preparation is estimated to be about five months:

| | |
|--|----------|
| Cost of horse | \$40 |
| Cost of keeping horse (per month \$25) five months | 125 |
| Total | \$165 |
| Cost of fifty horses (each \$165) | \$8,250 |
| One veterinarian, five months (\$100 per month) | 500 |
| Two experts, five months (\$150 per month) | 1,500 |
| One helper, five months (\$45 per month) | 225 |
| Apparatus | 1,500 |
| Total | \$12,075 |

At the end of the five months the following expenses will be necessary:

| | |
|---|---------|
| Fifty horses (stabling, \$25) | \$1,250 |
| Two experts (\$150 each) | 300 |
| One helper | 65 |
| Apparatus | 100 |
| Loss on horses | 250 |
| Total | \$1,965 |

It is estimated that each horse will produce sufficient serum to treat about fifteen cases per month. This is a conservative estimate, which would be for the 50 horses 750 cases per month. In other words, 50 horses would produce about 2,500 doses per month.

THE DOCTORS MOST OF ALL.

Referring to the public movement in this country in favor of good roads, the *Journal of Commerce* says that it is a mistake to suppose that only farmers are concerned in the movement for good roads. "City merchants and manufacturers," says the *Journal*, "who depend largely on the country for their patronage, are also interested, and ought to join the movement."

We might add, with much force the assertion, that the country doctor, and as well those doctors engaged in suburban practice, are as much interested as the farmers; indeed, four-fifths of the time given to practice is taken up in driving from house to house. It is therefore clear that no single class of our citizens, is more interested than the doctor, and when we consider that much of his travel is done at night, it is apparent that the doctor needs good roads more than any other. The whole profession therefore should use its powerful influence in support of all reasonable legislative enactments in favor of good roads. It is a mistake to allow such a wise and advantageous measure to drift into the custody of mere partisans or cranks, and physicians everywhere, having influence with legislators, should throw that influence in favor of this movement, for the doctor most of any, is interested.

HOSPITAL APPOINTMENTS.

Physicians in this country so commonly serve without salary or hope of reward on the staffs of our large hospitals, that it is only fair, that when a change is to be made, the Medical Board should be consulted.

A recent case in Philadelphia where a well-known physician, (DR. JUDSON DALAND) was summarily removed, without notice to himself or his colleagues on the staff, brings the matter once more to the surface.

It is greatly to the credit of the new appointee (DR. HOBART A. HARE) that he very properly and promptly declined to accept the appointment, which although complimentary to himself, he could not accept without seeming to acquiesce in the reflection cast upon his predecessor. Newspaper statements, unsustained by any investigations, reflecting upon DR. DALAND, were published after his removal, thus

adding a positive injury to the moral grievance sustained by the removed physician.

DR. HARE in thus acting up to the motto, *noblesse oblige*, has given the lay members of the hospital board a needed and useful lesson.

PUBLIC HEALTH.

Leper Home at Jerusalem.—A Moravian institution has long existed at the Holy city, for lepers. Its last annual report shows that the year was begun with twenty-eight patients, an increase of four; of these sixteen were males and twelve females. Two of them have been at the Home not less than twenty years. Six deaths occurred in the year, some of them from causes, as apoplexy, that were intercurrent with leprosy rather than secondary to it. The inmates are given light work to do, and when they consent to it, they appear to do much better physically than when they remain unemployed.

Improving Health Conditions.—In the closing week of December the reports of JOURNAL correspondents indicate a generally improving condition of the public health as compared with the month of November and with the first ten days of the present month. Although there has been some increase of smallpox since the beginning of colder weather, its anticipated epidemic spread has not taken place; on the contrary, there has been a decrease in the number of new cases in the two chief centers, Chicago and Milwaukee, as compared with November. On the 26th inst. there were 46 cases remaining in the Chicago Municipal Hospital, as against 64 on the corresponding date of the previous month; and for the same date there were 83 cases in Milwaukee—35 in hospital and 48 in homes—as against 106 in November. A similar decrease is noted in other localities. The reports also indicate a diminishing prevalence of diphtheria and typhoid fever toward the close of the month, but an increase of the death rate from pulmonary diseases, and especially from phthisis. This increase, however, does not swell the general death rate, and the closing days of 1894 show a condition of the public health which should be highly gratifying to the sanitarian, at least.

