I use the rotary air pump which keeps the pressure in my air reservoir at a hundred pounds to the square inch. However, I desire to emphasize the fact that I do not exert that amount of force in applying compressed air to the middle ear. By means of the compressed air meter mentioned by Dr. Würdemann, and that which I invented and brought to your attention about two years ago, one is able to so regulate the volume and force of the column of air as to use any amount desired. You can employ one pound of pressure or ten, twenty, forty or any number of pounds up to one hundred. With the small volume of air used through my cut off there is no danger of rupturing the drum head; but I have discussed this subject to such an extent in my paper before this Section in our meeting for 1892, that I will not dilate upon it further.

In the use of my air meter and improved inflator bulbs, containing volatilizable medicaments, it is not often necessary to use Eustachian catheter. In the class of cases under consideration, I usually saturate the sponges in my inflator with lavolin, or, when a more stimulating medicine is needed, with a 3 per cent. solution of camphor-menthol in lavolin. This is thrown in the form of a spray through the Eustachian tube into the middle ear, on the same principle that we follow in medicating catarrhal conditions of the nasal cavities. I follow this treatment with the pneumatic otoscope. For years I employed iodine, but have obtained far better results since I abandoned it. Where there is partial impaction of the foot plate of the stapes, I have obtained marked results from the application of my ossicle vibrator, by means of which I obtain decided movements in the chain of bones, sufficient to produce dizziness, or even faintness of a transitory character. On the subject of excision of the ossicles for dry catarrh of the tympanum, I am very conservative, and I am glad to see that those who were the most enthusiastic advocates of this procedure two years ago are assuming a more cautious attitude. Within the past few days I have had under treatment a patient upon whom this operation was performed about three years ago, by a well known exponent of surgical enthusiasm, and the deplorable results in this and other cases of which I know, and some of which I detailed to you two years ago in Detroit, deter me from courting a like fate.

⁷ Würdemann, H. V. Remarks on the Treatment of Proliferous Inflammation of the Middle Ear. Jour. Amer. Med. Assn., April 18, 1891.

⁸ Würdemann, H. V. The Operation for Excision of the Ossicle in Chronic Aural Catarrh with Instance of a Failure. Trans. Amer. Med. Assn., Sec. of Laryngol. and Otol., 1892. Jour. Amer. Med. Assn., Oct. 22, 1892.

It is but fair to state, however, that I have known patients to hear better after I had removed the mallet and anvil, either through the external canal, or incidentally to an operation on the mastoid process. Neither do I deny that there are certain cases that may be benefited by this operation, but I insist that the utmost patient care must be observed in selecting them, for carelessness is fatal to the welfare of the patient, our piece of mind and the good of our art.

DR. FULTON, of St. Paul, referred to the lessened use of the catheter in his hands.

DR. WURDEMANN—in closing the discussion. The difference between the use of high and low pressures has been sufficiently well pointed out in the body of my paper, but I can not but help again calling attention to the dangers attendant upon the high pressure apparatus in hands less skilled than those of our friend, Dr. Bishop. I do not think that we may do away with the Eustachian catheter and esteem it as yet one of our most useful instruments. The method of treatment advocated in my essay is supposed to be done by the catheter. If we use metal instruments and sterilize by boiling there is no danger from septic infection and for specific cases surely we can afford to have separate instruments.

In regard to the vapors used, one must decide whether the membranes need stimulating or antiseptic treatment, just as in nasal catarrh. Select the remedy accordingly.

SURGICAL TREATMENT OF CHRONIC OTORRHEA.

Read in the Section on Laryngology and Otology, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY CHARLES HENRY BURNETT, A.M., M.D.

AURAL SURGEON, PRESBYTERIAN HOSPITAL, ETC., PHILADELPHIA, PA.

Surgical treatment of chronic purulent otitis media consists in the excision of necrotic tissue from the tympanic cavity. Instillation, insufflation or mopping of medicaments upon the diseased parts in the drum cavity in many cases result in a cure, but there are many instances in which all these forms signally fail after a long and fair trial. In these unyielding cases it will be found that one or more of the auditory bonelets are necrosed, and in some instances that the tympanic wall in apposition to the necrosed bonelets is itself carious. Manifestly in such cases the plain surgical indication is to excise the diseased bonelets or their remnants, in order to remove septic material from the drum cavity. This improves the drainage of this space, promotes a free application of antiseptics to the tympanum and favors the healing of its muco-periosteal lining. Under such treatment, in most cases, *after the operation* the diseased mucous membrane heals and carious spots in the tympanic walls are covered over without resort to curetting.

There are some forms of chronic purulent otitis media, in which excision of the remnants of the membrana and ossicles, is especially indicated. These are the so-called attic suppurations, in which necrosis of one or more ossicles is always present, and in which the sole perforation is in the membrana flaccida. Unless the necrotic tissue is excised there can be no permanent cure in such cases.

The operation of excision in chronic suppurative otitis media, is like the removal of a polypus in similar conditions. It is the *first* step in the antiseptic treatment of the ear. In many instances, not until the operation has it been possible to thoroughly ap-

ply antiseptics to the ear nor to maintain antiseptic conditions in the suppurating space.

The length of time which may elapse between the operation of excision and the cessation of the chronic discharge of pus from the drum cavity varies greatly. The quickest permanent cessation in the writer's practice occurred in eight weeks, in an attic suppuration of six years' duration. In another attic case, permanent cessation occurred at the end of two and one half years. In some cases it has not occurred after the lapse of even three years. But after the operation of excision, a chronic purulent otitis media has a better chance of being healed than before the operation. It also runs less chance of extending to the brain cavity or causing pyemia than it did before the drum cavity was freed from septic matter, and better drained by the removal of carious bonelets and obstructive synechiæ. The patient to be operated upon must be under the influence of a general anesthetic, preferably of ether. Cocainization of the membrana and drum cavity does not produce sufficient anesthesia, and furthermore the risks of cocain poisoning are very great when this drug is applied to the drum cavity.

After etherization has been accomplished the ear may be thoroughly and safely illuminated by a six-volt electric lamp held on the operator's forehead, and supplied by a small portable battery. Now a thorough exploration of the drum cavity may be made by means of probes of various curves, for the first time, especially in children, where before anesthesia, the sensibility of the parts forbade such exploration. All carious ossicles excepting the stapes, must be removed from the drum cavity. The stapes is rarely found to be carious anywhere excepting in its head. In no case should more than this of this bone be removed, as the removal of its foot-plate in a case of chronic suppuration opens the way for the entrance of pus into the labyrinth and cranial cavity. All diseased membrane should be excised, especially from the region of the attic, and if polypi are discovered by such excision, as they often are, they are to be carefully removed. Then the seat of the operation should be gently mopped with a solution of bichlorid of mercury, 1 to 6000, and the ear left open, so as to promote the escape of oozing blood or pus. The ear after this must be treated like any other suppurating ear, by means of antiseptics until the entire cessation of the discharge. The improved drainage and the more direct treatment of the suppurating cavity now give hope of a cure, unattainable without excision of necrotic tissue.

It has been urged against excision of the remnants of the membrana and carious ossicles in chronic purulent otitis media, that it is sometimes followed by facial paralysis. When this unfortunate sequel of the operation occurs, it will be found that curetting the cavity of the drum has been done. I have performed seventy-five intra-tympanic operations of late, but curetting has been applied in *no* instance and I have not had a case of facial paralysis to mar the result. I rest content with excision of diseased ossicles and membrana and the removal of polypi. If carious spots are detected on the tympanic walls I know they will soon be covered in by the healing of the ulcerated muco-periosteum, under antiseptic treatment, after the removal of carious and septic matter.

The hearing usually improves as the discharge

diminishes. Sometimes it is improved greatly and immediately by the operation, as the removal of diseased bonelets, synechial bands and infiltrated membrana admits sound directly to the oval window.

The operation of excision in suppurative otitis media furthermore greatly diminishes and in many cases entirely removes the risks of cerebral and general infection.

If the tympanic cavity has become practically the outward opening of a sinus, clearing it of septic and obstructive matter at least favors drainage from deeper parts, and ought to be done before resort to cranial operations. If the suppurative disease is limited to the tympanum then the excision of carious tissue practically removes the disease which is threatening to produce brain-abscess, sinus-thrombosis and pyemia, and mastoid and cranial operations are not necessary and never may be. *Were excision of necrotic tissue from the drum cavity more frequently and promptly performed there would be less need of mastoid and deeper cranial operations.*

DISCUSSION.

DR. WURDEMAN, of Milwaukee—I am pleased with the moderate tone with which the author has dealt with his topic, and especially with his present conservative views in regard to the selection of cases for operation, as he has been known heretofore as one of the most ardent exponents of radical aural procedures.

While my experience (I have done more than fifty of these operations) is not quite as great as Dr. Burnett's (he having done about a third more than I), it is quite sufficient to substantiate the statements made in the author's paper. Such operations for chronic suppurative otitis media should be done only on those cases that have resisted antiseptic treatment for a sufficient length of time to warrant the assumption that they are incurable by simple means. Despite the fact that considerable literature has appeared in recent years, all observers agreeing upon the necessity for operative procedures, the public generally has not been educated up to this point and even some of the profession are opposed to it. They are those who either have not tried it or who have scored failures in the first attempt. The operation done through the canal is in no sense an easy undertaking. General anesthesia is necessary and the canal and middle ear becomes filled with blood, rendering inspection difficult, so that often the greater part of the operation has to be done by the sense of touch. It is almost needless to warn those who are not properly versed in the anatomy of this small locality (and its dangerous surroundings) from attempting the operation.

LARYNGEAL TUBERCLE TREATED BY TUBERCULIN.

Read in the Section on Laryngology and Otology, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY A. J. ERWIN, M.D.
MANSFIELD, OHIO.

At the Detroit meeting of this Association, I read before the Section on Laryngology a paper on the tuberculin treatment of laryngeal tubercle, in which I gave the history of seven cases treated in 1891. Three of the patients were still living. This paper is a continuance of that report. All have since died, but the results of the treatment seem to me to be of enough importance to deserve mention. I will briefly recapitulate the history of the three cases then living, in connection with their sequelæ:

Wm. Beiterbuecher, age 20 years; Lowdonville, Ohio. Cough,

fever, and night sweats began in January, 1891; had several hemorrhages in April. Consumption hereditary on each side. Examined April 23, 1891; reduced twenty pounds. Pulse 132, respiration 30, temperature 102. Cough frequent; some expectoration containing bacilli; râles and obstruction in apex of left lung. A deep ulcer on inner surface of the left arytenoid about five millimeters in diameter, also a tubercle on the first tracheal ring. I treated him with tuberculin exclusively from April 23 to August 15, making in all fifty-four injections of one-twentieth to 1 minim each. The tubercle in the trachea and the râles had disappeared by May 20, but the ulcer did not entirely close until about August 1. Two months later, cough and expectoration had ceased and he had gained twenty pounds in weight. About April 1, 1892, a catarrhal attack seemed to start afresh symptoms of tuberculosis, especially of the heart, which soon showed valvular infiltration and insufficiency, and consequent engorgement of the lungs, finally broncho-pneumonia, and death three months later, but without any return of the disease of the larynx, and with but little if any increase of tubercles in the lungs. The tuberculin treatment was not repeated.

Case 2.—Mrs. George McMullen, age 25 years, Mansfield, Ohio. Cough, fever and night sweats began in December, 1890; had two hemorrhages. Consumption hereditary on each side. Examined May 13, 1891; had lost over twenty pounds in weight. Pulse 92, temperature 100, respiration 22; râles throughout left lung, free expectoration containing bacilli. The left arytenoid was a little thickened but not ulcerated. I gave her thirty-two injections of tuberculin one-twentieth to 1 minim each, between May 14 and July 21. By June 1 the entire anterior surface of the left arytenoid had ulcerated; by June 15 the fever and night sweats had ceased. When dismissed, July 21, the arytenoid thickening had disappeared and the ulcer was about one-third of its former diameter, her appetite and digestion were restored and she had gained five pounds in weight. The cough and expectoration continued with but little abatement, but her general health had considerably improved. In March of 1892 she had a return of fever and night sweats with increased cough, probably of a catarrhal character, but did not return to me for examination until July 1, when I found her free of fever. Cough and expectoration about as at date of dismissal a year before. Weight and general health not changed. The ulcer of the larynx had entirely healed, leaving a little contraction of the left fold as the only evidence of former disease. The tuberculin treatment was not repeated, she varied but little in health until February, 1893, from which date the lung disease advanced rapidly and she died in April following without any reappearance of laryngeal disease.

Case 3.—Mrs. Albert Vaughn, age 28, Mansfield, Ohio. Cough, fever, night sweats and indigestion began July, 1890. Father and sisters died of consumption. Examination May 7, 1891. Weight reduced twenty-six pounds. Pulse 130, respiration 30, temperature 103. Obstruction and râles in apices of lungs. Left arytenoid twice as thick as the right; a deep ulcer about seven millimeters in diameter on its interior surface, from which pain extends to the ear; cough frequent, some expectoration containing bacilli. Began injections of tuberculin May 8, which were continued for one month daily one-tenth to 2 minims each, and for some months afterward at irregular intervals; by July 1, the fever, expectoration, obstruction and râles had disappeared; by September 1 the thickening had left the arytenoid but the ulcer did not entirely heal until about November 1. It left the cartilage considerably deformed but not irritable. She passed the winter without fever or cough of any consequence, with a good appetite and digestion, and a gain in weight of fifteen pounds. In March, 1892, she had an attack of the grip, during which râles re-appeared in the apex of the right lung, followed by some infiltration of the previously diseased arytenoid and a degree or two of fever. She returned to the tuberculin injections of 1 minim twice a week. Within three weeks the laryngeal thickening disappeared entirely without ulceration, and the fever, râles, and cough ceased a week or two later. In September, 1892, there was a little fever with cough and râles, but no thickening of the larynx, which was relieved again by three weeks' treatment with the tuberculin. In January, 1893, without any recurrence of fever, râles, expectoration or laryngeal irritation, cough and prostration began to follow slight exercise. Examination showed the heart to be weak and irritable with very dull valve sounds. These symptoms gradually increased and were followed by frequent attacks of that form of congestion of the lungs which we recognize as due to heart disease. At first

they were readily relieved by rest and the tincture of ammonia valerianate. These attacks became more frequent and more severe until she died in March.

I have thought it worth while on two accounts to bring these cases before you: 1, we have the unprecedented cure of three out of seven cases of laryngeal tubercle; 2, we have apparently the tubercular disease diverted from its original seats in the lungs and larynx to the heart, probably by the tuberculin.

SYPHILITIC DISEASES OF THE EYE.

Read to the Kentucky State Medical Society at Shelbyville, June 7, 1894.

BY DUDLEY S. REYNOLDS, A.M., M.D.

PROFESSOR OF OPHTHALMOLOGY, OTOTOLOGY, AND MEDICAL JURISPRUDENCE,
IN THE HOSPITAL COLLEGE OF MEDICINE, MEDICAL DEPARTMENT
OF THE CENTRAL UNIVERSITY OF KENTUCKY; SURGEON TO
THE EYE AND EAR DEPARTMENT OF THE LOUISVILLE
CITY HOSPITAL.

The syphilitic diseases of the eye should be divided into three classes, and for the sake of convenience, I should prefer to consider them as of the acquired and inherited. Then I should divide the inherited types: 1, those in whom the disease has been so recently acquired by the mother as that the secondary roseola appears some time after birth, or, about that time; 2, those in whom the syphilitic evolution has been apparently completed in the mother before pregnancy. Just how to reach that class of the third and fourth generations of syphilitic patients it is difficult to formulate rules, and I prefer making my third division embrace victims of *remote inheritance*.

If the syphilized mother has apparently recovered, and gives birth to a child with certain structural defects, such for example, as those imperfect developments of the lymphatic system described by Dr. Formad in his report on the anatomical peculiarities of struma, the muscular deficiencies, and the thin and imperfect development of the arterial walls, then how shall we expect to find marks of inheritance in those of the third generation?

It is distinctly and emphatically stated by nearly every recent writer on syphilis, that none of the normal secretions of the body contain the virus. It is manifestly clear, therefore, the spermatic fluid can never be accompanied by the virus of syphilis, excepting where abrasions, ulcerations, or gummatous deposits exist, either in some part of the testicle, or the walls of the excretory ducts. Since the period of incubation of syphilis has been fixed at from twelve to forty days, it is clear that abortion must necessarily follow in cases where the virus of syphilis reaches the ovum before placental attachment has been established, and every one knows that syphilized women can not bear children conceived during the periods of activity of syphilitic infection. It is an equally common observation that men in the most active periods of syphilitic infection actually beget perfectly normal, sound and vigorous children. It is already an exploded superstition that the father may communicate syphilis to his offspring, without first infecting the mother. I have many times seen children born of syphilized women about the time of the appearance of the secondary eruption, and more frequently before that period. Every obstetrician will testify that a pregnant woman seldom goes two months with a secondary eruption of syphilis, without discharging the contents of the uterus. Who has not observed the miscarriages and abortions of syphilitic women?

Mr. Jonathan Hutchinson in his great "Clinical Memoir on certain Diseases of the Eye and Ear, consequent on Inherited Syphilis," publishes at page 25, the following aphorisms respecting iritis in infants:

"1. The subjects of infantile iritis are much more frequently of the female than of the male sex:

"2. The age of five months is the period of life at, or about which, syphilitic infants are most liable to suffer from iritis.

"3. Syphilitic iritis in infants, is often symmetrical, but quite as frequently not so.

"4. Iritis, as it occurs in infants, is seldom complicated, and is attended by but few of the more severe symptoms which characterize the disease in an adult.

"5. Notwithstanding the ill-characterized phenomena of acute inflammation, the effusion of lymph is usually very free, and the danger of occlusion of the pupil great.

"6. Mercurial treatment is most signally efficacious in curing the disease and, if recent, in procuring the complete absorption of the effused lymph.

"7. Mercurial treatment previously adopted does not prevent the occurrence of this form of iritis.

"8. The subjects of infantile iritis, though often puny and cachectic, are also often apparently in good condition.

"9. Infants suffering from iritis almost always show one or the other of the well-recognized symptoms of hereditary taint.

"10. Most of those who suffer from syphilitic iritis are infants born within a short period of the date of the primary disease in their parents."

In the foot notes, Mr. Hutchinson says he has known the second eye attacked in a patient already under the influence of mercury for the treatment of the first eye affected. He has in a number of instances observed acute iritis occurring during the period of actual pyalism. I have seen a number of such cases myself. It is a well established fact that the poorly nourished subjects of inherited syphilis are not those most likely to suffer local lesions in the eye. This class of subjects seem to suffer in the digestive and assimilating organs, and have those artistic decorations of the skin which the Dermatologist delights to parade as brilliant illustrations of his diagnostic skill.

Syphilitic iritis notoriously occurs most frequently in the periods of the advancing secondary eruption, while inflammations of the optic nerve and retina are vastly more common in the later stages of the disease.

Keratitis is, however, a more remote manifestation of syphilitic infection than iritis and, although interstitial keratitis occurs in the subjects of acquired syphilis, it is by no means commonly due to syphilitic infection in this class of subjects; per contra, interstitial keratitis of syphilitic origin is accompanied by disturbances of the corneal epithelium, which presents the appearance of ground glass, and this is never seen in the subjects of acquired syphilis. Now, I feel like asking the question, Is it ever seen in the subjects of inherited syphilis, where the child was born before, or about the time of the secondary evolution of syphilization? It seems to me this distinction must be made. Mucous patches in the conjunctiva and on the surface of the cornea, are often seen as early manifestations of the tertiary period of syphilization, and especially in those who have been

born with the disease, yet in young adults in the same period of syphilization where the disease was acquired, these mucous patches are occasionally seen. I have known a number of instances where great injury resulted to the eye from local treatment for the relief of clearly defined and unmistakable mucous patches in persons who, at the time, had no other manifestation of syphilitic infection, excepting a small patch or two in the mouth. It is, therefore, of great importance that a diagnosis should be made in the outset, in order that the proper constitutional treatment may be commenced at once, and that no local interference with the mucous patches in the eye shall be attempted.

Gummatous formations in the cornea are not infrequently observed at the termination of the vessels in the limbus of the conjunctiva. Gummatous abrasions are vastly more frequent in advanced syphilis than in the early periods of infection; these gummatous formations at the periphery of the cornea are, therefore, observed more frequently in children of 5 or 6 years of age, than in younger persons. Interstitial keratitis seldom occurs as early as the fourth year, although Mr. Hutchinson reports several cases occurring at the age of one year. It is seldom delayed beyond the twelfth year, yet it is occasionally seen, as in one of Mr. Hutchinson's cases, as late as the twenty-sixth year of age, the patient having the characteristic teeth.

Many of the best writers believe inherited syphilis tends to run a milder course, and offers less protection against subsequent liability to syphilitic infection. Latent syphilis may be aroused into activity after long periods of time, by influences which diminish the *vis conservatrix* of the general system; hence, it is not rare to observe syphilitic affections in people of advanced age who have not been suspected even of syphilitic contamination since early manhood. Mr. Hutchinson believes the degree of severity of the inherited taint is proportioned to the short period which elapsed after the primary infection of the mother. The progeny of the subjects of inherited syphilis are often found with optic neuritis, neuro-retinitis, and choroiditis, early in life.

It is but natural the subjects of inherited syphilis should exhibit faulty bone formations, and faulty development of the teeth; indeed, it would appear from extended observation that the cornea and teeth, in particular, are more sensitive to the action of syphilis in those who inherit the disease, than any other parts of the organism. I have seen keratitis which presented the appearance of suppuration, and in one instance I saw paracentesis of the cornea practiced for the evacuation of what appeared to be pus in the anterior chamber, but which turned out to be a mass of pale gumma adhering both to the cornea and iris. A course of iodid of potassium wrought the miracle of complete recovery. Under its influence the gumma melted completely away, and the eye not only recovered so far as appearances go, but there was no appreciable impairment of the sight. Many eyes are lost from syphilitic inflammation of the iris extending into the ciliary body, which might have been saved by early and vigorous constitutional treatment, but for the fact of the misapprehension on the part of the medical attendant concerning the origin of the disease.

Prof. Noyes, of New York, is the author of the chapter on "Syphilitic Diseases of the Eye," in the

celebrated work of Prof. Keyes. I, therefore, find it difficult to obtain any valuable information from the observations of this great teacher, excepting his apparent endorsement of what Noyes has written.

The late Prof. Bumstead, whose "Clinical Treatise on Venereal Diseases," won him so much fame, was himself an experienced ophthalmic surgeon. He directs attention to the fact that the absence of severe pain and photophobia in syphilitic iritis offers valuable evidence in support of the suspicion of its syphilitic origin. The history of the case is seldom of value, and there are many persons in whom no cutaneous eruption or other sign of syphilitic disease may be discovered, and yet tubercular elevations of a brownish pink tint, sometimes light gray, and sometimes cream-colored, appear in the substance of the iris, or, upon its surface, the eye being but slightly sensitive to light, and often not at all painfully affected. A few doses of iodide of potassium serves not only to dissipate the gumma in the iris, but to bring out the characteristic cutaneous eruption. The stimulating effect of the iodide of potassium on the skin of syphilitic subjects has been often observed, and may often be employed to clear up the obscure symptoms and make clear the diagnosis.

Mr. Swanzy, of Dublin, and Mr. Hutchinson, of London, have both reported cases of retinitis pigmentosa in subjects of inherited syphilis. Prof. McNamara concludes this to be a peculiar form of pigmentary degeneration of the retina, in which the spots, although beginning in the periphery and accompanied by commencing choroidal changes, do not follow the vessels of the retina. Prof. Gradle says, in an article in the supplement to the "Reference Handbook of Medicine," page 300, that, "accompanying late syphilis, the retina is involved, beginning in the periphery, and extending gradually toward the center of the field, resembling retinitis pigmentosa in appearance, yet the etiologic data we possess regarding the origin of retinitis pigmentosa is consanguinity of parents in one-fourth to one-third of the cases." This in no wise impairs the laws of hereditary transmission, and it is by no means established that families having retinitis pigmentosa, although intermarrying with each other, were not themselves, or their parents the subjects of syphilis.

Sydenham, 1670, in his celebrated "History and Cure of the French Pox," says: "The disease first came to Europe from the West Indies in the year 1493," and that it was already at the time of his writing, languishing daily, and the phenomena growing milder. He considers that, whereas it was very malignant when first introduced into Europe, two hundred years dissipated its malignancy so completely that reason and experience dictated the disease might be cured by any sort of purge, given often and a long while. In another place he says: "Mercurial salivation will generally do the business of cure;" and on page 257, he says: "I think no instances can be produced where this disease was eradicated in any other way than by salivation with mercury, whatever some learned and unlearned men say of the cure of it by other means."

The incredulous student reading the history of the treatment of syphilis, through the publications of the great teachers in medicine, from Sydenham to Keyes, naturally wonder why, if mercury or anything else suffices for the cure, we have any such disease as hereditary syphilis.

Mr. Jonathan Hutchinson considers the distinction can be drawn in the character of the teeth and bone of those who inherited syphilis from the parents long subjected to mercurial treatment, and those who inherited it from parents who acquired the disease but a short time before the birth of the offspring. Upon sound pathological researches, rational systems of therapeutics may alone be based.

Neither Mr. Gascoyne, who reported a large number of cases of iritis successfully treated by the local use of atropine alone, nor Prof. Henry W. Williams, who employed no mercury in the treatment of his sixty-four cases of iritis, have been any more successful in their exclusive methods of treatment than Sydenham with his mercurial ptyalism.

Materia medica has so far yielded no specific antidote to syphilis, the local phenomena of which yield to a great variety of medication in a very prompt and satisfactory manner. To say that mercury cures syphilis is just as absurd and untrue as to say that all manifestations of syphilis can be cured without mercury.

Inflammations of the iris without accompanying lymphatic obstructions not only require no mercurial treatment but yield uniformly, in the painless cases, to the action of the iodids; while those cases accompanied by severe pain are promptly relieved by the alternating or occasional use of salicylates and iodides.

It is notoriously true that very emaciated subjects rarely have iritis, yet the ulcerative inflammations of the cornea and conjunctiva of syphilitic origin occur almost constantly in the emaciated subjects of syphilis. And, paradoxical as it may seem, my own experience leads me to believe that syphilitic emaciation is seldom overcome without at least the occasional use of mercury.

I think a combination of mercury with sulphate of quinine in doses of one-twelfth or one-sixteenth of a grain of quinine with one-fiftieth grain of bichloride of mercury, every three or four hours, for a child under 5 years of age, with a careful exclusion of all indigestible ferments such as cooked fruits, syrups, confectionery and pastry, with judicious bathing, outdoor exercise, and regular administration of nutriment in definite quantities such for example as one ounce of beef tea, or two ounces of prepared beef peptonoids, or malted milk, with each dose of medicine, yields wonderful results in apparently hopeless cases.

Now, as to local treatment in syphilitic diseases of the eye, two great principles must be constantly borne in mind. In all forms of iritis, sulphate of atropine, or the hydro-bromate of homatropine should be instilled every two or three hours, to thoroughly dilate and maintain constant dilatation of the pupil. This is absolutely essential to the ultimate recovery of the eye, no matter what constitutional agencies may be employed to check the advances of the infection upon which the local disease of the eye depends. In cases of abrasion or ulceration of the cornea or conjunctiva, some sort of mild antiseptic should be frequently applied to prevent local infection of the abraded surface, for it is well known that even syphilitic ulcers afford a good medium for the colonization and growth of those microorganisms which beget suppurative processes. The best applications are an ointment of the yellow oxide of mercury, carefully prepared, or an ointment of boric acid. Great care

is necessary in the preparation of the yellow oxide of mercury, as it is liable to contain caustic lime, potassium, sodium, or ammonium as foreign ingredients.

The officinal petrolatum is a better excipient for an ointment than vaseline, cosmoline, or any of the other preparations of petroleum. If this is not at hand, a combination of glycerine and starch, known as glycamil, should be used. Lanoline is sure to irritate the eye, and should never be employed in affections of this kind.

WHAT THE DOCTOR SHOULD KNOW, AND
WHAT THE SPECTACLE PEDDLER, DRUG-
GIST, JEWELER AND OPTICIAN
SHOULD NOT DO, ABOUT
AFFECTIONS OF
THE EYE.

Read to the Bond County, (Ill.) Medical Society, Sept. 6, 1894.

BY A. C. CORR, M.D.

CARLINVILLE, ILL.

I take the theme of what the doctor should know about diseases and affections of the eye, because it is one that I think should be better elucidated and more clearly defined in our minds, and more especially as it has been discussed more or less of late in the *National Medical Journal* by two eminent gentlemen, somewhat to the disparagement of the general practitioner. The two gentlemen who have so discussed the subject—the one, Dr. W. A. Fisher, of Chicago; the other Dr. F. T. Smith, of Chattanooga, Tenn., have agreed—the one that the general practitioner should not attempt to use the ophthalmoscope, and the other that he should not attempt to “fit glasses,” and that his conduct shall be reprehensible if he does not readily diagnose glaucoma and cataract, nervous atrophy and the general ophthalmia, inflammation of the conjunctiva and cornea—then they both forget their prey, the general practitioner, and go off in a scrap as to whether glaucoma and cataract may be satisfactorily diagnosed without the ophthalmoscope, and soon return with this precious bit of advice that you ought not to operate for strabismus unless you know how to determine and correct the error of refraction on which it depends.

Do not be awed by the “thus far” of the ophthalmic specialist, especially if he has just returned from his buncombe trip to Europe, for they have the same kinds of sore eyes over the pond that are met, and treated as successfully, in this country. We have cataract, glaucoma, and all the known errors of refraction and disassociation of ocular muscles that are met over there. We have the ophthalmia varieties of conjunctival with inflammations and ulcerations of the cornea, just the same. I repeat, do not be awed, for the gynecologist will say “thus far,” the neurologist will say “thus far,” the surgeon will say “thus far,” the official surgeon will say “thus far,” the aurist and the throat and nose specialist will say “thus far,” the dermatologist will say “thus far,” the thoracic auscultator and percussor will say “thus far,” the cylopoetic inspector will say “thus far,” the obstetrician and pediatric fellow will say “thus far,” and there will be nothing for you to do except to parade yourselves as some of the peripatetics are doing in our State—as specialists in everything. Rather assert yourselves in the face of specialists

and hurl at them a quotation from the centennial article of the late Samuel D. Gross, that, "I would rather trust the well informed general practitioner, for he is the only one who is competent to take in the whole situation;" and I believe that the well informed general practitioner is the best exponent of the intelligence and usefulness of the practice of medicine. If you do not so re-assert yourselves there will be nothing left for young physicians to do but to marry rich, join the "A." "M."—Master of Arts—Medical Association and devote much time to the discussion of very "polite literature." Rather make a religion of medicine, let your text-book be your prayer-book, the medical society your prayer-meeting, and always be present with your experience and inquiry. Familiarize yourselves with the literature of ophthalmology, not by reading many books, but study well some one or two good text-books, like Berry, Noyes, Juler, Smid-Rimpler, Fuchs, Nettleship. Learn all you can from the experience and observation of your fellows, but above all, learn to utilize your own observations. When you are asked to see a conjunctivitis or corneal ulcer do not become awed by what the specialists say, and feel that it is beyond your ken. If any specialist write you saying "thus far," write him what he ought to know about general practice. Tell him that well nourished, well fed people who have well developed muscular systems and well poised nervous apparatus and are used to out-doors and sunlight and not too much specialized labor, do not have much asthenopia, nor do they need their ocular muscles cut. That Dr. J. L. Thompson, of Indianapolis, in the Section on Ophthalmology, at the meeting of the AMERICAN MEDICAL ASSOCIATION, June, 1893, in discussing heterophoria, said: "It is bad to be picking at one muscle so often;" and, "I do not believe that a partial tenotomy ever benefited a case on this earth;" and Dr. H. Gradle said: "Patients complaining of asthenopia were relieved about as satisfactorily in as large proportion of cases before the subject of heterophoria was ever brought out;" and that Dr. M. Gould, in discussing the same subject in the Ophthalmic Section of the Pan-American Medical Congress, September, 1893, said: "This to me seems to be a true tenotomania and one illustration of the general surgical debauch of these days which has also been so well illustrated in gynecology." These three gentlemen are personally known to me. I heard them utter these words. They are eminently and well qualified to wield a bright and shining lance in discussion of these subjects.

I say do not become awed, but maintain your composure, investigate it as you would a pneumonia or a brain disease, nervous or renal affection. Use your usual tact and caution and analysis. Do not strive to think of a specific, for there are none any more than in general medicine.

The diseases of the eyes that most frequently come under the observation of the general practitioner, and constitute a large part of the ophthalmic practice, are the inflammations of the conjunctiva and cornea with corneal abrasions and ulcerations, and they, in their varied forms and results, will tax the patience and ingenuity of the physician fully as much as any other diseases of this important organ.

The etiology and pathology of inflammations of the tissues of the eye are, in common with those of other organs of the body, modified by the variety of tissue involved and the functional activity of the

part, subject to the laws of bacteriology and infection.

The nature and causes of the inflammations of the cornea and conjunctiva are sometimes functional, most times infectious, many times traumatic and not a few times symptomatic. These relations need to be well differentiated in diagnosis as a basis for rational treatment. Inflammations in these tissues tend to recovery when the causing conditions are stopped and the intercurrent aggravating conditions are removed. To determine what the aggravating and causing conditions are that tend to perpetuate a corneal or conjunctival inflammation, will many times test severely the tact and ingenuity of the practitioner, and will not a few times prove well-nigh inscrutable. Absolute cleanliness, not only from microbes and infectious microorganism, but acrid secretions and dirty dirt, is of prime importance, and should be maintained as long as the inflammation lasts.

When a case of corneal or conjunctival inflammation presents itself, inspect the whole conjunctiva and cornea very closely, in order to learn as much of the extent of the disease and of the causing and aggravating conditions as possible, removing all foreign bodies and every suspicious substance. Keep constantly at your command a disinfecting solution, or improvise when needed; in the proportion of

| Mix and ft. collyr. | |

Wash out the eye thoroughly with this remedy by squirting it into the opened eyes or everted lids copiously, and with sufficient force to dislodge everything desirable. This should be done with a dental bulb syringe that will hold from one-half to one ounce so the current may be copious all over, or held long in one spot. Roll a bit of absorbent cotton on a toothpick, and after dipping it into the solution, swab out the superior and inferior cul-de-sac and the canthi. If not contra-indicated order this, except the swabbing, repeated several times daily as a necessary part of the treatment. This is applicable to all corneal and conjunctival inflammations and all grades of the same, and in many cases of the latter will be all that is necessary. Other astringent and tonic remedies may suggest themselves.

Purulent ophthalmia—gonorrhœal—or neonatorum, the pathognomonic symptoms of which are suddenness and severity of attack, great swelling and copious purulent discharge, will require more thorough cleansing with the disinfecting collyria referred to, twice or many times daily, and the use of from gr. ij. to ʒij. to the ounce nitrate of silver once or twice daily. I regard the thoroughness in the cleansing and the application of the solution of the nitrate of silver of more importance than the strength of the dose of the latter. This injunction needs to be reiterated, for the infectious and aggravating material is reproduced very rapidly and by every part of the conjunctiva, and it must be remembered that this is one of the most severe and rapidly destructive diseases to which the eye is subject. If the cornea becomes involved, atropia should be added to keep the pupil dilated, if possible, and more vigor used in the cleansing and disinfection.

If there are corneal ulcers or abrasions, wash, scrape or cauterize their surfaces till they are clean,

clear of microorganisms—infiltrated tissue—or what not, and keep them so. Keep the pupil dilated and the ciliary muscle relaxed, the eye passive; the circulation and enervation free with atropia, so nutrition and repair are not interfered with.

I often pack the ulcerated excavation in the cornea with iodoform daily, till the glazed surface of healing is manifest, keeping the ciliary muscle relaxed with atropia, which I regard as the *rudder* in the treatment of ulceration and abrasion of the cornea. The ease with which the atropia dilates the pupil and keeps it so is something of an indication of the manageableness of the case. If the pupil is easily dilated it indicates tractableness in the corneal disease, and if it becomes gradually more easily kept so it indicates favorable progress in the disease. If the pupil and ciliary muscle be allowed to contract the eye becomes at once irritable and aggravated. The atropia is more certainly indicated where there is anesthesia of the cornea, which may be tested with the tip of a moistened camel's hair pencil or brush, or a bit of unsized paper moistened and twisted. In 1865 in the United States Des Marr's Eye and Ear Hospital, in Chicago, I saw the ciliary muscle cut to relieve this condition of corneal anesthesia. Little white specks of infiltration in the marginal area of corneal ulcers may recur from time to time during its treatment, which must be diligently sought for and subjected to the same treatment as the original ulcer. In some cases the ulcerative process may be so rapid and painful as to require the application of hot fomentations, and paracentesis of the cornea or perforation of the base of the ulcer to stop its progress. Tonics and other constitutional remedies may be required, and in hypopyon ulcer it may be necessary to evacuate the hypostatic infiltration. A bandage should be usually worn in cases of corneal ulcer, and the conjunctival cul-de-sac kept clean.

Irrespective of varieties of infectious material that may determine the type of conjunctival inflammation as functional, catarrhal, purulent, trachomatous or diphtheritic, I have observed three varieties of granular condition of the conjunctiva—the pathology of which is not yet clearly settled—that tend to perpetuate a conjunctivitis and to aggravate a keratitis or ulceration of the cornea. They are mostly confined to the palpebral conjunctiva and the superior and inferior cul-de-sacs. The one a fine, almost miliary vesicle, probably follicular; the other a larger semi-transparent mass, light in color—the sago-grain granule—few in number, probably lymphatic. These two are confounded as true trachoma, and are both susceptible of being bursted and obliterated and their viscid semi-transparent contents squeezed out. The third is a seedy-looking granule with solid structure only amenable to atrophy or absorption. The first two varieties should be burst and obliterated at first sitting after the parts are cocainized, or at subsequent ones till all are destroyed; best done with ring or roller trachoma forceps devised by Prince or Knapp. I know of no specific treatment for the third variety of granulations, more than the rational treatment of the conjunctival inflammation in which they are involved. I resort to squeezing, crushing, scarifying and curetting them, but have not been quite satisfied with the results. I think the sanguineous depletion produced by squeezing them with the forceps referred to, with thorough cleansing and the application once or twice

daily of a strong solution of tannin in glycerin—grs. xx to xl to the ounce will probably give best results. The treatment of this variety seems to be the sphere of usefulness of the ancient "blue stone" which used to be applied indiscriminately to all. I think it is applied two or three times weekly with caution as of yore. But they with their thickened and redundant mucous membrane will many times require weeks and months for their removal. These conditions of cornea and conjunctiva are sometimes very much aggravated by non-specific vaginal secretions. I have verified all the conditions necessary to such infection and aggravation in three cases.

The drainage and lubricating apparatus of the eye may need appropriate attention. Where entropium or trichiasis aggravates the corneal condition, I have usually made the operation devised by Dr. Hotz for its relief, and where there are only a few deviating cilia that touch the cornea and irritate it, I loop them up to and with the others with collodion, which may be done a number of times or kept so for a long time, when they will remain bent away from the cornea. In several cases this has given me great satisfaction and won the plaudits of my patient. I have not obtained good results from the electro-epiliary processes so highly recommended by some.

A slight or extensive pterygium in some cases aggravates a keratitis or conjunctivitis by retaining infectious or acrid substances under its folds against the cornea, when it should have appropriate treatment by removal.

I have observed a blocking of the meibomian ducts at their orifices on the margins of the lids in a marginal blepharitis as an aggravating condition. The ring trachoma forceps is a very convenient and admirable instrument with which to squeeze out their caseous contents so as to relieve their turbulence, which may then be readily treated with the Pagenstecher ointment.

R Yellow oxid of mercury gr. ii
Vaselin ʒ. ii
Mix. Rub well and ft. ung't and sig.

Rub on the border of the lids where they touch when closed, and among the cilia, once or twice daily.

The pannus and opaque infiltration of the cornea that results from chronic inflammation and degeneration of the palpebral conjunctiva may be very hard to remove by any known process. I adopt the boracic acid and massage recommended by Landolt in 1889, and by Holmes in 1890. A few minutes after instilling a drop of cocain, twice a week, the dry boracic acid is poured from a spatula on the ball with the lids everted or apart; the lids pulled over the powder so as to confine as much as possible, and rubbed for three minutes, exact time, or till the acid is dissolved in tears. This with a few drops of gr. ii sol. zinci. sulph., in each eye nightly after being washed with the disinfecting solution and as much protection as can be given the eye, constitutes the treatment. Dr. J. A. Lydston, of Chicago, uses and recommends for a similar purpose and in a similar way, equal parts of papoid and boracic acid, under the title of "Pannus and its Treatment by Digestive Ferments." Atropia should be used in conjunction with this treatment, especially if there is photophobia and an irritable iris. I am satisfied from the results in which I have used the dry boracic acid, varied somewhat from this, that it is a useful remedy in pannus and opaque infiltration of the character de-

scribed, and is a most admirable and convenient means of cleansing out and disinfecting an infected eye.

There is a crusty blepharitis marginalis, *sui generis*, which leads to plucking of the cilia—erroneously supposed to be wild hairs—in some cases, which I regard as almost pathognomonic of an error of refraction. It is easily relieved temporarily by rest of the eyes and the margins of the lids being anointed nightly with citrine ointment made with cod-liver oil, or the Pagenstecher's ointment.

I am satisfied from observation that errors of refraction tend to originate, perpetuate and aggravate inflammatory diseases of the eye, especially those of the conjunctiva and the cornea, and to retard and otherwise render difficult their cure. Hence, I regard a determination of the refraction of an eye affected with a chronic or frequently recurring inflammation, a necessary *part* of its examination, and if errors are detected, a correction, with suitable lenses and adjustment, a necessary *part* of its treatment. After such correction very simple remedies will often suffice.

Iritis is a disease, the symptomatology of which every physician should familiarize himself with; for very many eyes are lost by it and the treatment is comparatively simple. There are usually slight lachrymation, variable photophobia and headache, orbital or occipital, pupil slightly contracted and sluggish, aqueous, more or less hazy or murky. There may be posterior synechia. There is circumcorneal injection and tenderness in the anterior region of the ball, and the iris discolored as compared with its fellow.

The symptomatology and treatment of cyclitis is so nearly the same as that of iritis that if I add that in addition to these, cyclitis is characterized by punctate deposits on the posterior surface of the cornea and cloudiness of the anterior vitreous, the two may be grouped together. Cyclitis may be caused by traumatism or by continuity of tissue, from choroiditis, or iritis, or may constitute a link in inflammation of the uveal tract—uveitis, iritis, cyclitis and choroiditis combined.

The cause of an iritis can not always be easily determined. Traumatism, syphilis and rheumatism are oftenest referred to by the books. I am quite certain I have seen it arise from excessive functional activity of the eye, laboring under the disadvantage of an error of refraction.

The sheet anchor treatment both of iritis and cyclitis is mydriasis and potassio-mercurial medication and tonics, with absolute rest of the eyes. The mydriasis should be pushed to paralysis of accommodation so that the eye is as perfectly passive as may be. Severe cases with increased tension may require paracentesis of the cornea repeated, and iridectomy. If the iritis is recurrent, the iridectomy should be made.

In regard to the symptomatology of both iritis and cyclitis, I wish to reiterate with emphasis that the inception and progress may be so passive as to give rise to no subjective symptoms except that of slight or marked impairment of vision, which if occurring in one eye may not be heeded till the eye is beyond recovery.

To determine some of the conditions and symptoms of these two diseases and others to follow, the ophthalmoscope and bifocal illumination may have

to be brought into requisition. Bifocal illumination is sufficiently simple in its performance and mode of application, and revelations, to need no more than a reference, but the use of the ophthalmoscope may need some more explanation from books, cuts and illustrations. In order to familiarize myself with the use of the ophthalmoscope I did what I suppose almost any one may do with equal benefit—devised a schematic eye which has the lens in the front as near as may be like the natural eye—the globe in two sections, front and back, an image of retina, disc with blood vessels and yellow spot painted in relative position, order and size; mounted so the globe can be elongated or shortened anterior-posteriorly; made myopic or hypermetropic and with two cylindrical lenses concave and convex, to slip over the cornea, so as to make it astigmatic. The whole combination mounted so it has all the motions or positions of the normal eye. With this placed in proper relation to the lamp, for illumination, I soon acquired the facility of focusing on any part of the interior of the eye to get a perfect image. This instrument so devised, and made by an ingenious gunsmith, suited me better than any of the other similar devices I have seen illustrated. It is now like the scaffolding around a building, useless and laid on the shelf. I exhibit it to show how simply and easily one may acquire a degree of skill in ophthalmoscopy. The appearance of the interior of the eye, both normal and diseased, can be better learned from cuts in any of the books I have referred to than by description here.

The diseases of the crystalline lens are of so little importance in this connection, except as related to cataract, that little need be said except of that and its relief or removal by operation. The mere diagnosis of the presence in a given case of a mature cataract is not difficult. The want of vision beyond the mere perception of light, counting fingers only near the face between the eyes and a window, and a lightish colored opacity in the locality of the lens just behind the pupil, the light or white colored area enlarging with a dilated pupil, together with a history of gradual and painless loss of vision would ordinarily be thought conclusive. Bifocal illumination and the use of the ophthalmoscope, would if confirmatory of the nature and location of the obstruction of vision add greater certainty. For the one who is going to operate, the diagnosis involves much more. On these points depend the determination of the time and variety of operation to be devised. Besides the incisions to be made, every possible means of infecting the wounds and the interior of the eye must be guarded against and every precaution taken in the technique to preclude any infection, and with the least manipulation. The care of the case after operation is one that involves too much to discuss in so little space and time. The diagnosis of congenital or lamellar cataract is of importance and can be readily made by one at all familiar with the ophthalmoscope; not without, however.

The possibility and practicability of artificially ripening or hastening the maturity of a slowly progressing senile, or blinding lamellar cataract for early extraction, so zealously and ably advocated and practiced by Dr. Boerne Bettman, of Chicago, needs more than a passing consideration. It is done by directly agitating the lense with the intact capsule through an incision in the cornea with a spatula made for the purpose.

Disease of the vitreous, or hyalitis, as characterized by cloudiness, floating bodies, flakes, films, syphilitic dust, sychysis scintillans in the vitreous and muscæ volitantes, etc., is so largely symptomatic of choroiditis and irido-cyclitis that it is not worth referring to under any other head.

We were told while students of ophthalmology that glaucoma is a terrible disease and that the general practitioner, with reprehensible temerity, overlooks it till the eyes affected with it are irretrievably lost. I think I see twenty such losses from choroiditis to one from glaucoma in any of its forms. Indeed, I see many more from iritis that have passed unheeded either by the patient or the physician. I think it is not so much the practitioner's fault as the patient's, and even this is not to be wondered at when we consider how indefinite are the symptoms in many cases of the latter two diseases, in their inception and early progress; and how passive or nearly void of marked symptoms a choroiditis may be in its whole progress except in its almost by-gone stage. There are almost no objective symptoms except that in connection with the subjective ones of slightly impaired vision there is noticed cloudiness of and floating opacities or films in the vitreous. In this stage the ophthalmoscope reveals no marked lesions of the fundus and from these the diagnosis is almost a matter of inference till the past stage of atrophy with its scotoma begin to appear. I think that if we were to inculcate as an aphorism that all persons whose vision is gradually or suddenly diminished, for more than a few hours should immediately put their eyes absolutely at rest till the trouble has passed some time, or a more definite diagnosis is made, we would save more eyes and promote more happiness than is done by railing at the general practitioner for overlooking the importance of an occasional glaucoma.

I will say in this connection, as a criticism of the books and many of the teachers, that we are too much disposed to say, when a disease is passive in character and obscure in cause as choroiditis eminently is, that it is syphilitic in nature. I am satisfied that choroiditis does originate without the syphilitic taint and get well as it may during or after the use of potassium iodid and mercury.

I think we should not strive to draw the tail of some remote and imaginary diathesis across every diagnosis of iritis or choroiditis we make, so as to label it scrofulous, gouty rheumatic or syphilitic, but that we should regard such diathetic condition as merely modifying or otherwise aggravating a disease in itself originating in the deranged functional activity of the organ or tissue.

Retinitis is hardly distinguishable from choroiditis in its inception and early progress except by very close comparison of symptoms, and there is some doubt whether it ever originates as an idiopathic disease. Its diagnosis is largely by exclusion of choroiditis and inference from negative signs. Retinal amblyopia is in many cases purely a functional ailment and non-inflammatory.

Papillitis unioocularis is a very passive disease, and is liable to have progressed so far before coming under observation and treatment that the possibility of maintaining a useful degree of vision has passed. The only thing that may attract the patient's attention is slightly impaired vision. Its complications are likely soon to obscure all means of a definite

diagnosis. I saw a patient who on Saturday noticed some obscuration of vision, and on Monday following I found the outlines of the disc entirely obliterated and vision almost totally lost. The patient was at once put on tonic and laxative remedies preparatory to the alterative treatment indicated. After she had been on the latter a few days, I found the pupil moderately dilated and adherent to the lens throughout, and punctate deposits on posterior surface of the cornea, and aqueous and vitreous too cloudy to admit of viewing the fundus. Atropia was added to the medication and within another week the pupil was well dilated and detached from the lens, and in two weeks longer the aqueous and vitreous were cleared so the retinal vessels and a large spot of choroidal atrophy near the yellow spot were visible. This all transpiring with almost no subjective symptoms except the obscuration of vision, and only a very slight hyperemia of the ocular and palpebral conjunctiva; and there was no reasonable manifest cause except slight albumen uræa, without casts or other signs of permanent renal disease. The very latent and insidious progress of this and other eye diseases I have mentioned, and the fact that very many eyes are irretrievably lost by them, suggests that we should diffuse a better knowledge of these facts among physicians and a greater apprehension among the people.

Lately we have learned to recognize a large class of functional troubles that may be classed under the head of errors of refraction, such as functional asthenopia and asthenopia of the muscular apparatus of the eye, which together with the habit deformity of strabismus, requires the use of lenses and their adjustment, and sometimes a surgical operation to correct and relieve. In language that may seem rude one may become foot-sore in his or her eyes. Excessive walking will make one's feet sore, though the feet be normal, which will be perpetuated if the walking is continuous; but with the use of a horse and buggy the feet will get well while the traveling by another mode is going on. So will the eyes, disabled by excessive functional activity, if sufficient assistance is afforded with suitable lenses properly adjusted. If there is an error of refraction to be overcome by the visual effort the functional trouble will arise earlier and persist much more pertinaciously; when, if the error is corrected, it may enable the one so troubled to use the eyes for any and all purposes with immunity.

The errors of refraction requiring such correction are those of myopia, hypertropia and astigmatism and presbyopia, separate or variously combined, with also those disassociations of the muscular apparatus of the eyes, as strabismus and the varieties of heterophoria—hyperphoria right and left, where the deviation of one eye is above the horizontal, and esophoria and exophoria, where the deviation is to the right or left of the vertical line.

To diagnose or measure some of these errors of refraction and to detect some of the disassociations of the muscular apparatus and properly correct them singly or variously combined, is many times one of the most difficult problems in physical and medical science.

Many persons, from innate singularity of endurance, will bear a great deal of some one, or combination of these defects of vision without inconvenience; others will become worried and suffer great incon-

venience from eye work with little of either, single or combined. The degree of inconvenience varies from slight fatigue and redness of eyes through all the gradations of neuralgia, headache, nervousness, stupidity, mental worry and chorea to insanity. Hence their importance can not be ignored.

In the measurement of refraction for its correction, I deem an absolute measurement necessary, by which I mean the unmasking of all latent conditions and degrees by temporary paralysis of the ciliary muscle. In this way I have resolved all cases of manifest mixed astigmatism I ever saw except *two* into some one variety or compound variety. In this, I usually find hydrobromate of homatropin sufficient. I use a 2 per cent. solution,—one or two drops instilled every five minutes three or four times, after which I wait till the accommodation is so relaxed as to render the patient unable to read No. 5½ Snellen or No. 14 Jeager, at ten inches, within the area of diverging rays with less than +3 D. lens which I have adopted as a standard of relaxation.

I have verified the efficiency of homatropin with atropia gtt. 1, instilled three times daily in same patient. I do not regard it as always sufficient or satisfactory. Yet it is the most so, consistent with the time allowed in a mere refraction case. At least it is vastly better than to merely correct manifest errors without it. In anisometropia I usually correct both eyes if I can get fusion of images, binocular fixation and the two images nearly the same size. If the patient is not annoyed by the two images with full correction of both eyes, and one is dull, I order the use of the dull eye alone when convenient, for its improvement.

The spectacle business must ever be a matter of importance and interest to all literary, scientific and professional people, as well as many who are engaged in the arts and trades, and almost all who use their eyes with any constancy at the near point. It is not like the trade in food and clothing, merely protecting the body and furnishing nourishment, but the use of lenses for the eye is to correct an error, supply a deficiency, cure or prevent disease, and requires some degree of knowledge of anatomy, physiology, etiology, pathology and therapeutics, and hence belongs to the profession of medicine.

I frequently see most egregious blunders growing out of the efforts of the mere opticians, jewelers, druggists and spectacle peddlers, by various make-believes, trying to do this work.

It belongs to the profession to prescribe for such troubles as require lenses, and physicians *ought* to prepare themselves so as to in all cases do better for the patient than the optician, spectacle peddler, jeweler, or druggist who is ignorant of the mere physiologic principles involved, to say nothing of the anatomic, pathologic and physical ones. It will not require much time for any of you to acquire all the knowledge necessary in connection with what you should already know, to enable you to do far better for the presbyopic and many others than those of the trades I have mentioned. Read a few pages in some school philosophy or physics in the chapter on light, under the sub-title of dioptrics and catoptrics, and the formation and power of lenses, and a few under hypermetropia, myopia, and presbyopia, in some good work on diseases of the eye, which you all have no doubt. Get you a box of lenses and a pair of trial frames such as belong with the box, and a

dozen sample spectacle frames of a variety of shaped nose-pieces, and a pupilometer—King's—and a little rule for measuring frames, so as to be able to make a measurement of the face or determine the shape the frame should be, and a card with a variety of sizes of print from diamond to long primer, and a card of graded large type, Snellen's, to put on the wall fifteen or twenty feet away. This outfit is only to enable you to do better than which these trades pretend to do, that of correcting presbyopia, and some cases of hypermetropia and myopia. Farther than this these trades can not go and you do not want to. I do not mean that these trades ought to be prevented from selling optical goods, but they ought to be discouraged from prescribing or pretending to say or "make believe" what lenses ought to be worn. The physician may use them just as he does the druggist, and only so.

The proper adjustment of the lenses selected, to one's eyes and face is a matter of much more importance than is thought. The pupillary distance should correspond as nearly as may be, with the space between the center of the pupils when viewing the objects at the distance the lenses are to be used. The distance between the optical center of the lenses after they are placed in the frames in which they are to be worn, should correspond to this pupillary distance. The height of the nose piece should be so arranged that the line of vision for the same object should pass through the optical center of the lens. The prominence of the nose-piece should be so arranged that the posterior face of the lenses just clears the eyelashes, and the lenses should be so otherwise adjusted that their face should be at right angles with the visual line. If the lens is tilted from this, either vertically or horizontally, it becomes in that meridian in a degree a cylinder. I wish some of our physicians could see how urbanely and complacently, yet grotesquely they violate every one of these principles in their latest purchase.

Some of you no doubt are ready to ask: "Ought not we to wear nose-glasses?" Yes, if you can get a pair that you can put on twice alike, and that does not, when on, violate two or more of the principles of adjustment I have just laid down. They are very convenient but ought not, as a rule, to be worn for more than a few minutes at a time. Glasses need a firm and steady and always-the-same adjustment.

Some no doubt say: "Should I begin to wear glasses for my presbyopia early? You should begin to wear the correction of your presbyopia just when you can no longer do your near work at a convenient distance and with desirable comfort. Over-work of eyes from ill convenience and optical disadvantages is as liable to produce disease in these organs as over-work in any other organ of the body is liable to produce disease in the same.

I notice that physicians often order patients suffering with weak or sore eyes to wear periscopic London smoked coquelles. Now if you will think for a minute that most persons are hypermetropic, and that the London smoked periscopic coquelles are usually concave spherocylinders, it will readily occur to you that this ought not to be done, because it tends to fatigue the eyes. It is better to prescribe the plano or flat ones of the same color.

Formerly, as a general practitioner, I treated headaches with alteratives, quinia and tonics, with variable results. Now, in every case of persistent or

frequently recurring headaches, not easily attributable to other causes, I deem an absolute measurement of refraction a necessary part of the investigation of the case, and if an error of refraction is detected, its correction is a necessary part of its treatment. With this course I relieve a larger per cent. of headaches than I used to with a treatment by medication alone.

It is not true that all the patients suffering from ametropic or heterophoric headaches or other nervous sequences must ever after wear the correction to have relief, for many very soon stop the trend of nervous pain and discomfort, break the habit which mere circumstances do not reestablish and have immunity ever after. In this connection I would feel recreant to my trust if I did not say, with a full knowledge of the difficulties that may beset the measurement of refraction and the correction of visual errors, and the great embarrassment and evil following the mistakes made by the non-professional and ignorant spectacle vendor, pretending that he understands dioptrics and ophthalmology, that the physician or oculist who is a physician, is the only one who ought to prescribe lenses and their adjustment for eye troubles requiring such. These trades should be discouraged from prescribing lenses, as druggists should be discouraged from prescribing medicines. I do not mean to say they may not sell, but they ought not to prescribe lenses, for such is virtually "prescribing for disease" and "practicing physic." Since writing the above I see that Dr. A. R. Baker, Chairman of the Ophthalmic Section, AMERICAN MEDICAL ASSOCIATION has just said in his address before that body, that every practitioner should possess an ophthalmoscope and a few trial lenses, and should be able to fit spectacles much better than jewelers or druggists who style themselves opticians.

To which I say, learn all you can, do all you can to benefit, in a useful way your patients and when you would call council in any case call a specialist, or any one who may have learned more in this particular line, as an assistant. Or, if you do not want to treat such cases, refer them to some one whom you may think competent who does. But still maintain by knowledge, moral deportment and efficiency that the general practitioner is the best exponent of the intelligence and usefulness of the practice of medicine and is the only one who can take in the whole situation.

LEGISLATION FOR THE PREVENTION OF BLINDNESS.

Read to the Illinois State Medical Society, Decatur, Ill., May 17, 1894.

BY BOERNE BETTMAN, M.D.
CHICAGO, ILL.

Owing to a misunderstanding, the subject which I announced for this meeting does not appear on the program. I prepared a paper on "The Working of the Lunacy Law," the intent being to elucidate some of the measures of the new law, and indicate to you how imperfectly the essential feature, at least from a medical standpoint, is being carried out. I refer, namely, to trials by a board of medical commissioners. However, I propose publishing the article later on in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and hope its perusal will induce you to labor with the judges in your respective counties and influence them to do away with the old jury system and adopt instead a more enlightened and humane

method of investigation into the mental state of an individual, by a commission consisting of two well qualified physicians. The subject to which I will now call your attention, namely, "Legislation for the Prevention of Blindness," is also worthy of your attention and coöperation. It has been discussed so often and has been so repeatedly a theme of discourse that I will dispense with the reading of statistical tables showing the number of blind in the various communities, and the causes which are responsible for this affliction. Neither will I dwell upon the prophylactic measures which are so efficacious to prevent blennorrhœa neonatorum. I wish merely to inform you that the State Board of Charities of Illinois determined at its last meeting to induce the next Legislature to pass such measures as will reduce the percentage of blindness at least 25 per cent. The need of such legislation is probably felt more keenly in large cities. Of the 1,152 midwives in the State of Illinois, 700 are located in Chicago. Of the 28,742 births recorded last year in Cook County, more than one-half were reported by midwives. They do not carry out the preventive measures of Haussman and Credé. They do not render the vaginal tract aseptic; they do not make innocuous the germs which have lodged in the conjunctival sac of the new-born infant, and when ophthalmia neonatorum does make its appearance they frequently try home remedies for its alleviation. Only after serious damage has resulted to the eyes do they call in the aid of a physician; consequently they must be held responsible to a large degree for loss of vision in the young.

I have read two exhaustive papers on the subject in question at the Chicago Society of Ophthalmology and Otology and at the Chicago Medical Society, and requested both bodies to pass resolutions showing the need of legislation for the prevention of blindness. The necessity for adopting such a course will become more evident to our representatives if the contemplated act receives the indorsement of representative bodies of physicians. The resolutions passed by the Chicago medical societies contain a preamble and the intended bill which has already become a law in the States of Maine, New Jersey, New York and Maryland. The resolutions read thus:

WHEREAS, Statistics compiled in this country and Europe demonstrate that fully 25 per cent. of our blind owe their affliction to an inflammation of the eyes appearing a few days after birth; and

WHEREAS, Experience has proved that the inflammation can be cured and the eyesight saved in the majority of cases, if treatment is instituted at an early stage of the disease; and

WHEREAS, The destruction of the eye and blindness are usually the result of the delay of treatment; be it

Resolved, That we heartily recommend that the people of the State of Illinois, represented in Senate and Assembly, do enact as follows:

SECTION 1.—Should one or both eyes of an infant become inflamed or swollen, or reddened at any time within two weeks after its birth, it shall be the duty of the midwife or nurse having charge of such infant to report in writing within six hours to the Health Officer or some legally qualified practitioner of the city, town or district in which the parents of the child reside the fact that such inflammation, or swelling, or redness of the eye exists.

SEC. 2.—Any failure to comply with the provisions of this Act shall be punishable by a fine not to exceed two hundred dollars, or imprisonment, or both.

F. C. HOTZ, M.D.,
LYMAN WARE, M.D.,
BOERNE BETTMAN, M.D.,
Committee.

I have suggested to gentlemen to adopt similar recommendations in medical assemblies throughout the State, and in accordance with this idea the Central Illinois District Medical Society passed the following resolutions at their last meeting, held at Pana, April 22, 1894:

WHEREAS, Laws have been enacted by the Legislatures of several States relative to the prevention of blindness due to ophthalmia neonatorum; and

WHEREAS, Efforts are being made by the Illinois State Board of Charities to influence the passage of a similar law by the Illinois State Legislature of 1894-95; be it

Resolved, That the District Society of Central Illinois, convened at Pana, April 22, 1894, hereby indorses and commends the efforts being made by the Illinois State Board of Charities to secure appropriate legislation relative to the prevention of blindness due to ophthalmia of the newborn.

And now, gentleman, I hope this convention representing the united interests of the regular profession of the State of Illinois, will aid the good cause by encouraging, with your stamp of approval, the work of the State Board of Charities. I submit to you for acceptance resolutions containing the sentiment of those already read:

WHEREAS, Statistics compiled in this country and in Europe demonstrate that fully 25 per cent. of our blind owe their affliction to an inflammation of the eyes appearing a few days after birth; and

WHEREAS, Experience has proved that the inflammation can be cured and the eyesight saved in the majority of cases, if treatment is instituted at an early stage of the disease; and

WHEREAS, The destruction of the eye and blindness are usually the result of delay in treatment; and

WHEREAS, Efforts are being made by the Illinois State Board of Charities to influence the passage of an act for the prevention of blindness; be it

Resolved, That the Illinois State Medical Society, convened at Decatur, May 17, 1894, hereby indorses and commends the efforts being made by the Illinois State Board of Charities to secure appropriate legislation relative to the prevention of blindness due to ophthalmia of the newborn.

DISCUSSION.

DR. E. P. COOK, Mendota—Permit me to make a remark in connection with what Dr. Bettman has said, although he did not read his paper, in relation to the working of the law for the commitment of the insane. It is a subject in which I have taken a great deal of personal interest, and the Transactions of this Society show that I was the first to present the matter in this State Medical Society. By following up the movement it has gradually grown strong enough so that we have the present law. While it is true that we are working under a law that is defective, still it is very much in advance of that previously existing. My opportunity for observation of the working of that law has been so limited that I can not base any opinion of its merits upon that observation. Shortly after the law came into operation, in July, I saw the judge having in charge such matters, and had a case before the court. In the course of conversation with the court, however, he was unaware that there had been any change in the law, and that there was no provision for insane cases. He was astonished to hear the law had been changed. That was after July 1. He took an interest in the matter, looked it up, and shortly after had the case investigated in private. It was cruel to take the case before a court, and the judge was right and expressed his approval of the new law. The case was investigated at the home of the patient and the patient finally sent to one of the State institutions. It was a serious case, and later the remains of that party were taken to the former home.

As my observation has been so limited with reference to the working of the law, I would like to hear some expression of opinion from those who have given it more attention. It occurs to me the majority of cases should be so investi-

gated, as was suggested by some remarks, and the exceptions are those that should be publicly investigated.

THE CHAIRMAN—Can any one present give us any light on this subject?

DR. BOERNE BETTMAN, Chicago—There is a great deal to be said on this subject, and that was the object in preparing the paper alluded to. All of the lunacy cases are not tried by the new system of a board of commissioners.

Before coming to this convention I had statistics sent to me from Springfield, wherein it is stated that since August 10, 1893, up to May 1, 1894, there were all in all about seven hundred and thirty-one cases adjudged insane. Of this number about ninety-six were tried by commissioners, the rest by jury. In the city of Chicago there were 411 cases committed to various insane asylums, not one of this number being tried before a commissioner. In conversation with Judge Scales and Judge Brown—county judges of Cook County—as to the reason why they would not appoint commissioners to try insane cases, they said they were being called upon so frequently by shyster doctors of Chicago, who were so anxious to earn \$5 which they were entitled to for an examination of a case, that rather than have incompetent commissioners they would insist upon the old jury trial. In some of the out-lying districts, especially throughout the country here, a great number of cases, I am glad to say, are being tried by commissioners, and I am quite sure that if the physicians assembled here to-day would use their influence with the respective county judges in the various counties, and show them the necessity of appointing a board of commissioners, more cases would be tried in this way.

Section 5 of our new law was changed after the first reading. The first reading of the law read something like this, that "cases of insanity shall be tried by jury or by commissioners at the discretion of the judge," etc. The first seven words were retained after the first reading of the bill; the rest of the clause was erased for some reason that I could not learn. The following clauses, 9, 10 and 11, go on to elucidate the duties of the jury or commissioners. Section 5, as it now stands, however, states that the "trial shall be by jury." I have been told by some learned lawyers and judges that this one section—section 5—makes the others ineffective. Again, other lawyers and judges have told me that the true conception and essence of the law could not be obtained from the wording of one section; that in order to have a proper expression of the law all sections must be taken together. Therefore there are some judges who refuse trials by commissioners because they consider the law inefficient, while others say it is unconstitutional.

I have talked over the matter with several lawyers, and they say the only way to settle it would be to get an opinion from the Supreme Court, and I hope in a few weeks to have a case taken there for final decision.

DR. D. W. GRAHAM, Chicago—I would like to say just a word or two along the line of Dr. Bettman's remarks. The bill as originally drawn passed part of the way through, but there was a little coterie of lawyers who opposed anything that doctors proposed in the Legislature, and they thought it would kill the bill, or the essence of it, by striking out a certain clause in section 5, leaving the statement as Dr. Bettman has given it, that "trial shall be by jury." I was one of the members of the Society who had something to do with this matter, and after consultation with some of the experienced members of the Legislature and best lawyers, we were told that it was too late to try to get the bill amended; that the best thing to do was to get the bill through as amended, giving it as their opinion that the bill was efficient. It was claimed that the striking out the clause in section 5 had killed the essence of the bill. Other lawyers told us that in their opinion it would be a matter for the Supreme Court to decide whether the amendment did destroy the commission feature of the bill. But the understanding was that the law should be accepted as passed, and let the courts decide whether the present law, as amended, allows commissioners to try cases or not.

SOCIETY PROCEEDINGS.

American Association of Obstetricians and Gynecologists.

Abstract of the Proceedings of the Seventh Annual Meeting, held in Toronto, Sept. 19, 20, and 21, 1894.

(Continued from page 552).

DR. A. H. CORDIER, of Kansas City, read a paper on
HYDROSALPINX.

He said articles had appeared in medical journals by the so-called conservative writers in the last few months in which aspiration or catheterization of the Fallopian tubes filled with liquid of any character had been advocated as a procedure of relief and cure. Such articles had engendered a retrograde tendency on the part of many, and it is sure to be at the expense of an increased mortality from subsequent operative procedures to cure these cases after abandoning the unsurgical and uncertain tinkering. Hydrosalpinx had been looked upon as the least hazardous of all inflammatory results to the Fallopian tubes. The writer claimed that hydrosalpinx was a sequel of some old inflammatory diseases of the tubes, an offspring of a virulent process that had wrought permanent and irreparable injury to the delicate structures of the tubes. The writer did not consider hydrosalpinx as a retention cyst. Cases were rarely diagnosed prior to operation. A digital examination of one of these cases causes less pain than is produced in examining a pyosalpinx. In one case occurring in the essayist's practice the uterine extremity of the tube was largely dilated and filled with a clear fluid, while in the ampulla there existed a collection of pus, separated from the clear fluid by a closed stricture.

INFLAMMATORY DISEASE OF THE UTERUS AND APPENDAGES UNDER VARIOUS MODES OF TREATMENT.

By DR. JOSEPH PRICE, of Philadelphia. The methods of treatment of pelvic disease may be broadly classed as those that are proved, and those that are experimental. Many of the operations now successful were formerly failures because of the insufficient knowledge of how to deal with a wounded gut, how to make an anastomosis, or to do a bowel resection. Hence it is to be put down as a postulate in pelvic surgery that no man has a right to attempt it who does not know how to deal with all the complexities of intestinal surgery. To know when to stitch and when not to stitch the intestine, is as necessary as to know when and when not to operate. The leaving of pus tubes to recover of themselves is just one step removed to stuffing them with gauze and trusting to Providence. To puncture and evacuate and stitch a suppurating cyst—say a real ovarian cyst—would be derided out of sight, and yet, said the essayist, we have operators who do not hesitate to do this with the smaller pus tube.

DR. GEO. H. ROHÉ, of Catonsville, Md., said that conservative surgeons were very much shocked at first by the proposition to remove the uterus, together with the adnexa, in cases of inflammatory disease in the pelvis. However, the operation has won its way against opposition and must now be considered as an elective procedure in cases of extensive suppuration with adhesion, and especially in those cases so numerous in which the endometrium is likewise the seat of purulent inflammation. Gonorrhœal, puerperal or tubercular inflammations and dense adhesions, with displacement of the uterus, demand removal of this organ as well as of the appendages if permanent good results are expected. Total extirpation of the uterus and appendages by the vaginal method for pelvic suppuration was first done by Péan in 1886. Péan, Segond, Doyen, Jacobs and Landau have performed the operation upward of five hundred times with an average mortality of less than 5 per cent. The operation by the vagina is easier than abdominal extirpation, and in the hands of most surgeons who have performed it, is attended by less shock. It leaves the parts in condition for perfect drainage. The after-treatment is simple. Pa-

tients may sit up in a week or ten days. Forceps are preferred to the ligature for hemostasis.

THE PRESENT STATUS OF THE TREATMENT OF PELVIC INFLAMMATION; OR HOW SHALL WE DEAL WITH PELVIC INFLAMMATORY TROUBLES?

By DR. W. B. DORSETT, of St. Louis. The author drew the following deductions:

1. Pus in quantities is hard to deal with down in the pelvis in laparotomy cases and, if possible, should be evacuated prior to taking out the tubes and ovaries, either through the cul-de-sac of Douglas, or if between the layers of the broad ligament at the side of the uterus, laparotomy should be done at some future time.
2. Pus sacs in the tube near the uterine end of the tube can be evacuated through the uterus by packing the horn.
3. Parametritis or cellulitis of the ancients is, except under rare instances, a secondary trouble due to a foul uterine cavity. Clean out the cavity and stop the source of poison and you do the best thing possible to be done.

SECOND DAY—AFTERNOON SESSION.

DR. C. C. FREDERICK, of Buffalo, read a paper on
THE RELATIONS OF RENAL INSUFFICIENCY TO SURGICAL OPERATIONS.

The author reported observations based on nearly three hundred operations at the Buffalo Woman's Hospital, supplemented by the experience of several prominent operators. By renal insufficiency is meant any condition of the urine which shows deficient elimination of waste products whether from functional inactivity or from disease of the kidneys. Whether renal insufficiency is a contra-indication to operation depends on the consideration of three factors: 1, the amount and nature of the insufficiency; 2, the character of the lesions for which operation is proposed; 3, the causal relation which the patient's disease holds to the renal insufficiency. Every patient's urine before operation should be collected for twenty-four hours, except when operation is urgent, as in ruptured ectopic pregnancy, for example. In examination of urine the important fact to ascertain is, whether the kidneys are crippled, or in full or nearly normal functional activity. Women with chronic endometritis are especially liable to functional insufficiency. Most gynecologic patients who are run down physically, present the same condition. A knowledge of the state of the patient's kidneys is of value to the operator and anesthetizer. Renal insufficiency renders the patient more liable to shock from operation and a slower convalescence.

DR. I. S. STONE, of Washington, D. C., followed with a paper entitled "Some Results of Ether Anesthesia in Abdominal Operations."

DR. EUGENE BOISE, of Grand Rapids, Mich., read a paper on
THE CAUSE OF THIRST FOLLOWING ABDOMINAL SECTION.

The author, after stating the generally accepted proposition that thirst is a sensation indicating that the tissues of the body are in want of more water, argues that the sensation as felt in the mouth and throat is reflex, and that the real point from which the sensation arises is in the abdominal viscera; that from these the sensation is conveyed to the consciousness by fibers of the sympathetic system of nerves; that while ordinary thirst is caused by the withdrawal of water from the tissues to refill the veins depleted by excessive perspiration or otherwise, the thirst following abdominal section is caused by the withdrawal of water from the abdominal viscera to fill veins partially collapsed by reason of diminished blood supply because of contraction of the arteries of the viscera. He briefly stated those physiologic facts which are universally accepted or have been experimentally proven on which the theory is based:

1. Thirst is a sensation indicating that the tissues need more water.
2. The sensation felt in the throat is reflex.
3. The origin of the sensation is believed by leading physiologists to lie in the sympathetic system of nerves because: a, no cerebro-spinal nerves can be found which convey the sensation to the consciousness; and b, nutrition is presided over by the sympathetic system, and thirst is a disturbance of nutrition.
4. The origin of the sensation is probably from the abdominal organs because: a, these are so rich in sympathetic fibers; and b, introduction of water into the stomach so instantaneously allays thirst.
5. The sensation invariably follows the withdrawal of any considerable amount of fluid from the body; the with-

drawal of such fluid causes proportionate collapse of veins and capillaries.

6. Capillaries tend to remain at normal tension, and when suddenly collapsed in any degree attempt to regain that tension by taking water from the surrounding tissues.

7. Irritation of sympathetic nerves causes contraction of the arterioles supplied by such nerves.

8. Sudden contraction of the arterioles supplying any organ is followed by lessened tension in the capillaries and small veins of that organ.

9. Abdominal section invariably causes direct and reflex irritation of the abdominal sympathetic nerves.

10. Such irritation causes contraction in some degree of the arterioles of the abdominal viscera with consequent lessened tension in their capillaries, and compensatory withdrawal of water from their tissues. And is it not probable that such circulatory disturbances give rise to the sensation of thirst?

Dr. HULBERT, Second Vice-President, took the chair, and PRESIDENT ROHÉ delivered his address. He selected for his subject,

INTESTINAL OBSTRUCTION FOLLOWING OPERATIONS IN WHICH THE PERITONEAL CAVITY IS OPENED.

He said obstruction of the bowels causes between 1 and 2 per cent. of the deaths following ovariectomy and other operations involving opening of the peritoneal cavity. Sir Spencer Wells lost eleven out of his first series of a thousand cases of ovariectomy from this cause. Fritsch places his mortality from ileus post-laparotomy at 1.6 per cent. Klotz has reported 31 cases of intestinal obstruction with 5 deaths due to this complication in a series of 421 abdominal sections and 148 vaginal extirpations of the uterus. The speaker had seen a case where the small intestine was doubled upon itself, and so firmly adherent that the gut was entirely impervious. Similar cases have been reported by Skutsch and Tuttle. Joseph Price quotes an interesting case from Louis, where an adherent ovarian cyst, emptied by the trocar, so dragged upon the bowel as to cause obstruction. Volvulus sometimes occurs after abdominal section, but probably only after some previous adhesion or constriction of the bowel. Two cases reported by Nieberding illustrate this. The symptoms of intestinal obstruction post-laparotomy are essentially the same as those of primary obstruction. Klotz has had much success in treating acute obstruction following abdominal section by the following method: As soon as symptoms indicating obstruction appear, he washes out the stomach with from four to six quarts of warm salt solution. Should this fail to relieve the symptoms he repeats it, and then passes into the stomach through a tube a large dose (one and a half to two ounces) of castor oil. In all cases so treated the active peristaltic movements set up caused passage of flatus and feces within ten hours. Evidently it is only in cases of fresh and friable adhesions that this method can be successful. Rectal injections of water or air may at times be curative when the obstruction is due to intussusception, volvulus or soft adhesions of the lower portion of the intestine, but where the obstruction is due to cords or bands they can manifestly be of no avail.

THIRD DAY—MORNING SESSION.

Dr. L. H. DUNNING, of Indianapolis, Ind., contributed a paper on

NEPHRECTOMY

in which he reported four cases, of which the following is a synopsis:

Case 1.—Nephrectomy for painful movable kidney. An unsuccessful nephrorrhaphy had been done two and a half years previously. The patient had been bedridden four years. A lumbar nephrectomy was done, the patient recovering and obtaining entire relief from pain. The author deplores the necessity of removing a healthy kidney only because movable and painful. He thinks that the success of recent methods for anchoring the kidney will obviate the necessity of such a procedure.

Case 2.—Nephrectomy for persistent hydronephrosis, due to stricture of the ureter at its pelvic extremity. The tumor was mistaken for an ovarian one. It was removed by a median abdominal incision.

Case 3.—Sarcoma of the kidney in a child 2 years old. Nephrectomy and recovery. The tumor had been discovered only four weeks previously. A median incision (abdominal) was employed.

The writer has collected the histories of twenty cases of sarcoma of the kidney operated upon since 1885 in children

under 5½ years of age. Of these five perished and fifteen survived the operation, thus showing a mortality of 25 per cent. This is a surprising decrease in mortality, and is probably due to improved details in technique rather than to radical changes in the method of operation.

Case 4.—Nephrectomy for uretero-vaginal fistula following vaginal extirpation of a cancerous uterus. The operation was done four weeks after the hysterectomy. The ureter was torn across in enucleating a nodule of cancerous tissue from the folds of the broad ligament on removal of the uterus. Nephrectomy was done four weeks subsequently because of intermittent closure of the fistula and the morbid mental condition of the patient. The cancer had recurred in seven weeks, and patient died three months later of exhaustion and septicemia.

Dr. C. A. L. REED, of Cincinnati, read a paper with the caption,

PROGRESSIVE CUTANEOUS ATROPHY OF THE VULVA (*kraurosis vulvæ*.)

He reported six cases in which the pathologic and clinical features were characteristic. The first changes obvious to the naked eye consist of small vascular areas around the introitus vaginae. These areas are not elevated, as if seats of merely inflammatory engorgement, but are slightly depressed relatively to the adjacent epithelial surfaces. They are exquisitely painful to the touch and efforts at sexual intercourse are generally agonizing and futile. About this time inspection will reveal a narrowing of the vaginal orifice associated with diminishing elasticity of the structures. The cutaneous or muco-cutaneous surfaces will now be observed to have lost a certain proportion of their pigment, giving them a more or less translucent appearance which increases until it becomes so transparent that the larger capillaries and minute ecchymoses may be readily discerned beneath it. The skin thus affected becomes tense, effacing to a more or less degree all of the normal folds of the vulva and narrowing the vaginal orifice until, in the case of a multipara, "incredulity may be excused when the patient states that she has born children."

Knowledge relative to progressive cutaneous atrophy of the vulva is too nebulous to justify final conclusions. That which seems to be conclusively demonstrated may be summarized as follows:

1. Progressive cutaneous atrophy of the vulva is a distinct disease; 2, it is of very rare occurrence; 3, it is essentially inflammatory in character, differing from other inflammations of the skin in the marked progressive atrophy which succeeds the stage of hyperemia and infiltration; 4, it is limited in its manifestations to the vulva; 5, it is manifestly not of syphilitic origin; 6, its etiology is so obscure as to suggest a primary causal lesion in the trophic nerve supply of the vulva; 7, the affected areas may be successfully excised.

Dr. GEO. F. HULBERT, of St. Louis, read an interesting paper on "The Element of Habit in Gynecic Disease," an abstract of which would not do justice to its author.

One of the interesting features of the meeting were the remarks on intestinal anastomosis and a beautiful demonstration of the uses of the Murphy button by Dr. J. B. Murphy, of Chicago.

RESTORATION OF INTESTINAL CONTINUITY WITHOUT MECHANICAL DEVICES.

By Dr. W. E. B. DAVIS, of Birmingham, Ala. The purpose of this paper was not to claim originality for any special technique, but rather to consider the various operations and to show that mechanical devices can in a great proportion of cases be better dispensed with by the surgeon who has had much experience in intestinal work, either on the lower animals or on the human intestine. Still there is a place in anastomotic work for bone plates, catgut plates, and other devices of this sort, and the Murphy button, but the experienced surgeon will find the field of their application very limited. These devices are of great assistance to the surgeon of limited experience in this class of work, and should be recommended in the event of an operation having to be done by one who has not had the opportunity of becoming familiar and skilled in suturing of the intestines. The Murphy button is a valuable device for cholecystenterostomy and is superior to anything yet suggested for that purpose. The button is so small that it can pass through the intestine without causing any trouble, and it can be depended upon with almost absolute certainty to produce satisfactory adhesion and a competent opening between the gall-bladder and intestine. The end-to-end operation or circular enterorrhaphy is a dangerous procedure, from the fact that injury

to the mesenteric border is liable to produce sloughing, and it is never possible to say that a surgeon will not have this complication follow the operation. Besides any stitch method in the end-to-end operation requires so much time that it should be objected to usually on that account. The Murphy button can be used very satisfactorily for this purpose, and where end-to-end operation is to be resorted to, Dr. Davis is of the opinion that this device should be used unless the surgeon is an expert in intestinal suturing. The operation of Abbe is a plausible one, but is not so reliable as the one which has proven satisfactory in the experimental work of the author. The incision is not made so long as in the case of Abbe, and is about three inches in length. In the case of gastro-enterostomy the intestine and stomach are both brought into the wound, and the incision three inches in length made in both. Interrupted sutures are taken through the coats of the bowel and stomach around the entire length of the incisions and are tied on the inside, the last stitch being tied on the outside and turned in. A continuous outside safety stitch is then taken through the peritoneal and muscular walls. In bringing the small intestine together the same procedure is followed, the interrupted through-and-through stitch of large silk being taken instead of an over-hand stitch, as recommended by Abbe, and only one row of outside sutures which may be interrupted or continuous, preferably the latter. This operation can be done very quickly and is more reliable than the various ones with mechanical aids to anastomosis. Particularly is this method of operating valuable in cases of simple stricture of the bowel, and there will be a great many of these cases now, inasmuch as there are more operations done on the intestines.

Dr. F. BLUME, of Allegheny, Pa., reported a very interesting case of cholelithiasis in a woman 37 years of age, in which the number of calculi removed besides minute concretions was 123, weighing fourteen drachms. The stone removed from the gall bladder weighed four and three-quarter drachms.

THE REASON WHY PATIENTS RECOVER FROM TUBERCULOSIS OF THE PERITONEUM AFTER OPERATION.

By Dr. ROBERT T. MORRIS, New York. The author stated that he had been experimenting with a view to determining the reason for the cure of tuberculosis of the peritoneum after operation, it being a well-known fact that more than 80 per cent of these cases recover as a result of simply exposing the peritoneal cavity to the air. Dr. Morris collected fluid from the abdominal cavity of patients with tuberculosis of the peritoneum, placed it in an incubator for forty-eight hours and developed the bacteria of putrefaction which would ordinarily enter in such fluid exposed to the air. From this fluid Dr. Eiloart then isolated a toxalbumin the product of the growth of putrefactive bacteria in this peritoneal fluid. The toxalbumin employed to destroy tubercle bacilli in culture tubes destroyed them very promptly. A control experiment, which was not yet completed, was in progress for determining if these bacteria were absolutely dead. However, enough had been proven to show that tuberculosis of the peritoneum recovers after operation, because putrefactive bacteria produce a toxalbumin in the fluid which is fatal to tubercle bacilli in the peritoneum. The reason why it is more effective in curing cases of tuberculosis of the peritoneum, than tuberculosis of the knee joint, is because the lymphatic anatomy of the peritoneum is such that any toxic agent absorbed by the lymphatics of the peritoneum is brought into close contact with the entire structure; whereas in the knee joint the lymphatics are fewer and with more definite channels.

The following officers were elected: President, Dr. J. Henry Carstens, Detroit; First Vice-President, Dr. W. E. B. Davis, of Birmingham, Ala.; Second Vice-President, Dr. Henry Howitt, Guelph, Ont.; Secretary, Dr. William Warren Potter, Buffalo; Treasurer, Dr. X. O. Werder, Pittsburg.

The place of meeting for 1895 was referred to the Executive Council for decision.

American Public Health Association.

Twenty second Annual Meeting, held at Montreal, Canada, Sept. 25-28, 1894.

(Continued from page 554.)

Dr. A. N. BELL, of Brooklyn, regarding the paper of Dr. Lee, "The Cart Before the Horse." The writer distinguished the horse as the public and the cart as the contractor or plumber—although he meant no offense to the latter gentleman; that the horses or public are frequently neglectful

in doing their duty he had no doubt, and he thought the case often is that health officers neglect their duty also.

Dr. S. W. ABBOTT, of Wakefield, Mass., among other things said, that several of the laws were inoperative or ineffective; especially was this true in his State.

Dr. P. H. BAYCE, of Toronto, thought perhaps the Committee had overlooked the subject of purification and how to prevent pollution of public water supplies, yet their work had been splendid and the Committee might be excused on account of the limited length of time that they had to formulate their report.

Mr. JOHN MITCHELL, of New York, a master plumber and delegate from the Master Plumbers' Association, stated that they are in hearty support of vigorous laws and prompt and decided enforcement of such laws in this matter. He thought this body would be a power to enforce earnest and active laws of sanitary inspection. The architect directs no plumbing in the public buildings to-day; we are simply a machine. The architect, contractor and householder throw the responsibility on us, which we do not justly deserve. We desire participation in the plans as laid out by the architect and contractor. The plumbers are in earnest to help carry out this work, as suggested in Dr. Lee's paper.

Dr. LEE, discussing his paper, expressed his thanks for the feast of good things we have heard to-day. It would be invidious to refer to any paper. The one that appealed to him most strongly was the "Constant Pollution of the Homesteads of Farms," for surely the pollution of the family well is most prolific of this enteric form of trouble.

Dr. C. A. LINDSLEY, of New Haven, Conn., cited a case of failure of "the cart-before-the-horse" plan, as follows: In his city a law was passed by the common council to appoint a "plumbing inspector" to be approved by the State Board of Health. A gentleman was selected for this position and then presented himself before the State Board for examination. He failed to pass the necessary requirements, and the Board so reported to the mayor and council. The man was, nevertheless, appointed to the position without the indorsement of the State Board.

MANAGEMENT IN DIPHTHERIA EPIDEMICS IN RURAL DISTRICTS,

By Dr. CHAS. A. HODGETTS, L.R.C., Toronto, Ont., was the title of a well written paper. The author stated that he intended to treat more especially of the people who live in the land of the ax and hoe; and the treatment of the disease as it appears in lumber camps, and out-of-the-way places; how cases appearing there can be isolated, quarantined, treated, etc.; all of which was also particularly given in detail.

The next paper "Practical Difficulties of Medical Health Officers and Physicians in dealing with suspected Cases of Diphtheria," was by Dr. PETER H. BRYCE, Secretary of Provincial Board of Health of Ontario, Toronto. (Dr. Bryce's paper will appear in the JOURNAL at an early day.)

Dr. J. ED. LABERGE, Bacteriologist to the Local Board of Health of Montreal, read the next paper on

DE LA VACCINATION COMME PROPHYLAXIS DES MALADIES CONTAGIEUSES.

Dr. FORMENTO said that the paper of Dr. Laberge was of much scientific interest, as well as of excellent intrinsic value. It opens the field of preventive medicine, by treatment by inoculation of a formidable character. He personally thanked Dr. Bryce, as well as the other gentlemen, for the scientific and practical ideas each had advanced.

On motion of Dr. Bryce, seconded by Dr. J. Berrien Lindsley, further discussion of the series of papers on diphtheria was postponed until the next (Wednesday) morning.

The two succeeding essays were upon motion read by title: "Notes on the Soil Factor in the Development and Prevention of Infectious Diseases," by Dr. EDWARD PLAYTER, Ottawa, Canada; and "Drainage of Montreal," by Mr. ALFRED BRITAIN, Assistant-Surveyor of the city of Montreal, which was followed by Dr. J. D. GRIFFITH, of Kansas City, Mo., who read a lengthy paper on,

INNOCUOUS TRANSPORTATION OF THE DEAD.

The author took the ground that enough care is not taken in transporting dead bodies from one place to another. No undertaker is capable of making caskets perfectly air-tight, and cars bearing dead bodies are always pestilential. The precaution of wrapping bodies in solutions of disinfecting fluids is useless when it is remembered that a couple of hours dries the cloths. There is a danger of infection even from the bodies of victims of consumption, and besides the baggagemen of trains the general traveling public are exposed through their baggage. Dr. Griffith recommended a law

compelling the railways to divide a portion of the baggage-cars off as a large air-tight compartment for the carriage of dead bodies.

DR. BRYCE suggested that precautions should be taken to prevent the carriage by railways of persons suffering from consumption, as well as all contagious diseases. Consumptive patients are more dangerous than their dead bodies.

DR. HINGSTON was opposed to Dr. Griffith's scheme because he was opposed to increasing facilities for moving dead bodies. No bodies of people dying with infectious diseases can be removed from Montreal, and the railways will not carry them.

A young member suggested that no dead bodies should be allowed to be carried except as ashes after being cremated. On Dr. Bryce's motion a committee was appointed to discuss the whole question.

Adjourned at 6:20 o'clock.

The formal opening of the Association took place at Windsor Hall at 8:30 o'clock P.M. Many ladies graced the audience with their presence. The Address of Welcome by Lieutenant-Governor Chapeau, of the Province of Quebec, was a tribute to the Association, and the addresses of the Mayor of the city, Hon. J. O. Villeneuve; Dr. Robert Craik, Dean of the Faculty of McGill University; Hon. L. P. Pelletier, Provincial Secretary; the President, Dr. E. P. LaChapelle; Dr. Mendizabal, of Orizaba, Mexico, each in turn received round after round of applause.

The opening of the proceedings was fixed for 8:30. At that time the capacious hall was comfortably filled. Gruenwald's orchestra was on hand, and promptly at the time fixed for the opening struck up a medley of British, Mexican, United States and Canadian airs. In a few minutes an imposing procession began to file down the hall from the eastern entrance. Dr. E. P. LaChapelle, the

PRESIDENT OF THE ASSOCIATION, LED,

and following him were: His Honor Lieut-Governor Chapeau, Hon. L. P. Pelletier, Provincial Secretary; His Worship the Mayor; Dr. Anderson, U. S. Consul-General; Dr. R. Craik, Dean of the Medical Faculty of McGill University; Dr. Durgin, Boston; Dr. Paley, New Westborough; Dr. Formento, New Orleans; Dr. Montizambert, of the Dominion Quarantine Service; Dr. Gibon, of the U. S. Navy; Dr. Cormick, of Kentucky; Dr. Watson, of Burlington, Vt.; Dr. Hingston, Dr. Holden, of Burlington, Vt.; Dr. J. Bell and the Mexican delegates. These gentlemen were loudly cheered as they passed up the hall and ascended the platform. The orchestra having leisurely completed its selection, Dr. LaChapelle rose to introduce Dr. Craik. The Chairman was evidently a lover of brevity. "Your Honor, ladies and gentlemen," he said: "I have the honor to present to you Dr. Robert Craik, Chairman of the Local Committee."

DR. CRAIK proceeded to read a little address of welcome. The Association was one whose aims appealed to everybody, no matter what their

AGE, CREED OR NATIONALITY,

and whether he or she might take any interest in it or not. The object of this meeting was to introduce to the people of Montreal, a body of eminent men coming from all parts of this continent, from distant Mexico and from every part of the United States and of Canada.

Canada was not slow to recognize the power for good which such an Association offered, and had taken a prominent part in its operations. Canadians prominent in health and sanitary matters had from time to time occupied important positions among its officers, and our distinguished sanitarian and fellow townsman, Dr. E. P. LaChapelle, President of our Provincial Board of Health, had this year been its President; and it is largely to his influence and to the appreciation of his great gifts as a leader in matters connected with public health that Montreal owed the gratification of seeing the Association working in its midst to-day.

Dr. Craik proceeded to extend a welcome to all and concluded: "Let us, regardless of all

ARTIFICIAL LINES OF SEPARATION,

join together as one great family, striving earnestly to prevent as far as may be human misery, disease and premature death and to increase by every means in our power the sum of human health, happiness and prosperity."

The Chairman then briefly introduced Lieutenant-Governor Chapeau. His Honor was greeted with hearty applause when he rose to speak. He extended first a welcome in French. A governor had no right to speak, only to sign. He would have been proud to have had the privilege of sign-

ing the address of welcome to this important Association. He would extend a hearty Canadian *Bienvenu* to the Association. Then His Honor addressed the meeting in English. Mexico had treated the Association hospitably at its last meeting. Montreal was doing the same now and would continue to do so. There was no use for him to say how noble was the object of the Association. There might be labor congresses, peace congresses, and congresses for this, that, and the other thing. There could be no greater and more noble object than that of the Health Association, the object of conserving the health of this continent and of the world. People said that the length of life is decreasing; but that would no longer be a fact when the Association had succeeded in its noble aims. One thing they had succeeded in doing. They had stopped the great plagues which were once the dread of humanity. The questions which the Association discussed were large and important. Personally he could appreciate medical science. He had been a sick man for fifteen years, and as a good patient he appreciated his doctor. He could consequently appreciate the Association, the great doctor of humanity. He hoped that the fruits of its discussions would

BE TAKEN ADVANTAGE OF

by the national and civic governments of the continent. The Association had reason to be proud of what its members had done for Canada. The first Board of Health in Canada, that of the city of Montreal, was organized when one of the members of the Association, Dr. Hingston, was Mayor of the city. The President of the Association had also done much as Chairman of the Provincial Board of Health to perfect the system of provincial sanitation. So long as he was Lieutenant-Governor he should consider it one of the most important functions of the Government to assist in carrying out the work in which the Association was concerned. His Honor incidentally remarked that the efforts of the Association reminded him of the great benefits sanitary science had rendered to humanity in the question of food alone. It was for the Association to prove the falsity of the verses:

"Placid I am, content, serene,
I take my slab of gypsum bread,
And chunks of oleomargarine
Upon its tasteless sides I spread.

"The egg I eat was never laid
By any cackling, feathered hen;
But from the Lord knows what 'tis made
In Newark by unfeathered men.

"I wash my simple breakfast down
With fragrant chicory so cheap;
Or with the best black tea in town—
Dried willow leaves—I calmly steep.

"But if from man's vile arts I flee
And drink pure water from the pump,
I gulp down infusoriae,
And hideous rotatoriae,
And wriggling polygastricae,
And slimy diatomaceae,
And hard-shelled orphryocercinae,
And double-barrelled kolpodae,
Non-located ambrellae,
And various animalculae;
Of middle, high and low degree;
For nature just beats all creation
In multiplied adulteration."

HON. L. P. PELLETIER, the Provincial Secretary, was next introduced and read an eloquent address of welcome.

HIS WORSHIP, the Mayor, then took the stand and read a brief address of welcome on behalf of the city. He clinched the good effect produced by the simple words of welcome by expressing his wish to be enrolled as a member.

THE PRESIDENT called upon Dr. Gregarios Mendizabal, of Orizaba, Mexico, to reply on behalf of the Association. Although but few understood the speech, for it was in Spanish, the orator evoked round after round of applause by the very fervor of his eloquence and the musical cadence of his flowing periods. He was proud to speak in Montreal as the representative of the Spanish race. Science knows no country, but attends to the salvation of the people of the whole world, and the natural prosperity of all the peoples thereof. The fame of Montreal, and its great institutions of learning and beautiful benevolence had reached Mexico. Nor had the people of Mexico forgotten

THE GLORIOUS HISTORY

of the northern part of the continent. The people of Anglo-Saxon, French and Spanish ancestry had equal right to be proud of the development of Canada.

The President then delivered the annual address, in the course of which he said: The American Public Health As-

sociation, since its foundation, now twenty-two years ago, ever true to its mission, has never ceased to labor for the advancement of sanitary science—for the promotion of measures and organizations that should effect the practical accomplishment of the laws and principles of public hygiene. It has thus realized the brightest hopes and most enthusiastic provisions of its worthy founders, and has extended its benefits and influence over the whole of North America; to-day it embraces the three great countries that form this vast continent: The United States of America, the Republic of Mexico, and the Dominion of Canada, all three working together in brotherly emulation, recognizing no political boundaries, and valiantly striving to attain one unique and humane object—the dissemination to all of the knowledge of public hygiene and the development of respect for its decrees. Every year the Association changes its places of meeting, and this for good reasons. The spirit of its founders being to establish, above all, a body for the diffusion and popularization of public sanitary science, this object could not be better attained than by extending to its greatest limits the influence of the Association; and for this purpose, no surer means could be found than this bringing together of its distinguished members

IN DIFFERENT DISTANT CITIES.

Judging, as I do, from what has occurred elsewhere, I feel convinced that Montreal, and this province in general, will reap much benefit from this learned and important congress. Wherever the Association has met, it has stimulated and guided the march of progress, and it is becoming more and more respected and honored by the grateful public, for it ever leaves behind it tangible and irrevocable proofs of the good work it propagates. Hygiene is no longer the patrimony of physicians exclusively; it is a science open to all; laymen and clergymen, men and women. It needs supporters and workers in all classes; engineers, architects, teachers, chemists, etc. In a word, it appeals to all who are competent to aid its progress. Public opinion has been converted, popular prejudice giving way to unwavering confidence. Governments have thus been enabled, without risking their often precarious existence, to cause important decrees of hygiene to be sanctioned by parliaments, and to have the necessary funds voted to permit of their being put into practice. Hygiene having thus drawn their attention, they begin to understand the necessity of strenuous means being employed to assure its advancement, and they realize the fact that, instead of being detrimental to public commercial interests, sanitary measures favor their growth by protecting the country from disease. They recognize, to-day, that the money and labor spent in upholding sanitary principles are repaid manifold by the security afforded to public health, a more continuous and active trade being thus assured. May we not hope that governments, fully realizing the importance of those questions and wishing to afford greater facilities for protection, will soon see the necessity of creating a new department in their cabinets—that of Public Health; and that, in the near future, all Governments will be advised and supported by a competent specialist—

A MINISTER OF PUBLIC HEALTH?

We can easily foresee all the good that will arise from the creation of such a position. Although it is encouraging and pleasing to note the progress realized, the success obtained, we must not believe the task is done, and that all obstacles have vanished. For instance, the adoption of measures requisite to put into practice the solution of a question of sanitation, collides with two great and serious obstacles: Expenditure and personal interests. Such is the case when measures for quarantine, isolation, disinfection, the cleansing of towns and seaports, the prohibition of adulterated food, etc., are put into force. Quarantine, so needful to protect against the invasion of exotic epidemic diseases, is no longer, thanks to the progress of hygiene, what it was formerly; detention is shorter, I may say, practically suppressed by our modern methods of effective disinfection; but, nevertheless, even the slightest delay in the unloading of a ship begets expense, and brings constraint on personal interests. Typhoid fever and tuberculosis are even more malignant in their ultimate results than variola or great epidemics of other dreaded plagues, because their action is persistent, insidious and universal. The attention of the public and others is not thus thoroughly awakened to the threatening danger, and no efficient opposition is brought to bear against the ravages of those two devastating diseases. No expense or study should be considered to discover means of fully arresting the action of those scourges; the

demand is urgent; the answer, vital. It is deplorable to see the continual ravages of typhoid fever among young people; it seems to maliciously devote itself to cutting off in the prime of life the more healthy and useful subjects; in the end, the result is a most disastrous loss to the community. Water being the one great medium of its spreading, all efforts should unite to

OBTAIN PURE WATER SUPPLIES.

The cause and the remedy being known, it is the duty of interested persons and governments to procure such help from sanitary engineering and elsewhere, as will give the desired results. Do our municipal councils realize their responsibilities in this matter, and are they fully alive to their duty? We have before us to be imitated, the examples of the Romans and ancients, who drew back before no expense or labor, time or distance, to obtain wholesome water, and who built in every country where they ruled, those monumental aqueducts which still excite our admiration. This points to the urgency of developing and perfecting the study of sanitary civil engineering. It is a science that should be afforded all means of progress, and quickly placed in a position to give its much needed powerful help to the cause of hygiene.

Among all the diseases that have been the subjects of our labors, actually none forces itself more pressingly upon our zeal, than tuberculosis. This implacable affection, that may be rightly termed the scourge of mankind, continues, despite all science and philanthropy, to persistently thin the ranks of mankind, and reap its deadly tribute from every family. To it alone are due the enormous proportion of one-sixth of the deaths from all causes.

Thanks to the discoveries of modern science, we now know that this disease is produced by a germ or microbe; consequently that it ranks among contagious diseases and is amenable to hygiene. The resources of sanitary knowledge must, therefore, be immediately brought into action to per severingly check its destructive operations.

FOOD ADULTERATION

is, I should say, in most cases, a crime deserving the severest punishment; it is fraught with danger, and it is an important factor in the increase of premature mortality, especially among children. Even when life is not immediately endangered, a chronic intoxication is often produced that insidiously and irreparably undermines the health of many a human being, both young and old. Urgent appeals should be made to the press, to boards of health, boards of trade, and governments to raise their warning and protective influence to eradicate such criminal procedures. Municipal laboratories should be established throughout the land for the detection of such fraudulent doings, and justice should deal rigorously with all offenders. Alcoholism is the plague of many northern climates, and we are not without participating in its dire influences. It should not be allowed to escape our vigilant attention, for it is the ruin of health, of society, and of a nation. The Fates point to the gloomy picture of ancient times, but the experience of the past does not seem to have succeeded in rooting out this terrible evil, which is the harbinger and entertainer of the greatest part of all crime and vice. Alcoholism has for its share more than half the occupants of our prisons, hospitals and lunatic asylums. Not only do those addicted to drinking intoxicating liquors most of the time throw their entire families upon the State for support, but the latter is also obliged to look after their scrofulous, idiotic, and epileptic offspring, who are incapable of providing for themselves and are often dangerous to society. Their other children, although less affected by the original taint, are generally worthless subjects; lazy, criminal, and degenerate, and form loathsome mediums for the propagation of disease and vice. Under such conditions as these, and with such dreadful results, we pay too dearly the money that enters the coffers of the State or municipality under the title of tax or license. It is

SIMPLY SPECULATING ON VICE,

on the ruin of wealth, health, and talents, and such speculation is no wise justifiable, and should not be tolerated under any consideration. By every means in our power this plague should be opposed and if possible exterminated; it is more deadly than contagious diseases and more difficult to deal with. The problem is one for serious study and painstaking measures. Good work has already been done, and if the desired result has not yet been attained by the measures advocated, and tried up to the present, let us not be discouraged, but set to work again. Let us find out if there are no other ways of succeeding. Are men sufficiently educated in their

childhood on the dangers and terrible consequences of indulging in the use of liquors, even in a social way? And in this as in all other matters of hygiene, why not ask more of education and not trust exclusively to legislation?

After a few supplementary words of welcome by the Lieutenant-Governor, the meeting was declared adjourned and the orchestra struck up, "God Save the Queen."

SECOND DAY—WEDNESDAY.

The Association was called to order at 10:15 A.M., with Dr. LA CHAPPELLE, the President, in the chair.

The Executive Committee reported that twenty additional applications for membership had been considered, and upon motion the Secretary cast the ballot in their favor. The Committee also recommended the adoption of the resolution offered by Dr. Probst on the preceding day. (See JOURNAL October 6, page 554). On motion carried. The Committee also recommended the creation of a new committee to consist of five persons, "On Steamboats and Steamboat Sanitation," and upon motion the suggestion was adopted.

The following gentlemen were selected as the Advisory Council for the meeting, in several instances to fill vacancies, a number of whom "hold over" until the year 1895: Drs. Jerome Cochran, Mobile, Ala.; H. C. Dunnavant, Osceola, Ark.; W. F. Wiard, Sacramento, Cal.; Henry Sewell, Denver, Colo.; R. S. Goodwin, Thomaston, Conn.; Joseph Y. Porter, Key West, Fla.; William F. Bruner, Savannah, Ga.; Liston H. Montgomery, Chicago, Ill.; L. L. Whitesides, Franklin, Ind.; A. N. Cantwell, Davenport, Iowa; C. Jones, Topeka, Kan.; J. N. McCormick, Bowling Green, Ky.; Felix Formento, New Orleans, La.; A. J. Young, Augusta, Maine; J. F. McShane, Baltimore, Md.; Samuel W. Abbott, Wakefield, Mass.; C. L. Wilbur, Lansing, Mich.; E. S. Kelley, Minneapolis, Minn.; Wirt Johnson, Jackson, Miss.; J. D. Griffith, Kansas City, Mo.; F. D. Haldeman, Ord, Neb.; G. P. Conn, Concord, N. H.; John Mitchell, Trenton, N. J.; Friend Palmer, Cerrillos, N. M.; A. N. Bell, Brooklyn, N. Y.; Henry I. Bahson, Salem, N. C.; Devaux, Jamestown, N. D.; C. O. Probst, Columbus, Ohio; Charles F. Waldron, Oklahoma City, Oklahoma Ter.; Benjamin Lee, Philadelphia, Pa.; Swertz, Providence, R. I.; H. B. Horlbeck, Charleston, S. C.; K. M. O. Tiegen, Fargo, S. D.; J. Berrien Lindsley, Nashville, Tenn.; R. M. Swearingen, Austin, Texas; Canerty, Vermont; John B. Minor, Richmond, Va.; G. S. Armstrong, Olympia, Wash.; Louis D. Wilson, Wheeling, W. Va.; U. O. B. Wingate, Milwaukee, Wis.; Ralph Walsh, Washington, D. C.; Charles Smart, Washington, U. S. Army; A. L. Gihon, Washington, U. S. Navy; P. H. Bailhache, New York, U. S. M. H. S.

CANADA.

Frederick Montizambert, Quebec, Dominion of Canada; Peter H. Bryce, Toronto, Province of Ontario; Henry R. Gray, Montreal, Province of Quebec; Pattison, Winnipeg, Manitoba; Wm. S. Harding, St. John, New Brunswick; A. P. Reid, Halifax, Nova Scotia.

MEXICO.

Drs. Manuel Carmona y Valle, Federal District, Mexico; Jesus Chico, Guanajuato, Guanajuato; Jesus E. Monjaras, St. Louis Potosi, St. Louis Potosi; Gregorius Mendizabal, Orizaba, Vera Cruz; Juan Zavala, Guadalajara, Jalisco.

The PRESIDENT announced that he would leave the matter of appointment of members to the Advisory Council from the remainder of the States in the republic of Mexico, to the incoming President of the Association.

DR. CRAIK, Chairman of the Local Committee of Arrangements, made several announcements, among them one pertaining to the special train announced to depart from the Bonaventure Station at 2:45 o'clock, P.M., for Lachine, from which point members and their ladies were to board a steamer for a voyage through the Lachine Rapids.

DR. JOHN NAGLE, Registrar of Vital Statistics, New York city, (by permission) submitted printed reports as prepared by Dr. Cyrus Edson, of that city. Also a circular of information to physicians regarding the measures adopted by the Board of Health of New York for the prevention of tuberculosis, beside a paper in the form of a report on the antitoxin treatment of diphtheria. The following observations were given:

1. In diphtheria, death, as a rule, is due to the poisoning by a chemic substance (a toxin) produced by the diphtheria bacillus in the throat and absorbed.

2. A certain degree of immunity which is temporary only, is afforded by one attack of diphtheria, and this immunity is the result of an acquired tolerance to the "toxin." This applies to both animals and man.

3. If large animals are inoculated from derived cultures of the diphtheria bacillus they become gradually tolerant to its poisonous action.

4. This immunity is the result of the development in the blood of antitoxin.

When animals have thus been immunized, blood is withdrawn from the circulation in quantities varying with the size of the animal, and then employed through hypodermatic injections in the treatment of cases of diphtheria, and the antitoxin thus introduced neutralizes the toxin absorbed into the circulation of the sick person. By this method it is apparently possible to protect persons from diphtheria when they have been exposed and infected if the general symptoms have not yet appeared, and also to cure them, as a rule, when treated in the early stages of the disease.

A brief discussion ensued on the papers on diphtheria read on the previous day, as well as upon the report of Dr. Nagle, which was participated in by Drs. Ferguson, of New York; Hingston, of Montreal, and Formento, of New Orleans.

DR. E. GAUVRAU, Director of the Vaccine Institute of Ste-Foye, P. Q., contributed a paper on "Culture and Collection of Vaccine Lymph."

The next paper was read by DR. N. E. WORDIN, of Bridgeport, Conn., on

RESTRICTION AND PREVENTION OF TUBERCULOSIS,

In which the author took the ground that, since the wonderful strides made by the science of bacteriology, the germs of diseases are no longer unknown, unseen but dreaded organisms, but are things that we can see, handle and kill. The bacillus of consumption is fortunately one which science has many advantages in combating. It takes weeks and months to develop, and requires a special temperature and moisture to develop. Practically the only means of communicating the disease is through the sputum. There is little danger from the bacillus so long as it is moist. But there are some ways in which it may be directly transmitted, as by kissing. Among the hygienic commandments for consumptives and syphilitics there should be one, "Thou shalt not kiss." Direct inoculation may occur through coughing, by soiled hands and clothes. But the cases thus transmitted must be very few. The only danger worth considering is from the sputum after it has been dried. The solution, then, of the whole question resolves itself into this, that in order to prevent the spread of this terrible disease, it is necessary to destroy the sputum as soon as it is emitted from the person, as soon as it has become dried. The difficult thing is to get it before it has escaped into the air and become dried. Tuberculosis should be put on the list of infectious or communicable diseases to be reported to the health officer. Following this there should be a thorough disinfection of all houses in which tuberculosis has occurred. In the second place there should be compulsory disinfection of hotel rooms, sleeping-car berths, steamer cabins and prison cells which have been occupied by consumptives before any other persons are allowed to occupy them. In the third place there should be special hospitals for the treatment and prevention of tuberculosis. The Doctor emphasized the facts that no tuberculous female should nurse a child and that milk from a tuberculous animal should never be used, and that overcrowding in houses should be prevented. Michigan has taken the advance in requirements of notification and restriction of this disease. She has already reaped an abundant reward. In 1878 the cases of consumption were 71, and this proportion has steadily decreased every year, until in 1889 it was 49, which goes to show that an ounce of prevention is worth tons of cure in the restriction and prevention of this "great white plague" which claims its victims from those in the flush and bloom of youth, from the ranks of the fairest and best in the land.

The third paper was

EXAMINATION OF THE MILK SUPPLY FOR TUBERCULOSIS IN THE STATE OF NEW YORK,

By DR. F. O. DONOHUE, President of the New York State Board of Health.

In part this is what he said: Deaths in the State of New York last year were computed to be 17.42 per 1,000 inhabitants, of which 1.09 or about one-eighth of the deaths of the State were found to be due to consumption, and it followed that a certain number of these cases were due to the use of tuberculous milk, making it possible to entirely stop the disease. Forty million dollars worth of milk and its products were produced in New York last year from 2,000,000 milch cows in the State. A percentage comparison was then furnished of tuberculous cows throughout Prussia, France and elsewhere. The field of infection is through the stomach

The bacillus tuberculosis is killed by the sun in a few hours. Out of 22,000 head of cattle examined, in herds throughout various portions of the State, 700 were slaughtered on account of their being found tuberculous. The stigma on account of the reports published in the daily press for slaughter of diseased cattle in dairymen's herds, and the pecuniary loss to them, met with opposition as all innovations meet with opposition. At any rate it was found that tuberculosis existed in dairy cattle to such an extent that it led to the appointment May 1, 1894, of a special Tuberculosis Commission to prosecute the inquiry further, and clothed with all the powers of the State Board of Health, with the object and aim to determine the dissemination and presence of its prevalence. If the disease in animals is found to exist, the owner is compensated for loss of diseased cattle. This encourages the owners to help the Commission to ferret out affected animals and thereby it may not be impossible to eradicate the disease. Details were then given as to the use of tuberculin, although as the author stated, the tuberculin test is not infallible and can not be relied on in cattle in an advanced stage of gestation, and furthermore, the finest grades of cattle, or other distinctive breeds are apparently exempt from tuberculosis.

The fourth paper was a short one read by DR. PAUL PAQUIN, of the State Board of Health of Missouri, on

SHOULD THE MARRIAGE OF CONSUMPTIVES BE DISCOURAGED?

The reader stated that tuberculosis is transmissible between human beings as well as from animal to man. The close intimacy of man and wife make it infectious. Their home becomes an infection center. Expectorations when dried pollute the atmosphere. A healthy person will contract the disease from a tuberculous subject if married. Children are born feeble and are predisposed to it. This marriage of a consumptive couple establishes a pest-house, and children's rights are hazarded. They should be born healthy and not condemned to die young. It was a cruel system which put children in the world handicapped at the very start of the battle of life by feeble health. Marriages which would obviously result disastrously to the human race by producing weakly children should be prevented, and science should protest against the marriage of consumptives by judicious regulations.

The next contribution was an essay on

THE CLIMATIC SEGREGATION OF CONSUMPTIVES.

By DR. HENRY SEWELL, Secretary of the State Board of Health of Colorado. The essayist set forth the advantages of Colorado as a residence for consumptives. Although he mentioned the so-called arid region of the United States, exclusive of Alaska, which forms about one-third of the country and includes parts of the States and territories of California, Oregon, Wyoming, Washington, Idaho, Utah, Arizona, Nevada and New Mexico. This essay, however dwelt particularly upon the area of Colorado.

It is nothing new in history that the teachings of great truths need many exponents before they win disciples. The essay outlined a reasonable method for the frequent cure, the inevitable prevention, and perhaps the final suppression of consumption. It is no impertinence to assume that consumption is an infectious disease due to the implantation and growth of a living organism within the afflicted body, and that further, this organism exists in the sputa of pulmonary consumptives which becoming dry and pulverized is inhaled by healthy lungs and so elaborates the most common method of infection. Consumption has been called "the disease of civilized life," since it has not spontaneously invaded isolated savage tribes. He said in part: That a single one out of all known diseases should cause from one-fourth to one-eighth of all deaths in civilized communities, not to compute the disastrous effects of non-fatal cases; that this disease is demonstrably preventable, and even curable; it is small wonder that the splendid modern passion to relieve human suffering has concentrated itself upon the ways and means of overthrowing the reign of the "great white plague," consumption. Small consideration makes it evident that no single means within our power is competent to overcome the enemy. The most certain and speedy blotting out of the disease would follow the instant and permanent isolation in some far-off region of every individual afflicted with it; but mankind will choose to go on in suffering rather than shock its ethical nature in forcing such seclusion. Undoubtedly our main defense when the disease exists, depends upon the growth of broad and sound views of sanitary facts among the people; not merely the lip knowledge which repeats words, but the active realization of the burnt child who dreads the fire. It is a pity that those modern educators who have induced State Legislatures

to dictate that the evils which may follow the use of tobacco and alcohol shall be described in the school physiologies, should not have seen to it that the youthful mind might have demonstrated to it the nature and causes of infectious diseases and the modes of combating them. The author, believes that an appropriate course of bacteriology would be a fascinating, comprehensible and infinitely practical addition to the curriculum of the secondary schools.

In the experience of the past it is not a bold assertion that consumption is incurable by any known drug, and that the single hope the consumptive has is to improve the vital resistance of his own body. Moreover, it may be taken as established, that the one essential factor, more important than all others combined, in this improvement of militant vitality depends upon outdoor life with its incidents of fresh, circulating air and sunshine. Observation shows clearly enough that the place of residence of the consumptive is not indifferent; that, in general, it is better for him to change his abode from the place where the disease was contracted; that inland excel seashore resorts; that dry air is more beneficial than moist; that altitude above sea level is of decided advantage and, above all, that purity of air and absence of microorganisms and the matters incident to their existence from it are indispensable conditions for the improvement of the sick one.

Numbers of suitable places at once occur to any one who is familiar with Colorado; I may definitely specify the neighborhood of Colorado Springs several localities within a few miles of Denver, Perry Park half way between the two places, points to the north of Denver and Estes Park. Certain of these places are habitable all the year around and others best available only in summer. A salaried resident physician should be constantly on the ground for the moral comfort and physical demands of the patient. An unpaid medical sanitary director of known experience, making weekly visits, should have complete direction of the general conduct of the sanatorium. Such medical service could no doubt be obtained gratuitously. There would be no objection to these communities increasing to the size of villages of 300 or even 500 inhabitants, there being but one single essential proviso, *i. e.*, that all things and acts therein accomplished shall have reference to the benefit of the invalid and the restriction in the spread of disease. The essential sanatory laws are few, broad and accepted by all, and physicians at large might send to such an institution their private patients and still keep them under observation. The cottages should be constructed with sole reference to their uses, and might each accommodate from four to eight persons. An important part of the scheme would consist of a central building with rooms above for the accommodation of the weaker invalids and with an assembly room and various dining-rooms below. Patients who could afford it might be allowed to occupy a whole cottage and cater to a private table. The food for all should be of the best.

The land appropriated to the sanatorium should be extensive; not less than five or ten acres to the cottage, and it should be an object to raise, under proper restrictions, vegetables for the table, and to keep a special herd of milch cows. No effort should be spared to provide outdoor amusements, scientific and trivial, of every suitable description. Botany, geology, gardening, with the lighter outdoor games; even billiards, cards, reading, work with the microscope, under proper conditions, are open to prevent this terrible ennui of isolation. The summer sanatoria distributed in the various mountain parks would offer delightful outings and change of scene. At least monthly, patients should be examined physically, and as the cases improved they should be sent to higher altitudes which, when well borne, immensely facilitate recovery. Such sanatoria are by no means intended as permanent abodes. The invalid should be turned loose to provide for himself as soon as safely able to earn his own livelihood, and after he has acquired that simple but precious education through which he learns the habits that protect himself and others from the disease. For most favorable cases this time would average from three to six months and includes that critical period when the homesick, helpless sick one drifts, a stranger, into the hotels and boarding houses of Denver or Colorado Springs, and often because of his surroundings, receives a fatal impulse which determines his dissolution. I say no word of absolute cure. Undoubtedly cases occur in which after a few months' residence under favorable conditions the invalid may return restored to health, to the scenes and occupations of his downfall. But I know no means of ascertaining whether such a cure has been attained, and the humiliating fatal mistakes made by most skilful medical observers who have let their good will

direct their good sense, form a patent warning against such a course. There is, however, a cure which can almost be guaranteed; that this disease may be so arrested as to interfere in no wise with the usefulness or enjoyment of life lived under the conditions establishing recovery. This then is at least one great advantage that Colorado possesses over health resorts of the East, that means of earning a livelihood and the chief requisites of a happy existence are to be found almost at the doors of the sanatorium.

The Committee on restriction and prevention of tuberculosis, Dr. J. N. McCormack, Secretary of the State Board of Health of Kentucky, chairman, was upon request granted further time to submit its report.

A motion by Dr. Montizambert that each speaker be limited to five minutes prevailed. Dr. Nagle, of New York; Dr. Patterson, of Winnipeg; Dr. Slocum, of Defiance, Ohio, and Dr. Hopkins, of New York, discussed the papers and generally agreed with the views set forth by the authors of the series of papers that had been presented on this subject of tuberculosis. Dr. Nagle, of New York, explained that in that State, the sputum of all patients suspected of having tuberculosis is microscopically examined, and in the event of death or of removal the apartments occupied are disinfected, and friends of patients are furnished with simple but complete instructions for the care of the patients. One of the instructions is that the clothing of tuberculous patients should not be allowed to go to the laundry with the clothing of healthy persons. Dr. Ferguson, of the laboratory of the New York Board of Health, explained that investigation showed both consumption and diphtheria bacilli lie in wait on the shining glassware of the most aristocratic drinking glass, in the artistic combs, brushes and razors of the highest class of barber shops and in the communion cup. Bacilli from all of these articles had been procured by the Board. In the case of the communion cup he believed that the germs of consumption could be transferred from lip to lip with disastrous results. Continuing he said the sputum of animals and men were the same, and that twenty-nine different forms of bacilli had been found in the sputum of man. Dr. Lee, of Pennsylvania, expressed the belief that all State and Provincial Boards of Health should have bureaus to supply the public with information as to the dangers of consumption. He also objected to the philosophy of Dr. Paquin's paper on restricting marriage by legal interference with the rules of natural selection. This, the speaker stated, should be avoided. Dr. D. C. Ramsey, of Mt. Vernon, Ind., feared that the clinical thermometers of physicians were often the cause of conveying infection. Physicians should always have these in a perfectly aseptic condition. Dr. Paquin replied to Dr. Lee by explaining that he did not say a word in his address regarding legislative interference in this matter, simply to educate the public on the dangers of the continuance of the present system of marriage among consumptives.

(To be continued.)

SOCIETY NEWS.

Anatomic Material.—The Association of American Anatomists has issued the following circular: *Dear Sir:*—At the last meeting of the Association of American Anatomists, the undersigned committee was appointed to "consider the question of the collection and preservation of anatomic material, and to report, at the next meeting, what in their opinion are the best means of accomplishing these objects."

In order to make the work of the committee as comprehensive as possible, and to obtain information which will be of service in arriving at definite conclusions as to the best methods of accomplishing the purposes indicated in the resolution, the committee has deemed it desirable to send to the teachers of anatomy, not only in this country, but abroad, this circular letter, with the questions appended, and respectfully to request answers thereto, as fully as they can be made.

1. Is anatomic material obtained in accordance with a legal enactment, wholly or in part?

2. If there is an anatomic law in your country or State, please send a copy of it to the chairman of this committee, Dr. J. Ewing Mears, 1429 Walnut Street, Philadelphia, Pa.

Please state whether the law is satisfactory, whether it is readily obeyed by those upon whom duties are imposed by it, and mention any improvements you would suggest, as to its requirements.

3. Is the material received in good condition?

4. What disposal is ultimately made of the remains?

5. Please state what means are employed to preserve anatomic material for the purposes of dissection or operative surgery. If injections of preservative fluids are used, state their composition and the methods of use, at what point injections are made, whether at the heart or in the large arteries, and their effect in accomplishing the preservation, with any changes in the color or the character of the tissues. What length of time can material be used in dissection by the methods employed by you? If preservation by means of "cold storage" is employed, please state the cost of the machinery which it was necessary to construct for this purpose, and what means are taken to prevent decomposition after the subject is placed upon the table for dissection?

6. Please state the cost, by the method employed by you, for each subject: *a*, for receiving it; *b*, for injecting and preserving it.

7. Do you obtain an adequate supply of material for the purposes of anatomic instruction? How many students are assigned to each subject, and what is the method of allotment?

8. Please give any information which you may deem of importance. As the report will be general in character the name of the informant or institution will not be mentioned by the committee unless requested.

Your compliance with the request of the committee, at an early date, will be fully appreciated as rendering assistance to it in accomplishing its work, and it desires to thank you for the same in advance.

J. EWING MEARS, M.D.,

JOSEPH D. BRYANT, M.D.,

THOMAS DWIGHT, M.D.,

Committee.

The Cleveland Medical Society.—At the last quarterly meeting of the Cleveland Medical Society held Sept. 28, 1894, Dr. W. W. Keen, of the Jefferson Medical College of Philadelphia was present and addressed the Society on the subject of "Amputation of the Breast." On the following morning, Professor Keen also held a clinic in the Cleveland General Hospital to a large assemblage of the profession, demonstrating in his inimitable way the remarks of the previous evening. A large number of physicians from the northern and central parts of the State were present and all expressed the pleasure and the profit experienced by a close observation of Dr. Keen's thought and work. By no other means than the organization of a popular society (such as the Cleveland Medical Society has endeavored to be) could the local profession have been brought into such harmonious union on the great topics of ethics, higher medical education, State and National legislation, and so forth; and our efforts to broaden this union of feeling and action have happily been effected in great part at least, by our quarterly meetings. We are grateful for the spirit which animated Kelly and Pepper and Keen to sacrifice themselves in our behalf and their mission has already borne fruit. Since March, 1894, our average attendance at regular meetings has been over 100; and the papers and discussions have been of an unusually high order. Also the Society is alive to the attainment of more efficient State medical legislation of which our State is so much in need.

OSCAR T. THOMAS, Secretary.

The Capital District Medical Society of Illinois met in Jacksonville October 4. Dr. George N. Kreider, Treasurer of the Illinois State Medical Society, presided. Papers were read by Drs. H. W. Chapman, of Whitehall; L. C. Taylor, of Springfield; J. J. Connor, of Pana; G. N. Kreider, of Springfield; and L. A. Malone, of Jacksonville. Resolutions were passed calling on the Legislature to establish at public expense pathologic laboratories for the study and examination of infectious and contagious diseases, and named a committee, consisting of Drs. C. E. Black, Jacksonville, L. C. Taylor, Springfield, and E. J. Brown, Decatur, to study the contagious and infectious diseases peculiar to this locality, and report at the next meeting in Springfield in January.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, OCTOBER 13, 1894.

THE DEATH OF OLIVER WENDELL HOLMES.

The genial "Autocrat" passed away on Sunday, October 7, at the ripe age of 85.

He will be missed not only by his circle of friends in Boston, the pupils whom he led through the dreary details of anatomy for so many years, and the Massachusetts Medical Society, but the older members of the AMERICAN MEDICAL ASSOCIATION, who remember with pride that DOCTOR OLIVER WENDELL HOLMES was one of the founders of the ASSOCIATION, and at the first annual meeting, as Chairman, read the "Report of the Committee on Medical Literature."¹ In what more competent hands could such a report have fallen! The old members recall with affectionate remembrance his scholarly articles read at the earlier annual meetings, "On the Microscopic Anatomy of Bone,"² "Puerperal Fever as a Private Pestilence,"³ and the three Boylston Prize Essays. There are but few now who remember him as he was in his earlier days, and those think with him of many a companion of those days:

"The mossy marbles rest
On the lips that he has prest
In their bloom;
And the names he loved to hear
Have been carved for many a year
On the tomb."

The whole world not less than the medical profession owes a deep debt of gratitude to him for the keen words of wisdom contained in his essay on the cause and prevention of puerperal sepsis, written thirty years before the era of antiseptic douches and precautionary cleanliness. The many suggestions contained in the valedictory address to the gradu-

ating class of Bellevue Hospital Medical College in 1871 conveyed in his inimitable manner to medical men generally, rules for social and professional conduct, so valuable that they deserve perennial reproduction. His "Lectures on Homeopathy and Kindred Delusions," abound with that keen humor characteristic of his bright vivacious spirit; but even in satire he always avoided needless pain and severity. He never wrote anything which could cause him to be classed among those writers of whom he wrote

"Their discords sting through Burns and Moore,
Like hedgehogs dressed in lace."

As a medical teacher he invested even the most intricate details with a polish which was not merely veneer, for no one could have heard his famous dedication address at the opening of the Boston Medical Library without knowing that his wide knowledge of medical literature was one acquired not only by reason of years of love of the subject, but by hard and painstaking labor. The class of 1847 who heard Dr. HOLMES' lectures on anatomy at Harvard University, were astonished and delighted by his methods, and pleasant manner, and annually thereafter for nearly or quite thirty years, PROFESSOR HOLMES appeared before the class with military promptness.

We have not mentioned him as he appears to the literary world, for all the world is in mourning for him to-day, and his greatness in general literature has made his writings familiar to thousands of old and young readers who have probably learned for the first time, by reading the obituary notices, that he was a physician. He was not only a physician in every sense of the word, but a great physician, and one whose researches and observations would have made him famous had he never written a line of his illustrious prose and poetical works.

There is grief in the Massachusetts Medical Society, because he is no more, and many an eye will become dim with tears when his empty chair is placed at the annual dinner table.

In the album of a young lady, then at Bar Harbor, there was written by Dr. HOLMES in his old age, the following, which shows to what thoughts his mind was tending in his last days:

"From this fair home behold on either side,
The restful mountains or the restless sea;
So do the warm sheltering walls of life divide
Time and its tides from still eternity."

"Look on the waves, their noisy voices teach
That not on earth may toil and struggle cease;
Look on the mountains, better far than speech,
Their silent promise of eternal peace."

AMERICAN PUBLIC HEALTH ASSOCIATION.

The published transactions of this Association, extending over a quarter of a century, constitute a library of sanitary science full of promise for the fu-

¹ Transactions, Vol. I, p. 249

² Transactions, Vol. IV, p. 52.

³ Transactions, Vol. IX, p. 372.

ture. The Montreal meeting of the Association last week adds another volume of increasing interest. The membership includes all the leading health officers of both cities, States, and the governments of United States, Canada, and Mexico, also of the Army and Navy of these countries. It also includes sanitary engineers and plumbers, and officers who are dealing with questions affecting public health. From this the wide and varied character of the papers may be inferred. At this meeting sixty-one papers were read, and eight reports of the progress of science on special topics; together with one evening devoted to addresses of welcome and commendation.

A grand excursion to the Quarantine at Grosse Isle on the St. Lawrence, below Quebec, also a ride through La Chine Rapids, and a reception were given to the members. Outside of this, four days were devoted to the real work of reading and discussing the many topics.

As usual, in all such meetings, a certain number of papers are poor compilations of books and pamphlets, and a certain number contain a few facts of fresh interest, that could be stated in a few printed lines, but are covered up in words that stretch over twenty minutes. A small number of papers are always extreme in assumption, and dangerously dogmatic, and other papers seem to come up to the verge of originality, but fail in obscurity and confusion of statement. Then the usual advertising and commercial papers and the enthusiast with one idea and one theory to apply to all conditions of life and living. Beyond this common experience of every meeting, some excellent scientific work was presented. The filtration and sedimentation of water was presented with great clearness, and the results of original experiments given, showing that polluted waters passing over sand beds may be deprived of 95 per cent. of all their microbes and organisms. The efforts to extend the boundaries of exact science in this direction, were very clearly set forth by DR. SMART, of the U. S. Army, in a report on this topic. The disposal of garbage was the topic of several excellent papers, showing great advance and very thoughtful suggestive work in this field. The air and water of farm houses was the subject of some striking observations. Car ventilation, the danger from sputa in tuberculosis, and the infection of milk from tuberculosis were well presented. "The Influence of the Climate of Canada on Health," "The Influence of Inebriety on Public Health," and the "Long Island Water Basin," were notable papers. Drainage, ventilation, cremation, plumbing, climate, and other topics received very substantial contributions. The fact that over four hundred members were registered from all parts of the United States, Canada, and Mexico, is significant of a great advance in sanitary matters.

The science of medicine has expanded to such an

extent that these widely varying topics must be separated and studied by specialists. As in all new subjects, sanitary science and the questions of the prevention of disease must pass through the various stages of growth and evolution.

Health boards with their officers and inspectors should lead as teachers and instructors of public sentiment; while the general practitioner may be a good observer and reasoner of causes and effects in preventive medicine, he can not have the experience and facts to draw conclusions from, that health boards possess. Yet the impression grows stronger after listening to a long list of papers by men who are in a position to know the facts, that many of these sanitarians fail to use the knowledge in their possession, or to make the original observations possible in their positions. A little reflection makes it apparent that many persons connected with these health boards owe their positions more to political influence than to scientific attainments. This readily explains the disappointment in the character and quality of some of the work of these boards. While the blighting influence of politics is not peculiar to boards of health and sanitarians in general, yet it can be seen and felt in many ways in all these gatherings. This meeting of the Association showed a marked advance in many ways, over previous gatherings, and will be noted in its history as the starting point by the publication of its transactions in a quarterly. These large gatherings of men devoted to sanitary subjects have an excellent influence on the public, and if the rule of the Association was rescinded so as to allow daily papers to publish certain papers in full, the best results would follow, and more good would be done. Over a dozen papers read at this meeting would have been printed in full by the daily press, and read by a large number of persons to their great profit if the rules could have been changed. As it is these papers will be buried in the transactions and only a few ever appear in the public press. The sanitarians of this country have a great field before them, and this Association is doing a work of very wide influence.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

This Association held its fourth annual meeting in New York City September 25, 26 and 27, under the Presidency of PROFESSOR W. J. HERDMAN, of Ann Arbor. The scientific proceedings, which, we presume, will appear in full in the JOURNAL, were more than usually interesting and systematic, the plan of pre-arranged discussions on the physics and therapeutics of each form of current being followed. The spirit of the meeting, which was largely attended, seemed to be the discussion of the primary facts of electro-physics and their applications to medicine, and while but

few new facts were announced the full discussions elicited on these fundamentals were interesting alike to the expert and the tyro, and can not be other than highly useful in stimulating greater accuracy and thoroughness in the medical users of electricity. The presence and participation of a number of electrical engineers and distinguished physicists were significant.

On the evening of the third day the members were received by NIKOLA TESLA at his laboratory, and were treated to a display of the remarkable qualities of high frequency currents recently developed by this latest electrical prodigy. On Friday, through the courtesy of MR. EDISON, the whole Association and its ladies were conveyed to EDISON'S laboratory by special train and escorted through the works, after which a delightful banquet was enjoyed.

That New York fulfilled its social opportunities was well proven by the reception and banquet at the Academy of Medicine, and by its private hospitalities to visiting members.

"PICNIC MEMBERS."

Echoes of the recent season of congresses and meetings of medical, sanitary and other scientific bodies are finding their way across the waters. In a recent number of the JOURNAL, mention was made of the comparative failure of the Buda-Pesth Congress of Hygiene, through the multiplicity of sections and the counter-attractions which reduced the attendance at sessions below working point. Now the *Medical Press*, (London) deplores the changing character of the "hygiene and sanitary congresses," the success of which, it says, is at present measured at least as much by the magnificence and abundance of the festivities as by the scientific work accomplished at the meetings. All this is attributed to the fact that,—while membership in a medical congress is limited to those who possess a certain definite standard of education and technical competence, and valuable work is thereby secured—any one may become a member of a sanitary organization or participate in a congress of hygiene by paying the annual fee. The result is a very large proportion of "picnic members," by which phrase is understood "people who join simply with the object of participating in the social entertainments which have now come to form an integral part of such gatherings," and whose behavior at the *fetes* organized in honor of the congresses is, not infrequently, "calculated to raise a doubt in the minds of beholders as to their civilization"—behavior by which the *fetes* "but too often degenerate into orgies."

We have thus far been spared any such exhibition in this country and can only share sympathetically in our contemporary's indignation; but we are at one with him in the belief that the dignity and usefulness

of such meetings would be enhanced by limiting participation in the proceedings to those who are qualified by work and interest in the ostensible subjects. There is a growing danger, from this indiscriminate membership, that our public health meetings may come to resemble the picture which the *Press* draws of such meetings abroad: "At present the sanitary or hygienic congress is the happy hunting-ground of the faddist and of the irresponsible seeker after notoriety; and as the time for papers and discussions is always brought down to the irreducible minimum the result is that papers which really represent individual labor and research are crowded out, to the disappointment of their authors and to the annoyance of the discriminating public."

The International Medical Congress which met at the National Capital in 1887, and the Pan-American Medical Congress of 1893, are creditable examples of the American idea of such gatherings.

CORRESPONDENCE.

A Case of Hypertrophy of the Heart.

TECUMSEH, MICH., Oct. 4, 1894.

To the Editor:—Oscar H., aged about 32 years, an American by birth, had his first attack of articular rheumatism when he was 16 years old, which left him with a damaged heart. Since that time he has had several severe attacks of rheumatic fever, each affecting more or less the circulation. The symptoms in his case were those associated with lesions of the semilunar valves of the aorta. Finally, death took place from "heart failure."

October 4, forty-eight hours after death, a *post-mortem* examination was made by Drs. North and Teft, in the presence of Drs. Catlin, Howell, Woodward and Jenkins. Upon opening the thorax the heart was found greatly enlarged. A measurement of the heart before its removal from the cavity of the thorax gave the length seven and a half inches, breadth six inches, thickness four and a half inches, and its circumference eighteen inches. When removed from the thoracic cavity, its weight with the blood contained in its chambers was three pounds six ounces. After removing the *ante-mortem* and *post-mortem* clots the heart weighed thirty-four ounces. The semilunar valves of the aorta were ossified, and from their walls at their base were ossified projections, feeling very much to the touch like pieces of coral reef. The walls of the heart were thin, especially at the apex, where they were only about five millimeters in thickness.

J. F. JENKINS, M.D.

PUBLIC HEALTH.

Sterilization of Bread.—At the request of the Minister for War, MM. Ballaud and Masson were recently assigned by the Paris Council of Hygiene to conduct an investigation to determine whether baking destroys any microorganisms that might exist in the water, flour or other raw materials used in making bread. They have decided that the principal agents that destroy such germs are the acidity of the dough and the high temperature it is subjected to in the oven; and conclude (*Annales d'Hygiene*) that the center of a loaf attains a temperature of 100 to 102 degrees C.; that the center of biscuits attains 110 degrees C.; the combined action of these temperatures and of the acidity of the dough

suffices to assure practically the sterilization of bread and biscuit; that in dough prepared with yeast, where the acidity is diminished, sterilization is not assured to the same degree; that in any case those pathogenic germs which offer but little resistance to heat, such as the bacillus typhosus and the cholera bacillus, must necessarily be destroyed.

Ohio Pure Food and Drug Laws.—Operations under the recently enacted pure food and drug laws of Ohio were begun on the 7th inst., by the publication of a code of rules and regulations for the guidance of the wholesale and retail liquor dealers of that State, prepared by State Dairy and Food Commissioner F. B. McNeal. This was promptly followed by the prosecution of sundry Cincinnati druggists on charges made by Deputy Food Commissioner Luebbling and State Chemist Fennel, who have for some time been collecting and analyzing samples of drugs, proprietary articles, etc. Among the articles specified as sold in violation of the law are Vin Mariana, Paskola and unfermented grape juice; Paskola, which is represented to be a "predigested food, having the rich nourishing properties of the cereals and saccharine fruits, together with a sufficient percentage of albumen to take the place of meats," is pronounced by Professor Fennel, after analysis, to be simply confectioners' glucose. Cheap tinctures and condensed milks have been selected as the next subjects of investigation. The result of these efforts to secure pure food, drinks and drugs will be of interest to physicians, sanitarians and the public generally.

Growth of a Health Department.—When the Health Department of New York City was first organized in March, 1866, it was abundantly accommodated in a few rooms in the Police Department building, but in a short time the few rooms had increased in number to eighteen and then the various bureaus and divisions with their accumulations of records and other material overflowed into neighboring buildings until the Department was so much scattered as seriously to hamper its work. Within the past year or two the bacteriologic laboratory has increased so greatly in importance and in the scope of its operations that the demand for larger accommodations had become imperative. Last week the entire Department was removed to the new Criminal Court building, where it is now commodiously housed under one roof, with from four to five times more space than that formerly occupied. Even this is to be supplemented by an establishment on East Sixteenth Street for the production of the antitoxins, under the charge of the Bureau of Bacteriology; when this branch is in operation the New York Health Department will be one of the most perfectly equipped of its kind in the world and can not fail to exert a highly important educational influence upon public health administration throughout the country.

Regulation of Prostitution.—At the recent Congress of Syphilography M. Dron offered the following propositions: 1. Society ought to protect itself against venereal disease as fully as against any other of the contagious diseases. In order to lessen the ravages of syphilis, weekly inspections of the inmates of houses of prostitution should be imposed, and those exhibiting any symptom of venereal disease should be sent at once to hospital. While these measures would be beneficial they would not afford absolute guarantee, for all practitioners have seen patients infected by inspected women in whom no symptom of the disease was detected; again, if the disease is in the secondary stage syphilitic lesions may manifest themselves in the interim between inspections. In case any prostitute exhibits syphilitic symptoms she should be interdicted from plying her vocation until all danger of contagion is past; to be positive three years should elapse from the time of the primitive lesion or from the first appearance of secondary lesions; this is the length of time the proponent has exacted before permitting a syphilitic to contract marriage. In conclusion M. Dron thought the Congress would not be justified in indorsing a proposition to consider any female afflicted with syphilis as a prostitute!¹ On the whole the American or

modern proposed method of regulating this evil seems more decent and reasonable—to treat the male prostitute as at least equally culpable with his companion, and to subject him to the same measures of inspection, immurement in hospital and interdiction from his vocation and from marriage.

Leprosy through Four Centuries.—Goldschmidt, of Madeira, has just published the results of his twenty-six years of personal experience with leprosy. He affirms that his researches show that the disease has maintained its character essentially unchanged on that island for over four centuries. At the beginning of this century it was widespread throughout Madeira; then it sensibly declined, but within the last two decades it has gained fresh ground, owing to the increasing misery of the population. The leper hospital at Funchal, the capital, dates from the end of the fifteenth century; it is half prison, half hospital, and contains at present about seventy lepers, or six cases to every 10,000 of the total population. The village of Ponta do Sol is the most seriously infected locality; it has furnished nearly one-third of all the cases received at the hospital during the past sixty years. Leprosy persists and increases with misery and squalor. According to Goldschmidt, telluric influences have no effect upon the disease; altitude, however, has apparently a marked influence—the greater the elevation the greater the number of cases. The quality of the aliment seems to be no factor in the etiology; the population is sober and alcoholism almost unknown; the quantity of food, however, is a marked factor; for the unhappy inhabitants of the island eat but once a day and hunger is their normal condition. The government prohibits, instead of favoring, emigration. Promiscuity is general; the leprous father, mother and children all sleep together, naked, in the same bed; spoons, plates, drinking vessels, etc., are used in common by the leprous and the healthy; a grocer, with ulcers on his hands, waited on his customers himself. The author thinks heredity is not a predisposing cause, but that the disease is communicated by personal contact. In the treatment of the disease Goldschmidt uses injections of europphen, containing 28 per cent. of iodine, and insists on its energetic use kept up for a long period.

NECROLOGY.

CHARLES G. BARNEY, M.D., of Richmond, Va., September 15. Dr. Barney was born in New York in 1814. He graduated in medicine in that city, and practiced there for several years. He afterwards removed to Mobile, Ala. In 1855 he moved to Richmond, Va. Soon after the war he engaged in the insurance business, and was associated with Mr. Wyndham R. Bolling in that business at the time of his death. For some time before the war Dr. Barney was the Chairman of the Executive Committee of the Virginia Historical Society. He was one of the most active and valuable members of that organization up to four or five years ago. During the struggles of the Society, when the fighting around Richmond was at its height, many of the books and valuable records were stored away in Dr. Barney's barn, and he did a great deal toward preserving many of the manuscripts and pamphlets. He was fond of collecting books and papers bearing upon the history of the Old Dominion, and rendered valuable service in this direction. Among other collections he secured autographs of nearly all the signers of the Declaration of Independence, besides autographs of the most famous Virginians. A number of letters of Washington, Jefferson and other Virginians were secured by him. Dr. Barney was the owner of one of the original copies of "Hamor (Raphl), A True Discourse of the Present Estate of Virginia, and the Successes of the Affaires There, Till the 18th of June, 1614." This was published in London in 1615, and was a very rare book. Dr. Barney had 200 copies of it reprinted. He also made up more sets of the *Southern Literary Messenger* than any one else, including the one now in the State Library. Dr. Barney was one of the original members of the famous old Union Club, in New York, and is said to have been the last surviving member of the founders of that famous organization.

¹ Free translation from the *Gazette Medicale de Liege*.

OLIVER WENDELL HOLMES.

RUDOLPH SEIFFERT, M.D., of Chicago, October 4, aged 69 years. He was born in Vienna, and after completing his studies in the gymnasium he entered the University of Vienna. He completed a course in the medical school and afterward resumed his studies at the University of Heidelberg. After graduation he practiced in his native town until the beginning of the war of 1866 between Austria and Prussia, when he entered the army as regimental surgeon and served until its close. After peace was declared he came to Chicago, and in 1885 he became House Physician to the Alexian Hospital, a position which he filled to the time of his death.

PATRICK BOOTH, M.D., of Oxford, N. C., died recently, and his loss is feelingly referred to in the September Bulletin of the State Board of Health. Dr. Booth was a graduate of the Medical College of South Carolina, in the class of 1875. The Bulletin contains the following note: "It was with genuine sorrow that we learned last month of the death of Dr. Patrick Booth, Superintendent of Health of Granville County. We have received no details of his passing away, but the sad fact remains that we shall see him no more in this life. While our personal acquaintance was of the slightest our official relations were of the most satisfactory character. Earnest, zealous, faithful, prompt—he was an admirable Health Officer."

THE DEATH OF HENRY F. LYSER, M.D.—The Faculty of the Detroit College of Medicine held a meeting at the office of Dr. H. O. Walker, Thursday, October 4. On motion the following resolutions were adopted:

WHEREAS, Death having removed from this Faculty our friend and fellow teacher, Dr. Henry F. Lyster, we desire to

express our high appreciation of him as friend, physician and teacher.

Resolved, That in his death the Faculty of the Detroit College of Medicine has sustained a great loss, and that we shall greatly miss his counsel.

Resolved, That we extend to his family our sincere sympathies in this hour of their bereavement.

Resolved, That a copy of these resolutions be sent to the family of the deceased, to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and to the local press.

(Signed)

C. G. JENNINGS.

A. W. IVES,

H. W. LONGYEAR,

H. O. WALKER,

ANDREW P. BIDDLE.

Expressions of regret were made by various members of the Faculty and, out of respect to his memory, lectures at the Detroit College of Medicine will be omitted on the day of the funeral.

A. B. MILES, M.D.—The Tulane University has passed the following in memory of Prof. Albert B. Miles, M.D.:

Medical Department, Tulane University, La.

NEW ORLEANS, Sept. 28, 1894.

On the above date, the first opportunity (since his death on Aug. 5, 1894), was presented for the colleagues of Professor Miles to testify publicly to the love and esteem entertained for him and to the grief caused by his loss. The following resolutions were submitted by Professors Elliott and Souchon:

"WHEREAS, Professor Miles rendered this institution invaluable services during nineteen years, as Demonstrator of Anatomy, 1875 to 1885; Professor of Materia Medica, etc., 1886 to 1893; Professor of Surgery, 1893 to 1894; Assistant Surgeon to the Charity Hospital, 1882 to 1894; be it

Resolved, That we here record our profound sorrow that death has cut off, in the prime of life and in the meridian of his reputation, our young and brilliant colleague.

Resolved, That the Medical Department of the Tulane University of Louisiana has lost an experienced and beloved teacher, an impressive lecturer, and a surgeon whose skill as an operator placed him in the foremost rank of America's surgeons.

Resolved, That in his death we recognize the loss of a colleague whose calm and deliberate judgment rendered his counsel invaluable in the administration of the Medical Department, and whose constant endeavor was the advancement of medical education and the steady elevation of our standards.

Resolved, That in his death we recognize a civic loss to be deplored alike by city and State; the loss of a character tested throughout the years of his arduous professional life, wherein were manifested those high qualities which compel the confidence of a community and place the crown upon professional reputation."

Approved and published in behalf of a unanimous Faculty.
STANFORD E. CHAILLE, M.D., Dean.

A. B. THURSTON, M.D., of Keene, N. H., aged 35 years.

MISCELLANY.

Oliver Wendell Holmes, a Microscopist.—Forty-one years ago, Dr. Holmes, who was 85 years old on Aug. 29, 1894, taught Dr. E. Cutter how to use the microscope with direct illumination. He had an arrangement of his own—a six-inch black disc fastened to the tube and graduated so that turning the disc would act as a fine adjustment. Dr. Cutter says that Dr. Holmes worked a good deal with the microscope in those days and that the intellectual drill derived therefrom may have been used in literature. Is not the technical use of the microscope in college as good a discipline as the study of Greek? Surely the cyclops of the Odyssey would be better understood by one who has studied a living cyclops taken from a hydrant and shown under the microscope.—*The American Monthly Microscopical Journal.*

Tuberculous Peritonitis in a Child of 13 years Cured by Injection of Camphorated Naphthol.—M. Spillman has reported an observation of a case of tuberculous peritonitis cured by an

injection of camphorated naphthol. It occurred in a boy of 13 years who entered the hospital Feb. 20, 1894, for a well-marked ascites. A diagnosis of tuberculous peritonitis was made, and 850 grams of the fluid were withdrawn and injected into the abdomen of a guinea pig. The animal died tuberculous. After this 10 grams of a solution of camphorated naphthol were injected into the abdomen of the patient by an exploring syringe. The results were excellent. To-day the child is completely cured, the belly is supple and nowhere painful, and the digestive functions are well performed.—*Les Nouveaux Remedies*, Sept. 8, 1894.

Octogenarians in Switzerland.—In the U. S. Consular Reports for September, Consul Germain quotes from the last census of Switzerland which shows the number of people of 80 years, or over, who are still engaged in earning their daily bread. The respective occupations, and the total number of hands employed are given. The statistics shows that out 626,070 persons employed, 2,353 were 80 years old and over, or a percentage to the whole of 0.4 per cent; that agricultural pursuits give employment to the greatest number of aged people; that foresters live to a greater age than gardeners; that tailors number three times as many octogenarians as do the butchers; and that shoemakers have much better prospects of growing old than the bakers. A comparatively high number are found among the wood-turners and carvers, and a still greater number among the hard-working and confined straw-braid workers.

Football.—The football season has opened with rather more than its usual quota of contusions and broken bones of which the Harvard eleven got its full share; but thus far no player has been killed outright on the field. Meanwhile Dr. Charles Anderson Dana, of the New York *Sun*, has summoned divers learned Harvard bachelors and masters of athletics in consultation as to the condition of muscular diversion at Cambridge. While concurring in the opinion of the majority, "that want of skilled leadership and want of confidence are the causes of the anemic state of Harvard sport," Prof. Dana is inclined to add that a "multiplicity of advisers and a curious narrow attitude on the part of the Faculty have helped on the work of woe." He believes, however, that there are cycles and periods of athletic triumphs, as of other things, and that in the turning of the wheel Harvard may again be on top, and so salutes "the undergraduates, studious or record-hunting or both, of the Harvard's Learning Trust," and says "to every mother's son of them, in the language of the Latin reader:

"Tu ne cede Yallis sed contra audentior ito."

Sanitary Conference in North Carolina.—The September Bulletin of the State Board of Health gives a brief account of a conference held on the 13th ult., at Salisbury. The meeting was managed by Dr. John Whitehead, a member of the Board as well as Superintendent of Health for the County of Rowan. The citizens extended a very cordial reception to the scientific men, who gathered "to spread the light, and lend a hand." There was a large and constantly increasing attendance of ladies, giving a lively and active interest to the discussions. The meeting proved to the anxious members of the Board that the people can be brought out and respond in a grateful way to efforts made to instruct the citizens of the old North State on important health problems. Among the subjects prominently discussed were the following: "On the Quarantine and Disinfection required in Contagious Diseases," introduced by a paper by Dr. George G. Thomas, a member of the Board for Wilmington; "Drinking Water in its Relations with Malarial Diseases," by Engineer J. C. Chase, a member of the Board. The same writer contributed a paper on "Household Water Supply." At the evening session Dr. Albert R. Wilson gave an address on the

important subject of sterilizing the dejecta of patients having typhoid fever, proving his points by a lucid account of a recent endemic in Guilford County, of which county he is the Health Superintendent. The water supply of Salisbury was another subject of practical moment, on which the citizens were expected to unite in debating at the evening session, but the net results were not all that had been expected. Good seed, however, has been sown, and there are intelligent citizens in Salisbury who will foster the growth of that seed. The Rev. Dr. Murdoch, among others, is named as a non-medical sanitarian who takes a lively interest in the health interests of the "goodly burgh" of Salisbury. One other subject, the prevention of tuberculosis as understood at the present day, was made interesting by Dr. Battle, a member of the Board of Health for Asheville. The accepted theory of the contagiousness of tuberculosis was the leading feature of this discussion. The President of the State Board, Dr. H. T. Bahnon of Salem, and the Secretary, Dr. R. H. Lewis, of Raleigh, were present and contributed to the gratifying outcome of the undertaking. Very few of the nine members of the Board were absent from this conference.

Model Army Post Hospital.—On the left bank of the Potomac River, and just within the gates of the old arsenal grounds, at the foot of Four-and-a-half Street, in this city, there has been erected for the use of the Washington Barracks an Army post hospital that is conceded by Department officials to be a model of its kind, both in construction and the character of material employed. It is a three-story and cellar structure, 48x64 feet, with a rear building the same height, 27x42 feet.

The *Government Advertiser* gives the following description of the building: "The foundations are of Potomac bluestone and the superstructure is composed of pressed brick trimmed with Hummelstown brownstone, the whole finishing with a high-pitched, slated hip-roof. There is a broad porch at the entrance, with a similar portico on the east side of the back building. The joists and floors are of select Georgia pine lumber. The latter have been smoothed off, waxed and given a high polish. The architraves, base and other moldings are all of white pine, finished in its natural state. The staircase is of oak and Georgia pine. Throughout the building ornamental steel ceilings are used, decorated in soft pleasing tones.

"The cellar contains two large hot water heaters, which will guarantee an even temperature at all seasons. The first floor contains a neatly finished waiting-room, office, with tiled fireplace and handsome cabinet mantel in oak, an artistic chandelier depending from the center of the ceiling; a pharmacy, fitted with a marble-top counter, prescription case, shelving and other appointments usually found in a first-class drug establishment; a lavatory with exposed sanitary plumbing and tiled bath; a dark room for use of oculist, and one large ward, 24x42.6, excellently ventilated by large windows overlooking the broad river; dining-room and kitchen.

"On the second floor is found an operating room, two spare wards, steward's room, completely equipped lavatory, ward master's room, and one large ward, just above and similar in size and appointments to the one on the first floor. The top floor is as yet in an unfinished condition, and for a lack of funds will probably remain in that state for some little time. It will require about \$7,000 to finish it in keeping with the other parts of the building.

"When the proposals were opened for the construction of this hospital quite a number of bidders submitted figures. There was a difference of more than \$4,000 between the highest and lowest proposal. The contract was finally awarded William W. Winfree, of this city, who has executed the work in a remarkably short time and to the entire satisfaction of the War Department authorities. He gave it his personal attention, and was ably assisted in this direction by his superintendent, J. E. Reynolds. The building completed, including the approaches, grading and sodding will have cost about \$26,000.

Dr. MacLure of Glen Urthg; or "All for Mercy's Sake."—The *British Weekly* for June 14, has a medical sketch of a Highland practitioner, that is a classic of its kind. Dr. MacLure, the son of Dr. MacLure, is the subject of the sketch, the two covering nearly a century of practice between them, doing

DIET IN BRIGHT'S DISEASE.

BY JOHN M. BATTEN, M.D.

PITTSBURG, PA.

The diet in the management of a case of Bright's disease of the kidneys is a very important feature. It would seem as nitrogenous ingesta in great part undergo metamorphosis and yielding their nitrogen to be carried off in combination with a portion of other elements under the form of urinary products, that a non-nitrogenous diet or one approximating it is the proper food in this disease.

The experiments of Schmidt show that the amount of urea passed in the urine is related to the quantity of food ingested, the nature of it remaining the same.

He found that when a cat ingested 44.188 grammes of meat daily, that the amount of urea excreted per kilogramme, body weight, was 2.958;

| | |
|-------------------------------|--------------------------------------|
| 46.154 grammes were ingested; | 3.050 grammes of urea were excreted. |
| 75.988 " " " " | 5.152 " " " " |
| 108.755 " " " " | 7.663 " " " " |

It will be seen that when the cat was living on flesh diet that the kidneys excreted on an average 6.8 parts urea for every 100 parts of meat consumed, and that the great bulk of the nitrogen belonging to the food ingested passed out of the system in the form of urea. If all the nitrogen was excreted by this way the quantity of urea would amount to 7.88 per cent. of the weight of the meat; the nitrogen contained in 100 parts of flesh corresponding with that contained in 7.88 parts of urea. But there were 6.8 parts of urea produced instead of 7.88 parts, which may be spoken of as representing the actual equivalent, as far as contained nitrogen was concerned, of a 100 parts of flesh.

Lehman states from observations made on himself when he ate animal food wholly, that about five-sixths of the nitrogen ingested was found in his urine in the form of urea.

From the foregoing observations it must be admitted that nitrogenous matter undergoes metamorphosis within the system. It must also be admitted that nitrogenous matter must undergo changes in the system rapidly, as it has been found that the amount of urea excreted by the kidneys is quickly affected by the quality of the food ingested. Lehman also found that when he had breakfasted exclusively on animal food that his urine was so rich in urea as to throw down a copious precipitate of the nitrate on the addition of nitric acid.

In Dr. Parkes' observations on two soldiers, A and B, he also found that a change in the food ingested soon affected the quantity of urea excreted. These men were kept the first, second, third and fourth days on a regulated mixed diet; the fifth and sixth days on

a non-nitrogenous diet, the seventh, eighth, ninth and tenth days on a mixed diet, the eleventh and twelfth days on a non-nitrogenous diet, and on the thirteenth, fourteenth, fifteenth and sixteenth days on a mixed diet. A, during the first four days on a mixed diet excreted 35 grammes of urea as the daily mean. The fifth and sixth days on a non-nitrogenous diet, 20 grammes and 13.52 grammes respectively. On the seventh, eighth, ninth and tenth days on a mixed diet he excreted 20.67, 25.68, 26.29 and 29.67 grammes of urea respectively. On the eleventh and twelfth days on a non-nitrogenous diet he excreted 19.12 and 15 grammes of urea respectively, and lastly, on the thirteenth, fourteenth, fifteenth and sixteenth days on a mixed diet he passed the first day 20.8, second 26.36, third 28.32 and fourth day 30.10 grammes of urea. B, who was a much smaller man, the mean for the first four days on a mixed diet was 25.92 grammes of urea passed. During the fifth and sixth days on a non-nitrogenous diet the urea excreted was 17.3 and 12.65 grammes respectively. On the seventh, eighth, ninth and tenth days on a mixed diet the urea excreted 14.40, 23, 25.20 and 22.99 grammes respectively. On the eleventh and twelfth days on a non-nitrogenous diet he voided 16 and 13.20 grammes of urea respectively. Lastly, on the thirteenth, fourteenth, fifteenth and sixteenth, days on a mixed diet the urea passed was 23, 24.36, 24.57 and 21.36 grammes respectively.

The above observations show that urea excreted by the kidneys was increased or diminished according as nitrogenous or non-nitrogenous food was ingested.

Mahomet, age 22, and weight 165 pounds, who had been living on an ordinary mixed diet, conducted two experiments on himself with a view to obtaining more precise information with regard to the time required for metamorphosis of nitrogenous matter to occur and to lead to an increased elimination of urea. In order to do this, he took his dinner of mixed food as usual at 1:30 P.M., April 16, 1871. From this time, so as not to suffer too much from want of nitrogenous food, he restricted himself to tea, sugar, butter, arrowroot and rice, the latter being the least nitrogenous of the natural food products. This diet was continued throughout the 17th, and at 8 A.M. on the 18th he took four eggs so as to supply nitrogenous matter. By the following morning it would be expected that the urea excreted would be at a low point when a meal was taken of meat diet.

Under a restricted diet the urea steadily decreased from 21 to 9.05 grains per hour. After eating the eggs the urea readily increased within the next four hours to 13.82 grains, and during the remainder of the day the urea only underwent a little further increase. The following morning the urea had decreased to 10.62 grains per hour, then after eating plentifully of beefsteak at breakfast the urea rose to 21.16 grains per hour, and with a repetition of meat

diet the urea continued to increase throughout the day.

During the experiment the usual bodily and mental work was performed. He noticed, however, during the restricted diet that he experienced a feeling of faintness and some increase in his appetite. Before the experiment was commenced he noticed that his urine was loaded with alkalies. During the restricted diet his urine was clear and the quantity passed was larger than when animal food was being consumed. This shows that when an increased amount of urea was excreted a less amount of urine was passed. Had the urine been increased with the increased amount of urea excreted, it might be argued that the increased amount of urea was due to the increased amount of urine passed.

In the second experiment of two days, on a very restricted diet, the urea fell from a range of 21 to 25 grains per hour to 8.87 grains per hour. At the end of two days, on the very restricted diet, nitrogenous food was taken in the form of egg and milk, beaten together so absorption would take place more easily and quickly. Half an hour later an ordinary meal of cold meat was taken. During the three hours succeeding the first ingestion of nitrogenous matter, the urea excreted stood 12.43 grains per hour against 8.87 grains per hour, the mean amount for the eight hours previously.

Now in Bright's disease of the kidneys we have certain conditions to be met and ameliorated in order to benefit the patient so afflicted. It must be admitted that when the kidneys are diseased they are embarrassed by reason of having too much labor to perform and owing to their enfeebled condition, being unable to perform the necessary functions which is shown usually by a dropsical condition of the system. Reason would then dictate that the kidneys should be relieved of a part of their duties. Now from the foregoing observations we have learned that in order to diminish their labor it is necessary to prescribe for our patient so afflicted, such food as will produce the least amount of or excrete the least amount of urea. It has been shown that urea is most excreted when nitrogenous diet is ingested, and least excreted when non-nitrogenous food is ingested. It has also been shown that the bulk of the nitrogen in nitrogenous food is excreted by the kidneys in the shape of urea. The food necessary to be ingested then by a person suffering with Bright's disease of the kidneys should be principally non-nitrogenous or approximating it.

It has been shown, also, by the above observations that when non-nitrogenous diet is ingested, urea is very much decreased in quantity, and that the urine passed is clear and increased in quantity. Then it will be seen that non-nitrogenous food not only diminishes the urea excreted in the urine, but leads to an increased amount of that fluid. This being true, it must be admitted that the patient suffering from Bright's disease is doubly benefited by a non-nitrogenous diet ingested. Namely, rest to the kidneys and an increased flow of urine.

The patient with Bright's disease is also benefited by the carbo-hydrates for the reason that the cast off material from the ingestion of them is excreted by the bowels and skin and otherwise. This would also add to our armamentarium in the treatment of a case of Bright's disease. The bowels are kept more soluble, throwing off an amount of liquid that might

not otherwise be excreted and they also act as a diaphoretic, passing through the skin an additional amount of fluid.

DIPHTHERIA; OUR MODERN VIEWS — ITS ETIOLOGY AND PATHOLOGY, WITH REMARKS ON THE EARLY HISTORY OF THIS MALADY.

Read in the Section on Laryngology and Otology, at the Forty-fifth Annual Meeting of the American Medical Association, held in San Francisco, June 5-8, 1894.

BY J. MOUNT-BLEYER, M.D.

FELLOW OF THE ROYAL ACADEMY OF MEDICINE, NAPLES, ITALY; SURGEON TO THE NEW YORK THROAT AND NOSE HOSPITAL; LARYNGOLOGIST TO GERMAN WEST SIDE CLINIC, ETC., NEW YORK.

In the work of Hippocrates on dentition we find the following: "*Quibus cito in tonsillis ulcera serpentina consistunt, febrilis ac tussi per manebitibus, periculum est rursus esse generanda ulcera.*"

This is the first record of testimony regarding the recognition of the disease we now classify as diphtheria. Whether Hippocrates had in mind the simple apthous inflammation of the mouth or the well-defined disease itself is an open question. Suffice it to say, the above quotation is the first literature we possess upon ulcerative and exudative disease of the pharynx, tonsil, uvula, larynx, etc.

Aretæus gives us a more satisfactory clinical picture and intimates that Egyptians were quite familiar with diphtheria. Aëtius, who lived some two centuries later, left a manuscript giving clear evidence that he understood diphtheria. And so we pass on rapidly to the end of the sixteenth century. It was the distinguished French physician, Baillou, who it may be truly said gives us the first accurate description of diphtheria. He speaks of a false membrane which we can scarcely mistake for anything save fibrinous exudate of diphtheria.

Ever since the day of Baillou, diphtheria has prevailed in the various quarters of the world. We have the history of an epidemic of malignant angina in Paris toward the close of the sixteenth century; again we find it in Spain—as we learn from Villa Real, who studied an epidemic which raged in Spain in the early years of the seventeenth century, which he portrayed as *garotello* or more specifically *morbi suffocantis*, and which possesses without drawing the broad line of differentiation between diphtheria and the scarlatinal exudates.

Coming down to more recent times, we find such eminent observers as Dr. Patrick Blair, Schobinger, Ghisi, John Star, Huxham, Francis House, Trouseau, Samuel Bard and others engaged in the study of diphtheria. The first exact record comes to us in the form of two treatises on angina diphtheritis which were submitted to the French Academy of Medicine by Bretonneau in 1821. In these brochures he made the broad claim that an inflammation without an exudation is never diphtheria, while no inflammation with an exudation is diphtheritis, when it does not spread by contagion.

He believed that inoculation was the only means of conveying the disease from one to another, and held firmly to the opinion that the atmosphere did not act as a conveyor of the contagion. We have since modified our views regarding the spread of the contagion of diphtheria, and unfortunately the violent epidemics in France, Holland, Germany and our own country, where it raged from time to time, have

given us ample opportunity and material for the study of this feature of the disease.

It was Virchow who established the pathologico-anatomic basis upon which we have since based our investigation of the diphtheritic process. He taught us to direct our attention to the exudation in the substance of the mucous membrane, and the death of this membrane in consequence of the interference with its nutritive supply, in contra-distinction to croupous inflammation where the exudate does not penetrate the structure of the membrane but simply lies upon its surface.

There are still many who hold that diphtheria and croup are essentially similar conditions pathologically considered. Their numbers, however, are rapidly diminishing, and there seems to be little question that within the next decade we will all agree that the views of Wagner will have to give way to the more recent bacteriologic and pathologic discoveries.

Bahl considered diphtheria as a general infectious disease, entirely independent of any previously existing local disease, whose distinctive characteristic was a nuclear or cystoid growth of the submucous connective tissues which caused the death of the membrane by compressing the vessels of its vascular supply. To him the manifestation in the throat and tonsils was simply an indication, or symptom as it were, of the general infection just as the eruptive basis chose the skin as the most favorable seat of characteristic indication.

These are the views about which the profession at large are still at variance. The older practitioner, whose good judgment is based upon a large experience, is not yet ready to resign the theories in vogue during the longer period of his professional career, but there can be but one correct solution of the problem concerning the origin and character of a disease which even to-day is an almost unconquerable foe, and the weight of research prompts to the fact that we must accept and carry on the work laid out by Oertel, Huebner and Welsh if we hope to be able to cope intelligently with diphtheria. The bacillus, described by Löffler and Klebs, coupled with the study of the toxic ferment it ushers into existence, and which finds its way into the circulation, together with the pathology as Oertel has taught it to us, it seems accounts in a satisfactory way for the clinical manifestation of the disease. In other words, if I may be permitted to say it, we have only now begun to know something about the nature of diphtheria.

The etiology of diphtheria, in a great measure, is the practical lesson we have learned from the researches of Klebs, Löffler and their followers. Before the time of these observers we were apt to confound the exudative diseases of the pharynx, tonsils and upper respiratory tract. To day we know, with almost absolute certainty, that there are two forms of this class of disease, which to the eye of the clinical observer present similar changes in the mucous membrane, inasmuch as both are characterized by the appearance of a pseudo-membrane, at times dirty white, often tinted greenish or yellow white in color. Viewed at the bedside alone, in both you will observe alike, prostration, a febrile condition, swell-

ing of the submaxillary glands, disturbance of respiration, often slight it is true, so that a differential diagnosis, clinically, is a qualification to which few of us can lay claim. Notwithstanding this, the two are totally dissimilar. Examined bacteriologically, the exudate of one will reveal nests of bacilli which are found only in the exudate of true diphtheria, while in the other there are no bacilli, but instead the so-called staphylo- and streptococci.

The first variety is highly fatal, statistics showing a mortality of almost 50 per cent., while the second, so far as danger to life is concerned, is comparatively harmless. Thus it becomes of great importance, whenever we have a case of exudative disease of these parts to deal with, to make, if possible, a positive diagnosis of its true character. The New York Board of Health has instituted a most practical method by which every practitioner can ascertain beyond a doubt the disease under his care, and thus avoid mistakes. Where this mode, as aforesaid, can not be made use of, I will explain, when discussing the subject of bacteriology, a very simple manner in a comparatively short time, so that the clinical observer can avail himself of this means of confirming his diagnosis, thus saving much time and trouble.

The causation of diphtheria leaves us much in doubt. We know that it prevails at all seasons of the year, most extensively in the damp chilly weather of the late fall and early winter. We find it in all latitudes and longitudes, although quite recently I was assured by Dr. Angel Garvino, Professor of Bacteriology at the University of Mexico, who visited New York, that the City of Mexico, which lies in a very high altitude, some 1,500 meters above the level of the sea, was comparatively free from diphtheria; in fact so much so that the experience of a case of true diphtheria is regarded with rare interest by the medical men of that city. The disease, too, is not limited to classes. We find it among the rich and poor alike; in well and badly ventilated and drained houses; in the thickly and sparsely populated districts.

Essentially, diphtheria is a disease of early childhood, although no age is exempt from it. Sometimes we find it raging in epidemics, again it is met with in isolated cases in which the question of origin by contagion can have but little weight. In short, these are the conditions under which we find diphtheria.

Many valuable statistics have been collected on the subject, but the limits of a chapter like this do not permit of such detail. Then, again, profitable as statistics are to the specialist and the doctor at large, they make the driest of dry reading. For such as desire more in this regard, the late brochures of Huebner, Baginsky, Oertel, von Brieger, Sidney Martin, William Welsh and others may be consulted.

Diphtheria presents itself under two series of symptoms—the local, and constitutional manifestations, to which may be added a third form best considered, however, as the sequelæ of the disease. Thus in speaking of diphtheria we should bear in mind these conditions, although they do not always manifest themselves together in each individual case. The local disease makes its appearance in an inflammatory process upon certain mucous membranes and denuded parts of the skin, the most common seat of affection being the membranes of the throat and fauces, those most directly in contact with the air, and the inflammation leads to formation of a membranous exudate which is usually the first indication that causes us

¹ I have purposely avoided more extensive reference to the bibliography of the history of diphtheria which may be found in nearly all the works on diphtheria, particularly that of Oertel, Mackenzie and others. In order to devote my limited space to the consideration of the disease in its more modern aspect.

to suspect the existence of diphtheria. Upon superficial examination the clinical observer meets with grayish or dirty white false membrane deposits upon the mucous membrane of the mouth, the pharynx, tonsil, nose; in fact, anywhere along the upper air passages. It is under the same conditions found upon the conjunctiva, the rectum or vagina, or upon any of the mucous membranes of the body that are directly exposed to the air.

When this false membrane invades the deeper mucous membranes, such as that of the intestinal canal, etc., we are inclined to regard it as secondary infection, notwithstanding that we lean to the opinion that the diphtheritic process is usually circumscribed locally, and spreading by way of the general circulation all through the body. Thus we account for the evidence of diphtheria as we find it in the various organs as a primary condition. This, by the way, is the most modern view taken of the disease and the one which to us, after careful consideration, is the theory most in accord with clinical manifestations.

Diphtheria is an infectious disease, and may be classified as somewhere between simple excitement of the circulatory system, and the most aggravated form of typhoid fever and pyemic poisoning. The sequelæ, in my opinion, will depend more or less on the extent of the general invasion from the original local disease, and largely upon the quantity and nature of the septic ferments that find their way into the circulation, involving those organs that offer the least resistance. The latest investigations point to the necessity of turning our attention to the form of true diphtheritis as much as has been hitherto done to the local manifestations of the disease.

In the study of the etiology of diphtheria the first consideration is to explain, if we can, the process of the disease itself. Roux and Yersin, in substantiation of their theory that the systemic effect of diphtheria is not due to the bacillus described by Löffler and Klebs, but rather is caused by the ptomaines or poisonous substances produced by it, proved it by separating the bacillus from the ptomaines and subjected it to chemico-analysis and physiologic test. They described the disease as a toxemia, differing from others in the respect that the toxic acts as a ferment which when injected into living tissue, even in the most minute quantities, ushers into existence certain well defined albuminous substances or bodies.

Sidney Martin succeeded in isolating these poisonous albuminoids from the organs of persons who died from the disease. This substance was secured from the spleen and blood of children, was subjected to repeated alcohol falling and resolved itself into a proto- and deatro-albumose which he injected into the skin of rabbits.

In doses of 0.117 per kilo it produced a febrile condition and edema in the animal; slightly increasing the amount to 0.112 per kilo, rapid death of the animal followed. Intravenous introduction of this albumose in the same animals produced fever, progressive paralysis and degeneration of the heart, nerves and muscles, precisely analogous to those conditions we find resulting from diphtheria.

Löffler's theory of the local origin of diphtheria, when contrasted with the clinical manifestations of the disease, does not seem as plausible as when viewed from its bacteriologic and pathologic standpoint alone. True, he has given us a most careful

and competent description of the bacillus, since honored with his name, and the majority of clinicians agree that upon the presence of this bacillus alone can the diagnosis of true diphtheritis be made beyond peradventure. We are not all bacteriologists, and we propose to lay the greatest stress on the clinical view of diphtheria. I shall refer to its bacteriologic significance only so far as it can be practically made use of at the bedside and aid us in diagnosis, treatment and prophylaxis.

Ab intra diphtheria appears to be a disease which draws into sympathy certain organs, preferably the heart, muscles, kidneys and nerves, and thus it becomes at first glance difficult for us to understand how it is possible that such conditions can be brought into play by a microorganism that has its habitat near the surfaces, and it is even more difficult to harmonize with the insidious progress of the disease and the toxemic symptoms we observe. Once, however, we establish the presence and origin of the diffusible ferments, all these characteristic manifestations become apparent. Bear in mind that the bacteriologic investigations of recent years do not stand alone; we can carry them one by one to the bedside and study them side by side, and reason logically from cause to effect.

One thing judged by the weight of careful research appears true, that it is essentially certain we can no longer hazard a positive opinion upon a case of diphtheria without having ascertained the presence or absence of the bacillus. Many of us appreciate the force of this broad statement from practical lessons learned at the bedside where without any indication that would direct our attention to it, we have seen certain cases of diphtheria resolve themselves in from one to three days into simple exudative tonsillitis or angina lacunaris.

Skigo reports several such cases which he met with during an epidemic of diphtheria, where the tonsils were covered with disseminated spots of exudate the size of a pea; and he tells us that there was absolutely no clinical indication by which he could differentiate the cases which ran the violent course of true diphtheria, and those which took the milder course.

The value of the bacteriologic character of the exudate in this connection received much attention from Morton, who examined 200 cases of diphtheria that had been diagnosed by that eminent clinician, Dr. Simon, of Paris. In only 137 of these cases did he find the bacillus; 43 of the remaining 63 cases proved to be tonsillitis; 13 proved to be croup, of which 12 got well without operation; 7 cases proved to be diphtheria with croup, 6 of which developed bacilli after the operation of tracheotomy had been done, and which Morton says was clearly due to hospital infection.

It is necessary in the very first instance to differentiate between exudative tonsillitis and true diphtheria. This, if we are obliged to follow the procedure of Koch, which requires a bacteriologic experience which the average clinician does not possess. The cultivation of the bacillus in glycerin agar requires time and patience, to say nothing of careful work. The bacillus must be isolated from the membranous exudate. The cultivation of the bacillus in blood serum requires at least from twelve to sixteen hours, and a day or a day and a half, at least, in making the diagnosis. With a case of true diphthe-

ria to deal with, so much time can not be sacrificed, and hence we must look to other more rapid means of gaining the object of which we are in search. In hospitals, with all the facilities at hand, we can allow ourselves privileges that we can not think of in private practice.

But we have a simple means at hand of making a hurried and certain examination of the exudate, where one can not have the opportunities of a city board of health. The method is the one devised by Roux and Yersin, modified by Huebner. A bit of the yellow covering of the membrane from the tonsil is removed with a sterilized spatula, and rubbed over the surface of a cover-glass until the film is very thin and almost dry. The glass is then passed through a flame and stained with methyl blue. The specimen, it will be found, readily takes the stain, and inside of a very short time it is ready for the field of the microscope. An ordinary objective magnifying glass of 400 or 500 diameters answers the purpose, and with a little practice, between the detritus, mucus, pus cells and the various bacteria heaps, you will observe nests or pockets of mixed up bacilli about the size of the tubercle bacillus, most of them slightly bent, some club shaped, often irregularly seamed.

With the presence of these nests established you may be reasonably certain, in fact we almost feel like saying absolutely certain, that the case is one of true diphtheritis.

On the other hand, if you find only the cocci—the strepto- and diplococci, with here and there, short, thick, weakly stained bacilli not arranged in nests, you will, in all probability, in fact you may be certain the case you have to deal with is not a true diphtheria. The statistics of Huebner covering 113 cases examined by him during a period of six years after Löffler described the specific bacillus, go a great way toward supporting the above statement.

In thirty-six cases, Huebner found cocci, many solitary ones, with some side by side, but no nests of bacilli with stained ends. Ten of these cases were scarlet fever, and thirteen presented the clinical picture of follicular tonsillitis or croup. The exudate of the other seventy-seven cases revealed bacilli arranged in nests; of these the nests of bacilli alone presented, while in fifty-three there were nests besides cocci. Of these seventy-seven cases, fifty-three died with all the manifestations of true diphtheria. The mortality of the cases where the bacilli predominated in very large quantities was 66 per cent., and where the nests and cocci both existed 59 per cent. died. Of the thirty-two recovered cases, seventeen presented all the clinical appearances and were of the most violent type, four were tracheotomized and fifteen were mild cases without any of the marked characteristics of true diphtheria.

From this, alone, the high value of a bacteriologic examination becomes evident, and to say the least, it is beyond question the most reasonable diagnostic factor we have had in years and of undeniable practical value, for the reason that in each case the cover-glass method before described alone was sufficient to make a satisfactory examination.

"It is possible," says Huebner, "that a recovered case may show bacilli some days after the disappearance of the membrane." I can add my testimony to this, for in four cases similar, I also discovered sparsely filled nests, two days after all visible signs of the membrane had disappeared.

It must not be forgotten that you will find cocci in angina lacunaris to which Fraenkel called our attention in 1886. And lately the claim has been made that a small coccus is always found in the pseudo-membranous disease, which is pathognomonic of the disease. This still remains to be proved, although it appears to us to be a fact ready for acceptance, yet it will require more careful investigation before we can put ourselves on record with an unmistakable picture of this microorganism. Martin, of Paris, first described the organism which he pronounced to be pathognomonic of the pseudo-membrane, and I am inclined to agree with him. The significance and value of these recent researches will bear much upon our treatment of this malady.

With Laycock in 1858, we have the first intimation of the possible parasitic origin of diphtheria, the parasite being the oidium albicans. Later, Letzerich ascribed it as due to the zygodemus, and Tuscos and Joffe to the leptothrix buccalis.

In 1868, Oertel carefully studied the habits of micrococcus which he isolated from the exudate, membranous exudate. It occurred as a minute, dark, point-like microbe; some round, others oval, occurring singly or in masses—zöoglea; it was always accompanied by the rod bacterium. In 1883, Klebs examined the exudates obtained during an epidemic in hemorrhagic diphtheria in Prague, and claimed to have discovered the specific germ of true diphtheria—the microsporon diphtheriticum, a small micrococcus, arranged in round balls covered by a thin layer of gelatinous matter. These subsequently developed into motive bacilli and finally into tufts of mycelium.

In another epidemic occurring in Zurich, and characterized by a rapid extent of the membrane into the larynx, followed by interstitial inflammatory process in the internal organs, Klebs came across a microorganism that differed totally from the one he first observed. It was lobular and essentially belonging to the bacillus group. He naturally concluded that there were two forms of diphtheria, *i. e.*, diphtheria microsporon and diphtheria bacillaris. Klebs undoubtedly was on the right track, but he lost the scent, which also escaped Emmerich-Solomen, until Dr. Frederick Löffler took it up and accurately pictured to us the bacillus which we now accept as characteristic of true diphtheria. It is essentially the one observed long before by Klebs whose weak point seems to have been insufficient accuracy and evenness in conducting his investigations.

To Löffler we owe the streptococcus and the bacillus; the bacillus of which I desire to speak at length here. It is non-mobile, its form is difficult to describe in words that will give you an adequate idea of its appearance to the eye, for it is neither straight nor bent; in short, it is about the size of a tubercle bacillus, somewhat thicker. It is not found in the intestinal organs, and micrococci morphologically identical with those found by Löffler are observed also in various diseases accompanied by inflammation of the mucous membrane, like variola, typhoid and puerperal fever, but their presence there is regarded as purely accidental.

Löffler found his micrococci not only in the membranes, but also in the lymphatics, from which point they penetrated every part of the body, causing a tissue necrosis.

The micrococci are not always present. Inocula-

tion by injection of streptococci do not produce true diphtheria. This is the great evidence that they are not specific of the disease. Not so with the bacillus.

The bacteria of diphtheria is aerobic; that is, it requires oxygen for its life and growth.

The pathology of diphtheria.—As in the preceding pages on the etiology and bacteriology, I will not be able to go into details, but rather confine myself to the pathology, as it is most nearly associated with changes that are manifested by ordinary clinical observation. The most complete studies on the pathology of the disease have been made by Oertel, both as to the structure of the membrane and the changes in the tissues of the body, as we find them affected by diphtheria.

Let us take up the membrane first. In color, it is grayish or white, varying in thickness from one to three millimeters. It is tenacious, thick and closely adherent to the parts, and for this reason, on removing any of it for examination it is necessary to scratch with some vigor and not scrape lightly over the surface with a spatula. In the main it consists of degenerated fibrinous epithelium and faser stoff exudate. This with the coagulation of the fibrin produces a hyaline substance made up largely of degenerated cells and tissue elements. This occurs not only on the surface of the membrane, but deep down in the sub-epithelial tissue. The inflammation and fibrinous exudate is a secondary process.