The Therapeutic Sensation of 1894.—There is nothing of scientific importance to be added to the record of the diphtheria antitoxin—the therapeutic sensation of the year now drawing to its close. Dr. Hausemann's threatened demolition of its claims proved to be a lame and impotent attack, whatever force it might have had being more than offset by Professor Virchow's own statements at a subsequent meeting of the Berlin Medical Society. Hausemann, it will be remembered, is Virchow's assistant, and it was generally believed in Berlin that the attack was made at the instigation of the Professor. But Virchow himself has now indorsed the results of the diphtheria antitoxin treatment begun last March in the Kaiser and Kaiserin Friedrich Hospital, the figures of which are as follows: In the whole space of time 533 cases were treated—303 with the serum, 230 without; the former had a death rate of 13.2 per cent., the latter of 47.8 per cent. After an analysis and summing up of the results, Virchow said he held it to be the duty of every doctor to use the serum in diphtheria. "All theoretical considerations," he added, "must give way to the brute force of these figures." He, nevertheless, pronounced the current theory of antitoxin therapeutics a fallacy, and, while recommending the serum, to which he emphatically attributes a high therapeutic value, he insists that its theoretical explanation must be left to the future.

Phenomenally Hot Years.—The recent mild winter weather in this country somewhat breaks the force for us of the contrast which the *Journal d'Hygiene* endeavors to make in furnishing a list of phenomenally hot years as "agreeable reading now that cold weather is at hand." Among the most remarkable of these torrid years, all of which had serious effects on the public health, may be mentioned A.D. 738 when the heat was so great throughout Europe and especially in France, that nearly all the springs dried up and thousands perished of thirst. In 879 reapers who staid in the field after midday fell dead in great numbers. In 990 nearly all fruits dried up, occasioning a great famine and an enormous mortality. In the year 1000, amidst panic fears about the end of the world, the river sources dried up and vast numbers of fish putrified, giving rise to a general epidemic; it was widely believed that the end of the world by fire was at hand. In 1132 rivers and springs again dried up and the bed of the Rhine became a dry sandy road. In 1182 the sand was so heated that eggs were cooked in it in a few minutes. The Seine, Loire, Rhine and Danube could be passed over dry-shod in 1303. All fruits withered and animals dropped dead from the excessive heat of 1393. Four years of great heat and continuous dryness, from 1538 to 1541, caused many rivers to disappear entirely, crops were failures and famine and sickness carried off large numbers. There were fifty-eight consecutive days of extraordinary heat in 1646. There was no rain from April to October in 1710; the Reaumur thermometer marked over 36 degrees; in gardens which could be irrigated fruit ripened twice. In 1818 the theaters of Paris were closed for a month on account of the heat; the thermometer marked over 38 degrees R. During June and July, 1830, the centigrade thermometers registered over 38 degrees in Paris in the afternoons.

Circular of Information Regarding Scarlet Fever.—The following is a portion of a circular of information recently published by the Brooklyn Department of Health:

"Scarlet fever, sometimes called scarlatina or scarlet rash is a highly contagious disease, and may spread rapidly from person to person through contact or by means of books, papers, toys and articles of clothing. A patient suffering from this disease should be placed apart from the rest of the family, in a sunny and well-ventilated room, free from all unnecessary furniture and hangings, and, as nearly as possible, should be nursed by one person. Members of the family should avoid mingling with other people, and visitors, especially children, should not be admitted to the infected house. The scales from the skin are dangerous sources of infection, and during the period of peeling, the person of the patient should be sponged daily with soap and warm water. Discharges from the nose and mouth should be received on pieces of cloth, which should be burned or disinfected before removal from the sick room.

"Bed linen and underclothing, before removal from the sick room, should be placed for an hour in a solution of carbolic acid, in proportion of one pint of acid to four gallons of water. This solution is poisonous. The clothes should then be boiled in water. In no case should infected clothing be sent to a laundry.

"After recovery or death, the sick room and its contents should be thoroughly disinfected by the Department of Health or under the direction of the family physician, in the following manner: The walls, ceiling and woodwork should be rubbed with dry cloths, which should be burned without being shaken. The floor should be scrubbed with soft soap and the above mentioned carbolic solution. The room should then be fumigated with burning sulphur, 3 pounds to 1,000 cubic feet of space, for eight hours, care being taken to close the room tightly, and freely expose all woolen clothing, car-

pets, mattresses, etc., and to have steam in the room before lighting the sulphur. Books, papers and toys should be destroyed by burning. The Department of Health is now prepared to disinfect according to the latest improved methods, free of cost."

SOCIETY NEWS.

Association of Erie Railway Surgeons.—The Association of Erie Railway Surgeons will hold their annual meeting in Youngstown, Ohio, Jan. 10, 1895, under the Presidency of E. Griswold, M.D. The following papers are on the program:

The use of Alcohol in Traumatic Surgery, by Clayton M. Daniels, M.D., Buffalo, N. Y., ex-President Association of Erie Railway Surgeons.

Immobilization vs. Passive Motion in the Treatment of Injuries to the Joints, by Prof. R. Harvey Reed, M.D., Cleveland, Ohio.

Potts' Fracture and its Treatment, by Prof. C. B. Parker, M.D., Cleveland, Ohio.

Traumatism of the Ear, by R. Sayre Harnden, M.D., ex-President Association of Erie Railway Surgeons, Waverly, N. Y.

Delayed Union and Pseudo Arthrosis, by Wm. H. Buechner, M.D., Cleveland, Ohio.

Relations of Railway Surgeons to Claim Department, by W. E. Talcott, Special Claim Agent, N. Y., P. & O. R. R., Cleveland, Ohio.

The Treatment of Injuries to Fingers, by Prof. Webb J. Kelly, M.D., Galion, Ohio.

After 20 Years' Experience with Ether and Chloroform, by Henry Flood, M.D., Elmira, N. Y.

A Case of Sphacelus of Leg and Gangrene of Thigh and Inguinal Region, with remarks by E. Griswold, M.D., Vice-President, Sharon, Pa.

Some Reasons why we should have, and some of the Objections met with in organizing a Hospital System, by Emery H. Leyman, M.D., Huntington, Ind.

Tension, by S. B. Hiner, M.D., Lima, Ohio.

Opportunities of the Railroad Surgeon, by F. D. Bain, M.D., Kenton, Ohio.

MISCELLANY.

The Hartford Hospital.—Under the will of the late Henry Keney, of Hartford, Conn., the hospital of that city will receive \$50,000, also a share in a contingent remainder.

Some Curious Statistics.—A writer in the Lyons *Medical Gazette* has calculated that a man at 50 years of age has worked 156,000 hours; has slept 144,000 hours; has amused himself 96,000 hours; and has been sick 12,000 hours. During this period he will have walked 19,000 kilometers and eaten 36,000 meals, including 7,000 kilos of meat, 1,800 kilos of fish, eggs and vegetables and 4,200 liters of different kinds of liquids. Apparently they don't eat three meals a day in France and 30,000 hours of an existence of 50 years are passed in a state of Nirvana.

Goutre in Asia.—In some parts of Central Asia, goitre is extraordinarily prevalent, it being estimated that over 75 per cent. of the men are thus affected, and the prevalence of the disease is attributed to the bad water. The natives account for its origin as follows: A holy man of Khotan, named Sala Paikhumber, once went to the village of Posgam on his camel; he slept there in a cave, and, on awaking one morning, found his camel gone. Upon inquiry he found some of the people of the village had killed and eaten it, whereupon he cursed them and prayed to Allah that all the inhabitants of Posgam should have huge lumpy throats like the camel they had eaten.

A Japanese Hospital.—An American officer, now on duty at the seat of war in the East, has written home an account of his visit to an Army hospital at Nagasaki. The following is part of his report, the whole going to show that the Japa-

nese have a remarkable faculty for the selection of "the best," when they go abroad to learn what Europe and America are doing:

"The hospital was the admiration of the French and English surgeons, as well as our own. The medical staff were all Japanese, who had graduated in medicine and surgery either in America or England, then taken a post-graduate surgical course in clinics at the Paris and Berlin hospitals. They had the best modern instruments and systems, the newest antiseptics—everything a hospital on modern lines should have. And all this is the work of a generation. Truly the Japanese is a wonderful man."