The classification the modern observers are inclined to make, summed up is this: Diphtheritic pseudo-membrane is true diphtheria. Fibrinous pseudo-membrane is not true diphtheria. The two, as they appear clinically, are absolutely identical. There is absolutely no way of differentiating when viewed in gross. Practically speaking they are alike, and it is in this connection that the bacteriologic examination alone can determine the diagnosis. Both are a coagulation of fibrinous exudate.

The degenerative process in the spleen, in Peyer's patches, in the lymphatics, the solution and degeneration of the cells into coagulable hyaline substance are precisely similar to that which produces the pseudo-membrane in the larynx, trachea, uvula and pharynx.

The histologic structure of the membrane varies. The epithelium, according to von Wagner, is a fibrinous metamorphosis. Between the epithelium there are leucocytes which (*necrotistisch zu grunde gegangen sind*) have become resolved into hyaline substance, the masses of (*fibrinogener flussigkeit*), which transudated assumes in the epithelial structure the form of a network or fibrillated structure.

Masses of larger round cells are also intermixed, some broken down, others still retaining their apparent integrity, with disintegrated similar masses. The first change occurs in the nuclei of the cells.

The major part of the membranous masses of the pseudo-membrane is of secondary origin. It originates from the mucous tissue and the elements which form it have collected and originated in it. They were simply evolved from the depths of the membrane to the surfaces.

There is a fibrinous infiltration of the connective tissue observable in the lowest strata of the mucous membrane, also hyaline degeneration of the membrane; larger and similar round cells with the detritus of the breaking up of these cells, around which in the deeper layers we find healthy cells sickened, or

so affected that they have gathered in heaps ready to undergo further change.

These, in brief, are the pathologic products and changes we find in the structure of the membrane and its continuance indicates that the disease is advancing.

It is claimed that pathologic changes, such as have been described, may be produced by injections, in the membranes and the tissues directly underlying, of powerful irritants, and thus the possibility of producing diphtheria by mechanical means is claimed to be possible.

460 Lexington Avenue, New York City.

DUTY—LOYALTY—SUCCESS.

Read before the Joint Meeting of the Golden Belt and Northwestern Kansas Medical Societies, held at Ellsworth, Kan., Oct. 4, 1894.

BY WILLIAM B. DEWEES, A.M., M.D.

SALINA, KAN.

Fain would I call the attention of not only those within the sound of my voice, but of every member of the two Societies here represented, as well as of every reputable practitioner in America, to the too much neglected duty of contributing to and studying the proper current medical literature. By the right endeavor in this direction the great distinctive service of American practitioners of medicine may justly become effectually manifested by its counter-acting influence in removing the pedantry shown in some of our medical colleges and periodicals, and encourage the expression of original thought and observation in young physicians. The distinction of young physicians is made because it is from this rank that the future advance in medicine will be made, and also from the cognizance that most of the older members of our guild have never learned to write nor to observe or study, while as they become burdened with the cares of a large practice or the habit of indifference, it becomes impossible for them to acquire the art of writing. Thus, whatever knowledge they may possess of positive value to the profession, dies with them.

Advance in medical education follows the earnest endeavor of the thoughtful and observing doctor to learn something of profit and interest, and then place this before the profession in the most attractive manner. When a young practitioner has begun to realize that he can talk to the medical profession throughout the State, the nation, and even the world, life and study take on an entirely new aspect. To the day of small things will now be added the day of an enlarged and enlarging physicianhood. He who fully realizes this truth will never write a poor article for publication. The poor articles come from quite a different sort of doctors. To every young practitioner who would make the most of his powers I would say: Think and observe for yourself, and write for the best periodicals constantly. Though it be only one or two articles a year and much time be required to prepare the same, be sure to acquire and keep up the habit of correct thinking and observing, constant study and perfect writing.

With regard to studying the proper current medical literature, it is but necessary to call attention to the fact that no practitioner can be considered as progressive who has not provided himself, first of all, with the true representative periodicals of the profession of his State and nation. Therefore every

loyal physician in Kansas should consider it his first duty to become a member of the local medical society of his city, county or district, then to join the State Society and thus in turn hold membership in the AMERICAN MEDICAL ASSOCIATION. Then will follow the regular weekly visits to his table of both the *Kansas Medical Journal* and the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. These periodicals are the official organs of the State and national organizations respectively, and are independent, being controlled and issued by medical men for professional purposes only, and will allow a weekly interview and counsel with the best medical talent of the State and nation. This argues for State and national unitary medical organization. Why not? Our business remains to be the welfare of the people and raising the standard of our profession. We are thus to consider ourselves called upon to constantly arouse in the medical mind the recognition of the need of professional unity. Without unity we can not speak properly and effectively to the people or the profession, criticise abuses, or encourage faint and sporadic attempts to be in accord with nature. In unity we shall find strength and success, while singleness of purpose can only bring professional weakness and failure.

They only gain the largest success who improve every opportunity. By thus studiously applying himself the doctor may become as progressive in Kansas as anywhere else on the globe. We say progressive, because our profession is a progressive one; and every succeeding representative of a progressive cause, will find the pre-requisite to be more knowledge and a better understanding of the truths which the same embodies, in order to be properly qualified and merit the name of a representative. The knowledge and wisdom of to-day will not fully serve the needs and wants of to-morrow. What little we can do now and year by year, are like little seeds scattered by the wayside, yet falling upon good soil, will germinate and grow, and though planted by a tyro and watered by Apollo, the kind and ever careful Dame Nature will not fail to give them the rightful increase.

We know of no means by which success will come to our profession, save by untiring industry in both individual and united effort. The great danger of failure lies in knowing and doing too little and not in knowing and doing too much. It is work that gains the goal and wins the prize; and as we have nothing which we desire to lose but much to gain, we should have strong wills followed by strong deeds; such as will leave their impress as guides to our successors. A mark set high and a plan well laid are not often found in the *débris* following a failure; but stand out prominently as monuments of mature intellects, not easily shaken and much less destroyed. Let us then henceforth individually and jointly endeavor to "learn to labor and to wait," and see to it that our brethren do likewise—even though we shall find it necessary to "go out into the highways and hedges, and compel them to come in," (Luke xiv, 23) to work and be happy, to be loyal and deserve success in unity. Let our motto be in the language of Addison's "Cato:"

"'Tis not in mortals to command success

But we'll do more, Sempronius; we'll deserve it."

When thus we become really aroused to the proper sense of our duty and demonstrate effectually our loyalty to our profession with a spirit that will

strongly and convincingly awaken our brethren who are now dormant existing in professional desuetude, by driving home to them those conditions which are of a nature that pinch the conscious, and of which the only consoling element is to be found in the thought and act of "*We must be born again;*" then will the possibility present itself of increasing the membership of the Kansas State Society to upwards of 1,000, and that of the AMERICAN MEDICAL ASSOCIATION from less than 5,000 to a possible 50,000—which estimate will include only a limited number in excess of one-half of the practitioners of rational medicine in our State and Nation, respectively. Then, and not until then, may we confidently hope to find enlisted the requisite majority essential to ultimately have success reward our efforts by bringing about through unitary action, legislation in all things concerned with the well-being of the people, as it should be, namely: In dependence upon concerted medical advice. Will we do our duty, be loyal, and deserve success?

TOXIC AMBLYOPIA.

Read by title in the Section on Ophthalmology and Otolaryngology, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JAMES A. LYDSTON, M.D., Ph.G.

LECTURER ON OPHTHALMOLOGY AND OTOLARYNGOLOGY IN THE CHICAGO COLLEGE OF PHYSICIANS AND SURGEONS; MEMBER OF THE AMERICAN MEDICAL ASSOCIATION, THE CHICAGO MEDICAL SOCIETY, AND FELLOW OF THE CHICAGO ACADEMY OF MEDICINE, ETC.
CHICAGO, ILL.

Accustomed as we are to such precise and accurately descriptive terms in ophthalmology, it is a matter of some surprise that such vague and indefinite ones as amaurosis and amblyopia should have withstood the changes of years and still confront us as we scan the index of every well-arranged ophthalmologic text-book; but we presume that the ophthalmologist feels himself entitled to just as much license as does the author of every treatise upon the principles and practice of medicine, wherein we see an entire chapter devoted to jaundice, which is at best but a symptom of hepatic derangement. Were we to adhere strictly without qualification to the modern definition of amblyopia, we should confine ourselves strictly to those cases of visual perturbation in which there is no dioptric or structural change to account for the defective visual acuity; but in strict accordance with my subject I must depart from such a fixed classification and embrace all forms of impaired vision arising directly or indirectly from retinal or optic nerve changes due to toxic causes whether heralded by organic disturbances, ophthalmoscopically perceptible, or dependent upon retinal or optic nerve intoxication under the one significant title, toxic amblyopia. Inasmuch as in every case of optic nerve or retinal change, arising from toxic influence, it is only in the later degenerative stages that characteristic phenomena assert themselves and become sufficiently grave to be perceptible to ophthalmoscopic investigation. Thus grouping toxic amaurosis and toxic amblyopia together we find that a common cause is often the dominating etiologic factor. Thus we have uremic amaurosis and uremic amblyopia, designed to describe different degrees of impaired vision consequent upon one and the same cause. Therefore, with the remark that I shall not attempt to differentiate between toxic amblyopia and toxic amaurosis, regarding the two terms, as we must, as

simply differing in degree and descriptive of visual changes resulting from either moderate or severe retinal or optic nerve intoxication or structural change, I will at once invite your attention to a few clinically demonstrable facts that may serve to shed some light upon a subject which is at best but a poorly comprehended and complex topic.

Samelsohn is entitled to credit for having presented us with the knowledge that anatomic investigation revealed in all cases of toxic amblyopia an inflammation of that part of the optic nerve lying within the optic canal, which serves to explain many otherwise inexplicable optic nerve changes. Toxic amblyopia has been known to result from many and various causes. As significant of its origin, we are burdened with numerous names descriptive of the disease. Thus we have amblyopia uremica, amblyopia albuminurica, amblyopia saturnina, amblyopia diabetica, amblyopia nicotinic, amblyopia alcoholica, etc., and of all these, probably from their greater frequency, amblyopia nicotinic and amblyopia alcoholica are the most commonly described and more fully appreciated, and we find these forms to be accompanied by a chronic retro-bulbar neuritis which lies at the bottom of the subjective manifestations—defective vision, nyctalopia, scotomata, etc., which are the suggestive manifestations to the patient, and if the interstitial neuritis is overlooked will ultimately lead to permanent optic nerve changes such as atrophy of the nerve, blanching of the papilla, atrophic excavation, contraction or narrowing of the retinal blood vessels and consequent pronounced limitation of the visual field.

Arlt described the condition that we appreciate to-day as amblyopia nicotinic, under the title of amblyopia nyctalopia, inasmuch as nyctalopia was its most striking symptom, ascribing the nyctalopia to dazzling by intense illumination for lack of a better explanation; but thanks to Samelsohn, we are able to define a more plausible reason for the changes. Three well-marked and typical illustrations of toxic amblyopia, or better, retro-bulbar neuritis from toxic causes, arising from the excessive use of tobacco, and aggravated by alcoholic indulgence and excessive venery have presented themselves to my notice in the last few months, and in each instance I was able to define marked retinal ischemia, pronounced pupillary dilatation, together with sluggishness of the pupil under the reflex stimulus of light. In all cases the attention of the patient was directed to his eyes by great visual deterioration in both eyes, and that, too, to a similar degree in each. The constancy of nyctalopia as a symptom occurring in the early stages of this affection, I believe with Arlt is partially explicable on the ground that the pupil is dilated and therefore during the day permits light to enter the eye in floods, producing a disagreeable glare, dulling the retinal elements by over-stimulation. As we know that when the eye is suddenly exposed to the influence of the terrific glare of an arc light its retinal impressions are almost obliterated, as was typically illustrated in one of the electric light fitters in the Champlain Building, whose eyes I had the opportunity of examining ophthalmoscopically immediately after they had been subjected to the flash consequent upon a short circuit. In this case there was developed an acute traumatic conjunctivitis and amblyopia fugax, both of which symptoms disappeared with appropriate rest under atropin,

dark glasses, etc. Aside from hyperemia or ischemia of the disc, we may say ophthalmoscopic examination reveals no changes in early cases of toxic amblyopia. Testing the vision, however, we note gradual diminution of the visual acuity, the cause of which is a central scotoma. This scotoma is horizontally oval in form, extends from the macula lutea to the optic disc and corresponds to the maculo-papillary region of the retina. The gap is noted where the vision is tested by means of a white object, but red and green change in the region of the scotoma, appearing less highly colored than in other parts of the visual field, and as the case progresses, red becomes wholly imperceptible, and finally white disappears in the area corresponding to the scotoma, the vision is reduced to its extreme, and we now have an absolute scotoma, but here, as in other instances in which it is advisable to test the visual perceptivity of color, we must remember that even within physiologic limits the perception of colors is not the same in all portions of the visual field, *i. e.*, there may be a wide difference between central and peripheral color perception, and while we can test the central region with the colored skeins of Holmgren, the peripheral color acuity must be investigated by movable colored bodies which are forced into different positions, throughout the visual range, and thus are we able to define that the peripheral retinal domain is normally color blind.

The etiologic factor in that variety of toxic amblyopia styled amblyopia nicotinic is the excessive chewing or smoking of tobacco combined with excessive drinking, sexual excesses, etc., consequently most, if not all, cases are found among men, and not earlier than middle life, more frequently in cases of advanced age, as it seems that as age advances the optic nerves become less tolerant to the effects of nicotin, and again individual predisposition or particular susceptibility seems to be a prime factor in certain instances in this class of cases, therefore comparatively small quantities of nicotin are sufficient in exceptional cases to produce optic nerve intoxication to the degree of exciting amblyopia, while in others *per contra*, there seems to be almost complete immunity to this affection. A point possibly that exercises an important bearing in the way of explaining the occurrence of toxic amblyopia is the fact that in certain cases the physiologic excavation involves almost the entire disc, and the fibers corresponding to the area of the disc implicated in the physiologic excavation are consequently more prone to degenerative change. And again, another predisposing factor is in my estimation the fact that in adult life the optic nerve fibers lying adjacent to the pial sheath regularly experience atrophy, while coincidentally therewith atrophic changes assert themselves in the optic nerve fibrillæ lying contiguous to the central vessels which, complicated by the toxic influence of any poison having a particular predilection towards optic nerve degeneration, favors optic nerve change with consequent amblyopia.

With respect to treatment, the primal indication is to eliminate the exciting or predisposing factor. We must at once withdraw tobacco and advise complete abstinence from alcoholic beverages, excessive venery, etc.; in short, everything that tends to deplete or lower the vital powers of resistance must be eschewed. Proper regimen of the eyes advised and instituted, excessive close eye work, as well as exposure

to the dazzling effects of bright light should be avoided, and tonic measures of treatment at once applied. Among the remedies that stand preëminently forth in the management of toxic amblyopia from whatever cause, we yield the palm to strychnia, hypodermatically given, either at the nape of the neck, or in the temporal region. To Nagel belongs the credit of having first used strychnia in cases of optic nerve change, and Hippel has determined that it exercises a mildly stimulating effect upon even the normal nerve, increasing visual acuity in a transitory manner and widening the field of vision. In addition to strychnia hypodermatically and internally, iodid of potassium, in goodly sized doses, seems to exercise benefit by its eliminative tendencies, and at the same time probably separates nicotin into less poisonous compounds. Another efficient remedy is pilocarpin, both internally and hypodermatically administered, exercising its effects through elimination, diuresis and diaphoresis. Numerous other therapeutic agents are said to excite a retro-bulbar neuritis with consequent amblyopia, among the most conspicuous of which are stramonium, carbon bisulphide, lead, chloral, opium, quinin, osmic acid, etc. I have met with toxic amblyopia arising from huge doses of quinin, but here there were, as a rule, no diagnostic optic nerve changes, aside from retinal ischemia or hyperemia and slight swelling of the disc, and the amblyopic manifestations were fugacious in character, so that the diagnosis was necessarily based upon the immediate restoration of vision following withdrawal of the medicament, which was exercising a toxic effect exhibited by the amblyopic manifestations.

Suite 804, Champlain Building.

THE MARINE BIOLOGICAL LABORATORY AT WOOD'S HOLL, AND ITS POSSIBLE RELATION TO MEDICAL EDUCATION.

BY C. S. BACON, M.D.

PROFESSOR OF GYNECOLOGY, CHICAGO POLICLINIC.

Medicine, which lays under contribution all the natural sciences, chemistry, physiology, botany, zoology, etc., is interested in the development of each of its subordinate or fundamental parts, and hence can not be indifferent to any means which promises to aid the growth of any one of these foundation sciences. Such an agent in developing biology is the Marine Biological Laboratory of Wood's Holl, Mass. The questions that have been asked convince me that there is much interest among medical men concerning this station for science research and teaching, combined with as much ignorance of its practical workings. To satisfy this interest I will give the readers of the *JOURNAL* some idea of the aims and methods of this institution and then suggest how it can be of use to the medical profession.

Although marine laboratories have been in existence only for about twenty years, their objects or functions are well known to all who have to do with morphologic and physiologic functions. Prof. C. O. Whitman, Director of the Laboratory at Wood's Holl, in the opening sentence of an article in the *Atlantic Monthly* of June, 1893, makes the following suggestive statement: "The ocean is now regarded as the original home of life on this planet and its present inhabitants furnish records of life histories

and evolution phases which are absolutely indispensable to a deeper insight into the phenomena and laws of life." It may be added that for purposes of instruction marine forms can be studied in their natural habitat more easily and economically than land animals and especially is this true of the study of their embryologic and larval stages of development.

The laboratory at Wood's Holl differs in one important respect from other seaside laboratories, such as the well-known station at Naples. Our American laboratory combines the function of a station for research with one for instruction, while that at Naples is exclusively for original investigation. Any one who intends to enter upon any line of research but is unprepared in the details of technique may acquire in the school such preparation at a great saving of time and energy. The school is also made use of by teachers in colleges, normal and high schools who wish to keep up to date their knowledge of biology and the methods of study. For their benefit there have been organized classes in vertebrate and invertebrate anatomy, embryology, morphology, comparative physiology and botany. A more vivid idea of the way these courses are presented may be obtained by a short detailed description of the course with which I am most familiar, that in embryology. This class studies the fertilization, segmentation and early stages of development of various pelagic fish eggs, and the variations produced by securing abnormal conditions of pressure, rupture of cell membrane, etc.; learns the method of killing, staining, sectioning in parafine and celloidin and reconstruction. Some time is also given to the study of the holoblastic eggs of sea urchins and amphibians. This statement of the work at the tables, however, gives but a very incomplete idea of the value of the course. One of its most important features is the series of lectures and seminars with discussions of the vital questions of biology, such as the structure and nature of the cell, the questions of heredity and homology, etc. Here the broad-minded tolerance of the director and his wise, suggestive and stimulating influence are best seen and felt. The contact with the resident investigators and visitors who give the lectures is also as profitable and stimulating.

I shall not attempt any particular account of the research department further than to say that each investigator has his own room and is given every facility for collecting material that can be furnished by free use of the laboratory boats and a steam launch. A list of the workers who are here, or have been here, would include the names of a considerable proportion of those who are making original contributions to science. A list of the publications that have been prepared here would, no doubt, surprise many who have not realized the importance of a marine observatory.

It should be noted that this institution is not under the control of any school or sect, but is national in its scope and organization. Its trustees and instructors are from the faculties of Harvard, Brown, Yale, Columbia, Universities of Pennsylvania, Chicago, Michigan and other widely separated schools. Twenty institutions have subscribed for rooms or tables while the 133 students present this year represent 70 colleges, universities and schools.

In locating the station at Wood's Holl the directors profited by the earlier attempts to establish similar institutions at less accessible points, that of

Agassiz's summer school at Penikese and the school at Annisquam. Wood's Holl is at the southwest angle of that part of the Massachusetts coast that bounds Buzzard's Bay on the east and forms the northern boundary of Vineyard Sound, the eastern extension of Long Island Sound. It is easily reached from New York or Boston and is the starting point for boats to Martha's Vineyard and Nantucket. Buzzard's Bay, the sound, the ocean to the east with its numerous shoal banks, the long stretch of the coast line of the main land and the adjacent islands furnish excellent collecting grounds for both northern and southern marine forms. Brackish and fresh water ponds are near while the flora is rich and accessible. The United States Fish Commission is also located here and is of value to the laboratory in many ways. The climate is ideal for a summer resort. The invigorating sea breezes, the cool nights, the afternoon swim and the numerous excursions and collecting expeditions all tend to make one forget that there is a hot, bustling and uncomfortable city. If one does not care to do much laboratory work he can pass a most pleasant and profitable vacation of four to six weeks by renting a sail boat for the season at an expense of from \$10 to \$20, take in the lectures, come in contact with the workers, and thus imbibe the spiritual and climatic air. The laboratory furnishes a good "mess" at \$5 a week, while lodgings can be obtained at from \$2 to \$5.

The school is supported by donations from friends of scientific research and by fees from students. The courses in which instruction is given are \$50, while the investigators rooms are \$100 for the season. Many schools and colleges have subscribed for tables or rooms for the use of their most promising students. It has seemed to me a practical suggestion that medical colleges and societies subscribe for tables or rooms for the use of members of the faculty, or as prizes to students to be awarded for excellence in scholarship or of a thesis. The laboratory is now open only during the summer months as there is no provision for heating the building. An effort will soon be made to secure sufficient funds to erect permanent buildings and provide an endowment that will make the institution secure.

In considering the relation of schools in biology to medical education it is hardly necessary to discuss seriously at this day the proposition that the student of medicine should be well grounded in comparative anatomy and physiology, embryology and physiologic chemistry. These sciences are the foundation of human anatomy and physiology and hence the foundation of the science of medicine. Without them the physician would be like a watchmaker who should attempt to regulate the mainspring of a watch without a knowledge of its shafts and pinions, or a locomotive engineer who should attempt to manage his machine while ignorant of the properties of steam. In a few of the best medical schools this proposition is assumed, and such knowledge is made a condition of admittance. To supply it, a few schools have established short courses in embryology, bacteriology, etc. But teachers need teaching to keep their knowledge up to date. For many years it has been the custom for the teachers in our common schools, high schools and colleges to get together in their normal institutes and State and National conventions for the exchange of views, learning improved methods and securing the stimu-

lation necessary for success in their work. The State and National medical associations help physicians in the same way. These meetings, however, are hardly sufficient. They are too short, too much is crammed into a few days and there are too many social distractions. The recent growth of summer schools is very suggestive. The real meaning, purpose and uses of a vacation are becoming better known. A true vacation is not idleness; it is a change of work. Hence I believe that summer schools in biology furnish an ideal vacation for teachers in medicine or, indeed, for all physicians.

I will suggest, then, that teachers of anatomy in our medical colleges come to Wood's Holl and take the course in comparative vertebrate anatomy that is planned for the season of 1895. The course will be under the direction of a corps of instructors of national reputation and the animals dissected for the practical laboratory work will be of the most typical nature (amphioxus, shark, skate and an amphibian). The most modern and improved methods of microscopic and histologic research will receive special attention. After such a course I will warrant that they will no longer impose on their classes by reciting Gray and calling the performance lecturing on anatomy. The physiologist, pathologist and neurologist can also find here abundant material for work, while every physician who has a special interest in any line of work can certainly profit by learning the latest methods of original investigation.

FIBROID TUMORS OF THE UTERUS.

Read at the Meeting of the Illinois State Medical Society, May 15, 1894.

BY LOUIS A. MALONE, M.D.

JACKSONVILLE, ILL.

The natural history of uterine fibroids must include their course and development, from the smallest pathologic deviation to the fully developed growth, histologic anatomy, symptomatology, and, as well, classification.

In looking over the literature of this subject, it seems as if each one has endeavored to create for himself a new term to describe the same condition. The classification of these tumors which seems to meet with most general adoption and which most nearly expresses the pathologic anatomy is fibro-myoma.

Mr. Lawson Tait is clearly of the opinion that these so-called tumors of the uterus are simply perverted muscular developments, as in all cases of uterine fibroids where careful examination has been made by him or his assistants, characteristic, unstriped, involuntary muscular fibers have been found. In his classification he makes but two divisions—multinodular and soft edematous myoma. Of the two he says that edematous myoma is always interstitial, while the multinodular may be, and in fact generally is, at once submucous, interstitial, and subperitoneal.

This classification of Mr. Tait's hardly meets with the approbation of most writers on the subject. His edematous myoma appears, according to other writers, simply as a degenerated process of the same tumor which he classifies as multinodular. Like nearly all, or all, of the malignant or benign tumors of the body, they have their origin in the natural tissues of the body and are but degenerated muscular cells from the uterine body itself.

In an excellent paper read before the Mississippi Valley Medical Society, Oct. 4-6, 1893, by Dr. R. Stansbury Sutton, of Pittsburg, Pa., and published in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, the whole subject of uterine fibroids is carefully gone over. He has summed up in a most excellent form all that is known on the subject, and I am indebted to him for a great deal of assistance from this paper.

The term, fibro-myoma, is all comprehensive and will describe the histologic formation of all such tumors; in some the connective or fibrous tissue will predominate, while in others the muscular, so that the classification of subperitoneal, interstitial, and submucous fibroids will be simply the naming from location.

When it comes to dealing with the treatment of these tumors, however, and with the symptomatology, their location is of the utmost importance. The pathologic changes which these tumors may undergo are varied; and have also led up to an additional classification. Like tissues elsewhere in the body, these neoplasms may undergo different degenerations such as fatty degeneration, myxomatous, suppuration, gangrene, calcification, or cystic degeneration.

The subperitoneal or subserous fibro-myomata is simply an outgrowth from the wall of the uterus, pushing the peritoneum and part of the uterine wall before it, sometimes becoming pedunculated, at other times sessile, simply pressing out the sides of the uterus between the folds of the broad ligament or peritoneum, which subsequently forms a serous covering for it. This pedicle may remain thick or become attenuated to such a degree that nothing but the layers of the peritoneum and intervening cellular tissues, blood vessels and nerves intervene.

The tumor continues to grow in the cavity of the pelvis toward which it gravitates, retroverting the uterus if attached to its posterior wall, until finally it reaches such a size that it can not enter the superior strait of the pelvis. When it projects from the top or anterior wall of the uterus, the latter is retroverted as soon as the growth has attained any considerable size.

The growth of these tumors in the pelvis gives rise to distressing rectal irritation, and often to retention of urine; the narrowing of the caliber of the rectum causes constipation and hemorrhage. The irritation and obstruction to the circulation, both from the mechanical presence of the growth and in malposition of the uterus, produce profuse bleeding at the menstrual epoch. Once the tumor has become subperitoneal, it may contract adhesions to the viscera against which it rests.

When the pedicle is long it may become twisted as in ovarian tumors; but if a new blood supply has been established the tumor will not die, even though it may be separated from the uterus. When this variety of tumor drags the uterus upward, or the base of the pedicle is broad and the tumor falls backward, bending the uterus, the cavity is increased in depth. As the pedicle becomes elongated the uterine cavity shortens whether the tumor decreases in size or not; the uterus may be flattened out completely and adherent to the side of the tumor. After it has contracted adhesions to the intestines any rotary motion of the tumor is liable to produce intestinal obstruction, and to demand immediate operative interference to save the life of the patient.

In submucous fibro-myomata the tumor develops in the wall of the uterus just beneath the endometrium, pushing forward into the cavity of the uterus, and as it projects it carries the lining membrane before it. The pedicle of this variety may be very thick, and like the lining membrane of the uterus contains muscular tissue and very small blood vessels. After entering the cavity of the uterus, these tumors become pear-shaped due to the action of the muscular contractions of the uterus. They are usually expelled sooner or later from want of nourishment and the action of the uterine contractions. This is the class of fibroids in which ergot has been used extensively and great success has been accredited to the drug; but in the natural history of this tumor it is often expelled after the use of any remedy. This is the only class in which ergot can be used with any degree of safety.

The intramural or interstitial fibro-myoma develops in the uterine wall and is surrounded on all sides by uterine tissue; it receives a greater blood supply than any other form, and perhaps reaches a larger size, the patient often appearing like one at the full term of pregnancy. These tumors bulging out of the uterus laterally, spread apart the layers of the broad ligament, and the hypertrophied tubes are spread out high upon the tumor. The uterus and the tumor develop in such a way as to entirely alter the relative positions of the uterine appendages. In these cases the cavity of the uterus is deepened or shortened, and often rendered crooked, thus making it exceedingly difficult to find the os uteri in the vagina. These externally large tumors are usually single, and the walls of the uterus may be found either greatly hypertrophied or much atrophied; they occasionally undergo cystic degeneration, grow to an enormous size and constitute the edematous myomata of Tait.

Mr. Tait says that he never saw a nodule having its origin in the true cervix. This statement seems rather queer for one who has had so wide an experience. I have seen a few cases where the fibroid development reached a considerable size and which undoubtedly had its origin in the true cervix. These tumors follow the same laws as to location and development as those in the body of the uterus.

The symptoms produced by these degenerations vary greatly in different subjects; we see patients with large fibroid developments who seem to experience but little inconvenience, while others with comparatively small growths suffer very greatly.

In my experience I have found that the intramural and submucous fibroids are more apt to make invalids and the cases are more likely to terminate fatally, than any of the other growths. While ordinarily these are comparatively harmless growths, yet in many cases very active and energetic treatment is necessary for the relief of symptoms.

Prognosis.—The subperitoneal growth causes the fewest deaths; the interstitial, cervical and submucous are far more serious and the prognosis much more grave; especially is that true of the submucous, for there is likely to be a fatal hemorrhage even from a very small tumor. Yet if there be no cystic degeneration and the patient is not having any serious hemorrhage the prognosis can be hopeful, for after the menopause the tumors, in most if not all cases, grow smaller.

I have a case in mind of interstitial fibroid tumor where the patient was as large as a woman at full

term; two years after the menopause the growth had diminished fully one-half, and is still growing smaller. Another case where the growth reached the size of a fetal head at full term during gestation but entirely disappeared one year after labor.

The rapid disappearance of a uterine fibroid after the menopause occurs so frequently that it must have come under the observation of nearly every medical man.

EROSIONS AND LACERATIONS OF THE CERVIX UTERI.

Read in the Meeting of the Missouri Valley Medical Society held at Council Bluffs, Iowa, Sept. 20, 1894.

BY GEO. H. SIMMONS, M.D.
LINCOLN, NEB.

I hardly think it necessary to offer an apology for a paper on this subject. We hear and read so much of, and the time of our society meetings is monopolized so much with, the wonderful major operations of the day that it may seem cruel to bring you down from the scientific altitude you occupy in discussing laparotomies, hysterectomies, appendisectomies, (that is a new word) and a dozen other ectomies and otomies that can only be indulged in by the select few. But when we consider how very, very few women there are who need their ovaries or wombs removed,—whether they have it done or not; and when we realize how very, very many women there are suffering from pathologic conditions of the cervix, I am sure you will pardon me for taking up your valuable time with what some of you may think an invaluable subject.

"Ulceration of the womb" used to be the fad among women, and it was a fashionable thing to be under treatment with some popular physician for this trouble. It was just as much of a fad for the physician to call every trouble that affected the cervix, ulceration. But while we may have ulcers of the cervix such as chancres, tubercular, simple and corroding ulcers, we now know that the so-called ulceration of the womb is not an ulceration at all, there being no loss of tissue, but a new formation, or rather a pathologic transformation. We now call this condition, for want of a better name, *erosions*. Under the microscope we find that in the place of the normal pavement, epithelium, there has been a substitution of the cylindrical variety. There are small, reddish, semi-transparent and pedunculated masses in the orifice and extending more or less on the lips of the cervix. To the touch they seem soft, patulous and spongy, sometimes more or less granular, and often bleed at the slightest touch. The cause of simple erosions is often hard to trace. Fischel says that many women seemingly have a natural predisposition to erosions. These women have erosions from the slightest inflammation or a cold. Tyler Smith claims that the condition is merely a hernia of the mucosa, an ectropion similar to that of the conjunctiva from inflammation, although he probably here refers to erosions from lacerations. It often originates from a simple catarrhal inflammation of the endometrium, extending through the os and, from irritation, the epithelium proliferates, becomes softened and macerated by the morbid discharge. The inflammation extends deeper and, instead of the normal membrane, there appears an elevation of soft, deep red papillæ which readily bleeds. Another

great cause for these simple erosions is displacement. A badly fitting pessary has often in the past caused acute inflammation of the cervix which finally developed into a semi-chronic granulation. In fact, acknowledging the generally accepted views of the pathology of simple erosions, anything that will cause endometritis or cervicitis may cause that condition. It is, however, a rare condition without being complicated and really caused by laceration. Gallabin, Atthil, Macan, and other European authors, while hardly mentioning laceration as a cause, say that the condition is seldom seen in nullipara, a strong argument, certainly, in favor of the trauma occasioned by labor being the cause. Neither has it been my experience that simple erosion without laceration causes any particular reflex constitutional ailment.

The treatment ordinarily is simple and the results satisfactory. The cause, if possible, must be discovered and removed. Hot douches combined with rest will often alone effect a cure. A mild application of nitrate of silver, Churchill's tincture of iodine or iodized phenol may be necessary.

Coming now to laceration of the cervix, whether accompanied by erosion or not, we can not help but wonder how this condition remained unrecognized as long as it did. For twenty-five years after the invention of the speculum the condition which we now know to be simply a tear was looked upon as an ulceration without any traumatic cause. Grailly Hewitt, of London, writing in 1882¹ says: "Is it not a little remarkable that, largely used as the speculum has been in the investigation and treatment of the diseases of the uterus, cases of severe laceration of the cervix seem to have been overlooked until a very recent period, even by those who were most in the habit of employing the instrument." Probably it was because the profession accepted without question the dogmas of Bennett that displacements were the cause of ulceration, and ulceration the cause of about all the diseases with which women suffer. It was left to Dr. Thomas Addis Emmett to first describe the true character of this lesion and to give us a radical measure of cure. His first paper on the subject, published in 1869, brought it before the profession and while it was slow in being adopted, still twenty years ago it was generally accepted by the leading gynecologists of America, although it was many years before it was hardly discussed in Europe. And it is astonishing with what pertinacity some of the leading gynecologists of Europe are still opposing this operation. Tait, in his last work on diseases of women,² says: "A great flood of operations has gone through the practice of gynecology of recent years for the stitching up of this innocent fissure. The real trouble is the subinvolution and the consequent chronic metritis, and nothing more useless than Emmett's operation has ever been introduced into surgical practice." We believe that what he calls the "real trouble" that is, "subinvolution and the chronic metritis," is the result of the fissure as he calls it. Speaking before this of erosions and chronic granulations, he says: "It is very often a sequelæ of the first, or indeed of any labor or miscarriage." If this be so, is it not evident that it is caused from a laceration? I have not the slightest hesitation in saying that Emmett's discovery and his operation have done

¹ Diseases of Women, page 416.

² Diseases of Women and Abdominal Surgery, page 105.

as much good in relieving suffering among women than have the major operations, even including the so-called Tait's operation. In looking through the *London Lancet* for the last ten years the subject is mentioned scarcely half a dozen times. The only elaborate article is a long editorial review³ of an exhaustive thesis by Noeggerath, of Weisbaden.⁴ After reading the editorial, one is impressed with the belief that the editor, when he laid his pen down at the end must have heaved a sigh of relief and said: "That will end Emmett's operation for all time." Noeggerath sums up his investigation with the following six conclusions, which are heartily indorsed by the reviewer:

"1. Women with laceration are more prone to conceive than those without; they are also less likely to miscarry.

"2. The position of the uterus is not affected by laceration.

"3. The axis of the uterus is not elongated by laceration.

"4. Ulceration and erosion are as common in one class as the other and diseases of the cervical tissue are not more common in lacerated than unlacerated cervixes.

"5. Lacerations have no influence in producing uterine disease either as regards frequency or intensity.

"6. Eversion of the lips is never the result of a laceration. The restoration of the shape of the cervix can have no influence on the uterus."

It is needless to deny these propositions before a body of intelligent men on this side of the water. Stated exactly opposite to what they are, and they would be accepted as axioms by every gynecologist in the United States and by every gynecologist in Europe who has studied the subject conscientiously and without prejudice. During a fifteen months' study in Europe in 1883 and 1884, nearly all of the time in gynecologic work, I never heard the lesion mentioned, and trachelorrhaphy was never spoken of, and even to-day laceration of the cervix is still unrecognized in Europe except in very few instances, as a pathologic condition causing serious local and reflex results, and the operation for its radical cure has never been accepted as a necessary operation except by a few men.

Laceration of the cervix is the most frequent lesion resulting from child-birth although abortion at even the second month may produce it in spite of the fact that the softness and elasticity of the fetus would make it seem decidedly improbable. We need not enter into a discussion as to whether they are caused more often at the first, than at subsequent labors. Munde, and others claim that it is more often at the first, but, Pozzi has many followers who claim the reverse. His explanation is that although at the first confinement the os dilates more slowly it is in a healthy condition and is not so likely to tear as after the parts have lost, to some extent, their power of resistance from inflammatory action, the result of previous labors. The cause is nearly always beyond the control of the accoucheur to prevent, and it is the duty of the gynecologist to protect the obstetrician from any harm as he will have plenty of opportunity to do. The woman is nearly always ready to blame her physician for the trouble. And there is no doubt

that there are times when the physician is to blame. Application of the forceps before the os is dilated, the use of the fingers to dilate, the giving of ergot in the first stages of labor, are all causes of laceration, and thus far the physician is responsible. In the case of slowly dilating os with strong pains we are sometimes able with local measures to assist the relaxation and dilation of the os but further than that we can not go.

The next question is, Is the physician to be held responsible who attends the woman, the cervix being lacerated and he not discovering or notifying her of the lesion, taking it for granted that all lacerations ought to be repaired? I have always believed that "meddlesome midwifery" was bad; I have always believed that the less digital examination was made the less liability there was of septic infection, and I never can believe that the obstetrician is justified in introducing his fingers immediately after parturition when the parts are raw, lacerated, and in such an excellent condition to absorb septic matter. Again, in case of laceration it is sometimes impossible to discover it on account of the tumefied, patulous and generally contused condition. In case there is a laceration, how do we know but it will all heal up, for certainly there are lacerations and more than we probably imagine, that heal and leave no scar. Dr. Cleveland and others have urged that in every case of confinement the cervix ought to be examined and if torn repaired immediately. Dr. C. E. Ruth, of Keokuk, Iowa,⁵ says: "All women should be examined in two weeks after delivery and all lacerations of the cervix repaired before the woman is allowed to be on her feet, especially if the tears be laterally placed." Aside from the reason given above, the tissues are too soft and the sutures are most likely to cut through. But what about examining the patient after she is up and around? Are we to tell every woman what *may* have occurred and what *may* result if such a lesion is present? For our future reputation and the patient's good, I certainly think we ought to tell her what possibly may happen if the tear is left, and what she can have done to prevent its occurrence.

Laceration is often followed by subinvolution, by a chronic inflammatory condition of the neck and body of the uterus, and by hyperplasia of the glands of the mucous membrane. This condition may produce about every ailment that afflicts a woman and these are legion. The cervix is richly supplied by the sympathetic nervous system and anything that affects the cervix is liable to manifest itself in distant reflex symptoms. These may be obscure pains in the back, groin and pelvis, bearing down pains, disordered menstruation, irritability of bladder and rectum, leucorrhœa, a continued feeling of lassitude and weakness and general malaise. The cervix in its healthy condition and covered with its normal membrane is but slightly sensitive, but when it is inflamed or denuded of its membrane it is often excessively tender. In this condition there may be not only distant reflex symptoms but severe local pain and tenderness. After laceration the body of the uterus does not undergo the normal involution but remains or becomes large, heavy and congested and a seat of chronic inflammation. Year by year this heaviness gradually overcomes the natural supports, and falling of the womb is an almost sure

³ *Lancet*, Feb. 4, 1888, page 231.

⁴ *Berl. Klin. Woch.*, 1887, No. 41.

result, if not total procidentia. Metrorrhagia, or menorrhagia is often tracable to the laceration producing anemia with its train of symptoms. Sterility is often caused by laceration, although Hewitt's assertion⁶ that sterility results in 71.34 per cent. where the cervix was so injured is probably exaggerated. Abortions also are a fruitful result of this trouble. Leroty, in a thesis published in Paris in 1878 on "Hypertrophies of the Vaginal Portion of Neck," in which he describes beautifully the condition of laceration but does not recognize it as such or even mention such an occurrence, says: "One is struck by the large number of abortions which it seems to have produced." As long ago as 1856, Dr. A. K. Gardner, of New York, wrote: "Among the married, lacerations of the os and cervix in a first confinement are not unfrequently followed by subsequent barrenness, the accompanying symptoms being those of dysmenorrhea and the severest forms of uterine diseases, profuse leucorrhœa," etc. Noble, of Atlanta,⁷ Ga., says: "There is no trouble so likely to cause premature expulsion of the ovum as a lacerated cervix. In pregnancy the engorgement and eversion is greatly intensified and the lips swell and roll from the turgescence and irritation." I might elaborate on the sequelæ and symptoms resulting from laceration, but the above is sufficient to show that the results are bad enough for us to consider well our duty in the matter. Therefore I believe it is the duty of the accoucheur to examine the woman after he has given nature time enough to repair the damage she has done, and if a laceration of the second or third degree exists, operate. Understand, I am speaking now of our own cases, those we have attended in labor, or where we discover the condition within three or four months after its occurrence. The fact that she has that which may develop into, and cause innumerable afflictions, and which can be removed by a simple operation, makes it the duty of the physician to advise it. But I would not be understood as recommending that we should examine every woman who has borne children to see if she has a laceration, and if we have to operate. By no means. I believe trachelorrhaphy is being done more often where it is not necessary than it is not done where it ought to be.

Dr. Howard A. Kelley⁸ makes the following classification: 1, where the cervix although lacerated remains soft and flaccid, there will be no consequent symptoms; 2, when cicatricial tissue is developed or ectropion is present, marked reflex symptoms will ensue; and 3, when there has been natural repair but with inclusion or formation of hard or scar tissue there will be marked reflex symptoms. He advises operation in the last two classes.

The question "when to operate," in old standing cases, ought not to be hard to answer, and yet it is and has been a cause for considerable discussion. There are no hard and fast lines to draw from, but the general rule to operate only when there is a probability that the laceration is doing harm, is a good one to follow. In laceration of the third degree—that is to the vaginal border or cul-de-sac—we ought to operate if the woman is under 40, for if there is not trouble already the probability is there will be. It has been said that an operation in the

first degree where the laceration is but slight, is never called for. Yet we sometimes find a very slight laceration causing exquisite tenderness and bad reflex symptoms. The tenderness is as great as, and the appearance often simulates, the ordinary rectal fissure. In the stellate form, from the nature of the case, the results are not as deep as they seldom need an operation.

We need not enter into a discussion as to whether cancer of the cervix is caused by laceration or not. While dozens of articles have been written to prove that it is never caused by that lesion, because it is sometimes discovered where laceration does not exist, still the preponderance of evidence is decidedly to the opposite view. At least the assertion of Munde may be accepted as true when he says that a malignant growth is more sure to develop on a lacerated than on a normal cervix. Emmett's⁹ assertion that nearly all, if not all, cases of epithelioma or cauliflower growth have their exciting cause or origin in a laceration of the cervix, is certainly a strong one in the opposite direction. If this were true he ought decidedly to have urged that every laceration should be operated on, whereas he claims, and probably with truth, that not more than half the cases need the operation.

The technique of the operation is simple, yet failure often results from neglecting little things. In the first place the parts must be in such a condition that healing will take place. In certain forms of endometritis, failure is very likely to ensue if this is not eradicated. Where there are granulations on the lips we may expect that they have extended into the endometrium which will result in menorrhagia and irritating catarrh resulting in non-union. In the latter case I always dilate, curette and thoroughly wash out the cavity with a mild bichlorid solution at time of operation. Ordinarily three or four local treatments will put the patient in satisfactory condition, although rest in bed with hot douches for a week or ten days may be necessary. But first cure the catarrh, then remove the cause by curing the laceration. One especial point, to remember, however, is to thoroughly remove the hyperplastic, or so-called cicatricial tissue from the angles of the womb. More failures to effect a cure of the symptoms result from neglecting this than any other thing. It is necessary to thoroughly cut into the angle of the fissure to remove all the adventitious tissue. Neglecting to do this might result in the operation doing more harm than good. If union did not take place it would be lucky for the patient, for in case of healing this tissue would be liable to produce a train of reflex symptoms that would leave her worse off than before. There is little danger of going too high. If the circular artery is cut, a suture rightly placed will check the hemorrhage. Bleeding, aside from this, can be checked with hot water. Care must be taken to prevent too much narrowing of the os externum, preventing free drainage of uterine secretions. Great injury may be done by pulling the uterus down too much. Ordinarily there is not very much pain from the cutting or suturing, but the strained position, the speculum, etc., will often make it necessary to give an anesthetic. I have operated several times without, but I believe it is more satisfactory to both operator and patient that she be anesthetized. Until the last two years I have used silk sutures as prepared

⁶ Diseases of Women, page 117.

⁷ Medical Record, September, 1889.

⁸ Journal of Obstetrics, 1886.

⁹ Gynecology, 1884, page 509.

by Dr. Skene, but recently I have used silver wire and believe I like it better. After the operation pack the vagina loosely with iodoform gauze which is left in for two or three days, giving an injection daily for, say a week, after its removal. The stitches are left in from five to eight days although no harm is done by leaving them longer.

In conclusion, let me say that I have never done an operation for a lacerated cervix where the patient did not rejoice that she had it done, and my experience makes me feel like heartily indorsing Munde when he says: "In my opinion the operation for laceration of the cervix, as introduced by Dr. Emmett, is one of the greatest triumphs of gynecology in the last quarter of a century." At the same time I would not be understood as urging the operation when it is not necessary.

THE INTRA-UTERINE TAMPON.

BY S. W. RANSON, M.D.

DODGE CENTER, MINN.

The gynecologist has for years been fully alive to the valuable therapeutic properties of the intra-uterine tampons; both after operations on the non-puerperal uterus, and for diseased conditions of this organ, so that it is now almost routine practice to employ it to control hemorrhage, promote involution, stimulate healthy granulations, and maintain permanent drainage.

The obstetrician and general practitioner have, however, shown a temerity, amounting almost to reverence for the puerperal uterus that has kept them from the use of this valuable agent in similar conditions to which the gynecologist has applied it.

I shall not now endeavor to show the value of the intra-uterine tampon in the accidental hemorrhages of labor at term, but will confine this short paper to its use in unpreventable abortion.

"Straus and Toledo have found that microbes do not occur either in the parietes or secretions of the normal uterus, and it is only in the vagina where there are accumulations of epithelial masses that the bacteria find a favorable medium upon which to develop. In normal vaginal secretion the vaginal bacillus of Doderlein is regularly found and the thrush fungus and yeast cells, are often met with, while staphylococcus, pyogenus albus, citreus and aureus are no rarities."—(Schenk). Recent bacteriologic investigations to which I am not at this time able to refer, have demonstrated that the normal vaginal bacilli undergo alteration as pregnancy advances. So regular and progressive are these changes that their character can be noted from week to week. They become softened and lose their activity until, at term, they are practically innocuous.

May not this be one explanation why sepsis is much more liable to occur after abortion than after labor at term?

In treating cases of abortion we ought to recognize this fact, that it is only the healthy normal uterus that is free from danger of sepsis. That as soon as there sets up a pathologic condition such as we have in abortion, especially if any of the secundines remain, we have within the uterine cavity a culture medium favorable for the propagation and growth of bacilli, and their migration to and development in this organ are an assured fact unless nature or art interposes to remove the secundines and stimulate

the uterus to normal healthy secretion. If we remember the additional fact that up to the third month there is no placenta. That previous to this time the ovum may pass through a small os, so small as to barely admit a uterine sound, and that the decidua vera must be expelled before the abortion is completed. That even after the formation of the placenta the fetus may pass, and the os close so as to prevent the introduction of a finger or placental forceps. That when the finger can be introduced the placenta may be attached to the fundus out of reach of the finger even though forcible bimanual efforts are made to remove it. Add to this the further fact that in the early months of pregnancy the cervix retains its full length, the os is rigid, the uterus has not undergone that hypertrophic muscular development characteristic of the later months of pregnancy. Hence cleavage and expulsion of the placenta and secundines are necessarily slow and difficult.

Two methods of treatment of unpreventable abortion have been in practice for many years: 1, the expectant plan which consists of ergot, vaginal and intra-uterine douch and vaginal tampon; 2, the active plan which consists in the speedy emptying of the uterus with finger, placental forceps, curette or by expression. The objections to the expectant plan are that it exposes patient to danger of hemorrhage and sepsis, while it involves loss of time to patient and anxiety to patient and physician. The objections to the active treatment mentioned are: 1, to be successfully done requires considerable dilatation of the os, a condition not commonly found in most cases of abortion; 2, an anesthetic will be required if the divulsors have to be used for dilation, or great force in extraction of placenta with fingers, or the curette used; 3, the use of the curette which is the most efficient and certain is unsafe in inexperienced hands, while neither finger nor placental forceps can remove the decidua vera if still adherent.

Four years ago, while attending a case of retained placenta after abortion, it occurred to me that to tampon the uterus with gauze would prevent sepsis and hemorrhage, and promote uterine contractions to expel the placenta.

The introduction of the intra-uterine tampon was followed by vigorous contractions and expulsion of tampon and secundines in about three hours.

Since that time it has been almost routine practice with me to employ the tampon in every case where I could not easily remove secundines with fingers. If the os is dilated so as to admit a finger it is a very easy matter to pack the uterus, but if undilated, or only slightly so it is more difficult. But with speculum to expose the os, tenaculum to steady it and straighten neck with body, a uterine sound and slim pair of dressing forceps and six or eight feet of iodoform gauze one-half to one inch wide, I have found little difficulty in tamponing any uterus, where a pair of dressing forceps could be barely inserted. I have always endeavored to fill the uterine cavity with one continuous piece of gauze, and leave an end hanging from the os. I then place a pledget of gauze against the os and tampon the vagina with absorbent cotton.

Careful preparation must be made, an antiseptic vaginal douch given, and strict asepsis enforced. Having carefully tamponed the uterus under strict antiseptic precautions, the physician may rest assured that his patient is perfectly safe, and can leave her bedside and attend to other duties. If the case

is near, and the physician not pressed for time, he may call again in six to twelve hours, but if otherwise, he may defer his visit for twenty-four hours.

If the case is at the third month or later, and no opiates or other anodynes have been recently given, prompt uterine contractions will take place expelling the tampon and secundines in three to six hours. If the abortion is before the third month, especially if during the first weeks, the uterine contractions will not be so prompt and expulsive, but in a large percentage of cases it will be sufficient to empty the uterus in twenty-four hours. At your first visit after tamponing the uterus, if active pains have come on and subsided for one hour, remove the vaginal tampon. If you can not get a history of expulsive pains let the vaginal tampon remain for twenty-four hours, when it should be removed. If the intra-uterine tampon has not been expelled, re-pack the vagina and leave the intra-uterine tampon in place for one to two days more, when, if not expelled, it may be removed by traction on end of gauze, hanging from uterus. The decidua vera will come with it, being forced into the meshes of gauze. A vaginal douch may now be given, strict asepsis maintained for a week or more, and the case discontinued.

In conclusion, I beg leave to make the following claims for the superiority of the intra-uterine tampon over all other methods of treatment of retained secundines of abortion:

1. Insecurity from danger of sepsis and hemorrhage.
2. Requires but slight dilatation of the os, consequently it is applicable to every case where sepsis does not already exist.
3. Is not painful, hence does not require an anesthetic.
4. Produces no traumatism.
5. The ease and safety of its application by every physician.
6. It favors prompt involution and normal healthy secretions of the uterus.

SOCIETY PROCEEDINGS.

American Public Health Association.

Twenty-second Annual Meeting, held at Montreal, Canada, Sept. 25-28, 1894.

(Continued from page 588.)

WEDNESDAY EVENING.

The evening's session convened shortly after 8 o'clock, President LaChapelle presiding. As the public was especially invited, the Association Hall of the Y. M. C. A. Building contained a large number of ladies, and members and their friends.

DR. FREDERICK MONTIZAMBERT, General Superintendent Canadian Quarantines, delivered a lecture on

QUARANTINE APPLIANCES.

The subject was illustrated by lantern slides as used at Grosse Isle. The subjoined is a brief description of the illustrations:

General view of the quarantine station in the St. Lawrence River, thirty miles below Quebec; a profile view of the island showing detention buildings, hospital, etc.; view of the hospital (100 beds); same building from another view; disinfection room in hospital; ambulance to go to wharf; view of central part of station; view of same building and doctors' quarters; eastern part of central division and disinfection building; same building for first class passengers; steam disinfecting building; front of three boilers of 40-horse power each; one of the chambers open; a chamber

with railroad track standing in it; a telemeter with figures on dial, etc.; one of the dials of the telemeter greatly enlarged; a small detention building for steerage passengers; inside of a shed for use of steerage passengers; a view of a spot of historical interest when, during the famine in Ireland in 1847, Irish immigrants died of typhus fever and were buried there; closer view of same, and monument erected in memory of the medical officers who contracted the disease while administering to those that fled from pestilence and famine in Ireland, who also succumbed to the disease. In all, 5,424 persons found a grave in America at that place during the latter part of May, June, July, August of that year; a view of one of the quarantine disinfecting steamers; a view of one of these steamers alongside of a ship; the other disinfecting steamer, the *Challenger*, which has a ship's cabin only and carries all the appliances to disinfect a steamship; two of the men with jars containing mercuric chlorid solutions, proper steam dredge and pipes, etc.; same view reversed, also to show in the distance where the work of disinfection is done.

The methods of steam sterilization were especially dwelt upon, in addition to which Dr. Montizambert stated: "It may be within the recollection of some of my hearers that last summer remarks were made in some of the papers about a party of Poles who were stated to have evaded quarantine inspection and disinfection at Quebec. Now, it is impossible for immigrants to avoid or evade the quarantine inspection, because no immigrants arrive by the St. Lawrence except in a ship, and no ship from outside Canada can make customs entry at the port of Quebec or Montreal without exhibiting, as the very first paper called for, the certificate of its inspection at and discharge from quarantine. This is under a penalty of the Collector of Customs or customs officer, of \$400 and imprisonment for six months for allowing customs entry of any vessel in the absence of the production of a quarantine clearance in accordance with the requirements of the regulations. And this is not simply an enactment hidden away in the printed regulations, and unknown to those who have not occasion to study them, but it is quoted in full upon the face of every quarantine clearance, so that it is being kept continuously under the notice of the pilots, captains and customs officials. Furthermore, in the case of all passenger vessels, the clearance granted by the quarantine officer is conditional on the landing of immigrants and their luggage at the disinfection sub-stations at Quebec and Levis at the deep-water termini of the railways. The supervising officer of such disinfection has to count the immigrants as they land, and if he finds the number tallies with that marked on the clearance of the quarantine officer (the whole number on board, or those from infected countries as at present), and has satisfactory evidence that all their luggage has been landed with them, he shall punch the clearance at the place marked for that purpose, which shall then alone become valid for customs entry.

"So you see evasion is impossible on account of the safeguards with which the Dominion Government has surrounded the processes of inspection and disinfection. Intentional removal of evidence of disinfection we can not guard against. It was thus with those Poles to whom I referred, who were found at Toronto without their luggage, bearing evidence of disinfection. They had been inspected at quarantine, and their luggage had been sterilized and tagged at Quebec. There was the interval from Tuesday morning at 7, to the Sunday following between their leaving Quebec and their being found at Toronto. During this time they are stated to have undertaken work at Cornwall and from thence to have been taken on by a 'boss' to work in the States. This being so, they would naturally remove all possible traces of recent arrival, so as to evade the alien contract labor law at the frontier. We inspect, we disinfect, we tag, we warn immigrants to preserve the evidences of disinfection, and we provide against accidental loss of these by the use of a stamped seal and almost unbreakable wire attachment; but we can not prevent the intentional removal of the tags, once the luggage has been claimed by its owner and removed. Dr. Montizambert referred to the wish that he, like other sanitarians, entertained, that the word quarantine could be dispensed with. It was founded on an idea which science had outgrown, and its retention caused modern methods to inherit, undeservedly, the objections rightly urged against the old. The key-note of the old system was prolonged detention; that of the modern system was prompt disinfection."

In conclusion, Dr. Montizambert reminded his hearers that there must always be the possibility of exotic disease passing the quarantine barriers in an invisible and unrecog-

nizable stage and condition, and first declaring itself in the interior of the country. This could not be entirely avoided without such routine detention and disinfection of all vessels, passengers, and merchandise at the ports of arrival, and such consequent interference with trade and commerce, as would be quite unjustifiable and impracticable. "Quarantines," he said, "may be held accountable for dealing with actual cases of infectious disease, with infected vessels and effects, and those suspected of being infected, but they must not be expected to do the impossible, nor should they be leaned upon as an excuse for lessened effort inland. Coast quarantines and inland health organizations must form our double line of defense, or, to borrow an illustration from the game of cricket, the coast quarantine is the wicket-keeper and the health board the long-stop. But the well equipped and well worked quarantine can, and should, strain out and protect the country from a very large percentage indeed of the exotic diseases which threaten it from time to time, and so do a great and very valuable work. I think that from what you have heard and seen this evening you will agree with me that the Dominion Government has placed the quarantine service of the St. Lawrence in a condition thoroughly to perform its onerous and important duties, and to be an actual and potent protection to this country. And as the people of Canada and the United States become more generally acquainted with the manner in which work is really done at our ports, and the safeguards the Government has provided to prevent the evasion of quarantine inspection and disinfection, there will be an ever increasing confidence in the quarantine service and leave less and less unnecessary uneasiness and fear for themselves."

The succeeding paper was on

SOME POINTS IN THE HYGIENE OF THE YOUNG IN SCHOOLS,

Illustrated and read by DR. J. CHALMERS CAMERON, Professor of Obstetrics and Diseases of Children, McGill University, Montreal. The paper was a distinct arraignment of school boards for neglecting to provide hygienic appliances. The lecturer pointed out that some thirty years ago it was remarked by Mr. Herbert Spencer that the first requisite of success in life is to be a good animal, and that to be a nation of good animals is the first condition to national prosperity. As the nation is an aggregation of individuals, the history of the nation is in a certain sense the history of its individual merits. Its strength, progress and development depended upon the strength, progress and development of its members; therefore, other things being equal, that nation will be most prosperous which secures the highest development for its members. From the age of 4 or 5 up to 15 or 16, the period of active growth and development, most children are at school, being educated and trained for their life work. If the schools fulfil their important functions well and turn out their scholars good animals, well equipped for the battle of life, the first condition of national prosperity will have been attained; but in whatever degree they fail to secure the best results, in the same degree will they hinder national progress.

It seems, therefore, peculiarly fitting that the American Public Health Association should examine carefully the methods of the public schools and inquire whether the best possible is being done, and whether sufficient attention is being paid to the all-important matter of hygiene. However we may theorize as to the nature of man, we can at least distinguish two essential parts, mind and body; and however we may speculate as to their essence and mode of union, we know at least that all life long they are linked together for weal or for woe—they develop together, mature together, decay together, ever dependent upon each other, reacting upon each other, sympathizing with each other, suffering with each other. When we strengthen the body we invigorate the mind; when we starve and neglect the body, we starve and enfeeble the mind. It follows, therefore, that for the proper development of the individual, the body must be considered and cared for, as well as the mind. According to Nature's plan, body and mind develop simultaneously, not alternately. While bone and muscle, nerve and gland are growing and specializing, the child is busy observing, testing, comparing, gaining a knowledge of his environment and learning to reason and think. So the process goes on, but by-and-by the child is sent to school. Is the same plan of development continued? Do our school boards realize that education should look to the physical as well as the mental needs of their scholars, and that strong bodies are as essential to success in life as well stored minds?

When we look at the curriculum of our schools, we find no lack of studies; perhaps the courses are too extensive, and too much is being attempted. We find that the scholars are carefully graded and arranged in various forms and classes; that their work is thoroughly systematized and that they are taught and examined *secundum artem*. All are cared for, none are overlooked. But in how many schools is adequate attention paid to the physique of the scholars? In how many is their physical condition examined and studied? Before they are promoted to a higher form they must obtain a certain percentage of marks in their examination, and demonstrate their ability to undertake more advanced work. But is there ever a question as to their physical ability for the new work? At the end of the year they are examined to determine their scholastic proficiency. Is there ever a question as to how the body has fared meanwhile? Some schools have playgrounds and give a recess presumably for play, but play is optional—the children may play or not as they please—there is no grading, no direction or supervision. Some schools have a gymnasium, but in how many is there a competent instructor to examine the scholars and grade or supervise their work? What sort of progress would there be in a school if the scholars were allowed to choose whatever studies they pleased, go into whatever classes they pleased, and study or not as they pleased? And in like manner what sort of bodily development can be expected when the arrangements for physical training are so crude and unsatisfactory? In respect to physical culture our educational system is sadly deficient. Childhood is the time to detect and prevent such deformities as spinal curvature and pelvic deformity.

Not only should children be taught in school how to stand, sit and walk, but more important still, they should be taught how to breathe. In the larger cities a valuable addition to the educational staff would be an inspector of physical culture. School desks are responsible for a good deal of deformity. The desks and seats are of uniform height, while the pupils are of various sizes. If too tall the children must stoop; if too short they must reach up somehow. No matter whether the spine is curved or the shoulder raised, the chest is compressed. Could not there be, asked the Doctor, some simple arrangement of raising and lowering the desks and seats like a piano stool? The Doctor considered the bar-bell exercise as most generally applicable to school work. Physical exercise in schools should aim to cultivate the habit of sitting, standing, walking and breathing properly. A child that sits improperly is apt to stand and walk improperly. If the bad habit is not corrected more or less permanent spinal curvature is apt to result.

Much has been done in investigating the causes of disease and preventing the spread of infection. Can we not go a step further and develop in children strong bodies which will resist the inroads of disease? Bacteriology has taught us that many diseases are directly traceable to the action of microbes introduced into the body from without. The seed, the infective microbe, is one factor; the suitable soil, the debilitated body, is the other factor. Dazzled by the brilliant discoveries of bacteriology, have we not overlooked somewhat the necessity of rendering the soil unsuitable for the growth of the seed by developing the existing powers of the human body? If we attack the problem from both sides, its solution will be easier and more satisfactory. We live in an age of restless activity; now, more than ever, is there need for strong physical frames to bear up in the ever increasing struggle of life. Now, more than ever, are men and women breaking down in middle life, their usefulness cut short when they have become most valuable to society and the State. Now, more than ever, is the battle to the strong, and staying power is essential.

The next paper was by MR. JOHN MITCHELL, President of the National Association of Master Plumbers, New York. The author said he would recommend that annual or semi-annual inspection of old buildings be made. A plea was made for the support of the Association in procuring certain legislation desired by the plumbers of the United States. The paper also pointed out the close relation between honest plumbing and sanitation, and closed by suggesting the passing of a resolution urging the members to exert themselves for the enactment of a law that "pure air and pure water shall abound in every home."

DR. ARTHUR R. REYNOLDS, Commissioner of Health, Chicago, said, in accordance with the suggestion of the reader of the paper, he desired to offer the following resolution:

Resolved, That the American Public Health Association, in convention assembled, approve and recommend the enactment of sanitary plumbing and drainage laws in the

future construction of our buildings for the better protection of the health of our people."

Under the rules, this was referred to the Executive Committee without debate.

INFLUENCE OF INEBRIETY ON THE PUBLIC HEALTH

Was read by Dr. T. D. CROTHERS, Superintendent Walnut Lodge Hospital, Hartford, Conn. This was the last paper presented at this session. Among other things he said: The contagion of saloons is like an infection. Inebriates and saloon-keepers were the prominent factors in the recent riots of our country. For 2,000 years this subject has been studied, accepted and denied. A summary of these conclusions is given here: Inebriates in the pauper class should be under legal restraint, as they are dependents and are parasites. They could be organized into self-supporting colonies and producers. They should have medical care and be under military restraint. There are 500,000 of this class in this country. What an army! Their conduct should be studied from a physical standpoint. Moderate drinkers were included with those who were a standing menace to public health. Drunkenness he considered as much a subject for isolation and quarantine as persons afflicted with the cholera or smallpox.

Dr. GHON inquired of the essayist if he intended to classify inebriates and moderate drinkers and occasional drinkers all within one category. If so, he thought that the paper was better suited for a temperance society than for this Association.

Dr. CROTHERS replied that occasional drinkers are periodic and spasmodic drinkers, while moderate drinkers are those who imbibe five or six times daily.

At 10:15 o'clock the Association adjourned.

THIRD DAY—THURSDAY SESSION.

The Association was called to order at 10 o'clock by the President. The first business was the announcement by the Chairman of the Local Committee, Dr. Craik, who, in reminding the meeting of the *conversazione* and reception to be given to the members of the Association at McGill College to-night, said that he wished them to consider this as University day. The grounds and buildings would be open all day for inspection, and it is hoped that all would take advantage of the opportunity to look into the Science Buildings and the Peter Redpath Museum, which in some respects could not be excelled on the continent. Their attention was particularly drawn to the collection of shells in the Museum. The medical buildings, with the modesty characteristic of the profession, were situated in the background. They would also be welcome this afternoon at the Royal Victoria Hospital. The ladies Dr. Craik reminded the gentlemen, were not to be left behind. And if any of the members wished to inspect the new incinerator at the Gregory farm, everything would be explained and made interesting to them through arrangements made by the city engineer. All who intended to go to Grosse Isle would require to send in their names beforehand. The boat would stop at Quebec on the way down, so that those who desire it may stop over till its return.

SECRETARY WATSON read the following telegram, dated Mexico, September 26, in response to the resolution sent by the Association on Tuesday to the Mexican *confreres* who were unable to attend:

"Special circumstances painfully prevented us from meeting you at Montreal. We hope to have the pleasure of shaking hands with you at our next meeting.

"MANUEL CARMONA Y VALLE,

"EDUARDO LICEAGA,

"DOMINGO ORVANANOS."

The next order of business was the report of the Treasurer, Dr. Henry D. Holton, of Brattleboro, Vt., which is as follows:

| | |
|--|-------------|
| Receipts 1893, to Sept. 24, 1894 | \$2,154.37. |
| Cash received from sale of volumes | 74.00. |
| Cash received from annual dues | 1,405.25. |
| Total | \$3,633.62. |
| Disbursements, itemized total | \$2,266.38. |
| Cash on hand Sept. 26, 1894 | \$1,367.24. |

The report was referred to an auditing committee, consisting of Drs. J. N. McCormack, Henry I. Bahnson, and J. Berrien Lindsley.

The Secretary read a report on the subject of "A Journal of the American Public Health Association." He recommended the publication of a quarterly journal or magazine to be issued in January, April, July and October, to supersede the annual volume. A quarterly journal would cost

\$464 less than the annual proceedings, and these figures would secure 100 additional copies for distribution among libraries, etc. A journal of this kind would be more popular in character, and enhance the reputation of the Association, so that it would receive the recognition that it merits, as well as secure for it an increased power in sanitary matters. The suggestion was favorably received, but upon motion, it was referred to the Advisory Council for consideration, which met at 3:30 o'clock that afternoon.

Dr. E. R. CAMPBELL, of Bellows Falls, Vt., drew attention to the last paper read at last evening's session. He moved the following resolution:

"Resolved, That the American Public Health Association in convention assembled records its protest against the use of alcoholic liquor as a beverage, especially among the young, believing that such use is attended with great danger to the health, the individual and society."

The resolution was referred to the Executive Committee. The following resolution, moved by Dr. Henry Sewell, of Denver, Col., was also referred to the Executive Committee:

"Resolved, That a committee consisting of not more than five members be appointed by the President of the American Public Health Association to consider the best form of sanatoria for consumptive invalids, and the most favorable locations for the same within the United States, the report of the committee to be made at the meeting of the Association held in 1895."

Dr. GEORGE HOMAN, of St. Louis, Mo., offered the following resolution:

"WHEREAS, It is the sense of the American Public Health Association that the pollution of potable waters in America has reached such a point that the national governments should be asked to take cognizance of the matter with the view of devising means of prevention and relief; therefore be it

"Resolved, That this Association memorialize the Congress of the United States and ask that they shall authorize the appointment of a competent commission clothed with power to fully investigate the whole subject of the pollution of rivers and lakes by municipal and manufacturing waste, and provided with sufficient means to enable them to conduct the examination in such manner as shall be deemed best, the results of said examination to be published from time to time for the public information."

Which was referred without debate to the Executive Committee, owing to the lateness of the hour of adjournment at last evening's session.

Dr. J. G. ADAMS, of Toronto, presented a paper on "The Condition of the Children's Teeth of the Present Day, and the Effects of Decayed Teeth on the Health of the Children," which was read by title.

Dr. RALPH WALSH, of Washington, D. C., read a paper

ON VACCINE AND VACCINATION,

which was deferred from the Wednesday forenoon session. The reader maintained that there is absolutely no danger in vaccination so long as the virus is pure and the operation properly performed. During epidemics, vaccinations are hastily performed and often there is no after inspection. The lymph used may be very feeble or the operation badly done. The remedies are, honest responsibility resting upon the part of the propagation of vaccine, and the physician who uses it. The writer's conclusions summarized are as follows: So-called cow-pox is modified variola; the admixture of glycerin with vaccine lymph will destroy all "extraneous bacteria" without injury to its peculiar active principles; the admixture of glycerin with vaccine lymph not only destroys the extraneous bacteria but prolongs the activity of the lymph; the selection of the lymph and the simple but important operation of vaccination has not received from the profession the attention it deserves; the physician should see that each infant brought under his care is successfully vaccinated during the first year of its life, and each child again at 16, or better, to the point of saturation during infancy; the accumulation of unvaccinated material and consequently the increased danger of outbreaks of smallpox is caused by the general practitioner neglecting to perform his duty at the proper time.

The paper was briefly discussed by Dr. Roberts, of New York, who explained that the "raspberry mark" was due to a rupture of a capillary or several capillaries, during the operation.

The next paper on "Car Sanitation; the Present Sleeper," by Dr. JAMES PATTERSON, of Winnipeg, Chairman Provincial Board of Health of Manitoba, was on account of the absence of the author read by title.

DR. GRANVILLE P. CONN, of Concord, N. H., presented the report on Car Sanitation. (This report will be printed hereafter.)

In the brief discussion that followed, Dr. Gihon said the problem of car ventilation had been solved several years ago. He held that the railways were criminally negligent in failing to provide their cars with an efficient ventilator, for a suitable one had been tested by this Association at Charleston, S. C., a few years ago when it met there. The trouble was the expense; the railways must be made to overlook that in the cause of public health. The present unsanitary condition of railway cars is simply scandalous. When coming to Montreal he had been in a Wagner car, the air of which was so atrociously foul that he awoke in the morning with an unbearable headache. He would like some attention paid to the cars which with their filthy floors are simply hot-beds of disease, especially when the means of propagating consumption and other communicable diseases are considered. In France, spitting on the floors is prohibited. On this continent, syphilitics and others, are allowed to spit on the floors of street cars at their own will.

DR. H. B. HORLBECK, Health Officer at Charleston, S. C., indorsed very forcibly the remarks of the gentleman who had preceded him. Drs. Montizambert and Lee, also Mr. E. C. Joidan, of Portland, Me., coincided in the main with the views set forth in the chairman's report.

DR. CONN, in closing, said he thought there should be a federal head, such as a Department or Bureau of Health having authority over these matters. He thinks if a copper covered floor is provided in passenger cars and closets it would be the most modern and ideal method in which they could be kept clean.

DR. FELIX FORMENTO, of New Orleans, La., chairman, submitted "The Report of the International Committee on the Prevention of the Spread of Yellow Fever," of which the subjoined is an abstract:

The Committee expressed its regrets that neither Cuba or Brazil are represented at the meeting, also the absence of sanitary engineers on committee. The principal engineers and sanitarians of Cuba, Brazil and Mexico have been invited to give their views on prophylactic measures in their respective countries.

The report considered briefly the natural history, causes and nature of yellow fever, first positively recognized towards end of fifteenth century in San Domingo and Porto Rico, thence invading Mexico and Central American countries. In the seventeenth century it extended along the coast of the Atlantic as far north as Providence and Boston. It was fatal in New York in 1700 and raged a frightful epidemic in Philadelphia in 1793—(4,000 deaths in a population of 40,000 inhabitants). In 1761 it was first introduced in Havana; permanent in that city since. In 1853, from the seaports and localities near the sea, it extended in the interior at great distances, invading many Southern States. Type most malignant; large mortality. Same extension of the disease noted in 1867 and 1878, the latter the last extensive epidemic in the United States; disappeared in the North since early part of this century; occasionally a few imported cases.

In the South, yellow fever has existed almost every year up to 1878. The report gives the number of epidemics throughout the cities in the United States during the past half century. Permanent fever in Vera Cruz, Havana and Brazil; introduced in latter country as late as 1849, has become a secondary fever.

Interesting accounts of different visitations in American cities from 1693 to 1878. In the seacoast country the disease affects all ages and dates, but blacks and young children are less subject to the disease. The report speaks of the so-called immunity of the Creole or natives which really does not exist; they have become immune by a previous, generally mild attack. Children died in large numbers during epidemics (formerly) but their deaths were attributed to malarial, croup and pernicious fevers, etc.

Local favorable conditions for the development of disease; does not belong to the South, not indigenous in any part of the United States. Changing conflicting opinions in regard to quarantine, even in the South, as a preventive measure. No doubt exists any longer as to the possibility of protecting the whole country, of preventing the introduction of yellow fever among us by an efficient system of quarantine, such as exists in Louisiana; fourteen years' experience proves this; since 1878 not a case in New Orleans. Nature of the disease a specific microbe, not yet satisfactorily demonstrated, requiring special conditions of temperature, bad sanitary conditions, etc., for its development. Numerous interesting

examples given of its mode of transmission through infected articles, etc.; explains the so-called immunity of Creole adults and children.

Even in real yellow fever countries (where the disease is indigenous) this immunity does not exist, as is proven by numerous instances given by Dr. Ruiz, of Vera Cruz. The disease has gradually disappeared in the North by improved local sanitation, also in Norfolk, Charleston, Savannah and Memphis. The same results will follow in indigenous yellow fever countries. Extensive engineering works, which will change the local sanitary conditions of these countries may require the assistance of their government. Governmental interference is necessary.

In the meantime, every possible sanitary improvement should be adopted. Cremation recommended; proper disinfection of excretion; paving, drainage, sewerage work, removal of all organic refuse and isolation of the sick, etc. Additional reports should be made to secure the coöperation of the governments of Cuba, Mexico, Brazil, and Central American republics. The report is highly interesting in the vital question of stamping out yellow fever from this continent.

The report was briefly discussed by Dr. Horlbeck and Dr. S. R. Olliphant, of New Orleans, President Louisiana State Board of Health, who offered the following resolution which was referred to the Executive Committee:

"Be it Resolved, That it is the sense of this Association, that federal surveillance, control, or interference with State quarantine service as maintained, is unwarranted and meddling. That the test of the efficiency of a quarantine service should be its past record, and the confidence and approval of neighboring States and other quarantine officers. That the solution of the quarantine problem should be left to the local health authorities to be worked out in accordance with their individual requirements and all progressive steps encouraged so long as such advances are made within the limits of safety. That the formulation of regulations by the U. S. Marine-Hospital Service for control of State quarantine stations without conference with the local quarantine officials is to be deprecated, and can result only in conflict between State and National authorities. That the U. S. Marine-Hospital Service has rendered valuable assistance in the way of collecting and disseminating information bearing on quarantinable disease, and that it can become otherwise useful by rendering assistance when called upon."

FINAL DISPOSAL OF GARBAGE AND REFUSE,

Was the next paper announced, which was read by Dr. N. E. WORDIN, of Bridgeport, Conn., in which he advocated its destruction by incineration. He also recommended the use of domestic incinerators for the destruction of household garbage. In connection with this matter, the following resolution was offered by Dr. M. S. Inglis of Winnipeg:

"Resolved, That a committee of this Association be appointed by the Executive Committee for the purpose of promoting the collection and distribution of sanitary literature and health by-laws on, and regulations to, the members of this Association, to be known as the Committee on Distribution of Health Regulations and Reports. Said Committee to have power to make such financial arrangements with members as will cover the cost of such distribution."

This was followed by the reading of the report of the Committee on the Disposal of Garbage and Refuse, by MR. RUDOLPH HERING, C. E., New York, Chairman. He referred to the manner of the destruction of refuse in Europe, having just returned from there, where he found that incineration is about the only system employed to get rid of garbage. There are great differences in the refuse of Europe and of America, and for that reason systems which are efficient in one place may not be in the other. He had no faith in the schemes for the disinfection of garbage. The plan of separating or reducing the garbage also offers dangers, and, all things considered, incineration seems to be the best of all systems.

The next paper presented was

THE COLLECTION AND DISPOSAL OF THE REFUSE AND GARBAGE OF LARGE CITIES AND THROUGHOUT THE COUNTRY,

By COL. W. F. MORSE, of New York City, in which he remarked that New York had to deal with 6,000 loads of garbage a day, or 1,800,000 a year. The three systems at present in vogue there, are: Disposal by reduction, by cremation, and by dumping at sea; the latter method includes the use of electricity to disinfect the refuse, etc., by throwing off iodine and chlorine of the salt water; within the next six or

eight months New York will be able to announce which method is the most satisfactory.

DISCUSSION.

Dr. S. H. DUROIN of Boston, stated that he was trying to introduce in his city an appliance by which all householders could dry and burn their own refuse. His device was a small cylinder to place in the kitchen furnace flue. The speaker had one in his own house. The kitchen refuse is put in this receptacle and it is placed in position, and kept there for twenty-four hours. By that time the refuse is merely a mass of carbon which burns in the fire with a pure white flame. The next day's refuse is then enclosed in the receptacle, and so on from day to day. The appliance costs about \$4. He called the apparatus a drying "family garbage crematory," and exhibited photographs of same.

Dr. E. S. KELLY, of Minneapolis, said that no garbage in his city is emptied into the Mississippi River; it is removed daily from the city to distance of eighteen miles on railroad cars. So, too, are dead animals removed in a similar way and are taken in separate cars. His city expends \$40,000 a year to carry its refuse to this sandy tract. He mentioned, as an interesting fact, that an analysis of the water of the Mississippi below New Orleans showed it to be almost identical in composition with that of the river close to its source.

Dr. T. H. MCKENZIE, of Connecticut, offered a brief paper bearing upon this subject, which was in the nature of a written discussion containing in the main, analogous suggestions, and indorsing those already known.

The succeeding paper,

INFLUENCE OF CLIMATE OF CANADA ON HEALTH,

Was read by Dr. W. H. HINGSTON, in which the writer touched briefly on the geographical situation and the topography of the country, and then went on to show that, after a residence in the country of shorter or longer duration, a change in the constitution of a person could be observed. The high color which flushed the cheeks of some Europeans faded somewhat, and the skin became less soft, the hair became darker and more like the aboriginal type and the muscles were less prominent. The hot weather did not last long enough to produce any great disturbance of the liver and the cold was exhilarating. The ratio of mortality in Canada was lower than that of Great Britain, and, with the exception of Malta, this country was the healthiest station of the British army. Statistics gathered from the States showed that all constitutions were healthier as they approached the great northern lakes. Canada has no native malady. Most countries could boast of having some malady of their own; Canada had no such boast. If the health of a climate could be gathered from the natural increase of its population, Canada was one of the healthiest of countries, for the increase of its population was something enormous, especially one section of it, the offspring of 60,000 of which had, in a century and a quarter, grown to millions. There was a large death rate among children, the mortality being chiefly due to the fact that they were fed upon too strong food at too early a period. In conclusion, he said that the mortality in Canada was less in winter than in summer, which was different from most countries, and that consumption is arrested during the colder months of the year in Montreal.

The two succeeding papers were read by title, namely, "Mechanical Ventilation," by MR. RICHARD FLEMING, Engineer to the Montreal Sanitary Association; and "Breves Consideraciones sober la Fiebre Amarilla en Vera Cruz (Mexico) y su Profylaxis," por el Dr. GREGORIO MENDIZABAL, Orizaba, Mexico. ("Brief Considerations on Yellow Fever in Vera Cruz, Mexico, and its Profylaxis.")

The Association adjourned at one o'clock.

THURSDAY AFTERNOON.

The Association re-convened at 3 o'clock with the President in the chair, no less than twenty papers being announced on the program, of which the first two were read by title, namely, "Hygiene in Medical Education," by Dr. J. I. DESROCHES, editor of *Journal d'Hygiene Populaire*, Montreal; and "Instruction in Hygiene in Schools and Colleges," by Dr. C. O. PROBST, Columbus, Ohio.

A paper on

THE ADVISABILITY OF TEACHING THE RULES AND PRINCIPLES OF HYGIENE IN THE PRIMARY SCHOOLS BY MEANS OF OBJECT LESSONS,

was read in Spanish by Dr. JESUS E. MONJARAS, Inspector-General of Public Health, etc., St. Louis Potosi, Mexico.

The annexed abstract is a translation from the contribution, a novel feature of which was the suggestion to teach young children a collection of facts which form the bulk of hygiene, by means of toys and magic lantern slides, so as to deprive the pupil of the unavoidable aridity and dryness of books, with the hope that a great deal more is to be attained by dint of perseverance in showing the children toy disinfecting stoves, toy sanitary water closets of different kinds, toy models of drain pipes, etc., thereby forcing them to commit to their memory a large number of words which they can not otherwise possibly understand. A few phrases of explanation from magic lantern slides are easily stored forever in their tender minds. A doll-house properly ventilated, provided with suitable sanitary appliances, in which the ground is shown drained with toy pipes, gives them a perfect idea of how a dwelling house should be built according to the best principles of hygiene; better than twenty pages of hygienic printed matter. Toy manufacturers should be encouraged to devise hygienic contrivances which will be more useful in the instruction of young pupils than the usual methods employed; besides this, their utility will occupy many leisure hours of a child from infancy until they attain 8 to 10 years of age. After they grow older and having learned these object lessons, children should be given a good general knowledge of human anatomy with a view of teaching them how to prevent the human form from deformity; the composition of the air and water with the necessity of maintaining their purity should be demonstrated, and above all, boys and girls should be taught the elements of sanitary architecture. Every good citizen should know how to intelligently do his share in preserving the public health.

The following paper was then read by title: "On Teaching the Principles of Hygiene to the Young," by Dr. GEORGE G. GROFF, of the Pennsylvania State Board of Health. Then a paper on

IMPORTANCE OF TEACHING HYGIENE IN ELEMENTARY SCHOOLS

Was read by Dr. S. GAUTHIER, Medical Officer of Health of Upton, Quebec.

"In the country where I live," he said; "and where I have passed sixteen years of my life, practicing the art of medicine, I must admit that I have encountered great difficulties in putting into execution the rules of the Board of Provincial Hygiene.

"In several places, burying grounds immediately adjoining the church, and even with charnel-houses under the latter, are to be seen. In my village, situated on the border of a river, the ground presents a well-marked declivity towards the shore; the bulk of the population naturally massed around the church, which is situated on an elevation and the river is on the southeast, the cemetery at the back of it, the convent to the north and the college to the west. The natural drain of all these edifices winds its course towards that part of the village where the population is more dense, thus exposing it to the pestilential emanations of the surrounding establishments.

"The infiltration of the cemetery water, which works its course through the cellars of the habitations towards the river, together with the contents of the drains of the buildings mentioned above, is a real source of infection.

"I myself was made the target of public vengeance, when I protested against the erecting of a charnel-house in the cellars of the sacristy. I must add, gentlemen, that this plan was supported by the cure of the parish and approved by an able architect of the city of Montreal; happily, the authorities of the Council of Provincial Hygiene prevented the construction of such an abomination.

"Now, our citizens are to construct an aqueduct. As regards the promoters of the project itself, they undoubtedly deserve to be congratulated; but gentlemen, I feel confident that you will be very much surprised in learning that they omitted to utilize the same excavations for the drains."

The writer closed by stating that the best way to promote this subject is to force its special study in the elementary schools, and oblige the instructors to learn it by making it a part of the curriculum of academic studies.

A paper on

INSPECTION OF SCHOOL CHILDREN WITH REFERENCE TO EYE-SIGHT,

Was then read by Dr. T. D. REED, of Montreal. The writer maintained that it had been found that the conditions of town life generally, and the conditions of school life in towns especially, were distinctly unfavorable to the development and improvement of the faculty of vision. With the yearly

advance of studies in schools and colleges the number of defective eyes increases, from which it is concluded that part of the price of education as at present carried on, is damage to the delicate organs of sight. How necessary therefore that the benefits of the ophthalmic science should be afforded to the young as soon as education begins. The author pleaded for general introduction into schools of the simple tests recommended by the Anthropometric Committee of the British Association for the Advancement of Science. Refraction and eye-strain having been attended to he would urge the possibility of educating the eye in rapidity and accuracy of action. The Indian and other aborigines accustomed to exercise their vision in endeavoring to see distant game, or lurking enemies, acquire a sharpness and quickness of vision much exceeding that of modern city residents. Would it not be well to test systematically the vision of school children, and stimulate the exercise of it as a matter of competition. All the special senses are improved by exercise and many of the physical disabilities incidental to town life have been diminished by the popularity and prevalence of physical education. Prizes for accurate and extensive seeing should take a recognized place among those given at athletic contests and the first steps in such a direction should be taken at school.

The next paper in this series was

A FEW REMARKS ON SCHOOL HYGIENE,

Read by Dr. T. M. BRENNAN, of Montreal. The writer held that should such matters as that of hygiene in schools not be looked into, mankind may in a few generations more be nearly extinct as regards health, and men become merely walking columns of microbes, a conglomerate of all the actually known bacilli and a host of others newly hatched or spored by cross-breeding. What fun they would have with our cells! The only way to avoid such a perambulating microbial stage is to surround the child with all the protection available; make him strong for the combat. The satisfactory teaching of hygiene should be obligatory in all schools. All persons having charge of the rearing of children should have a sound knowledge of hygienic laws. The Doctor described the "entombing of children in convents and colleges, over-crowded and often without any efficient hygienic supervision" as deplorable. He did not wish to insinuate that all scholastic institutions were unhealthy, for certainly they are becoming more inhabitable, and things are better than formerly; but he affirmed that there are great things left for hygiene to do, even in some of the best institutions. He had seen girls contract grievous ailments from which they could have been protected by timely warning and proper care. No false modesty should arise and deprive the ignorant girl of her right to protection. Each punishment, too, should receive serious study from a moral and from a hygienic standpoint. The tobacco and alcoholic habits should be strictly dealt with, and their pernicious consequences brought out. This both in girls' as well as in boys' schools. In women the habit of tipping is far more prevalent and disastrous than is generally imagined. Within the last four months he had seen four women, each the mother of several children, and moving in good society, die from the effects of chronic alcoholism. The lecturer would like to see almost every child who enters school provided with a certificate from the family doctor setting forth the weak points in the child's nature. Nobody knows the constitution of a child better than the family doctor. In each school there should be a school physician endowed with power to act. There should be some system of general hygienic supervision. The support and cooperation of local and general boards of health and of the board of public instruction should be assured.

A paper entitled

AN EPIDEMIC OF ONE HUNDRED AND TWENTY CASES OF PARALYSIS IN CHILDREN

was read by Dr. ANDREW MACPHAIL, of Bishop's College. The paper contained an account of an epidemic of infantile paralysis, which occurred in the State of Vermont during July, August and September, and which Dr. MacPhail investigated. He first stated that the belief was held that it was an outbreak of cerebro-spinal meningitis, but he showed in the clearest possible manner that it was a true myelitis. He quoted the notes of 91 cases out of the 120. In some children the paralysis came on without any symptoms, in others there was a preliminary illness of a few days resembling indigestion. He described in detail the fatal cases, of which there were eighteen, and forty-two in which there was permanent paralysis. There were also notes of six cases in

adults, three of which ended fatally. He then referred to the origin of the malady with full statistics of temperature, rainfall and humidity, and geologic factors. There were besides twelve deaths from the same cause among horses, and fowls were likewise affected. In conclusion he dwelt upon the necessity for having in every State a properly conducted laboratory and a competent staff to deal with such outbreaks, and a board of health with authority to investigate epidemics and perform autopsies. The paper had additional interest from the fact that this is the first epidemic of the kind reported in America and the third which has occurred in any country. Dr. MacPhail refrained from expressing any views or propounding any theories till the pathologic work which he has in hand should be completed.

The following paper was read by title: "What Organization Ought to be Given to Boards of Health?" by ROBERTO GAZOL, C.E., Mexico, Mexico. It was followed by a paper entitled

A PROVISIONAL ARRANGEMENT OF CAUSES OF DEATH,

which was read by Dr. CRESSY L. WILBUR, Registrar of Vital Statistics, Michigan State Board of Health, Lansing, in which he explained the classification that he has adopted in the Michigan Registration Reports for temporary use, until a satisfactory modern classification shall be authoritatively introduced. Dr. Farr's system, the basis of the classification employed in most registration reports, is hopelessly antiquated. Many of its terms are obsolete and some are at present understood in quite other than their original meanings. The plea of uniformity has no weight at present in favor of the retention of Dr. Farr's classification, for scarcely any of the registration reports that employ it agree in the details of its use.

Two of the five great classes of Dr. Farr's original classification are especially objectionable at present, namely, "Constitutional Diseases and Developmental Diseases." The removal of tuberculosis, the type of the former class according to the pathology of fifty years ago, to specific infectious diseases, practically destroys the class. In like manner returns of "old age," "infantile" and "debility" should in most cases be regarded as equivalent to cause of death unspecified, and thus the class of so-called "developmental diseases," largely constituted of these indefinite forms, practically disappears. Such radical changes, rendered necessary by modern knowledge of the causation of disease, quite alter the relations of the old classes, and render a new system imperative.

The provisional arrangement illustrated was intended for use in Michigan in connection with the work of the State Board of Health. Deaths from disease (deaths from violence, unknown causes and still-births being separately taxed) are divided into two lists: 1, dangerous communicable diseases, as defined by the State Board of Health under the State law providing for their restriction; and 2, diseases not so defined at present. The latter list contains certain specific infectious diseases, as pneumonia, that will probably be eventually included in the first list. The object at present is simply to illustrate the work of the State Board of Health in the prevention of those diseases which it has undertaken to restrict. Ultimately a classification of diseases may be made somewhat as follows, only the broadest outlines being suggested:

TOTAL DEATHS FROM ALL CAUSES.

A. Deaths from disease.

1. Specific infectious diseases, including all diseases in which the chief etiologic factor is one or more vegetable or animal microorganisms.
2. Local or organic diseases, consisting of all those diseases dependent chiefly on changes in the anatomic or functional constitution of the body, and not due to a specific infection.

B. Deaths from violence.

The exact form that the new classification shall take is a matter that should be settled by the Registrars—National, State, Provincial and municipal—who will be called upon to employ it in their reports. An Association of Registrars of Vital Statistics was suggested for the purpose of settling this question as well as many other points of practical importance in registration in which greater uniformity is desirable than at present prevails. Such an association would encourage a feeling of the dignity and responsibility of the work, and lead men of special fitness to engage therein. Comparison is essential to the proper interpretation of results in vital statistics, and this demands closer association and cooperation on the part of officers engaged in this work in different localities.

The next topic of interest was the report of the committee on nomenclature of diseases, and forms of statistics, presented by the Chairman DR. SAMUEL W. ABBOTT, Secretary of the State Board of Health of Boston, Mass. The Chairman recommended that nothing be done until the various medical authorities throughout the country could be communicated with, and it was so ordered. This was followed by the reading by title of the subjoined half dozen papers: "Difficulty in the Exact Diagnosis of Pathogenic Bacteria," by DR. GEORGE ADAMI;

"Notes concerning the Nourishment of Children in Their earliest Infancy, exclusive of Nursing at the Breast," by Drs. S. Arthur Simard, and R. Fortier; "Ventilation of Schools," by J. E. Doré, C.E., of Montreal; "The Burial Ground," by Dr. J. A. Beaudry, Quebec; "Prevention of Venereal Diseases," by Dr. Elzéar Pelletier, Secretary Board of Health of the Province of Quebec; "Sanitary Value of Certain Waters," by Dr. R. F. Ruttan, Quebec.

THE ADVANCES OF PUBLIC HEALTH IN THE CITY OF MONTREAL,

Was read by Dr. L. LABERGE, Medical Officer of Health of the city. He described the organization of the Health Department of the city and its history. Twenty-five years ago the Health Department of Montreal consisted of a few inspectors, who visited the yards and lanes and ordered the citizens to execute themselves the necessary cleaning. In respect of sanitary regulations Montreal had been moving backward since the days of its foundation. Under the French rules the representatives of the king prescribed to the people certain sanitary laws and ordinances which were quite sufficient to meet the requirements of such a small village as Montreal then was. The streets and yards had to be cleaned at stated periods, butchers were directed to deposit the offal of their stalls only in certain places, etc. By the English conquest, the officers whose duty it was to enforce these ordinances were removed, not to be replaced until many years afterwards by a municipal government. The justices of the peace, whose duty it was to maintain law and order under the early English régime, felt that they had fully accomplished their task when they had punished the more brutal forms of crime.

With such a system Montreal fell an easy prey to every form of disease. The death rate varied from 35 to 43 per 1,000 annually, and the city was indisputably the most unhealthy in the whole of North America.

The first attempt to remedy this terrible condition of affairs was made in 1874, when Dr. Hingston was elected Mayor of Montreal as the representative of the medical profession.

One of the first works undertaken to improve the hygienic condition of the city was the construction of the great sewer along Craig Street. In the early part of this century Craig Street was still occupied by a stream, which was the natural drain of the eastern and northwestern portions of the city. One of the branches of the stream started near the western extremity of St. Catherine Street and ran along the ravine now occupied by Ontario Street down to Parthenais Street, where it joined the streams coming from the north and east, then turning west crossed Papineau road at Dorchester Street, and flowed into the Craig Street valley. The united streams then flowed west to Chabillez Square, where they fell into the stream flowing east from St. Henry, and turning south passed through the hay market and finally fell into the St. Lawrence near Custom House Square.

This Craig Street stream having become a public nuisance it was inclosed, about 1842, in a brick sewer seven feet in diameter, which started from St. Lawrence Street and flowed west to McGill Street and down to the river. The eastern part of the city was drained by a sewer constructed along Lacroix Street in 1845, and another along Colborne Street. The object of constructing a new tunnel along Craig Street, flowing east from Victoria Square, was to prevent the pollution of the water opposite the city and to provide for the future. The work was a difficult one and it occasioned much discussion. It was finally completed on May 13, 1878. It has a diameter of eight feet and a length of 8,765 feet and cost \$259,010.81.

The main sewers of the city are now considered adequate, but Mr. J. E. Doré, the City Sanitary Engineer, as well as other experts, complain of the large number of "dead ends" in the system of small sewers, the effect of these being to stop the circulation of air and to cause the gases to come up in the houses. Mr. Doré also, in this connection, complains of the want of ventilation in many houses, and says that this is due to the fact that Montreal has no by-law on plumbing. Such a by-law has been prepared by the Health Com-

mittee, and it now awaits consideration from the Council.

The beginning of the scavenger system also dates back to 1877. The work was then done by the Road Department, and was done on a very modest scale, the appropriation for that purpose being only \$7,000. As a consequence of improved methods the death rate has fallen from 37 per 1000 in 1872 to 24 per 1000 in 1892.

Mr. J. E. Doré presented a report on the ventilation of schools. Mr. Doré is a champion of mechanical ventilation. He concludes thus: Natural ventilation through the windows can be employed under certain climates; but here where the difference between the temperature of the rooms and that of the outside is enormous we do not believe that it is practicable. Under such conditions, the fresh air can only be heated by mixing with the vitiated atmosphere. And we have already said that it is highly important to avoid the mixture in so far as possible. The many arrangements devised such as perforated panes, English double windows the one open at the top and the other at the bottom, openings provided with screw wheels do not change the situation. If by any means the mixture of the two airs is prevented, the result is that the fresh air arrives cold. There remains then only ventilation through chimneys and through mechanical devices. We believe that the most satisfactory solution can be reached by combining these two systems.

Mechanical ventilation in cities is not now as difficult to obtain as it was years ago. The motive power necessary to run the ventilator can be electricity, which is so conveniently and cheaply distributed. The plant costs next to nothing and the running expenses are very low. As to the advantages of the system they are so well known that we need not dwell on them.

We conclude that the mode of ventilation in buildings devoted to educational purposes, is a mechanical system which shall cause a current of from 400 to 500 cubic feet per pupil to circulate from bottom to the top, the fresh air having been heated before its introduction to about 5 degrees below the temperature to be maintained in the room. The heating apparatus placed in the rooms to compensate the loss of heat through the walls should also be planned on this basis.

The remaining papers of the session were read by French colleagues; "La Myopie dans ses rapports avec l'Hygiène Scholaire," by DR. A. A. FOUCHER, of Laval University, in which he showed that the disease was more prevalent in the secondary than in the primary schools, and suggested that greater attention be paid to the matter of lighting schools and the clearer printing of school books.

"Durée physiologique du travail au point de vue Intellectuel et Physique," was read by DR. L. L. FORTIER. The only participant in the discussion was Dr. Hopkins, of New York, who while willing to acknowledge the great importance of this question of hygiene in schools, drew attention to the difficulties of teaching hygiene. Some knowledge of the physiology of sex is essential, but how is it to be taught? "How," he asked, "are you going to give the growing girl of from 14 to 16 a complete knowledge of herself and still leave her her modesty? How are we going to crowd the amount of work necessary, to do all the study considered necessary now, in the short school hours demanded by fashion nowadays and still feel confident that she at the end of the school session, will be physiologically and anatomically what she should be? How, too, are we going to remove that handicap from which the grown up woman suffers from the time she puts on the long skirt which makes prisoners of her most important limbs until she goes under the care of the specialist? How are we to give her the advantage which her brother possesses of indulging in healthy recreation?"

The speaker furthermore said in the course of a long practice among children he had never found myopia caused by study either in school or out. The reading of cheap novels he believed to be more responsible for the existence of the trouble than study.

The Association adjourned at 6:30 P.M.

(To be continued.)

Registration of Bakeries.—The London County Council has determined that the interests of the public require a regular and strict supervision of bake-houses. To this end, it has been ordered that a new system of permits or licenses shall go into effect, and that there shall be a periodical inspection by the inspectors appointed for that purpose.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, OCTOBER 20, 1894.

THE ARMY MEDICAL DEPARTMENTS OF THE
EASTERN BELLIGERENTS.

Many members of the ASSOCIATION having expressed a desire to know something of the provisions made by the belligerents in the far East for the care of the sick and wounded of their armies and fleets, we have instituted inquiries at the Departments and Legations in Washington, D. C., to obtain authentic information on the subject. Details concerning medico-military matters in China are so meager that we must infer a corresponding imperfection in the provisions. A former Secretary of the U. S. Legation in Peking stated that there was no organization for the care of the wounded, and that the only medical officers in the service of China were a few Europeans who held special positions. There is no centralization in China. The armies of the various provinces are organized, armed and equipped at the will of their respective governors. According to information from the Chinese Legation, the armies of the provinces differ from each other in their medical service only in that some have none whatever while others have "a few doctors—foreigners, and some hospitals—small ones." As a rule the wounded of a victorious Chinese army lie on the field until succored by friends or comrades, or by camp followers or the non-combatants of the vicinity impressed into service for the emergency. In fact, battle-field conditions similar to those existing in Europe during the wars of the Middle Ages flourish at the present day in the "Flowery Land."

LI HUNG CHANG, Grand Secretary of State and Viceroy of the Province of Chi-li, whose official residence is at Tient-sin, and who is represented in official letters to our Government as the leading states-

man and patron of progress and enlightenment in China, formed in 1889 the decision to establish a medical service for the Chinese Army and Navy on the basis of the best Western models. The plan included a Medical Department to combine both services, military and naval, at the head of which was to be a foreign surgeon-general with an adequate staff of assistants, hospitals and dispensaries at various places, a medical school and native surgeons for the fleet and military stations of North China. The Secretary obtained from our Government a complete collection of the various official publications, for several years back, of the Medical Department of our Army and Navy. In April, 1891, he expressed his great pleasure in acknowledging this courtesy from our Government and his anticipations of benefit to the newly formed Imperial Medical Department from the timely gift. The army of North China is probably the only one which has attached to it the few small hospitals and foreign medical staff mentioned by the attaché of the Chinese Legation.

It is otherwise with Japan. Its progressive government, since its establishment in 1868 on the overthrow of the power of the Tai-kun by the Mikado and the daimios or provincial princes, has built up a modern empire on the insular barbarism of ages. Every military, naval and medical school of any prominence in every country of Europe and America has been visited by young Japanese students whose aim has been to gather knowledge for the benefit of their native country, and who are now leading her armies, commanding her war vessels and, like KITASATO, studying in the advance line of modern medicine. In 1872 a French military commission was imported to organize the Army of the Mikado on a European footing. The work was accomplished in eight years. Naturally the Japanese army bears manifest traces of its French origin in its uniforms, organization, drill regulations and in the grades of its military hierarchy. The infantry regiments have each a regimental surgeon, with an assistant surgeon for each of its battalions. But there is also a strong general medical staff, its *personnel* filling all grades from the surgeon-general who has the rank and pay of a major general, to the first and second class of infirmary privates who have no more pay and allowances than soldiers of the line. The Japanese medical service was as complete at the outbreak of the war as it could be made in time of peace. It included ambulance corps and field hospitals for the immediate treatment of the injured and transportation to general hospitals removed from the seat of war. The Japanese branch of the Red Cross Society has increased its membership greatly since hostilities were begun. No foreigner holds a commission in the Japanese army or navy. Candidates for positions on the medical staff must be natives of Japan.

After passing a competitive examination the candidates have to undergo two courses of study at the governmental medical school for which \$5,000 is appropriated annually in addition to the salaries of its five professors and three assistant professors. Communications are received daily at the legation in Washington, D. C., from young medical men anxious to volunteer for service in the war. The Japanese Minister appreciates the friendly sentiments of those seeking service, but explains that even Japanese doctors who desire to serve can be accepted only after examination and the regular courses of the Army School. The government is not under the necessity of employing any persons in addition to those who have been trained specially in the duties of military medical officers.

The Japanese troops are armed with the Murata rifle, invented in 1887, and named after its Japanese inventor. Its caliber is .315 inch and it carries eight rounds in its magazine. The bullet is of copper covering a core of hard lead. It weighs 238 grains and is fired with a charge of 36 grains of Wettern smokeless powder. It is probable that from the Army Medical Department of Japan we shall have our first reports on war wounds from small caliber projectiles as observed if not among their own men, at least in the cases of wounded Chinese prisoners.

WHY ARSENIC ONLY?

An apparently authentic statement has recently been made that the use of arsenic by women, to improve the complexion and personal appearance, has become so common throughout the country as to lead to an official investigation of the subject by Dr. CYRUS EDSON, Health Commissioner of the city of New York, and others. These gentlemen have been "filled with alarm" by the disclosures of their investigation, and "are moving to have heroic measures adopted to put an end to the pernicious use of the drug." It is further stated that, as a result of their efforts "the health authorities of thirty of the largest cities and of nine States have combined to crush out the growing evil;" that a bill has been drafted, to be introduced in State Legislatures, designed to impose restrictions, under heavy penalties, upon the sale of the drug, except on a physician's prescription; and that the investigation was undertaken none too soon, and no measures too severe can be adopted to stamp out a habit in which "has been discovered the secret of many a mysterious death and of many an untimely-filled grave."

This is a commendable and most befitting undertaking on the part of these gentlemen. But why "arsenic" only? The same publication which furnishes the foregoing momentous information also contained a short time previous an account of the murder of a rural visitor to one of these "largest cities" under the follow-

ing circumstances: He had dropped into a beer garden, where some women of the town, frequenters of the place, induced him to "treat" them to "refreshments," in paying for which he exposed a roll of currency; two of the women immediately left the place, went to a neighboring drug-store and returned in a few minutes with three powders of morphin; one of these powders was administered to the man in his next glass of beer, but not succumbing at once another powder was given him within thirty minutes, whereupon he became insensible and died in the ambulance *en route* to the hospital; the women were arrested and the two who purchased the morphin were tried, convicted of manslaughter and sentenced to the penitentiary—one for six, the other for eight years. And the druggist? He had violated no law and was guilty of no crime, either of omission or of commission, of which the courts of his locality take cognizance, and is still free to sell any lethal agent in his stock to any person in his discretion, without record or inquiry as to the identity or residence of the purchaser, credible assurance of its intended use or any other safeguard or restriction whatsoever, save that the article must be labeled "poison" and the person must *say* that he or she is more than 15 years of age and that the "poison is to be used for a legitimate purpose." But this same druggist may not, under severe penalties, sell an ounce of alcohol, whisky, wine or other fluid which may be used for intoxicating purposes—except on a physician's prescription—without being licensed so to do by the United States Government and by the municipality; nor without making, and keeping open for inspection at all times, a record of the name of the purchaser, his or her address, date of purchase, article purchased, quantity, name of salesman and intended use or purpose; nor shall he sell such article at all except for medicinal, mechanical, scientific or sacramental uses.

The condition is not peculiar to the city referred to, but is common, with few exceptions to cities, large and small, throughout the country generally. National supervision and State or municipal control interfere to prevent the druggist being an agent for the promotion of the "drink habit," but leave him practically unrestricted as the most efficient promoter of the morphin habit, the cocain habit, of chloral tipping, of opium smoking, of suicide and of murder.

Why single out the "arsenic habit" for official investigation by the heads of National and civic health services, and restrictive legislation? The whole business of the sale of poisons by druggists needs investigation and legislation, and none would welcome such action more cordially than the large majority of the druggists themselves. Such legislation should not only prohibit the sale or dispensing of any lethal or toxic agent except on a physician's pre-

scription, but should apply also to the refilling of such prescriptions without express authorization and to proprietary preparations containing such agents.

Here is a field in which the health authorities, not only of thirty cities and nine States, but of every city and of every State in the Union may find work; and there is no member of the AMERICAN MEDICAL ASSOCIATION who will not lend his assistance and bid them God speed!

THE TREASURER'S NOTICE.

Under the heading of "Association Notes" we again print the notice issued by our ASSOCIATION Treasurer who very properly gives the reasons why members in arrears should lose no time in promptly remitting the amount of their annual subscriptions due last June. Every sentiment of professional pride and ASSOCIATION fellowship should enlist our members in the good work of supporting the Trustees in their efforts to give the members and the medical profession of America one of the best medical journals in the country.

It should be a source of pride to the ASSOCIATION that its JOURNAL office is now prepared to do all the work required of it, but it must be remembered that heavy drafts on the ASSOCIATION treasury were made in order to accomplish it. The presses are paid for, and the new equipment has not a penny of indebtedness resting upon it, but it will require money to maintain the mechanical department, purchase news and keep up the standard. There will be no lack of funds if our members who were not in attendance at the last meeting will kindly respond to our worthy Treasurer's call without further delay.

CORRESPONDENCE.

Cataract Extraction an Office Operation.

Reply to Dr. T. E. Murrell by Dr. Charles W. Kollock, Charleston, S. C.

To the Editor:—In my communication to the JOURNAL some weeks ago, it did not seem necessary to enumerate and specify the reasons why extraction of cataract should not be performed in our offices or dispensaries, and the patient allowed to walk or ride some distance to his home immediately afterward. I thought that good reasons against such a proceeding would come quickly into any man's mind, but Dr. Murrell wishes them given and I shall therefore give them as they appear to me, and I think to many more who are and are not engaged in ophthalmic practice:

1. Most persons are more or less excited after an operation has been performed upon themselves, and as quiet is the best treatment for all forms of excitement it should always be advised, especially where so much depends upon the result.

2. No operator can know when he will meet with a case of fluid vitreous, and I feel sure that even Dr. Murrell will not contend that it is just as safe for such cases to walk or ride to their homes after an operation as to remain quietly in bed.

3. Many cataracts have been successfully extracted and after the operations have been entirely finished the eyes

have been lost from hemorrhage caused by the rupture of a retinal vessel. An atheromatous vessel may break at any moment, and certainly such an accident is more likely to occur when the heart's action is quickened by the exercise of walking rather than when the patient remains quiet.

4. A patient upon whom the operation has been performed does not usually see well out of the fellow eye and, though he may be assisted with the utmost care, is not as safe in walking or riding to his home through crowded streets as he would be in remaining perfectly quiet. The mere fact of having had an operation performed, upon the success or non-success of which useful vision or blindness depended would tend to make one nervous and therefore more liable to accidents. Again, the class of patients who are subjected to this experiment are, I take it, not among the well-to-do or wealthy, and more frequently walk than ride to their homes which are probably in the less fashionable quarters where uneven pavements are found and shaky steps must be climbed, and I am sure this can not be called a safe and harmless proceeding.

5. Much depends upon the success of this operation, for nothing can cause the feeling of desolation and misery that blindness brings. We have been enabled to restore useful vision in the majority of those cases by performing a "neat operation," but it really seems foolhardy after having performed the operation without a mishap, to subject the patient to the many risks which even those with good vision must run in a crowded city. It seems that any one of the above reasons is sufficient for not performing the operation in our offices and dispensaries, because they all show risks and why should we take chances in such momentous cases when they are entirely unnecessary? The operation is not one of emergency and can wait until the busy surgeon finds an off day or hour for its performance.

Dr. Murrell says, "every operation on the eye is attended by some risk, and we can not always foresee where the point of danger lies, but we usually see it afterward." He could not have made a truer statement, but it is poor comfort to a man who loses his eye by some accident happening on his way home after the operation, and if the Doctor lives long enough and continues his present practice he will have bitter proof of his words.

As I have said before, we have no right to subject our patients, be they ever so poor and humble, to any risks we would not take ourselves, and just here I may say that Dr. Murrell has seen fit to ignore my questions as to whether he would perform the operation in his office upon a patient from whom he expected to receive a good fee, and whether he would permit himself to be operated upon under similar circumstances. This is where the shoe pinches. Are we doing conscientious and honest work when we take these risks with the poor and do not with the rich and well-to-do? I shall not comply with Dr. Murrell's request to make a test of his method, for such a test would only prove how long it might be continued before losing an eye from unnecessary risk, and I am not at all interested in such statistics or experiments.

Finally, it appears that Dr. Murrell thinks I have made an ungenerous and unwarranted attack upon him. I can only say, that when he published his views he gave them to the public, and as such they are open to criticism. No personal motives have actuated my criticisms, and having expressed my opinion upon what I considered dangerous doctrines, I shall have nothing more to say.

Colleges In "Good Standing."

SHOSHONE, IDAHO, Oct. 12, 1894.

To the Editor:—Will you be kind enough to write me what

organization or body governs the medical colleges in "good standing" of the United States, and how the State is to know the legal difference between a diploma from a college in "good standing" from one "not recognized" or fraudulent?

W. H. BAUGH, M.D.

Answer.—Each State has its own laws on the subject. For a summary of them see this JOURNAL, March 10, 1894.

Woman's Medical College of Philadelphia.

PHILADELPHIA, PA., Oct. 11, 1894.

To the Editor:—In your issue of Oct. 6, 1894, I see that you have given the Woman's Medical College of Pennsylvania an extended notice, for which we are greatly obliged, but I beg to call your attention to a very serious error, viz., you have placed our reading room fee for each of the four years at \$50 instead of 50 cents, making a total of \$200 instead of \$2 for the course. May I ask you to correct this error and oblige,

Yours very respectfully, CLARA MARSHALL, Dean.

It was the derelict decimals.

PUBLIC HEALTH.

Imported Smallpox.—A case of smallpox was detected among the steerage passengers of the steamer *Kron Prinz Friedrich Wilhelm* arrived at New York on the 15th inst., from Naples. The vessel was disinfected and released after forty-eight hours detention, but the steerage passengers, 499 in number, were vaccinated and transferred to Hoffman's Island where they will be held under observation for two weeks.

Public Health Legislation.—At its recent meeting the Michigan State Board of Health resolved to ask the next Legislature of that State to enact laws prohibiting any person from teaching school or acting as a professional nurse without a certificate from a reputable physician that he or she is free from any communicable form of tuberculosis; and also prohibiting the sale of milk from cows that have not been examined by the tuberculin test and found free from the disease.

Statistics of Contagious Diseases.—The Council of Hygiene of Paris has decided (*Bulletin Médicale de Paris*) to issue a weekly bulletin of all contagious diseases reported in that city. Those interested in the sanitary condition of the French capital will thus have official information. In the *Bulletin* the term, "cholera," will be given under two titles, so as to avoid the confusion and uncertainty heretofore caused by failure to discriminate between genuine cholera and the choleric form diseases which are often reported as "cholera."

Vaccination with Animal Lymph.—Dr. Bordesen, in a paper read before the Copenhagen Medical Society (*Trans. Med. Soc., Copenhagen*), states that at the Royal Establishment for Vaccination among 1,221 children vaccinated with bovine lymph 99.84 per cent. of the inoculations gave a positive result and in 95.9 per cent. pustules were produced. In 1893 out of 24,335 vaccinations 95.8 per cent. were successful. He attributes these results to care in the production and handling of the lymph.

Memphis Sanitation.—The Tennessee State Board of Health *Bulletin* notes with approval that the city of Memphis seems to take the lead in that part of the world in a very important feature of public sanitation, to-wit: The summary destruction of buildings unfit for human occupancy. In the daily papers of that city are to be found, from time to time, lists of houses condemned by the City Board of Health and recommended to the City Council for demolition—which the

Bulletin says "usually follows." From being the unhealthiest city in the Mississippi Valley Memphis has become, within a dozen years or so, one of the most healthful; but it has only been by vigorous and persistent sanitary effort pushed, in the face of the most serious difficulties, by her medical profession and public-spirited citizens.

The Chaotic Confusion of the International Congress of Hygiene.—The special correspondent of the *Times* (London), September 14, last, attributes the chaotic confusion which characterized the ending of the Congress to three principal causes: 1, the overwhelming development of what may be called the picnic element. Social entertainments and amusements are a recognized part of these gatherings, and serve a useful purpose, when confined within proper limits, by bringing the members together in a friendly way; but when carried too far they distract attention from the business proper and make it impossible to carry out the proceedings in an efficient and orderly manner. A hundred distractions were organized to run simultaneously with the supposed business of the Congress, and the business went to the wall. Overwhelmed and wearied by the laborious pleasures to which the members were hurried, one after another, even those who took a real interest in the proceedings, ceased to follow them. 2, the abuse of the system of passing sectional resolutions. An enormous mass of resolutions were brought before the general conference, many of them hopelessly impracticable, some positively ridiculous, and others very ill advised. A compulsory eight-hour day for labor for instance, and free medical treatment for the poor at home as well as in hospital. If any respect is to attach to the conclusions of the Congress, as has been the case in some notable instances in the past, they must be few and practical, and passed with all the weight derived from a full sitting. 3, the enormous number of papers contributed. The agenda paper contained the titles of between eight hundred and nine hundred papers distributed over twenty-six sections, nineteen of which were devoted to hygiene and the rest to demography. In some sections many of the papers were not reached at all, and even so, there was no time for discussion. The reports of the various national committees were largely responsible for this state of things. These reports are one of the most valuable features of the Congress, but they are often exceedingly long, and before they have been got through every one is tired and all the time is gone. In the exceedingly important sitting devoted to diphtheria, for instance, the reading of the German, American and English reports fairly exhausted the patience of the crowded audience, keenly interested as it was in the subject. Surely it would be better to have abstracts of all the reports distributed and to take the papers themselves as read, passing on at once to discussion.

Prophylaxis and Cure of the Bacterial Diseases.—None but the most favorable reports of the new prophylactic and curative treatment of diphtheria continue to be recorded in our British and Continental exchanges. It has been adopted in the two hospitals for children in Berlin, and the municipal authorities of Dresden, Nordhausen, Christiana and several other cities have taken steps to supply their hospitals with the diphtheria antitoxin and to give free treatment to all diphtheritic patients. The Pasteur Institute in Paris, having expressed its regret at being unable to furnish the serum to every physician in France on account of its cost, *Figaro* opened a popular subscription for the purpose, which has since been followed by the insertion of a credit of 100,000 francs in the budget of the Chamber of Deputies, to be used, according to a dispatch of the 15th inst., in a test of the serum as a prophylactic. The British Institute of Preventive Medicine has also begun the production of the antitoxin on a large scale. Its production and use in this country, however, are still delayed, presumably, as heretofore intimated, on account of financial considerations. It is estimated that a plant for the production of the antitoxin would cost \$30,000—at least that is the sum appropriated for the purpose by the New York City Health Department.

While this application of Behring's and Kitasato's theory of the treatment of bacterial diseases by the serum of immune animals is thus pronounced a brilliant success, on the other hand, Dr. Viquerat's claims of similar success in the treatment of tuberculosis by asses' serum are being subjected to skeptical criticism. These claims rest, thus far, on the results of the treatment of twenty-five cases all told, and an analysis of the cases shows ten of them to be surgical disease alleged to be tuberculosis, but of which no proof is given; while in a number of the remaining fifteen cases grave doubts are expressed as to the accuracy of the diagnosis. Koch's unfortunate experience on similar lines is recalled in connection with a previous announcement by Viquerat himself, of a therapeutic discovery which proved to be a *fiasco*. It may be that Viquerat's work is not yet fully or correctly reported; those interested in the protection of the public health can not but hope for his success; and it remains that in such work lies the promise and the potency not only of curative but of preventive medicine in dealing with the so-called zymotic diseases. For this, among other reasons, it is gratifying to learn that the reported failure of the Haffkine anti-cholera inoculations at Lucknow has been greatly exaggerated. Dr. W. J. Simpson, Medical Officer of Health for Calcutta, recently submitted to the municipality a further memorandum detailing his experience during the previous three months in that city and the observations made on the recent epidemics in Cawnpore and Dinapore. These afford strong additional evidence of the protective value of Professor Haffkine's inoculations, and Dr. Simpson shows that the Lucknow failures "only teach the necessity of using virus of a higher protective power and of having a special laboratory for its preparation," which was wanting at Lucknow.

ASSOCIATION NOTES.

Treasurer's Notice.—Members of the ASSOCIATION knowing themselves to be in arrears will please send the amount of their annual subscription to the Treasurer, HENRY P. NEWMAN, M.D., Venetian Building, Chicago, without delay.

The great expense on account of the establishment of the new JOURNAL office, makes it more than ever necessary that our members should be prompt in their response to this notice.

SOCIETY NEWS.

Northwestern Wisconsin Medical Association.—The Northwestern Wisconsin Medical Association held its quarterly meeting October 9.

Ohio County Medical Society.—The Ohio County Medical Society of W. Virginia held a meeting in Wheeling, October 4, and the following officers were elected: President, Dr. H. B. Baguley; Vice-President, Dr. Harriet Jones; Secretary, Dr. Walden; Treasurer, Dr. E. A. Hildreth; Board of Censors, Drs. R. J. Reed, R. McC. Baird and Charles Frissell.

Clark County (Ky.) Medical Association held a most interesting meeting at Charlestown October 10. About twenty physicians were present. The morning session was taken up in a discussion of two interesting cases reported by Dr. F. M. Carr, and a case of cerebral tumor reported by Dr. I. N. Ruddle. The banquet was served at the Reeves House. The after-dinner speeches were witty and wise. In the afternoon Dr. Ruddle read a paper on "The Uses and Abuses of Ergot," and Dr. Cad Jones a paper on typhoid fever. The Association adjourned to meet in Jeffersonville the second Tuesday in April, 1895.

Eastern Kansas Medical Society held its fall meeting in Kansas City, October 9. There were sixty in attendance. The following papers were read: "Fractures of the Base of the Radius," Dr. George M. Gray, Kansas City, Kan.; "A Muscular Spasm," Dr. W. S. Lindsay, Topeka; "Ophthalmia Neonatorum," Dr. J. W. May, Kansas City, Kan.; "The Place of Education in the Treatment of Diseases of Women," Dr. Frances Storrs, Topeka; "Report of a Case," Dr. A. P. Tenney, Kansas

City, Kan. The next meeting will be held in Topeka in January. The officers of the Society are: Dr. R. E. McVey of Topeka, President; Dr. George M. Gray of Kansas City, Kan., Vice-President; Dr. R. S. Magee of Topeka, Secretary, and Dr. Ida C. Barnes of Topeka, Treasurer.

West Virginia State Association.—The West Virginia State Association of Railway Surgeons held its second annual meeting in Grafton, October 5. Dr. R. W. Hall, of Moundsville, was re-elected President for the ensuing year; Dr. A. H. Thayer, of Grafton, was elected Vice-President; Dr. J. F. Reger of Littleton, Secretary; Dr. W. F. Vankirk, of Grafton, Treasurer, and Dr. W. M. Sivey, of Tunnelton, member of the Executive Committee for three years. The Committee on Transportation consists of Drs. A. H. Thayer, chairman; R. W. Hall and J. F. Reger. The dues were fixed at \$1 per year. The next meeting will be on the first Thursday in October, 1895.

Railway Surgeons.—The first annual meeting of the Iowa Association of Railway Surgeons was held at Sioux City October 10.

Dr. J. N. Warren was chosen temporary chairman and J. D. McCrae, Jr., of Council Bluffs temporary secretary. The Association was permanently organized with the following officers: President, J. N. Warren, Sioux City; Vice-President, J. W. Philpott, Fort Madison; Secretary, Donald McCrae, Jr., Council Bluffs; Treasurer, J. M. Knot, Sioux City. Judiciary Committee, G. W. Coit, Missouri Valley; C. C. Bronley, Manchester; Dr. Adair, Anamosa. Papers were read by Dr. J. N. Warren, of Sioux City, on "Spinal Injuries;" "Anesthetics," Dr. A. C. Bergen of Sioux City; "The Hot Water Fad," Dr. A. M. Vail, of Rock Rapids; "Compound Fractures," Dr. Donald McCrae, of Council Bluffs.

The Wyoming County (N. Y.) Medical Association held a meeting in Attica, October 9. The meeting was called to order by the President, Dr. M. J. Wilson, of Warsaw, after which the proceedings of the last meeting were read by the Secretary, Dr. A. B. Straight, of Perry. The first paper was read by Dr. A. G. Ellinwood, of Attica, subject, "Thrombosis and Embolism;" followed by Dr. Frank R. Barross, of Attica, upon "Practical Points on the Elbow Joint." Dr. Burbanks, of Pavilion, presented an interesting paper upon "Quacks and Quackery," and Dr. C. R. Seeley, of Attica, gave a paper upon "Notes of Cases in Practice." An illustration of the value of "Antiseptics" was given by Dr. Stanton, of Varysburg, followed by an interesting article on "Peritonitis" by Dr. Hulette, of Arcade. Dr. M. J. Wilson, of Warsaw, closed the afternoon session by opening a discussion upon "Professional Work From a Business Standpoint." Among those in attendance were Dr. G. H. Peddle, Wethersfield Springs; Miss J. W. Finley, M.D., Castile; Dr. William Stanton, Varysburg; Dr. Fisher, of Arcade, Vice-President of the organization; Dr. Z. L. Stage, of Bliss; Dr. Parker Davis, of Darien. Among the new names presented to the organization for membership were Drs. Z. L. Stage, C. R. Seeley and Parker Davis. Upon motion of those present Dr. Frank F. Ellinwood, of Attica, and Syracuse, was made an honorary member of the Association. A banquet was served at the Edwards Hotel.

Vermont State Medical Society.—The annual meeting was held in Montpelier October 11 and 12. The following officers were elected: President, J. H. Linsley, Burlington; Vice-President, F. F. Chaffee, Strafford; Secretary, D. C. Hawley, Burlington; Executive Committee: J. H. Linsley, D. C. Hawley, and F. R. Stoddard (of Shelburne). Publication Committee: D. C. Hawley, J. B. Wheeler (and H. C. Tinkham. License Censors: E. S. Albee, C. M. Ferrin and H. S. Brown. The attendance was the largest in the history of the Society. Dr. Frederic C. Shattuck, of Boston, read a valuable paper on "The Modern Treatment of Typhoid Fever," and Dr. John C. Irish, of Lowell, Mass., presented one on the "Surgical Treatment of Uterine Neoplasms." The annual banquet was spread at the Pavilion Hotel at 10

p.m. Thursday and was enjoyed by about 150, including the members of the Society, the Governor of the State, V. A. Woodbury, of Burlington, also the Speaker of the House of Representatives and other officers of the Legislature. The Anniversary Chairman was Dr. A. P. Grinnell, of Burlington. The next annual meeting will be held in Burlington.

American Academy of Railway Surgeons.—The first meeting of the American Academy of Railway Surgeons will be held in the parlors of the Grand Pacific Hotel, Chicago, Nov. 9 and 10, 1894.

First session, executive, Friday, 9 a.m. Only charter members of the Academy admitted.

Call to order, by Chairman, Committee on Permanent Organization; election of temporary chairman; election of temporary secretary; roll-call of charter members; appointment of Committee on Constitution and By-Laws.

The Objects and Aims of the American Academy of Railway Surgery, by C. K. Cole, Chief Surgeon Montana Central Railway, Helena, Mont.; Reasons for the Organization of the Academy, by W. J. Galbraith, Chief Surgeon Union Pacific Railway, Omaha, Neb.; A Symposium on Permanent Organization, by R. Harvey Reed, Consulting Surgeon Baltimore & Ohio Railway, Columbus, Ohio; Opening of the discussion on these papers, by W. H. Elliott, Chief Surgeon Central Railway of Georgia, Savannah, Ga. Miscellaneous business. Adjournment.

Second session, open, Friday, 2 p.m. Nothing but scientific business transacted, and open to all interested.

1. Injuries of the Tendons in Railway Accidents.

(a) History and Symptoms, by J. B. Murphy, Chief Surgeon Wisconsin Central Railway, Chicago, Ill. Discussion opened by W. A. Adams, Chief Surgeon D. T. & Ft. W. Railway, Fort Worth, Texas.

(b) Diagnosis and Prognosis, by W. D. Middleton, Chief Surgeon C. R. I. & P. Railway, Davenport, Iowa. Discussion opened by Brise L. Riordan, Surgeon G. T. Railway, Toronto, Canada.

(c) Treatment, by Geo. W. Hogeboom, Chief Surgeon A. T. & S. F. Railway, Topeka, Kan. Discussion opened by Solon Marks, Chief Surgeon C. M. & St. P. Railway, Milwaukee, Wis.

2. Traumatic Neuritis.

(a) History, Symptoms and Differential Diagnosis, by A. P. Grinnell, Chief Surgeon Central Vermont Railway, Burlington, Vt. Discussion opened by Chas. H. Merz, Surgeon L. E. & W. Railway, Sandusky, Ohio.

(b) Prognosis and Treatment, by E. A. McGannon, Surgeon G. T. Railway, Brockville, Ontario, Canada. Discussion opened by J. H. Ford, Chief Surgeon C. C. C. & St. L. Railway, Wabash, Ind.

3. Treatment of Traumatic Aneurism, by G. S. Worley, Chief Surgeon J. St. A. & I. R. Railway, St. Augustine, Fla. Discussion opened by N. Y. Leet, Chief Surgeon D. L. & W. Railway, Scranton, Pa.

Adjournment.

Third session, executive, Friday, 8 p.m. Only charter members of the Academy admitted.

Report of committee on constitution and by-laws; appointment of committee on nominations; miscellaneous business.

Adjournment.

Fourth session, open, Saturday, 9 a.m. Nothing but scientific business transacted, and open to all interested.

1. Should a Railway Surgeon be Required to Procure a History as to the Cause of an Accident over the Signature of the Injured?

(a) Reasons Favoring such Report, by S. L. McCurdy, Surgeon P. C. C. & St. L. Railway, Pittsburg, Pa. Discussion opened by R. W. Bruce Smith, Surgeon G. T. Railway, Seaforth, Canada.

(b) Reasons Opposing such Report, by Geo. Chaffee, Surgeon L. I. Railway, Brooklyn, N. Y. Discussion opened by J. M. Dinnen, Chief Surgeon N. Y. C. & St. L. Railway, Fort Wayne, Ind.

2. The Best Method for Approximately Determining the Amount of Damage Sustained by a Traumatism from a Monetary Standpoint, by R. S. Harnden, Surgeon N. Y. L. E. & W. Railway, Waverly, N. Y. Discussion opened by John E. Owens, Chief Surgeon C. & N. W. Railway, Chicago, Ill.

3. The Best Methods for Determining the Value of Life when Death has been Caused by Accidental Means, by M. Cavana, Surgeon N. Y., O. & W. Railway, Oneida, N. Y. Discussion opened by A. D. Bevan, Chief Surgeon Iowa Central Railway, Chicago, Ill.

4. The Environments of Railway Surgery, by B. Merrill Ricketts, Chief Surgeon C. P. & V. Railway, Cincinnati, Ohio. Discussion opened by C. B. Kibler, Surgeon N. Y., L. E. & W. Railway, Corry, Pa.

5. The Use of Horse Hair in Surgery, by C. M. Daniels, Chief Surgeon W. N. Y. & P. Railway, Buffalo, N. Y. Discussion opened by A. C. Scott, Chief Surgeon G. C. & S. F. Railway, Temple, Texas.

Adjournment.

Fifth session, open, Saturday, 2 p.m. Nothing but scientific business transacted, and open to all interested.

1. Not a Case of "Railway Spine," by Webb J. Kelly, Surgeon C. C. C. & St. L. Railway, Galion, Ohio. Discussion opened by W. B. Rogers, Chief Surgeon K. C. & M. B. Railway, Memphis, Tenn.

2. Comparative Value of Plaster of Paris and Silicate of Soda as a Dressing for Fractures, by Milton Jay, Chief Surgeon C. & E. I. Railway, Chicago, Ill. Discussion opened by C. B. Parker, Surgeon L. S. & M. S. Railway, Cleveland, Ohio.

3. The Treatment of Burns of the Conjunctiva, by D. C. Bryant, Oculist, Union Pacific Railway, Omaha, Neb. Discussion opened by Wm. Thompson, Oculist Penna. Railway, Philadelphia, Pa., and J. A. White, Consulting Oculist S. Railway Co., Richmond, Va.

4. Traumatism of Joints, by R. H. Cowan, Surgeon N. & W. Railway, Radford, Va. Discussion opened by C. B. Powell, Surgeon C. B. & Q. Railway, Albia, Iowa.

5. Colloidion in Solutions of the Continuity of the Soft Parts, by N. A. Drake, Surgeon C. R. I. & P. Railway, Kansas City, Mo. Discussion opened by Chas. B. Fry, Surgeon Big Four Railway, Mattoon, Ill.

Adjournment.

Sixth session, executive, Saturday, 8 p.m. Only charter members of the Academy admitted.

Report of the committee on nominations; election of officers; selection of next place of meeting; miscellaneous business; adjournment to the banquet hall; banquet.

Adjournment.

TRANSPORTATION.

The managers of the various railroads have very cordially agreed to furnish the necessary transportation to enable the members of the Academy to attend the coming meeting. Those who need transportation will apply for the same at once through their proper officers.

NECROLOGY.

OMER T. GILLETT, M.D., of Evansville, Ind., at Colorado Springs October 5—G. A. Muller, M.D., at Menasha, Wis., October 5, aged 40.—A. B. Dobson, M.D., formerly of Iowa, at San Jose, Cal., October 1, aged 61. He was a Surgeon of Volunteers, during the civil war.—Benton J. Holm, M.D., of Bloomington, Mo., October 6.—D. B. Hill, M.D., of Lock Springs, Mo., September 30, aged 73.—B. J. Howe, M.D., of Bedford, Ind., October 6.—James Goodier, M.D., of Monroe County, Mo.—William H. Brooks, M.D., of Fort Wayne, Ind., October 13, aged 83 years.—D. C. Wilson, M.D., of Painesville, Ohio, September 26, aged 56 years.—G. W. Moody, M.D., of Huron, S. D., October 13. He was one of Dakota's earliest settlers and was President of the Territorial Board of Health. He had been surgeon for the Chicago and Northwestern Railway in Dakota for fourteen years.—Reid Alexander, of Topeka, Kan., October 8, aged 34 years.

MISCELLANY.

Change of Address.—L. W. Steinbach, M.D., has removed to 1309 N. Broad Street, Philadelphia.

For the Legislature.—J. H. Brownfield, M.D., of Fairmount, W. Va., has been nominated for the Legislature. The *West Virginian* says: "Dr. Brownfield's nomination was apparently demanded by everybody, and was enthusiastically received."

Foreign Body in the Bronchus.—Oneida County (N. Y.) Medical Society closed its semi-annual session October 9. Dr. Brownell, of Utica, reported a case of foreign body in the bronchus in the case of a boy 4 years of age. The boy was suspended by the ankles every few minutes during the night, and at 4 A.M., the foreign body (apparently corn husks) was coughed out. The child made a prompt recovery.

Injections of Blood-Serum in the Treatment of Diphtheria.—The experiments that have been made in Vienna, at the Children's Hospital, show that the injections of blood-serum have been followed by many successes. Children whose cases have been regarded as hopeless of recovery under the usual treatments, have been found to recover under this new treatment in the proportion of three recoveries to one death.

Appointments.—Dr. Dalby has been appointed Health Commissioner of Salt Lake to succeed Dr. Beatty.—H. J. Neely, M.D., has been appointed postmaster of Brush Creek, Pa.—E. R. Hardenbrook, M.D., of Buffalo, N.Y., has been appointed house surgeon of the New York State Industrial School at Rochester.—E. C. Jacobs, M.D., of Milwaukee, has been appointed assistant physician at the Northern Hospital for the Insane at Oshkosh, Wis.

On the Administration of Chloral to Young Children.—Dr. J. C. Wilson places much reliance on the soothing influence of chloral hydrate over the irritations of scarlet fever. As a rule, the drug is easy of administration and well borne by the stomach. I have found its acrid after taste best masked by the administration in Abergier's syrup of lactucarium diluted, thus:

R. Chloralis gr. xxx.
Syrup, lactucarii (Abergier) } ññ ʒjss.—M.
Aque }

Sig.: A teaspoonful in iced water every two, three or four hours.

The administration of nourishment immediately after the medicine is desirable. The sleep-inducing properties of the drug manifest themselves rapidly, but are not prolonged; therefore, its repetition at intervals of two or three hours is called for.

Bequest for Autopsies.—Professor Verga, of Milan, describes a curious institution in that city, somewhat resembling the Society for Mutual Autopsies in Paris. It is a bequest made to the city authorities in 1881, by P. M. Loria, a citizen of Milan, to defray the expenses of autopsies for poor families, the survivors of which wish to ascertain the true causes of death and the weaknesses and organic degenerations which menace their descendants. M. Loria also hoped that these autopsies would remove one of the principal obstacles to cremation, by proving that death was due to natural causes. During the last year thirty-two autopsies were made by Professor Verga—twenty-two males and ten females; two-thirds of these were of persons over 60 years of age. The conditions of the bequest provide that any specimens remarkable from a pathologic or anthropologic standpoint shall be preserved—the former in the hospital museum, the latter in the civic museum.

Dr. Robinson Wins a Suit.—Dr. Robinson has been buying tickets and refusing to pay an extra fare between Alameda and Oakland for years. His suits have been innumerable and always ask for \$200 and costs.

He contended for the right to buy stop-over tickets between San Francisco and Alameda by which he could stop at Oakland and afterward go on to Alameda. Superior Judge Hunt of San Francisco gave judgment in favor of Robinson, and the Supreme Court sustains it. This will probably settle the matter and give the Doctor a goodly sum. A Bretz, the Popular candidate for the Assembly, has not been idle during this time, but has evidence that will net him about \$1,500 or \$2,000 in like suits. When the Seventh Street locals

commenced collecting fares, Dr. Robinson made several vain attempts to ride without a ticket, and now he will undoubtedly take a turn at that case. The decision is of the utmost importance to all Oakland and Alameda people. Dr. Robinson thought that the decision might affect the standing of the State Railroad Commission, but it did not, according to the report given to the press.

Semeiotics in Fiction.—Dr. A. Conan Doyle, the famous novelist, who is visiting this country to enjoy the plaudits of a contemporaneous posterity, has achieved his success by use of the qualities which make the successful physician or surgeon. A master of semeiotics—the science of signs or symptoms, *medicæ*. symptomatology—he created the character of "Sherlock Holmes," the ideal detective, and endowed the creation with the skill and penetration in interpreting the endless significance of small details which made his preceptor, Dr. Joseph Bell, of the Edinburgh University an object of wondering admiration to his students. Conan Doyle was especially struck with this faculty of Dr. Bell's and with the seemingly marvelous insight into his patients, the result of circumstantial evidence built up on little details usually considered insignificant or entirely overlooked. This, Dr. Bell was wont to impress upon his students as the foundation of diagnosis, and Dr. Doyle, who proved himself an apt pupil, has turned it to good account in his works of fiction—works which have very probably contributed more to "the gayety of nations" than his skill as a physician could have done.

Dangerous Sting of the Conorhinus.—In *Insect Life* for September, a California correspondent of Professor Riley states briefly his personal experience with a sting or bite of a cononose (*Conorhinus*). This writer was stung in the night time while he was in bed, upon the middle toe of his left foot. He first gently rubbed saliva over the toes in order to possibly ease the itching sensation, but this continued and gradually spread over the foot and thence upward. The instep, legs, thighs and loins, where large flat blotches were raised were affected. It finally extended further up the hands and arms; his lips swelled; his neck, nose and eyebrows itched and swelled on scratching, and his scalp was a mass of lumps from the same cause. He stood this as long as he could and then went out to a water ditch and soaped and bathed his body in cold melted snow-water, and applied some bacon grease thoroughly. A little later he became sick at his stomach and took a strong cup of coffee. About 6 o'clock in the morning the itching abated, but the swelling remained on his hand and foot until the next day. In a later letter the writer states that he has noticed that the *Conorhinus* is attracted by carrion, and he explains a large number of the poisonous effects of the bite by the mechanical conveyance of putrid animal matter to the wound made by the beak of the insect.

Faith Curists may be Held for Trial in New Jersey.—A Mrs. Glenn, of Palmyra, New Jersey, whose patient died while under a faith-cure treatment, will be tried under a law passed by the last session of the Legislature. The patient was a woman, aged 17 years, who had had pulmonary tuberculosis for some time. The claim was made by Mrs. Glenn that by abandoning the use of medicines, and by a reliance on the faith healing methods, she had been able "to put a new lung into a patient who had been given up to die by Dr. Pepper." But the poor deluded patient grew progressively worse and died. This was followed by a condemnatory verdict by a coroner's jury and the arrest of the illegal practitioner. This is the first case under the new law. The New York *Herald* reports the following interview with Dr. Watson of Jersey City:

"Dr. W. Perry Watson, of Jersey City who is Secretary of the State Board of Medical Examiners and who drafted the General Medical bill which is now a law, said in reply to an inquiry: "The medical law is working well and I fail to find any of the faith curists and mind healers who were beginning to operate quite extensively in this State. In Jersey City those whom I did know have quietly taken down their

signs and gone over to New York. The law has worked well in preventing the fraudulent practitioners from operating here, and particularly those who came over the river. The State Board will prosecute them wherever they are found."

An Army Promotion Board.—A board of officers consisting of Lieutenant-Colonel Charles R. Greenleaf and Johnson V. D. Middleton, Deputy Surgeon-General, and Captain William L. Kneidler, Assistant Surgeon, has been appointed to meet at San Francisco, Cal., for the examination of certain army medical officers with a view to determine their fitness for promotion to the grade of Captain. The officers ordered before the board are First Lieutenants Charles Willcox, Harlan E. McVay and Euclid B. Frick. These examinations are a recent requirement of the War Department. Formerly a lieutenant and assistant surgeon became entitled to the relative rank, pay and emoluments of a captain of cavalry by virtue of the expiring of his fifth year of service. Now, he, like all other officers of the staff or line below a certain grade, has to pass an examination to demonstrate his fitness physically and professionally to perform the duties of the higher grade. Examination is first made into the physical condition, and if this is found defective the board immediately concludes its inquiry in the case by finding and reporting the cause which in its judgment has produced the disability and whether the disability was contracted in the line of duty. The professional examination covers army regulations, customs of service and methods of the medical department; Hospital Corps administration and drill; hospital management; camp, post and hospital sanitation; and such professional subjects as have been developed by new views, experiments, operations, observations, etc., during the five years of the young officer's lieutenancy.

Status and Pay of Japanese Army Surgeons.—The Surgeon-General of the Imperial Army has the rank of major-general and the same amount of salary, 300 yen per month, the yen being equivalent to about 75 cents of our money. Surgeon inspectors, whose position is analogous to that of colonel and assistant surgeon-general in the U. S. Army, have the rank of colonel and a salary of 193 yen per month, or 3 yen more than a colonel of cavalry receives, and 15 more than a colonel of infantry. Surgeons of the first class rank as lieutenant-colonel and their pay, 143 yen, bears the same relation to that of a regimental lieutenant-colonel that the pay of an inspector does to that of regimental commanders. Surgeons of the second class with the rank of major draw 93 yen monthly. Assistant surgeons of the first class and pharmacists of the same grade have 52 yen or the pay of a captain. Assistants and pharmacists of the second class rank as first lieutenants and have the pay of that grade, 32 yen. Assistants and pharmacists of the third class have the rank and pay, 26 yen, of the second lieutenant. These medical, like other officers of the army, have increased pay when assigned to special duty; those on duty in the War Department, for instance, having an increase amounting to about one-third of the regular salary of their grade. They have, in addition, certain emoluments such as are given to officers in the army of the United States as increased pay for length of service, commutation of quarters, etc., and a retired pay or pension when unfit for service by disability from accident, disease or age. The Hospital Corps of the U. S. Army has only three grades: private, acting hospital steward and hospital steward; but the Japanese have better facilities for discriminating between good and indifferent men. The infirmary sergeant-major has 6,950 yen per month, the sergeant 5,019, the corporal 3,680, the private of the first class 1,612 and the private of the second class 1,369, with clothing and other allowances and increased pay for second and subsequent enlistments, as provided for troops of the line.

New Ruling by the Illinois State Board of Health.—From the following communication in which names are omitted from the original, it will be seen that the Illinois State Board of Health will not recognize Dental, Pharmacy or Veterinary Colleges as entitled to recognition for *any part* of a medical college course:

CHICAGO, Oct. 7, 1894.

Last Saturday a graduate in veterinary science who has never attended a medical college hitherto, called on me, professedly on your suggestion, to inquire whether he could legally graduate from your College at the end of one course of lectures. I turned to page 21 of the Fifteenth Annual Report of the State Board of Health and read to him from the minutes of the January meeting, 1892, as follows:

"*Veterinary Colleges not Recognized.*—The Secretary presented a communication from the clerk of the ——— Medical College, with an inclosure indorsed by ———, asking for a ruling" etc., etc., and in answer to this communication, it was "Resolved, That the Illinois State Board of Health declines to recognize the degree of Doctor in Veterinary Science as the equivalent of any part of the minimum requirements fixed by the Board as characterizing a medical college in good standing, etc."

I infer that you had overlooked or forgotten this ruling and, as I have some reason to think you are not familiar with a more recent ruling of similar import and wider application, I make free to quote from page 19 of the Sixteenth Annual Report:

"Resolved, That the Illinois State Board of Health declines to recognize the degree of Ph.G., D.D.S., or V.S., as the equivalent of any part of the minimum requirements fixed by the Board as characterizing a medical college in good standing within the meaning and intent of the Illinois Medical Practice Act."

"This Board does not recognize a licensed pharmacist as on a different plane from any other non-graduate in medicine."

"That as to 'persons holding certificates of examination,' the Board holds that they should establish the fact of four years of study and three full courses of lectures before being granted the degree of M.D."

I have the records and addresses of a number of students belonging to the categories referred to, whose applications for advanced standing in the ——— College were rejected—in some instances, regretfully—on account of the foregoing rulings.

WM. E. QUINE, M.D.

The Defenses of Great Britain against Cholera.—The *Daily Graphic* of September 25 gives the British public a view of the official methods of protecting the United Kingdom against invasion by cholera. It speaks in glowing metaphorical terms of the medical officer of the Local Government Board, Dr. Thorne-Thorne, seated, as a general, in his room at Whitehall calmly noting on his maps the progress of the enemy, deliberately making preparations to meet and avoid its attack on Great Britain, and sending out his lieutenants and aids-de-camp to destroy the advanced scouts of the invading force, which, in spite of all vigilance, sometimes succeed in gaining an entrance at the seaports.

Information is first obtained by telegraph through the Foreign Office or from the British Consuls abroad that an infected or suspected ship has left an infected port. Directly the vessel arrives at a British port it is boarded by the port medical officer of health. All the cholera cases are at once taken off the ship and placed in hospital, and further, all suspected cases are detained forty-eight hours in order that it may be seen if they develop cholera. The rest of the passengers are allowed to depart after they have given their names and the addresses to which they are going. The medical officer of health of the town or district named is then notified that such a person will arrive, and on arrival he visits him and keeps him under surveillance until all danger is past. If the suspect sicken of cholera, or even of diarrhea, he is at once isolated, his clothes are burned, all discharges are disinfected, the drains, etc., of the house flushed with disinfectants and precautions taken to avoid infection of the water supply. In this way each case of cholera all over the country is detected and watched, and the spread of

the disease arrested from the outset. Thirty-five cases of cholera were imported into England in 1892 during the period that Hamburg suffered so severely; and of these six occurred among persons who had left the seaport of arrival in a condition of apparent health; but owing to this system of surveillance the exact whereabouts of each was known, the disease treated and its spread arrested without delay. This was the history of cholera in England in 1892. Since then the medical inspectors of the Cholera Survey have been engaged in visiting the ports all round the coast and those inland towns where a heavy enteric fever mortality gave an indication that they might be suitable places for breeding cholera, owing to their various sanitary neglects; in fact, all places where the water supply was subject to pollution. This work has been done quietly and without publicity—perhaps too much so; the corporations or sanitary authorities meet the medical inspectors; the faults of imperfect sanitation are pointed out to them and they are advised how to provide the available remedies so as to make the population of whose health they have charge safe against the invasion of cholera.

From the point of view of this great improvement in local and general sanitation the *Graphic* speaks of "that blessed word cholera. Cholera scares have been, in fact, blessings in disguise, and have done more than anything else to improve the health conditions of this country." Much credit is given to the medical officers connected with this service. Their work is characterized as truly admirable. "It demonstrates once more, if any such further demonstration is needed, how great are the services quietly and devotedly rendered by medical men, not only in the cure, but also in the prevention of disease. The port medical officers have time and again spent days and nights on the water, sleeping on board ship so as to be ready at a moment's notice, regardless alike of personal risk and individual comfort. The really heavy work has fallen, to a great extent, on them, and no one acknowledges their distinguished services more emphatically and enthusiastically than Dr. Thorne-Thorne himself, who loses no opportunity of doing justice to them. The medical inspectors of the Local Government Board have also been incessantly on the alert, traveling by night and working by day, and although the cholera scare has temporarily passed away their vigilance is not relaxed and the Sanitary Survey is still going on." The health officers of London, Newcastle-on-Tyne and Hull, Drs. Collingridge, Armstrong and Mason, are specially mentioned in the article for their earnest and valuable services.

Hospital Notes.

THE AUGUSTANA HOSPITAL of Chicago is to issue an edition of 10,000 circular catalogues.—The Children's Hospital of Buffalo, N. Y., held its annual meeting December 9. The old officers were re-elected.—A meeting was held in Sangerbund Hall, Brooklyn, to organize a German Hospital, October 8.—Dr. E. E. Montgomery, after fifteen years' service in the Philadelphia Hospital, resigned and his place was filled by the election of J. M. Fisher, M.D., who is an instructor in gynecology at Jefferson Medical College.—The New York Foundling Hospital celebrated its silver jubilee October 17. Since its foundation it has received 25,697 infants and 5,000 needy mothers; out-door employment has been given to more than eleven hundred nurses and \$3,000,000 has been paid them.—Francis B. Keene, of Milwaukee, has donated to the Episcopal Diocese of that city the Keene homestead to be used for a hospital. It will be known as the Keene Memorial Hospital, the donation being made in memory of his father, the late Dr. Keene.—The new Consumptive Hospital, established by several New York women, will soon be ready to receive patients. The Hospital is founded for the reception of consumptives, working girls, that they may receive treatment without the loss of time from their daily labor.

Washington Notes.

MEDICAL SOCIETY OF THE DISTRICT.—At the regular meeting of the Medical Society, Dr. Irving C. Rosse read a very elaborate and scientific paper entitled, "Some Medico-legal Features of the Schneider Case." He differs with the experts on insanity for the prosecution, taking the ground that the

defendant was insane at the time of her execution. H gives the results of *post-mortem* examinations and criticises the ruling and charge of the presiding judge. Dr. W. K. Butler presented a large calculus from the tonsil of a young negro boy. Dr. Joseph C. Price, of Philadelphia, was invited to read a paper before the Society during the present month.

The Committee on Typhoid Fever presented its report as laid before Congress and published by the Public Printer. This is now a public document and as such will be distributed.

CENTRAL DISPENSARY AND EMERGENCY HOSPITAL.—At the meeting of the Board of Directors on the 10th inst., Hon. John W. Foster, ex-Secretary of State, and Mr. John B. Wight, Secretary Washington Board of Trade, were elected to membership.

THE CHILDREN'S HOSPITAL.—The annual report of the Children's Hospital was submitted to the Commissioners this week through Col. John Tracy, Superintendent of Charities. The income of the Hospital during the year amounted to \$25,221. Of this amount \$10,000 came from the government; \$4,400 from the J. C. Hall fund; \$1,300 from subscribers; \$1,000 from the charity ball and \$8,521 from contributions. The ordinary expenses of the Hospital amounted to \$19,194; \$5,000 was paid on the debt during the year, leaving a balance due of \$22,000. Had it not been for the contributions there would have been a deficiency, which would have compelled the directors to limit the number of admissions so that there should be at no time more than forty white and forty negro children in the Hospital. An infant ward has been added with a limit of twelve infants. An appropriation of \$15,000 is asked for the support of the Hospital during the next fiscal year. The number of patients treated during the year was 379, 41 of whom died. The dispensary patients numbered 3,051.

THE GARFIELD MEMORIAL HOSPITAL.—A meeting of the Board of Trustees of the Hospital was held on the 9th inst., with the President, Mr. Justice Harlan, in the chair. Reports were read showing the operations of the Hospital during the previous year, and the rapid growth of the institution during that time. The demand for accommodations for patients has led to the opening of four wards since March of this year; these have filled as soon as ready, and there is still need of more room.

During 1893, 515 patients were treated in the Hospital. During nine months of 1894, from January to October, 573 were admitted. The cases treated come from nearly every State in the Union and from the city and county. Over sixty cases of typhoid fever alone were treated during the year, the larger number of these being admitted during July, August and September of this year. In one instance four members of one family suffering from typhoid fever were received and treated. One hundred and fifty surgical operations were performed during the past eight months.

So many applications were made to the Hospital for treatment by poor patients who were not ill enough to be admitted to the wards, that it was decided to begin a free dispensary service. This was opened July 12, 1894, and from that date to October 1, 403 cases have been treated.

The large central building erected for the administration and for the accommodation of the nurses has added greatly to the architectural beauty of the Hospital and to the comfort of the business management. The training school is also located here. The number of nurses on February 1 was fourteen; on October 1 twenty-seven. Regular instruction is given by a corps of lecturers and by the Superintendent of the school, Miss Nevins, during the winter and spring months, and after a two years' course of instruction the nurses receive a diploma. The Ladies' Aid Society has ren-

dered valuable service during the year. They have supplied thirty sets of bedroom furniture; twenty for the nurses' rooms and ten for ward C. They have also supplied linen for the wards, and curtains and awnings for the new buildings. The rooms of the Superintendent of the training school have been furnished throughout by Miss Edwards. The ladies have also in contemplation the erection of a new operating room, a building that is much desired on account of the inconveniences of the present room. A pathologic department has been established for the purpose of scientific study. It is proposed to establish at no distant date a nurses' directory and home in connection with the training school.

Medical Staff: Consulting Staff, Drs. William W. Johnston, President; Nathan S. Lincoln, James W. H. Lovejoy, Henry S. Yarrow.

Attending Staff: Drs. Geo. N. Acker, Samuel S. Adams, G. Wythe Cook, Henry D. Fry, Arthur A. Snyder, J. Ford Thompson. Drs. Swan M. Burnett, diseases of the eye and ear; Joseph H. Bryan, diseases of the throat and nose.

Chief Resident Physician, Dr. A. L. Stavely. First Assistant, Dr. Middleton S. Elliott.

Superintendent of the training school for nurses, Miss Georgia M. Nevins.

Ladies' Aid Association. Board of Managers: President, Mrs. John A. Logan; first Vice-President, Mrs. John M. Harlan; second Vice-President, Mrs. Julius C. Burrows; third Vice-President, Mrs. Henry A. Willard; fourth Vice-President, Mrs. David J. Brewer; fifth Vice-President, Mrs. Earl English; Corresponding Secretary, Mrs. Anderson D. Johnston; Recording Secretary, Mrs. J. Frank Aldrich; Treasurer, Mrs. Thomas L. Tulloch.

HEALTH OFFICERS' REPORT.—The reports of mortality received at the Health Department show a decrease in the number of deaths during the past week as compared with the previous week. The death rate fell from 22.9 to 21.7, and infant mortality declined from a total of fifty to that of forty of those under 5 years old. The four deaths from pneumonia present an early indication of the presence of this malady. There was a material decline in the number of deaths from diphtheria, and the week's reports show a remarkable absence of all the other dangerous contagious maladies.

THE PUBLIC SERVICE.

ENLISTMENTS IN THE ARMY HOSPITAL CORPS.

On October 2 the Surgeon-General of the Army issued a circular of information for persons desirous of entering the Hospital Corps of the Army. A number of vacancies occur from time to time in the various grades, which are filled in part by enlistment from civil life and in part by transfers of desirable men from the line. All enlistments are for the grade of private, but provision is made for the speedy promotion of those who show themselves to be in earnest, intelligent, capable and trustworthy. Not only does service in the Hospital Corps offer excellent pay, but it at the same time gives a training which will be of great usefulness should the member at any time return to civil life; if, however, he have promotion in view, it opens to him the most valuable position attainable by an enlisted man in the United States Army. Applicants for enlistment must be between the ages of 18 and 30 years, unmarried, of good character and habits, able-bodied, free from disease, and must be able to speak, read and write the English language. Such minor defects of vision as may be corrected by glasses are not regarded as a bar to enlistment. The pay is \$18 per month for the first year, increased with subsequent years of service; but intelligent men look rather to promotion to Acting Stewardships and Stewardships open to them after one year's service as a private soldier. Those who have had special training in civil life as students of pharmacy or of training schools for nurses may not be required to serve the full year of probation. As the members of the Corps receive from the Government quarters, rations, clothing, bedding, etc., the monthly money allowance practically represents what remains of the wages of a man in civil life after the payment of the ordinary expenses of living, clothing, etc. The United States takes care of its soldiers in sickness, and continues their pay and allowances during that time. It also insures their lives and health, for if the former is lost because of disease or injury incident to the service dependent relatives will receive pensions, while on the other hand, if a soldier is permanently disabled he is entitled to pension, the amount depending on the extent of the disability. After thirty years' service the retired list of the Army is open to them with three-fourths of the pay of the grade

held at the time of retirement. Applications for enlistment, accompanied by testimonials as to character, physical soundness, special knowledge (as of pharmacy, cookery, mechanics, etc.) should be addressed to "The Surgeon-General, U. S. Army, Washington, D. C." (who authorizes enlistment); or candidates may apply in person to any recruiting officer of the Army, or preferably to the medical officer at any military post or station.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Oct. 6, 1894, to Oct. 12, 1894.

Capt. GEORGE E. BURNELL, Asst. Surgeon, will be relieved from duty at David's Island, N. Y., by the commanding officer of that post, on the receipt by him of this order, and will then report in person to the commanding officer, Ft. Hamilton, N. Y., for duty at that post, reporting by letter to the commanding General, Department of the East. By direction of the Acting Secretary of War.

Capt. C. N. B. MACAULEY, Asst. Surgeon, extension of leave of absence granted in S. O. 55, Dept. of the Colorado, Sept. 14, 1894, is further extended one month. By direction of the Acting Secretary of War.

Major CURTIS E. MUNN, Surgeon, upon abandonment of Mount Vernon Bks., Ala., is ordered to Benicia Bks., Cal., relieving Capt. OGDEN RAFFERTY, Asst. Surgeon. Capt. RAFFERTY, on being relieved by Major MUNN, is ordered to Presidio of San Francisco, Cal., for duty.

First Lieut. CHARLES E. B. FLAGG, Asst. Surgeon, relieved from duty at Presidio of San Francisco, Cal., and ordered to Angel Island, Cal., for duty.

Major VAN BUREN HUDDARD, Surgeon, relieved from duty at Ft. Spokane, Washington, and ordered to Ft. McPherson, Ga., for duty at that station.

Major JAMES P. KIMBALL, Surgeon, upon abandonment of Ft. Marey, N. M., is ordered to Ft. Wingate, N. M., for duty. Upon arrival of Major KIMBALL at Ft. Wingate, Capt. C. N. B. MACAULEY, Asst. Surgeon, will take station at Ft. Apache, Ariz., for duty, relieving Lieut. M. W. IRELAND, Asst. Surgeon. Lieut. IRELAND, on this being relieved, will take station at Ft. Stanton, N. M., relieving First Lieut. F. R. KEEFER, Asst. Surgeon. Lieut. KEEFER, on being relieved, will proceed to and take station at Washington Bks., D. C.

Major CURTIS E. PRICE, Surgeon, upon abandonment of Ft. Supply, O. T., will proceed to and take station at Ft. Sill, O. T.

First Lieut. ISAAC P. WARE, Asst. Surgeon, is relieved from duty at Ft. Supply, O. T., and ordered to Camp Eagle Pass, Texas, for duty. Upon arrival of Lieut. WARE at Camp Eagle Pass, First Lieut. ALEXANDER N. STARK, Asst. Surgeon, will return to his proper station at Ft. Sam Houston, Texas.

Capt. E. F. GARDNER, Asst. Surgeon, upon abandonment of Ft. Mackinac, Mich., is ordered to Boston, Mass., for duty as attending surgeon and examiner of recruits, relieving Major M. W. WOOD, Surgeon, who, on being thus relieved, will proceed to take station at Boise Bks., Idaho, to relieve Capt. WILLIAM STEPHENSON, Asst. Surgeon. Capt. STEPHENSON, on being relieved, will proceed to and take station at Vancouver Bks., Washington.

Major MARSHALL W. WOOD, Surgeon, is granted leave of absence for twenty-five days, to take effect upon his relief from duty at Boston, Mass. By direction of the Secretary of War.

Capt. FRANCIS J. IVES, Asst. Surgeon, having proceeded with troops to Ft. Ethan Allen, Vt., is relieved from further duty at Ft. Sheridan, Ill., and will remain on duty at Ft. Ethan Allen until the arrival there of Capt. AARON H. APPEL, Asst. Surgeon, when he will report in person to the commanding officer, Plattsburg Bks., N. Y., under the requirements of par. 10, S. O. 221, A. G. O., Sept. 20, 1894. By direction of the Secretary of War.

First Lieut. GEORGE D. DESHON, Asst. Surgeon, upon arrival of Major JOSEPH K. CORSON, Surgeon, at Ft. D. A. Russell, Wyo., will be relieved, and ordered to Ft. Logan, Col., for duty.

Capt. ALFRED E. BRADLEY, Asst. Surgeon, upon abandonment of Ft. Sully, S. D., is ordered to Ft. Keogh, Mont., for duty.

First Lieut. HENRY A. SHAW, Asst. Surgeon, upon abandonment of Ft. McKinney, Wyo., is ordered to Ft. Niobrara, Neb., for duty.

Capt. JEFFERSON D. POINDEXTER, Asst. Surgeon, upon abandonment of Ft. Bowie, Ariz., is ordered to Ft. Riley, Kan., for duty.

ORIGINAL ARTICLES.

THE NEW PHARMACOPŒIA.

Read in the Section on Materia Medica and Pharmacy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY JOSEPH P. REMINGTON, PH.D., F.C.S.
PHILADELPHIA, PA.

The wide-spread interest in the last revision of the United States Pharmacopœia, both in this country and abroad, and the fact that the AMERICAN MEDICAL ASSOCIATION and the American Pharmaceutical Association are especially represented in the Decennial Convention for revising the book, seem to be good reasons for the presentation in this Section of certain information regarding the work which may be of especial interest to physicians. The Convention which met in Washington on May 7, 1890, was by far the largest and most representative body ever assembled for the purpose of revising a National work of this character. All incorporated universities, medical and pharmaceutic colleges, medical and pharmaceutic State Associations and bodies connected with both professions with the United States Army, Navy and Marine-Hospital Service sent delegates to prove the interest which existed in providing a representative and authoritative guide for the selection and preparation of the armamentarium of the physician. The most important change recommended by the Convention was the entire abandonment of the antiquated, confused and unscientific system of weights and measures which has harassed the souls of pharmacists and physicians for centuries, and the acceptance of the metric system with the principle now thoroughly established in English-speaking countries of weighing solids and measuring liquids. This change received the almost unanimous vote of the Convention; the previous convention having largely paved the way for the action by adopting the principle of parts by weight in the Pharmacopœia of 1880. The fears that many expressed at the time, that the Pharmacopœia would not be accepted by pharmacists because of the introduction of the metric system have fortunately not been realized; there have been up to this time many more of the books disposed of than in any previous revision, and every day witnesses an increase in the number of pharmacists using the metric system in making preparations. There can be no question of the ultimate acceptance of the metric system, for its simplicity, conciseness and freedom from confusing characters must finally win the support of all.

The action of the Convention in excluding from the book those synthetic remedies which can not be produced otherwise than under patented process, or which are protected by proprietary rights has been probably more criticised from a medical point of view than any other.

It is difficult to convince those not engaged in commercial pursuits and not understanding the principle involved, of the evils which would follow if official sanction were bestowed on the immense number of remedies now exploited, and at present in favor with the medical profession. America has proved easy prey for the synthetic operations of European chemists who have flooded the country with their products which in many cases have realized enormous profits to the monopolies controlling them. One of the principal objects of a Pharmacopœia is to establish standards, to prove the identity and purity of the substances admitted; in order to make such operative, it is necessary to have more than one source of supply or manufacture. The manufacturer controlling a specialty is a law unto himself and can change the standard of purity of his product whenever he wishes. If the Pharmacopœia were to admit a proprietary remedy, and fix a standard of purity for it, and the manufacturer to suit any purpose that he might have in his mind chose to market an inferior product, no redress whatever could be secured. With all other remedies not so controlled, a preparation not conforming to the official standard may be rejected and a purchaser can buy a better article from other sources, but in the case of patented or proprietary substances the maker's authority is greater than that of the Pharmacopœia, and it would be a case of "take what I give you, or go without." If the Pharmacopœia of 1890 had given its official sanction to 50 synthetic remedies in common use, the Pharmacopœia of 1900 would probably have to admit 500 of equal standing, owing to the precedent having been established. Those who use proprietary specialties must take them on the *ipse dixit* of the maker, and stand or fall by what he chooses to give them.

The new Pharmacopœia contains now nearly 1,000 articles, 92 which were previously official having been dismissed, while 89 new ones have been introduced; the duty of deciding the admission and dismissals devolved upon the members of the committee who were physicians, it being the opinion of the general committee that they were the best judges of the relative importance and value of the various remedies in common use, while the pharmacists were better able to establish the standard of purity and contrive the formulas for the various preparations of the drugs which the physicians had selected. It will be readily conjectured that it was no easy task to determine upon the articles to be admitted and place the ban upon others which the march of progress had doomed to dismissal. To aid them in arriving at just conclusions, reports had been presented to the previous committee from various parts of the country, and from a number of incorporated medical and pharmaceutic bodies throughout the United States, and although a criticism like this is occasionally heard from a physician: "I never used in my life such

and such an article," it will undoubtedly be found that the substance in question is placed in the Pharmacopœia because it was shown to have been in demand in some part of the country; and the name on the title page of the book: "The Pharmacopœia of the United States of America" must be constantly borne in mind, for if this title is to be justified it must represent the demands of the whole country and not those of one particular section.

The history of the remedies in common use would, if written, contribute many pages of interest to members of both professions; many galenical preparations, for instance, trace their origin from some favored prescription of a well-known practitioner. A particular combination of remedies proving valuable to a physician is communicated to some of his friends and before long it has a local reputation; in time this extends beyond the city or town and it may, before its life-work is over, enjoy the distinction of admission to the National authority. Having been accepted in this way, it must not be supposed that its time of probation is over; it can not be said of it, in the language of the poet-laureate:

"Men may come and men may go,
But I go on forever."

A preparation remains in the Pharmacopœia only as long as it proves useful and until it is displaced by something better, but it often happens that preparations which have been of great service in the past and have been replaced in the more progressive centers of therapeutic knowledge can not be safely dismissed from the Pharmacopœia because of their extensive use in other parts of the country, which have not yet thrown off the old and taken up the new. These considerations must be taken into account before condemning the admissions or rejections. It is not within the scope of this paper to refer to that portion of the revision which especially concerns pharmacists, yet even a cursory examination of the work would indicate the amount of labor expended upon the chemical descriptions, assays, the experimental work upon the strictly pharmaceutical preparations and the botanic researches. The committee have been guided by a conservatism which, while holding fast to the proved and the true, has not been so obstructive as to prevent the acceptance of progressive subjects where these were justified by results.

It will doubtless be a source of congratulation to the members of this Section to know that financially the work has been equally successful, the plan of having the committee publish the work at its own expense, and then putting the price at as low a figure as could be afforded has had the effect of largely increasing the use of the book, and a sufficient balance has been left in the hands of the committee to expend for research work and for settling a number of mooted points for the next revision.

In concluding this brief summing up of the work performed in the revision of the last Pharmacopœia, it will not escape the observation of the members of this Section that the successful character of the work which has been done proves the necessity for the continued effort of those who have been laboring for years for closer scientific and professional relations between physicians and pharmacists; during the whole time of revision entire harmony has existed; the opinion of the majority has always prevailed, but the minority have always been given a respectful hearing and, in almost every case, after

thorough consideration was given a subject under discussion the minority cheerfully joined the majority. If such results proceed from the work of a committee, composed almost equally of physicians and pharmacists in a work of this important character, the question may be most pertinently asked: Why can not physicians and pharmacists solve in the future the many perplexing problems which confront both professions, by adopting the methods used in the revision of the Pharmacopœia of the United States of America?

THERAPEUTIC ACTION OF POTASSIUM PERMANGANATE.

Read in the Section on Materia Medica and Pharmacy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY H. I. JONES, M.D. L.R.C.P.

MEMBER CALIFORNIA STATE MEDICAL SOCIETY; SAN FRANCISCO COUNTY MEDICAL SOCIETY; AMERICAN MEDICAL ASSOCIATION.
SAN FRANCISCO, CAL.

In bringing this subject before the Section it is not the object or aim of this paper to consider the relative value of this salt, but to present a summary of how we stand in regard to the advantage which may be derived from the application of it to the cure of disease. Singleness of action in a drug is as valuable as singleness of purpose in a man. The profession has become tired of empiricism; it is anxious to know the pathology of disease, because its therapeutics can then become rational.

Permanganate of potash is, as you all know, a dark purple prismatic crystal, freely soluble in water, forming a rich purple solution. It is often objected that permanganate of potash is so quickly decomposed on coming in contact with organic matter that its action is feeble and transitory; this objection can not be maintained, as in reality a very definite influence is exerted on the blood. When it is injected locally for the bite of a venomous serpent the poison is destroyed by a process of oxidation. Given internally in small doses, say two or three grains, well diluted, it exerts no irritating effect on the mucous membrane of the stomach, but if administered in a large dose, or in a concentrated form it produces local heat and a sense of burning pain. It was once stated that it can not act beyond the stomach, because its oxygen must then be appropriated by the organic matter contained in that viscus, but there is good evidence that it does produce a marked systemic effect. The investigations of Binz, of Berlin, and others, have cleared the matter up. Binz, in personally experimenting on the action of this salt, found his respiration deeper and easier, and a general feeling of well-being and exhilaration after medicinal doses, and attributes them to the liberation of nascent oxygen, or rather ozone, during its decomposition. Sydney Ringer and others have shown by their writings, the stimulating powers of this salt. In amenorrhœa, due to deficient activities, it promotes the function in a very remarkable degree. It is best adapted for those cases characterized by torpor and anemia.

Dr. Robert Bartholow, in his excellent clinical lecture some years ago, finds as the result of a large practical experience, that it is best given in the form of compressed tablets without any excipient. A small dose repeated at short intervals, a grain or two every half-hour until four to six grains have been

taken, is preferable to this quantity at one dose. When made into pills, care should be taken not to combine any vegetable or animal ingredient.

Permanganate of potassium is contra-indicated whenever an acute congestion of a general condition of sthenic reaction exists. It is obvious that a power which can stimulate the sexual apparatus, must when exerted in other directions, prove equally effective. From its irritating effect it must not be given in acute gastritis, but will be found of great value in chronic gastric and gastro-intestinal catarrh, accompanied by fermentative changes in the food. Eructation of gas and vomiting of yeast-like material are promptly relieved by the administration of this salt. The permanganate checks fermentation of food elements prone to this process. It promotes oxidation in the tissue undergoing metamorphosis. According to clinic investigation, uric acid in the urine is converted into urea. Physiologic deduction has shown that it is of great value in lithemia; the hepatic form of glycosuria.

Dr. Bartholow states that there is no remedy more effective for obesity and digestive disorders than this salt. I have myself, (some years ago, when in general practice) used it in functional amenorrhœa with brilliant success. I have also found it excellent in catarrh of the bladder to wash out that viscus. For the qualitative analysis of drinking water we found it an excellent companion when on the march in the East Indies; by adding a few crystals of this salt to the suspected fluid, it confirmed the information when the drinking water contained organic matter, by turning it of a reddish dirty color. As a bath in skin disease, it is found to act with great benefit, 1 gram to one bucket of water. It is of great value as an antidote in phosphorous poisoning. It acts by coming in contact with the phosphorus in the stomach and converting it into ortho-phosphoric acid (Bokar). As an antiseptic it is more desirable than corrosive sublimate, because it is non-toxic and has great oxidizing power and is a true disinfectant.

Recently, Dr. Moor, of New York, in the *Medical Record* of Feb. 17, 1894, publishes his clinical experiments. According to his views, morphin is rapidly oxidized by the permanganate even in the presence of peptones and albumen. He pronounces permanganate of potash a reliable antidote for morphin. He gives .60 to .90 dissolved in half a pint of water, repeated at intervals of thirty minutes. Cases are reported in the same journal from different parts of the country in which permanganate of potash is employed hypodermically. In the *Medical News* of May 5, 1894, a physician from Pittsburg, Pa., reports a case where a patient had taken two ounces and a half of laudanum, of unknown strength, three hours before admission to the hospital. In addition to the usual treatment including coffee, hypodermic injection of atropin, artificial respiration and so on, and when the case seemed hopeless, repeated injections of a half saturated solution, in doses of 8 grams were administered at intervals of half an hour; after the fifth injection the patient recovered. No doubt if such a powerful oxidizing agent as potash permanganate is brought in contact with morphin a mutual destructive reaction would take place, but the question arises does it follow into the blood after the morphin is absorbed? Can it have a physiologic as well as a chemic action?

Since writing my paper, I read an editorial in the

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for May 19, commenting on Dr. Moor's article. It states that "it is possible that when hypodermically administered although decomposed in the tissues, the nerve centers may be influenced by some of its products, but even so, it would not be permanganate *per se*, but something else that does the work."

"VIBURNUM PRUNIFOLIUM."

Read in the Section on Materia Medica and Pharmacy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY H. R. HOLMES, M.D.

PORTLAND, OREGON.

It has been said that drug medication is a popular delusion of the nineteenth century. In these days of polypharmacy, the value of a single drug can not be always satisfactorily decided. The commerce of drugs, too, suggests so rapid an introduction of new remedies that even the names of many are quickly forgotten.

It is rare that a remedy is discovered which will occupy an entirely new place in therapeutics. The reliable effects of remedies now being introduced and those, the actions of which are yet to be studied, will be proven, and yet seldom may it not be said that these can, at best, but substitute those whose offices have been faithfully fulfilled for long periods of time. Since we have so many drugs credited with such similarity of action surely choice will ramble, hence the reason that the true value of some of our most valuable remedies is at times not strongly emphasized.

Cerna considers viburnum prunifolium briefly among the new remedies and it may appropriately appear here, for Bartholow in his "Materia Medica and Therapeutics," published in 1886, neglects its mention, and H. C. Wood in his exhaustive treatise on "Materia Medica and Therapeutics," published as late as 1889, leaves it out entirely.

Although Dr. Edward Jenks in 1876, published his observations on "The Influence of Viburnum Prunifolium in Diseases of Women," and although before he had written of it, it had really only a reputation in preventing abortion, he invited the attention of the profession to its great value in all uterine disorders characterized by the loss of blood.

It is not my purpose to consider viburnum prunifolium or black haw botanically, more than to say that it is a beautiful shrub growing about as large as the common osage orange, and is said to flourish in the Southern States, east of the Mississippi, but it does not grow sporadically on the Northwest Pacific slope. Like the cinchona tree, the bark is the part which yields the medicinal virtues. It has a specific action on the female reproductive organs and is anti-menorrhagic and anti-metrorrhagic. Infusions and decoctions may be used, but in these days of refined chemistry there is a fluid extract which requires no further recommendation than its simple mention. Parke, Davis & Co's. fluid extract is the preparation which I have mainly relied upon, but their compressed pills and tablets of the solid extract have also attracted my notice, and I shall proceed to prescribe them, providing they prove particularly pleasant to the palates of patients.

The liquor sedans containing black haw, golden seal and Jamaica dogwood combined with aromatics, is

an excellent preparation, to which in certain cases, ergot may be profitably added.

My practice, all things being equal, is to prescribe black haw to prevent abortion; to control menorrhagia and metrorrhagia from uterine fibroid or edometrial fungosities; as a sedative in ovarian congestion and its ordinary consequences, etc., and too, in almost all kinds of pelvic irritation, congestion and inflammation. May I just here inject the remark that had Hodge, a quarter of a century ago, known the value of our remedy, he would have been gratified by its influence in the treatment of what he termed "irritable uterus." Not willing to suggest to what class this remedy more properly belongs, I desire to consider it from a purely clinical point of view and will proceed at once with the narration of a few illustrative cases:

Case 1.—Mrs. M., age 30; married eight years; called me in January, 1892; had within last six years aborted four times at fourth month; general appearance healthy; about four months advanced in pregnancy; within last two hours had a smart uterine hemorrhage as was usual about this period in her gestations. Ordered patient to bed, and prescribed a drachm of fluid extract viburnum every hour until three doses were given. Within three hours all hemorrhage had ceased; a week later the patient was walking about, taking a dose of her medicine three times a day, which she continued about a week longer. Two months later patient had another similar attack with similar result on same treatment. The forward march of her gestation was without remarkable event, and in June following she was delivered of a healthy male child.

Case 2.—Mrs. S., age 29; married one year; called March, 1893; had metrorrhagia for three years to the extent of keeping her in bed half the time. Thorough examination resulted in diagnosis of submucous fibroid of uterus, size of hen egg. Squibb's fluid extract of ergot was given ʒj, *ter in die* for two months, while patient was kept in bed with very little perceptible effect on quantity of flow. A drachm of fluid extract of ergot with the same amount of liquor sedans being prescribed daily the patient who had been bed-ridden for half the time for nearly three years, within a fortnight was able to be up and about and is now enjoying what she calls good health. At menstrual times the flow lasts four days and is about right in quantity. Sometimes when undergoing unusual fatigue about menstrual time, the flow increases although the remedy has excepting then been discontinued. She has learned on such occasions to rely on her tonic as she terms it and so far it has checked any undue freedom of flow. So much for viburnum prunifolium so far in this case. To be sure this patient may in time to come need Apostoli's electrical treatment; she may require oöphorectomy, or Martin's operation of ligation of the uterine arteries, or hysterectomy, but these propositions are at least deferred.

Case 3.—Mrs. B., age 22; consulted me August, 1892; began menstruating while racing for a prize at college six years ago and eight months following a severe spell of scarlet fever. Soon after, though her memory is not precise on this point, she found herself irregular in her turns and has been so ever since, but for the last three years has flowed very freely about every three, four or five weeks; the period lasting usually as long as eight or ten days. Examination shows a retro-displaced uterus, a granular erosion about the os uteri, a conoidal cervix and pruritis ani. Patient was advised to take ether and allow the conoidal cervix to be treated surgically as well as the endometrium to be curetted, for chronic endometritis had been diagnosed and dilatation of the sphincter ani was also proposed. However, as the extremely nervous state of the woman made her regard any mention of operative procedures with intense dread, she was put on the following prescription:

| | | | | |
|---------------------------------|-----|----|--|----|
| R. Ext. ergot fld | ʒvj | 24 | | M. |
| Ext. vibur. prun. fld | ʒjj | 64 | | |
| Tr. nucis, vom | ʒjj | 8 | | |

Dose: A teaspoonful three times daily. Within three months a steady improvement had announced her relief from anemia; menstrual flow was not excessive or painful; the rectal congestion and pruritis ani had subsided. Early in 1893, Mrs. B. became pregnant and in November was delivered of a healthy male child. The sphincter ani and

recto-vaginal septum for an inch and a half above it were torn. These have, by surgical interference, been repaired and the patient appears to be in good health.

Other cases could be cited, but the variety brought forth, it is hoped, will serve sufficiently to illustrate the therapy of this valuable remedy.

SOME OF THE USES OF CHLORALAMID.

Read in the Section on Materia Medica and Pharmacy, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY CHARLES C. BROWNING, M.D.
HIGHLAND, CAL.

So many excellent and exhaustive articles have been written regarding the use of chloralamid since its introduction, that I will confine myself to a brief mention of observations in regard to a few conditions in which it has been reported of value to others and proven as such to myself. In one condition I go more into detail, because I have not seen a report of its having been used in this condition by others. Its utility is favorably reported in several conditions not herein mentioned.

I began the use of chloralamid in 1890 while a member of the medical staff of the New York City Asylum for the Insane, and have used it with satisfaction in the following conditions, viz., neurasthenia, hysteria, pleuritis, phthisis, typhoid fever, melancholia, mania, dysmenorrhœa, epilepsy and disorders due to organic diseases which were not accompanied by an extreme degree of nervous excitement or pain, especially in diseases of the digestive and genito-urinary systems. I have also used it with good result in irritable condition of the nervous system due to cigarette smoking.

I have frequently had it happen, that in cases of neurasthenia several nights' sleep would follow the administration of a single dose.

In typhoid fever I have found it especially advantageous on account of the absence of any depressing influence on the circulation, and it was suggested by Dr. Clevenger, of Chicago, in a paper published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, March 10, 1894, that we have "an almost wholly nutrient hypnotic in the compounding of chloralamid,"—that is, one which supplies material which has been exhausted in the nerve centers. This quality materially adds to its usefulness in a disease accompanied by such great exhaustion. I have seen convalescence established after a few hours' rest procured by a single dose, when other drugs had failed in doses which were regarded safe. The delirium which had previously existed would be absent on awakening, the temperature reduced, the pulse approaching the normal and sleep would again come without the aid of hypnotics.

In melancholia accompanied with hallucinations which produce only a mild degree of excitement, and in the mild forms of mania, chloralamid has proved useful in my hands.

In these cases, which had frequently required some hypnotic every night for a long time, or get no sleep during the night, I have been able after using chloralamid for several successive nights, frequently to suspend its use for several nights and the patient still sleep well. In most cases I have at least been able to gradually reduce the dose. In cases where I have used it for several months continuously, I have noticed no ill effects on its withdrawal. This class of cases usually require from 30 to 40 grain doses. In

cases of melancholia with frenzy and mania, cases attended with much excitement, chloral hydrate is more satisfactory on account of its more rapid and decided action.

In nervousness accompanying disorders of the uterus and its appendages, I have found 10 or 15 grain doses taken after each meal to reduce the nervous irritability during the day, and rest at night to follow without any unpleasant symptoms.

I have not had opportunity to test its curative powers in the treatment of epilepsy, although its use in this connection has been suggested. However, I used it in one instance in which it appeared to exert marked influence in controlling the seizure; a summary of the case will give a better idea of the results obtained:

Patient, female; age 42 years. Was in the epileptic ward of the New York City Asylum for the Insane. Had been an inmate of the institution for seven years. Had been subject to epilepsy since childhood. Convulsions usually occurred in groups of ten or twelve in twenty-four hours, after which she would not be affected for several days or weeks.

Jan. 15, 1891, had nineteen convulsions which always began on the right side of the face, extended successively to the right side of the neck, right arm, right lower limb, and finally became general. They were always accompanied by a cry and complete loss of consciousness. The pupils remained unchanged. The character of the convulsions was such as to point to cortical irritation. January 16, there occurred sixty-one convulsions of the same character as above described. After about forty-eight hours the convulsions were confined to the right side of the body. This continued three days longer, after which they were confined to the right side of the face and neck. While the convulsions had become less extensive they had become more frequent in spite of numerous remedies employed, until the 25th inst., when between the hours of 7 o'clock A.M., and 7 P.M. there occurred 150 convulsions. During this day she took 2 drachms of chloralamid in six doses. That night she slept from 8 P.M., until 6:30 A.M., and had no seizures. The pulse and respiration were normal, notwithstanding her exhausted condition.