Abdominal Palpation of Obese Women.—Dr. Harris Slocum has written, in the *Philadelphia Polyclinic*, on a new method of examination of very stout females. He has found a narrow zone on the abdominal walls where the fat in the muscular layer is deposited to a less extent than at other points. He describes this as a depressed curved line running from one anterior spine to the other, with its convexity toward the mons veneris. Along and near this line little fat is lodged. By depressing the finger tips the pelvic organs may be felt, the fat about the navel and below the zone being pushed out of the way by the pressure of the hand. In this way, he says, an effective palpation may be obtained even in the most obese. He has had a satisfactory experience with it, personally, beyond that which had formerly been possible by palpation over the abdomen at large. The method can not be carried out when there is much gaseous distension of the intestines, or when the dress is tight.

Guaiaicol in the Treatment of Orchitis.—Balzer and Lacour have communicated to the Hospitals Medical Society of Paris the results of their treatment of orchitis with guaiacol (*Ann. de Derm. et Syph.*) Their attention was directed to this agent on account of its sedative and antithermic action. Pure guaiacol applied in the quantity of one gram, morning and evening, causes a somewhat marked smarting sensation which, in about ten minutes, becomes a simple sense of heat lasting for a couple of hours; the pain is first relieved and then disappears completely, sleep becomes possible and the temperature falls to normal. Pure guaiacol often gives rise to erythema and desquamation of the serotum; it is, therefore, advisable to use five or ten grams of the drug to thirty grams of vaselin. With this mixture the smarting is hardly noticeable, but the sensation of heat is the same as with the pure drug; the therapeutic effects, while somewhat less prompt, are equally satisfactory, pain is rapidly lessened, temperature lowered and sleep made possible. The ointment as a rule does not irritate the serotum. Theunctions are made with three to five grams of the mixture, repeated twice daily, the serotum being covered by a compress held by a T-bandage.

Nerve Supply of the Ovary.—Devosa, in order to ascertain the distribution of the nerve fibers up to their ends in the ovary, used Golgi's staining method and furnishes the results of his study in the proceedings of the Academy of Medicine of Belgium. He made use of several different animals—the dog, cat, rat, mouse, guinea pig, turtle and calf. He describes a network of nerves, which accompany the arteries, arterioles, veins and venules; but found no vasomotor system along the capillaries nor, in general, at points where there is no unstriped muscular fiber; neither did he find any ganglion cells. Besides the network just mentioned, there exists in the ovarian stroma, and especially in the cortical zone, a plexus very rich in trunks and fibers interlacing in every direction. This plexus penetrates into the albuginea and some parts reach the base of the germinal epithelium, outlining the young follicles and forming a compact network around the adult follicles. The author found fibrillae even in the granular layer, where they terminate in

cylindrical swellings, but he was not able to prove these to be end-organs.

Liability of Physicians for Want of Skill.—A physician, undertaking the care and treatment of a patient standing in need of his services and employing him, it has become a familiar and well-established principle of law, contracts that he possesses ordinary skill, that he will use ordinary care, and exercise his best judgment in the application of his skill to the case which he undertakes. Nor does this question of his liability depend upon the skill he possesses, but upon the fact whether he has applied that reasonable skill and diligence which is ordinarily used in his profession. Whether he has exercised that skill, or has been guilty of a lack of ordinary care, and want of ordinary skill and attention in any given case, is always a question of fact for the jury. This is the language of the Supreme Judicial Court of Maine in the late case of *Cayford v. Wilbur*, which was brought to recover damages sustained in consequence of the alleged careless, unskillful, and negligent manner in which a surgeon treated a patient in reducing a fracture of both bones of the latter's leg. A verdict was rendered for \$2,075 which this court refuses to set aside. It says that, with the evidence conflicting, it was the province of the jury to decide those controverted questions, and this it had done. Nor were these damages so excessive does the court think, as to justify it in disturbing the verdict on that ground. If the party suing was entitled to recover, then the damages in a case of this nature, and from all the evidence in the case upon that branch of it, it says, did not seem to be excessive. As a general rule, the parties are entitled to the judgment of the jury, and not of the court upon the question. There are cases, to be sure, where the court will intervene; but those cases will be governed by the evidence and circumstances of each particular case. The court will not, however, set verdicts aside on the ground that the damages are excessive or inadequate, unless it is apparent that the jury acted under some bias, prejudice, or improper influence, or have made some mistake of fact or law.