On awakening the convulsions reappeared with less frequency at first, but gradually became more frequent until during the twenty-four hours from 7 P.M. of the 28th inst., until 7 P.M. of 29th inst., there occurred 447 seizures. Patient was very much exhausted and as she would partly regain consciousness, would murmur, "so tired, so tired." Chloralamid was again administered. This time half drachm doses were given every six hours. After the second dose she slept about one hour, during which time the convulsions ceased. They commenced immediately on awakening. After third dose she slept three hours. After sixth dose the patient slept six hours, until awakened. The chloralamid was continued every six hours in same doses. On being aroused would answer questions rationally, say she had had a good sleep and was getting rested. Continued to have convulsions when awakened which grew lighter and less frequent until February 3, when they ceased, having had 3,242 convulsions in eighteen days. After resuming the use of chloralamid the convulsions occurred as follows, to wit: On the first day 168; the second 143; the third 95; fourth, 22. She was kept sleeping continually three days longer, making five days in all, she had slept, excepting when aroused every six hours.

At no time was there noticeable any depression of the circulation or respiration. She would at all times answer questions rationally, eat what was prepared for her and attend the calls of nature when aroused. Secretions appeared normal. About twelve hours after taking last dose she awakened of herself. Complained of slight headache. Was drowsy during the day and slept well the following night. Next morning awoke feeling refreshed and rapidly regained her former health.

I have not had opportunity to again test the drug in this manner as I was compelled, on account of ill health, to sever my connection with the institution, and have since been able to engage in practice to a very limited extent until recently.

Much depends on the manner of administration of chloralamid, and to this may be attributed a portion,

at least, of the disappointments experienced by some in conditions which have been reported favorable to its use by others.

The dose as generally stated is from 1 to 3.50 grams for adults. I most frequently begin with a small dose and increase as I find necessary to produce the desired effect. Sleep usually follows the administration of the proper dose in one or two hours and is of six to eight hours' duration. If a feeling of lassitude follows, it is probable that a smaller dose will suffice and be free from any unpleasant symptoms.

It should be administered dry only when stomach digestion is good. It should then be given in a fine powder, not in the crystals in which it occurs in commerce, and immediately after the ingestion of food, while the contents of the stomach are acid.

Good results have been obtained by administering it with an alcoholic beverage during the interim of digestion, but this mode is less reliable. When administered in powder it should be placed dry on the tongue or in capsule and washed down with water, whisky or wine. The only advantage in giving it in powder is to avoid the taste, which is neither very disagreeable or persistent.

The preferable manner of administration is in solution. It may be dissolved in alcohol in proportion of 1 grain to 1½ minims. It is slowly dissolved in water and more readily in water to which about 3 minims of dilute hydrochloric acid to each 1 gram of chloralamid to be dissolved has been added. These solutions may be diluted with water or other agreeable vehicle for administration. In no case must it be dissolved by aid of heat or administered in hot liquids. It is incompatible with caustic alkalies and the alkalin carbonates.

As compared with chloral hydrate, it may be said that chloral is more rapid and powerful in its action and is to be preferred in cases attended by extreme degrees of pain or nervous excitement, notwithstanding its well-known disadvantages. Chloralamid is safer, less disagreeable to the taste, free from disturbance of the circulatory and digestive systems, and free from depressing after effects. Sulfonal is followed by more languor and general depression.

In conclusion, I desire to quote approvingly from the excellent paper of Dr. Clevenger before referred to, regarding its hypnotic action:

"It would be folly to expect that any single remedy for insomnia would be available in all instances, for just as sleepless states may be caused by any of the multitude of maladies to which the body is liable, so must there be numerous appropriate measures of relief, when relief is at all possible. The advice, to seek and remove the cause of sleeplessness is sensible enough, though in too many instances the cause is only conjectural. Nevertheless, a rational system of hypnotic use can be secured on a physiologic basis, and with far more satisfactory results if we duly regard the cause of the loss of sleep and existing bodily conditions. For example, a dose of ergot in some hyperemic states may relieve pain or cause sleep by lessening the vascular tension upon which these disabilities depended. A hot bath may distribute the circulation and act derivatively upon organs which, when congested, caused the distress and wakefulness. Massage acts similarly when scientifically applied, and when unskilfully made use of may add to the discomfort; for example, if derivation from the head is set up by massage it will

relieve cerebral hyperemia, but add to cerebral anemia, so this method must be resorted to with full knowledge of the physiologic results aimed at.

"In a general way, we may classify hypnotic action as accomplished by derivation, such as by removing irritative quantitative causes; by elimination of quantitative or qualitative causes, as of some toxic agent; reconstructive action by re-supplying parts in states of defective nutrition; sometimes by minimizing activity until rehabilitation can overtake waste with supply; by restoring normal function as with digitalis or alcoholics. The least desirable of all methods being such as merely stupefy and overload the circulation with effete or poisonous material through interfering with elimination, or by destructive changes induced in nerve tissues or the blood upon which the nerves depend for sustenance.

"So eliminative functions should be kept in good repair, if possible, when almost any kind of a hypnotic is given, particularly such as are likely to add some toxic material to the system; but the ideal sleep procurer would be one that abstracted nothing from the nervous system that it contained normally, nor added thereto anything deleterious; and as sleep is a process of repair or feeding of the nerves and their ganglionic centers, still more effective would be whatever caused sleep by repair of such waste; and unless credible evidence to the contrary appears in the course of time, we are in possession of such a hypnotic in chloralamid."

PRESCRIBERS AND DISPENSERS.

Read in the Section on Materia Medica and Pharmacy at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY W. M. SEARBY, Ph.C.

SAN FRANCISCO.

The courteous invitation given by the AMERICAN MEDICAL ASSOCIATION to the American Pharmaceutical Association to be represented by delegates at this important gathering and the further courtesy of requesting some of these delegates to read papers, would seem to indicate a generous out-stretching of the hand on the part of your ASSOCIATION toward ours. On behalf of the American Pharmaceutical Association I accept, therefore, the proffered hand, and reciprocate the desire for more cordial relations between these two branches of science and art—medicine and pharmacy. And I avail myself of this opportunity to make an effort in the direction referred to; for it is not to be denied that, while professedly friendly, and actually so in the main, there is yet a good deal of friction at certain points, and unfriendly remarks are sometimes heard, and ungenerous actions indulged in by members of these two great bodies toward each other. Occasionally these expressions find their way into the journals, but more frequently they are not out-spoken and therefore can not be replied to by the party who might feel aggrieved thereby. The proper way to deal with wrongs, real or imaginary, is to look at them dispassionately and if possible to let the injured parties meet and frankly discuss whatever differences there may be between them.

Medicine and pharmacy are so dependent upon each other that they should go hand in hand, and should not allow minor differences to alienate them from each other. It has seemed to me that of late the tendency has been more than ever towards an un-

friendly feeling between the members of the two professions. Physicians of prominence are known to be so inimical to pharmacists, as to openly advocate doing away with drug-stores altogether, and I have heard pharmacists, accomplished men, who for a life-time have scrupulously kept those ethical observances which are due to physicians, declare that in their opinion doctors cared nothing for druggists and would "down" them if they could. Recently a prominent medical journal has thrown out a hint that doctors might stock their offices with ready-made prescriptions as a kind of retaliation upon druggists for prescribing. As an offset to this, graduates in pharmacy finding that they can not obtain their share of prescription business without paying commission which they can not conscientiously do, are taking degrees in medicine in order to practice both professions, still further crowding medicine without relieving pharmacy. It seems to me that this tendency from two opposite directions, to unite the practice of medicine and pharmacy in the same individual is a retrogressive movement; and I venture to suggest that a more dispassionate view of our respective grievances is necessary if we would check the evils of which we complain.

Let us consider, then, in the first place, who should prescribe medicine? Upon this point there can be no two opinions. The physician by his knowledge of *anatomy, physiology, pathology*, and the other branches of medical science in which he has been educated, is the only competent person to diagnose disease and to prescribe treatment. But is he the only one who does prescribe? By no means. Many people prescribe for themselves, and if they are told the same truth concerning medicine, that has become proverbial as applied to law, namely, that he who is his own doctor has a fool for his patient, they are apt to become indignant and reply that they know what they are about. There is another large class of persons who take pleasure in prescribing for their friends, and these persons again can not be made to believe that, so far as the case in hand is concerned, they do not know more than all the doctors. The evils of such prescribing as this can not be reached by codes of ethics or by any measure of reform instituted by physicians and pharmacists.

But there is a certain amount of prescribing done in drug-stores by men who lay no claim to a medical education, and whose practice in this regard can not be defended. Reputable pharmacists, as well as physicians, are anxious to see this irregular practice abated, as it is an infringement upon the province of physicians and therefore unfair, and also has the effect of lowering pharmacy in the esteem of the public as well as of physicians. In what way can this counter-prescribing be lessened? I suggest in the first place that it can not be checked by scolding or by retaliation, but rather by cultivating more cordial relations between the two professions, and by a certain degree of concession on both sides. It is to be borne in mind that any retaliatory measures adopted by physicians in this matter will affect the reputable pharmacists who are not doing the counter-prescribing, while those who are transgressing will not be affected thereby.

It is not to be forgotten in a discussion of this question that some physicians are inordinately sensitive on this subject, so they would prohibit the dispensing of almost all drugs and medicines that are

not ordered by physicians. Whatever our views of the case may be, whether we like it or dislike it, the fact can not be denied that the American people will not submit to such stringent regulations. You can not compel an American citizen to employ an architect when he wants to build a dog-kennel. In regard to the use of drugs and medicines they feel themselves free to consult a physician or not, according to their own judgment, and can not be driven into it, by the combined efforts of all the doctors and druggists in the country. Again, those who have had much experience behind the counter in a drug store, will bear me witness that even when there is the most conscientious and scrupulous regard for the rights of physicians and the most painstaking adherence to medical ethics, it is still impossible to answer many of the questions that are daily put to the druggist in regard to the nature, property and doses of medicines without appearing to suggest the use of certain ones in specified cases. Not only is the druggist consulted in regard to disinfectants, antiseptics and many other hygienic and remedial agencies, but his opinion is frequently asked in regard to the nature, use and doses of drugs, the best method and time of administration, etc. A refusal on his part to give the desired information would be attributed by the majority to ignorance, and by the remainder to boorishness. As a business man he can not afford to allow his patrons to leave his store with any such misapprehension concerning himself or his establishment. Furthermore, there are a few slight ailments which the public absolutely expect a druggist to prescribe for, which do not partake of the nature of medical treatment, since the patient diagnoses his own case, such for instance, as a morning headache, slight bruises or trifling injuries; in fact, any such ailments as people are in the habit of prescribing for themselves. The druggist, when requested, is expected as a matter of course to suggest a remedy, and there is no more thought of medical treatment than when a bar-keeper mixes, a "pick-me-up," or a shoe dealer selects for you a shoe that will not hurt your corns. When physicians interpret ethical relations so rigidly as to prohibit druggists from performing these trifling courtesies for their customers, they widen the breach between the two professions, having no experimental knowledge of the injury the pharmacist does himself if he declines to render this service. The conscientious druggist is between two fires. On the one side are customers expecting information which he could readily give, and abundantly satisfied that any advice he might offer would be given rather as a friend than as a medical adviser. On the other side stand the medical profession jealous to a degree, lest by giving any advice whatever he prevent the applicant from consulting a physician. He has to fall back on his common sense, which will lead him to gratify such requests as are reasonable in the direction I have intimated, and yet to avoid assuming the functions of a medical man.

If we now ask the question, "Who shall dispense medicines?" the answer is no less positive than that given to our first query. The pharmacist is the proper dispenser of medicaments. This statement will bear no more qualification than my previous assertion that the physician is the proper person to prescribe. And yet there are circumstances in which physicians may dispense medicine with advantage to themselves and their patients. Common sense again puts in a

plea and prevents a too rigid application of the general custom of separating prescribing from dispensing. It is necessary for the doctor in some cases to secure immediate relief for the sufferer, and so the pocket case and hypodermic syringe are his constant companions, more frequently used than the surgical instruments which were formerly his chief or only *vade mecum*s. The greatest stickler for the keeping apart of medicine and pharmacy can not raise any valid objection to a physician having in his office or in his residence a few remedies for emergencies, nor is a doctor to be classed among the old fogies because he chooses to control the use by his patients of such drugs as morphin, chloral hydrate and cocain, by dispensing these himself in tablet or other convenient form, so long and so long only as the need of their use exists. Other cases will suggest themselves to the minds of those present, where physicians may advantageously dispense remedies for temporary use. But these exceptions to the general rule do not constitute an argument for the abrogation of the rule itself.

The drift of the times in all professions and businesses is toward specialism. Particularly is this the case in the practice of medicine in which we have almost every organ of the body a subject of special study, and every class of diseases treated by specialists. If the study of medicine is so large, so vast, so difficult, so comprehensive, that no man can accomplish it all, why should the physician seek to add to his already over-burdened curriculum a knowledge of pharmacy? Medicine can not be correctly dispensed without an underlying knowledge of chemistry, pharmacognosy and pharmacy to a degree that is quite beyond the attainments of the average physician, I think I might say, of any physician, who at the same time keeps himself abreast of the times in his own profession. The sciences upon which pharmacy is dependent are advancing with strides no less marked than those of medicine. Pharmaceutic manipulations and processes are continually being improved, and these improvements are largely dependent on a better knowledge of organic chemistry and of the constitution of drugs. Busy pharmacists even find it difficult to keep pace with the times both in these branches of knowledge and in the improved methods of administration; how then shall a physician, already overburdened with his practice, keep himself up in these studies?

Strictly speaking, then, physicians are the only ones who should prescribe. Any deviation from this rule, such as I have hinted at, would only apply to trivial, common, every-day experiences, and the pharmacist should always use his influence as far as he can, not only to avoid prescribing himself, but to dissuade his customers from doing the same. He should seek to check the pernicious habit many persons have of repeating their own prescriptions *ad infinitum*, and particularly of allowing these same prescriptions to be repeated for the benefit of other people, "friends of the family," and so on. A great injury is often done to physicians by this practice, and it must be admitted that where the medicine is not of a dangerous character, such as preparations of cocain, morphin, chloral, etc., druggists are not as careful to prevent repetition as they ought to be in justice to the doctors. Only by a more friendly relation between them can this habit be checked.

But while holding that physicians should do the

prescribing and pharmacists the dispensing, I would call your attention to the fact that much of the prescription-making and compounding is done by a class of persons who are enemies of both physicians and pharmacists. I refer to the large army, which is daily increasing, of proprietors of pharmaceutical specialties. This class of persons are not owners of corner drug stores or physicians in legitimate practice, but wealthy corporations and private individuals who trade upon the weaknesses of humanity, particularly upon those of physicians. Able to command unlimited capital, they hire physicians to act as decoy ducks to bring other doctors within range. Their immense wealth and patronage enables them to subsidize medical journals, if indeed they do not own them outright, and by the power of money and plausible presentations and representations enlist a large portion of the medical fraternity in their service. Playing upon the ignorance of some, the indolence or recklessness of others, they have succeeded in bringing the practice of medicine in the United States to such a pass that the modern druggist's prescription-file is a curiosity, owing to the large percentage of orders for special preparations, many of them of unknown composition, most of them made by unknown processes. If these preparations were any better than those made by the intelligent pharmacist, surpassing the latter either in their purity or elegance, there would be some reason why physicians should so commonly prescribe them; but as a class the articles I refer to are in no way superior to similar preparations made by reputable pharmacists. There is some slight excuse for their prescribing by name certain polypharmic remedies because the trouble of writing out a long formula is of some consequence to a busy man, but the days of polypharmacy are passing away, and many of the prescriptions for special preparations call for one article only. A lazy prescriber is a good subject for the medical drummer, but the latter has a better friend in the ignorant one, who is content to let the manufacturer of pharmaceutical specialties do his prescribing for him. This class of men, with one stroke of the pen write a prescription, copying the directions from the printed circulars with which they are so abundantly supplied. Medical men generally are fully aware that this class of prescribing is injurious to the druggist, whose profit on such prescriptions is no larger than the drygoods man's profit on dress goods, notwithstanding the responsibility the druggist has to bear, arising from the powerful nature of some of these medicines.

I do not wish to be understood as objecting to a physician's specifying the name of the maker of a few articles that are of superior quality to those usually made by good pharmacists, nor to such as by their greater attractiveness in appearance, taste, etc., make them more acceptable to the patient. It is the province of the pharmacist to aid the physician to overcome the repugnance many persons have to nauseous doses and nasty local applications, by preparing medicaments so as to be as agreeable as possible without sacrifice of effectiveness. I am objecting to secret or semi-secret preparations with copyrighted names, and to the thousand and one ready-made elixirs, syrups, solutions, etc., most of which are no better than those made by any good pharmacist. Physicians are not generally aware of the injury they do themselves by sending out such pre-

scriptions. Any druggist who will be candid enough to admit the whole truth will bear me witness that a large portion of their more intelligent customers soon find out that their prescriptions in such cases call for a ready-made compound, the name of which they find some means of ascertaining. Should the medicine prove beneficial, they not only take it themselves on future occasions when similarly affected, but recommend it to their friends. Soon these specialties, which are practically patent medicines, secure a large sale, chiefly through the influence of physicians who were the first to introduce them favorably to the public. When this has been accomplished, the proprietors usually cease catering for the patronage of physicians exclusively, and advertise their wares indiscriminately like any other quack medicines. Thus, in one way or another such preparations as Scott's Emulsion, Fellows' Syrup, Bromo-caffeine, Listerine, Bromidia and many other compounds, some of them harmless and some dangerous, have passed out of the hands of physicians and are bought by persons who use them without medical advice. These are not poor people, but mostly of the well-to-do class, who are able to pay the doctor's bill, and who when sick do not think of asking a druggist for advice.

Now where is the necessity for a physician prescribing such compounds? Does he not know enough of materia medica and therapeutics, of the properties and doses of medicines to select his own remedies? Of what avail is all his instruction in these branches of medical education, if, when he engages in practice he lets the patent medicine manufacturer or the manufacturing pharmacist do his prescribing for him? And of what use to the pharmacist is his education in pharmacognosy, chemistry and pharmacy, if he has nothing to do when putting up a prescription but to count out a few ready-made pills or hand out a bottle of ready-made elixir?

The professions of medicine and pharmacy are both suffering from the inroads that are being made upon them. The outlook for both is discouraging. The young practitioner is shut out from practicing among the poor, by dispensaries and clinics that are now doctoring millions of patients every year, who have no right to claim eleemosynary service of this kind. He can not get practice among the rich because he is unknown; the wealthy preferring to employ eminent physicians for whose services they are well able to pay. So the young medical graduate waits, and waits, often eking out a precarious existence, "living as a gentleman on forty pounds a year." The pharmacist's legitimate occupation is already invaded by the substitution of ready-made pharmaceuticals of every kind, by the free dispensaries and clinics, as well as by the fraternal societies who furnish medical attendance for a song and medicines at cost. Yet, while both professions are already injured and still further threatened we are ready to quarrel over trifles, when we should join hand in hand for material advances against our common foes. Once more, let me plead for a little common sense. Let us stop our quarreling about trifles and come to some agreement whereby, in a general way we can defend and protect each other. Let physicians be careful about prescribing pharmaceutical specialties, let them frown upon the unprofessional puffing which these preparations receive in the medical journals. Let us see that dispensaries and

clinics are not abused, to the despair of the young practitioner and the grievous injury of the drug trade. On the other hand, let pharmacists be more cautious to avoid exercising the functions of physicians by declining to give advice when asked for it, except in most trivial matters. In fine, let physicians and pharmacists observe the Golden Rule, and their relations will be more pleasant and their calling more profitable.

DISCUSSION.

DR. F. E. STEWART, of Watkins, N. Y.,—called attention to the fact that pharmacy as now conducted in this country is a trade and not a profession, and therefore can not be recognized in scientific and professional bodies. It was his opinion that pharmacy should drop all claim to proprietaryship in its preparations; it should publish its working formulæ, and do away with secrecy. When they do this, pharmacists could be recognized as professional men, and secure a standing in scientific and professional circles. He also called attention to a paper of his own on the same subject, entitled, "A New Medical Specialty," published in the *Medical and Surgical Reports* for 1880, or thereabouts. In this paper, he had maintained that pharmacists should graduate in medicine and then practice pharmacy as a medical specialty. If pharmacists would graduate in medicine and practice pharmacy in a professional manner, then they could join the Section on *Materia Medica* and Pharmacy of the AMERICAN MEDICAL ASSOCIATION, and we would have a Section worthy of the name. Some time ago the *Druggist's Circular* published a paper of mine entitled, "Is Pharmacy a Profession or a Trade?" A prominent firm of pharmacists in Baltimore read this paper and determined to start a pharmacy run on the principles therein enunciated. They did so, eliminating from their business the proprietary medicines, fancy goods, soda water, cigars and other things not belonging to the pharmacy. The success of this firm has been remarkable, and it has secured the indorsement of the entire medical profession of Baltimore.

DR. FRANK WOODBURY, of Philadelphia,—said that there are tradesmen in all professions, and that in pharmacy just now the question is: "Who shall rule; the tradesmen or the professional men?" He was glad that the American Pharmaceutical Association had accepted the invitation of the AMERICAN MEDICAL ASSOCIATION to send a delegation each year to this Section on *Materia Medica* and Pharmacy. There had been too much neglect of pharmacy during the past in medical schools. There is even at present such ignorance of pharmacy upon the part of physicians that their prescriptions are the laughing-stock of the pharmacists, on account of the ignorance displayed, both of pharmacy and chemistry. On the other hand, pharmacists exhibit much ignorance of the physician's responsibility by their willingness to prescribe. There are many little things the pharmacists might do to aid patients who come to their drug-stores for help, but when a patient comes in the store and calls the pharmacist "doctor," and asks him to prescribe, he should at once repudiate the title and frankly say that he is not a doctor but a pharmacist, and refuse to take the responsibility. Whether physicians should dispense their own remedies or not, is a question that must be answered by circumstances. The custom of physicians dispensing their own remedies is not an improper one but it has been a failure as the rule, in the large cities, but in the country, where the facilities for dispensing on the part of the pharmacist are poor, it is a different matter. I would have the pharmacists study medicine so that they can appreciate the responsibility of the physicians as prescribers, and then they would do well to refuse to prescribe, but adhere strictly to

their specialty of dispensing medicines. This would solve many difficulties. In some countries, the pharmacist and physician is combined, notably so, in Central and in South America. Young graduates in medicine, educated in both departments, might practice both for a time until established, and then branch off into either specialty as the circumstances directed.

The firm referred to by the last speaker have won the respect of the medical profession of Baltimore beyond their expectations. The friendly feeling for this house manifested in that city is a strong argument in favor of the idea that the ordinary pharmacist is an enemy to the physician. In England they prosecute through the medium of the pharmaceutical societies, those pharmacists who prescribe over the counter, the practice being forbidden by law under severe penalties.

SERTHERAPY; INOCULATION WITH SERUM IN TYPHOID FEVER.

A CASE FOLLOWED BY RECOVERY.

BY ALFRED C. GIRARD, M.D.

MAJOR AND SURGEON, U. S. ARMY, FORT SHERIDAN, ILL.

The treatment of various disorders with toxine inoculations is as yet in its infancy—it may turn out to be a fallacy. It can not be denied, however, that it has in a number of well-authenticated instances achieved remarkable results, and there is sufficient justification for its use, at least in sickness where all the usual remedies have proved unavailing.

When a number of such cases shall have been collected in the literature, establishing favorable effects, this method of treatment will find more general introduction and the statistics of a larger number will then assign it its proper place. This is my reason for publication of this case:

J. F. H., aged 23, after two weeks of prodromal symptoms—headache, general aching, irregular chills followed by short attacks of fever, loss of appetite, was admitted to hospital with a temperature of 103.4, severe headache, loose discharges, heavily coated tongue, roseola over abdomen—a marked case of typhoid fever, result of common infection with twenty others under my care.

After a week of gradual defervescence, the temperature rose to nearly 106, with general aggravation of all the symptoms, especially a large number of alvine discharges, and remained, with slight irregular defervescences due mainly to application of cold and to antipyretics, in the neighborhood of 104 degrees for two weeks. The countenance became pinched and dusky—profuse sweats several times daily—total loss of consciousness with muttering delirium and subsultus tendinum—involuntary discharge of urine and feces. Dissolution appeared only a question of hours.

The treatment had been the usual one, successful in twenty other cases of the same epidemic, excepting one case of perforation.

In this extremity I determined to give the patient a chance with inoculation of serum, as reported by W. E. Hughes and W. S. Carter in their paper on "Injection in Pneumonia and Typhoid Fever of Serum from Convalescents," in No. 6 of the *Therapeutic Gazette* (June 15, 1894), to which I refer for the rationale of the treatment. They report only three cases, of a rather mild type, with injections on the twelfth day, (in two of the cases repeated twice on succeeding days), with steady defervescence resulting.

The serum was obtained either by venesection or by blistering from convalescents, in whom somewhat less than two weeks had elapsed since the end of fever.

I selected a convalescent who, after a typical case of typhoid had been free from any "temperature" for seven days. The skin was carefully disinfected and a blister raised with cantharidal plaster, from which eight cubic centimeters of serum were received into a sterilized test

tube. This was injected subcutaneously in the abdominal skin of my patient.

No immediate marked effect was expected or observed in the general condition, but the temperature rose no more than up to 102, except the second day, when it rose to 102.8, but fell to 100.5; the third day it rose to 103.4 and fell to 100.5; the fourth to 101.8 and fell to 98.4; rose again to 101 on the fifth day, and thereafter with slight changes remained normal. The patient gradually recovered consciousness and is now, nineteen days after injection, although extremely reduced after his fearful ordeal of twenty-seven days of fever, on a fair way to recovery.

This may be a case of *post hoc, ergo propter hoc*; but on the other hand it may be an additional evidence in favor of the toxine treatment.

There seemed to be no agent at work, outside of a dispensation of Providence, to account for this steady improvement at that particular time, and the result appears to be as clear as most clinical observations.

NOTES ON LITHIUM.

BY ENNO SANDER, Ph.D.

LATE PROFESSOR OF MATERIA MEDICA AT ST. LOUIS COLLEGE OF PHARMACY; EX-PRESIDENT OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.
ST. LOUIS, MO.

When Augustus Arfvedson, a Swedish student at Upsala, presented to his friend and teacher, the celebrated Berzelius, the new substance that he had separated from the rare granitic mineral *petalite*, found at the mines of Utoë in Sweden and which he had determined to be an alkali, he requested Berzelius to suggest a suitable name for it. After much thought, they finally decided to call it lithium (Greek, *lithos*, a stone), because it was the first alkali that had been obtained directly from the mineral kingdom.¹

Lithium, symbol *Li*, the elementary substance, appears as a silver white, soft metal, whose specific gravity is only 0.59 or about six-tenths the weight of water; it is consequently the lightest of known metals. Its chemical equivalent is 7, and its atomic volume 11.9. In the spectrum it is recognized by a beautiful bright red line.

While lithium does not occur free in nature, it is found in a certain class of micas, ingredients in the primordial rocks,² in company with its congeners, potassium and sodium. The composition of these micas is more or less definite and consists, in the main, of aluminium, the alkalies (lithium, sodium, potassium, and even caesium and rubidium), small quantities of iron, and manganese combined with silica and fluorine. Where, however, aluminium is replaced by iron or manganese or both of them, phosphoric usually replaces the silicic acid; as, for instance, in amblygonit, lithiophilite, triphylin, etc. The lithia micas which are found in the granitic rocks of New England have been fully described by F. W. Clarke, of the United States Geological Survey,³ whose report contains also a number of analyses of the most important specimens. They are met with all over the world, although seldom in sufficient quantities to render the extraction of lithium profitable. These granitic rocks become gradually disintegrated under the combined influence of water and the atmosphere with their accompanying gases, and the ingredients rendered soluble by the influences named are leached out, and the solutions stored up to reappear in mineral springs. These, flowing into brooklets and thence into rivers, finally reaching the ocean, permeate the alluvial soil, and from this are taken up by growing plants. From the latter they

pass into the animal organism, and thus it is that mineral constituents, like lithium, are distributed throughout nature, organic and inorganic. Sometimes they occur in such minute quantities that their presence is discoverable only by means of the spectro-scope, that wonderful instrument by which we are enabled to analyze the light of the fixed stars and declare their constituent elements, though the agency through which the message comes to us, light, may have been thousands of years on its way.

Although the minerals, in which lithium occurs, are found in the primordial rocks of almost every region of the earth, they occur but sparingly, generally in small masses; embedded in the granitic rocks, which carry very small proportions of lithium, from a mere trace to, at the utmost, 10 per cent.

It is not the intention of the writer to enumerate in this paper the various minerals in which lithium has been found, nor to give its percentage in these minerals; however, it may be interesting to the reader to know that a large percentage of them are found in the New England granites; but, as has been stated, in few of them only does the element occur in such quantities as to make them commercially available in the production of lithium salts. The same is true of the most of the European granites. Two of these minerals only appear to be thus available, triphylin and lepidolith. Triphylin is a mineral in which the alkaline and metallic bases are combined with phosphoric acid. It is found in large discrete masses in the granite of Rabenstein in Bavaria, and is easily decomposed and well adapted to the manufacture of lithium salts.⁴

The bases in lepidolith are combined with silicic acid. It occurs principally in the decomposed granitic masses of Bohemia and Moravia. Since its discovery the world has drawn from this source its principal supply of the salts of lithium.

Filsinger⁵ describes the processes used by Schering in the preparation of lithium carbonate, including the treatment of the mineral, which are very similar to the methods of H. Müller (see above) and others. The following is a *résumé* of the processes referred to: Lepidolith, pulverized and levigated, is made into a thin paste with sulphuric acid carrying a portion of nitric acid, and the mixture is kept in a warm place, with frequent agitations, until lumps have been formed. Heat is now applied until the free acid is driven off, and the residue is calcined. The mass, while still hot, is leached with boiling water, which leaves an undissolved residue of almost pure silica. The liquid thus obtained is treated with potassium sulphate which, combining with the alumina present, forms crystals of potash alum. The liquor drawn from the alum crystals is concentrated by evaporation during which process alum continues to be formed. Finally, lime is added to precipitate any possible residue of alumina, from which the liquid is filtered off. Barium chloride is now added to the filtrate, and the sulphates present converted into chlorides. The liquid is drawn or filtered off, evaporated to dryness, and the mass treated with dilute alcohol. From this solution the alcohol is recovered by distillation, and the watery residue treated with ammonium oxalate, which precipitates the lime, iron, etc., still in the solution. The liquid filtered off from the precipitates, and containing all the alkalies in the form of chlorides, is further concentrated and the concentrate treated with ammonium carbonate. This

throws down the lithium in the form of the carbonate salt (Li_2CO_3) which is washed with alcohol of 60 per cent. and thus freed of impurities. By this process lepidolith yields about 8 per cent. of lithium carbonate, equivalent to 1.51 per cent. of metallic lithium.

For a score of years after its discovery by Arvedson, as mentioned in the beginning, lithium received but little attention. Berzelius gave it a bare mention in 1824, and it is merely alluded to by others, who found it in the waters of various springs in Bohemia and elsewhere. In 1841, Lipowitz published a paper in the *Annales de Chimie et de Pharmacie*, in which he reviewed the combinations of lithium with various acids, and dwelt particularly upon its marked affinity for uric acid, with which it forms an acid salt, "the most soluble of all the urates, being soluble in 60 parts of water at 122 degrees F., and not separating therefrom on cooling."⁶ Dr. Alexander Ure, in 1843, refers to it as a remarkable solvent of sodium urate, but his use of the substance in practical therapeutics was rendered impossible by its scarcity and high price, and it was not until 1858 that it again attracted any attention in therapeutics. About that year Sir A. B. Garrod writes that he "commenced the administration of lithium salts as an internal remedy, both in cases of uric acid diathesis connected with gravel, and likewise in chronic gout, and was much gratified at the results." But he subsequently adds, "the great bar to the free use of lithium salts in medicine has been their expense."⁷

The price of the remedy, however, does not seem to have deterred Garrod from its continued use, since we find him, in the treatise referred to, devoting a very considerable space to a review of the important therapeutic results personally obtained by him from the use of the salts of lithium, and their undeniable superiority over any other alkaline salts whatever, for both internal and external exhibition. An indorsement so unqualified, coming from such high authority, as a matter of course at once attracted the attention of the medical world to the remedy, and gave an immense impetus to experimental investigation with lithium salts in therapeutics. It is seldom, however, that the individuality of an investigator or observer is sufficiently pronounced to carry universal conviction of the truth of his observations or conclusions, especially in researches of this description; and here we find the medical profession at once divided as to the correctness and value of Garrod's conclusions. A controversy was inaugurated, on both sides of which talent and learning were enlisted, and which has brought about a very decided advance in knowledge of the behavior of the alkalies in general, and especially towards uric acid. We need not dwell on the merits of this discussion, but pass to more modern matters.

The behavior of lithium carbonate toward uric acid, and its influence upon the solubility of the urates in the human economy, have in many instances without doubt, been greatly exaggerated, a fact due mainly to the lively imagination of owners of certain mineral springs, who herald their waters not merely in the daily press but in medical and trade journals through advertisements, in which to quote Dr. A. C. Peale:⁸ "The fact that the water contains lithia, if only a trace, is made prominent by the incorporation of 'lithia' into the name or designation of the spring."

Louis Siebold rose against these unwarrantable ex-

aggerations and usurpations in a paper on "Medical and Chemical Misconceptions about Lithia," read before the British Pharmaceutical Conference in 1889, the substance of which is that the lithium compounds "owe their place in the materia medica originally to the observation that, as compared with potash or soda, a smaller amount of lithia suffices to form a soluble salt with uric acid, and that this salt is more readily soluble in water than the corresponding potassium and sodium salts. From a chemical point of view, its greater antacid or neutralizing power presents itself as owing to its low atomic weight." "It follows from the atomic weight of lithium and potassium that 74 parts of lithium carbonate possess the same acid saturating power and are likely to dissolve as much uric acid as 138 parts of potassium carbonate." This saturating powers however, is confined only to the carbonate and indirectly to the citrate, (which becomes converted into the carbonate within the organism); but "it is extended to a number of mineral waters containing lithia, generally mere traces of it, notwithstanding the fact that what there is of lithium in these waters generally occurs there as chloride or sulphate, salts which neither directly or indirectly act as alkalies and possess no solvent action on uric acid."

While such rational arguments are convincing to all reasoning men who, in fact, never entertained a different opinion to that expressed by Siebold, they are eminently dissatisfactory to those who prate of "God-given," "Heaven-endowed" fountains of health, "medicines wrought in the laboratory of Nature," and who are ready to apotheosize lithium and place it in the firmament alongside of Hygeia, or with the benign goddess of Greek mythology who hovered over mineral springs and endowed them with healing virtues. This idea seems still to be a favorite one with some mineral-spring proprietors, whose cards and advertisements display conspicuously the winged female with scanty drapery and small regard for the proprieties.

The occurrence of lithium in natural waters is necessarily limited, not merely on account of the limited amount in which it is found, but more especially on account of its existence *always in combination with the most insoluble constituents of the primordial rocks*. One need not, therefore, be surprised at finding that the average content of the lithium salts in mineral springs is not more than 4 parts in 100,000 of water, or say 1 grain in $3\frac{1}{4}$ pints.

"Despite the long list of 'lithia springs,' whose advertisements we find in the medical and secular journals of the day, the actual number of those containing upward of four grains of lithium bicarbonate (equal to about two and five-tenths grains of the dry carbonate) to the gallon, is but fifteen,"⁹ and this amount has been reduced by more recent analyses in which more accurate methods for the estimation of lithium were followed.

The physiologic investigations of the last decade into the nature of uric acid, and the importance of the rôle played by it in the human economy have maintained and even intensified the interest in the therapeutic value of the behavior of the salts of lithium towards this acid, first introduced by Garrod and sustained by his successors. The opposition to the views of Garrod, which sprung up years ago, culminated two years since in an elaborate work by Dr. Alexander Haig ("On Uric Acid," 1892), who

undertook to prove experimentally on his own person that lithium administered for the elimination of uric acid from the system, not only failed to accomplish the purpose, but "diminished the excretion of uric acid." In defense of this position he quotes from Rose to the effect that lithium forms "insoluble compounds with phosphate of soda and triple phosphate of ammonia and soda, salts generally present in animal fluids." The work of Rose has not been accessible to me and I, therefore, am not in a position to assert whether or not Haig properly quoted or understood him, but I find that Dr. Halberstadt asserts that "sodium phosphate causes, in not too attenuated solutions of lithium salts, a crystalline precipitate of normal lithium phosphate;"¹⁰ and Sir Dyce Duckworth¹¹ states that "the normal and bi-urate of lithium easily dissolve in alkaline fluids, also in phosphate of sodium."¹¹

This is in accordance with my own experience, but I found also by actual experiment that no precipitation took place, even after several days, when such solutions are further diluted to 1 part in 250 or more parts of water before being mixed. When we take into consideration the minute amounts of sodium phosphate and lithium salts that can possibly meet in the blood-serum at any given moment, and that each meeting must occur in rapid motion, we must conclude that other causes have been instrumental in producing the results of Dr. Haig's experiments.

Another protest against the conclusions of Haig was recently published by a well-known French pharmacist, M. P. Ardoue, in *L'Union Pharmaceutique* (quoted in the *National Druggist*, Vol. xxi, p. 162), who records a case of gouty rheumatism, in which he had examined the urine of the patient before, during and after treatment, and determined a very decidedly favorable action of lithium salt in the excretion of uric acid.

The four experiments of Gorsky ought to be mentioned also, which he carried out in the year 1889 at the laboratory of Loersch at St. Petersburg on healthy men, each lasting twenty-four days, and by which he arrived at the conclusion that "carbonate of lithia administered in gradually ascending doses, from 2 to 8 grains a day with an effervescent water, increased the daily amount of urine and with it the daily amount of the excretion of uric acid;" and, he continues, "it is very probable that lithia favors the transformation of uric acid into urea, and hence by freeing the system from the acid, promotes a more energetic cellular action." It would therefore seem that the usefulness of lithium salts as a therapeutic agent had not yet outlived itself; but, on the contrary, that the salts will long continue to be employed as a great alleviator of human suffering.

BIBLIOGRAPHY.

¹ Just now while most physicians are better acquainted with the therapeutic properties of lithium than with its history as an element, I deem it proper to resurrect the true etymology of the word, as I find that many members of the profession connect its derivation with its solvent properties towards the stone-like concretions formed in the kidneys and bladder by uric (formerly called lithic) acid. This remarkable property, which earned for it the significant appellation of "lithontriplic," was not discovered until twenty-five years after the separation and naming of the element—a discovery, which while a mere coincidence would have been hailed with delight, had it occurred in other days, by the adherents of the "doctrine of signatures," who believed that every substance in nature, which possesses any medicinal property, indicates the same by some well-marked characteristic or appellation. Thus eye-bright (*cyprasin officinalis*) was deemed sovereign in diseases of the eye; saffrage as a lithontriplic, etc.—(The author.)

TREATMENT OF POTT'S DISEASE.

A Clinical Lecture delivered before the New York Post-Graduate School and Hospital, Sept. 26, 1891.

BY A. M. PHELPS, M.D.

PROFESSOR ORTHOPEDIC SURGERY NEW YORK POST-GRADUATE SCHOOL AND HOSPITAL; PROFESSOR ORTHOPEDIC SURGERY NEW YORK UNIVERSITY; PROFESSOR SURGERY UNIVERSITY OF VERMONT; SURGEON TO THE NEW YORK CITY HOSPITAL.

There is some difference of opinion in the profession in regard to Pott's disease and lateral curvature of the spine, and their treatment. Only a few years ago certain gentlemen in the profession claimed that they cured lateral curvature of the spine after serious bone changes had taken place. It is needless for me to say that their statement is incorrect. I am willing to concede that it is much easier to treat patients with Pott's disease of the spine or lateral curvature, in private practice than in clinics; but lateral curvature when treated even in private, when bone changes have taken place, can not be perfectly cured. That it may be arrested and the physiologic curves remedied, and the patient rendered comfortable, is true of almost every case. Then our aim in the treatment of lateral curvature is directed more particularly to the prevention of the increase of deformity than to the cure of pathologic changes which have taken place in the vertebra from pressure.

In regard to the causes of lateral curvature, I believe that curves occurring high up in the vertebral column, either in the dorsal or cervical region, are nearly always congenital or rachitic. A rapidly growing girl, who sits in awkward positions, or stands in such a manner as to constantly curve the spine, will no doubt develop lateral curvature. The curves which occur in the lumbar region are more frequently due to this cause, a shortened limb or a twisted pelvis, than any other. These, to my mind, are the most frequent causes of lateral curvature. Paralysis of the muscles undoubtedly produce many cases. The serious curves with which we have to deal are located more frequently in the dorsal region, for the reason that, as the spine bends, there is a change in the ribs and in the muscles between the ribs; and before a curve of this kind can be remedied it is necessary that the deformity of the ribs shall be overcome. This is practically impossible according to our present knowledge.

The deformity in lateral curvature is produced by absorption of the vertebra from pressure. As the spine bends, rotation always takes place in the direction of curves. Then we say that nearly all cases of lateral curvature are to be considered as cases of lateral rotary spinal curvature. When more than one curve occurs it is then called double lateral rotary spinal curvature. One of the most common symptoms of lateral curvature is the projecting shoulder-blade and the drooping shoulder. These are cases that find their way to various bandagers, who adjust worthless appliances, and the apprehensions of the mother are put at ease by such charlatans until after a year or two, when the orthopedist is consulted, he finds an incurable curve in the vertebra produced by absorption. Then the projecting shoulder-blade, the drooping shoulder, the prominence of the ribs on one side of the vertebra—as the patient is bent forward—the absence of pain and

spasm of the muscles, the general good health of the patient, are symptomatic of the deformity under consideration. And the case which I present here illustrates well the points which I have tried to emphasize. How different from this other case which I present to you; a child 12 years of age with Pott's disease in the third dorsal vertebræ. This child has pain in the thorax, anteriorly; difficult breathing; walks with that peculiar gait of Pott's. When it stoops to pick up an object it crouches down. The slightest pressure on the head produces pain; bending forward of the body elicits a cry; when the body is moved, as you see, it moves in mass, indicating that all of the muscles of the body are affected by spasm, producing the rigid spine, and then when the patient is bent backward and the head lifted, almost total relief of the symptoms.

You will observe that there is also a slight bony prominence in the third dorsal, projecting posteriorly. From these symptoms you would have no trouble in making a diagnosis of Pott's disease of the spine. It is your duty to make your diagnosis before the deformity appears, and to do so in a child only 1½ years old is sometimes quite difficult. But if you will observe these points you can always make a diagnosis even though the child can not speak to you: There will be the night cries; screaming of the child when the mother lifts it; bending forward of the body elicits pain anteriorly from the point of disease; the patient placed upon its back when lifted to an upright position with the hand under the head rises with a rigid spine; patient in the sitting position, you standing behind it, will present a rigid spine when bent from side to side; if the disease is located in the lumbar region the good old doctor has probably treated the case for worms; if in the dorsal region, for asthma. But when the symptoms which I have enumerated are present, although there is no deformity as yet of the spine, you would be quite certain of making a diagnosis of Pott's disease. So you see that there is a vast difference between the symptoms of lateral curvature and Pott's disease.

As regards the principle of treatment of each: In lateral curvature of the spine, effort is made to develop the muscles of the back by massage and proper gymnastic exercises. The patient's physical condition is rendered strong by appropriate food and exercise; and in cases where deviation of the spine amounts to more than one-half of the diameter of the vertebra, a support to prevent absorption of the vertebra at point of curvature is most emphatically demanded. In Pott's disease of the spine, however, the principle of treatment is entirely different—it consists in absolute immobilization and extension to the point of comfort to relieve the pressure between the diseased vertebræ.

The deformity in lateral curvature is produced by pressure on one side of the vertebra, resulting in absorption. In lateral curvature of the spine I believe the plaster-of-Paris corset, or the wood corset with lacings so that they can be removed at night, are the best forms of brace yet devised. The aluminium corset is excellent but expensive. In the muscular forms of curvature, corsets with steel stiffening, particularly for young girls, I have found very satisfactory. These appliances are made while the patient is suspended to the greatest amount possible. This relieves the pressure upon the bodies of the vertebræ and stops absorption. The corsets are removed at

night—the patient while in a recumbent position being in the position of extension. When the patient is in an upright position, with the corset adjusted, pressure is relieved and absorption must necessarily stop.

Now in Pott's disease of the spine the patient is fixed in an apparatus while in the position of suspension, to the point of comfort. The corset which is adjusted, is not allowed to be removed; it is put on and permanently worn. *It has this advantage over all steel braces which, to my mind, are almost absolutely worthless, in that the nurse or mother can not remove it.* It is worn with comfort, and holding the spine as it does in an extended position, and fixing it better than it can be fixed in any other way, ankylosis will take place.

No brace or corset of any description can be applied effectively to a child under 3 years of age, owing to the narrow hips, that will support the spine. For that reason I have devised a plaster-of-Paris portable bed, in which the child is placed. This enables the nurse to carry it into the open air, and is better than confining it to a bed in a close room. Bonet's wire cuirass, used by Dr. Sayre, is a most efficient apparatus but is more expensive than the plaster-of-Paris portable bed and is no better. If the disease is located above the third dorsal vertebræ, no corset or brace without the aid of the jury-mast can be adjusted so as to be a support, owing to the fact that the weight of the head and shoulders operate upon the point of disease or curve. In such cases the jury-mast should always be so adjusted, as to transmit the weight of the head through the corset to the hips. *All of the arguments which have ever been advanced against the use of the corset amount to nothing in the presence of an established fact. You will observe that this child with lateral curvature, after the corset is adjusted is two and a half inches taller than without the corset. If anybody can explain to me what makes this child taller, outside of the support he is given by the corset, I will concede that the corset does not support. Until this question is answered I will continue to believe that the arguments advanced against the support of the corset are all fallacious.*

To make proper corsets from plaster-of-Paris, suitable material must be used. H. B. Claffin & Co. make for me a special crinoline known as No. 100 hospital crinoline. It has the proper amount of sizing and material and a total absence of indigo. The plaster-of-Paris I have had the White Dental Manufacturing Company, of New York, put up in fifty pound tin packages, fresh from the oven. This cloth and plaster-of-Paris, when properly united, makes a perfect plaster bandage. Tear the crinoline into strips six inches wide and six yards in length; draw the cloth over a pile of plaster-of-Paris on a table, and with the hand rub off all excepting enough to simply fill the mesh of the cloth; roll the bandage loosely, that it may take water quickly, and it is simply perfection. A tight fitting shirt must now be adjusted to the patient. The shirt which we now use is a long stocking, and costs about 25 cents a yard. Mr. Ford, of Thirty-second Street and Fifth Avenue, New York, furnishes it to us. It fits perfectly tight and a piece can be cut off at any length. It comes in three sizes. Allow the patient with lateral curvature of the spine to suspend himself to the greatest possible extent. In Pott's disease, use the arm-pieces, and suspend the patient to the point of comfort. The dinner-pad has been placed under the

shirt; three or four bandages are now placed in water; one of these is wound snugly around the body just above the crest of the ileum, making two or three turns, then the hips are enveloped down to the great trochanter,—use one or two bandages at this point. Begin at the bottom of the corset each time, and roll on the bandages up to the arm-pits, rubbing each layer until there is no longer air in the meshes of the cloth. Six bandages will do for a child under 7 years. From eight to twelve for adults. When the plaster is setting, stand behind the patient and gently crowd the corset in over the crest of the ileum and firmly against the ribs. After the corset has firmly set, remove the dinner-pad and spring the corset antero-posterior, to throw it off the antero-posterior spinous process, otherwise excoriations will surely follow. Cut the corset off at the bottom and top; leave it on permanently in case of Pott's disease. In lateral curvature cut off the corset, trim the edges with lacing, and you have an elastic, light and durable spinal brace.

If the patient desires a wood corset, fill the plaster-of-Paris corset with plaster, which makes a cast of the body, upon which the wood corset is made.

The corset in Pott's disease should be worn from six months to a year without removal. In lateral curvature it should be removed each night. Proper exercise, forcible redressment, gymnastics and so on, as already mentioned, should be used.

If an aluminium corset is desired the plaster-of-Paris cast is sent to the foundry, the anvil is made, and upon this the aluminium is worked. This undoubtedly is the most beautiful corset made.

I wish to present to you a case of club-foot operated upon by Phelps' method. Before the operation the child walked on the outside of his feet. You see now the feet are as perfect as it is possible to make them. The child walks almost perfectly, with nearly perfect motion of every articulation of the foot. Some have criticised the operation by saying that paralysis and a sensitive scar is the result. I think I can now speak authoritatively, because I have operated over three hundred times and I have not observed either. I have seen some feet which, from bad shoeing, after years have resulted in a moderately flat foot, but not enough to inconvenience the patient. This case had been treated in the Fifty-ninth Street Dispensary for four years with braces, and the result was entirely unsatisfactory. Three months ago we performed this operation making this simple cut, as you see, through which we divided everything contracted, and forced the bones into their normal position, and the foot into the super-corrected position. The child wears the plaster-of-Paris shoe, which extends a little over the ankle, over which an ordinary shoe is worn. This will be continued for one year when, as a rule, these cases have passed the period of relapse. I consider it bad practice to treat any case of club-foot for years with any form of brace when the patient will allow us to operate. The results are not so good as when following this operation.

One word more, and then I have done. No case of club-foot should be operated upon by any form of osteotomy until subcutaneous tenotomy and open incision with great force has been employed. After this, the various forms of osteotomy find their place. In my series of nearly three hundred cases, osteotomy has been necessary in nearly 12 per cent. of all the

cases, and in nearly all of these three hundred cases, operations of various kinds or prolonged instrumental work had been employed. Several of them had had the astragalus removed. Others had had cuneiform resections performed. But with this small cut that you see and dividing the contracted soft parts, all of these feet were placed in the super-corrected position, with the exception of 12 per cent. It is true, great force was required in many of them.

NOTE.—In this series of 300 operations if we had resorted to osteotomy there would have been twelve funerals, as the mortality from osteotomies is about 4 per cent.

40 West 34th Street, New York.

CRANIOTOMY IN MICROCEPHALUS.

Lecture delivered to the Post-Graduate Medical School, Chicago, 1893.

BY CARL BECK, M.D.

CHICAGO.

PROFESSOR OF SURGERY AT THE POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; ATTENDING SURGEON TO COOK COUNTY HOSPITAL.

The era of aseptic surgery has not only brought about important changes of old operative methods and simplified our surgical apparatus, but it has also given a stimulus to bold undertakings in surgery.

A large group of operations, which we could designate with the collective name of plastic operations, in the broad sense of the word, and which have the ideal purpose to correct the errors and faulty works of nature, have made an immense progress; but not only the common malformations as cleft palate, congenital dislocations, etc., have been attacked surgically, but the most delicate organ of the human body, the brain, has been a field of speculation by surgeons. Malformations and retarded development, mental disturbances of many kinds were considered and subjected to surgical experiments, and many of these experiments proved to be a success. But as it always happens in such instances, the use of these operations was extended over cases that were quite different from those for which they originally were indicated, and so it came that the operation seems to be discredited in the opinion of many conservative and even progressive men of our science.

The French surgeon, Lannelongue, first tried to operate on an idiotic microcephalic child, and he called the operation craniectomy. It was an operation designed to relieve the brain of the child of the restraining pressure from a prematurely ossified skull, by removing a strip of the skull capsule and allowing the brain to develop. The plan was based on hypothetic grounds entirely and on wrong suppositions partly, but it was successful, and though nobody could exactly explain the success, this latter was an undeniable fact and sanctioned the undertaking. The experiment was carried out time and time again, by truthful and scientific men, but with various results, and caused on the one hand an unjustified enthusiasm; on the other a sad disappointment.

Whoever reads the following expressions of authorities—and both men whom I am going to quote, are authorities recognized in the world of science—does not know whom to believe. Verneuil, the great French surgeon, who has witnessed the results of Lannelongue's cases, adds to the paper of this author, which he presented before the Academy of Medicine of Paris, the following remarks: "I call the attention of the members of the Academy to an entirely new operation that gives the greatest honor to the distinguished surgeon who has inaugurated it and carried

it out with success. We have not to deal here with an empiric task undertaken by chance (*tentative faite au hazard*), neither with a human vivisection which is done too often nowadays. The resection of a piece of the cranial skull for microcephalus is a perfectly reasonable idea inspired by the anatomy and pathologic physiology, and it has, as it was *a priori* to be expected, given a remarkable result. Undoubtedly the undertaking seems to be bold and will remain so, but it is less rash if we consider the benignity of operations in children, the simplicity of our operative apparatus, and above all the extreme broadness which the practice of antiseptics allows to our surgical undertakings. I have seen the little girl this morning myself, and I have examined another child who has recently undergone the same operation. Both are doing marvelously well. From to-day on, we can count on the operative success of the craniectomy as M. Lannelongue has performed it. As to the therapeutic success the future will decide, and besides the last word is not yet spoken about the technique and the improvements that can be brought about."

This critique, of Verneuil's, an authority of high rank is very flattering.

One year afterwards we read Bourneville, an authority in nervous diseases and hear to our surprise:

"Generally speaking it seems to me that the surgeons have little knowledge about idiocy in its various forms. We find as reasons for undertaking such an operation as craniectomy the following: The condition of this child is so deplorable, that there is hardly a risk to undertake any operation at all, which gives a chance for relief (Wyeth) and another: As far as I think, it is a very lucky invention, for if we can not help such children it is better for them to die than to live such a miserable existence. (Keen). These are surgical views *fin de siècle*. We have to condemn them. The medicine we were taught, has the mission to cure, to better or relieve the sick that are trusted to us, and not to assume the function of an executioner. If there is a law from the social standpoint, that orders to kill all idiots it is not our business as physicians; leave this to the public executioner. But there is no such law. The physicians have always tried to ameliorate the physical and moral conditions of the idiots and imbeciles. The surgeons ought to visit the institutions for these unfortunates in the United States and in England, and see how these poor human beings are educated. They ought to read what is published about the pathology of these disturbances and they will be convinced that their action is not justified in a large number of cases."

Reading two such entirely opposite views on one subject, we are apt to be at a loss as to what to do. So it was with me when I first met a case that I thought belonged to this class of malformations. I undertook it to study up on this question to the fullest extent, and the fruit of these studies is the following paper.

In going at the subject I had to study the literature, which is quite extensive, for the pathologic part of it was a well-known matter of controversies and discussions and has accumulated an extensive literature from very competent and diligent observers; and the literature on the therapeutic measures has assumed large proportions since Lannelongue's publication. To this I had a modest experience of my own. I thought to make this a critique of what has

been done, gathering the single observations and calculating what may be done in the future. There are several questions to be answered:

1. What is microcephalus?
2. What is craniectomy?
3. What is the possible physiologic connection between one and the other?
4. What was done so far, and how were the results?
5. What are our objective conclusions in regard to the advisability and outlines of indications for the operation?

From what I read in the respective articles, it would seem that microcephalus is a type as strongly and well defined as any pathologic condition, for instance cleft palate, but this is not so. There is a chaos of pathologic views and facts are thrown together with so many hypotheses and symptoms that it is hard to form an opinion about the true pathology of this malformation. Historically the question and investigation developed as follows: The large group of idiotic individuals showed that there were some of that kind whose heads even to the non-scientist appeared as too small, and the small size of the head was accused as the cause of the idiocy. Darwin's theory, which brought about so many changes in our thoughts in regard to the development and relations of different classes of animals has brought the microcephalus question to the foreground. In the development from the highest animal, the monkey, to man, there seemed to be a gap, which to fill, the lowest human being, the Bushman of Middle Africa, seemed to fail. Here some interpreters of natural development found that the microcephalus—the homo animal *Blumenbachii*—was the right individual to fill that gap, and scientific men argued pro and con in hot discussion. Men like Gratiolet, Rudolf Wagner, Sander and others sought to prove the contrary, but Carl Vogt, who wrote the most extensive paper on microcephalus, has scientifically developed the theory of the descent of microcephalus. He measured the surface of the brain, covering it with stanniol paper and then measuring the same, he weighed the brains, he compared the brains of microcephalus with those of monkeys, the details of which would lead too far—and he seemed to prove that we have atavistic forms in our microcephalic individuals and that they form the link between the monkeys and human beings. These assertions brought the microcephalus into discussion. But Wagner as well as Vogt had not studied on good pathologic material and they did not base their studies as well on pathologic facts as scientists could with all improved methods of examination during our latest time. Giacomini, of Torino, is one of the latest authors who gave a comprehensive study on this subject. He points out that among the microcephali there have been counted many different varieties of cases, some, where there was no brain (Starr's case), which ought to be classed as anencephalus, and others where the brain weighed 950 grams (Krause); such a case comes near the normal. But it is not right to classify the degrees of microcephalus by the size of the skull or brain, because this simply gives relations and nothing else. The central nervous system is the main indicator. Two questions arise to the author: Is microcephalus a type and can it be explained by the theory of descent?

Giacomini had rich material in the museum of

the Anatomical Institute of Torino. Of his two predecessors who wrote about this question, one had only one brain at his disposal (Rudolf Wagner—microcephalus of Iena), and the other none at all, but only plaster-of-Paris casts of skulls and brains (Carl Vogt). Giacomini observed eighteen cases and examined the bodies carefully. They ranged from 7 to 66 years in age; the brain weighed from 171 to 968 grams. There existed no type, no typical microcephalic brain, but as many different microcephali as there were different brains. This uncertainty of symptoms causes the absence of a typical microcephalus, and as there are no points of distinction there is no grouping and no classifying. Weight and capacity of the brain have nothing to do with the abnormality and they have to be discarded as points of division. The impossibility to deduct conclusions of the higher intelligence of normal individuals by the size of their heads prevents us also from forming an opinion regarding abnormal individuals, but the relative weight of different parts of the brain is of more importance because of the harmony of the development. To diagnose a case of microcephalus proper, it is essential that pathologic conditions or brain lesions be absent; microcephali with pathologic conditions are designated pseudo-microcephali. For instance, if a brain is smaller because of porencephaly, or hydrocephalus chronicus internus, or sclerosis, it is a morbid condition and not a congenital disturbance.

As to the etiology of the microcephalus proper, there have been several theories:

1. The atavistic or descendance theory, that is the theory that the history of the development of the single species is repeated in the history of the embryonal life of the newborn, and that this newborn can with one leap take the shape and form of its representative. (Charles Vogt.)

2. The theory of arrested development, which means that the development of the individual regarding brain and skull, suddenly stops during the embryonal life on account of some impediment, and from that point on remains at that stage of development all the rest of the life. (Wagner, Gratiolet.)

3. The theory of premature ossification of sutures and fontanelles and the consequent pressure of the brain. This theory has been supported by none less than Virchow and has overshadowed so much any other that it is hard to part with it. In fact, it seemed to be the most probable and least difficult to understand, and this is the theory upon which the plan of our surgeons was built though indirectly. Nevertheless, this hypothesis is to be rejected and even Virchow and Lannelongue gave it up as untrue. The reasons for this are manifold. First we do not find this premature closure of sutures in all cases of microcephalus. Carl Vogt, who has studied forty-two cases of microcephalus and whose work on this subject has received the Godard prize from the Academy of Paris, found the sutures perfectly open in three cases of young microcephali, and not quite ossified in seven adults. Dr. John von Mierjewski, of St. Petersburg, examined a splendid case of microcephalus of a fullgrown man (Mottey) and found the sutures grown together only partially. Besides this, other authors have made the same observation, while in many other cases the ossification was perfect. But Giacomini points out another reason for the improbability of this hypothesis and that is, that

there exists some smallness of the spinal cord and medulla oblongata with every true case of microcephalus, but at the same time a normal canal for these centers. Why is this, if the ossification of the sutures is primary and the microcephalus secondary?

4. Hydrocephalus chronicus internus has been accused by some authors of causing the abnormality, but inasmuch as Giacomini in none of his cases has found such a pathologic condition this theory can *similariter* be discarded.

5. Smallness of the carotid foramine which prevent the blood from giving enough nutrition to the respective tissues, has been another theory favored somewhat, but it shares the fate of the last one because of the coexistence of the micromyelia, while the circulation of the spine is not impeded and the spine nevertheless affected.

6. It remains, therefore, only the agenesia cerebri; that is, the opinion which is upheld mostly by Giacomini and which I think is correct, that the microcephalus is of purely central origin; that there exists an arrest of development of the brain and spinal cord, where all the constituent parts are less developed. The cylindraxes of the nerves are smaller in number and size, the convolutions are smaller (microgyria), *en tout* the brain is only a model of the real one—a brain *en échelle réduite*. This is the true microcephalus; all other forms are combined.

For instance, in my second case, in which I was able to do a careful anatomic examination, I found that I had to deal with a microcephalus with enormously enlarged ventricles, so that when the fluid had escaped the shell of the brain collapsed and folded in on some points, like the occipital region, as it can be readily seen on the specimen. This was a case of microcephalus combined with hydrocephalus chronicus internus.

The conclusions about microcephalus briefly we would say are:

- a. Microcephalus is essentially an agenesia of the central nervous system.

- b. Deformity of the skull is the consequence of the same.

- c. There is always micromyelia co-existing.

- d. The agenesia can start at any period of the embryonal life.

- e. Pathologic changes can occur at the same time. (Giacomini).

The symptoms of microcephaly are as different as the representatives of the abnormality. They attracted the attention of the anthropologists first. Blumenbach called them human animals, because they were similar in their actions to monkeys with the expression of human beings in their faces. In psychologic respects they were not similar one to the other; one is active and agile, very skilful in climbing up a tree, with physical strength, an active and expressive mimic in the face. Others are awkward, walk lazily and interruptedly, with very feeble mind, but they understand everything belonging to the necessities of their life, have some combination and can talk some words. Others can not talk at all. Physically they have a splendid healthy appearance, their sexual qualities being not developed at all or being developed to more than usual vivacity (Weise and Schüttendreyer, two cases of Charles Vogt).

But if we look at the table that I have prepared, we do not find these symptoms mentioned in the respective cases and we must ask ourselves, why?

The cases which have been operated show almost idiocy of the lowest kind, and only a few cases are imbecile individuals of the character mentioned above. They have the symptoms; they can not walk, nor talk, can not even sit, must be fed, do not pay any attention to what is going on around them. They belong to great extent to the early youth and infancy, where many of the first mentioned symptoms can not be developed yet at all.

But there is one important point which seems to me to have great weight as to the practicability of the operation, and that is whether the symptoms existed since birth or began to develop later on. Some of the most striking results as in Case 11, of the table, are obtained in the cases, where symptoms appeared after a period of apparently normal development elapsed. We will refer to this point later on more emphatically.

The prognosis of the microcephalic idiot up to late years was very *triste*, and has not gained very much yet by the operation. Nothing could be done very often for them, and all that was done was to educate them. Lannelongue introduced the surgical treatment, the craniectomy.

What is craniectomy? Etymologically the operation consists in removal of the cranium, as thyroidectomy consists in the removal of the thyroid gland. Keen finds this illogical and suggests the term craniotomy, but this is insufficient, as well because it does not indicate the removal of the strip, but the incision only. We will use therefore the term, craniectomy, as do most of the writers.

Lannelongue first removed a longitudinal or antero-posterior strip on one side of the skull. Since that time the operation has been modified many times. The strip has not been made exactly longitudinal but curved. There has been taken out a parallel strip on the other side of the skull (double craniectomy). The two strips have been combined by a third one, crossing the skull, so that we distinguish a V-, U-, and H-shaped craniectomy. The preparations for this operation are as usual for brain operations. The head is shaved thoroughly the evening previous, washed and covered with an antiseptic dressing. The anesthetics are administered very carefully as there are cases of shock on record. The skull is exposed by an incision of skin and periosteum according to the plan of the operation. Some surgeons remove the periosteum over the strip of bone that is to be taken away, in order to prevent the formation of bone at the place of the removed strip, but in most of the cases the formation of bone failed to appear even when the periosteum was left. The first incision into the skull generally is made with the trephine and then the excision is continued both sides of the hole with a special forceps. I have used a modification of Luer's double cutting forceps. Care has to be taken not to lacerate the dura mater which is likely to happen in crossing the sutures. The dura mater has to be freed first from the bone, which can expediently be done by one of the blades of the *rougeur*. As much care has to be taken not to lacerate the venous sinuses.

In most of the cases this has been sufficient to complete the craniectomy, and the purpose has been regarded as fulfilled; in others, the dura has been opened and pathologic products as cysts, hematomata or tumors have been removed. But this latter operation does not belong to craniectomy. There is no drainage used, except the dura had been opened

and the serum had to be drained off. The dressings are as usual. The hemorrhage is usually slight and can be checked by pressure and ligature. Esmarch's bandage is very effective to check excessive hemorrhage.

What are the consequences of the operation immediately after?

The operative result is, if the operation has been done aseptically, a good one; primary union usually. Does the skull enlarge any? Some observers have noticed such an enlargement and given it in figures (Ransohoff and others, see table). Unless the incision is very long if longitudinal, or if the incision is curved, so that it forms a flap on one side (V-shaped or U-shaped craniectomy) there is no possibility of enlargement of the skull. If we compare the skull to a firm globe, of which a strip has been taken out, we can see readily that the cavity of the globe can not enlarge much, if the incision is not very long and the coherent part is similar in its action to an elastic charnière-joint. So it is with the skull, and the conclusion is therefore, that the incision must be very long in order to be effective. Such a strip would go from above the eyes down to the occiput. The linear craniectomy is therefore without value even if very long, and only the curved incisions whether single or better, double, are to be considered as able to enlarge the cavity of the skull. The figures that have been recorded as proofs of the enlargement can not be taken in earnest, for the measures of an eighth of an inch in such cases can be brought about by other causes than the enlargement of the cranial cavity. The bone does not re-appear on the place where it was taken out. Sometimes the dura bulges out and shows clearly that there is a hyperpressure on the cranial contents.

So far extends the operative result, and it is in most cases very good. What is the curative result? This question I shall answer after having recorded the cases.

Now, is there any reasonable causal connection between such an operation as the craniectomy and the abnormality for which it has been used—the microcephalus? and is it justified to extend the operation over other non-microcephalic cases of idiocy, as it has been done in some instances?

As I stated in the first few lines, Lannelongue has used the operation to enlarge the head, though he knew that the premature ossification of the sutures had nothing to do with the arrested development of the brain. He simply thought that the opening in the skull should give an impulse to the brain, and so it seemed really to happen. We may say the connection is as follows: Microcephalus is of central nervous origin; premature ossification of the sutures is only a consequence of the arrested development, but afterwards this prematurely ossified skull prevents the brain from developing and so we arrive at a *circulus vitiosus*, where the cause becomes the consequence and the consequence the cause. If we take out one link of that vicious circle, we have broken that circle and the brain can develop again. We see that it is not absurd to make a craniectomy for the development of the brain, but must not think it verbally true that we free the imprisoned brain by that operation.

But how is it to be explained that the operation was a success in cases of non-microcephalic idiocy? If we review the single examples in which it was

performed, we find that the inaugurator himself has enlarged very much the field of indications.

In his paper about this matter read before the Congress of French Surgeons, 1891, Lannelongue says that he thinks that the premature ossification is only a morbid state of the bones due to hereditary syphilis, alcoholism and rachitis, just as well as the rest of the pathologic changes of the brain, partial sclerosis, hydrocephalus, etc. Even in cases where no ossification of sutures took place, there are pathologic changes to be found as too narrow fontanelles or sutures, partial obliteration, the bones thickened. These symptoms Lannelongue found in three microcephalic skulls, which he had chanced to examine, and these symptoms led him to make such cases, if they even were not quite typical, indications for craniectomy. They belonged to the series of pathologic subjects of arrested development and the operation seemed to be successful. He therefore puts down the following indications:

1. Primitive lesions of the brain, which are not recognized by us very early, because the functions of the brain surface are not developed in early infancy, but in later periods.

2. Secondary (*tardifs*) lesions, which occur at the age between 4 to 6 years, and are consequences of diseases, entero-catarrh, whooping cough, erysipelas, etc.

3. Traumatic influences (during birth). It is not certain, whether a part of the idiocy is not due to such a compression during delivery.

4. Congenital affections as described by Lannelongue and Ménard (*Maladies des Bourgeons de l'Embryon*, 1891), the intra-uterine compression on account of lack of waters. This compression is to be distinguished from that caused by delivery in this way, that the diameter is not shorter in one and longer in another direction by compensation, as after childbirth, but that it is smaller in all directions.

5. Meningeal hemorrhages, occurring during birth and consecutive pathymeningitis, atrophies and porencephalies—in other cases there is some serous accumulation and the opening of the skull will remove it quicker.

6. Hyperostoses of the skull caused by syphilis; then the thickening of the skull consecutive to hydrocephaly.

7. Pathologic changes of the brain itself; that is, atrophies caused by mal-development on account of bad circulation; in this case the opening of the skull will bring a new relaxation, an increased conflux of blood and better development.

8. Furthermore, in cases of limited or general sclerosis, well known in the adult, which Bourneville has studied and described under the name of sclérose cérébrale tubéreuse hypertrophique.

The fact is undeniable, it was useful to remove a strip of the cranium; but what the causal connection between operation and result may be can not be stated with exactness.

I should think that the following process takes place: Physiologically the fontanelles and sutures gradually ossify and are perfectly solid at an advanced age. If the brain stops developing further at an early age the sutures ossify as in old age; but if the brain is freed by an operation, a new conflux of blood and a new impulse of development occur, and if this new growth keeps on and is aided by the

pedagogical method then the child improves and keeps on improving. But in some cases the operation does not help or it helps only for a time, and then the child falls back to the old condition of idiocy; in these cases the development and improvement seems to be comparable to the nearly burnt out coal, that flashes up once more if blown into, though the material is burned up, and then dies out altogether.

(To be continued.)

A CASE OF SINGULTUS TREATED SUCCESSFULLY WITH NITRO-GLYCERIN.

BY E. GRISWOLD, M.D.

SHARON, PA.

This troublesome spasmodic condition, whether we term it a disease, or only a symptom, may well be classed as one of the opprobria medicorum; presenting as it does in its clinical history the appearance of a spasmodic disease, and in its therapeutics almost negative results as regards the action of antispasmodics and nerve sedatives, the practitioner may well inquire after a new explanation of its pathology and a new departure in its treatment. Most practitioners of large experience have doubtless met with cases in which this singularly annoying and debilitating condition has continued for many days, even running into weeks, in spite of their best therapeutic efforts, with scarcely any intermissions, unless asleep, and which sleep came but seldom and was transient. Any *new* remedy or *any* old remedy whose successful application to the treatment of this condition is new, deserves the attention of the profession.

There are some things in pathology and in practical medicine that science, so far as we have been able to apply it to our professional work, has not made clear. We are obliged to work experimentally in cloudy fields. When therefore experiment meets with success in an individual case we should follow its line until we discover whether or not the success is a coincidence or a result. Inasmuch, however, as opportunities are rare for carrying on such experiments, I desire to report my result (or coincidence) and to ask the profession at large to try the remedy and do likewise.

On August 2, ultimo, a man aged 50, who formerly had been a habitual drinker for many years, asked advice. He was haggard, despondent and discouraged. His tongue was coated, voice feeble and pulse frequent and weak. His mind, however, was tolerably clear but a little sluggish. He hiccupped continuously, but managed with considerable effort to give the following history:

For nearly two years he had abstained, by the aid of the *pledge* made to his confessor. Six weeks previously he had begun a drinking debauch which he continued for about three weeks, when his stomach gave way and his bodily functions became generally perverted. Hiccoughs were now added to insomnia and he sought medical relief. He could only get a little sleep and an arrest of the hiccoughs when deeply under the influence of morphin; but the sleep was transient and the hiccoughs returned as soon as he awoke. He felt far more disturbed by the hiccoughs than the insomnia, and had taken prescriptions from several physicians without relief. Believing that he had already taken all the ordinary remedies, and knowing their uncertainty and inefficiency from former experience, an excursion through the mental materia medica for a new one was made, which resulted in the following prescription:

R. Pill nitro-glycerin 1-150 gr. No. xii. Sig.: One pill at intervals of 3 hours.

The first was taken at 9 A.M. In half an hour the hiccoughs ceased. At 12 M. he took the second pill and some cabbage soup. Shortly after finishing the soup the hiccoughs re-

turned and continued until about half an hour after taking the *third* pill at 3 P.M., when an intermission took place. This lasted until about 6:40 P.M., or forty minutes after he took the *fourth* pill, followed by more cabbage soup; when the hiccoughs again returned. He was seen a few minutes after this return, and the fifth pill given, there being then about an interval of an hour between the fourth and *fifth* pill. In less than half an hour the hiccoughs left him and have not since returned. He slept fairly well that night, ate a light breakfast next morning and has been making a fair convalescence since that time. It may be noted that the treatment in this case lasted from 9 A.M. to 7:30 P.M., a period of ten and one-half hours and that the amount of the medicine used was one-thirtieth of a grain.

A CASE OF NEURITIS SIMULATING PROGRESSIVE MUSCULAR ATROPHY ASSOCIATED WITH NYSTAGMUS AND INCREASED KNEE JERKS.

BY HAROLD N. MOYER, M.D.
CHICAGO, ILL.

The following singular grouping of symptoms came under our observation a short time since, and we deem it worthy of report because we have not seen such described in the literature nor has a similar case ever come under our observation:

A young woman 21 years of age presented herself at the clinic for nervous diseases of Rush Medical College, complaining of a progressive loss of strength and wasting of the hands and arms. She stated that the trouble had come on four years before. There had been no injury or serious sickness. At the time her occupation, that of a servant, required her to have her hands frequently in cold water. At first there was much pain in the hands, which would dart up the forearm; associated with this condition was numbness and tingling. After a time she noticed a progressive loss of strength, and still later that the hands and forearms were diminishing in size. As the disease advanced the pain and numbness ceased, giving place to a marked loss of sensation.

At the present time the hands show a marked loss of muscular structure, the thenar and hypothenar eminences have for the most part disappeared. The spaces between the metacarpal bones are deeply hollowed. The hands are commonly held in a semiflexed position (claw-like) but there is no contraction of the flexor tendons. A little motion is possible with the hands and the patient has a feeble grasp. The strength of flexors is practically *nil*. The forearms are much wasted and the extent of atrophy is exactly the same in both arms. Fibrillary tremors are occasionally to be seen. The arm muscles have escaped, the biceps, triceps and muscles of the shoulder girdle are all intact. The supinator and pronator are not involved. Sensation in the left arm is abolished as high as the middle third. Tactile, common, pressure, and temperature senses are equally involved, though deep pressure seems to be preserved to some extent and the muscular sense is not markedly impaired. The right arm is similarly involved, the anesthesia reaching to the shoulder and involving a portion of the surface of the chest at and below the axilla, corresponding to the distribution of the nerve of Wrisberg and the lesser internal cutaneous. The electrical reactions are altered in different degrees; in some muscles there is complete reaction of degeneration (interossei and muscles of the little finger and thumb). In some of the flexor muscles there is only a partial reaction of degeneration though in all affected muscles a c. c. precedes c. c. Faradic irritability, is mostly decreased or even absent (interossei) but in a few muscles seems slightly increased. Station is good, sensibility is elsewhere intact. The general health is good and the functions of circulation, respiration and digestion are not affected. Nystagmus is present, vision is good and the eye-grounds are normal in both eyes. The patellar tendon reflex is markedly exaggerated in both legs, and prolonged ankle clonus is present in both feet.

A brief glance at the foregoing reveals a very anomalous symptom grouping. That the trouble with the forearms and hands was a peripheral neuritis is, we think, shown by the fact that there was at first pain and paresthesia succeeded by a loss of sensation

which still persists, and that the anesthesia is approximately coincident anatomically with the muscular atrophy. On the other hand, the distribution of the paralysis is exactly such as we get in acute polio-myelitis, of the lower arm type of Remak, in which the supinators and pronators escape, while the disease is perfectly symmetrical on the two sides. This is hardly to be looked for in neuritis, though it does sometimes occur; indeed, it is uncommon in polio-myelitis. Again, the gradual onset speaks in favor of a neuritis. While the polio-myelitis may have a gradual progress, it is usually by successive steps; as each group of cells are successively attacked there is a rapid disappearance of corresponding muscles. In this case there seems to have been an even progress in the wasting similar to that noted in the essential forms of progressive muscular atrophy. In this connection we might premise that in some cases it is practically impossible to make a diagnosis between peripheral disease and anterior horn lesion.

The nystagmus and exaggerated reflexes probably have no connection with the peripheral neuritis. Unfortunately, the history of the patient does not throw any light on the possible origin of these symptoms. Had the patient presented herself with these signs alone, we should have felt justified in making a diagnosis of disseminated sclerosis, and such in fact we believe the case to be. Indeed, there is nothing to be said against the view that this may be an instance of *sclerose en plaques*, in which the peripheral nerves share as well as the central nervous system. There is just one thing that may be said against this diagnosis, and that is the symmetrical character of the disease which in disseminated sclerosis is decidedly exceptional.

SOCIETY PROCEEDINGS.

American Public Health Association.

Twenty-second Annual Meeting, held at Montreal, Canada,
Sept. 25-28, 1894.

(Continued from page 618.)

FOURTH DAY—FRIDAY.

The Association convened at 10:15 o'clock, DR. LACHAPPELLE presiding.

The Executive Committee reported by Secretary Watson, substitutes for several of the resolutions that had been presented by various members. Among the resolutions laid upon the table was that offered at Thursday forenoon's session by Dr. Olliphant (see JOURNAL October 20, page 615.) The committee recommended that Dr. Sewell's resolution be referred to the Committee, "On Restriction and Prevention of Tuberculosis." Dr. Homan's resolution was recommended to be referred to the Committee "On the Pollution of Water Supplies." As a substitute for Dr. Campbell's resolution, the Committee recommended a resolution providing for the appointment of a committee of three to consider the question of the abuse of alcoholic liquor from a sanitary point of view. A motion unanimously prevailed that the recommendations and substitutes of the committee be concurred in by the Association.

The report of the Advisory Council was then submitted as follows:

Mr. President:—I have the honor to present in behalf of the Advisory Council the following report. The Council desire to recommend to the Association the following officers for the ensuing year, viz., President, Dr. Wm. Baily, of Kentucky. First Vice-President, Dr. Granville P. Conn, of New Hampshire. Second Vice-President, Dr. Gregorius Mendizabal, Orizaba, Mexico. Secretary, Dr. Irving A. Watson, of New Hampshire. Treasurer, Dr. Henry D. Holton, of Vermont.

For three members of the Executive Committee to be

ected: Dr. Henry I. Bahnson, of North Carolina; Dr. Peter H. Bryce, of Ontario; Dr. E. P. DeVaux, of North Dakota.

Invitations were presented for the Association to hold its next meeting in Denver, Colo., Minneapolis, Minn., and Banff Springs, Manitoba.

The Council desires to recommend that the meeting in 1895 be held in Denver, Colo.; to favor the acceptance of an invitation from Davenport, Iowa, to stop one day in that city, en route to Denver, to inspect the water filtration plant and other interesting sanitary features.

The Association was invited to hold its meeting in 1896 in the city of Nashville, Tenn. It was voted to indorse the invitation and to refer it to the next Advisory Council.

The following resolution was adopted:

Resolved, That the question of publishing the Transactions of the Association quarterly be referred to the Executive Committee to arrange for such publication if the scheme be found practicable." C. O. PROBST, Secretary.

The report was upon motion unanimously adopted, and the Secretary was authorized to cast the vote of the Association for the offices named. The list of names upon the new Advisory Council and special committees was also announced, which is practically the same as those for this meeting.

Upon motion of Dr. Montzambert, a committee of two was appointed to escort the President-elect to the platform. Dr. Montzambert and Dr. Gihon were appointed. Dr. Bailey said substantially as follows:

Mr. President and Gentlemen.—Those of you who know me well, will I trust not be afflicted by this mark of appreciation on your part. In view of the honor you have conferred on me I express to you my happiness and gratification. For fifteen years I have been a member of this Association, going about quietly and unostentatiously. I understand that your choice for the Presidency of this Association for next year has been by acclamation, yet withal, I am fully conscious of my faults and weakness, therefore this administration can not hope to rival or equal the one now about to close. I hope to rely on the good will and receive the cordial support of the members, and I feel that this is the proudest hour of my life."

The Executive Committee then recommended that the Committee "On the Centennial of Vaccination" be dropped, which was accordingly done.

The Auditing Committee, by Dr. McCormack, chairman, reported that the books, accounts and vouchers of the Treasurer had been carefully examined and were found correct. Indeed, the business affairs of the Treasurer and everything else were so systematically arranged that the duties of the Committee were very easy to perform. The report was adopted unanimously.

MEDICAL DIRECTOR GIHON, U.S. Navy, offered the following:

Resolved, That the thanks of the American Public Health Association be cordially and earnestly given to His Excellency, the Lieutenant-Governor and the Government of the Province of Quebec; to His Honor, M. Villeneuve Mayor, and the Municipal Council of the city of Montreal; to the Federal Government; to the citizens of Montreal; to the authorities of McGill University; to Drs. Craik, Pelletier and Baudry and their associates on the Local Committee of Arrangements; to the members of the press; and lastly, to Montreal's attractive sanitary exhibitions—the ladies—who demonstrated in their own persons the salutary and beatific influence of the Canadian climate, and who contributed so much to the entertainment of the members, and those who accompanied them."

The adoption of the resolution was unanimous.

TRIBUTE TO THE LATE DR. JOHN H. RAUCH.

FRIDAY AFTERNOON.

Dr. H. D. Holton offered the following in memoriam of Dr. John H. Rauch:

"Since our last meeting, Death has taken, in the person of Dr. John H. Rauch, one of the organizers and promoters of this Association, a man whose love of his fellow-man gave him enthusiastic zeal in the work of sanitation.

"We desire to place on record our appreciation of his inestimable work in the field of medical education, and in the organization and continued support of this Association. While we mourn the loss of his personal friendship and the admonitions of his wise counsels, the memory of his devoted and courageous efforts in all the departments of his life-work shall be an inspiration to us to take up the work he has left, with an increased devotion."

DR. MONTZAMBERT moved that the resolution be adopted in silence, by a rising vote, which was so ordered.

The annexed list of papers and essays were read by title: "La Cuarentena en la Viruela," por el Dr. Nicolas R. de Arellanos, Mexico, Mexico; "On the Etiology of Mexican Typhus," a new contribution, by Dr. Jesus Chico, of Guanajuato, Mexico; "Algunas Consideraciones acerca de la Prostitucion," por Juan J. R. de Arellanos, Mexico, Mexico; "Prevention of the Spread of Yellow Fever," by Walter Wyman, M.D., Supervising Surgeon-General of U. S. Marine-Hospital Service; "The Free and Liberal Ventilation of Sewers," by Mr. C. Baillargé, F.R.S. C., Quebec, P. Q.

A paper, "A Plea for Aseptic Vaccination," was read by DR. M. T. BRENNAN, in which the essayist urged the necessity of performing vaccination under complete antiseptic conditions.

Another paper

UPON INFECTION BY THE BACILLUS PYOCYANEUS AS A CAUSE OF INFANTILE MORTALITY,

With a report of cases, was submitted by Drs. GEORGE ADAMI, and KENNETH CAMERON, of McGill University. The paper was read by Dr. Cameron, who briefly stated main points: "Popularly, pyocyanus is known as "blue pus." Doctors were often surprised to remark that bandages of wound dressing became blue. For long the color was supposed to be due to ozone or something else. Bacteriology showed it to be due to bacilli. A European savant had had a case where it had resulted fatally. The three McGill doctors within a few months have investigated three fatal cases at the Foundling Institute. The bacillus was discovered and studied for the first time in America. Cultivations of these bacilli were introduced into the systems of rabbits by inoculation, and resulted fatally. Investigations had been conducted to ascertain whether vaccination against the disease could be used. Cultivations of the bacilli had certainly rendered animals immune. The cooperation of other practitioners in prosecuting the inquiry was asked.

The following are the author's conclusions:

1. That the infant tissues are susceptible to the invasion of the bacillus pyocyanus.

2. That the bacillus is distinctly pathogenic, setting up a disease similar to the experimental pyocyanic disease.

3. That this disease is characterized by a train of very definite symptoms, namely diarrhea, fever, rapid emaciation, rigidity of the legs, and hemorrhagic bulbous eruptions.

4. That the disease appears to be very fatal, and this combination of symptoms occurs infrequently in young children especially when congregated in nurseries and foundling asylums. We venture to infer that a certain proportion of the deaths which now appear upon our records of vital statistics under the heading of gastro-enteritis, purpura, or marasmus are in reality cases of generalized pyocyanic disease. As to prophylaxis, nothing definite was offered, beyond the strict observance of the laws of hygiene, and that it is a disease eminently suited for trial of "serum therapeutics."

The final paper was upon "The Evolutionary Development of Domestic Plumbing during the past Thirty Years," read by Mr. J. W. HUGHES, of Montreal.

The paper prepared by Dr. JESUS CHICO, of Guanajuato, Mexico,

ON THE ETIOLOGY OF MEXICAN TYPHUS,

As the author claimed is a new contribution, and was read by title. The subjoined is a brief abstract of the points noted. The author read a paper on the same subject at the meeting of the Association in Mexico in 1892. He maintains that the proportion of patients who contract typhus fever without any previous communication with another patient suffering from the same disease is above 90 per cent.; that the number of people who contract typhus when nursing one of its victims is exceedingly small and that there is evidently a relation between the ground and this ailment, because it is a fact that there are houses which are haunted by it, preferably to others, notwithstanding the care with which they are cleansed and disinfected.

In his new contribution he expatiates upon this topographical feature of the etiology of the disease, showing by several examples how its appearance and spread followed in the first case from excavations in the ground of the streets, and that in the second, spread of the disease followed the ground and not the atmosphere.

A vote of thanks was then, upon motion of Dr. Smith of Maine, tendered to Dr. LaChapelle, the courteous and able "bachelor" President, the same being seconded by Dr. Mendizabal, and was suitably acknowledged by the retiring Executive.

The Association, at 11:30 o'clock adjourned, *sine die*.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, OCTOBER 27, 1894.

THE PASSING OF THE EUCALYPTUS.

One by one the fads and barnacles attached to the medical practice craft, are scraped off by the attrition of time. For several years everybody has believed that the planting of Eucalyptus trees in a malarious district, was one of the natural means of prevention of malarial poisoning. They were rather rudely jostled by TOMASI-CRUDELLI and KLEBS through the discovery of the *plasmodium malarix*, but they were not entirely dislodged.

The article in the September number of the *U. S. Consular Reports* on the uses of the Eucalyptus tree would seem to have given the final stroke which sends the old belief to the limbo of exploded theories. That the fad has still a firm hold on the public is evident. CONSUL HALL, stationed at Nice, says:

"To illustrate the firm hold which this tree and its health-giving properties have upon the popular mind in this department, I am told that when these trees are trimmed in the early spring days in the Jardin Public, in the gardens of private villas, and on the streets, the branches are eagerly sought by all classes of people, who hang them with their cones on the walls of their bedrooms with the view of keeping off fevers and of getting rid of moths, mosquitoes, and other insects. Many persons make rosaries of the burs, and strings of beads, which they wear around their necks."

CONSUL JONES, stationed at Rome, says:

"Up to date (1886) not a single instance of hygienic improvement by the sole means of Eucalypti has been ascertained, but the possibility of so doing is not denied. It can be admitted that these trees sometimes prove useful in certain malarial soils. I frankly maintain, however, that frequently they are of no use whatever, and that it is well to guard against exaggerations that often blind the judgment."

"It would have been possible to avoid these exaggerations and the disappointments which followed as a consequence if, instead of regarding these plantations from a theoretical point of view, the public had begun by studying their results in the very home of the Eucalypti. It would then have been known in time that even in the southern hemisphere, where the Eucalypti thrive better than with us, there are forests of Eucalypti in which malaria reigns supreme, as has been stated by PROFESSOR LIVERSIDOE, of the University of

Sydney. In Italy, although the newspapers had persuaded every one that the farm of the "Tre Fontane," near Rome, had become healthful by means of the Eucalypti, it proved a disagreeable surprise to learn of a sudden outbreak of malaria in 1882 that caused much sickness among the farm hands while the rest of the Campagna remained particularly healthful.

The experiments with the Eucalypti at "Tre Fontane" are interesting and instructive. On the road to Ostia, about three miles from Rome, is situated the abbey of the "Tre Fontane." There is a monastery of Trappist monks there who, for many years, have been endeavoring to improve the land adjacent to the monastery by means of setting out extensive vineyards, draining the soil and planting the Eucalyptus. It was reported that the hygienic condition of the locality had been much improved, and this improvement was ascribed by the public and the Government to the planting of the Eucalyptus by the Trappist; hence it was decided to extend the setting out of these trees.

To facilitate this experiment, the Government in 1880 established an agricultural colony of penitentiary convicts and put them in quarters near the monastery, that is, on that part of the farm supposed to have already been improved by the Eucalypti. The convicts were surrounded by hygienic conditions far superior to those of the agricultural laborers of the Campagna, and, notwithstanding this, nearly all the convicts were taken down with malarial fever more or less severe, in 1880. The Trappists started the setting out of the Eucalyptus in 1870.

During the summer and autumn of 1882, all of the inhabitants of the "Tre Fontane" were attacked. The Trappists, it would seem, suffered from slight attacks, but all suffered. Some of the convicts had slight and some severe attacks. Nearly every guard had a severe attack; the guards had all to be changed. There were no deaths, because medical assistance was at hand. The fever-stricken patients were well cared for in one of the hospitals of Rome.

DR. MONTECHIARE, a practicing physician of Rome who for years was physician to the penal colony at "Tre Fontane," tells me that his experience justifies him in declaring that no beneficial result against malaria has been derived from the planting of the Eucalyptus. The monks set out no less than 50,000 trees on a few acres. Had the efficacy of the Eucalyptus proven real, the entire settlement of the "Tre Fontane" would have become a veritable Eden on account of its wholesome, balsamic air, which has by no means been the case. In 1870, DR. MONTECHIARE, being in charge of St. John's Hospital, experimented with all the preparations of Eucalyptus against malarial fever, and found that not one lowered the temperature of the patient by a tenth of a degree. The only value of the elixir of Eucalyptus consists in the alcohol that it contains. The efficacy of the Eucalyptus for the improvement of the air is no greater than that of the elm, pine, and mulberry. If it recommends itself by its rapidity of growth, the trees just mentioned recommend themselves by being hardier and more easily grown.

PROFESSOR (NOW SENATOR) TORELLI has also written on the subject of the Eucalyptus. He sums up by declaring that the much-vaunted merits of the Eucalyptus have not been established.

Thus perishes the Eucalyptus hypothesis, but the tree itself will, we trust, continue to be planted and to thrive. In America the need of quick growing useful forest trees is so evident that even the loss of its reputed medicinal virtues should not condemn the Eucalyptus. We need more trees and denser forests for economic purposes quite apart from direct medical properties.

SANITATION IN JAPAN.