Liability for Sale of Poisons to Minors.—The Supreme Court of Mississippi rendered a decision Oct. 15, 1894, in the case of *Meyer v. King*, which contains several points of interest. This was an action brought by a father to recover damages from a druggist for the death of his minor son, caused by the latter's taking chloroform sold to him while intoxicated. The minor was one of years of discretion. Because it was not alleged of him that he was inexperienced in the use of chloroform, that there was anything in the character or disposition of the minor that rendered it dangerous to put the chloroform in his hands, or that he was ignorant of its use, it is held that there was no cause of action presented. The death could not, it is said, be connected with the sale, as cause with effect, but it was due to the new one of the minor intervening, and operating as an independent cause to produce it. Moreover, the court holds that a minor old enough to earn, as a clerk in a grocery store, a reasonable and substantial compensation and old enough to be about town drunk,—and that was the case made out here,—was old enough to be chargeable with contributory negligence arising from voluntary intoxication, and that, therefore, the very allegation intended to show a cause of action in this case showed, when taken advantage of, that there was none. The minor, if he had survived, could not, under such circumstances, have maintained a cause of action. The liability of the druggist depended upon the nature and quality of his act in making the sale, as characterized by the circumstances of the sale, as between him and the minor. This act took its quality and color, not only from what he did in making the sale, but from the presence or absence on the minor's part of such contributory negligence, in his conduct at the time as would bar him had he lived and sued. The presence of such contributory

negligence, if it existed, was an essential part of the legal quality of the act as imposing liability as between the minor and the druggist, and it was only where he, had he survived, could have sued, that the father, after his death, could. Finally, the court decides that he who violates Section 1,592 of the Code, which forbids the sale of poisons to minors, is punishable for such crime by fine and imprisonment under Section 1,454. Code 1892, and is civilly guilty of negligence. But whether such negligent act makes him liable for the special damage sustained depends upon whether it is the proximate cause of the injury.

Abandonment of Newport Barracks, Ky.—In looking over the available material for a few remarks in the way of good-bye to the now abandoned military post of Newport Barracks, Ky., one is struck by an amusing illustration of heredity in the army medical officer. The surgeon of the United States Army was so accustomed to be stationed on the outskirts of settlement and civilization that every remark made by him concerning the climate, fauna, flora, etc., of his station was accepted as an addition to our knowledge of the hitherto unknown. The army medical officer came, therefore, to feel that it was his bounden duty to report on these subjects wherever he was stationed. In this way we find an explanation of the fact that in an official report of the conditions at Newport Barracks, published in 1870, it is gravely announced in relation to two or three hundred men stationed at the post: That the climate may be classed among the temperate and that the seasons are tolerably well defined; the seasons change by quite a regular gradation, etc. . . . "The geologic formation at this post is that of the lowest silurian; the blue limestone containing the trilobite and other characteristic organic remains of this period is about sixty feet below the surface and is covered by alluvium, sand and gravel. The primitive forest growth in the neighboring country is beech, walnut, hickory, sugar tree, white oak," etc. All this while there are more than a quarter of a million people living in the cities surrounding and swamping the few soldiers in whose interest the report was written.

From the status of a military post for defensive and offensive warfare, Newport Barracks became at one time a depot for recruits and at another an arsenal. For some years past it has been garrisoned by only a few men, the post of Fort Thomas, Ky., having taken its place. A commodious and well appointed brick hospital was built in 1874; but on account of the probable abandonment of the post it has not been kept in repair, and indeed, of late it has practically been unoccupied. The barracks were three-story brick buildings, the lower floors occupied as kitchens and messrooms, the upper as dormitories. The officers' quarters were of brick, facing the Ohio River. Most of the buildings were old and in bad repair. Water was supplied by connection with the Newport waterworks. The prevailing diseases were intermittents, diarrheal and venereal diseases.

Drunkenness as an Excuse for Crime under the New York Penal Code.—At common law, drunkenness was not only an excuse for crime, but evidence of intoxication, while admissible, and to be considered in some cases, was yet generally of no avail. If a man made himself voluntarily drunk, it was no excuse for any crime he might commit while he was so, and he had to take the responsibility of his own voluntary act. If the assault were unprovoked, the fact of intoxication would not be allowed to affect the legal character of the crime. The fact of intoxication was not permitted to be even considered by the jury upon the question of premeditation.

The strict rule of the common law has, however, been slightly relaxed by the New York penal code, which provides that "No act committed by a person while in a state of voluntary intoxication shall be deemed less criminal by reason of his having been in such condition. But whenever the actual existence of any particular purpose, motive or intent is a necessary element to constitute a particular spe-