In the last issue of the JOURNAL we spoke of the excellent organization of the Medical Department of the Japanese Army and the special training of its members. The Japanese Government, however, has been progressive in other than military lines. It has been as careful of the welfare of the general population as of the health and efficiency of its military

support. Early in its history the present government instituted a Central Sanitary Bureau to remedy insanitary conditions and preserve the people especially from the ravages of imported cholera. Measures of general sanitation and for the prevention and suppression of all infectious diseases were at first under the entire control of this Central Bureau; but in 1888 a system of Local Sanitary Government was instituted, by which all sanitary and preventive measures were to be carried out by the people themselves through the medium of the local authorities of cities, towns and villages, the general government exercising only a necessary oversight. The occurrence of cholera and its rapid spread in 1890, soon after the institution of this change gave rise to much anxiety lest the unfamiliarity of the local authorities with measures of prevention should result in disaster. Happily, however, these measures, fully indicated in various memoranda issued by the Central Bureau, were generally well carried out; and the feeling of anxiety gave way to one of assurance that future epidemics would be met more effectively than the last, as it was expected that, with the development of the principle of self-government, the local authorities would become increasingly familiar with the execution of sanitary measures.

The reports of the Bureau are late in making their appearance, as they consolidate the reports from the various governmental districts; but the aggregation of facts published annually is really equivalent to that which the United States attempts to issue only once in ten years for the census year. A cursory glance over the report for 1890, just received, would occasion much surprise to those who have not followed the progress of Japan in reconstructing her institutions on models derived from our modern civilization. It may be of interest to cite a few points:

With a population of 40,692,808 the births numbered 1,145,174, or 28.15 per thousand; still births 91,752; illegitimate 66,253 or 5.8 per cent. of the total. The deaths numbered 821,043, equivalent to a rate of 20.18 and this notwithstanding the incidence of cholera, which was responsible for 35,248 deaths. The mortality is tabulated under twelve disease headings, and by sex and years of age (from 1 to 107) in the various districts. Of infectious diseases, cases as well as deaths are reported. There were 34,736 cases of typhoid fever with 8,464 deaths, a fatality rate of about 25 per cent. and a mortality rate of nearly 21 per 100,000 of the population. Typhus was rare,—a total of 251 cases with 67 deaths. Smallpox was equally rare, and the tabulations of successful and unsuccessful vaccinations explain its rarity. The statistics are given of the examinations of prostitutes for syphilis under the registration laws.

At Tokyo a committee on city improvements decided to raise a loan of 6,900,000 yen (\$5,175,000)

for water works; and the general government appropriated 150,000 yen annually for fifteen years to aid the city in paying the interest, as it highly commended this improvement, considering it to be the measure most urgently needed for the protection of the people from cholera while having the added advantages of "removing the causes of other diseases, improving the general health, prolonging life, affording protection from fire and generally increasing the pleasure of living as shown by the experience of various European countries." A similar appropriation of 50,000 yen annually was made on behalf of the city of Osaka.

Of 40,215 registered physicians only 30,003 practice, by virtue of their status before the passage of the acts regulating the practice of medicine; the others have been examined or are entitled to registration by their graduation from Imperial schools. Midwives, druggists and manufacturers of medicines are also registered and hedged in by controlling laws; and the sanitary laboratories of the Central Bureau at Tokyo, Osaka and Yokohama make examinations of various articles on behalf of the public, particularly with regard to water, food supplies and drugs.

Many of the items that we have just cited serve to show how far the young pupil has distanced some of her teachers. Even the report itself calls to mind that the United States has no such Sanitary Board to consolidate its vital statistics, and to consider those questions of public health that are of greater breadth than the lines limiting the jurisdiction of States and municipalities.

ERYSIPELAS TOXINS IN THE TREATMENT OF MALIGNANT TUMORS.

There is so much of promise in the recent developments of serum therapy, especially in the brilliant success of the antitoxin treatment of diphtheria, that new interest has been aroused in the work of experimenters in this line with other diseases. The labors of SPRONK of Paris, COLEY of New York, GEHRMAN of Chicago and others in the treatment of the malignant tumors by the erysipelas toxins shares in this revival to an extent which warrants some review of the subject.

The theory of an antagonism between the products of growth of the *streptococcus erysipelatosus* and some forms of sarcomata and carcinomata is founded upon observations that these tumors occasionally disappear coincidentally with, or subsequent to, an attack of erysipelas in a distant part of the body. It was found that they had undergone tissue necrosis with absorption or extension; that lesions of lupus and of tertiary syphilis were similarly acted upon, but that non-malignant growths were not affected by the incidence of erysipelas. Further investigation showed that the irritation which causes and perpetu-

ates tissue proliferation in a malignant growth is removed by the action of the erysipelas toxalbumins—the cells degenerating from want of blood supply; that the irritating agent in malignant and in non-malignant tumors differs in nature and result; and that the antagonism is systemic—probably brought about by changes in the blood serum, chemical and not phagocytic in nature. The results of these investigations led to the culture of the albumins produced by the bacteria of the disease, and their use in the form of definite infection dosage. The best method for the utilization of these toxins is not, as yet, positively determined; it is still under experiment and the results thus far demonstrate the necessity of great care in the culture of the bacteria and the preparation of their toxic products.

All cases do not react alike under the injections; thus far the sarcomata in general are more beneficially affected than the carcinomata; and of the sarcomatous growths osteo-sarcoma gives the least favorable results; in some cases marked improvement is noted at first, only to be lost in a short time by renewed growth. The treatment is not yet sufficiently developed to warrant its application in cases that offer reasonable assurance of non-recurrence after removal. There is, however, a sufficient percentage of cases in which there has been an entire disappearance of the tumor, of others in which there has been a marked decrease in size or delayed growth, and of still others in which there has been great relief of pain, to commend this method of treatment to further study and consideration.

It is asserted that the failure thus far to treat all malignant tumors successfully by the erysipelas toxins is due solely to want of knowledge of the specific nature of the growths and of the properties of the toxins and their combinations; and that the researches now being carried on offer good promise of ultimate ability to determine scientifically the special antagonism required in each variety of tumor.

But with the monumental failure of tuberculin in mind, let us wait patiently the full developments to be made by expert investigations.

A CO-OPERATIVE BACTERIOLOGIC INVESTIGATION.

The Committee on the Pollution of Water Supplies, of the American Public Health Association in its report submitted at the meeting in Montreal, Canada, September 25 last, suggested a coöperative investigation by American bacteriologists into the, at present, confused state of our knowledge on the important subject of the bacteriology of water supplies. The Association approved this suggestion and commended the efforts of the Committee in carrying out the work, to the officers of State and municipal boards of health, to the individual members of the Association, and to all persons interested in the purity of

water supplies, for such special assistance as they may be able to render. The proposition of the Committee was to the effect that each laboratory willing to coöperate in the work devote itself particularly to the investigation of a single so-called group or species of water bacteria; and that uniform standard culture media be adopted, with the employment of these along the line of a definite systematic scheme of laboratory work. The Committee, when its membership is complete, will consist of those participating in the work. In the meantime its organization is in progress. A sub-committee charged with the duty of making a preliminary survey of the field and elaborating the framework of a scheme of combined work to be submitted to those interested, has issued its first circular letter, a copy of which appears in another column of this issue of the JOURNAL. The advantages to be derived by bacteriology from this scheme of coöperative work are obvious; and the practical results lying in the pathway of such an investigation are lessened sickness and mortality from diarrheal diseases and typhoid fever.

We shall look with interest for further information concerning the progress of the organization of this committee of co-laborers in the field of sanitation and preventive medicine.

THE TREASURER'S NOTICE.

Under the heading of "Association News" we again print the notice issued by our ASSOCIATION Treasurer who very properly gives the reasons why members in arrears should lose no time in promptly remitting the amount of their annual subscriptions due last June. Every sentiment of professional pride and ASSOCIATION fellowship should enlist our members in the good work of supporting the Trustees in their efforts to give the members and the medical profession of America one of the best medical journals in the country.

It should be a source of pride to the ASSOCIATION that its JOURNAL office is now prepared to do all the work required of it, but it must be remembered that heavy drafts on the ASSOCIATION treasury were made in order to accomplish it. The presses are paid for, and the new equipment has not a penny of indebtedness resting upon it, but it will require money to maintain the mechanical department, purchase news and keep up the standard. There will be no lack of funds if our members who were not in attendance at the last meeting will kindly respond to our worthy Treasurer's call without further delay.

CORRESPONDENCE.

Mitral Stenosis and Pregnancy.

CHICAGO, Oct. 13, 1894.

To the Editor:—Some years ago there came to my consulting room a young woman, bride of two summers, wife of a

prominent criminal lawyer. She was in her third month of utero-gestation, and consulted me regarding an annoying cough, dyspnea and a slight hemoptysis, the latter on the morning of the day she called at my office.

From facial landmarks I feared my visitor a tuberculous subject. Her penciled-like eyebrows, long, silken eye-lashes, clear sclerotics, rather prominent cheek bones, and slender tapering fingers all pointing in that direction, but mark you my surprise when I placed a stethoscope over the heart and found I had a pronounced case of mitral stenosis; this told the story of how the sputum came to be tinged with blood. We know that the auricle must accommodate for the defect, and if it does so imperfectly, the accumulation of the blood passes through it to the veins of the lungs, capillaries and arteries until it reaches the right ventricle, which in turn dilates or hypertrophies, giving rise to the condition my patient described, and which was indeed more marked at the fifth month, and thus caused hypertrophy and dilatation of both ventricles, for we know that with mitral insufficiency during diastole of left ventricle from the dilated auricle, there flows the blood which has accumulated in quantity and pressure, dilating it and forcing the auricle to dispose of the overplus of blood, thus sending part forward to the aorta, and part is sent back through the mitral orifice into the auricle, which becomes in time hypertrophied.

My patient at full term was delivered of a healthy male child—nothing over ordinary having disturbed the mother until an hour after delivery, when she was distressed for breath, and the peculiar sputum of pulmonary congestion with the tumultuous heart action threatening to carry, by its sudden onslaught, the new parental life beyond all human aid. Fearing this sort of trouble, I was careful to notice that my patient was not given ergot, and that she was kept well covered, and flowing encouraged. I gave hypodermatically atrop. sulphate strych.; also carbon of ammonia by mouth, but not until I gave oxygen inhalations did my young mother manifest any sign of improvement. It was gratifying, indeed, to me and a great blessing to this parent life, to watch its grand supporting, restorative and therapeutic action.

This wife has since said date safely presented to her liege lord another heir without any untoward symptoms through the free inhalation of oxygen.

My patient during attacks of dyspnea which occur somewhat frequently, finds instantaneous relief through inhalations of pure oxygen, and claims that she is enabled to perform her domestic duties without feeling fatigued or further disturbed, either in respiration or circulation.

J. A. McDONELL, M.D.

About Rotten Row.

CHICAGO, Oct. 8, 1894.

To the Editor:—On my return from a summer vacation, in glancing over the medical literature that has accumulated on my library table, I find among the articles attracting my attention one appearing under the name of our eminent colleague, Prof. Edmund Andrews, of Chicago. In this he makes a most earnest, well-timed, and important plea for the use of English, pure and undefiled, in the writing of medical articles. Far too little attention has been given to this subject in this country. In England and in France, a man appealing in print to the attention of his *confrères*, must, in order to secure a hearing, use his native language in its purity and simplicity.

But Professor Andrews has made a singular error in his interesting paper to which I desire to call your attention. He refers to the title, "Rotten Row," the name of one of the Hyde Park driveways (or, as it would be called in this coun-

try—not in France—"boulevards") and suggests that it originated from a row of tumble-down structures which had been removed in order to improve the Park. The pertinence of this allusion is in the line of illustrating the force, vigor, and homeliness of the pure speech of the Anglo-Saxon.

But the facts are different. Hyde Park in London has been reserved for practically its present purposes ever since the days of Henry VIII. and Edward VI. Even in the time of Elizabeth its acres were devoted to "herbage, pannage, and browsewood for the deer." None of less rank than a knighted gentleman could have charge of its fine oaks and gardens even as early as 1596. There is no record in its history of a row of old buildings torn down to make space for a driveway, and which survive in the "rotten" appellation of the modern Park road.

The name "Rotten Row" is a corruption, common enough on English lips which never did take kindly to foreign names, of the "*Route de Roi*," or king's highway; the English name of which is as classical in our tongue as many other simple words for which so good a plea is made in the article to which I have referred above.

AMERICANUS.

Columbian Ambulance Association.

CHICAGO, Oct. 18, 1894.

To the Editor:—The Ambulance men, patrolmen, policemen and firemen of this, our city, have no training in handling or relieving the needs of the sick or injured people who come into their hands. For the sake of humanity we propose to take up this work and commence in these departments. In a short time we hope to have the majority of the men trained to relieve the sufferings of an injured man as much as is possible. This will result in saving untold sufferings; in life and limbs.

We have already made arrangements with the Chief of Police to start at the Harrison Street Police Station.

The cost of each class is about \$60.

We hope to raise the money for this and for the purchase of a model ambulance and equipment, later on, so that sick, bed-ridden and injured people may be transported in a manner satisfactory to patient and medical attendant alike.

For these purposes we require the sum of \$5,000 which we hope to raise by 1,000 memberships of \$5 each.

Please send your check to D. J. Wile, Treasurer, Unity Building.

By order of Executive Committee,

ADA C. SWEET,
H. W. GENTLES,
Committee.

ASSOCIATION NEWS.

Section on Materia Medica and Pharmacy.

Annual Meeting held in Odd Fellows Hall, San Francisco, June 5-8, 1894.

DR. FRANK WOODBURY, of Philadelphia, Chairman, called the meeting to order, and DR. GEORGE F. HANSON, of San Francisco, was appointed Secretary, in the absence of DR. F. E. STEWART, who was detained until the second session.

THE CHAIRMAN said that a formal address on the present state of materia medica and pharmacy would be unnecessary in the presence of members of the American Pharmaceutical Association, who came as invited delegates to attend this meeting, and also in the hearing of others present who were widely known as authorities and teachers on these subjects. He deprecated the recent great multiplication of new remedies many of which have toxic properties. Every agent capable of disturbing the physiologic processes of the

human body sufficiently to give it value as a remedial agent, may on the other hand cause a disturbance of the system which is injurious. In other words, according to the old adage: "A remedy is a two-edged sword," and may do harm as well as good. The vulgar mistake therapeutically, which is often made, is to suppose that remedies have only the one special action which is designed to be attained, when it may have a number of others which, if fully recalled, would contra-indicate its employment. It is a great evil that general practitioners are appealed to by specious arguments, to prescribe unknown novelties to their patients on the strength of newspaper advertisements. Every proposed new remedy should be thoroughly studied in the laboratory and hospital under scientific conditions, and not until its value and limitations had been thus fully determined should the physician venture to employ it in his private practice. The great objection to the employment of proprietary remedies is that nothing is known of their composition, and until this is divulged they can have no scientific standing, therefore a grave responsibility is assumed by a physician who orders such an unknown preparation for his confiding patients. It is a subject of congratulation that since our last meeting a new edition of the Pharmacopœia has appeared, and also a new edition of Wood, Remington and Sadtler's United States Dispensatory. Although pharmacy has sustained a severe loss in the death of Professor Maisch, yet it is a source of gratification that his work on the American Dispensatory had so nearly approached completion that the work has appeared at the expected time.

In view of the great importance of medical botany to the physician, as well as the pharmacist, the following resolution is submitted in the hope that it may be approved by the Section:

Resolved, That the AMERICAN MEDICAL ASSOCIATION directs the attention of the medical colleges of the country to the general neglect of the study of botany by medical students, and it is the sense of this Section that the teaching of general descriptive botany should be made a part of the curriculum of study in every medical school.

The above resolution was immediately acted upon, and unanimously adopted, and ordered to be sent to the general session with the addition of the following sentence:

"The delegates from the American Pharmaceutical Association present at this meeting, concur in this action."

The following resolution was also offered at the suggestion of the Chairman, and the same action taken:

Resolved, That the American Pharmaceutical Association be invited to contribute to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION reports of examinations of proprietary and secret nostrums, made under its direction. The officers of the Section on Materia Medica and Pharmacy to act with a committee to be appointed by the American Pharmaceutical Association as a Committee of Conference in order to carry this resolution into effect.

Report of Nominating Committee: For Chairman, Frank Woodbury, Philadelphia, Pa.; for Secretary, Geo. F. Hanson, of San Francisco, Cal.; for members of the Executive Committee, Drs. Frank Woodbury, of Philadelphia; F. E. Stewart, Watkins, N. Y.; H. M. Whelply, of St. Louis, Mo.

Dr. WOODBURY declined to serve another year and nominated Dr. H. M. Whelply, of St. Louis, Mo., as Chairman. The report of the Nominating Committee was then adopted as amended.

Circular by the Permanent Secretary.—The Permanent Secretary has issued the following circular:

At the session held June last, the following was adopted: "WHEREAS, This ASSOCIATION has long recognized the advantages to be derived from the more intimate relation between the State Medical Societies and the AMERICAN MEDICAL ASSOCIATION; it is hereby

Resolved, That we request the various State Medical Societies to perfect their local organizations, so as to include

as far as possible, in the membership of their district societies every regular practitioner within the State;

"That these local societies shall actively coöperate in urging a general attendance upon the annual meetings of the State Societies;

"That the date of the same be so fixed that it shall not interfere with the attendance of those members who are delegates and members of the AMERICAN MEDICAL ASSOCIATION; in order that a general unification of the interests of the medical profession be promoted, and the AMERICAN MEDICAL ASSOCIATION become in a yet higher degree the exponent of the profession;

"That we also request the State Societies to unite in establishing a uniform standard of professional requirement for admission to the practice of medicine and to aid, as far as possible, in advancing the scientific status of the same by the appointment of State Examining Boards, independent of the teaching faculties of the medical colleges. To this end we further direct that the Permanent Secretary of the AMERICAN MEDICAL ASSOCIATION enter into correspondence with the secretaries of the several State Medical Societies and furnish annually a written report of the membership of the State Societies and the working effectiveness of their organizations."

Please acknowledge the receipt of this communication, and send me the following information to enable me to report as directed:

Number of members of your society.

List of auxiliary local societies, and, if you can, the membership of each.

Any other information which you may deem of interest in this connection.

Our next meeting will be held in Baltimore, Md., May 7, 1895.

Yours very truly,

WM. B. ATKINSON, M.D.

Treasurer's Notice.—Members of the ASSOCIATION knowing themselves to be in arrears will please send the amount of their annual subscription to the Treasurer, HENRY P. NEWMAN, M.D., Venetian Building, Chicago, without delay.

The great expense on account of the establishment of the new JOURNAL office, makes it more than ever necessary that our members should be prompt in their response to this notice.

SOCIETY NEWS.

The Medical Association of Western New York held a meeting in Buffalo, October 16.

The Franklin County (Pa.) Medical Society held a well attended meeting October 17.

The Hartford County Medical Society held its semi-annual meeting in Hartford, October 24.

Wabash Railway Surgeons.—The twelfth annual meeting of the Wabash Railway Surgeons will be held in St. Louis, November 1.

The Oshkosh Hospital Association is the title of a new corporation with a capital stock of \$25,000 divided into shares of \$100 each. The incorporators are E. P. Sawyer, J. H. Jennings, W. A. Gordon, G. M. Steele, and B. C. Gadden.

The Military Tract Medical Association, of Illinois, held its annual meeting in Quincy, October 19. The following officers were elected: President, L. L. Ryan, of Galesburg; first Vice-President, Louis Becker, of Knoxville; second Vice-President, C. B. Horrell of Colchester; Secretary and Treasurer, H. M. Harrison of Quincy.

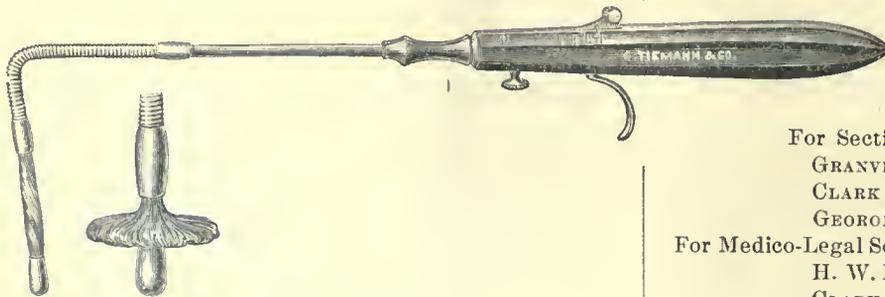

The Central New York Medical Association held its twenty-seventh annual meeting in Buffalo, N. Y., October 16. The attendance was about one hundred and twenty. The following officers were elected: President, F. S. Crego, of Buffalo; first Vice-President, W. S. Cheesman, of Auburn; second Vice-President, E. L. Mooney of Syracuse; Secretary, E. B. Angell.

Ohio State Medical Society.—The third semi-annual meeting of the Ohio State Medical Society was held in Dayton, Oct. 12. The following officers were elected for the ensuing year: President, W. L. Buechner, Youngstown; First Vice-President, James F. Heady, Glendale; Second Vice-President, A. T. Quinn, Wilmington; Secretary and Treasurer, C. H. Mertz, Sandusky. Member Executive Committee, B. M. Ricketts, Cincinnati.

The Lycoming County (Pa.) Medical Society at their September meeting had a report of a case of stab wound of the stomach with recovery, by Dr. Fleming. Drs. Bell and McCormick discussed the question as to typhoid fever being a self-limited disease. The former asserting there was no drug or form of treatment that limited its duration, and the latter took the position that there was nothing in its clinical history or morbid anatomy which would place it among the self-limited diseases, and that if seen early it should be aborted.

Dr. G. D. Nutt presented and described a new instrument for removing the obstruction in membranous croup.

The many objections raised to intubation in pseudo-membranous croup has suggested the feasibility of an instrument by which the false membrane in this disease, which is often loose and easily detached, might be removed prior to the introduction of the proper tube; or in severe and protracted cases, by clearing the trachea from time to time, afford sufficient relief to breathing. Thus allowing the patient to take medicine and nourishment.

A rough diagram was made containing the principles of the introducer of O'Dwyer's tubes, and the bristle probang of the throat, and sent to Geo. Tiemann & Co., who made the neat and efficient instrument so plainly shown in the accompanying wood-cut.

The instrument is to be introduced in the trachea in the same manner as we place a tube, having the mouth kept open by a gag. Then spread the bristles the desired width, and remove it. The bristles are supposed to catch and remove the loose membrane. The proper width of the bristles can be obtained by the distance we push the knob on the handle. A small indicator near the knob shows the different diameters the bristles can be spread. I have had only one opportunity of using the instrument since it was made. It was on a child aged 5 years, having diphtheritic croup. It was easily introduced, and caused but little distress. On its removal a complete cast of the trachea, about one and one-half inches long was expectorated, with some of the membrane clinging to the bristles. The relief to breathing was quite marked and continued for several hours, but the child subsequently died from exhaustion.

New York Academy of Medicine.—There will be a joint session of the Medico-Legal Society and the Section of Medico-Legal Surgery, at the Academy of Medicine, New York City, on Thursday, Nov. 15, 1894, at 8 o'clock P.M. President H. W. Mitchell, M.D., in the chair. The program is as follows:

Election of new members and miscellaneous business; nomination of officers for the ensuing year.

Session of the Section on Medico-Legal Surgery, Chief Surgeon Granville P. Conn, M.D., in the chair.

Opening Address, by Chief Surgeon Granville P. Conn, M.D., on "Hygienic Training of Men in Charge of Railway Trains." Discussion of same limited to five minutes each.

"Expert Examination of Plaintiff in Damage Cases, when Ordered by the Court." By George Chaffee, M.D., ex-President New York State Society of Railway Surgeons. Discussion, limited to five minutes by Clark Bell, Esq., Judge Roger A. Pryor, Nelson Smith, Esq., Judge Abram H. Dailey, H. W. Mitchell, Professor Stillings, of N. H., Chief Surgeon V. C. R. R., M. Cavana, M.D., and ex-Surrogate R. S. Ransom.

"The True Line of Duty of the Railway Surgeon." By Clark Bell, Esq. Discussion, five minutes each, by Surgeon George Chaffee, M.D., Surgeon A. M. Phelps, M.D., R. S. Harnden, M.D., C. M. Daniel, M.D., S. S. Thorne, M.D., J. B. Murdoch, M.D., Nicholas Senn, M.D., W. B. Outten, M.D., G. P. Conn, M.D., and others. Eminent surgeons have been invited to submit views on this subject who can not be present. Reports will be read from various parts of the whole country.

"Medical Witnesses." By R. S. Harnden, M.D., ex-President Erie Railway Surgeons. Discussions, five minutes each, by H. W. Mitchell, M.D., Chief Surgeon Estes, Lehigh Valley, R. R., M. Cavana, M.D., C. M. Daniels, M.D., and others.

The New York State Association of Railway Surgeons holds its annual meeting at the Academy of Medicine on same day—morning and afternoon session—to which all our members have been invited, and the members of that Society are cordially invited to attend our meeting, and take part in the discussion.

A general attendance is requested. Members, not on program, wishing the floor, on either subject, will forward their views, in brief, to the Secretary, if unable to be present. Members will please be prompt in attendance.

For Section on Medico-Legal Surgery.

GRANVILLE P. CONN, Chairman.

CLARK BELL, Vice-Chairman and Secretary.

GEORGE CHAFFEE, M.D., Treasurer.

For Medico-Legal Society,

H. W. MITCHELL, President.

CLARK BELL, Secretary.

F. B. DOWNS, M.D., Assistant Secretary.

NECROLOGY.

STUART DOUGLAS, M.D., died Monday, the 14th inst., at New York City. He was a native of Alexandria, Virginia, born there in January, 1861. He graduated in medicine at the University of Virginia when he was 20 years of age, after having taken both the academic and medical courses. He also took a medical course at one of the New York colleges, and soon afterward received an appointment as physician to the Asylum on Ward's Island. In 1887 he was promoted to the responsible position of Physician-in-Charge at the Insane Pavilion attached to Bellevue Hospital. He became a member of the New York Academy of Medicine and of the staff of the Vanderbilt Clinic. His teaching positions in the line of his specialty, in nervous and mental diseases, were in the New York Post-Graduate School and in the University Medical Department. He was frequently called upon to testify as an expert alienist. His fatal malady was Bright's disease of the kidneys. He was unmarried.

CHAS. P. SMITH, M.D., of Chester, New York, died Oct. 12, 1894, in the sixty-seventh year of his age. He was a graduate in medicine from the Castleton School, class of 1851. He had been a practitioner of Orange County over forty years and had been the President of the local Board of Education. He left a widow and seven children. He was a man of refinement and scholarly attainments.—Wm. Mitchell, M.D., of

Monmouth, Ill., October 14, aged 82 years.—Stephen E. Mossop, M.D., of Seymour, Ind., October 16, aged 79.—H. L. Cowan, M.D., of Ingleside, W. Va., October 14. He was a graduate of the Virginia Medical College, and the University of Virginia, and about 42 years of age.—A. S. Hickey, M.D., of Auburn, N. Y., October 17 aged 56.—Jacob Newkirk, M.D., formerly a practitioner at Roxbury, Delaware County, New York, died at Binghamton, on August 13 in his ninetyeth year. He graduated over half a century ago, at the now extinct medical school at Fairfield, that bore the almost forgotten name of "The College of Physicians and Surgeons of the Western District of New York."

PUBLIC HEALTH.

Of no Further Interest.—Latest advices—cable dispatches of the 23d inst.—announce such a decrease of Asiatic cholera in Europe as to deprive the disease of any further interest this season to public health authorities. For the week ending October 10, Surgeon Fairfax Irwin, U. S. M. H. S., reports a decline of nearly 50 per cent. in the number of cases in Austro-Hungary, which has been the principal seat of the disease in Europe outside of Russia. In this latter country, also, the decrease has been marked and the belief is expressed that the advent of cold weather will put an early end to the epidemic. The port of Marseilles has been declared free from the disease and inspection of vessels has been discontinued; "sporadic" cases continue to occur elsewhere in France and in Holland and Belgium, but these excite no alarm and the cholera epidemic of 1894 in Europe is practically at an end.

Hygiene in A. D. 1900.—The program for the exhibit of progress in civil and military hygiene, at the International Exposition to be held in Paris in 1900, is already completed and is published in *The Medical Week* of October 5. It embraces nine divisions, the scope of which are sufficiently indicated in the following titles: 1, science of hygiene, its history and progress; 2, personal hygiene and hygiene of dwellings; 3, hygiene in public buildings and collective establishments; 4, hygiene in rural communities; 5, hygiene and sanitation of cities; 6, defense of frontiers against pestilential diseases. 7, provisions and utensils; 8, mineral waters and sanatoria; 9, sanitary statistics and legislation. As is entirely proper, the application of the discoveries of Pasteur to the prophylaxis of infectious diseases will be given a prominent place, as constituting one of the chief glories of France. The sanitary services of the Army and Navy and of societies for extending aid to the wounded are to be grouped in a separate class. A curious dispute, by the way, has arisen in connection with the date of this International Exposition. It was projected to celebrate the birth of the twentieth century rather than to commemorate the nineteenth. But M. Camille Flammarion and Dr. Bertillon disagree as to which century the year 1900 belongs to, and two sharply opposing parties have formed under their respective leaderships—the one contending that the nineteenth century will end with the close of the year 1899; the other arguing, with equal earnestness, that the twentieth century can not possibly begin until Jan. 1, 1901, just as the second decade of figures begins with 11, while 10 closes the first. So heated has become the discussion and so uncompromising are the opposing parties that, according to the Paris correspondent of the *New York Sun*, it has been proposed the Government shall fix the *Fin de Siecle* by official decision. At the proper time, placards like theatrical posters are to be displayed: "Tomorrow, close of the nineteenth century! Day after tomorrow, opening of the twentieth century! Entrance free!"

Smallpox and Darkness.—The mild autumn weather seems thus far to have retarded the anticipated diffusion of smallpox. There is, nevertheless, a sufficient number of foci in the country to keep health authorities on the alert and to lend interest not only to preventive efforts but to suggestions of new modes of treatment. The *Texas Sanitarian* calls attention to the use of the bichlorid solution "discovered" by Dr. T. C. Osborne, Health Officer of Cleburne, Texas, and "is surprised that a claim to a discovery of such vast significance and value, given to the profession by a veteran physician of unimpeachable integrity and of half a century of observation in an extensive practice, should have attracted so little attention." Dr. Osborne "adds a teaspoonful [of the mercuric chlorid] to a bowl of water and applies it freely to the entire surface." If the "discovery" has as yet failed to receive proper attention it may be, as the *Sanitarian* sagely remarks, because "one swallow does not make a summer, nor one case establish a truth," and the claim thus far is based on one case only. The "red chamber method," on the other hand, is just now receiving a vast amount of attention on the Continent, recent issues of *The Medical Week* containing elaborate papers on this method by Drs. Oettlinger, of Paris, Finsen, of Copenhagen, and others. This treatment—which consists in isolating the patient in a room into which only the red rays of the solar spectrum are allowed to penetrate; or, carried to its extreme, in a room kept in complete and unbroken darkness—is a revival of a method in vogue in the eighteenth century, but abandoned since the days of Sydenham. Frequent attempts at its revival have been made during the last twenty-five years, but they have never before attained such importance as at present. In this country it was announced during last winter that one of the smallpox pavilions on North Brother Island in New York harbor was to be fitted up with red glass windows and with red glass globes for the lights used at night, and otherwise prepared for a trial of the method. Some such test on a large scale will be necessary before there is any general reversion to the exclusion of light and air, the clothing of the patient in red garments and his bed and room in red coverings and draperies, as was the practice in the pre-Jennerian days and as is still the custom in Roumania and other parts of Europe and in many provinces of China.

With Benevolent Reserve.—Even that congenital skeptic Prof. Mariano Semmola, of Naples, who was among the first to condemn—and justly, as the event proved—the tuberculin of Koch, approves with what the *Lancet* (London) quotes as "benevolent reserve," the wonderfully successful serum treatment and prophylaxis of diphtheria. Semmola's "reserve" is, confessedly, inspired by a present inability to comprehend the true mechanism of the antitoxin action—an inability which in one of his exacting logical nature, arouses incredulity. It is no doubt true, as he asserts, that "we have no demonstrated example of salutary chemical antidotisms which take place in the circulatory torrent based upon reactions analogous to those of the recognized antidotes." But that is only to say that we do not yet know "the altogether" of the vital forces and their action. Meanwhile, the Professor has been so far impressed by the accumulating mass of evidence of successful results that, as the *Lancet* records, he has been instrumental in sending a distinguished alumnus, Dr. Alfredo Montefusco, to Paris, there to master at the Pasteur Institute the new method of treatment, with the object of testing and "checking" it at Naples under Semmola's own supervision. The only other dissonant note in the general chorus of praise of the diphtheria antitoxin is that sounded by a few who hold that a sufficient period has not yet elapsed in which to fully test its merits—it has been used now for about three years; that the present incidence of diphtheria, in which such almost miraculous results have been obtained may not be of the severest type, and that it remains to be seen whether antitoxin will

stand the test of one of the severe epidemics—the *foudroyant* cases, that carry off their victims in a few days.”

Appeals for subscriptions to defray the expense of free antiphtheria treatment continue to appear, among recent ones being that in behalf of the Children's Hospital in Berlin, signed by Virchow, Skrzewska and Siegmund, and another headed by Prince Schoenaich-Carolath, who has accepted the chairmanship of a committee to furnish the serum free for the treatment of the poor. The German Imperial Board of Health has proposed that the production of the serum be made a State monopoly, but the proposition has not met with favor, and instead it is suggested that the Government make special appropriations of funds for its purchase for the use of hospitals and clinics under State control. The British Institute of Preventive Medicine, which, as previously noted in the *JOURNAL*, has undertaken the production of the serum on a large scale, has secured the services of Sir Joseph Lister under whose supervision the antitoxin “plant” has been placed, and it is expected to supply the product at sixpence a dose; the present price is about the equivalent of \$1.75 to \$2.50 a dose, according to the strength of the serum. Finally, a cable dispatch of the 24th inst., announces that M. Casimir-Perier, President of the French Republic, has visited the Pasteur Institute, inspected the establishment, including the horses which furnish the serum, and took the occasion to decorate Professor Roux with the order of Commander of the Legion of Honor in recognition of his services in connection with this, the most notable achievement of Pasteurism yet recorded. M. Roux, in expressing his appreciation of the honor, modestly disclaimed pre-eminence and declared that MM. Behring and Löffler were the first discoverers of the properties of the antitoxin.

MISCELLANY.

Dr. Austin Flint, of New York, has been elected President of the New York State Medical Association for the ensuing year.

Dr. Arthur W. Hurd is to be appointed Superintendent of the Buffalo State Hospital, Buffalo, N. Y., to succeed the late Dr. Judson B. Andrews.

The Marion-Sims College of Medicine, St. Louis, opened with 265 matriculates, and with a Senior class of 70. The Faculty has authorized a delegation to represent the College at the unveiling of the statue of J. Marion-Sims in New York City, on the 18th inst.

Medical Press Association.—The following has been issued: “The Medical Press Association (of France), following its fraternal work in favor of Dr. Lafitte, hopes to realize its project of a subscription in aid of the children of our unfortunate *confrère*. A committee has been formed to collect the subscriptions which should be addressed to Dr. Marcel Baudoin, 14 Boulevard Saint-Germain, Secretary-General of the Association.”

Lucrative Charlatanism.—The police of Kieff recently arrested a farrier who had arrived there from Warsaw and was “curing” all sorts of diseases with his “Miraculous Pills.” In his rooms were found 3,782 letters asking for these pills and containing 11,807 rubles. Among the writers were not only individuals of the so-called intelligent classes, clergymen, etc., but pharmacists and chemists. A French contemporary remarks that these pills were no doubt “miraculous”—but the miracle was wrought in favor of the seller, not the purchaser.

Village Sanitation.—A resolution adopted by the Tropical Section of the International Congress of Hygiene at its recent meeting at Buda-Pesth has as much interest for the rural communities of this country as for the inhabitants of India, on whose behalf it was adopted after the reading of a paper by Miss Florence Nightingale. The Section considered that the best results would be obtained through the coöperation of the people themselves if they are instructed

in the primary rules of health. The most pressing needs appear to be a wholesome water supply and the removal of refuse and other insanitary matter from the neighborhood of dwellings.

Ernest Hart on Holmes.—In the current number of the *British Medical Journal*, Mr. Ernest Hart, its editor, gives a most interesting, albeit discursive, account of his last visit to Oliver Wendell Holmes, made during Mr. Hart's tour of this country during the World's Fair year. The account closes with the following appreciative tribute: “And so I passed away from the presence of one of the most lovable and notable figures of modern medicine, a personality pregnant with the perfume of ripe and sweet old age, and leaving recollections of a rarely perspicuous and sympathetic insight, a playful and pungent but not caustic humor, and a pervasive benevolence which was far reaching but discriminating.”

Medical Women in Bosnia.—In connection with the Hygienic Congress recently held at Buda-Pesth, it is reported that a document was issued, on behalf of the Government of Bosnia and the Herzegovina, in which it is stated that there is reason to hope for an important improvement in the sanitary condition and health of the female population of Mahomedan countries through an increase in the number of lady doctors. Mahomedan women have, on religious grounds, an invincible antipathy to treatment by men. The sad consequence of this repugnance is that they are almost exclusively attended by ignorant and superstitious nurses. Under such circumstances it is easy to conceive what a high death rate prevails. The Bosnian administration is endeavoring to lessen this evil by the introduction of lady doctors.

Princess Christian's Paper at the Buda-Pesth Congress.—The subject of the paper prepared by the Princess, as President of the Royal Association of British Nurses, was the progress made in the care of the sick and the extension of sanitary and hygienic knowledge in Great Britain during recent years. The paper was read in Section 19, the Sanitarian Federation, by Dr. Thorne, the Secretary of the Association. The subject was the importance of special education and training for nurses for the sick, and the steady and encouraging progress made in this direction in the United Kingdom. No hospital of importance was now considered complete without a training school for nurses. The paper gave a *résumé* of the Royal Association of British Nurses, the roll of which now bears the names of two thousand nurses, a of whom have undergone three years of probation. The curriculum was then described and the hope expressed that the time was not far distant when the State would see the importance of recognizing a definite diploma of nursing, and giving an official sanction to the maintenance of the register. In conclusion, emphasis was laid on the fact that nurses must also be good women, in the highest and best sense of the word.

The Angel of Death is Fleet.—The *Glasgow Medical Journal* has the following antique legend, the moral of which is that Azrael had every facility at his disposal for the harvest of souls whenever the dread message was pronounced. According to the legend the ingenuity of man is wasted in trying to circumvent the grim pursuivant. The story is of King Solomon, who figures largely in Oriental tradition outside of Hebraic lore. It is told of him that, walking one day in a great city, accompanied by a friend, an awesome figure was perceived by them at the head of the street.

“Who is that?” inquired the friend in terror.

Solomon looked and answered: “It is the Angel of Death.” Then the friend begged of Solomon, who had the power of

instantaneous transportation, to send him at once to some far off spot, and Solomon despatched him in a moment to India, thousands of miles away.

The Angel of Death meanwhile approached Solomon and asked: "Who was that man with whom you were just talking?"

Solomon gave the name, and the Angel of Death said: "Strange that he should have been here, for I am ordered to call for him to-night in India!"

What Constitutes the Port of Departure.—To prevent the introduction of contagious diseases into the United States from foreign countries, Congress passed an act (27 Statute 449) in 1893, requiring that each ship leaving a foreign port must obtain from the United States consul stationed there, a clean bill of health. Should the vessel stop on the way at other foreign ports, a similar bill must be obtained at each of such ports. Without such bill or bills of health, it is, by the above-named act, unlawful for a vessel to enter a United States port, and a fine of \$5,000, or less is declared the penalty for non-conformance with this act. In the case of the United States v. the steamship *Dago*, carried to the United States circuit court of appeals, it was shown that the *Dago* cleared from Bristol, England, for Baltimore, without having obtained the bill of health. It was therefore alleged by the United States that the seizure of the ship by the collector of customs at Baltimore, to be released on payment of not more than \$5,000 (the exact amount to be fixed by the court) was in accordance with the law. The vessel filed an answer claiming that she had complied in all respects with the requirements of the law, having procured a bill of health from the American consul at Newport, Wales, which she claimed as her last port of departure, although it was shown that she merely called there on her way to Baltimore, having cleared from Bristol, England. The court of appeals held (May 22, 1894) that this was not a valid defense, as the port of departure was not the port last touched at, but the port cleared from, and the bill of health, to meet the requirements of the law, should have been procured at Bristol. By means of this wise decision vessels can not, hereafter, claim to be conforming with the law if they "clear from an infected port, stop on the way at another port not so infected, secure the bill of health that would enable them to enter the ports of the United States," and thus defeat the object of said act of Congress by carrying infection to American ports.

Dates of First Snow Falls in the United States.—In the last *Monthly Weather Review*, issued by the Agricultural Department, Prof. Cleveland Abbe gives a table of the dates of the first snowfall of the winter at each of 108 stations of the Signal Service or Weather Bureau, for each of the eight years, 1886-87 to 1893-94 inclusive. Cases in which snow was reported as having fallen on the mountains near by are not included, nor are the mountain stations of Pike's Peak and Mount Washington, because although snow appears nearly every month of the year at these places this is to be considered as indicating the condition of the air in the cloud regions into which their summits penetrate, rather than the climatic conditions proper to the lower arable earth where snowfall is so important to agriculture. The earliest recorded fall was at Buffalo, N. Y., Aug. 28, 1891, but this seems to have been a purely local phenomenon as none of the other stations had a snowfall on that day. Some parts of the extreme Northwest get snow in September and nearly always before October has passed. Occasionally snow appears in New England in October, and failing that, certainly in November. The dates of first snowfall in New York and Philadelphia do not differ much from those of New England. In Chicago the earliest fall was on Oct. 18, 1888, the latest first fall on Nov. 17, 1886; last year it occurred on November 15. The South Atlantic States had no snow in 87-88, nor in 1890-91. Key West, Fla., Yuma, Ariz., and San Diego and Los Angeles, Cal., had no snow during the

period of eight years; and Brownsville and San Antonio, Texas, would have been added to this list but for a light fall in 1887-88. "A chart showing the total snowfall from July 1, 1893 to June 30, 1894 is being prepared for publication in the *Review* when the important relations between snowfall and topography, geology, forestry, agriculture, water supply and other matters will be mentioned."

A Co-operative Bacteriologic Investigation.—The following is the circular letter referred to in our editorial remarks under the above heading. It is requested that replies be sent to Dr. Adami, McGill University, Montreal, Canada:

AMERICAN PUBLIC HEALTH ASSOCIATION. (*Committee on Water Supply.*—*Letter No. 1.*)

Sir:—Owing to the unsatisfactory state of our knowledge in regard to the differentiation and identification of species of bacteria in water, a proposal that coöperative work upon the subject should be undertaken among American bacteriologists was recommended in the report of the Committee of the American Public Health Association upon "Pollution of Water Supplies," at the meeting of this Association in Montreal, Sept. 25, 1894. This proposition, emanating from the McGill University, Montreal, advises the adoption of uniform standard culture media and the employment of the same along the lines of a definite systematic scheme, to be determined upon by the associated workers. It was further proposed that each laboratory, willing to coöperate in this work, devote itself particularly to a single so-called group of species of water bacteria. The necessity for some such coöperative plan is generally recognized by experienced bacteriologists, and this recommendation received the cordial and substantial support of the American Public Health Association in the form of a grant for preliminary expenses.

We, the undersigned, having been appointed a sub-committee and charged with the duties of discovering to what extent the bacteriologists of America are willing to coöperate to this end, what laboratories there are possessing the required facilities for carrying on a work of this nature, and what work has in them been accomplished in the identification and differentiation of species, beg you to inform us whether you or any of those working in your laboratory are willing to coöperate in this work. At the same time (in order that the sub-committee may without delay be enabled to lay the framework of a scheme of combined work before those interested), we shall be thankful to you if you will aid us by answering the following questions at your very earliest convenience:

1. What evidence has been obtained in your laboratory as to the variability of species?
2. What culture media have you in most common use?
3. Will you kindly give us as detailed a description as your time will permit of the composition and methods of preparation of the various culture media employed in your laboratory?
4. What system do you follow in the employment of the various media for the identification of species?
5. Can you mention any special points in the preparation and employment of media, which you hold to be of material aid in the identification of species?

Inasmuch as most of these questions admit of being answered at varying length, according to the opinions and experience of different observers, we have thought fit not to print them on spaced forms. We would esteem it a favor if they be answered by number and in such a way that each reply may be tabulated and preserved. And as this may be the first of a series of letters we would suggest that, for future reference and correspondence, copies be kept of the replies sent by you.

We inclose an extra copy of this letter, begging you to give it to any one whose name is not upon the inclosed list of those to whom the letter is being addressed in the first place, who in your opinion is likely to coöperate in the event of the scheme here indicated being found practicable. We are, Sir,

Yours faithfully,

C. SMART, M.B. M.Ch.,

Major and Surgeon U. S. Army, Chairman of the Committee on Pollution of Water Supplies, A. P. H. A.

G. W. FULLER, Sc. B.,

Biologist in charge of the Lawrence Experimental Station, Massachusetts State Board of Health.

WYATT G. JOHNSTON, M.D.,

Bacteriologist to the Board of Health of the Province of Quebec.

J. GEORGE ADAMI, M.A., M.D.,

Professor of Pathology, McGill University, Montreal.

The First Recorded Death in Hypnosis.—The death of Ella Salamon, in Tuzer, Upper Hungary, at her home, on Sept. 17, 1894, while in an hypnotic state, has attracted much attention, owing to the fact that it is the first recorded instance of death of this kind. We are able to give the following abridged statement from the pen of Dr. William von Vragassy, who was visiting at the home of Count Lászlo Forgách, an uncle of the unfortunate victim, and who was present during the hypnotic experiment, and witnessed her death and the subsequent autopsy:

"Miss Salamon was hypnotized in the presence of her parents and several relatives and friends; the operator, Mr. Neukomm, with the permission of the family and a full understanding with Miss Salamon, wished to induce in her an hypnotic state to gain information concerning the illness of the operator's brother, about whose malady the attending physicians differed. As Miss Salamon passed into hypnosis she seemed to be fatigued. The operator explained that he would attempt a very interesting experiment. He stated that for some time his brother, in Werschetz, had been raising blood, and the physicians could not agree that it came from the lungs or the stomach. Calling upon Miss Salamon to exercise clairvoyance while hypnotized, she gave a wonderful description of the patient's lungs, with the topography, pathology, diagnosis and prognosis. The operator said to her: 'We are now in Werschetz; do you see my brother?' 'I do not see him,' she replied. He then explained to her the location of the house in which his brother lived, and said: 'My brother is in the third room.' 'Yes, yes!' said the subject, in tones of conviction, 'we are there.' 'How is my brother?' he questioned. She replied: 'He is very ill.' In answer to more questions, the subject then went on to explain the details of the patient's malady. She spoke of the lungs of the distant patient as though they were before her on a plate. She used technical language with the greatest exactness, though she had never had medical training. After this, the subject's face was very pale and she seemed exhausted. The operator asked her a final question: 'What do you think of my brother's disease?' With difficulty she answered, 'Be prepared for the worst.' At that instant she fell from her chair with a hoarse cry; her tongue protruded from her mouth, and she became collapsed. Her head was lowered, clothing loosened, artificial respiration performed after Sylvester's method, and ether injections given; later she was wrapped in blankets, but she died almost in a few seconds in spite of all.

"The autopsy was conducted by an assistant in the Pathologic Institute in Buda-Pesth in the presence of Dr. Jozsás and myself. The brain exhibited a high degree of anemia and consecutive malnutrition, with indications of edema; otherwise there was no abnormality. I consider the causes of death, acute anemia of the brain, incident to the hypnotic state, with syncope and heart failure."

Professor R. von Kraft-Ebing writes: "According to reports, the case is so unheard-of that there must have been concurrence of quite extraordinary circumstances. In medical experience it is the first case of death in hypnosis. Inasmuch as there are thousands of hypnotic experiments performed daily by the laity without injury to health, one must regard this exception as inevitable.

"There is no doubt that Ella Salamon died in hypnosis, but that she died by hypnosis is questionable. In the absence of a history of her life and a detailed description of her mental and physical condition during the fatal hypnosis, the manner of death can not be determined with certainty.

"It appears that Miss Salamon was about 23 years old, very nervous, and that she had often been hypnotized. On this occasion she seemed weary. The hypnotizer, in accordance with an unscientific belief of the laity, induced in her an alleged capability of clairvoyance, which for a person so intelligent as Miss Salamon, was a new and very trying experiment, calculated to cause her great emotional excitement. Miss Salamon then exerted herself, according to report, to be agreeable and useful in the suggested capacity. While in the hallucinatory state she believed that she saw a diseased lung, and she gave a long description of the pathologic condition, in an excited and agitated manner. The final question of the operator had an intense emotional effect on her, and caused her collapse.

"The brief report of the autopsy leaves no doubt that she died of cerebral anemia. It can be certainly stated that she did not die of suffocation (there was no spasm of the

tongue); nor from cerebral hemorrhage; and not from auto- or imparted suggestion—causes which might prove fatal under certain circumstances. All the symptoms given point to the brain as the organ concerned in inducing death, but it is uncertain whether through serous apoplexy or so-called nervous apoplexy.

"The question of the cause of death in this case probably permits this answer: The unskilful use of hypnosis by a layman and the unusually violent cerebral excitement stand as the causes of death; but it must also be considered that the victim was probably a morbidly constituted person, with a personality which reacted abnormally to stimulation, and whose death might have been hastened when awake by a violent psychic force.

"This case teaches that the laity should not practice hypnosis; that one must not play with hypnosis. In Austria there is an enactment of Oct. 26, 1845, which permits only authorized physicians the use of magnetism (hypnotism), and makes its use by others punishable."

Washington Notes.

THE SIBLEY MEMORIAL HOSPITAL, adjacent to the Deaconess Home, 1140 North Capitol Street, will be dedicated Friday, October 19, at 2 P.M. Bishop Bowman, Bishop Hurst, Mrs. Clinton B. Fisk, Dr. Wilson, Dr. Widerman, Dr. Naylor, Dr. Brown and B. H. Warner will take part in the exercises.

OUT-DOOR MATERNITY SERVICE.—The maternity service of the Central Dispensary and Emergency Hospital is now in operation and will give assistance to many poor families and instruct the undergraduate and beginning practitioner. The officers are Dr. H. L. E. Johnson, in charge; Dr. Edward E. Morse, Associate Chief; Drs. R. D. Boss, James Stuart and F. C. Boyer, Assistants.

SMALLPOX AND CHICKENPOX.—A baby from South Pomfret, Vt., arrived here three weeks ago with what was claimed to be "confluent chickenpox," and died last week. The colored girl who washed the clothing of the child, was sent to the pest-house suffering with smallpox. The Health Officer, Dr. Woodward, has taken measures to prevent the spread of the disease.

MEDICAL SOCIETY OF THE DISTRICT.—At the Wednesday meeting of last week, Dr. Nason read the history of, and presented a patient suffering with unilateral hypertrophy. The entire right half of the body was involved. Dr. Neke presented a specimen of malformation of the heart and read the history of the case. The origin or cause of an abscess in the brain in this case brought out an interesting discussion. Dr. Lamb made the following report on the specimen:

"The malformed heart of a child 9 years old. The aorta and pulmonary artery are transposed; the former arising from the right ventricle, the latter from the left ventricle; the latter, however, arises as a cul-de-sac and there is a rudimentary valve. The foramen ovale is large and patulous. There is a large opening in the upper part of the interventricular septum. The blood of the auricles and ventricles therefore commingled. The ductus arteriosus is obliterated. The lungs were supplied with blood by a right and left pulmonary branch which were given off from the transverse arch of the aorta, in addition to the usual branches. The entire assemblage of anomalies dates back to about the seventh fetal week, perhaps earlier; and makes rather a unique picture. A small extra ventricular abscess of left middle lobe 1x2 inches."

THE WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—The annual business meeting of the Society was held on the 19th inst., for the election of officers and resulted as follows: Drs. H. D. Fry, President; S. S. Adams, and G. B. Harrison, Vice-Presidents; G. W. Cook, Recording Secretary; W. S. Bowen, Corresponding Secretary; Committee on Business, Drs. J. T. Winton, F. S. Nash and E. L. Tompkins. Committee on Admission, Drs. J. F. Scott, L. Elliot and H. L. E. Johnson. Committee on Publication, Drs. G. W. Cook, L. Elliott, H. B. Deale and W. M. Sprigg. Committee on Microscopy, Drs. G. N. Acker, Brown and Scott. The following named gentlemen were unanimously elected

to Honorary Membership: Drs. H. P. C. Wilson, of Baltimore; Theophilus Parvin, of Philadelphia; W. T. Lusk, of New York; Matt D. Mann, of Buffalo; John P. Reynolds, of Boston; John Byrne, of Brooklyn.

THE HEALTH DEPARTMENT,—under date of Oct. 13, 1894, reports a decrease in the mortality of the city. "In face of the cold and changeable weather which prevailed last week, there was a decided decline in the number of deaths as against that of the previous week. The decrease amounted to nearly 20 per cent. and the death rate fell from 21.7 to 17.5 in that time. The improvement was general. There were very many less deaths comparatively among both the aged over 60 years and the children under 5 years old. There was a continued absence of fatal forms of contagious diseases, except the six cases of diphtheria and of the various malarial ailments. The health of the city is good and the present hygienic conditions are only a continuation of the same favorable state characterizing the present fiscal year. During last year there were four hundred and thirteen less deaths than in the preceding year, and the returns of the first quarter of the present fiscal year show a falling off of one hundred and twenty-eight up to the first day of this month.

St. Louis Notes.

DR. GIVEN CAMPBELL, JR., has resigned the Chair of Bacteriology in the Marion-Sims College of Medicine, St. Louis, on account of ill health. Dr. Hugo Summa has assumed the duties of the chair made vacant, by adding them to his work as Professor of Pathology.

ST. LOUIS ELECTRIC STREET RAILWAYS.—The electric street railway companies of St. Louis are thoroughly awakening to the importance of precautions against liabilities for injury of passengers and others. The evidence of this is a new regulation that will soon be enforced, namely, a thorough ophthalmologic examination of all persons employed in the running of the cars. The wisdom of such a departure is at once apparent when it is remembered that among the hundreds of men thus employed visual anomalies can not but occur in their common proportion, and that the safety of passengers and persons on foot often depends upon the accuracy with which the motor-men and conductors instantaneously calculate distance when standing on a rapidly moving car. Probably the contingency of an accident where a motor-man or conductor could be shown to have defective vision, and the certain liability of the company under such circumstances, have led the managements of the roads to consider the adoption of this safeguard. This is only another instance where the selfish interest of corporations steps in to make regulations to insure the safety of the public where the government granting such corporations charters has neglected to do its duty and insist upon the safeguards that science has shown to be reasonable and necessary. It is to be hoped that every road in the city will follow the example of those that will require the necessary standard of vision in their employees.

THE *Occidental Medical Times* contains an allusion to St. Louis from the pen of Dr. Albert Abrams, of San Francisco, that seems to call for comment. After enumeration of an unheard-of number of medical colleges, he continues: "I overheard the following conversation between two men in St. Louis: Said the one, 'Hallo, Bill! you aint driving a car no more?' 'No,' said Bill, 'it's hard work; and besides that, I'm going to become a doctor. It's a blamed sight easier to wear a plug hat and glasses than to drive a car. Doc. (referring to a professor in a regular school) said I'd get through all right if I paid the fees.' This, I hope, will not be accepted as an apt illustration of the status of medical education in St. Louis." There need be no fear that this medical joke will pass in St. Louis as an "apt illustration" of anything but the tendency there is in all humorists, born, made, lay and medical, to make the facts support the witticism invented for the occasion. Had the reported conver-

sation been decked out with a few St. Louis colloquialisms the writer might have convinced St. Louisians that he really knew "where he was at" when sojourning here. But the "conversation" contains the strongest evidence of its artificial nature; there are no car-drivers in St. Louis, for she now boasts of only motor-men and conductors. No, this is not quite true; there are a very few car-drivers on one insignificant line where the cars run only frequently enough to keep the charter, and it must be granted that possibly the Doctor overheard an ex-driver of this line. What a pity the name of the professor in a regular school alluded to was omitted; but possibly it could not be recalled.

Louisville Notes.

GRAND LODGE OF THE STATE OF KENTUCKY.—At a meeting of the Grand Lodge of the State of Kentucky just adjourned, it was decided unanimously to celebrate the centennial of the Grand Lodge in 1900 by dedicating a Masonic Infirmary, which is to be built as an adjunct to the Masonic Widows' and Orphans' Home, now so prosperous. There was much enthusiasm displayed and steps taken at once to raise the funds with which to begin the work.

WATER SUPPLY.—The citizens have been much wrought up over the condition of the city water supply; as it has transpired upon investigation by Health Officer White that the basins had not been cleaned since their erection some eleven years ago. The Water Company sold the fish in the reservoirs to a local dealer for \$200, and several thirty and forty pound fish were caught, beside numberless small ones. The question of filtration of the city water supply is being agitated and it is very much desired that some means will be found that will make it practicable.

OPENING OF THE SCHOOLS.—The fall schools have gotten under full sway again for the session of 1894-95. Owing to the general adoption of the three-year graded course the schools have opened this year with fewer matriculates than heretofore. There have been some changes in the faculties, but they are practically the same as those of last year. In the Louisville Medical College, Dr. J. G. Cecil occupies the Chair of Practice, held for so many years by Dr. W. H. Galt, deceased, who was also for many years Health Officer of this city. Dr. Robert Sievers is Lecturer upon Pediatrics. The spring schools are equipped and ready for work; the Hospital College occupies its new building as does the Kentucky School of Medicine, which has about completed a commodious Dispensary and Hospital adjoining its old building.

NOTIFICATION OF CONTAGIOUS DISEASES.—Louisville is very much behind many of her sister cities, in that there is no law here requiring the reporting of contagious diseases, or an appropriation sufficient to enable the Department to properly isolate and disinfect houses where such diseases exist. There has been more than the usual amount of diphtheria in the city of late, not an epidemic but an unusual prevalence, and the President of the State Board of Health, Dr. Mathews, and the local Health Officer are using all of their influence to have a contagious-disease act passed by the Council. The one prepared for presentation to that body is a very comprehensive one, and will enable the Health Officer to do good work toward the prevention of the spread of contagious diseases.

DIPHTHERIA.—An epidemic of diphtheria was reported to the State Board of Health at its last meeting, as raging in the city of Frankfort, this State. Dr. H. E. Tuley, of this city, was sent as its representative to assist the local authorities in the suppression of 'the trouble. The public schools were found closed, and upon investigation it was ascertained that there had been some twenty-nine cases with nine deaths, and no effort at isolation or disinfection. This was owing to the fact that there was no local Health Board to control it, the old Board having resigned owing to a misunderstanding of the new law recently passed. A special meeting of the Council was called by the Mayor, a

Board appointed and a very comprehensive and thorough law passed giving full power to the Board to act in all such epidemics. Since, there has been no further trouble.

THE PUBLIC SERVICES.

Promotion in the Hospital Corps, U. S. Army.

Surgeon-General Sternberg, under date October 10, issued a circular relating to promotion of deserving men in the Hospital Corps which may be regarded as a continuation of that of October 2 relating to enlistments in the Corps, an abstract of which was given in the JOURNAL of October 20. Those eligible for detail as acting hospital stewards are privates who have served one year or more in the Hospital Corps and have displayed particular merit; but those who have had previous service as non-commissioned officers in the line or who have special training in civil life, such as a course at a college of pharmacy or training school for nurses may not be required to serve the full year of probation. No person is eligible for promotion to the position of hospital steward unless he has demonstrated his fitness therefor by service of not less than twelve months as acting hospital steward. The examination for acting hospital steward and hospital steward will embrace the same subjects, but the questions for candidates for the lower grade will be less difficult and less comprehensive. Formerly minor surgery and elementary hygiene, a knowledge of which was required on the part of the steward, were not included in the scheme of examination for the lower grade. A re-examination before first reenlistment may not be required of a hospital steward if the post surgeon and medical director state that the steward has performed his duties efficiently. He is submitted to re-examination before his second reenlistment; but no subsequent re-examination will ordinarily be required. This is an alteration of former regulations, which called for re-examination prior to each reenlistment until the steward had become a veteran of twenty years' service. The examinations are conducted by a board composed of all the commissioned medical officers of the post at which the candidate may be serving or to which he may be sent for examination. The results of the examination by the board are entered on a merit roll under the following headings: 1, physical condition; 2, character and habits, especially as to the use of stimulants and narcotics; 3, discipline and control of men; 4, knowledge of regulations; 5, nursing; 6, dispensary work; 7, clerical work; 8, principles of cooking and mess management; 9, Hospital Corps drill, and 10, minor surgery, first aid and extraction of teeth. Written questions on the following subjects are prepared and transmitted from the Surgeon-General's office: 1, arithmetic; 2, materia medica; 3, pharmacy; 4, care of sick and ward management; 5, minor surgery and first aid; 6, elementary hygiene. Proficiency in penmanship and orthography are estimated from the papers submitted. In conducting the written examinations a second sheet of the questions sent from the Surgeon-General's office is not given to a candidate until he has completed his answers to those on the sheet already submitted to him; and all questions submitted at one session are to be answered during that session. The board is required to certify that the replies were made without recourse to books, memoranda or other sources of assistance. The report of the board with the written examination papers are forwarded to the Surgeon-General in whose office they are examined and marked for the grading of accepted candidates. Assignments are made as far as practicable in order of merit from the list of passed candidates to fill vacancies occurring during the year. Those who from their low percentage fail to receive appointment during the year following their examination will be permitted to come up for competition with the next class to enable them to obtain a higher percentage and thus improve their prospect of appointment.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Oct. 13, 1894, to Oct. 19, 1894.

Capt. EUGENE L. SWIFT, Asst. Surgeon (Ft. Yates, N. D.), is granted leave of absence for one month, with permission to apply to the proper authority for an extension of one month.

First Lieut. ISAAC P. WARE, Asst. Surgeon, so much of par. 1, S. O. 233, A. G. O., Oct. 1, 1894, as directs him to report to the commanding officer, Camp Eagle Pass, Texas, after his relief from duty at Ft. Supply, is so amended as to direct him to report in person to the commanding officer, Ft. Clark, Texas, for duty at that post. By direction of the Acting Secretary of War.

NAVAL MEDICAL SERVICE.

A candidate for examination and appointment in the Medical Corps of the Navy must be between 21 and 26 years of age and must apply to the Honorable Secretary of the Navy for permission to appear before the Naval Medical Examining Board. The application must be in the handwriting of the applicant, stating age and place of birth, also the place and State of which he is a permanent resident; and must be accompanied by letters or certificates from persons of repute, testifying from personal knowledge to his good habits and moral character and that he is a citizen of the United States.

On receipt of the desired permit he has to notify the President of the Board of the fact and request him to appoint a time for his examination. He will be expected to present to the Board, testimonials of educational and professional fitness. The Board is required under oath to report on the physical, mental, moral, and professional qualifications of the candidate, so that the examinations are necessarily rigid and comprehensive, though simple and practical, and not beyond the attainments of any well educated physician. No allowance is made for the expenses of such persons undergoing examination, which, if interrupted, is usually completed within a week or ten days. An applicant found "not qualified" may be allowed a second examination after one year, but not a third. Appointments are made as vacancies occur, and in the order of merit reported by the Board, but a qualified candidate not appointed within a year, must be re-examined. However, for many years vacancies for successful candidates have always existed. The examinations are held at the Naval Laboratory and Department of Instruction, Brooklyn, New York, or at the Naval Hospital, Mare Island, California where there are permanent boards. There are no fees. The order of examination is 1, Physical. 2, Oral. 3, Written. 4, Clinical, and 5, Practical.

The physical examination is very thorough. The oral and written examinations are on the following subjects: General history, natural science, botany, geology, zoology, general literature, anatomy, histology, physiology, theory and practice of medicine, principles and practice of

surgery, chemistry, legal medicine, toxicology, materia medica, therapeutics, pharmacy, obstetrics and diseases of women and children, hygiene, quarantine, and microscopy. The clinical examination of patients is made at a naval hospital and includes the use of the microscope, thermometer, laryngoscope, ophthalmoscope and other aids to physical diagnosis, and a written clinical report on one or more medical or surgical cases. The practical examination comprises surgical operations on the cadaver, the application of splints, bandages and surgical dressings, the use of the microscope for clinical purposes, and chemic and pharmaceutical manipulations. Candidates possessing special knowledge of the higher mathematics, literature, art, and ancient and modern languages are given full credit for their proficiency. After having passed this examination, the successful candidate, having been commissioned an assistant surgeon, is sent to the Naval Laboratory and Department of Instruction for a three months' course in the special duties required of him in the service. This school was established recently. It requires no fees and is devoted exclusively to special instruction of medical officers recently admitted to the service. The staff consists of members of the Naval Medical Examining Board and the medical officers on duty at the Naval Hospital. The subjects taught are 1, Chemistry, analytical and organic. 2, Hygiene and Sanitary Science. 3, Microscopy and Microbiology. 4, Military Surgery and operative work. 5, Clinical medicine and hospital work. 6, Construction and ventilation of modern war ships. 7, Examination of recruits and life-saving methods. 8, Navy regulations, navy ration, hospital fund, pension fund. 9, Keeping medical records at hospitals and on board vessels of war, and blank forms pertaining to Bureau of Medicine and Surgery. These subjects are taught with special reference to the needs and requirements of the naval service, and therefore embrace particularly gunshot and other wounds, transport of sick and wounded on ships of war and ashore, recruiting, tropical and other diseases to which sailors are exposed in service, examination of water and air, general principles of diet, examination of food, sanitary requirements of ships, hospitals, and camps, clothing, prevention of disease, disinfection of ships, quarantine, etc.

The officers under instruction are under no expense for quarters and as members of the Medical Corps, draw their full shore pay.

After having passed through this excellent course of instruction, under skilled teachers in each special branch, they are examined on the subjects taught and the record of each, together with his other examination papers is bound and kept in the Bureau of Medicine and Surgery as a guide in assignment to duty according to professional and other qualifications. Each assistant surgeon is examined at the expiration of three years' service, and, if successful becomes a passed assistant surgeon.

MEDICAL STAFF OF THE NAVY.

The officers of the Medical Staff of the Navy are as follows: Medical Directors, Medical Inspectors, Surgeons, Passed Assistant Surgeons and Assistant Surgeons. Vacancies in the grades (by death or retirement at the age of 62 or for other causes) are filled in the order of seniority and for each step of promotion a physical and professional examination is required.

| Rank and Pay Table. | At Sea. | On Shore Duty. | On Leave or Waiting Orders. |
|---|---------|----------------|-----------------------------|
| Assistant surgeons | \$1,700 | \$1,400 | \$1,000 |
| Passed assistant surgeons: | | | |
| First five years after date of appointment | 2,000 | 1,800 | 1,500 |
| After five years from date of appointment | 2,200 | 2,000 | 1,700 |
| Surgeons: | | | |
| First five years after date of commission | 2,800 | 2,400 | 2,000 |
| Second five years after date of commission | 3,200 | 2,800 | 2,400 |
| Third five years after date of commission | 3,500 | 3,200 | 2,600 |
| Fourth five years after date of commission | 3,700 | 3,600 | 2,800 |
| After twenty years from date of commission, | 4,200 | 4,000 | 3,000 |
| Fleet surgeons | 4,400 | | |
| Medical directors and medical inspectors at sea. | 4,400 | | |

ORIGINAL ARTICLES.

INTERESTING CASES OF APPENDICITIS.

Read before the New York State Medical Association, Oct. 9, 1894.

BY JOSEPH D. BRYANT, M.D.

NEW YORK CITY.

Believing that the results of experience constitute the only true guide to the wisdom and efficiency of any measure, especially one of a surgical nature I have, therefore, no hesitation in placing before you now for the purposes of thought and practice a record of four cases of appendicitis that have come recently under my observation, together with the lessons they teach:

Case 1.—That of E. B. J., M.D., of Pennsylvania, aged 28, and of good habits in all respects. This patient came to my office for consultation and treatment June 13, 1894, with the following history:

1. Had always been in good health up to the time of the first attack of appendicitis.

2. Had suffered from four attacks of this disease before coming to my notice, from the last of which he had just recovered.

The first attack happened without apparent cause, during the last week in November, 1893, six months before I saw him. This attack was a slight one, lasting but three or four days, and was not severe enough to prevent proper attention to office duties. The second attack happened about six weeks later, and was not severer at the outset than the first one. This attack lasted four days, and on the second day a slight chill occurred, attended with some elevation of temperature. Subsequent to this attack, tenderness in the right ileo-inguinal region was constant in a varying degree. No definite tumor was discernible. The third attack was about three months after the second one, and it will be noticed that this was the severest attack of all. This, like the others, came without apparent cause, but unlike them was announced by a sudden, severe sharp pain which obliged the patient to go to bed at once, where he remained for the next four weeks. During the greater part of this time he had a marked elevation of temperature which, however, did not reach above 101 F. per rectum during the entire course of the attack. A hard, tender tumor made its appearance in the right iliac region during this attack which increased to the size of one's fist; then gradually diminished in size and sensitiveness but did not wholly disappear. The fourth and final attack occurred May 30, 1894, or only about two weeks after recovery from the third. This attack resembled in all essential respects the first and second ones. At all events, following this one the patient made a long journey by rail and reached this city June 13, 1894.

A physical examination at the time of arrival disclosed a hard, tender and somewhat movable tumor, about the size of a hen's egg, located in the ileo-inguinal region, somewhat nearer the brim of the pelvis than to the iliac spine. Rectal examination revealed nothing abnormal. In all other respects the patient was in as satisfactory condition as the fatigue of the journey and previous illness would warrant. Since the patient had come expressly for the benefits of an operation, and was professionally qualified to estimate the advantages and dangers attending it, and was anxious for immediate action, he was sent at once to St. Vincent's Hospital, where it was performed on the following day in the presence of many of the visiting and the house staff of the Hospital. I will not weary you with extended details of this operation, which are already worn threadbare by repeated description from other sources, but rather submit at once, in one, two, three order, those phases of it that are always

essential to advancement; that is, the disclosures attendant on the procedure. At this time it seems proper to say that, owing to the nearness of the tumor to the pelvic brim, and the mobility and ease of its delineation, I expressed the opinion before operation that the diseased appendix extended downward and inward to, and possibly over the brim of the pelvis, and had a long mesentery. The incision made through the abdominal parietes was about five inches in length, and was located about two inches from the anterior superior spine of the ilium and directly upon the inner portion of the ileo-inguinal tumor. No difficulty was experienced in exposing the tumor, which was found to consist of the major part of the appendix surrounded by abundant inflammatory exudation. Only the extreme end of the appendix—about one-half inch—was entirely free from the exudation. This extremity was attached slightly to the peritoneum covering the brim of the pelvis; so slightly, in fact that, although easily detached, there was great danger of rupture, as the structure was frail by reason of internal ulceration.

No adhesion between the tumor and the anterior parietal peritoneum existed, nor was there evidence of present or past suppuration. The tumor was located below the so-called cecum, was attached to its under surface and extended toward the cavity of the pelvis. No evidence of complete perforation of the appendix could be found. Great difficulty was experienced in exposing the portion of the appendix imbedded in the exudation. During the course of the manipulations directed to this object, the frail pulsatious extremity of the organ was easily torn off. However, this accident afforded the opportunity at once of passing a small grooved director into the remaining portion of the appendix for about one inch, then an obstruction was met which was found to be caused: 1, by a complete occlusion of the lumen at that point and 2, by a nearly right-angled bend of the organ. This portion of the appendix and the super-imposed lymph were divided with scissors, thus exposing the lumen to the point of constriction. Afterwards, with some difficulty, the constriction was overcome, and a probe was passed through the remaining inch of the appendix into the caput coli. This, the latter part of the appendix, was much dilated and contained offensive fluid material, while the remaining portion of the organ contained inoffensive pulsatious matter. The appendix was tied within one-half inch of the cecum and the remaining external portion was slit up in the manner before described and cut off at the seat of ligature. On account of the obstinate capillary oozing that attended all efforts to dissect the appendix from its environments, a complete removal was not accomplished. However, all offensive matter was scraped away together with much of the appendix itself, the external incision was reduced to two inches in length by wire sutures; the wound, after thorough disinfection, was lightly packed with iodoform gauze, and the patient was put to bed.

The remaining portion of the history is entirely uneventful. The temperature at no time rose above 101.4 F. per rectum, and after a few days subsistence on milk, koumiss and the like, he was permitted to partake of a more substantial diet. At the end of two weeks he was allowed to sit up, and was discharged about four weeks after operation. At the time of discharge there was a very small sinus, thread-like in size, leading down into the wound. This was due no doubt to the presence of the silk ligature there, employed to tie the appendix.

Case 2.—A. F. S., farmer, aged 45, temperate and with good family history. This patient came under my notice through the advisement of Dr. L. J. Brooks, of Norwich, N. Y., on June 18, 1894, with the following history:

Had always enjoyed good health until the summer of 1893, during which season he had suffered from occasional diarrhea and uneasy sensations in the "right side of the belly," as he expressed it. Suddenly, in September, 1893, he was attacked with severe pain at the right side of the lower

part of the abdomen, and for this reason was obliged to go to bed, where he remained for two weeks. Swelling occurred at the seat of the pain and it was tender there. However, the swelling gradually subsided as the attack "wore off." He made a slow recovery, resuming labor some time in November. He did not regard himself as well then, since he was unable to perform the usual amount of labor, and suffered from great despondency at the same time. Suddenly on April 9, 1894, he was again seized with severe pain in the same region, and was confined to bed for eight days.

Since the last attack the patient has had more or less soreness and dragging sensation in the right iliac region, and has been unable to work. The pain attending the attack radiated toward the ribs of the right side and down the right thigh. Following the attack he suffered frequently from a dull pain extending down the left thigh. Neither vomiting nor diarrhea attended the attack and his appetite was unimpaired.

Physical examination revealed no organic disease. In the right ileo-inguinal region a small, slightly tender and movable tumor could be easily outlined. It was situated about two inches from the anterior spinous process of the ilium and extended directly downward; this the patient said had been the seat of all previous acute local pain and tenderness. He was advised to submit to an operation at once, for the double purpose of removal of the appendix and relief from despondency. Accordingly, on June 20, 1894, he was subjected to operation in the presence of the visiting and resident staff of the Hospital. The operation developed the following items of interest:

1. The incision was made directly upon the tumor, as there was no reason to believe that it extended toward the pelvic cavity.

2. It was placed about two inches from the anterior superior spinous process of the ilium.

3. No difficulty was encountered until after the division of the peritoneum. Then there was found to be a thick layer of distorted omentum lying in front of the caput coli. This structure extended down to Poupart's ligament and was everywhere attached to the abdominal wall, except at the outer border of the incision.

4. The caput coli was bound down by old adhesions and rolled outward, so that the fibrous band leading to the base of the appendix could not be seen until after the separation of the gut from the abdominal wall and its normal replacement had been made.

5. The appendix was turned upward and outward below the caput coli in such a manner as to cause the apex to lie to its outer side.

The organ was entirely enveloped in dense lymph, somewhat vascular, but easily separable from the contiguous tissues. There was no perforation of the appendix. The lumen was distended with jelly-like inoffensive products.

6. At the outer side of the upper part of the caput coli was found a small amount of caseous pus, evidently the product of an antecedent inflammation.

Such were the conditions and in the order of their appearance. It may be well now to speak of the technique employed to meet the unusual conditions. The interposition of distorted and adherent omentum is not of common occurrence in my experience. However, the obstacle was easily though slowly overcome by tearing an opening through the tissue over the seat of the caput coli. It was believed that this bowel would promptly protrude as soon as the measure was taken, and consequently expose to view the fibrous band of the colon that leads to the base of the appendix. Such, however, was not the case, as only small intestines appeared and the caput coli was nowhere observable. The edges of the wound were then drawn widely apart, and after careful sponging, an "account of stock" at hand was taken. It was seen after careful scrutiny that the ilium appeared to rise from the anterior surface of the head of the colon instead of the accustomed location, and that the head of the colon was rolled outward, which explained the unique relation of the ilium to it. The adhesions were easily separated, the head of the colon placed in the proper position, the appendix and the surrounding exudate separated *en masse*, appendix tied with a silk ligature, cut and removed. The caseous pus was dissected and scraped away; hemorrhage checked, wound partially closed and dressed as in the preceding case. In this case I think the wound could have been permanently closed with safety. But, inasmuch as pus products might have tainted it, despite the closest attention, I deemed it wiser to treat it by the open method. The patient made an uneventful recovery, the temperature at no time going above 101 F. per

rectum, and this for a day only. In two weeks he was permitted to sit up, and in six weeks was sent home in a most cheerful mood.

Case 3.—Mr. S., aged 27, student, good family history. This patient came to my attention on July 3, 1894, in St. Vincent's Hospital, from a neighboring city. He gave the following history: Had been the subject of diarrhea for a long time, before the appearance of any complicating trouble. During the summer of 1891 he had an attack of diarrhea and vomiting, in the course of which he was seized suddenly with a severe pain in the right side, followed by tenderness there and an exaggeration of the first-mentioned disorders. As the result of these manifestations he was confined in bed for five days, but at the end of two weeks he regarded himself well again, notwithstanding slight tenderness yet remaining in the right inguinal region. He declares that he had a fever during this attack. Twice after this, at intervals which he is unable to recall, he was confined in bed for a short time with diarrhea and pain in the right side. Suddenly in November, 1892, he had a severe attack and was confined to bed for two weeks and unable to work for three weeks thereafter. During this attack the axillary temperature was somewhat increased. The exact record is in doubt and will not be quoted. After this attack he was able to attend to his duties with comparative comfort, although he suffered from pain in the side only as the result of indigestion and active exercise. During the last two winters he has been afflicted with a severe cough, which disappeared with the incoming of spring. Thinks he may have had malaria at that time.

Physical examination shows the patient to be organically sound. Slight tenderness can be elicited on deep pressure in the right iliac fossa at the place where previous tenderness had existed. The presence of tumor could not be detected. In view of the long continued trouble and the clear history of previous attacks of appendicitis, as diagnosed by very reputable physicians of his native place, and the seeming loss of courage to continue his labors without operative aid, I advised prompt operation, which was done on July 9, in the presence of many of the visiting and surgical staff of the Hospital. The following items will be of interest in connection with this case:

1. No tissues were cut except those lying on the aponeurosis of the external oblique and those beneath the transversalis muscle. The opening was made in each of the other tissues by separating the fibers of the respective structures in the long axis at a point directly over the caput coli. The sub-transversalis tissues were divided in the same direction as were those above the external oblique. It is apparent at once that this plan of procedure permits the separated fibers to return to their proper relationship when all restraint is removed, thus securing to the abdominal wall the greatest possible strength at the seat of the operation, and doing all that is possible at that time to obviate consequent hernia. The peritoneum and the integument with their associated tissues were united in the manner common to each. To Dr. McBurney belongs the credit of this which now appears to be a most valuable suggestion in the technique of abdominal incisions for this trouble. When this course is taken it is contemplated that the wound shall be closed at once, which was done in this case. However, I am of the opinion that similar steps are proper when the wound is to be treated by the open method, and for similar reasons also.

2. The appendix was not less than five inches in length and extended into the pelvic cavity. No evidence of present or past disease was seen, except that indicated by the congested appearance of the appendix itself, which was best marked near the middle of the organ. An incision into the lumen, made by Dr. Gouley, disclosed the presence of a small fecal concretion surrounded by a surface of well-advanced ulceration. The appendix was ligatured with catgut and removed, leaving a stump about one-half inch in length. This patient made a prompt recovery so far as the operation was concerned, the wound was healing by first intention without an unfavorable local manifestation. During the course of recovery, however, the patient experienced an attack of sub-acute pleurisy of the left side, and also of mild malarial fever. For these reasons it is impossible to properly estimate the symptoms dependent on the operation alone.

Case 4.—Lieutenant C. F. P., aged 32, member of U. S. Army. This patient's previous history is good in all essential respects. He came to my attention August 16, and was referred to St. Vincent's Hospital for operation two days afterward. On admission the following history was elicited: Was perfectly well until May, 1888, when, without apparent

cause he was seized with a sudden severe pain in the right inguinal region, which was so intense that he could not move. At the end of a week a considerable tumor was found in the right inguinal region which, however, gradually disappeared during the succeeding two months. During this time had an increased and varying temperature. Aspiration of the tumor disclosed no pus. A short time after recovery from this attack he experienced another of less intensity, which confined him to bed for six weeks. No tumor was noticed during this time. One year after this, he had a slight attack of one week's duration, and the outset of which was coincident with an attack of indigestion. From this time until the present attack (August 3, 1894) any intestinal disturbance was quickly followed by pain in the right side. Since the first attack (1888) the patient has suffered from constipation with attendant colicky pains.

The present attack began August 3, 1894, with pain and tenderness in the side, loss of appetite and vomiting. For the next three days he attended to his military duties, although with much difficulty on account of pain and tenderness. The temperature was above normal during the last two days. He was sent from the State Camp at Peekskill to St. Vincent's Hospital on August 11, 1894. At this time he had pain, tenderness and tension of the right side, and a tender tumor was easily located just inside the anterior superior spine of the ilium. Rectal temperature 103 F.; pulse 82; respiration 26 at this time.

The patient was subjected to operation August 12, 8:45 A.M., at which time the rectal temperature was 102½, and in all other respects the condition was similar to that of the preceding day. Before the operation I expressed the belief that the appendix, in this instance, was curled upward and outward below the cecum, the apex lying somewhere at the outer side of the caput coli. I ventured this prediction because of the fact that the entire painful induration was placed at the outer side of the caput coli, and also because the tension and tenderness were noted not only there, but also above the iliac crest of the same side. During the course of the operation the following facts were demonstrated:

1. The contiguous parietal peritoneum was adherent to the outer and upper surfaces of the caput coli.
2. Extensive induration was found at the inner side of the anterior superior spine of the ilium, extending upward and downward considerable distance.
3. An abscess containing about two ounces of offensive pus was discovered at the posterior and outer surface of the caput coli.
4. The appendix could not be seen. Evidently it was confined in the mass of induration, and was no doubt perforated at or near the apex, and opened into the abscess cavity. The base of the appendix could, I am sure, have been located by following downward the fibrous band of the colon that leads to it. But the realization of this proposition would have required the direct opening of the peritoneal cavity through the peritoneum mentioned already as adherent to the head of the colon. In view of the fact that it was deemed unwise to thus expose a healthy peritoneum to the septic influences of the abscess close at hand, the appendix was not disturbed. The abscess was drained through the loin, cleansed and lightly packed with iodoform gauze. The patient made a rapid and uneventful recovery. The induration disappeared quickly. At the present time the wound is nearly healed and the patient complains only of the constipation, which dates from the time of the first attack.

It will be noticed at once that each of these cases is a secondary one, and therefore of special significance, since the afflicted have thus far escaped fatal termination. The first case sustained four attacks, the second two, the third and the fourth three each, thirteen in all. Seven of these attacks were severe ones confining the patients in bed from two weeks to two months. Six were slight, causing confinement of some, four days to two weeks. The recorded intervals between attacks vary from five years to two weeks. Well marked fever attended the majority of attacks. The duration and degree of fever, however, could not be ascertained with sufficient certainty to be of reliable importance, except that of the fourth case, which was under the observation of Dr. Nelson Henry while at the State camp. Tumor was noted in six of the attacks. Pus was evacuated in the fourth case by

operation, and found in the second in a caseous state during the operation. The appendix extended downward and inward in two instances. In one (third) it was five inches long and extended into the pelvis. In the first the diseased apex was adherent to the peritoneum covering the brim of the pelvis. In the remaining cases it curved outward and upward below the cecum. In three-fourths of the cases intestinal disturbances were pronounced as an initiatory symptom or probable exciting cause. Mucopus was present in the appendix in two instances; a fecal concretion in one; in the other the appendix was not found. It appears to me that considerable importance can be attached to the fact that the tumor of the first case was movable, comparatively near the pelvic brim and easily defined, because these peculiarities indicate: 1, a long mesentery of the appendix; 2, circumscribed tumor contiguous with intestinal folds; 3, an appendix within or near the pelvic brim. All of which bespeaks great danger to the patient from general peritonitis if rupture had taken place.

If these conclusions be true, then prompt operative action should follow the detection of a tumor having these peculiarities. If no tumor were found following a perforation of an appendix thus located, then, indeed, is the danger enhanced and all possible operative dispatch is demanded. The presence of the softened extremity of the appendix in this case, of itself, demanded operation, for obvious reasons.

Case 2.—In this the tumor was below the cecum, of small size, and pain occurred in the right thigh. These facts indicated that the appendix extended downward, and that the diseased action had involved the crural nerves. Although less dangerous than the former under unfavorable conditions, still easy general infection could quickly ensue from a perforation of appendix or of abscess in this situation. The dragging sensations of the right side which annoyed the patient before the operation, disappeared after recovery. This suggests that they were caused by the adherent omentum that defined this case, the relief coming from the division and separation of it that was necessary to properly expose the caput coli.

Case 3.—No tumor was discernible in this case, but deep and long-standing tenderness, and occasional pain called for operation here. The presence of the fecal concretion near the middle of an ulcerating appendix, without the slightest external adhesions, emphasize the probability of subsequent sudden perforation, followed by pelvic inflammation and possible death.

Case 4.—The presence of the greatest pain, tension, tumor and tenderness, at and above the spine of the ilium in this case indicated that the appendix turned outward and upward below the cecum, and extended above the spine at the outer side of the caput coli. The situation of the abscess at this point, together with the fetid pus it contained and its limitation on all sides at this situation, is confirmatory of the fact that the appendix was thus placed. It is fair to assume that the environments of this appendix were such that the dangers from perforation, or from rupture of abscess, were reduced to a minimum. The long interval of time (over four years) between the last and the previous attack, emphasized the fact in no undoubted manner that one without operative relief is constantly menaced by this disease.

The appendices were tied about one-half inch from

the cecum, the end touched with cautery, and in two instances the tissues were turned inward by sewing. But recently I saw two other cases which resembled in the physical aspects the fourth of the series. One was a secondary case.

It appears to me that the results of these cases justify the following conclusions:

1. That prompt operation in the interval of attacks is an advisable and safe procedure.
2. That the physical characteristics of the local changes define quite clearly the situation of the appendix, and thus indicate with much certainty the prognosis of the case.

CRANIOTOMY IN MICROCEPHALUS.

Lecture delivered to the Post-Graduate Medical School, Chicago, 1893.

BY CARL BECK, M.D.

CHICAGO.

PROFESSOR OF SURGERY AT THE POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; ATTENDING SURGEON TO COOK COUNTY HOSPITAL.

(Concluded from page 646).

What has been done so far? I have been able to collect seventy cases of this operation, all being on record; all histories were not obtainable; many cases have not been published. Most of the reports come from France and America, only one each from Germany, Italy and Spain. This shows clearly that the German surgeons are conservative or reluctant in this question. They do not operate in these instances. Their standpoint is clearly shown in the discussion, which was held when Case 47 of our table was presented before the Medical Society of Vienna. The histories of all cases of Lannelongue, though I tried to get their details I could not obtain, and must only refer to his *résumé* before the Congress of French Surgeons in which he gives a detailed account of what he has done. I have purposely excluded all cases that have been trephined on account of other diseases, which were combined with idiocy but not of the microcephalic kind, because they do not belong to this class of arrested development.

In the accompanying table I give a short account of two cases of Lannelongue; two cases of Horsley; three cases of Keen; seven cases of Roswell Park; two cases of Lane; two cases of Maunoury; two cases of Wyeth; two cases of Chenienx; one case by each Heurteaux, Auger, Kurz, Largeau, Prengreber, Frank Fuller, Lanphear, Miller, McClintock, Bauer, Gerster, Trimbl, Ransohoff, Larabrie, Cerne, Estor, Binnie, Duran, Shears and Van Lennep, Gersuny, and last, two of mine.

There are two claims of priority, one by Dr. Fuller, of Grand Rapids, who has done, we can say, a regular craniectomy with good success in 1874, and has reported it; one by Dr. Lane, who operated in 1888, but did not report this operation until 1892; nevertheless Lannelongue remains the pioneer.

I, myself, have operated for microcephalus twice, and I will now give the history and *decursus* of the cases:

Case 1.—Josephine McC., age 15 months; fireman's child; came Oct. 4, 1892, to the children's department of the Polyclinic, service of Dr. Detlefsen, who recorded the following history: Since the third month of her life, her mother noticed that the fontanelles were closed, and that the child had jerks in arms and legs, and spasms; the latter twice or three times a week, the former almost continuously. No hereditary disease. Present condition: Strongly built child, good muscles and structure of bones. The skull too

small for the face, fontanelles closed; slight depression on the left parietal bone. The head is not held upright but falls passively backward or forward. Pupils large, equal reaction. The eyes always directed toward the right side. Contractures in arm and shoulder muscles; good deal of resistance to stretching. The left leg seems less movable than the right one. No contractures in the legs. If the muscles are pinched there is no expression of pain noticeable. The spinal column is held very stiff. The patient referred to Dr. Beck's clinic. Oct. 10, 1892, Dr. Harnisch examines the eyes; negative results. October 16, capillary bronchitis. November 7, operation in chloroform narcosis, by Dr. Schalek. Assistants, Drs. Wagner and Gaffney. The head appeared, when shaved, very small in its frontal and parietal region; less disproportionate in the occipital. The measures have been taken exactly, but inasmuch as they have no weight, I omit to record them.

The operation was done in the above described manner; the skull exposed by an incision forming a large flap with the base toward the squamous portion of the temporal bone of the left side. The hemorrhage was not heavy, for we used Esmarch's compression. One button was removed with the trephine and anteriorly and posteriorly a strip taken out with Luers forceps. The craniotomy being done on the left side only and in an extension of about twelve centimeters length and one centimeter width, it seemed to me sufficient at that time for at least the first trial, and I closed the wound without drainage. It healed by primary union, without the slightest local reaction.

Immediately after the operation the parents, who were instructed to watch the child carefully, and who were intelligent enough, noticed a great change. The child had hardly a jerk for the first few days, looked brighter, did not roll the eyes and the contractures disappeared. It looked altogether like a healthy child. This very promising condition continued for a few weeks, when some jerking occurred again but no spasms; the parents sometimes thought that the child showed some intelligence. It looked around when its little sister passed by, and tried to laugh at her, but these slight improvements changed so very little for a long time that it seemed to me that the operation had only a temporary result. I had shown the little patient to several well-known physicians and nervous specialists before and after the operation, and they agreed that the child had improved some. Still the change was not so well marked as to warrant the truthful opinion that it was due to the operation alone, and not to the increased attention of the parents after the operation. At present, about one year after the operation the condition of the child is as follows: The physical change is remarkable, the head larger and if measured shows great difference between now and before the operation. There is no disproportion between face and skull. The jerks are still the same, but the spasms have disappeared. The mental condition is not very much improved; the child seems to notice the light, seems to turn the head toward her mother calling her name, but it has not learned to speak any or to sit up. The contractures of the muscles appear once in a while. Altogether the result is a slight but progressing improvement.

Case 2.—Anton Hopp, aged 2 years; cigarmaker's boy. Was referred to me by Dr. S. Goldmann, of Chicago. The father gave the following history: He and his family had been always healthy; there was no hereditary disease either in his or in his wife's family. The child was the fifth of his second wife. The confinement normal and nothing abnormal was noticed in the child during the first few weeks. At the age of about 4 weeks the parents noticed that the child bored the head constantly backward into the pillow, and tried to stretch it even when there was no pillow, but the hard table. A physician who was consulted at that time found that the child's skull was abnormally small and that there was no trace of fontanelles. From this time on the child grew worse, the overstretching of the head kept

RECORD OF CASES OF CRANIOTOMY.

| Name of Operator and source. | Date of Operation. | Age and Sex of P. | Disease and Symptoms. | Operation. | Immediate Result. | Remote Result and Remarks. |
|---|--------------------|---------------------|--|---|---|---|
| 1. Fuller (Grand Rapids), Chicago Medical Record, Vol. viii, No. 9. | 1874. | Child, ? | Chronic compression of brain. Not able to swallow, continuous spasms. | Three buttons removed by trephine and spaces chiselled out. | Spasms ceased immediately and deglutition possible. | Improving steadily. |
| 2. L. C. Lane, Journal Amer. Med. Asso., Jan. 9, 1892. | Aug. 28, 1888. | ? | Microcephalus due to premature ossification of sutures. Imbecility. | ? | Death 14 hours after operation, on account of prolonged anesthesia. | |
| 3. L. C. Lane, Journal Amer. Med. Asso., Jan. 9, 1892. | 1892. | ? | Microcephalus. Imbecility. | H-formed craniectomy. | Better result; gives signs of better intellect. | |
| 4. Lanneiongue, L'Union Médicale, 1890, No. 81. | May 19, 1890. | Girl, 4 years. | Microcephalus. Idiocy. Has no intelligence at all; can not walk, constant salivation. No contractures, no paralysis, no epileptic fits or equivalents. | Left linear craniectomy. | Child is more calm, not crying since day after operation, laughing, seems to be interested about her surroundings can pronounce some words. (Dupré, interne June 15, 1890.) | |
| 5. Lanneiongue, L'Union Médicale, 1890, No. 81. | June 20, 1890. | ? | Microcephalus, with more pronounced idiocy than Case 4. | Left linear craniectomy. | | |
| 6. W. W. Keen, Medical News, Nov. 29, 1890. | Nov. 5, 1890. | Girl, 4 yrs. 7 mos. | Microcephalus. Closed fontanelles and sutures. Never walked; could speak a few words when small, then lost speech. No contractures, no paralysis; had slight convulsions. | Nov. 5, 1890, left linear craniectomy, Feb. 17, 1891, craniectomy on opposite side. | Child more quiet, looking around at what is going on. | Since second operation no amelioration. Altogether the child is some better but not to that degree as Lanneiongue's case. |
| 7. Bauer, St. Louis Clinique, April, 1890. | 1890. | ? | Microcephalus. Of low intelligence but not imbecile. Since 6 years unable to walk. Motor paresia and contractures. | Linear craniectomy, two buttons removed space chiselled out. | Five days after operation less rigidity, patient can walk. | |
| 8. John A. Wyeth, N.Y. Medical Record, Feb. 21, 1891. | Jan. 2, 1891. | Boy, 11 years. | Microcephalus (head of baby 2 months). Cranial bones firmly ossified, fontanelles closed when 4 weeks old; cataleptic attacks, jerks in hands, talipes, equino-varus. | Linear double craniectomy with side incisions. | Collapse during operation, rallied well; 3 days after operation some improvement, less jerks, inversion of feet less noticed. | One month after operation change surprising and gratifying, remarkable increase of intelligence. |
| 9. W. W. Keen, American Journal of Medical Science, June, 1891. | Jan. 16, 1891. | Boy, 16 months. | Microcephalus. Idiocy. Ant. fontanelles small at birth, closed at seventh month; convulsions. | Left linear craniectomy. | Death 1½ hours after operation; heart failure. No postmortem. | |
| 10. Heurteaux, Nantes, Congrès des Chirurgie, France, 1891. | Feb. 1, 1891. | Girl, 5½ mos. | Microcephalus. Idiocy, epileptic fits, convulsions, vomiting of even blood, contractures of hands. | Craniectomy. | Immediately after operation child takes breast, does not vomit, no convulsions, then growing worse. Death March 7, 1891. | No enlargement of head. |
| 11. Th. Auger (Paris), Congrès des Chirurgie, France, 1891. | Feb. 11, 1891. | Girl, 8 years. | Normal size of head but depression on left side. At 15 months child began to walk, fontanelles long time open and depressible. Since age of 18 months retarded development of intelligence. | Linear craniectomy. | Eight days after operation asking for soup and salad. | March 16, 1891, mother writes: "All the people find a remarkable change of intelligence in my child." |
| 12. Maunoury (Chartres), Congrès des Chirurgie, France, 1891. | ? | Girl, 4 years. | Microcephalus, with premature ossification of sutures. Fontanelles closed at age of 3 years, never walked; contractures of hands, convulsions. | Linear craniectomy. | Immediately after operation better. | Later on the same improved condition. |
| 13. Maunoury, ibid. | March 2, 1891. | Boy, 2 years. | Microcephalus. Fontanelles closed at 7 months, idiot with convulsions and strabismus internus. | Left linear craniectomy. | Death 21 hours after operation. | |
| 14. I. C. McClintock, St. Louis Courier, 1891. | March 28, 1891. | Girl, 3 yrs. 8 mos. | Microcephalus, due to premature ossification. No fontanelles; idiocy; can not walk nor stand, nor be well nursed. Nothing noticed up to age of 2 years; blind, right eye protruded (pressure); contractures. | Double craniectomy | | Mother says: "Since operation child tries to sit up, is not so restless and tries to play with others." |
| 15. Roswell Park, Medical News, Dec. 10, 1892. | June 21, 1891. | Boy, 5 yrs. 6 mos. | Skull small for his age. Retarded mental development though not imbecile. Baby, jerking convulsions at age of 6 mos; grand mal. | Linear craniectomy, with side diacission over fiss. Rolandi. | | He now runs and plays with other children. (Dec. 10, 1892. |
| 16. Roswell Park, Medical News, Dec. 10, 1892. | June 13, 1891. | Girl, 4 years. | Congenital microcephalus. Imbecility, muteness. | Linear craniectomy, with side incisions over fiss. Rolandi. | After result. | Practically nil. |
| 17. Largeau, Congrès des Chirurgie, France, 1892. | July 2, 1891. | 8 years. | Microcephalus due to premature ossification. No fontanelles, never walked, never talked, can not grasp anything (mother has a congenital luxation) and contractures. | Craniectomy & lambeaux. | July 4. Sitting up and eating. July 6. No contractures, brighter. | Seven months later: Head larger, can call brother, grasps objects, can not walk yet but does not fall. |
| 18. Victor Horsley, British Medical Journal, Sept. 12, 1891 | Sept. 12, 1891. | Boy, 8 years. | Microcephalus idiot; can not feed himself, eating his excretions, moving constantly, good physical health. | Left linear craniectomy. | Three days after operation child better; nurse (who has been with patient 9 mos. before) says less restive, much quieter. Father and nurse struck with rapid improvement. | Dr. Wylie: "Improvement most marked and continued." |
| 19. Parkhill, Medical News, Feb. 27, 1892. | Oct. 9, 1891. | Boy, 4 years. | Microcephalus. No speech, no sense, falls down on his face two or three times a day. | Incision elliptical 3¼x6½ inches. | Condition very much better after operation. | |
| 20. Roswell Park, Medical News, Dec. 10, 1892. | Oct. 20, 1891. | Boy, 18 years. | Upper portion of cranium relatively small though not conspicuously; intelligence of a child of 3 years. | Irregular triangular piece chiseled out. | Arachnoid and pia mater edematous, bone thick, 1 cm., death several hours after operation from exhaustion. No postmortem. | |

| Name of Operator and source. | Date of Operation. | Age and Sex of P. | Disease and Symptoms. | Operation. | Immediate Result. | Remote Result and Remarks. |
|---|--------------------|--------------------|--|--|--|---|
| 21. Binnie, Kansas Medical Index. | Nov. 6, 1891. | ? | Microcephalus. Idiot, at 4 mos. all fontanelles and sutures closed; eyes and head rolled, seems to recognize friends, stretching arms towards them | Left linear craniectomy. | Condition very poor right after operation, death 15 hours after. (Chisel and mallet used necessitated inversion during operation.) | |
| 22. Roswell Park, Medical News, Dec. 10, 1892. | Nov. 7, 1891. | Boy, 15 years. | Helpless idiot with epileptic fits. | Linear craniectomy. | Death from shock. No postmortem. | |
| 23. Roswell Park, Medical News, Dec. 10, 1892. | Nov. 14, 1891. | Boy, 9 years. | Microcephalus, with Aztec-like skull. Idiot, with epileptic fits. | V-shaped craniectomy. | Immediately after operation, less fits. | One year later speaking plainly—astonishing results. |
| 24. Roswell Park, Medical News, Dec. 10, 1892. | Nov. 14, 1891. | Boy, 12 years. | Asymmetry of skull, depression on right side. Imbecile, epileptic. | Craniectomy. . . . | Three months after operation, less fits. | One year later, no improvement since last time. |
| 25. Roswell Park, Medical News, Dec. 10, 1892. | 1892. | ? 14 months. | Microcephalus. Closed fontanelles, seems to recognize between dark and light. | Craniectomy, | Death one day after operation. | |
| 26. W.W. Keen, American Journal of Medical Science, June, 1891. | Dec. 8, 1890. | Girl, 18 months. | Microcephalus. Idiotcy. | 1. op. Craniectomy on one side, March, 1891. 2. op. Craniectomy on opposite side. | Hospital attendants are decidedly of the opinion that she is quieter and calmer at her head much less than before. Keen himself can not see much difference. | Progress like his first case. |
| 27. Gerster and Sachs, American Journal of Medical Science, June, 1891. | ? | Girl, 4½ years. | Microcephalus. Idiotcy; several attacks of convulsions, loss of speech, closed fontanelles. | Linear craniectomy. | Death. | |
| 28. Shalders Miller, British Medical Journal. | March 21, 1892. | Boy, 8 months. | Microcephalus. Complete ossification of fontanelles (not at birth), blind (optic neuritis), contractures, cryptorhinism, bad deglutition. | Linear craniectomy (periosteum removed). | Spastic condition diminished, testicle descended, all symptoms improved very much. | May 18. Still improving. |
| 29. J. Frank, Chicago Medical Rec., Vol. VIII, No. 9. | 1892. | Boy, 3½ years. | Microcephalus. Ossification of sutures, no fontanelles, spasms from birth, tonic and clonic contractures, totally blind, impaired hearing. | Double linear craniectomy (chisel and mallet). | Ten days after operation, suppuration, enlargement of head ¼ of an inch antero-post. | No improvement whatever. |
| 30. Ransohoff, Medical News, June 13, 1891. | ? | Girl, 8 yrs. 7 mos | Microcephalus. In progress of ossification, left parietal bone overlapped the right, left arm less used. | Linear r. craniectomy | Gratifying degree of success, enlargement of diameters, mental action clearly present. | |
| 31. Larabrie, Semaine Med. April 1, 1892. | ? | 5½ mos. | Microcephalus. | Craniectomy. | Improvement 48 hours. Death five weeks after operation. | |
| 32. Cerné, LaNormandie Médicale, Oct. 15, 1892. | ? | 8 yrs. 3 mos | Microcephalus. | Craniectomy. | | At the end of one year the result seemed perfectly satisfactory. |
| 33. Estor, Montpellier Medical Journal, June 4, 1892. | ? | ? | Microcephalus, with usual symptoms. | Craniectomy. | No appreciable improvement in the child's mental condition. | Only benefit child derived, it could stoop down and pick up things without falling. |
| 34. E. Kurz, Nr. Med. Presse, Oct. 23, 1892. | March 31, 1892. | 18 months. | Microcephalus. Idiotcy, with epileptic seizures, | Craniectomy. | Eight weeks after operation perfect restoration of bone, seizures lighter, child continues to become brighter. | ? |
| 35. Chénieux, Congrès des Chirurgie, France, 1892. | ? | Small Girl. | Microcephalus. Ossification of sutures. | Double craniectomy, à deux temps. | ? | |
| 36. Chénieux, Congrès des Chirurgie, France, 1892. | ? | Boy. | Microcephalus. | 1. op. done by Laune-longue; linear craniectomy. 2. op. done by Chénieux in V-shaped form. | Some amelioration from first operation, but family wished still better results. | |
| 37. Duran, Revue Intern. de Bibliologie, March, 1892. | ? | 5 years. | Microcephalus. Idiocy, strabismus, constant moving of head. | Linear craniectomy. | Following day all symptoms improved, strabismus disappeared, child brighter. | Eighteenth day after operation death from smallpox. |
| 38. Lanphear, Medical Brief, St. Louis, Sept. 1892. | July, 1892. | Boy, 4 years. | Microcephalus. Idiot, hopping walk, no speech, never showed the slightest evidence of sense. | Double craniectomy, à deux temps within six weeks. | Now, two months after operation, child begins to walk, to say mama, papa, cat, dog, etc. Can feed himself. | |
| 39. Victor Horsley, British Medical Journal, Sept. 12, 1891. | ? | Boy, 7 years. | Microcephalus, with usual phenomena. Epileptic fits since age of 7 months, | Craniectomy. | During operation the pulse became weak, the breathing fast. Death 3 days after operation. | |
| 40. Lanphear, Kansas Medical Index. | November, 1891. | Girl, 11 years. | Microcephalus. Idiocy. When 7 years old began to go to school, to learn to read, etc. Then fits of convulsions, head became smaller, intelligence decreased. Otitis med. supp. | Craniectomy, with opening of dura. | Death 42 hours after operation. Autopsy: Cyst above center of speech, lepto-meningitis. | |
| 41. Wyeth, Int. Surgic. Journal, Nov. 1891. | ? | Boy, 6 years. | Microcephalus. Closed fontanelles. Idiot, with epileptic convulsions. | Double craniectomy. | The child showed very much improvement the following week. | |
| 42. Prengreber, Gazette des Hôpitaux, Jan. 1892. | ? | Boy, 9 years. | Microcephalus, with asymmetry of skull. No fontanelles and prematurely ossified sutures. Has the intellect of a child of 4 years, does not walk nor talk, constant salivation, loves music, used to walk when 3 years old. | Left linear craniectomy. | First day: Brighter, clear language, no salivation, wipes his mouth, blows his nose, plays with small trumpet and cannon, asks for vessel. | |
| 43. Trimble, Medical News, 1891. | Nov. 8, 1890. | Boy, 3 years. | Microcephalus, with ugly temper. Can not raise his body from horizontal position, can not talk, constant salivation. | Right linear craniectomy. | Temper better. | Sits in baby's chair, calls papa, mama, and peek-a-boo. Evidently improving. |
| 44. Van Lennep, Hahnemannian Monthly, 1891. | ? | Girl, 14 years. | Microcephalus. Looks like a two-year old girl, takes no interest in anything, can not stand by herself, no paralysis. | Linear craniectomy. | Some improvement. . . . | Has been very quiet since. |
| 45. Hartley Starr, N.Y. Med. Rec., Jan. 1892. | ? | Girl, 7 years. | Epilepsy. Weak mind, hemiplegia. Was born healthy and remained so up to age of 5 mo. | Linear craniectomy. | No marked improvement, is often unconscious. | |

| Name of Operator and source. | Date of Operation. | Age and Sex of P. | Disease and Symptoms. | Operation. | Immediate Result. | Remote Result and Remarks. |
|--|--------------------|-------------------|---|---|--|---|
| 46. Sheara, <i>Mahne-mannian Monthly</i> , 1893. | ? | Girl, 6 years. | Microcephalus. Irregular head. Idiotcy, can not walk, no control over urine and feces. | Left linear craniectomy. | At once signs of improvement. | Three months later, control of urine and feces, uses three words. |
| 47. Gersuny, <i>Nr. Med. Wochenschrift</i> . | September, 1892. | 8 months. | Microcephalus. Three months normal development, then epileptic fits; synostosis of sutures and fontanelles. | Circular craniectomy. A strip removed horizontally through vertical incisions in the scalp in two sittings. | Primary union, fits less frequent and less in intensity. | Five months later, very few fits. (Dr. Rie.) |

on, the hands, arms, legs and muscles of the body became stiffer until the child was so stiff that it could be kept straight like a stick, if supported by the head and having its feet on the ground, the body being in oblique position toward the ground. At the same time the saliva dribbled constantly from its mouth, the eyes rolled incoordinately about and never rested on one object. This condition kept on all the time and is the same now, Aug. 28, 1893; the physical condition is otherwise very good. The child shows not the slightest trace of intelligence nor can it sit nor creep, nor does it speak. From time to time it has attacks, sometimes every few hours, of short quick breathing, sometimes jerks all over the body. These jerks and clonic convulsions do not last very long and at the end of each such attack the child cries a little, a sign that the contractions are painful. The head is small, altogether as the picture shows, but the smallness is due to the reduced size of the skull while the face is, comparatively larger. There is no

skin and periosteum flapped back to both sides, on each side a button removed with a trephine, and forward and backward curved excisions of bone made with my modified Luer's forceps, so that the excisions met near the line of the frontal suture in front, without going over one into the other; that is, a double linear craniectomy. The child stood the operation very well and soon afterward the contractures disappeared. The dura did not bulge nor bleed any, nor did the diploë bleed to any extent, the hemorrhage from the skin having been well prevented by a rubber compressive tube. During the first few hours the child was normal, but toward evening of the same day the temperature rose to 100, the pulse being uncountable. On the next morning I looked at the wound because the fever had reached 102, and I found that one stitch-hole was covered with a yellow crust, and on removing the silk-worm gut a drop of yellowish thin pus-like fluid escaped. The wound was washed out with sublimate

CASE I.

CASE 2.

difference between this case and the first one, in regard to the size of a particular region of the skull, but the whole skull is reduced. The fontanelles can not be found, but there is a slight depression on the spot where the small fontanelle normally is situated. The sutures can not be felt through the skin, but they seem to be at least very firmly united, if not obliterated. Measures of the skull were taken, but they are valueless.

We have to deal here, as in the first case, with a microcephalic idiot of low degree with arrested development at an early period of life. Though the case did not seem to me very favorable, it was nevertheless a case worthy of trial of a craniectomy.

August 29, operation was done under chloroform (Dr. Goldnamer) with assistance of Dr. Wagner, before the class of the Post-Graduate School. A median incision from above the glabella down to the protuberantia occipitalis was made,

solution, and the temperature sank some, but afterward rose every day; the child became weaker and weaker, it had chills and strong contractures and died on the seventh day after the operation.

The autopsy made on the next morning showed the following state: The wound was united by primary union except a small place where the stitch had been removed, but the dura was covered with thick yellow pus-like membrane; the diploë next to the excised bone was of yellowish appearance and the putrefaction had evidently gone into the bone. The inner side of the pachymeninx and the brain did not show any trace of a suppurative process. The brain itself is characteristic of a microcephalus; it shows micro- and polygyria, but it shows at the same time hydrocephalus chronicus internus. The ventricles were so dilated and filled with an opalescent fluid that the brain substance, gray and white, appeared only as a comparatively thin shell and sank in when the fluid had escaped. It weighed when measured fresh, 240 grammes; that is for a 2-year-old child

somewhat small. The harmony of the brain is a little disproportionate, inasmuch as the cerebellum seems to be comparatively larger than the cerebrum. The cerebrum will be examined microscopically and the report will be the subject of a special paper.

In regard to the septicemia that had killed the child, I found, that previously to the craniectomy, on the same morning, in the same operating room, a maxillary periostitis had been operated upon, at which the same nurses attended, and dressing partly, from the same jars was used. This shows again that clean operations though perfectly, carefully and aseptically prepared can suffer if done in the same room where infected wounds are operated on, for we can not help infecting against our best will.

I have operated twice more for idiocy, without microcephalus, but I will not report these cases in connection with this abnormality.

We will now consider the peculiarities of the single cases, and from the results obtained, so far, draw our conclusions. As to the age of the patients of the different authors, we find mostly representatives of the early infancy and youth, and only a few children of advanced age; that is over 10 years. There are cases of 5½ months (Larabrie and Heurteaux), but both died after the operation. It seems that this very young age does not bear well such a shock. Lannelongue's cases ranged from 8 months to 12 years, but Roswell Park had an operation of an individual of 18 years, and another one of 15 years, and these both died, so that we might say, if we are allowed at all to judge from these two cases, that older children do not bear the operation as well either. The conclusion may be fallacious, as I say, but time will prove it. By all means an age from 1 to 10 years will be the most favorable for an operation on account of the following points:

1. This age bears the operation well.

2. If we presume that the pathologic changes are progressing, they have not reached an incorrectible state.

As to the sex of the patients there were about as many males as females. The symptoms of the greater number of patients were similar, so that we find pretty nearly the same description in their histories; the physiologic expression is typical, though the anatomy does not show a type. Idiocy, lack of speech and lack of coördinate movements; the patients could not walk and often had contractures of their limbs. Strabismus is mentioned frequently. Restlessness and malicious and wicked temper are also noted. One important factor shows itself as favorable for the result, and that is the occurrence or rather the beginning of the idiocy after somewhat normal conditions of life; the outset of the symptoms in a previously normal child, as in the cases of Auger (Table No. 11), Lanphear, (Table No. 40), etc. We shall refer to these cases later on.

The kind of operation; that is, the different modifications of the original method, vary much in the single cases. In the earlier operated cases, linear craniectomy on one side was mostly practiced; later, double craniectomy with flap formation was done, and this seems the only rational and effective way, though results have been obtained by the one-sided operation. The sizes of the pieces of bone taken out vary as well, in fact they vary so much that the measures have been left out of the *schema*. Periosteum was taken out corresponding to the slit in the

bone, in order to prevent the growth of the bone and closure of the openings made by the operation, but many authors as Kurz, for instance, remark expressly that the bone did not re-appear within months. So it was in my first case, where I can to-day feel the openings. The *modus operandi* consisted in most of the cases of using the trephine first, then a rougeur forceps, the modification of Luer's bone cutting forceps. This method is the simplest and safest. In some cases, as those of Lanphear, Binnie, Roswell Park and others the mallet and chisel was used; but both authors described the use of this method as very unfavorable, because it produced shock in the respective instances. The concussions of chisel and mallet are greater than those from trephine and the saw.

As to the effect of the operation we have to state the immediate effects of the same, the dangers and possible complications, or operative result, and last the remote or curative result. The following table shows the death rate of the operation which is still rather high, if we consider Lannelongue's results with those of the other authors:

| Name of Operator. | No. of Operations. | Deaths. |
|-----------------------------|--------------------|---------|
| Lannelongue | 25 | 1 |
| Fuller | 1 | .. |
| Lane | 2 | 1 |
| Keen | 3 | 1 |
| Bauer | 1 | .. |
| Wyeth | 2 | .. |
| Heurteaux | 1 | .. |
| Anger | 1 | .. |
| Parkhill | 1 | .. |
| Maunoury | 2 | 1 |
| McClintock | 1 | .. |
| Roswell Park | 7 | 3 |
| Largeau | 1 | .. |
| Horsley | 2 | 1 |
| Binnie | 1 | 1 |
| Gerster | 1 | 1 |
| Miller | 1 | .. |
| Frank | 1 | .. |
| Ransohoff | 1 | .. |
| Larabrie | 1 | .. |
| Cerné | 1 | .. |
| Estor | 1 | .. |
| Kurz | 1 | .. |
| Chénieux | 2 | .. |
| Duran | 1 | .. |
| Lanphear | 2 | 1 |
| Prengrueber | 1 | .. |
| Trimbl | 1 | .. |
| Van Lennep | 1 | .. |
| Hartley and Starr | 1 | .. |
| Shears | 1 | .. |
| Beck | 2 | 1 |
| Gersuny | 1 | .. |
| | 72 | 12 |

This makes a mortality of nearly 17 per cent., while Lannelongue's mortality is only 4 per cent. The mortality without Lannelongue's cases is nearly 23 per cent. These figures have a relative value only; that is to say, the mortality will be much smaller the larger the number of cases will be from each single operator, as it is always the case with new operations.

The dangers of the operation are:

1. Shock.
2. Hemorrhage.
3. Infection.

As to the shock, we can say that chisel and mallet have been justly accused and ought to be abandoned

in this kind of brain surgery. The operation ought furthermore to last as short a time as possible. My first operation took twenty-five minutes altogether, but it was simple and uncomplicated, the anesthesia perfect; the second forty minutes. It was a double craniectomy; but we find operations that lasted one hour and a half. Such a prolonged operation can not be without influence on the heart of the patient. Hot applications to the head and reversion of the patient, head downward, have been recommended by Horsley and others as effectual to remedy this accident, and bring back the missing pulse and the respiration.

Hemorrhage has been once the cause of death (Gerster). It can come from the diploë, but generally this spongy tissue does not bleed very much, and the bleeding can easily be checked by pressure. But another source of hemorrhage is more serious, that is the lesion of a sinus. Such an accident can happen and would perhaps be fatal, though in operations on the brain of an adult it has been followed by recovery. Hemorrhage from the scalp is the most common, and can become serious; my experience is that an Esmarch rubber band, fastened tightly around the head can render the operation pretty nearly bloodless. Infection is mentioned as a cause of death in one case; in Lannelongue's only case of death. He thinks that the acutest sepsis killed the child. Asepsis will prevent such an event.

Complications that can happen besides these are manifold: A bulging of the dura may occur after the incision, and may even be so great as to cause fear of a hernia cerebri, but this is rare. The dura may be injured but not purposely; it must be sewed up again. This accident involves a great danger, that is the loss of cerebro-spinal fluid.

To classify the deaths according to their cause:

| | |
|--------------------------|----------|
| Shock | 6 cases. |
| Heart failure | 1 " |
| Loss of blood | 1 " |
| Infection | 2 " |
| No cause given | 2 " |
| | — |
| | 12 " |

The immediate result of the operation has to be distinguished from the remote or curative. The success of those cases that did not die within a few days after the operation was almost a perfect recovery, primary union and an apparent euphoria. The cases which have been described too early, refer to this result only, and these descriptions are valueless, therefore, for our judgment of success. In some descriptions we find the remark that the patients got along very well at first; their conditions improved, they showed advancement, but soon afterwards the old conditions recurred. Such a result must lead to the belief that the development of the brain began, but soon subsided, because the sutures or rather the openings were drawn together again by the tightening cicatrix; such a pathologic change is not proven. In other cases, observed well otherwise, we find that the authors relied too much on expressions and judgments of mothers and nurses; I must warn you, because I know as well as any author who has put on record such remarks, how much can be suggested to the prejudiced physician, how much more to the prejudiced mother or relative. "*Quae volumus, libenter credimus.*"

One author, whose patient died, did not hesitate to record the remark, that the improvement, the brighter

and clearer face of the patient some moments before death were reward and justification enough for such an operation. This is over-enthusiasm.

The improvement that follows the operation and steadily increases, until the child is in normal condition is what we expect and must try to accomplish. Such an improvement has been accomplished in some well authenticated cases by authors whose veracity is beyond reproach.

There is one factor that helps to reach such an improvement; that is the pedagogic. This never has been doubted and is brought to the foreground by the adversaries of the operation. We must concede that a child who has been idiotic for a long time and has been growing worse constantly is neglected as to this point, and therefore can not get better; while to a child after such an operation as craniectomy, with new hopes, the best attention the greatest care is given, and all inventive speculations to improve it are carried out. It gains by this treatment.

Who ever saw the accomplished works which were exhibited at the World's Fair in Chicago, the products of such an education of the feeble-minded and idiots; whoever saw the artistic work that was shown there, and which was done as it is stated, often without supervision of the teachers of the respective schools of the United States, must agree with Bourneville, who advises the surgeons to go and to see the schools of our country that are model institutions and have the proudest results. But that does not exclude the fact that some microcephalic idiots derive great benefit from the operation and later on are able to attend such schools with success.

To classify the results in figures, we would divide the cases in the following categories:

1. Perfect and lasting improvement.
2. Perfect improvement but stationary for some time after the operation.
3. Slight improvement, but good prospects by pedagogic methods.
4. No improvement.
5. Worse condition than before.
6. No results stated, or too early reported.

First category, 16 cases.
 Second category, 4 cases.
 Third category, 1 case.
 Fourth category, 1 case.
 Fifth category, 11 cases.
 Sixth category, 27 cases.

In the first category we would find all the successes, as far as they can be judged, for it would take years to form an opinion. In the second category we find cases that showed marked improvement, but later on remained stationary, or recurred to the old condition. We would have to examine whether the operation was not carried out to the fullest extent or, perhaps, the disease had progressed too far, hence the failure. The other categories are easily understood.

CONCLUSIONS.

1. Craniectomy is a justifiable operation and apt to be successful in the treatment of microcephaly with idiocy.
2. The success depends on the kind of microcephaly and the degree of idiocy.
3. Acquired and late forms give a better prognosis than congenital forms.
4. The danger of the operation is not very great.

5. The operation ought to be quite extensive, that is, the incision in the skull large enough, to permit dilatation, and the circular method of Gersuny ought to be given a trial.

6. The patients must be given a thorough pedagogic treatment afterward.

7. The single cases ought to be followed up for years and reported from time to time.

PRACTICAL DIFFICULTIES OF MEDICAL HEALTH OFFICERS AND PHYSICIANS IN DEALING WITH SUSPECTED CASES OF DIPHTHERIA.

BY P. H. BRYCE, M.A., M.D.

Secretary of the Provincial Board of Health of Ontario.
TORONTO, CANADA.

It is within the recollection of almost all of us that it is not more than ten years since scientific investigation gave us any actual idea of the immediate cause of the disease known as diphtheria. At that time even its contagiousness was disputed by many; and while medical practitioners having experience with the disease had noted its special incidence in certain localities and still more in certain dwellings, yet the cause was by most supposed to be due to local unsanitary conditions wherein the decomposition of organic matter, whether animal or vegetable, in cellars, sewers, etc., was supposed to exert a causative influence. While to-day such conditions are readily acknowledged to exert influences favorable to the occurrence of the disease, yet actual observers of this as of other zymotic diseases give such influences the secondary place, and speak of them as exciting causes rather than as the immediate cause. The part which the presence of decomposing organic matters plays in the dissemination of the disease must not, however, in my opinion be for a moment lost sight of, as otherwise the working sanitarian, *i. e.*, the executive health officer, will often be robbed of an argument of the greatest value in his efforts to suppress outbreaks of the disease, or to supply a

fairly satisfactory explanation of the occurrence of so-called sporadic cases.

Before discussing further, however, the importance of decomposing organic matter in favoring outbreaks of diphtheria, it will be well for us to make some observations on what we call the immediate cause of the disease. Within the two or three years after the announcement by Löffler of his discovery of the bacillus which he asserted to be the true cause of diphtheria, pathologists in many laboratories published the results of their researches made along the lines laid down by him, and many asserted with equal positiveness that Löffler's bacillus while certainly present in many cases of diphtheria was yet by no means necessary to the appearance of the disease, *i. e.*, of a diphtherial exudate on the mucous membrane of the pharynx. I need only recall on this point the work of Professor Prudden, of the College of Physicians and Surgeons, of New York, on the streptococcus of diphtheria. Without dwelling further on the results of other investigators it need only be said that with the multiplied labors of many bacteriologists we now know that the mucous membranes of the mouth and air passages having air to the amount of over eleven cubic meters in twenty-four hours passing over them, must necessarily become the receptacle of all floating particles existing in this volume of the atmosphere.

When it is further remembered that microbes according to various experimenters will not rise from moist surfaces, and that air expelled from the throat through a sterilized tube is incapable of inoculating a culture medium of beef broth, it is apparent that the mouth with its mucous membranes maintained at a temperature of 38.4 degrees C., must act very similarly to a culture medium in which microbes from dust, whether in air or on food, begin the struggle for existence; those forms finally triumphing which find the environment most completely in harmony with individual peculiarities and local conditions.

To illustrate in some degree this point the following figures may be given: Air respired by an average man in twenty-four hours, 11.05 cubic meters; average number of microbes in cubic meter of air of Paris, France, in 1884, 3,480; in center of Paris, 1893, 6,040; in new park of Montsouris in 1884, 480; in park clothed with turf and trees, 1893, 275; in ward in Hotel Dieu, 3,250; in air of Paris sewers, 4,070.

In this connection it may be mentioned that Miquel has found that while in winter the external air of Paris contained molds to bacteria in proportions of about 6 to 1, yet the ratio in the air of the Hotel Dieu was, molds 1 to 20 bacteria.

Bacteria in mouth and nasal passages: Von Besser found on nasal mucous membrane in eighty-one cases: *Diplococcus pneumoniae* fourteen times; *staphylococcus pyocyaneus* fourteen times; *streptococcus pyogenes* seven times; *bacillus Friedlanderii* two times.

Black, in ten healthy persons, found: *Staphylococcus pyocyaneus* seven times; *staphylococcus pyoalbus* four times; *streptococcus pyogenes* three times.

This table, necessarily very incomplete, is enough to illustrate the important point that both in theory and by observation the transference, from the dust of streets and still more of habitations, of numberless living forms is constantly going on, and that therefore it need cause no surprise if every form capable of overcoming the protective influences present on

the respiratory mucous membrane should from time to time and in different climates, localities and under different conditions make their presence in the system recognized, owing to the exudative processes resulting in the formation of a so-called diphtheritic membrane.

Without referring to these influences promoting diphtherial exudations, I propose for the purposes of my paper to refer to the results of the most recent experimental work on the subject of the diagnosis of true diphtheria, in order that the difficulties experienced in dealing with the disease may be made apparent. I refer especially to the bacteriologic and clinical observations made by MM. Chaillou and Martin, Internes of Hôpital des Enfants, Paris, carried on under the direction of Dr. J. Simon, of the Hospital, and Dr. Roux, of L'Institut Pasteur.

Reverting to the varieties of microbes found in diphtherial membrane it may be said that the work of Yersin and Roux published in 1891 indicated with great clearness the importance of the bacteriologic examination of diphtheritic membrane in the case of all patients brought to diphtheria hospitals, before their admittance to the wards, from the fear that such patients if not affected with the Löffler bacillus would in the wards be exposed to the contagion.

Since that time, attempts more or less systematic have been made to give practical direction to such examinations by urging the measure in private practice. This, however, from causes manifest to all has been possible only under exceptional circumstances, and everywhere practitioners proceed in the old way of diagnosis by merely clinical signs and symptoms; although, as MM. Chaillou and Martin state in the outset of their paper, published in the July number of the *Annales de L'Institut Pasteur*: "Les nombreux savants qui ont écrit dans ces derniers temps sur le diagnostic de la diphtherie s'accordent à reconnaître que dans les angines blanches, seul l'examen bactériologique peut fournir un diagnostic certain."

In the complete supervision and study of 200 cases as internes of the Hospital (Hôpital des Enfants) they have been able to say that the bacterial diagnosis being made it was then possible with a systematic observation of the clinical signs as of the adenopathies, albuminuria, temperature, pulse, and respiration to make very accurate prognoses.

From what has already been stated with regard to the dissemination of microbes we shall be prepared for the following results of their work on those points we are at present specially concerned with. Their examinations included 198 cases in all: Anginas or throat invasions, ninety-nine; croups or laryngeal, ninety-nine. Of the anginas they established three divisions:

Anginas non-diphtheritic twenty-nine; deaths none.

Anginas purely diphtheritic forty-four; deaths ten.

Anginas diphtheritic with associated forms twenty-six; deaths eighteen.

Thus more than one-fourth of the sore throats were not true diphtheria. It is explained that this work being done in the hospitals in winter the number of throats with non-diphtheritic exudation is less than in summer as shown by previous experiments. These non-diphtheritic cases consist principally of coccus forms (single or diplococcus but not in chains), some disappearing in two or three days,

but in half the cases some membrane, mostly of white points, continued for six days and over. In some of the cases the membrane appeared in the nose or the larynx—in one case necessitating tracheotomy. Essentially these membranes seem more creamy, less adherent and less elastic; but it is practically impossible by the eye to distinguish these from the milder cases of diphtheria. Albuminuria was found in five cases. Five maintained it during the presence of the membrane and the pulse oscillated with it, nevertheless the general state was good, appetite good and face keeping its color, while even in the most serious cases the observers did not hesitate to give a good prognosis. One case had the pneumococcus of Fraenkel and four cases had the staphylococcus form. In these four cases it was the sole cause of the disease and the cases were seldom mild.

Other instances of an undetermined bacillus occurred and eleven cases with a streptococcus; three of these supervening in cases with scarlatinal eruption. These cases were not true diphtheria as shown in several ways, although the membrane in its gross appearance was most characteristic—the scarlatinal redness of the throat chiefly making the distinction. Such cases were transferred to the scarlatina wards; and the course of this disease were there exhibited. In eight of the cases there were streptococci without scarlatina, these having whitish gray membrane adherent to tonsils and surrounding parts; but patchy and in two instances pultaceous and having the staphylococcus pyogenes associated with it. Such cases were sufficiently serious. Summing then these up there were: Eleven cases with a coccus; one case with a pneumococcus; four cases with a staphylococcus; two cases with a coliform bacillus; eleven cases with a streptococcus, or twenty-nine in all. They found cases presenting for a number of days serious anginas, but which rapidly became ameliorated and were all healed in from eight to ten days.

There were forty-four pure diphtherias of which ten died. Of these, thirty were so mild that they had not been recognized as diphtheria without bacteriologic examination; while the other four were diphtheria from clinical appearances. The first had but little membrane; eight cases had mere white points like follicular amygdalitis. These increased but little during succeeding days or even rapidly disappeared. While these observers never found the bacillus of diphtheria without some membrane, yet in several instances it was found only after very close examination. In fifteen cases with more membrane the glands were always engorged. Unequal bilateral extension and glandular enlargement of the two sides were characteristic of true diphtheria. In thirteen cases there was no albuminuria; while in fourteen severe cases it was present from the outset, and of these ten died and four recovered. In these cases the membrane was grayish white, very adherent and sanguinolent and often had extended over all the back of the throat. Albumen was found in every case at an early stage and persisted till death; while the interrupted pulse was a most significant prognostic, much more so than the temperature.

In the diphtheritic anginas with other associated bacteria the Löffler bacillus overgrows in cultures the other forms, and these are got only by numerous repeated isolations on different cultures. Of these there were twenty-six cases, the chief being the streptococcus growing after twenty-four hours on the

gelatin as distinct fine points. Of fourteen of these cases, thirteen terminated fatally; although inoculated in guinea-pigs with the two forms cultivated separately they are not always very virulent. In three cases, for several days no albumen appeared but did on the sixth or seventh day. In these cases the patients presented the pale faces, the venous-hued lips, the yellow eyes, the fetid breath, the torpor and generally stricken appearance presaging approaching death.

The cases with associated staphylococcus were likewise very fatal, five in all, and all dying.

A similar history of the variation in the bacteria present is given in the cases of croup discussed in the paper by MM. Chaillou and Martin. The authors draw several most important conclusions:

1. That in order to give a prognosis, the knowledge of the microbes associated with the Löffler bacillus is necessary.

2. That some of these were present, as the coccus, augur a favorable issue to the case, and that others, notably the streptococcus, indicate a grave prognosis.

3. Some seemed to aid the growth of the Klebs-Löffler bacillus; others to hinder its development.

This summary of work illustrates, I imagine, almost every phase of diphtheria which those of us who have had much to do with the disease have experienced.

The detailed peculiarities of different cases, referred to in the extended monograph, have one after another seemed to call up memories of cases within my own experience, which, owing to imperfect knowledge at the time, seemed in their varying characters to be inexplicable on the basis of a common cause. The bacteriologic results therein set forth, so far as separating non-diphtheritic cases from true diphtheria, have been already taken practical advantage of by a number of public health departments, and on this continent I believe New York City was the first to adopt the method by which test tubes with a culture medium are left at certain stations throughout the city, as drug-stores, where physicians can obtain them with instructions as to the manner of inoculating them with membrane, thereafter to forward them to the laboratory of the City Health Department.

With a view to aiding medical health officers throughout the Province to determine with the local physicians the real nature of doubtful cases of the disease, the Provincial Board of Health of Ontario has notified local boards to forward, as per printed instructions per express, specimens to the Provincial Laboratory for examination. This work has been in operation for only a few months, and too few specimens have as yet been examined to enable us to give an estimate of the average percentage of cases in which the Löffler bacillus is likely to be present or absent, so as to serve as a standard for the locality.

There are, as pointed out by MM. Chaillou and Martin, likely to be seasonal differences, and probably different localities, climates and cities will show variations in the prevalence of one or more of the specific pathogenic forms referred to by different bacteriologists.

The advantages which the precise knowledge of the cause of membranous exudates have given, both in the prevention and treatment of diphtheria, while considerable, have nevertheless brought into prominence certain points, which are likely if not intelligently weighed in their practical bearings, to bring perplexities and difficulties to both attending physi-

cian and health officer, quite as great as those existing formerly, where acrimonious disputes have arisen as to whether the sore throat was diphtheria or simply amygdalis with exudation.

The advantages which the accurate differentiation of the microbe causative of the exudate in any case brings us are principally:

1. That within twenty-four hours in the ward annex of an hospital, a scarlatinal sore throat with streptococcus can be differentiated and be prevented from exposure to the true disease in the diphtheria ward.

2. That, similarly, cases where simple cocci or diplococci are present may be kept from exposure to the true diphtheria in the general hospital wards.

3. That physicians will be able to arrive at more intelligent conclusions as regards the duration of a case and its prognosis than hitherto has been possible.

4. That an intelligent differentiation of cases suitable for treatment with the antitoxin against the Löffler bacillus has thereby become possible.

5. That the probable length of infectiousness of any case can in some degree be determined by the form of microbe present in the membrane.

Such progress is notable, and the needs supplied thereby are fully indicated when we study the reports of contagious disease hospitals. For instance, in the 3,064 scarlet fever admissions into the North-eastern Metropolitan Asylums Board Hospital, London, England, for 1893, there were:

1. Of post-scarlatinal diphtheria .36 of 1 per cent.

2. A number, not stated, of cases of scarlatina accompanied in the acute stage with membranous exudation.

3. Some cases with diphtherial exudation admitted which proved not to be scarlatina.

It is noteworthy that in the report of Dr. R. A. Birdwood, the Superintendent, no mention is made of the bacteriologic differentiation of the several forms of throat exudations.

As, however, with every advance in our knowledge, we find that the practical benefits are often limited by unforeseen difficulties, we find that these bacteriologic results at once bring into prominence the difficulty which a health officer finds in dealing with cases of sore throat. Summed up, they are:

1. That the physician, being by these recent investigations made aware that at least 25 per cent. of diphtheria cases are not caused by the Löffler bacillus—or as some would say, are not diphtheria—will naturally hesitate to call a disease probably non-fatal by a name placing it under the ban of the Health Act.

2. That physicians endeavoring, as has sometimes occurred, to hide cases in the supposed interest of their clients, will conveniently shield themselves behind the assertion that they could not tell, nor any one else, whether the disease is diphtheria or not.

3. That supposing the health officer on investigation finds that the Löffler bacillus is not present, he at once is in doubt as to whether the public health interests demand isolation of the patients, or even if he thinks they do, whether he has legal authority to isolate what is not diphtheria.

4. That even though he isolate such cases as he does deem true diphtheria, can he maintain the isolation for the length of time, say four weeks, fixed by the best authorities, as necessary for this disease?

5. That assuming he can differentiate between cases; can he, with the known serious nature of many cases in which the Löffler bacillus is not present, afford to treat these as non-infectious when, as a matter of fact, they must have been caused by germs carried to the respiratory passage from the air or other medium in the same manner as the Löffler bacillus, and therefore infectious?

Personally, from the standpoint of an executive officer, I recognize most serious difficulties as certain to arise from what all must agree is a notable addition to our knowledge of throat diseases. I do not at present recognize, for working health officers having to deal with sore throats with exudations, any other alternative than to continue to insist on the isolation of all cases of sore throat with exudation as being diphtheria or croup within the meaning of the Public Health Act; since, while occasional instances of admitted hardship in an unnecessary extension of isolation may be inevitable, yet they will, on the other hand, have avoided the certain and most serious dangers arising from three-fourths of the cases, which are those of true diphtheria, and will have succeeded as well in limiting those other throat diseases not wholly free from danger.

The old adage seems here particularly applicable: "*Incidit in Scyllam qui vult vitare Charybdim.*"

THE MANAGEMENT OF EARLY ABORTIONS.

BY S. L. JEPSON, A.M., M.D.

PHYSICIAN TO CITY HOSPITAL, WHEELING, W. VA.

This subject is rendered interesting by reason of the frequency of the occurrence of early abortions, and by the unfortunate consequences so very often resulting, it being a well-recognized fact that a large number of the cases of uterine disease to which women are subject can be directly traced to prior abortions. That by a proper management of these cases many evil results can be prevented, all will admit, and hence exists the necessity of scientific treatment, with the cultivation of some patience, for, as in all forms of pelvic disease in women, there is too great a tendency to speedily resort to surgical methods, the physician not placing sufficient reliance in nature aided by wise, conservative therapeutic measures. Several years since, in this city, a physician just returned from a course of post-graduate instruction in New York, was preparing a table upon which to place a patient to remove the placenta of a six weeks' abortion. The consulting physician, an elderly and very intelligent man, but without any recent post-graduate ideas, suggested that perhaps at so early a period the placenta had not yet "materialized," whereupon the table was put to one side and the patient made a speedy recovery without any surgical aid. Having never yet, in an experience of twenty-six years, lost a patient after an abortion, I am forced to believe that the methods of treatment which I have pursued can not be radically wrong. Other and more active methods may possibly give as good results in other hands, and in country practice, where the physician has not the advantage of telephones and quick transit, a modification of treatment will doubtless often be necessary.

As to the general principles of preventive treatment, I will only say that perfect and prolonged rest is of the first importance. Many cases of threatened miscarriage are precipitated by allowing the patient

too early to abandon the recumbent position. The only drugs I ever use in these cases are, opium, potassium bromid and viburnum; and perfect rest is better than all of these. Rest can be better secured with than without them, however, and hence they are valuable aids.

But suppose all our efforts to prevent the threatened abortion have failed, and the expulsion of the ovum is in our judgment inevitable, what course shall be pursued? The thing to be desired clearly is, to have the ovum expelled unbroken, and every step taken should be with this object clearly in view. An unnecessary, a meddling interference while the ovum is intact, very generally terminates in the rupture of the delicate membranes, with expulsion of the fetus and retention of the placenta, the very result most to be deprecated, and that should be most carefully guarded against. Therefore I differ emphatically from the recently expressed ideas of Dr. McKinney, of Illinois, who, in a paper before the State Medical Society said: "The only safe rule is to immediately evacuate the contents of the womb in all cases where it is decided that abortion is inevitable, due care being taken to avoid rupture of the membranes." (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Vol. xxii, p. 809.) Rupture of the membranes *can not be avoided*, in my judgment, except in those rare cases in which the cervix is widely open, and even the placenta partially detached; and in these nature will very soon expel the whole ovum much better than the doctor can do it. It must be remembered that the placenta is in the early months—say the third and fourth—very firmly attached to the uterus, and unless loosened by uterine contractions prior to rupture of the membranes, it is very apt to maintain a healthy connection with the uterus when the membranes have been broken by too early manual interference, and may remain an indefinite time, greatly to the annoyance of both patient and physician.

However great, then, the temptation may be, when we find the cervix partially dilated and the membranes protruding, to introduce the finger in the hope of removing the whole ovum, unless free hemorrhage be present, I believe the safe rule is, "hands off," for the presence in the cervix of the unbroken ovum will in a natural manner bring about the dilatation of the cervix and also excite expulsive contractions of the uterine body, and the ovum will often, without any interference whatever, be expelled entire, or the placenta speedily follow the fetus, when a rapid convalescence, with future immunity from uterine disease, may be expected.

Under the circumstances here spoken of, prior to the expulsion of the ovum, ergot is given as a routine treatment, but I have little faith in its power to excite uterine action, since the contractility of that organ is very limited during the first few months of pregnancy, and certainly much more difficult to excite than at or near the full term. Some aid in lessening hemorrhage may possibly be had by the action of this drug on the blood vessels, and by some condensation of uterine muscular fiber, and this action is more efficient when the ergot is given hypodermically. Opium may be combined with it to advantage. This will tend to lessen hemorrhage and secure some rest for the patient while nature is loosening the ovum. Some authors speak favorably of lead, acids, hamamelis, hydrastis and other drugs

at this period, but I have never found it necessary to test their value. Within the first two months, when internal manipulation of the uterus, even in suitable cases, is very difficult, if not impossible, on account of the small size of the organ, Fordyce Barker very strongly advised that a large quantity of hot water, 104 to 110 degrees F., be thrown into the vagina. He says: "I believe that one may always be sure that this will positively, absolutely and efficiently arrest the hemorrhage. In all cases where I have resorted to this method, I have never found it necessary afterward to subject the patient to manipulations for the removal of the ovum. It has always come away spontaneously, sometimes the next day, or the next but one, and absolutely without hemorrhage."¹ This accords with my own observation in early cases, and Leishman says: "In the first and second months, the placenta being undeveloped, the ovum is generally expelled entire with little risk to the woman."² Within the period above named, it is not at all likely that the remedies here indicated will fail to check the hemorrhage. If, however, such should be the case, the tampon must be tried before forcible extraction of the ovum be resorted to.

Cases of abortion occurring after the second month of pregnancy are much more complicated because the placenta has grown, and formed many and very intimate adhesions with the uterus, a separation of which is apt to be accompanied with serious loss of blood, and yet the uterus, not having the contractility it later acquires, is often not able to expel the placenta, which hence remains after the fetus is expelled. When called to a case of this kind in the third or fourth month, we should take every precaution to preserve the ovum. If hemorrhage is not considerable, we may use ergot and give nature a reasonable opportunity to try her powers, which often are sufficient to completely empty the uterus. We would not advise too long delay, however, without some interference. Unless the patient can be frequently seen, or if hemorrhage is at all serious or threatens to become so, the vagina should be well tamponed. This serves the double purpose of controlling the hemorrhage and exciting reflex uterine contractions. Neither end can be accomplished unless the tampon be so applied as to exert firm pressure on the cervix, which means that the vagina must be well filled and firmly packed. I have always used the method of Lusk, and desire no better. This "consists in soaking cotton wool in carbolyzed water, and then, after pressing out any excess of fluid, in forming from the carbolyzed cotton a number of flattened discs about the size of a silver dollar. The patient is then placed in a latero-prone position, and the perineum retracted by a Sims' speculum. The dampened cotton discs are introduced by dressing forceps, and under the guidance of the eye are packed around the vaginal portion, then over the os, and thence the vagina is filled in from above downward."³ Fordyce Barker never depends upon any form of vaginal tampon, but always introduces a sponge tent when he thinks artificial dilatation necessary, only introducing sufficient vaginal packing to retain the tent *in situ*. In these days of antiseptics and asepsis, sponge is at a discount, and I would much prefer a tupelo tent as large as can be conven-

iently inserted, great care being taken to avoid rupturing the membranes in the act of introducing it. Whatever form of tampon be used, the vagina should be well washed out with an antiseptic solution both before each introduction and after the last removal of it.

How long should we continue to employ tampons, to the exclusion of manual interference? If not commenced until dangerous hemorrhage threatens, in very many cases the ovum will be found detached from the uterus at the expiration of ten or twelve hours after its first application, or certainly after a second application of like duration. There is a decided tendency among excellent men to limit the use of the tampon to two or at most three applications of about twelve hours each, when internal manipulation should be resorted to if the desired end has not been accomplished. In spite of antiseptic solutions both in the tampon and by injections, if tampons are retained too long or used too frequently offensive odors will arise, the vagina and uterus will become irritated if not inflamed, and septic poisoning and inflammations may ensue. No absolute rule can be laid down, as much will depend upon the period of pregnancy and the symptoms and local conditions present in each case. I believe, however, that I have never found it necessary to make more than a second application of the tampon in any case. After this, the cervix will be usually found either well dilated or dilatable, when the finger can be carefully introduced and the whole ovum removed, but not always removed whole. The patient may be congratulated when this end is accomplished, for with this her trouble is at an end, and nature will do the rest.

Unfortunately we see many cases for the first time after the fetus has been thrown off, the placenta still remaining within the uterus. Or we may rupture the membranes in unwise efforts to remove the ovum, and find the placenta still adhering more or less firmly to the uterus. The cervix may be closed, or so little dilated as to render extremely difficult any effort to enter the uterus. With this condition present, if the patient is left unaided one of several consequences will result, viz.:

1. The placenta, if not already so, will become partially detached, and hemorrhage, serious, dangerous or even fatal may result. I have seen cases in which syncope occurred from loss of blood under these circumstances. In a case seen in consultation some time ago, the patient was so reduced from repeated hemorrhages resulting from retention with partial detachment of placenta, that she was in a quite critical condition. An excessive pallor, cold surface, nausea, vomiting and an irregular and very feeble pulse were symptoms marking a condition demanding speedy and vigorous interference. Although life may by prompt measures almost always be saved in even apparently desperate cases, yet there is the risk of a diseased uterus and future impaired health.

2. Decomposition of the placenta and its discharge piecemeal, with probable septic infection. The consequence of this may be the death of the patient, a not rare result, or a protracted convalescence, with a damaged uterus, or inflammatory exudations that may terminate in suppuration, thus entailing long continued or permanent suffering and ill health. Very many cases of pelvic disease can be directly traced to just such cases as those now referred to.

3. Uterine action may cease, the cervix close, and

¹ Medical Record, Vol. xv, p. 232.

² Op. cit., p. 378.

³ Medical Record, Vol. xv, p. 222.

for a time the patient feel well. Later, a partial separation of the placenta occurs, marked by periodical pain and hemorrhage, which, if neglected, will result in impaired health. I have removed one placenta that had remained *in utero* sixty-nine days, and another one hundred and fifteen days after the expulsion of the fetus. In neither was there the least evidence of decomposition. The removal was in both cases followed by the prompt recovery of the patients, and in a few months by pregnancy. One woman had a normal labor, the other died in labor from rupture of the uterus, which I have always feared was due to injury inflicted at the site of the placenta. For over three months after the abortion, no symptoms arose in this case demanding the presence of a physician. (Full report in *Am. Jour. Obst.*, October, 1883.)

4. A polypus or a mole may result.

5. Some excellent authorities hold that the placenta may be entirely absorbed, but many likewise oppose this teaching; hence the question must be considered as still *sub judice*.

Since, then, the consequences of placental retention are so varied and serious, the importance of completely emptying the uterus at the time of or soon after the expulsion of the embryo, is apparent. I do not agree, however, with an editorial writer in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, May 26, 1894, who says: "Two courses lie open to the physician: He can either trust to nature, . . . or he may take the better course and empty the uterus with his own hands." Such advice is not applicable to all cases, and such a course might prove very unwise. I doubt very much whether or not the practice advised can always be adopted without at times inflicting unnecessary pain and damage upon the patient. The writer quoted above says: "The operation is not a difficult one." Cazeaux says: "Sometimes the adhesions of the placenta are so numerous that it is impossible to destroy them and extract the placenta." Leishman says that from the eighth to the eighteenth week the connections between the uterus and placenta "are often to be severed only with the greatest difficulty." ("Midwifery" p. 378.) Thomas says: "It is no easy task, even for an expert to dilate the cervical canal and remove the placenta." (*Am. Jour. Obst.*, vol. xi, p. 774.) The latter statements more nearly correspond with my own observations, and hence I naturally regard them as the more correct statements. To leave the case to nature or to immediately extract the placenta as stated by the *JOURNAL* editorial, are not the only alternatives; and whether one of these or neither shall be adopted, will depend upon the conditions present:

1. If the cervix is sufficiently dilated or very dilatable, the finger should be carefully introduced, when, by slowly and carefully insinuating it between the placenta and uterus, the latter may be completely emptied. If any great difficulty is encountered, the patient should be placed on a table and an anesthetic administered.

2. If the cervix is not dilated or quite dilatable, or if the placenta is found to be very firmly adherent, or if hemorrhage is to be feared and the physician live at some distance from the patient, the vaginal tampon should be employed as already described, with a tupelo tent in the cervix when needed, and ergot should be administered freely. Cazeaux says: "The conjoint use of ergot and the tampon rarely fails to arrest hemorrhage and bring on a sufficient

degree of contraction to expel the secundines." I think it is a common experience that the placenta is found, after this treatment, completely detached. When this is the case it only remains for us to remove it and cleanse the uterus and vagina. A second application of the tampon is not often necessary, but would be proper if its first application has not accomplished its purpose. Thomas says that, "when a woman is bleeding in consequence of retained placenta, he never invades the cavity of the uterus. By tamponing the vagina the blood will percolate between the deciduæ, rip off the placenta, form a clot in the uterus and subsequently be expelled by uterine contractions." (*Am. Jour. Obst.*, Vol. xi, p. 775.)

There is still another class of cases to which I have not referred. We may first see a case several days after the expulsion of the fetus, but the placenta remains, and an offensive odor is present, with or without fever. The placenta is decomposing and danger is near. These are the cases in which I feel that the most prompt and vigorous measures are justifiable. Fortunately the difficulty in removing the placenta is usually not so great in these as in other cases, since the cervix is, as a rule, open so that the finger can readily pass to the fundus, and the placenta is not so firmly adherent as before decomposition commenced. One caution is necessary, and that is to avoid wounding the uterus in our manipulations, for any traumatism is apt to be followed by the absorption of septic matter, this showing itself by a chill and increased fever soon after the operation. To guard against this result, the uterus should be carefully washed out with an antiseptic solution, both before and after the operation, and during it as well, if any difficulty is encountered. In such cases we should endeavor to avoid instrumental aid, but the dull curette may be found necessary. Here the irrigating curette is very useful. A case in the practice of my friend, Dr. Ackermann of this city, forcibly illustrates the necessity for, and results following the removal of a putrid placenta. He was called to a patient whose temperature was 107 degrees, and found lying loose in the cervix a very offensive placenta. He removed it, washed out the uterus with antiseptics, and in twenty-four hours found the patient's temperature normal. Not often will we secure such happy results as were reached in this case, but when the operation is carefully and thoroughly done, good may be confidently anticipated.

As a rule, quinia in full doses is required in the septic cases, and special symptoms may demand other remedies at times. These will suggest themselves to the intelligent practitioner.

In conclusion, I may say that this paper, while containing nothing new and much that is quite old, is written as a mild protest against the radicalism of the present day; a radicalism practiced by myself before experience taught me that nature, aided by time and the measures here advised, can better expel a premature ovum and entirely cleanse the uterus, thus bringing about complete involution, than can the most expert physician with finger, forceps and curette, when used before nature has prepared the way by softening the cervix and loosening the ovum.

NOTES ON SPERMINE.

Read at the Chicago Medical Society, Sept. 17, 1894.

BY G. KREIGER, M.D.

SURGEON TO CHICAGO HOSPITAL, ETC.

Last April I had occasion to exhibit before you a patient previously suffering from a severe form of chorea, who recovered completely, and permanently after six injections of spermine. Since then I have had an opportunity to see the efficacy of this treatment in a similar case still more pronounced than in the one exhibited.

The patient who now stands before you is a boy, 6 years of age, who has since the last two years been suffering from chorea. During this time he was under treatment of several physicians who applied the common remedies and electricity without success. Last May the boy was brought to Dr. Bettmann for examination of his eyes. Dr. Bettmann, who will report more definitely, prescribed suitable glasses. Two months later the Doctor referred the case to me for a treatment with spermine injections.

When I first saw the boy, his fingers and muscles of the face were constantly jerking in a spasmodic way, and his gait was so uncertain that at times he stumbled. After two injections of 8 minims, the boy became decidedly more quiet, and from the fourth day on, he did not show the slightest symptom of chorea. His nervousness disappeared; his gait, appetite and sleep improved, and his manners and general actions when playing with other children became perfectly normal.

Such rapid changes of the nervous system, especially in cases like this, where any reflections as to the hypnotic influence or suggestive power of a new treatment may readily be excluded, are certainly hard to explain, and answering to many inquiries on this subject, I would like to give my views referring to the physiologic effects of spermine, by quoting a few interesting facts:

After it had been proved that most of the animal glands contain spermine, and that it circulates in the blood, further investigations have shown that it is a very active factor, by its power to promote oxidation. The poisoning effects of many drugs, as chloroform, ether, oxydul of nitrogen, carbon oxyd, strychnia, etc., is due to a disability of the red blood corpuscles to absorb oxygen. This disability is lessened or totally removed by the action of spermine. This explains the reviving effect of spermine injections in narcosis, poisoning by strychnia, etc. It also characterizes the efficacy of spermine in cases with exhausted conditions of the organs and the nervous system, as in phthisis, diabetes, scorbutus, anemia, neurasthenia, marasmus, etc., because all these conditions are brought about by a lack of intra-organic oxidation.

The final effect of spermine will, therefore, be increase of vitality of the respective organs, and the whole organism. That such an increase of vitality, especially in the nervous centers, can really be obtained, has been shown by the following experiments:

1. When after a spermine injection, a frog's spinal cord is cut, the paralysis of the bladder and extremities is not as complete as it usually is without the use of spermine.

2. When a frog is poisoned with strychnia, after an injection of spermine he will not suffer from tetanic convulsions to the extent that he does without spermine.

From such and similar evidences, it is not illogical to conclude that a higher intra-organic oxidation is in fact a self-defense of the organism against agents which in any way have a depressing effect.

This theory is substantiated by the effect of spermine upon cultures of cholera bacilli. A virulent cholera culture, when in contact with sulphuric acid which is free of nitrous acid, shows a scarlet to purple red color, a reaction which is recognized as specific for genuine cholera, and commonly known as the "cholera red reaction." In the presence of spermine this reaction does not take place, the development of the culture is greatly retarded and its virulence is reduced to such an extent that its pathologic effect is about equal to that of the vibrio found in cholera nostras or catarrh of the intestines.

This fact might suggest that a practical use could be made of spermine as a therapeutic agent in cholera. But as the action of chemic substances observed in the test tube does not always correspond with their effect in the organism, it remains to be seen whether or not spermine will act in the above mentioned way within the intestines. The experiment would certainly require to flush the intestinal tract with a large quantity of spermine solution. So far, similar experiments made with antiseptic fluids failed on account of the toxicity of same when given in large doses, and I think in this respect the use of spermine, which is absolutely harmless in any quantity, will manifest a decided advantage of its own over other substances heretofore used for the same purpose.

It will be a question, if spermine can be manufactured cheap enough. As yet, the process of preparation is pretty expensive, and not always successful. I have here a specimen of macroscopic crystals larger than are usually obtained. The liquid is tungstate and sulphuric acid, in which they are insoluble. In order to ascertain the presence of spermine in any fluid, a few drops of the latter may be placed in an evaporating dish and a saturated solution of alloxan added. When heated, the previously colorless fluid will leave a purple red spot which, with caustic of soda or potash, turns to violet, and by addition of acids, is again discolored.

With special reference to chorea, I wish to suggest the following theory for the origin and cure of this disease:

By chemic transformation in the nervous substance, free nitrogen is formed under certain conditions, based upon lack of oxydation. This nitrogen when in proper proportion with lecithin and phosphoric acid forms a substance of very little stability and inclined to rapid dissolution, by which a sudden irritation of the nervous centers is brought about and such irritations become visible by their effect to the various muscles. When the normal oxydation is restored, the noxious nitrogen is eliminated, and in this way the cause of forming an irritating substance is removed.

This theory may seem somewhat artificial or peculiar, but looking over what we know, positively, regarding chemic and pathologic changes in the animal system, we can easily find corresponding facts, which explain the occasionally observed strange action of substance.

During the process of cellular nutrition, the albumen of the cell is changed by regressive metabolism into different products, the last of which is urea. We may distinguish three degrees of differentiation: The

products of the first degree are the albumins, some of which, especially when in contact with noxious microbes, are poisonous; toxalbumins.

The products of the second degree are the derivatives of ammonia. Armand Gautier distinguishes three groups of these: 1, the xanthines; 2, the keratines; 3, the various bases as cholin, muscarin, and acids, as glycocoll and hippuric acid.

The products of third degree are uric acid and urea.

The intermediate products are partly harmless and partly deleterious to the organism. When the latter for lack of further transformation remain in the system, the effect is an auto-intoxication as most clearly seen in uremia. Such auto-intoxications are in fact the cause of many diseases, which can be proven by the different toxicity of the urine. For instance, the urine of a healthy person hypodermically injected into a rabbit will do considerably less harm than the urine of a person suffering from any disease which is based upon weak functions of the organs, or, to speak chemically, upon an incomplete change of substance on account of lack of oxidation. For the same reason the urine discharged during the night shows a higher toxicity than the urine discharged while a person is awake and active. According to Bouchard's investigation the coefficient of toxicity for normal urine is 0.465. This coefficient increases during acute fevers, as scarlet, typhoid, pneumonia, acute tuberculosis, and in all anemic patients to the extent of 50 to 100 per cent. Leprieu and Aubert found that hypodermic injections of urine taken from patients with certain nervous diseases causes clonic spasms. The toxicity of such urine is directly proportional to the amount of leucomaines and other intermediate products present. Babinet and Silberer succeeded in preparing three leucomaines from a case of strumexophthalmia or Basedow's disease, and experiments with these substances were to the effect that animals inoculated with same showed symptoms similar to the original case. Griffith also isolated from the urine of an epileptic patient a leucomaine, which injected into a dog caused spasms, vomiting, dilatation of the pupils, and finally death.

Such deleterious leucomaines are without doubt forming constantly in our organism, and would do much more harm were they not eliminated or balanced by natural chemism, in particular by oxidation. The necessary impulse for these chemic actions is given by catalytic agents, the analogues of the well-known ferments which are instrumental in the process of digestion.

Some noted physiologists, as Traube, Tacquet, Gautier and others, have anticipated the existence of these agents long before the scientific researches of Brieger and Ehrlich threw light upon the different leucomaines and toxins, and with other investigators of this subject I believe that the most important catalytic agent is found in the substance of spermine.

This idea is strongly supported by the following undeniable facts:

1. The chemic properties of spermine as an oxidizing agent.
2. The clinical observations that removal (extirpation) of certain glands in which this and similar substances are produced, is followed by cachectic conditions (cachexia strumipriva—orchidipriva, Addison's disease.)
3. The stimulating effect of spermine in cases of depressed and exhausted condition.

DISCUSSION.

DR. CLARKE GAPEN—The particular phase of the subject Dr. Krieger has alluded to has not received from me the attention it deserves. I have made no trials of spermine in the treatment of nervous diseases, but it is my intention to make a systematic trial of this remedy in conditions of nervous exhaustion, especially those neurasthenias that take the form of mental derangement. I would ask Dr. Krieger in closing the discussion to give his method of using spermine, and the best source from which to obtain it, as I wish to make a trial of it on rather a large scale.

DR. D. R. BROWER—My experience with spermine has been limited. Shortly after Dr. Krieger read his former paper I expressed a wish to try it. At the time I had at St. Joseph's Hospital an exceedingly bad case of chorea of two or three years' standing. Dr. Krieger kindly furnished the material, and a number of injections, I should say a dozen at least, were given the patient, but in that particular case we saw no benefit from its use; but, as I say, the case was an extremely bad one, having resisted all the ordinary forms of treatment. It was such a case as I have time and again seen benefited by the hypodermatic use of arsenic, but in this case that drug entirely failed and the patient left the hospital unimproved. With the Brown-Séquard testicular fluid I have had some experience. I have used the preparation in some cases of locomotor ataxia, epilepsy and neurasthenia. I have used it side by side with the phosphate of sodium, and it has occurred to me that whatever benefits this preparation may have is due to the phosphates it contains, although the Doctor's explanation of the action of spermine is altogether different and exceedingly ingenious, and may be correct. In several of these cases I tried the phosphate of sodium side by side with the testicular fluid, and if there was any advantage I think it was in favor of the phosphate of sodium, and I quite indorse the observations of those gentlemen who have suggested this remedy as a substitute for the animal compounds. One of our most striking cases was one of spinal sclerosis that had passed, as was supposed, into the paralytic stage. It seemed to be a case that was past any sort of benefit from remedies, but the use of the phosphate of sodium gave that man a start toward improvement and, while he is not well, he is no longer bedridden. In this case we tried for a time the Brown-Séquard testicular juice with scarcely any benefit. I am very glad to have heard Dr. Krieger's paper, and I shall take pleasure in pursuing some experiments with spermine. This boy he has presented to-night with chorea of two or three years' standing, to be improved to the extent he has been by half a dozen injections is certainly very remarkable, and I do not think the effect can be explained by suggestive therapeutics, but I think it shows the remedy is of value. There are some cases that will not yield to anything, and I am inclined to think the case we experimented upon at the hospital was of that sort. I think this is due to an organic change in the brain that neither spermine nor anything else probably will remove. I wish personally to thank Dr. Krieger for his contribution to the therapeutics of this disease.

DR. BOERNE BETTMANN—I do not intend to make any statement about the action of spermine, because I have had no experience with it, but I rise merely to corroborate the statements made by Dr. Krieger as far as they have reference to the history of this little boy. He came to me several months ago suffering from chorea. Whether it was a case of hysterical chorea or so-called chorea minor, I do not know. I learned from his mother that he had been suffering from the trouble for some time, and he certainly manifested all the symptoms of chorea at that time. Thinking probably it might be due to some error of refraction, I placed the boy under homatropin and succeeded in establishing a hypermetropia of about two and one-half dioptres. It is an interesting fact that during the time he was under the influence of homatropin, his mother noticed that the choreic symptoms decreased markedly, and thinking that probably the chorea was reflex and due to spasm of accommodation I kept him under the influence of atropin for a week or two, and at the expiration of that time he returned to my office without having further improved, although

while under the influence of the mydriatic the symptoms did decrease somewhat. I then gave the boy a correction of about one and one-half dioptrics. He came back in a week without having improved and he was then sent to Dr. Krieger. After a few injections of spermine he again came to my office, and was then in the condition you see him this evening. Since then I have heard from the father that the child has discarded his glasses. There has been no reappearance of the attacks of chorea.

Dr. H. T. PATRICK—I hope Dr. Krieger will not detract from the value of his paper by failing to give the symptoms of this case more in detail when it is published. From his statement we do not know whether it was hysterical chorea or the ordinary chorea minor, and anybody hearing or reading the paper could say that it was not proved to be a case of chorea at all. I simply call attention to this omission that the value of the paper may be increased.

THE PRESIDENT—I will ask Dr. Krieger when he closes, to explain to the members of this Society the difference in the action of spermine and nuclein.

Dr. C. G. KREGER in closing the discussion said: In regard to the question of the President I will state that I have not had experience in using nuclein. From a chemist standpoint it is altogether different from spermine, which has a certain formula and is uncomplicated, while nuclein has no formula at all to my knowledge, or at least a complicated one, so I do not know how I could make a comparison between nuclein and spermine. With reference to the dosage, I generally start with small hypodermic doses of the solution of spermine, about 7 to 8 minims for an adult, and for a child 3 to 4 minims, gradually increasing to the full dose, which is 15 minims for adults, and 8 to 10 minims for children. I first give one injection every day, and if I see quite an effect from it I usually give one injection every other day for two or three weeks or longer. As a rule, I discontinue the treatment after the tenth or twelfth injection, to see what effect it will have.

1003 Columbus Memorial Building.

Surgeon-General Sternberg's Annual Report.

After presenting a statement of the disbursements made during the fiscal year ended June 30, 1894, the Surgeon-General discusses various matters of interest pertaining to his department, of which the following abstract gives a satisfactory account:

Library of the Surgeon-General's Office.—There are now 114,567 bound volumes and 183,778 medical pamphlets and theses in the Library. Volume XV, of the Index Catalogue, including from "Unversidad" to "W," forming a volume of 842 pages, has been completed and is now in the printer's hands. The preparation of the manuscript of Volume XVI is already well advanced.

Army Medical Museum.—The total number of specimens received during the year was 1,363; the number on hand June 30, 1894, was 32,269.

Artificial Limbs.—During the fiscal year there were furnished, under the laws relating to artificial limbs, 343 artificial legs, 4 arms, 2 feet and 2 apparatus, and the commuted value of an artificial leg was paid in 2,997 cases of amputation; of an artificial arm in 3,184 cases, and of an artificial foot in 72 cases. Commutation was paid also in 3,496 cases in which the use of a limb was lost. The money expended consisted of \$586,391.44 from the appropriation for the year, \$4,823.55 from the appropriation for 1893, and \$500.40 from that of 1892—a total of \$591,715.39.

There are at the present time 16,750 approved cases of loss of limb or loss of use of limb on the rolls; 3,395 cases of loss of arm, 3,603 cases of loss of leg, 99 of loss of foot, and 9,653 of loss of use of limb. These cases come up for payment every three years. Their commutation value amounts to \$927,575, but as about 500 cases elect to be furnished with limbs in kind, this sum has to be increased by about \$20,000 for the transportation of these maimed soldiers from their homes to the place of manufacture and return. It is estimated that the whole of the \$194,000 appropriated for the current year will be required to meet the cases maturing during the year, and that \$130,000 will be required for the next fiscal year.

Army and Navy General Hospital.—Fifteen officers and 101 enlisted men were admitted. Five of the former recovered after an average stay of ninety-four days. Of the latter, fifty-nine or nearly 58 per cent. of the whole, were returned to duty. Among those returned to duty were several men whose discharge for disability had been recommended by

post surgeons. The Commanding Officer renews his recommendation for the introduction of electric light, and that cottage quarters be built on the grounds for the junior medical officer and the quartermaster, who now have to live in the town of Hot Springs. I concur in these recommendations.

Providence Hospital, Washington, D. C.—Relief was afforded, under the appropriation for this hospital, to 1,051 desitute patients. The average number treated daily was 104; the average number of days treatment per case was 36.

Medical Officers.—During the year the Medical Department of the Army lost eleven of its members; one by death, an assistant surgeon-general with the rank of colonel; and ten by retirement.

An Army Medical Examining Board was convened in October, and remained in session during the month for the examination of candidates to fill the vacancies then existing. Thirty-seven candidates were invited to appear before the Board; five of these were found qualified and were thereafter appointed assistant surgeons with the rank of first lieutenant.

At the close of the year there were ten vacancies in the number of appointments then allowed by law, and a board had been convened to select the individuals to fill these vacancies; but inasmuch as the Military Committee of the House of Representatives in drafting the Army appropriation bill for the current year seemed to regard a reduction of the numerical strength of the Medical Corps as desirable, the order convening the board was at my request rescinded, and the candidates who had been invited to appear for examinations were notified of the indefinite postponement of the examinations. The bill when passed directed that the number of assistant surgeons be reduced to 110, a loss to the Corps of 15 young officers instead of 35 as originally proposed.

The report of the Committee on Military Affairs to accompany H. R. 6373, the appropriation bill above mentioned, says: "When this Department was re-organized by law in 1869 there were 210 military posts and stations in the country. This number has already been greatly reduced, so that there are now but 120 military posts and stations, and a still further reduction is proposed and will be effected within a few years. It is evident that if 193 officers in this Department were sufficient when the number of posts and stations was 210, there can be as great a reduction as is proposed in this bill when the number of posts and stations is reduced to 120."

As a matter of fact there were 184 acting assisting surgeons in service in 1870, after the re-organization referred to, and these acting assistant surgeons performed all the duties of junior medical officers. They were made responsible for medical property and were ordered wherever their services were required, in the field with troops, as assistants at large posts, and as post surgeons at small posts. As the number of posts was reduced and the exigencies of the service permitted, their number was reduced until in 1893 none remained in service. At present, private physicians can be employed only by the visit, and there is no proviso of law by which they can be placed in charge of the Medical Department at a military post. They are therefore not available for taking charge of a post hospital and the medical and hospital property necessary for the care of the sick and wounded of a garrison, or for the discipline and drill of the Hospital Corps detachment, for the sanitary supervision of the post, or for medical services to the families of officers and enlisted men.

The report of the Committee further states that: "It may be necessary in several instances to employ outside attendance of physicians for these smaller posts, but that can always be done and efficient services secured at a cost of from one-fifth to one-fourth of the present average of salaries of the officers of the Corps." As a matter of fact private physicians have been employed during the past year and are now employed at all the arsenals of the country. The number of men at those stations is comparatively small and a saving is made by paying for medical services by the visit. But it is a mistake to suppose that private physicians could be employed at garrisoned posts, whether large or small, at the low estimate cited above. Indeed I question if there are more than half a dozen posts in the country where satisfactory medical attendance could be provided at less cost than the pay of an Assistant Surgeon of the Army, \$133.33 per month. Moreover, a post medical officer has various and important duties to perform in addition to caring for the sick. In fact his presence as a member of the garrison is more important than that of any other officer, for no other officer can perform his duties, whereas any line officer pres-

ent can perform the duties of quartermaster, commissary of subsistence, adjutant or commanding officer of a garrison. The Major-General Commanding, on page 12 of the Committee's report is cited as saying: "At military posts it is in my judgment impracticable to supply the necessary service, including that in the hospitals, in any other way than through the regular commissioned officer."

The report of the Military Committee further says: "In time of peace these men (enlisted men) and officers should be, generally speaking, in sound health physically and mentally." Great care is exercised in the examination of recruits and they are in sound health physically and mentally at the date of enlistment; but under the most favorable circumstances a considerable number require the services of a physician after enlistment. This is shown by the fact that at the three recruiting depots, all in comparatively healthy localities, the average number on sick report every day during the year ending June 30, 1894, was

| | |
|--------------------------------------|--------|
| At Columbus Barracks, Ohio | 57.68. |
| " David's Island, N. Y. | 24.49. |
| " Jefferson Barracks, Mo. | 24.80. |

It may be observed also that these averages represent the number borne on sick report; probably an equal number at every post has to be examined and prescribed for, although not taken up on the reports.

Again, an important part of the duty of a medical officer in a garrison is to decide whether enlisted men who report themselves sick are in reality unfit to perform their duties, or whether they feign sickness for the purpose of avoiding their duties. A private physician called in by the visit is not present at sick call to determine this question, and when it is left to the decision of a non-professional person, a company officer or non-commissioned officer for instance, the man who feigns sickness has a better chance of success and the really sick man is often compelled to do duty because he is suspected of malingering.

It is, however, when troops are ordered out for active service that the weakness of a Medical Department, consisting in part of medical men attending and paid by the visit would be mainly felt. The principal reason for supporting an army in time of peace is that an efficient organization may be maintained which will be ready for service in any emergency and serve as a nucleus for the larger army which will be required in case of war. This applies to the Medical Department as well as to the fighting force. The duty of our medical officers is not only to attend to the sick at their stations, acting at the same time as health officers for their command, but to be prepared, and to prepare their Hospital Corps detachments, for any emergency, and especially for field service. The call to service in the field is more common in our army than is generally supposed. During the year 1893 the number of men constantly in the field was 789, as reported by the 69 medical officers who were out with the various detachments which constituted the average field strength. The largest number of medical officers out in one month was 23, in September, with detachments aggregating 2,954 men, and giving an average strength for the month of 1,663 men. It is for such field service that the need of the junior officers of the Medical Department is chiefly felt. In 1892, 76 medical officers were on field service, the average number of men thus serving having been 1,010. In 1891, 93 medical men were out with various detachments of troops having an average strength of 899 men, and in 1890, 143 medical officers with an average strength of 1,210 men. If attendance on the sick at military posts be made the gauge of the strength of the Medical Department, no provision of medical officers can be made for troops on active service unless certain posts be deprived of their medical officers.

During the recent troubles at Chicago, Ill., when 1,775 men were suddenly concentrated in that city, 3 medical officers on leave of absence threw up the unexpired portion of their leaves and reported for duty with the troops and thus helped out the Department in the emergency.

It must be remembered, also, that medical officers are as liable as other officers to break down under the exposures and accidents of field service or from other causes. During the past three years a little over 5 per cent of them have been constantly non-effective from sickness, or 10 officers of the 192 allowed by law up to the time of the passage of the current appropriation bill.

Again, these officers are as much entitled as other officers to leaves of absence; but inasmuch as the Regulations of the Army prescribe that leaves will not be granted "so that a post will be left without competent medical attendance,"

many of the medical officers have to do, year after year, without leaves such as are enjoyed by others. During the past ten years the leaves of absence granted to medical officers were equivalent to an average leave annually of a little less than fourteen days for each. To enable the Department to permit its officers to have one month's leave annually and at the same time provide competent medical attendance at posts, a strength of 8.3 per cent. is needful over and above that necessary to man the posts.

In view of these considerations I regard with regret the policy which has cut off fifteen officers from the Department.

The Army Medical School.—I take pleasure in reporting the successful establishment of the Army Medical School authorized by General Order No. 51, A. G. O., June 24, 1893. The value of a special course of study for passed candidates for the military service is recognized by the Medical Department of many European armies. The absolute necessity of special training for the officers who are to be intrusted with the great responsibility of keeping the army in its best sanitary condition was demonstrated in the British service during the progress of the Crimean War; and their Army Medical School was a product of the experience so dearly bought in that war. It has been in continuous and successful operation since 1857. The duty of an army medical officer is to preserve the efficiency of his command by guarding it against unsanitary influences and preventing disability from diseases that are known to be preventable. To this end he examines every candidate for enlistment, rejecting those who have any imperfection of physique or taint or weakness of constitution that would probably result in disability under the ordinary exposures of active military service; and he exercises a careful supervision over the health of the soldiers, that the sound physique brought with them into service may not be injured needlessly. To accomplish this in a satisfactory manner requires special training. Any well educated medical man may be placed in the wards of a hospital and intrusted professionally with the care of its sick; but this, although of high importance, and particularly from the point of view of the patient, is a minor duty compared with that of preventing or suppressing the sickness that would otherwise fill the wards. The medical graduate, equipped as a general practitioner, is not qualified for such duty. Some of our medical officers have not only recognized this defect in the qualifications of their juniors, but have appreciated how much better their own early work might have been had their education been perfected as is that of the British medical army officer at the Army Medical School at Netley, England. I need hardly say, therefore, that the want of such a school in this country has been greatly regretted, particularly by those who are conversant with the work of the European schools. The absence of facilities—of teachers, lecture rooms, laboratories and their equipment, has always presented an obstacle to the realization of any suggestion in this line. The expense of building up such an establishment and meeting its current requirements seemed to throw the proposition out of consideration in view of the small number of young men that would be required annually to undertake its course of study prior to filling the vacant places in the Medical Department. And yet the very paucity of the number is, in my opinion, a principal reason why the abilities of each individual joining the corps should be trained sedulously in the lines of his future work. It is on the efficiency of the members of the Medical Department of our small army that the care of the sick and wounded of the armies of the United States would chiefly devolve in the event of war. Every expenditure whether of effort or of money for the improvement of the Medical Corps is a sound investment, which will produce returns in an improved sanitary condition of our Army in time of peace, but will bear its best fruits, its golden harvest of good work, in those times of anxiety and danger when the services of an army are needed for active field operations.

Being fully convinced of the accuracy of these views it was with much satisfaction that I recognized the possibility of improvising a school which, although adding nothing to the expenses of the Army Medical Department, would afford all the advantages that could be derived from one costing heavily for its establishment and maintenance. The building provided by Congress for the Library and Museum gave the necessary lecture rooms, and the accumulation of material for bacteriological and chemical study in the Army Medical Museum furnished everything essential for laboratory work, so that by utilizing these, together with the abilities and experience of those medical officers already on duty in this city, who have been appointed members of the Faculty, I

was enabled, with the approval of the Secretary of War, to inaugurate this important work. The transfer of the Hospital Corps Company from Fort D. A. Russell, Wyoming, to Washington Barracks, completed the equipment of the School by providing facilities for instruction in drill, company administration, first aid and battle-field management.

The report of Colonel Alden, President of the Faculty, which I have embodied in my own report, gives the details of the course of study during the session beginning Nov. 1, 1893, and ending Feb. 28, 1894. To this interesting document and its appendices I desire to invite attention, as showing fully the scope of the work of the School and demonstrating its importance and value.

I desire, also, to thank the members of the Faculty for the earnestness with which they entered upon the work of the session, and carried out its details, notwithstanding the large amount of additional labor which this imposed upon them. Most of these gentlemen served during the War of the Rebellion, holding positions of high responsibility in the Medical Department, and are eminently qualified to hand down to the younger generation the lessons of their earlier experiences as modified by after thought and matured study. Without their hearty cooperation the School would have been one only in name. This cooperation so zealously given has been a source of gratification to me in manifesting the complete concurrence of these officers in my views not only as to the importance but as to the practicability of the undertaking. I unite with Colonel Alden also in thanking the gentlemen who kindly enriched the course by valuable lectures on special subjects.

The progress of the School has been watched with interest and approval by the medical profession, and particularly by the medical officers of the National Guard.

In concluding this subject I desire to invite the attention of the Secretary of War to the recommendation given by Colonel Alden, that the examination of student officers at the close of the session be taken into consideration in determining relative rank. At present the rank of these officers is already fixed, by the examination for entrance, when the session begins, and their work during its continuance can not alter their relative standing. This takes away an important stimulus to well doing. I therefore concur in the recommendation of the President of the Faculty that the relative rank of those commissioned on the same day be made dependent on the result of the examination by the aforesaid Board, and that of the examination held by the Faculty of the School at the end of the session, and recommend that legislation authorizing this change be asked for.

Inspections by Medical Directors.—I desire here to place on record my appreciation of the value to the Medical Department and to the Service generally, of the inspections made by medical directors under the requirements of A. R. 1662. These visits to the military posts in their departments are of great importance to medical directors, for without the thorough knowledge acquired by personal observation and inquiry it would be impossible for these officers to discharge their duties intelligently. It is an every-day occurrence for communications relating to suggested changes and improvements to be referred to them for their views and action. Necessarily the value of their opinion in such cases depends on the accuracy of their knowledge of the sanitary conditions involved. In like manner the satisfactory performance of many of their duties depends on that intimate knowledge of the character and professional qualifications of their subordinates, which can be obtained only by personal contact. The Surgeon-General in making allotments for the construction and repair of hospitals and hospital stewards' quarters, and in making assignments of medical officers and others, has frequently to be guided by the views of medical directors who owe their more intimate knowledge of the facts in any case to the opportunities afforded by these inspections. There are, moreover, many articles of drugs, surgical instruments and appliances, microscopes and microscopical accessories, and chemical and bacteriological apparatus, which require expert knowledge for their inspection. It is impossible for an officer who is not a medical man to act appropriately on such articles. It is impossible also for a non-medical inspector to determine the professional qualifications of medical officers, or to appreciate the methods of treatment carried out in the hospitals, or the progress of the Hospital Corps members in pharmaceutical and other special work. Nor can the non-medical inspector take the place of the medical director in advising the younger officers of the Medical Corps in difficult medical or surgical cases or on mooted points of local sanitation which often involve large expenditures of money.

Hospital Corps.—The work of the Hospital Corps continues to demonstrate the wisdom of establishing this branch of the Service, not only by the better care of the sick and wounded at our military posts, but by its efficiency in field work during the recent riots. The number of Hospital Corps members in service June 30, 1893, was: Hospital stewards 122, acting hospital stewards 79, privates 589. The authorized quota consisted of 146 hospital stewards, 95 acting hospital stewards and 598 privates; but from motives of economy a continuous effort was made to have the current work of the Corps performed with the smallest number consistent with satisfactory results. The appropriation for the year for the support of the Corps was \$215,000. By carefully watching the numbers from month to month so that the cost for each period should not exceed its proportion of the appropriation, the expense of the Corps has been kept within this limit.

The Schools of Instruction have continued their highly valuable work, and although it has not been practicable on account of necessity for economy in transportation, to secure the instruction of the Corps at large at these schools to the extent that is desirable, they have been of great and essential service, especially in the case of those enlisted from civil life. The training given at these schools covers all the duties which the Hospital Corps non-commissioned officer or private is liable to be called on to perform, viz., nursing, and first aid to the sick and wounded; pharmacy and dispensary work; clerical work in the preparation of papers and reports; cooking, mess management and such field work as pitching of tents and cooking and caring for the sick in the field.

The instruction of company bearers in stretcher drill and first aid has been continued during the year at all the posts, but as has before been pointed out, under great difficulties owing to the impossibility of securing the regular attendance of the bearers and their frequent change of *personnel*. It has been suggested and the suggestion has been acted on at some posts experimentally, to instruct each organization at the post in turn in these duties, under the idea that it would be desirable that as many men of each company should be acquainted with the stretcher drill and the principles of first aid as possible, so that in case of action or emergency there would be a certainty of having qualified bearers on hand.

Identification of Deserters, etc.—Fewer identifications were made during the past year than in any one of the three preceding years; 76 in 1891, 97 in 1892, 133 in 1893, and only 60 during the past fiscal year. This diminution in the number of identifications is not to be attributed to any defect of the system. It is the natural consequence of its successful operation. When deserters and others, of the kind sought to be identified by the outline figure card system, become aware that detection is sure to follow their examination for enlistment they will naturally avoid the recruiting office. The object of the system is to keep the ranks free from these undesirable men; and it is accomplished by excluding them even better than by weeding them out.

The office has now accumulated the cards of a little over 9,000 men whom it is desirable to keep out of the ranks; and should any one of these men present himself for enlistment under an assumed name his identification would follow as soon as his outline figure card was received.

Medical Department of the National Guard.—Although there has been but little official communication between the Medical Department of the Army and that of the National Guard, the fourth annual meeting of the Association of Military Surgeons of the United States, held in Washington in May last, afforded an opportunity for personal contact and interchange of views between the members of the various organizations. This Association was organized by the surgeons of the National Guard for cooperation in making the medical department of the military forces of each State thoroughly fitted to take its place in the field, either by itself or as a component of a National Medical Department. This office looked favorably upon the organization of the Association as a medium by which it might keep *en rapport* with the medical corps of the State forces, and sent delegates to its meetings to ascertain the views and practice of these medical officers. The meeting in Washington was attended by the Army medical officers on duty in and near the city, and by several from neighboring posts in the Department of the East. Several others, who were prevented from being present by their duties or the distance of their stations, sent valuable papers on professional subjects to be read by proxy. The Association was pleased to elect me its presiding officer for the coming year, an honor which I re-

garded and accepted as a recognition of my official position, and which gratified me as demonstrating the closeness and strength of the bond uniting the Medical Department of the Army to that of the military forces of the States.

Health of the Army.—The health of the Army has differed but little during the year from that shown by the best of our medical records. The admission rate per thousand of strength present was 1,289.04, practically the same as the rate of the previous year, 1,270.42, a great improvement on the average annual rate of the previous decade, 1,424.20, and only slightly greater than the lowest rate, 1,247 (in 1887) ever furnished by our troops. The number of sick daily was 40.15 per thousand of strength as compared with 39.60 during the preceding year. The number of days lost by sickness was equal to 14.7 for each member of the strength of the Army, as compared with 14.5 days during the preceding year and with 15.8 days for the average annual number of the previous decade. The rate of discharge for disability reached its lowest point this year, only 14.93 per thousand of strength, as contrasted with 18.35 during the preceding year and with 28.82 during the years of the previous decade. The lowest rate recorded prior to that of the present year was 17.23 in 1891. This satisfactory result is certainly due to the greater care taken in the selection of men for enlistment, for were it owing to the retention of disabled men the non-effective rate would give evidence of the fact. The deaths from all causes equalled a rate of 6.91 per thousand living, the lowest rate heretofore recorded having been 6.33 in 1889. Last year the rate was 6.44 and during the years of the previous decade 8.51. Excluding accidents and injuries the death rate was 4.01 which is practically the same as that of the year 1889, the year of least mortality when the death rate from disease was 3.95 per thousand living.

Omitting from consideration detachments, arsenals and small posts, the recruiting depots Columbus Barracks and Davids' Island in the Department of the East had the largest admission rates. The rates of the former have always been high and are due to the location of the depot within the limits of a city. Reference has been made to this in previous reports from this office. During the past year one-third, 333.33 per thousand of the strength present, was affected with venereal disease and the disability caused by this was equal to 24.08 men, per thousand of strength, constantly sick during the period devoted to perfecting the physique of the recruits and their education as soldiers. At Davids' Island the admission rate has been steadily increasing for the past five years from causes that are not shown clearly on the reports.

Outside of the depots for recruits, the military posts having admission rates in excess of 2,000.00 per thousand of strength are Forts Bliss and Clark, Texas, Mount Vernon Barracks, Ala., Fort Myer, Va., and Washington Barracks, D. C. The occupation of the new post of Fort Bliss will no doubt lessen the malarial rate hereafter in this locality. The contamination of the spring water supply by surface inflow is believed to be the cause of the autumnal fevers at Fort Clark, where the use of distilled water is expected to suppress their prevalence. The reports do not indicate why the rate at Mount Vernon Barracks is so high, unless on the allowable assumption that the dissipation which gives large rates for alcoholism and venereal diseases increases the susceptibility to all other causes of disability. At Fort Myer and Washington Barracks the increased rates result from autumnal fevers; at other seasons these two posts have excellent records.

The posts having the best records for the year are Fort Custer, with 333.33 admissions and 13.17 non-effective per thousand of strength; Vancouver Barracks, with 518.18 and 15.06; Fort Yellowstone, with 520.00 and 20.77; Madison Barracks, with 600.00 and 21.43, and Fort Niagara with 666.67 and 17.38.

Quarters.—The remarks made in my last annual report concerning the dilapidated condition of the quarters at a number of posts, as at Forts Keogh, Custer and Yates, Whipple Barracks and San Carlos, continue to be applicable at the present time. At Whipple Barracks crumbling foundations, broken ceilings, leaky roofs, with overcrowding and the closing of the ventilators in the ceiling to prevent down draughts, gave rise to many cases of catarrh, sore throat and febrile malaise, and no doubt increased the predisposition to the typhoid epidemic which prevailed at the post during the year. The miserable accommodations at San Carlos were fully described in my last report. At Ft. Grant, Ariz., the barracks are low adobe buildings entirely inadequate and unsuited for their purpose, with little or no space below the floor, badly ventilated and intolerably hot

in summer. The old buildings at Camp Eagle Pass are in exceedingly dilapidated condition; four of them have been reported by the post quartermaster as unsafe and not worth repairing. At all these posts modern, airy and comfortable buildings are imperatively needed if they are to be continued in service.

Overcrowding in the quarters of the enlisted men was noted specially at the recruiting depots at Davids' Island and Columbus Barracks. At the former the floor space was at one time inadequate, although the height of the barracks gave a fair cubical allowance. The surface barely permitted a passage between the beds and the expired air of one man was breathed by others before admixture with the general atmosphere of the rooms. At the latter depot some of the beds were so close as to nearly touch; and the large sick reports during the winter months were attributed to this overcrowded condition at a time when the windows could not be left open for free ventilation.

Overcrowding in guard houses was of more common occurrence; and exception was taken to the dilapidated and otherwise unsuitable condition of the building in several instances, as at Davids' Island, N. Y., Fort Marcy, N. M., Fort Sherman, Idaho, Fort Myer, Va., and the Presidio of San Francisco, Cal.

Drainage and Sewerage.—Faults of drainage are mentioned in the sanitary reports of the year at three posts only: Angel Island, Cal., Fort Grant, Ariz., and Fort Brady, Mich. The disposal of waste water by open drains is unsatisfactory at Ft. Sully, S. D. The pits at Fort DuChesne, Utah, fully described in my last report, have been replaced by earth closets. Faults in the sewerage system and plumbing of Fort Whipple, Ariz., and Fort Sill, Oklahoma, have been reported. Blocking of sewers occurred at Forts Wadsworth and Schuyler, N. Y. The imperfect and dangerous condition of the sewerage system at Fort Monroe continues as stated in my last report.

The construction by the city of San Francisco of a sewer, called the Locust Street sewer, across a part of the reservation of the Presidio, has resulted in a nuisance which has continued for the past eighteen months. The sewage enters a little rivulet which flows over the southern margin of the reservation into a marsh just below the post hospital where it spreads over the surface. This nuisance should be abated.

Water Supplies.—The water wagon continues in use at Fort DuChesne, Utah, and camp at Eagle Pass, Texas. An insufficient supply was reported from Fort Hamilton, N. Y., and Jefferson Barracks, Mo. At Fort Warren, Mass., and Fort Grant, Ariz., insufficiency was remedied during the year. Improvements in the supply were reported from Fort Bowie, Ariz., Fort Niobrara, Neb., and Mount Vernon Barracks, Ala. A good and free flowing well of water had been obtained at Fort Stanton, N. M., and an artesian well sunk at Fort Myer, Va. The question of a water supply at Fort Reno remains unsettled.

Food and Cooking.—Considering the large number of posts from which reports are received, regularly, covering the subjects of food and its cooking, the small number of references to deficiency or inferior quality of the articles of the ration or to faults in their preparation, demonstrates the amount of care and attention given to these matters by the officers responsible.

From several posts, such as Forts Supply, Reno and Sill, fresh beef was reported at certain seasons as dry, lean, tough and with an excessive proportion of bone. So long as beef contracts are awarded for so long a period as a year, and at a price which prevents the contractor from supplying any other beef than that from the neighboring ranges, poor beef is to be expected with every failure of the local pastures. The suggestion of the Post Surgeon of Fort Sill that contracts should be made to cover two periods appears to merit favorable consideration. From May to December the local pastures are good and contract should be made with a view to accepting range fed beeves; but during the remaining months of the year the stipulation should be explicit for corn fed beef or its equivalent in grade.

Clothing.—During the year many reports were received concerning the unsatisfactory character of the shoes issued to the troops. They were characterized as stiff, heavy and ill fitting. Late in the year a new style of calfskin shoe was issued which is reported as being an improvement on that formerly provided.

The adoption of a white uniform for troops serving in warm latitudes is regarded as having contributed to the health and comfort of the men. The Post Surgeons of Forts Sill and Barrancas speak strongly in favor of this uniform during the heated months.

Habits, Cleanliness, Athletic Exercises, etc.—The reports of medical officers regarding the habits of the men are generally favorable. At some posts where houses of bad repute are established in the vicinity, the sick report often becomes burdened with the results of dissipation, particularly after pay day. The unfortunate exposure of the recruits at Columbus Barracks to harmful influences of this kind has already on several occasions been pointed out.

Several references to inadequate facilities for bathing have been noted, but none charging any command or part of a command with lack of personal cleanliness. Inadequate provision is reported from Forts Canby and Washakie, Key West and St. Francis Barracks, and from San Carlos and Camp Eagle Pass.

The benefit accruing from systematic work in gymnasiums is appreciated by all army medical officers.

Report of the Surgeon-General of the Navy.

The report of Surgeon-General Tryon embraces a statement of the naval hospital fund, the naval medical establishment and other matters of interest pertaining to the Bureau of Medicine and Surgery. It has been the endeavor of the Bureau to have the Medical Department of the Navy as efficient as it can be under existing laws, and, so far as the appropriations will allow, to have the hospitals at different stations always in readiness for the reception of their full quota of sick, to make modern changes and improvements, to pay special care to roads and grounds, and to keep the buildings in a proper state of repair. To this end the electric light has been installed at the naval hospitals at Boston, New York, Washington, Norfolk, Mare Island, and Yokohama, Japan. The repairing and equipment of south wing of naval hospital, Norfolk, Va., fitting up antiseptic operating rooms and introducing elevators at the several hospitals, and supplying them with modern ambulances are all under consideration.

The repairs and improvements made during the year at the various naval hospitals, navy yards and receiving ships are given in the report in detail. A sudden increase of sick at the Naval Hospital, Philadelphia, Pa., required occupancy of the entire hospital, and the north wing, which has been out of commission for several years, has been restored to its legitimate purposes. This part of the building was found sadly out of repair, requiring new water-closets, renewal of surface drains and connections, new water and waste pipes, repair of verandas, roof, gutters, ventilators, chimneys, water-tanks, steam boilers, and heating apparatus, and repainting of all tin, iron, and woodwork to put in habitable condition for the reception of patients. On the completion of the work the hospital will be in condition to meet the wants of the station, and have accommodations for the sick that may have to be transferred from New York during the repairs of the hospital at that station.

The necessity of enlarging and improving the New York Hospital was brought to the attention of the Department last year, and authority was asked and granted by Congress to use \$69,000 from the appropriation "Naval Hospital Fund" of the sum accruing from the sale of New York hospital property under Act of July 2, 1890, to the city of Brooklyn. The buildings and grounds have been carefully inspected with a view of commencing as soon as possible the much needed work, and plans and specifications relating to the proposed changes will be submitted at an early date.

Recommendation is made that, through Congressional action, the Secretary of the Navy be authorized to dispose of the hospital at Widow's Island, Me., and that the proceeds of the sale be devoted to the renovation of such naval hospitals as require to be placed in a modern sanitary condition. This hospital was built in 1887, by a special appropriation of Congress, to meet the necessities then existing for some suitable hospital accommodations in a northern latitude for the reception of patients returning home in infected ships. Before the rehabilitation of the Navy, vessels were built entirely of wood; many of them had been in service during the war, and all of them, by gradual decay, filled with rotten timbers and worn-out construction material, defective ventilation, etc., had become susceptible to yellow-fever poison whenever a port in the West Indies or elsewhere was visited where the disease existed. It was almost impossible at that time, in spite of the greatest care and strictest sanitary rules, to keep such a class of vessels free from yellow fever. Scarcely a summer passed but two or more vessels returned with the disease on board, and the only refuge was at some point North, where the vessel could be broken out and the

sick sent ashore for treatment. Had like conditions continued to exist, the hospital at Widow's Island to-day would be a most valuable and necessary part of the naval medical establishment. As it is, however, everything is changed; naval architecture has undergone a radical departure, wooden vessels have disappeared, and steel ships of every class and size, well ventilated and equipped, have taken their place. These new steel vessels, with ordinary precautions, are susceptible only in a small degree to the introduction and retention of the yellow-fever poison, and should one of this class of vessels arrive North with the fever, or any other infectious disease, on board, under the present enlightened methods of ship sanitation, the vessel would not be ordered to make a long cruise to Widow's Island, where there is only hospital accommodation without a modern plant disinfection, but would be sent to the quarantine station at New York, where all improved appliances exist, where the sick could be cared for, and vessels with their equipment declared free in a very few days, with little inconvenience, and certainly with much less loss to the Government, than by the obsolete methods proposed to be carried out at Widow's Island. Not a patient has been treated in treated in this hospital since its erection, and the buildings year after year require additional repairs to keep them in serviceable condition. In view of all these facts, it is deemed advisable to dispose of the property as soon as it can be done on satisfactory terms.

The health of the Navy, according to the statistical tables, was most favorable during the year. There are few special hospital notes submitted; but among them it is stated that thirty-three cases of acute pneumonia were admitted into the New York Hospital and that of this number thirty-one recovered and were returned to duty. The average age of these men was 24 years. The rate of mortality was very low, and the number of recoveries correspondingly large. The method of treatment adopted is believed to be largely responsible for the result attained, and consisted in the hypodermic use of sulphate of strychnia, one twenty-fifth to one thirtieth of a grain, repeated every three or four hours, according to the severity of the disease, and liberal doses of alcoholic stimulants.

The health of the squadron in the infected harbor of Rio de Janeiro during the recent troubles in Brazil affords convincing proof of the reliability of sanitary rules, if carefully and closely followed. During periods varying from two to five months the *San Francisco*, *New York*, *Charleston*, *Newark*, and *Detroit*, with a combined complement of 1,762 officers and men, suffered exposure to epidemic influences of yellow fever and the sanitary precautions used against the introduction of the disease were the only safeguard, and proved most efficient, thereby enabling an effective military force to be kept constantly on the spot. While war vessels of every other nation had the disease on board, and while merchant vessels from different parts of the world were, in many instances, deprived of their entire crew, there was only one case, a paymaster's yeoman, on an American man-of-war, and that one, from its history, was preventable. The experience at Rio affords a valuable lesson in sanitary history and should not pass unheeded. Interesting reports have been received from the medical officers of the above-named vessels relating to the epidemic, and when all the replies are received to the Department's circular letter of June 21, 1894, relating to the "precautionary sanitary measures used and supposed to contribute in preventing the introduction of yellow fever on board," it is hoped such reliable information will be obtained that the Department will be able to formulate sanitary rules and regulations on the subject that will be of value as a guide to vessels of the Navy when obliged in future to serve in an infected port. Such "general sanitary rules" embracing special precautionary measures against the introduction of yellow fever and cholera on board vessels of war will be submitted at an early date with the request that they be made Department regulations.

Recruiting.—The examination of recruits for the naval service is one of the most difficult and exacting duties to which medical officers can be assigned, and upon them devolves the responsibility of selecting the material on which the efficiency of our Navy depends. Moreover, every medical officer, when ordered on such duty, should be impressed with the importance of the work on which he is entering, and to which he should devote the utmost care and attention. The conditions of life on board ship to-day are so radically different from what they were a few years ago that far greater care is required in the selection of recruits. Formerly, when vessels made long cruises under sail, and the

men lived practically on deck in the open air, their physical condition, if below par at date of enlistment, would improve. Now, however, on board of our new ships, with complete change of environment, as well as the character of the work demanded of them, recruits should be, as far as practicable, free from all physical imperfections.

Enlistments on seagoing ships should be prohibited by regulation, from the fact that many of our new ships are unprovided with suitable accommodations for such examination; some of them with no examining rooms or sick bays, and even in those having sick quarters, they are entirely inadequate for the proper performance of this work. Conceding, therefore, the benefit that would accrue to the service if enlistments were conducted under more favorable conditions, it is suggested that the Department establish a central rendezvous on shore, preferably at the navy-yard, New York, for the examination of all recruits, suitably fitted up with all necessary appliances for the performance of this duty, well ventilated, lighted and so situated as to be free from all disturbing influences. In the course of a few years the Department would recognize an appreciable improvement in the general health of the Navy, as shown by a smaller annual percentage of sick on board of our ships, as well as a great reduction in the number of medical surveys upon men whose disabilities existed prior to their entry into the service, and who probably would not have been enlisted had their examination been made under more favorable circumstances.

Vacancies in the Medical Corps of the Navy.—During the year ending June 30, 1894, thirty permits were issued by the Navy Department to candidates to appear before the naval medical examination boards in session at New York and San Francisco. Of this number, ten failed to present themselves for examination, five were rejected physically, twelve were rejected professionally, and three were found physically and professionally qualified for admission as assistant surgeons into the Medical Corps of the Navy.

The above record, showing a rejection of 85 per cent. of candidates examined, is not satisfactory, particularly when we contrast the large number of properly qualified applicants for similar positions in the Army and Marine-Hospital services, and the promptness with which such vacancies are filled.

The examination to which candidates for admission are subjected is in accord with the teaching and requirements of our medical schools, being within the capacity of every young medical man, properly equipped for the practice of his profession, and the large percentage of failures, as shown by the record of the examining board can only be accounted for on the supposition that the naval service, from lack of suitable inducements, does not attract the class of men who would tend to advance the standard of professional excellence, or from whom the highest degree of medical and military efficiency might be expected.

Notwithstanding that every reasonable effort was made by the Department to fill the corps, there remained at the close of the fiscal year ending June 30, 1894, eight vacancies.

Attending Surgeons.—Officers of the Medical Corps of the Navy, assigned to duty as attending surgeons in the various cities on the Atlantic and Pacific coasts, have rendered valuable service, and have been able to profit by the advantages offered for the study of diseases and operative work at the large hospitals and dispensaries. Coming in contact with the learned general practitioner and accomplished specialist, they are afforded opportunities for seeing unusual types of disease and accident, and of gaining invaluable professional information to assist them in their future duties on board ship.

Passed Assistant Surgeons.—The bill for the examination and commissioning of passed assistant surgeons, submitted to Congress with the approval of the Department, was favorably considered by the committees of both the Senate and House of Representatives, but legislative action was postponed pending the consideration of the bill relating to the *personnel* of the Navy. A physical, mental, moral and professional examination should obtain for every promotion in the service, and particularly for this grade in the Medical Corps, where, under existing regulations, no examination to determine physical and professional qualifications can be exacted until promotion to medical inspector, an average period of nearly thirty years since the last examination.

It is strongly recommended that the Department urge the passage of the present bill, now pending in Congress, so as to remedy, as soon as possible, the defective system acting injuriously to the interests of the Medical Corps of the

Navy, provided the question is not settled in the *personnel* bill at the next session of Congress.

U. S. Naval Laboratory and Department of Instruction.—The regulation issued by the Department over a year ago, creating a system of instruction for assistant surgeons immediately after passing a successful examination for admission into the Medical Corps of the Navy, has proved as valuable as predicted. The medical officers attached to the hospital, examining board, laboratory and department of instruction, New York, have all been interested in the work, and the rules and regulations during the period of instruction have been fully complied with. Four assistant surgeons have had the advantage of the prescribed course, and the records of their work, on file in the Bureau, afford satisfactory evidence of the manner in which it has been done. Two medical officers have taken partial courses in bacteriology and analytical chemistry, and two assistant surgeons who have just completed successful examinations are at present undergoing instruction.

U. S. Naval Museum of Hygiene.—By order of the Secretary of the Navy, dated Jan. 20, 1894, the old Naval Observatory buildings and grounds, situated at Twenty-third and E Streets, N. W., were transferred to the Bureau of Medicine and Surgery, to be used by the Museum of Hygiene. This transfer was requested, as the rented building was no longer adapted to the wants of the museum, on account of the large and increasing value of the exhibit and the necessity of having it properly grouped and classified for the purpose of study and observation; also to provide proper accommodations for the prosecution of microscopic and bacteriologic investigations, which constitute an important feature in the administration of the museum. The transfer of the exhibits was made on the expiration of the lease of the building, June 30, 1894, and necessary minor repairs were commenced as soon as the naval appropriation bill for 1894-95 was approved.

The interest that has been manifested by the service and by professional and scientific bodies in the growth and development of a museum identified with the practical study and advancement of sanitary science is shown by the steady increase in the number of exhibits. By the removal of the museum to commodious and permanent quarters the object of its organization can now be satisfactorily fulfilled, and opportunities offered for accomplishing good work in the future.

One hundred and ten new exhibits were added to the collection during the past year, including the complete and interesting "model of the system of disinfection practiced at the quarantine station at New Orleans." This model was exhibited at the Columbian Exposition at Chicago and presented to the museum by the Louisiana State Board of Health. Thirty specimens of animal parasites, contributed by the Department of Agriculture, have also been received, remounted and labeled.

The delegate recently appointed to represent the Medical Department of the Navy at the Eighth International Congress of Hygiene and Demography was directed to make a complete and thorough inspection of the museums of hygiene at London and Berlin, and to report in detail. Advantage will be taken of all valuable information thus obtained, and efforts made to make the Naval Museum of Hygiene as complete in every arrangement and detail as establishments of like character abroad.

To provide for the growth and proper classification of the instructive exhibit, so as to show the advances that have been made up to date in sanitary science, and to facilitate the further practical study of hygiene, so essential to the welfare of the Navy and the public at large, it is recommended that a small amount be used annually from the "Naval Hospital Fund" to render the establishment, now organized on a permanent basis, complete in all its appointments. Legislation is therefore requested, authorizing the Secretary of the Navy to use annually, when deemed necessary, from the appropriation "Naval Hospital Fund," a sum not to exceed \$5,000 for the benefit and improvement of the present U. S. Naval Museum of Hygiene, located in the old observatory grounds, Washington, D. C.

Statistical Report and Book of Instructions.—The statistical report has been carefully revised and elaborated, having in view the necessity for more complete and accurate data on which to base the health record of the Navy.

As soon as practicable the subject of the revision of the Book of Instructions for Medical Officers will be considered, in order to make it accord with the regulations, general orders and circulars issued subsequent to its publication.

The Bureau has also under consideration the preparation

of a form for the guidance of medical officers in making their annual reports.

Revision of Supply Table.—The supply table of the Medical Department of the Navy has been revised and enlarged to meet the changes and advancements that are constantly taking place in the department of applied medicine. In its preparation the Pharmacopœia has been carefully consulted; new drugs of recognized professional value have been added to the list, and many articles that have become obsolete or regarded as of doubtful utility have been abolished.

The supply of tablet triturations, compressed powders, and hypodermic tablets has been increased with the view of meeting the requirements of the service, and much care and attention have been given to the selection and rearrangement of supplies under the heads of hospital stores, surgical dressings, and dispensary and hospital furniture.

The necessity for such revision becomes obvious when we realize the rapid strides that are annually taking place in all that pertains to modern and progressive medicine, and such changes in the list will be made whenever new appliances and remedies receive official recognition by the profession, and as often as the interest of the service demands it.

There has been a complete revision of the outfit of surgical instruments and appliances, and the Medical Department of the Navy will soon be supplied with every article the practice of modern surgery demands.

Hospital Corps for the Navy.—The necessity of an organized Hospital Corps, well instructed, drilled, and equipped for all duties it is called upon to perform, becomes more and more apparent as new modern vessels of war are being completed and placed in commission. The services rendered by such a corps would be invaluable to the Navy. Its usefulness has already been demonstrated in our Army, and the attention that is being paid to perfecting the system by all first-class naval powers is convincing proof that immediate action should be taken in the matter by our own service. Many important questions relating to the handling of wounded on board modern vessels of war in action, forms of ship ambulances, different methods of transportation, landing parties on shore, instructions to men, first aid to wounded, proper care of sick and wounded ashore and afloat, etc., have all to be considered, and reasonable and effective plans adopted that can only be done by an efficient organization created solely for such special work.

It is strongly recommended that this subject may receive the sanction of the Department and be submitted for legislative action during the next session of Congress.

Ambulances.—It is absolutely necessary that our large hospitals be supplied with ambulances of modern construction, and a system of drill adopted at the different establishments, so as to have a complete and effective system for the transportation of sick and wounded men. This subject has never received the attention it merits, and the delays and discomforts attending the transfer of men to hospital are largely due to the lack of properly constructed ambulances and an efficient organization. Until this service is organized and incorporated in the duties of a Hospital Corps, modern ambulances should be supplied at once to our principal hospitals, which would be a great improvement over the present plan for transporting the sick, and save no end of discomfort and suffering. With light modern ambulances at all of our hospitals, subject to telephone call either night or day from ships or navy-yards, the summons could be answered at once, and there is scarcely a station where the sick or wounded man would not be delivered to the hospital inside of thirty minutes.

The present clumsy method of transportation of the sick and wounded, with their bags and hammocks in the same uncomfortable vehicle, without any pretensions to ambulance fittings, should be abolished.

Sick Quarters on Board Vessels of War.—A special report relating to the importance of providing suitable accommodations on board of our ships for the care and treatment of the sick and wounded of the Navy has already been submitted to the Department. The plans of all vessels in commission undergoing construction and nearing completion, have been carefully examined with a view of selecting suitable locations for sick quarters, and recommendations made when required. On board of ten vessels no quarters are designated for the treatment of the sick and wounded; in the case of the *Minneapolis* the omission was probably due to an oversight, as this vessel was designed on similar lines to her sister ship the *Columbia*. Subsequent to the examination of the plans of our uncompleted warships, the drawings of the armored cruiser *Brooklyn* and the battleship *Iowa* were submitted to the Bureau and, in consultation with the Pres-

ident of the Board of Inspection and Survey and the Bureau of Construction and Repair, suitable sick quarters were located.

It is earnestly suggested that hereafter, before sick quarters are assigned on our ships this Bureau may be consulted as to their location.

Representation of the Medical Department of the Navy at Medical Association Meetings.—Acting upon the recommendation contained in the Bureau's last annual report, application was made to the Department by the secretaries of several associations for the detail of medical officers to represent the Medical Department of the Navy at their annual meetings. Medical officers detailed for such duties were required to notify the Department of the nature of the subjects which they proposed presenting at the meetings, and on adjournment were directed to submit reports in full on the papers presented, and any points of interest that may have developed during their discussion.

At the fourth annual meeting of the Association of Military Surgeons of the United States, which took place in Washington, D. C., May 1-3, last, the Department was represented by Medical Director Gihon and Surgeon Beyer, who read papers on the "Transportation of Sick and Wounded on Board Ship" and "First Aid on the Battle-field," respectively.

At the meeting of the AMERICAN MEDICAL ASSOCIATION, June 5, last, at San Francisco, Cal., the delegates of the Department were Medical Inspector Geo. W. Woods and Surgeon Crawford. The former read a paper on "The Use of Acetanilid in Medicine and Surgery, with Special Reference to its Surgical Applications;" the subject selected by Surgeon Crawford was "Stricture of the Male Urethra." These papers are appended to the report of the Surgeon-General.

Medical Director Gihon was delegated to the meeting of the American Public Health Association, held at Montreal, Canada, September 24, last. His report of the proceedings will be submitted at a future date.

In order that the Medical Corps should be officially represented at the Eleventh International Medical Congress, Rome, Italy, from March 29 to April 4, 1894, inclusive, the Navy Department detailed Medical Inspector Dubois and Surgeon Siegfried for this duty, directing them to report by letter to the Surgeon-General of the Navy for special instructions. The reports of these officers, relating to the subjects to which they were directed to give special attention, and forming part of the proceedings of the Congress, are submitted with the Surgeon-General's report under the head of special reports.

Medical Director Gorgas, in charge of the Naval Museum of Hygiene, was ordered to proceed to Buda-Pesth as the representative of the Medical Department of the Navy, at the Eighth International Congress of Hygiene and Demography, Sept. 1-9, 1894. He was also ordered to report to the Surgeon-General for special instructions in connection with his duty, and his paper on "Naval Hygiene," read before the Congress, together with other subjects of professional interest to which his attention was directed in his letter of special instructions, will be submitted in a future report.

When the system is inaugurated of detailing officers as naval medical *attaches* at important embassies abroad, as suggested in my last annual report, the duty above referred to will be performed by such officers, avoiding the necessity of ordering special delegates from the United States.

SOCIETY PROCEEDINGS.

New York State Medical Association.

Eleventh Annual Meeting, held in New York, Oct. 9, 10 and 11, 1894.

FIRST DAY—TUESDAY, OCTOBER 9.

THOMAS D. STRONG, M.D., Chautauqua County, President
DR. ZERA J. LUSK, of Wyoming County, reported a case in which he had removed by lateral lithotomy a wire nail three inches in length. It is said to have been in the bladder for four years. He also reported a successful case of operation for traumatic epilepsy. Ten days after the injury he had trephined and had found in addition to a fracture, a firm epidural clot covering the lower part of the fissure of Rolando. There had been twenty-eight convulsions on the day preceding the operation, and paralysis of the arm and face, wit-

aphasia. The convulsions ceased two days after operation, and on the fourth day he was able to speak a little.

DR. E. D. FERGUSON, of Rensselaer County, referred to a case in his practice in which, although the symptoms pointed to a lesion rather high up on the fissure of Rolando, the operation revealed a large blood clot near the base of the cranium. This was removed and the patient recovered rapidly.

DR. DARWIN COLVIN, of Wayne County, reported a case of epilepsy due to a gunshot wound, in which he had effected a cure by trepanning the skull.

DR. EDEN V. DELPHEY, of New York County, exhibited a non-conducting speculum made of hard rubber, and intended for use in connection with post-partum intra-uterine douches. He also recounted the principal points brought out in a recent suit for damages. The writer had assisted Dr. A. H. Goelet in anesthetizing a man of 52 years, preparatory to amputating a gangrenous finger. His urine had been previously examined with negative result. After giving not more than 1 drachm of Squibb's chloroform on an Esmarch inhaler, ether was substituted, and administered in the usual way. Just about this time the man suddenly stopped breathing, and in spite of prompt resort to artificial respiration, and its continuance until after the heart ceased to beat, they were unable to resuscitate him. The deputy coroner who made the autopsy reported that he found pulmonary edema and incipient disease of the kidneys, and also pachymeningitis. Judge C. H. Truax, in his charge, instructed the jury to pay no attention to the statement that the family of the deceased had interfered, and had objected to his taking any anesthetic, as they had no legal authority to do so, particularly as the man was competent at the time to judge for himself. He also called attention to another matter of general interest to the medical profession, viz., that if a physician gave any medicine to a patient contrary to that person's wish, the physician was a trespasser, and could be held as such for any serious results that might ensue from the administration of the medicine.

DR. E. D. FERGUSON said that he understood that the courts in Pennsylvania, at least, had held that physicians simply witnessing an operation, without assisting at all, could be held as co-defendants in such a suit.

DR. J. W. S. GOULEY, of New York County, sent a paper in which he suggested the term "typhlenteritis" as being more accurate and appropriate than "appendicitis."

DR. JOSEPH D. BRYANT, of New York County, in a paper entitled "Some Interesting Cases of Appendicitis," (see page 61) reported four cases of secondary appendicitis, representing various types of the disease, in which he had operated successfully.

DR. F. W. GOODALL, of Vermont, said he had been palpating the vermiform appendix, and he had found it quite easy of accomplishment.

DR. J. G. TRUAX, of New York County, said that his experience had led him to believe that if the primary attack was properly treated, there would be very few secondary attacks. The treatment he considered appropriate was keeping the patient in bed on a milk diet, and with an ice-bag over the cecocolic region until all induration had vanished. For two or three weeks after this, the patient should be still kept on a milk diet, although allowed to be up and around. After this he should have a farinaceous diet for five or six weeks.

DR. H. O. MARCY, of Boston, defined an appendicitis to be a proliferation of the bacillus coli communis locked up in a small process of the bowel," and argued from this that we could not freeze them out, or do much good except by operation. After his extensive experience with this disease he was more than ever inclined to go back to his former position as a "radical." One or 2 per cent. represented the mortality from operations performed at an early stage. To operate after rupture of the appendix into the abdominal cavity was only to bring surgery and one's self into disrepute.

DR. E. D. FERGUSON said the fact that operating surgeons saw such a large proportion of cases demanding immediate surgical interference was easily explained. Personally, he had found that the great majority of cases had only a single attack.

DR. BRYANT, in closing the discussion, said that from 60 to 75 per cent. recovered from the primary attack without operation, and that secondary attacks occurred in from 11 to 15 per cent. As it was impossible to tell how near the appendix was to rupturing, he was in the habit of urging immediate operation. He had given up trying to palpate the appendix for two very good reasons, viz.: 1, because he had

rarely been able to feel the appendix; and 2, because palpation might very easily give rise to rupture of a gangrenous appendix.

DR. W. H. PARK, of New York County, then read a paper entitled, "Recent Studies on Diphtheria and Pseudo-Diphtheria." After referring to the work of the New York Board of Health, he said that it had been found that the diphtheria bacilli usually persisted in the throat for about seven days after the membrane had gone, and that healthy persons might carry these bacilli in their throats, and so infect others without themselves being sick with the disease. Pseudo-diphtheria had not been found especially contagious. Unlike true diphtheria it was especially prevalent at certain seasons of the year. Experiments conducted at the Willard Parker Hospital had shown that irrigation of the nose and throat with warm normal salt solution was as good, if not better than irrigations with bichlorid of mercury, or peroxid of hydrogen. The antitoxin treatment had also been given a trial at the same hospital, and so far with excellent results, both as to the curative and preventive powers of the antitoxin.

DR. JOHN CRONYN, of Erie County, then read a short paper in which he argued from the incubative period of the disease, and from the phenomena observed in certain cases, that diphtheria was at first a constitutional infection. He said that necrosis of the mucous membrane must take place before the diphtheritic exudate could make itself manifest.

DR. HERMANN M. BIGGS, of New York County, said that as it was known beyond a doubt that true diphtheria bacilli might be present without any membrane, it seemed absolutely essential to a proper sanitary surveillance of the disease that systematic bacteriologic examinations should be made. He had had excellent opportunities of studying the antitoxin treatment in Berlin, and he had found that the eminent scientific investigators there, engaged in studying this method of treatment, of one mind as to its efficacy.

DR. A. PALMER DUDLEY, of New York County, read a paper on "The Technique of Cæsarean Section," and exhibited three patients on whom he successfully performed this operation.

DR. JOSEPH TABER JOHNSON, of Washington, D. C., read a paper entitled "Hysterectomy for Uterine Fibroma by Baer's Method, with Report of Nine Successful Cases." He had found convalescence after this operation exceptionally smooth and rapid, and the operation itself was quickly performed.

DR. W. R. PRYOR, of New York County, then read a paper on "Hysterectomy in Pus Cases," in which he advocated the removal of the uterus in addition to the pus tubes, on the ground that a large proportion of such cases were not relieved of their symptoms by a simple salpingo-oophorectomy. Another argument in favor of this procedure was the fact that the uterus was often the original source of the disease, and in about 20 per cent. of the cases, the uterus had been found to be tubercular. In his opinion, the removal of the uterus added but little to the shock and risk of the operation.

DR. H. O. MARCY then made some remarks on "The Anatomic and Surgical Treatment of Inguinal Hernia in the Male," illustrating the subject with many stereopticon views.

SECOND DAY—WEDNESDAY, OCTOBER 10.

DR. DOUGLAS AYRES, of Montgomery County, read a paper entitled "Fractures of the Inferior Extremity of the Humerus involving the Articulating Surface; with Report of two Cases Occurring in Children." The author thought the best results in such cases would be obtained by: 1, early elevation of the limb; 2, by cold applications; 3, careful immobilization in the bent position; and 4, by an early resort to passive motion.

DR. A. J. VAN VRAKEN, of Albany County, in discussing the paper emphasized the fact that it was wise to invariably anesthetize children with fractures or dislocations before making the diagnosis.

DR. JOHN CRONYN said it was rare to get a perfect result in this class of injuries, and consequently it was prudent for the surgeon to state this fact very plainly to the family at the outset, and tell them if they know of any one whom they think will be likely to do any better, you would recommend them at once to procure that surgeon's services.

DR. JOSEPH S. GIBB, of Philadelphia, read a paper on "The Stearate of Zinc Compound in Atrophic Rhinitis." The treatment he had found the most successful for this obstinate condition was a thorough cleansing of the parts, both anteriorly and posteriorly, followed by the insufflation of a powder of stearate of zinc containing 25 per cent. of euro-

phen. He had been able to follow thirty-two cases, twenty-seven of which had been entirely relieved of crusts and odor while the moist appearance of the normal mucous membrane had been restored.

DR. DWIGHT L. HUBBARD, of New York County, in discussing the paper, said that while he could from personal experience testify to the benefit to be derived from the use of the stearate of zinc, he still felt that the major part of the improvement noted in the author's cases was to be attributed to his thorough method of cleansing the parts.

DR. GIBB replied that no doubt much of the benefit was due to this cause, but still he had not obtained such good results where the same cleansing process had been used without the stearate of zinc. The chief virtue of the stearate was its adhesiveness.

DR. WILLIAM H. ROBB, of Montgomery County, reported a case of "Suppurative Cellulitis Following an Injury to the Hand." The special interest of the case centered in the fact that in spite of the free use of antiseptics, and finally even of amputation of the arm, the process extended, and eventually proved fatal. This unusual result was attributed by the reader of the paper to the fact that the wounded hand had remained wrapped up in woolen rags full of germs for nearly four hours before there was an opportunity for a surgeon to apply antiseptics.

DR. J. D. SULLIVAN, of Kings County, said that an ordinarily healthy individual ought to have sufficient vitality to resist the onslaught of the microbes for four hours. He was inclined to think the catgut might have been septic. The best treatment for severe cases of this kind was to immerse the limb continually in a bath of some appropriate antiseptic solution.

DR. CHARLES A. CHURCH, of Essex County, said that the effect of the bath treatment could be more conveniently obtained by enveloping the part in bichlorid gauze kept moist with a 1 to 4000 solution of bichlorid of mercury.

DR. E. D. FERGUSON called attention to the liability of having the antiseptic solution become too concentrated by evaporation when applied in the manner just described by the last speaker.

DISCUSSION OF THE PREVENTION OF TUBERCULOSIS.

DR. HERMANN M. BIGGS, of New York County, opened this discussion. He referred to the recent action of the New York Board of Health, compelling notification of all cases of tuberculosis occurring in all the public institutions, and requesting physicians in private to send to the Department similar information. In preference to adopting any plan of disinfection of apartments that had been occupied by tuberculous persons, the Board had decided to require the owner of the apartments to have the rooms freshly kalsomined or papered. If the owner refused to do this, the door of the rooms was placarded, and all persons forbidden to occupy them until the landlord had complied with the requirements of the Board.

DR. LAWRENCE FLICK, of Philadelphia, then exhibited a series of lantern views to emphasize his remarks on the nature of the localities where tuberculosis was most widely disseminated. He exhibited maps showing how health resorts had become an important factor in spreading this scourge. Then followed pictures illustrating the part played by the ordinary life of the tenements. He predicted that as a result of the prophylactic measures now being adopted in various cities—indeed largely by the simple diffusion of knowledge regarding the communicability of tuberculosis—this disease would be completely stamped out in the near future.

DR. J. H. HUDDLESTON, of New York County, spoke of the importance of properly concentrating sputum before examining it for tubercle bacilli.

DR. JOSEPH D. BRYANT described the various steps by which the recent action of the Health Board in regard to tuberculosis had been brought about. It was the result of efforts extending over about five years.

DR. E. G. JANEWAY, of New York County suggested that hotels should have separate rooms, and distinctive bed-clothing and other furnishings for consumptives.

DR. J. G. TRUAX, of New York County, said that tuberculin was now recommended as a diagnostic test, but unless his experience with this agent had been exceptional, it was likely to prove dangerous.

DR. BIGGS replied that Professor Koch, who had been using it extensively in Berlin, had told him that if used in pure tuberculosis it was perfectly harmless, and might even be curative; but that when employed in cases of mixed infection, it was certainly harmful.

DR. J. BLAKE WHITE, of New York County, read a paper on "The Diagnosis and Treatment of Pleurisy." He spoke of the sharpness and distinctness of pleuritic crepitation as an important help in differential diagnosis. He did not approve of the treatment by strapping, as he thought it was likely to lead to permanent changes in the lungs and pleura. Aspiration should be resorted to as soon as the presence of serous effusion was detected. For empyema, simple incision without resection of a rib was the best.

DR. H. O. MARCY, of Boston, paid a glowing tribute to the now historical labors of his old teacher, Dr. Bowditch, in connection with thoracentesis.

DR. CRONYN said he taught his pupils to aspirate before there was more than a pint of fluid in the pleural cavity. It should be remembered that while morphia would relieve the pain of pleurisy it was not like crude opium, distinctly curative.

DR. FRANK VAN FLEET, of New York County, read a paper entitled, "The Treatment of Retinitis Albuminurica in Pregnancy from an Ethical Standpoint." The author showed by quotations from the statutes that the law justified abortion only when this was necessary to save the life of the mother or of the child—nothing was said about permitting it where the mother's sight was jeopardized. As retinitis did not occur until the nephritis was quite advanced many physicians would hold that the mother's life was endangered by the nephritis, and that without taking into consideration the question of the risk to her vision, the prompt termination of pregnancy was justifiable. He then considered at length the moral aspects of the case, giving opinions from certain well-known ecclesiastics.

DR. DARWIN COLVIN, of Wayne County, said that the author had implied that under the conditions supposed to exist in the class of cases under discussion, the death of the fetus was inevitable. This was certainly a mistake, and could be refuted from his own experience. He then reported a case in which he had himself advised the immediate termination of pregnancy, but the patient not consenting to this, she had been liberally bled twice before labor, and had been in due time delivered of a living child. This woman had remained totally blind for about a month after labor, and when he heard from her about one year later was still suffering from defective vision. He had known of two other instances in which notwithstanding marked nephritis, a living child had been born.

DR. E. D. FERGUSON said that fortunately owing to the improved medical and surgical measures of the present time, one was not often called upon to decide absolutely upon the destruction of human life.

DR. CRONYN said the Catholic church consented to Cæsarean section on the assumption that the child would be born alive, and that the risk to the mother was not extreme. It also permitted the induction of premature labor provided the child was viable.

THIRD DAY—THURSDAY—OCTOBER 11.

DR. DARWIN COLVIN, of Wayne County, in a paper entitled, "Reminiscences of a Country Doctor during the past Fifty Years," stated, that in his opinion, the mortality in child-bed was no greater fifty years ago than now. In those days digitalis was almost the sole medicine used for cardiac affections, and when it was remembered that it was prescribed as a depressant, in deference to the then prevailing opinion that all diseases of the heart were inflammatory, one could but feel appalled at the recollection. The older practitioners believed that opium possessed certain curative properties in peritonitis and pleuritis that did not belong to morphia; and to this day he preferred opium to morphia except when he desired to employ hypodermic medication. He did not believe that the next half century would see any such great advances in medicine as had been witnessed in the last fifty years, except in materia medica and brain surgery.

DR. CRONYN, and the PRESIDENT, both spoke emphatically in regard to the greater curative properties of opium in pleurisy and peritonitis, and indorsed fully the statements made by the author regarding the changes that had occurred in medicine in the past fifty years.

DR. THOMAS H. MANLEY, of New York County, in a paper entitled, "A Practical Study of Grave Abdominal Contusions, with a Clinical Report of Twenty Cases," described certain experimental studies that had been made on this subject, and asserted that his own experience had taught him to look upon the free administration of mercury by inunction as of great value in the early treatment of traumatism of the abdominal viscera.

DR. JOHN G. TRUAX, of New York County, read a paper entitled, "Some Facts about the Treatment of Typhoid Fever." After describing the results that he had obtained from the administration of iodine, the use of the cold bath treatment, etc., he stated that he had secured the best result from the use of intestinal antiseptics, and the application of an ice-bag to the ileo-cecal region.

DR. CHARLES A. CHURCH, of Essex County, said that he could heartily indorse the treatment of typhoid fever by the administration of intestinal antiseptics. His plan was to give half a grain of calomel and two grains of soda at the outset every four hours until the bowels moved, and then begin the administration of the sulpho-carbolate of sodium as an intestinal antiseptic.

DR. FARQUHAR FERROUSON, of New York County, then exhibited an interesting specimen of hermaphroditism. The specimens were removed from a person who had been employed as a cook in a physician's family. The hair of the head was like that of a woman, but there had been beard on the face, and the latter, as well as the pelvis, were of the male type. There were a rudimentary penis, a short vagina and normal Fallopian tubes and ovaries. There were also two extremely large supra-renal capsules.

DR. FREDERICK HOLME WIGGIN, of New York County, read a paper on "Intestinal Anastomosis," reporting a case in which he had performed intestinal anastomosis, and also the results of twenty experiments which he had made on dogs. The dangers of the Murphy button he considered to be numerous. It was occasionally retained, necessitating a second laparotomy for its removal; the spring of the button was made sometimes too strong, so that it would cut through the intestine; the weight of the button might, as in a case cited, anchor the bowel in a flexed position, and so cause obstruction; it was liable to become plugged with hard fecal matter; and lastly, the sharp edges of the small lateral openings were very liable to cut through all the coats of the intestine except the peritoneum. He preferred Maunsell's method, which was adapted for any portion of the intestine, and could be readily and safely performed by any experienced surgeon.

DR. PARKER SYMS, of New York County, read a paper on "The Arthropathies of Locomotor Ataxia." The pathologic changes found in this disease, he said, involved both the bone and the soft parts, and the process was in the nature of a degeneration rather than an inflammation. It might be either hypertrophic or atrophic. Some of the characteristic early symptoms of locomotor ataxia were ordinarily present. The fact that the disease was sudden in its onset, and that there was increased joint mobility would serve to distinguish it from arthritis deformans.

DR. J. E. JANVRIN, of New York County, read a paper on "The Early Diagnosis of Tubal Pregnancy, and Primary Laparotomy in such Cases." He said that in addition to the usual early symptoms of pregnancy there would be a tipping of the uterus laterally, an elastic swelling could be detected at the site of the ovum, and an exquisite tenderness would be noted at this point.

DR. CHARLES A. LEALE, of New York County, in a paper on "Restoration of Function of the Lung and Pleura after Thoracentesis," said that in children the lung would often fully regain its function after having been compressed for months. It was important after thoracentesis to keep the patient from tubercular surroundings.

DR. AUSTIN FLINT, of New York County, was elected President of the Association for the ensuing year.

Chicago Academy of Medicine.

[Reported exclusively for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.]

The Academy met on the evening of Oct. 12, 1894, at the Saratoga Hotel. DR. F. HENROTIN presided.

The subject for general discussion was

EPILEPSY.

DR. SANGER BROWN opened the debate with remarks upon the

SEMIOLOGICAL RELATIONS OF EPILEPSY.

DR. BROWN said: Mr. President, it occurs to me in considering this subject that very little can be said upon the pathologic anatomy of the disease. But what is wanting in that particular can be made up in the symptomatology. It is a broad subject, and in the time allotted me I can say

comparatively little in regard to it. The most important points in the symptomatology of the disease refer to the prodromal symptoms, the aura, the minor attacks of epilepsy, and to the post-epileptic conditions.

The epileptic attack is so well known to you all that it does not demand at such a time as this very much discussion. In regard to the prodromata, they are usually divided into the remote, that is those extending over a few days, and the immediate, the usual warning or aura. For instance, in my clinic just before coming to this meeting, I had an excellent illustration of the remote premonitions. In my experience they are comparatively rare. This girl had had epilepsy for nine years, and her friends could tell for days in advance when she was going to have a series of attacks by the peculiar enlargement of the eyes. I do not recall seeing this mentioned anywhere before. The patient herself was not conscious of this enlargement of the eyes. She had the immediate aura also. In regard to the remote prodromata, I had under my care at the Bloomingdale Asylum a gentleman, a colonel in the war, who had received a gunshot wound of the mastoid process, causing facial paralysis and some general hemiplegia. At first he had Jacksonian epilepsy, and finally developed the idiopathic form of the disease. His attacks occurred once or twice in two or three months, and for three or four days prior to a seizure he would begin to tell us how well he felt and how clear his mind was. Things that had been previously obscure to him were now perfectly clear, and he would lay plans for the future, and then we knew he was going to have a seizure in the course of a few days. When the seizure came it was maniacal in character, and he was entirely oblivious to all of his surroundings and would remain so for several days. He would have several severe attacks of the disease, and all the time during the several days he would be violent and very hard to manage. Then he would go perhaps for several months without an attack. The usual treatment seemed to do him no good.

In regard to the aura of the severe attacks, the symptoms are usually classified as sensory, motor, and of the special senses. The motor phenomena can not be taken up in the short time at our disposal; but I desire to say this, that in considering the peculiar sensations that patients begin to feel in the arm and extending up through the body, gastric sensations, a sense of fear and tremor, I do not think we are warranted in regarding them as evidences of epilepsy unless they are attended by at least some degree of loss of consciousness. In persons whom we know to be afflicted with epilepsy, it is undoubtedly true that very often they have these strange sensations without any disturbance of consciousness, and then we know that they were a symptom of epilepsy; unless they occur in such persons, it would not be proper to so regard them, because many of us who have never had epilepsy have had every one of the aura. The minor attacks require that special attention be given to them in cases where patients are brought to us by their friends, and convulsions and unconsciousness are described.

In referring to the post-epileptic manifestations, I should say that a true paroxysm of hysteria is not uncommon, especially in young men and young women at the age of puberty, and it is a true hysterical attack. This is of the utmost importance, as there may be an attack of petit mal or grand mal, and the true epileptic nature of the attack is very apt to be overlooked, because the manifestations of an hysterical attack last so much longer and have such a peculiar nature that they are more likely to attract the attention of the relatives than a brief attack of petit mal or of grand mal.

In connection with the post-epileptic conditions that have been described, and in which I have had experience in several instances, there are cases of what is known as automatism; that is, the patient immediately after an attack will begin to undress himself and has no recollection of what occurred afterwards. He will pick up things and put them in his pocket, no matter where he may be, and by so doing get himself into trouble. A very interesting case of this kind occurred in the person of a physician in London, showing the extent and importance of these automatic manifestations. The physician during his office hours had an attack of petit mal. His office was full of patients, and he was attending one when the attack came on. He attended to all of his patients, made several calls, and then returned to his house when consciousness returned. He went over the

work he had done during this period of unconsciousness and found he had done it practically all right. He had diagnosed correctly one case of pneumonia in which he had been called, had instructed the nurse properly, and had written the proper prescription for its treatment while he was entirely unconscious. But here, too, I think there has been too much of a tendency on the part of physicians, because there are a few well authenticated cases of this kind, to conclude that where automatism occurs in this way it is conclusive proof of epilepsy. That certainly should not be the case. I knew of a young man in New York, 17 years of age, in good health and with no hereditary taint who went several blocks from home to the house of a friend to get up lessons in the evening, and about 9 o'clock he started to return. He remembered leaving the hall but did not go home, and three or four days thereafter when he regained consciousness he found himself in the upper part of New York where it was not thickly settled, sitting along a railroad track with his feet in the water. That was suggestive of epilepsy, but was not absolute proof of it. This circumstance occurred ten years ago, and the young man has been perfectly well ever since.

FORENSIC RELATIONS OF EPILEPSY.

DR. HAROLD N. MOYER—About the most uncertain chapter in the domain of forensic psychology is that which deals with epilepsy. With reference to this discussion I have consulted several of our standard works on medical jurisprudence, and have found many errors. I mention one in passing: All agree that the importance of the epileptic attacks depends upon their severity, that is, whether it be *petit mal* or *grand mal*. That doctrine is erroneous.

It is a difficult thing to get a starting point from which to discuss the question of the responsibility of the epileptic. But I will advance briefly one or two propositions that are I think well taken; first, that no epileptic shall be held to full accountability who has committed a crime of violence without rational motive. A second is that every physician called upon to investigate one of these cases in the presence of a crime, without adequate or rational motive, should look most earnestly for the evidences of epilepsy.

For the forensic physician, the diagnosis of the epileptic attack is often beset with difficulties. It is but rare that the examiner will have an opportunity of observing an attack himself; and even if he does, must be on his guard lest he be deceived by a shrewd malingerer.

Doubtless many of you are familiar with what in thieves' parlance is known as a "dummy chucker," a man who imitates perfectly the epileptic convulsion. We remember to have observed one such case at the Cook County Poorhouse, who was detected by the fact that the thumb was clinched *outside* the fingers. We have one infallible guide and that is the loss of light reaction in the pupil. At the onset of the attack the pupils are always invariably dilated, but the reaction to light is always lost. This sign alone will enable us to detect a feigned attack.

In cases where we are not able to observe a convulsion, we must rely largely on the history of the case and what we can learn from those who have observed the patient. The essential starting point in this interrogation is the loss of consciousness; it is doubtful if this occurs in every case, but it is so frequent that it is always to be looked for, and if present establishes the diagnosis beyond all doubt. A diagnosis may sometimes be made by carefully interrogating the patient over long periods of time; this may develop the amnesic conditions so common in epilepsy.

I do not accept a classification that would place the psychoses of this disease in a separate class under the term "epileptic insanity." Nor do I believe that clinically we can demarcate between melancholia, mania, confusional insanity, circular insanity and other forms of mental disease associated with epilepsy and those which originate from other causes. When the epileptic becomes insane, the mental disorder may be considered apart from the epilepsy and its forensic relations are the same as those of any other psychosis.

We now come to the last division of our subject, the peculiar mental states which very often accompany, precede or sometimes follow the attacks, and which are often of considerable duration, and again are exceedingly transitory. To my mind this is one of the most interesting and one of the most difficult questions in forensic psychiatry. For hours preceding an attack there may be a condition of insanity, or there may be a condition of unconsciousness in which automatic acts are performed just as Dr. Brown has cited to you, and in which criminal acts may be done wholly without the consciousness of the person. The men-

tal state succeeding the attack is frequently accompanied by marked hallucinations and delusions that often lead to very outrageous acts. The delusions are often of a suspicious character; the people around them are transformed into frightful shapes, and often assume in their distorted imaginations, a violent attitude toward them, and they strike out to defend themselves. Many of the violent acts of homicidal lunatics are to be attributed to this mental state succeeding an attack.

This, then, will conclude a very brief survey of the forensic relations of epilepsy. We will briefly recapitulate a few points we have made. The diagnosis of epilepsy itself is of the utmost importance because it is such a common disease, and one that may be so easily overlooked. In every crime of violence without adequate motive, search carefully for epileptic manifestations. When it is once established that a patient has epilepsy who has committed such a crime, I do not think any one, in the present state of our science, is justified in saying that he is fully responsible. In the psychoses which accompany, precede and succeed the attacks for a varying length of time, very great judgment and circumspection must be used in giving an opinion in a particular case. I know of no special rule to guide us.

ORAL RELATIONS OF EPILEPSY.

DR. EUGENE S. TALBOT—From my experience, there is no form of brain disease that presents so much stigmata of degeneracy as is found among epileptics. Through the kindness of Dr. Dewey, some two or three years ago, I had the pleasure of making a thorough examination of patients in the Kankakee Insane Asylum, and from the classification and facts obtained at the office of the institution, I was able to make a very complete examination of the patients there. The deformities that I noticed among the different forms of insane people are arrest of development and excessive development. These conditions are spoken of in books as hypertrophy and atrophy. These abnormalities of the osseous system are produced early in life, which would go to show that the cells of the brain which preside over the development of the structures of the body affect nutrition. I found the smallest number of deformities of any one class among the alcoholic insane; these individuals might have become insane probably later in life after the osseous system had developed. I found 44 per cent. of deformities in the jaws alone, and at that time I was not paying as much attention to deformities of the face, nose, ears, etc., as I have done later. Among the paranoiacs I found 87 per cent. of deformities. I mentioned this to give you an idea of the deformities I noticed among the epileptics. I found 72 per cent. among the males, and 80 per cent. among the females. It will be noticed that the average of deformities among the epileptics was nearly up to the highest number. It is singular, in examining patients in asylums, that as large percentages of deformities are not found among them as in private patients, people that are born in this country and come to our offices for treatment. I have had the opportunity of examining mouths of some eight or ten epileptics among my own patients, and invariably found these deformities very marked; either a V- or saddle-shaped arch, are the result of arrest of development of the jaws. Then, quite frequently hypertrophy of the tongue, of the lips, the salivary glands and alveolar processes are found. In the mouths of these individuals the saliva collected in the floor of the mouth and upon the surface of the tongue. While operating the saliva moved back and forth upon the lips, showing that there is an excessive development of the salivary glands. In all of the patients in my practice I found deformities of the nose, ears, and face. An arrest of development of the jaws was quite marked in almost every case, I should say 90 per cent., showing that this disease is manifested very early in the condition of the cells of the brain. Unfortunately, not being a specialist in nervous diseases, my examinations are almost entirely limited to the osseous structure and conditions of the mouth. You will invariably (in the patients that come to you) find either an arrest of development or excessive development of the tissues of the mouth and jaws.

(To be continued.)

Bulgarian Students in France.—According to the *Gazette de Gynécologie* of Oct. 15, 1894, the number of Bulgarian students in France has greatly increased since the action taken by the Bulgarian government, in refusing recognition to the diplomas of Swiss universities. It is estimated that from 350 to 400 Bulgarians will complete their studies under French auspices this year.

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, NOVEMBER 3, 1894.

THE STATUE OF DR. J. MARION SIMS IN BRYANT PARK.

For the first time in the history of the United States, a public statue has been erected to the memory of a member of the medical profession.

On Oct. 20, 1894, in one of the most beautiful parks in New York City, in a spot of ground selected and set apart for statues of literary and scientific men considered worthy of such honor, there was unveiled a statue in bronze of a man well known in scientific circles, as well in Europe as in America.

The inscription upon the pedestal tells in concise language almost the story of the man whose statue it supports, and why such distinguished honor has been conferred upon a physician.

On it is written:

"J. MARION SIMS, M.D., LL.D. Born in South Carolina, 1813. Died in New York City, 1883. Surgeon and Philanthropist, Founder of the Woman's Hospital in the State of New York. His brilliant achievements carried the fame of American surgery throughout the civilized world. In recognition of his services in the cause of science and mankind, he received the highest honors in the gift of his countrymen, and decorations from the Governments of France, Italy, Spain, Belgium and Portugal." And on the reverse,

"Presented to the City of New York, by his professional friends, loving patients and many admirers throughout the world."

JAMES MARION SIMS was born in Lancaster district, South Carolina, Jan. 25, 1813. He was the son of JOHN SIMS, a farmer, and MAHALA MACKAY; a descendant of people who took a prominent part in the struggle for independence during the Revolutionary War.

Early in childhood, his father selected this son as the one who gave most promise of achieving a career for himself, and being a poor man, not able to give a college education to each of his children, he gave all the benefit of a common school education in their native district, but sent the subject of this sketch to the South Carolina College, through the regular grades of which he passed, and graduated in 1833.

Selecting for himself a career in medicine, he attended the lectures at the Medical College in Charleston, and later on entered the Jefferson College of Philadelphia, from which he was graduated in 1835.

In 1836 he settled in Montgomery, Alabama, in the practice of his profession. There he founded a private hospital for the treatment of surgical diseases, taking a special interest in diseases of women. In 1845 he systematically began and by 1848 he at last succeeded in inventing a method for the cure of vesico-vaginal fistula by the use of metallic suture, the disease up to that time having been incurable:

By 1849 he had devised a number of instruments, ingeniously constructed, which soon became and still remain an indispensable part of the surgeon's armamentarium. In 1851, he published the result of his efforts in the *American Journal of Medical Sciences*, which attracted such general attention that he was encouraged to seek a wider field of labor. In 1853 he removed with his family to New York City, to establish himself in his profession, and soon after organized the Woman's Hospital Association, which resulted in the construction of the large institution situated at 49th Street and Park and Lexington Avenues, in New York City.

The State Legislature granted a charter to the hospital, the common council of the city gave it a block of ground and an appropriation for its construction.

In 1862 DR. SIMS visited Europe, performing his celebrated operations before large classes of physicians in the principal cities of the old country. So successful were the results that his fame spread rapidly throughout Europe, and with this his services were in such demand that he concluded to remain in Europe for a number of years, located for the greater part of his time in Paris, where he enjoyed a very lucrative practice.

As the result of his operations and demonstrations before the learned bodies of Europe, various Governments conferred upon him the decorations above named. He was made Chevalier of the Legion of Honor by the Emperor Napoleon, and such was the popularity achieved in the organization and command of the Anglo-American Ambulance Corps in the Franco-German War, that, after the cessation of hostilities, he was made a Commander of the Legion of Honor by the Republic of France.

In 1875, he was elected President of the AMERICAN MEDICAL ASSOCIATION, and presided at the World's

Centennial Exposition Meeting of the ASSOCIATION in Philadelphia in 1876, and was also President of the American Gynecological Association. In 1881, he made public his ideas in regard to the treatment of gunshot and other wounds of the peritoneal cavity, which, though not accepted with favor at that time, have since been universally adopted and the ideas evolved by him then may now be said to be the practice of the advanced surgeon of this day.

DR. SIMS married, Dec. 21, 1836, ELIZA THERESA, daughter of DR. BARTLETT JONES, of Lancaster, South Carolina, who survived him seven years. His death occurred on Nov. 13, 1883.

New York in thus placing in public view, the statue of one of the ablest medical men of our time is entitled to the grateful thanks of the medical profession of America. How different the feeling in New York in regard to this great man and his memory, from that dark time in which he founded the Woman's Hospital! That most pathetic autobiography ever printed ("The Story of My Life") tells of the heroic efforts of the almost friendless physician, who with mighty aspirations but feeble fainting frame founded that great charity. The shining metal might well bear upon its escutcheon in letters of gold the legend, "IN ATONEMENT," and those reading the golden letters would learn anew the great lesson of tolerance. The medical profession of the world is the better and nobler for having once had a SIMS, and it is well to thus honor his memory.

BRITISH NEWSPAPER DISCUSSION ON VACCINATION.

It is not needful to discuss statistics of smallpox mortality before members of the AMERICAN MEDICAL ASSOCIATION to establish the practical value of JENNER'S discovery; but as a matter of current news it may be well to refer to a series of interesting letters, spiced with a considerable dash of temper, that appeared in the columns of the *Times* (London) during the month of September, concerning which our article of September 22 was written. The writers were MR. ERNEST HART, Chairman of the National Health Society on the one side, and MR. J. T. BIGGS, member of the Leicester Sanitary Committee. MR. WILLIAM TEBB of the Devonshire Club, London, and others of lesser note on the other. The first mentioned lays himself open to attack by giving utterance to an overestimate of the immunity conferred by vaccination. The others triumphantly assail this weak point and carry the war into the enemy's country by an array of statistics which in the minds of many lay readers who do not see wherein lie the fallacies must raise doubts and questionings, if indeed they are not accepted as showing that smallpox is more prevalent and more fatal in the vaccinated than in the unvaccinated. Speaking of the epidemic of the

last eighteen months in various districts of England, MR. HART says that there has not been a single death of a vaccinated child under 10 years of age nor of a re-vaccinated adult. MR. TEBB overlooks the limitation to the recent English epidemic and shows by German statistics of twenty years ago that such deaths have been recorded. He shows that in the city of Berlin in the year 1746 there were 186 deaths from smallpox in an unvaccinated population of 80,000, giving a rate of only 2.3 deaths per thousand living, while in 1871, with a vaccinated population of 823,569 the deaths were 5,085 or 6.2 per thousand, and he shows moreover that more than half of these later deaths occurred in children under 10 years of age. These statistics of vaccinated and unvaccinated Berlin are very striking; but MR. TEBB does not point out that nearly all the deaths in 1746 were of young children because the others of the population had already been rendered immune by previous smallpox. These deaths were merely the regular tax paid annually to the pest. Nor does he point out that 1871 was an epidemic year in which the city was called upon to pay for its carelessness in respect to vaccination, which was not made compulsory until 1874. Nor does he inform us that from 1874 to 1885 (the last published official figures) there were altogether in the whole period of eleven years only 177 deaths. MR. HART, however, was led enthusiastically to assert that children under 10 years of age, according to the official reports of the recent English epidemic, are wholly and entirely immune from smallpox and can not be infected. The replies of the anti-vaccinationists fairly bristle with figures to show, as they sarcastically phrase it, "the kind of immunity which vaccination affords;" but, indeed, they could have convicted their opponent from his own later utterances, for in the issue of September 22, under the heading of "Immunity from Death of Vaccinated Children under Ten Years," he tabulates eighty-four recent cases of smallpox in such children.

The only other application of statistics to anti-vaccination argument which we have space to notice is a bold and startling comparison of some figures from the records of the British Army with the smallpox death rate of the city of Leicester. This latter is stated to have been 89 per million during the late epidemic. "Perhaps nothing," says MR. BIGGS, "is more frequently appealed to in support of the efficacy of re-vaccination than our re-vaccinated army, yet at page 278, Royal Commission Report, No. 2, we find that '3,953 re-vaccinated soldiers in the British Army suffered from smallpox from 1860 to 1888, of whom 391 died of the disease.' This gives a smallpox death rate of nearly 99,000 per million among a strong, healthy and specially selected re-vaccinated adult population. Compare this appalling death rate of 99,000 per million of the 'efficiently vac-

cinated' and 're-vaccinated' or 'doubly protected' with the death rate of only 89 per million among our mixed and for the most part 'unprotected' population at Leicester, and we may repeat: 'Wherein is the necessity of the operation?' This is positively a superlative comparison!

A careful perusal of this series of letters leads to the conclusion that no good can be accomplished by cultivating a correspondence with men who are disingenuous enough to affect such *tours de force* in their statistical presentations, and particularly in the columns of a daily newspaper not all of whose readers are capable of putting a proper valuation on the data.

TYPHOID FEVER AMONG PLUMBERS.

It is a question not infrequently raised in boards of health, whether it is allowable or not to send plumbing inspectors to houses where typhoid fever exists. Also, if plumbing in such houses is defective shall orders to do the required repairs be enforced while the fever yet remains. It is the practice in some towns to leave the matters of inspection to those plumbers who have no dread of the work, and not insist that a plumber shall go, whether he will or no. There will ordinarily be some one or more inspectors at the service of the health officers, ready for this class of work. As to compelling the prosecution of repairs during the pendency of the malady, it may be assumed that the dangers to the workman can be reduced to a minimum, by the thorough and frequent disinfection of the evacuations of the patient, and of the drainage system by which those excreta are carried away.

When the water closet in the house drains into a cesspool, an arrangement common in many suburban places, where sewers do not exist, the cesspool should be drenched with disinfectants; when the case is recovered the cesspool should be cleaned to the bottom in the presence of an abundant use of chlorid of lime or other approved disinfectant. That plumbers may not with impunity engage in this kind of repairing work we have proof in a case that lately occurred at Montclair, New Jersey. In a recent report by the Health Board of that town, mention is made of a plumber being attacked by typhoid fever in consequence of having done repairs in one or more of the houses where the fever had occurred.

EX-JUDGE W. S. HOLMAN.

Every physician residing in the Fourth Indiana Congressional District should remember that W. S. HOLMAN, as chairman of the Appropriations Committee of the House of Representatives, did all he could to defeat the appropriation for the Pan-American Medical Congress, and that he persistently votes against every measure which is for the advancement

of medical science. If he were governed by purely patriotic motives no one could impugn them, but when we know that a worthless member of his family was foisted on the Geological Survey and there retained for a long time on the public pay roll, we can assume reasonably that his so-called "watch-dog-of-the-Treasury" act is one of hypocrisy, and for demagogic purposes only.

If the doctors in the Fourth Indiana District will exert themselves a little, this interesting person will be properly retired at the next election.

AN ARGUMENT FOR THE ANTI-VACCINATIONISTS.

The wordy war on the value of vaccination, carried on through the medium of letters to the editor of the *Times*, London, which gave occasion to our editorial remarks in the *JOURNAL* of September 22, is continued hotly in October with many fresh participants. Among the letters is one which will bear reproduction:

"Sir:—A few words of common sense would not be amiss. I am 70 years of age. In my boyhood it was scarcely possible to walk a quarter of a mile in London without meeting one or more grown-up persons marked by smallpox. In my own small circle there were three persons so marked.

"At the present time I walk about for days and never see a marked face, although my eyesight is as keen as ever. It might be interesting to learn the experience of other Londoners on this subject, and to know how the anti-vaccinators account for the change that has taken place.

"Your obedient servant, OLD STAGER."

OUR READERS will greatly regret to see in the *Neurology* column an account of the death of WILLIAM GOODELL, M.D., of Philadelphia, a notice of which arrived as we were going to press. His wide acquaintance in the *ASSOCIATION*, his professional skill, and his literary ability leave a void which will not be easily filled.

CORRESPONDENCE.

Status of Eclectics, et al.

AUSTIN, TEXAS, Oct. 4, 1894.

To the Editor:—Yes, we are all proud of the *success* of the *JOURNAL*! It has forged ahead, in spite of prejudice and local jealousies, and now is beyond the experimental stage of its life. See herewith a clipping from our daily paper, of _____ Company, quoting. In various cities and towns of the United States there are both homeopathic, and eclectic physicians who would scorn to drag medicine in traffic-slime, as this company does. Now these said homeopathic and eclectic physicians thrust Dr. _____'s advertising "rot" under my nose, and say, tauntingly: "How do you get on, Mr. Regular?"

You, personally, are well and widely known as a large-hearted liberal man and representative physician of the common sense class. And I hope you will be brave enough (as well as discrete enough, to give us—the rank and file—some definite basis upon which to act, in reference to society affiliation with those homeopathic and eclectic physicians who demean themselves as honorable, well educated physicians and refined persons.

The people at large know full well that *very few* "regulars" refuse to meet with this class (if any class) of homeopathic and eclectic physicians, especially if a good fee is in sight or the patient be a person of consequence. There is not a single physician in this city who refuses to meet homeopathic or eclectic physicians, in professional consultation, under said favorable circumstances. Individually, I have never been a slave to any creed, or suppliant to any sect. The Golden Rule, is enough "code" for any well intending person; other sorts of persons only use codes as a cloak while perpetrating the most contemptible meanness—at least, such is my observation, from various quarters of the United States. I do not mean that all, or nearly all physicians, who advocate the strenuous upholding of the written Code, are dishonorable persons, nay, verily. But we, so-called "regulars," have, by years of misguided management, raised and endeavored to maintain an issue. Now it is high time we met such issue, if we would, as a profession, continue to command the respect and esteem of intelligent people at large.

Yours very truly, Q. C. SMITH, M.D.

ANSWER:—As to meeting or affiliating with any physicians, only those are kept out who announce themselves as adhering to some dogma. We use any means for the cure of our patients that clinical experience or common sense leads us to believe would prove of value, whether it be homeopathic, eclectic, or what not. When a physician announces that he uses only a certain line of remedies ignoring others which are known to be of value, how can a thoroughly educated physician consult with him? When he ceases to use such a line of remedies, he ceases to be truly a homeopath, etc., and is a physician. We do not raise the issue. In many sections, there are persons who are good members of our societies, though they either did not receive a diploma or one from an irregular school, but having ceased to announce themselves as practitioners of a pathy, and as being guided by common sense and employing whatever means to relieve disease had been found of value, they had become practitioners of medicine without dogma.

The following fully explains the correct view of the ethics:

Resolved, That clause I, of Art. IV, in the Code, is not to be interpreted as excluding from professional fellowship, on the ground of differences in doctrine or belief, those who in other respects are entitled to be members of the regular medical profession. Neither is there any other article or clause of the Code that interferes with the exercise of the most perfect liberty of individual opinion and practice.

Resolved, That it constitutes a voluntary disconnection or withdrawal from the medical profession proper, to assume a name indicating to the public a sectarian, or exclusive system of practice, or to belong to an association or party, antagonistic to the general medical profession.

Resolved, That there is no provision in the Code in any wise inconsistent with the broadest dictates of humanity, and that the article of the Code which relates to consultations can not be correctly interpreted as interdicting, under any circumstances, the rendering of professional services whenever there is a pressing or immediate need of them. On the contrary, to meet the emergencies occasioned by disease or accident, and to give a helping hand to the distressed without unnecessary delay, is a duty fully enjoined on every member of the profession, both by the spirit and the letter of the Code."

Announcements in the Press.

NEW ORLEANS, Oct. 13, 1894.

To the Editor:—Please inform me if there is anything in the Code of Ethics to prevent a practitioner: 1, from announcing in the *daily newspapers* that his practice is limited to the diseases of special organs; 2, ditto in the *medical papers*; 3, from announcing in sealed circular letters to the *medical profession* at large that his practice, etc.; 4, ditto to *laymen* at large, etc.

Yours truly,

EDMOND SOUCHON, M.D.

ANSWER:—Art. I, Sec. 4: "Duties of physicians to each

other and to the profession at large." "It is derogatory to the dignity of the profession to resort to public advertisements," etc.

2. While in some parts of the country, physicians do publish cards in medical papers, it is not regarded as wanting in the true dignity of a physician, but as a question of taste.

3. Certainly, there can be no objection to a sealed circular to the profession, announcing that practice is limited, etc. But we find that when a physician is limiting work to a specialty, it soon becomes known to the profession of his town, and by his papers on that subject in the medical journals he soon attracts a *clientèle*.

4. A circular to laymen can not fail to produce in the minds of those who receive it, a doubt as to the ability of the one sending it.

A large acquaintance with the profession in all parts of the country causes us to believe that the dignified earnest practitioner can acquire a practice without resorting to any of these plans.

The Missouri State Board of Health.

St. Louis, Mo., Oct. 26, 1894.

To the Editor:—The Missouri State Board of Health at its meeting held in St. Louis on October 25, unanimously adopted the following resolution:

"No medical college guilty of issuing a catalogue or prospectus in which are contained material misrepresentations concerning its teaching facilities, course of study or false representations in the list of students matriculated, or in attendance, shall be in good standing with this Board."

Very respectfully,

F. J. LUTZ, M.D., President.

BOOK NOTICES.

Addresses, Papers and Discussions in the Section on Obstetrics and Diseases of Women, at the Forty-fifth Annual Meeting of the AMERICAN MEDICAL ASSOCIATION, held at San Francisco, Cal., June 5-8, 1894. Pp. 168. Chicago. 1894.

The volume opens with the Minutes of the Section meeting, and then the chairman's address, by Dr. Joseph Eastman, and concludes with the case of didelphic uterus by Dr. Werder, of Pittsburg. The latter article, by the way, is the first pamphlet entirely finished in the JOURNAL office on one of the new presses, and has therefore an interest beyond its intrinsic merits. All the papers in the volume have been heretofore printed in the JOURNAL, but those interested in the work of this Section will naturally be glad to have the collection in book form for permanent preservation.

The Retrospect of Medicine: A half-yearly Journal, containing a Retrospective View of every Discovery and Practical Improvement in the Medical Sciences. Edited by JAMES BRAITHWAITE, M.D. Volume CIX. January-June, 1894. London: Simpkin, Marshall, Hamilton, Kent & Co. 1894.

This is the bound volume of "Braithwaite," so well known in this country and in Great Britain that it needs no introduction at our hands. There was a time when a volume of this size was extremely useful, but the field of medicine is now so vast that it is not possible, in the small compass of such a book as this, to do more than make excerpts from a few medical journals. Considering its narrow and limited horizon, it serves very well those of its patrons who take the *Retrospect* simply because they always have taken it.

The Nurse's Dictionary of Medical Terms and Nursing Treatment.

Compiled for the use of Nurses; and containing descriptions of the principal medical and nursing terms and abbreviations, instruments, drugs, diseases, accidents, treatments, physiologic names, operations, food appliances, etc., etc., encountered in the ward or sickroom. By HONOR MORTEN. Second Edition. Philadelphia: W. B. Saunders. London: The Scientific Press. Chicago: A. C. McClurg & Co. Price \$1.50.

The title page tells the whole story, and makes the reviewer's task a light one. It is an excellent dictionary for nurses and one, we think, very well calculated to be of ser-

vice to them. Now that nursing has become a branch of medicine, one of the most important divisions of therapeutics, it is necessary that special dictionaries should be compiled for the nurse's use, and this volume, which will doubtless grow with each succeeding edition, seems to fill the requirements.

Materia Medica; Pharmacy, Pharmacology and Therapeutics. By W. HALE WHITE, M.D., F.R.C.P., and REYNOLD W. WILCOX, M.D. Second American edition; thoroughly revised. Philadelphia: P. Blakiston, Son & Company. 1894. Chicago: E. H. Colgrove & Company. Price \$3.

This is an excellent manual, well arranged, and carefully compiled. It has been revised to conform to the American Pharmacopœia with the single exception of dosage, which still remains as in the original British edition. As the British Medical Association at its last meeting appointed a committee on the adoption of the metric system, it is probable that they will join the remainder of the world in due time. The index is very complete and adds much to the convenience and usefulness of the book.

Prescribing and Treatment in the Diseases of Infants and Children. By PHILLIP E. MUSKETT. Third edition, pp. 334. Edinburgh and London: Ewing J. Pentland. 1894.

This little book, which is narrow and slender, may be carried in the pocket and is an epitome of the subject. It is divided into three parts, the first dealing with dosage and therapeutics. The second with the treatment of disease in infants and children, and the third part is given to recipes. It has an interesting summary of the list of drugs and dietary substances which have been found useful in the treatment of diseases of children in Sydney, Australia. Each chapter is alphabetically arranged. Some of the titles, however seem to be rather colloquial than scientific, such as "Inward Fits" page 182; "Rickets in Australia," page 240. The book will be found extremely useful. It is well printed and convenient.

Practical Manual of Diseases of Women and Uterine Therapeutics. For Students and Practitioners. By T. McNAUGHTON-JONES, M.D. Sixth Edition. London: Baillière, Tindall & Cox. 1894. Four hundred and ninety-seven illustrations and two plates. Pp. 766.

This is one of the best manuals of gynecology in the English language; concise, clear and complete. This edition is largely re-written, re-arranged and newly illustrated. There is a large increase in matter and in the illustrations, and many additions have been made in the pathologic and surgical portions. The chapters on diseases of the mammary gland have been omitted, and new chapters on uterine reflexes, sutures and ligatures, surgical fibromata, affections of the Fallopian tubes, tubal pregnancy and ovarian affections, have been added. The author is a man of positive convictions, and he does not hesitate to express his views frankly. His chapter on massage is a refreshing one in these days of namby-pamby, hesitating literature. To McNaughton-Jones a spade is a spade, and not an uncertain "agricultural implement."

Public Health Papers and Reports. Volume XIX. Presented at the twenty-first annual meeting of the American Public Health Association, held in Chicago Oct. 9-14, 1893, with abstract of the records and proceedings. Concord, N. H. 1894.

Many of the papers published in this volume appeared in this JOURNAL at the time of the meeting, and a full report of the proceedings will be found in the JOURNAL of Oct. 21, 1893. The publication of the transactions is of value to those who wish to preserve them in permanent form, and no volumes have been better prepared, or printed in better general style than those of the American Public Health Association. In some respects, it will be a pity if the committee shall abolish the plan of printing the annual transactions, and with the additional matter that will properly come with the quarterly journal of public health, there will come also a feeling of regret at the absence of the scholarly and good-looking volumes from the library shelves. There would seem to be no particular cause for this action, when the medical journals of the country now so fully and accurately publish to the world the doings of this great and public-spirited Association.

The volume under consideration contains necrologic reports of the late Dr. Edward H. Janes, of Massachusetts; Dr. Jones, of Maine; Dr. T. F. Wood, of Wilmington, N. C.; Dr. V. T. Atkinson, of Chicago, and Dr. Joseph W. Redden, of Delaware.

Transactions of the American Surgical Association. Volume XII. Edited by DE FOREST WILLARD, M.D. Philadelphia: Printed for the Association by William J. Dornan. 1894.

This volume of transactions contains the papers read before the Association at the meeting held May 29-31, and June 1, 1894, together with brief obituary notices of Professor Billroth, Drs. B. A. Watson, W. W. Dawson, T. J. Dunott, and James McCann. The frontispiece of the volume is a picture of a gavel which, the volume informs us, is one made from a portion of the office chair of the late Prof. Samuel D. Gross, presented by the retiring President, Dr. Mears, to the Association for the use of its future President.

The papers have been previously published, some of them in this JOURNAL. There is a paper on "Methods of Teaching Surgery," by a gentleman who has neither taught or practiced surgery for the last twenty-nine years, and can not therefore be considered as an expert on the subject. The one paper in the volume that stands out as a landmark is the paper of Dr. Fenger, of Chicago, on "Surgery of the Ureter."

Syllabus of Lectures on Human Embryology: An Introduction to the Study of Obstetrics and Gynecology. For Medical Students and Practitioners. With a Glossary of Embryological Terms. By WALTER PORTER MANTON, M.D., Professor of Clinical Gynecology and Lecturer on Obstetrics in the Detroit College of Medicine; Fellow of the Royal Microscopical Society, of the British Zoological Society, American Microscopical Society, etc., etc. Illustrated with Seventy Outline Drawings and Photo-Engravings. 12mo. cloth, 126 pages, interleaved for adding notes and other illustrations. Price, \$1.25 net. Philadelphia and Chicago. The F. A. Davis Co.

This volume is intended for the class room and laboratory more than the library, and as such will be found a trustworthy guide. Section IX, on "practical work" is very useful. The study of embryology has been too much neglected in medical schools in the past, and this book has been prepared in recognition of the evident need of medical students for a compact book on the subject. While it only purports to give an outline of the subject, it answers very well the demands of those who have not time or opportunity to master the larger works on embryology such as Minot's. It is vastly better that the student should master the contents of this little book than that he should have no acquaintance with the subject. No one can master the fundamental truths of pathology without an acquaintance more or less profound with embryology.

First Aid to the Injured and Management of the Sick. An Ambulance Hand-book and Elementary Manual of Nursing for Volunteer Bearers and Others. By E. J. LAWLESS, M.D. Illustrated with forty-nine engravings. Philadelphia: J. B. Lippincott Company. 1894. Price, \$1.25.

The author in this book has arranged the subject of first aid to instruction to suit the requirements of those attending regimental classes, and the book will be found useful, not only to members of volunteer and civil ambulance classes, but to various ambulance associations. Part I is devoted to first aid to the injured, and contains, beside, the introductory twelve lessons. Following this are questions and answers to the foregoing. Part II is devoted to management of the sick, and contains seven chapters. The appendix of Part I contains a chapter of miscellany relating to fresh air and ventilation, germicides, the administration of medicine, removal of boots in injuries to the ankle or foot, bed sores, field kitchens, directions for pitching tents, ambulance wagons, hand carts, forms of reports, table of poisons and the index. There are forty-seven illustrations. The book will be found of great value to those for whom it is intended, and it would appear as if the great sympathy of the English for the Chinese would necessitate the issuance of a special edition, to be distributed through military channels from the central office at Peking, as from all accounts there

is great lack of organization. The truth is, there have been almost as many books written on aids to the injured as the average man sees of the injured during a lifetime. Many of them are excellent, and it would be difficult to improve upon the one under consideration, but there are simply too many of them—at least in English speaking countries.

Text-Book of Nervous Diseases, being a Compendium for the Use of Students and Practitioners of Medicine. By CHAS. L. DANA, A.M., M.D. Third edition, with two hundred and ten illustrations. New York: William Wood & Company. 1894.

The author has endeavored in this book to place modern neurology in a small and accessible space. He says: "I do not expect or intend to make a light and restful piece of literature; the science of nervous diseases can not be honestly presented in any such guise; but by following the instructions of the preface, the student can master the essentials of neurology without encountering any hard waste of words, and the practitioner who wishes to study special subjects can, as I fondly believe, find them presented concisely and with a fair degree of completeness." This manual is one of the best of its class, and the student or practitioner who masters this book may well indeed warn his antagonist to beware of the man of one book, for he will surely vanquish him if they meet in debate in a medical society, or in the pages of the current medical journal. Dr. Dana, like others of his family, is a master in the use of the English language, and the family trait is shown to perfection in this book. Those who have the pleasure of a personal acquaintance with the author know him to be one of the most painstaking of mankind and one of the most studious. What he says of his own knowledge may therefore be accepted as an unquestioned fact, and what he states upon information has been subjected to the test of a judicial mind.

Lectures on the Diagnosis and Treatment of Diseases of the Chest, Throat, and Nasal Cavities; including physical diagnosis and diseases of the lungs, heart, and aorta; laryngology and diseases of the pharynx, larynx, nose, thyroid gland, and esophagus. By E. FLETCHER INOALS, A.M., M.D. Third edition revised and enlarged. Octavo, 640 pages, 240 illustrations, including colored plate of stained tubercle bacilli. Price \$5. New York: Wm. Wood & Co. 1894.

This well-known and standard treatise has required no great alteration in the text of this edition from that of the second one, which was issued in 1892, and the author, as he says, has evidently succeeded "in his efforts not only to aid laryngologists in their daily work, but also to place those subjects clearly before students and a large class of general practitioners who, of necessity, must be prepared to meet any emergency. Fifteen chapters are devoted to diseases of the chest; fourteen chapters to diseases of the throat; eight to diseases of the nose, and one chapter to diseases of the thyroid gland and esophagus. In the appendix will be found formulæ for various prescriptions, including gargles, troches, inhalations, pigments, insufflations, nasal douches, and the like. In the next edition, we trust the author will conform to the new Pharmacopœia by using the decimal system of dosage. Few books have been published which in the same number of pages contain more references to pertinent contemporaneous literature, and at the same time show such care and originality. The work is a model of its class.

Annual of the Universal Medical Sciences: A Yearly Report of the Progress of the General Sanitary Sciences Throughout the World. Edited by CHARLES E. SAJOUS, M.D., and seventy associated editors, assisted by over two hundred corresponding editors, collaborators and correspondents. Illustrated with chromo-lithographs, engravings and maps. Five volumes. Philadelphia, New York and Chicago: The F. A. Davis Company.

It is probable that at no period has the diamond of medical literature received a handsomer setting than has been given it in this now well-established Annual. Every phase of medical discovery with its many-sided characters are here fully set forth and duly credited to their authors, real or supposititious. No man can possibly keep abreast of the entire range of medical science. Few men are able to keep in touch with any one branch of medical science. Nothing but the steady and continuous work of a corps of men, such

as are gathered together under the able direction of Dr. Sajous, could accomplish from year to year a work of such scope and minuteness as the *Annual of the Universal Medical Sciences*, and there can be no question but that the conceded importance in American medical literature in the past few years has been largely due to the influence of two publications, namely, the *Index Medicus* and the *Annual of the Universal Medical Sciences*, works which serve the same purpose to the general reader and writer as the "Index" to the frequenter of the public library, but the *Annual* is something more than an index. It is an editorial review of all the topics of the year. It is as much superior to the annuals, year books and retrospects hitherto published, as a modern treatise on bacteriology is to the work of Redi on the Generation of Insects.

Home Treatment for Catarrhs and Colds. A handy guide for the prevention, care and treatment of catarrhal troubles, cold in the head, sore throat, hay-fever, hoarseness, ear affections, etc., adapted for use in a household and for vocalists, clergymen, lawyers, actors, lecturers, etc. By LEONARD A. DESSAR, M.D. New York: Home Series Publishing Company. London: Ballière, Tindall & Cox. 1894.

The author says in his preface that an apology seems necessary for having written the work; that it was written "with a view of supplying the general reader with a trustworthy guide of instruction for the proper care, prevention and treatment of catarrhal troubles of the throat, nose and ears, and their complications." He neglects, either in the preface or elsewhere, to inform us what the complications of the nose and throat may be, but he says: "There are thousands of persons throughout this country who use their voice in their vocation, such as vocalists, clergymen, lawyers, actors, orators, and yet who are unfamiliar with the best means of keeping the vocal organs in a condition of health or caring for them when diseased." The author fears the purpose of his book may be misunderstood, for he further says: "We would urge most strongly that the purpose of this little book is not to supplant the physician, but to acquaint the reader with the principles of promoting the health of these organs."

There are thirty-eight chapters which seem to mention most of the general topics included in the subjects under consideration, from bleeding at the nose, to frost bites. The author begins: "The nose serves a double purpose. It is the organ of the sense of smell, assists in breathing, and in the production of speech." This would seem to be a triple purpose by the ordinary rules of mathematics. We doubt if this book will be of much service, as it is extremely problematical if it will ever reach the class for whom it was intended. It is too technical to be read by them, and is too elementary to be useful to the profession.

Landmarks in Gynecology. By BYRON ROBINSON, B.S., M.D., Chicago. Paper, volumes I and II. Detroit: George S. Davis, Publisher. 1894.

The landmarks in gynecology which the author considers of chief importance are "anatomy," "menstruation," "labor," "abortion," "gonorrhœa," "tumors." Exactly why they should be called landmarks, it is a little difficult to understand, but inasmuch as the matter is correct it is of little consequence what title shall be given.

The author is well known as a frequent contributor to this and other journals, an indefatigable worker, and untiring investigator. The present book is an abstract of some of his lectures delivered at the Post-Graduate Medical School.

In conclusion, the author, himself an experienced operator, offers the following practical suggestions: 1, remember it is criminal to learn to do a laparotomy on a patient; 2, do not attempt to do a laparotomy in a private house with no nurses; 3, before undertaking laparotomy, study under a master and a system, if possible, so that you can see the pathology in the abdomen and the methods of removing it. Ask to be allowed to tie a knot once in a while. Never lose the chance of assisting or witnessing a laparotomy; 4, learn the after-treatment; half the battle is with the intestines; 5, study carefully the abdominal and pelvic viscera on the cadaver and as many cadavers as possible. Never lose the chance of doing a *post-mortem* or attending one. Study the viscera of animals; 6, be sure to make systematic experiments on the abdominal viscera of dogs. Always do the autopsy on the dogs yourself. Note what dam-

age to the peritoneum your manipulations have done. Observe what peritonitis really is; 7, be clean without chemicals. Learn to use very few instruments. Beginners should always invite a laparotomist, one who will suggest and criticize in a friendly spirit, to be present; 8, be careful of promises.

A Treatise on the Medical Jurisprudence of Insanity. By EDWARD C. MANN, M.D. Albany, N. Y.: Matthew Bender. 1893. 8 octavo, leather, pp. 420.

This handsome volume on this branch of the insanity question contains not only the views and opinions of one thoroughly expert in matters of which he treats, but gives such authoritative and definite statements concerning the subject as to make it of great value to all who wish to keep abreast of the modern decisions and views. The book is divided into twenty-one chapters, of which several are devoted to the psychologic aspects of various cases. Thus, Chapter XIV is given to the psychologic aspects of the case of Edward Newton Rowell; Chapter XV the same in the case of Lucille Yesult Dudley; Chapter XVII, Chas. Guiteau; Chapter XXI, the case of Prendergast.

In regard to Guiteau the author expresses his unqualified conviction that he was insane. In the matter of Prendergast, his conclusion is not clear, but in this connection he states: "Society must punish crime, not for revenge, but to protect society from evil deeds, to put penal restraint on the criminal and to deter others by the example and him by the memory of his sufferings from a repetition of his acts. The punishment of an insane person or idiot is no benefit to him, as he can not learn by it, while the example of its infliction, so far as serving a warning to others, is an outrage of social feeling and brings discredit on the administration of justice."

He quotes briefly on page 112 the opinions of Judge Edmunds and of Recorder Hackett as to what constitutes insanity. This is what Judge Edmunds says: "A sane man is one whose senses bear truthful evidence; whose reason can draw proper conclusions from the evidence which is received; whose will can guide the thought thus obtained; whose moral sense can tell the right and wrong of any act growing out of that thought; and whose acts can, at his own pleasure, be in conformity with the action of all those qualities. All these things unite to make sanity. The absence of them is insanity." This from Recorder Hackett: "The state of sanity is one in which a man knows the act he has committed is unlawful and morally wrong, and has reason sufficient to apply such knowledge and be controlled by it."

This book will be found of value not only to experts in insanity and the legal profession, but to all physicians wishing to keep pace with the progress of legal medicine.

A Manual of Modern Surgery, General and Operative. By JOHN CHALMERS DA COSTA, M.D. With 188 illustrations and 13 plates in colors. Cloth, pp. 800. Philadelphia: W. B. Saunders. 1894.

The author says in the preface: "The aim of this manual is to present in clear terms and in concise form the fundamental principles of the chief operations and the accepted methods of modern surgery. The work seeks to stand between the complete but cumbersome text-book and the incomplete but concentrated compend." From the earliest times the *Ἀριστον μέτρον*, the "golden mean," has been sought by the *literati*, but alas, like the bag of gold at the end of the rainbow, it has thus far eluded search. We hope that this new aspirant for honors in surgical literature may be more successful than any of its predecessors; but it is a difficult task when the excellence of many of the text-books on surgery which are now in the field is considered, and the charge of "cumbersome" can scarcely be applied to some of them. In Moullin, for example, it is said that the last edition was revised with the deliberate purpose, among others, of eliminating all superfluities of words and phrases.

The author in the preface apologizes for his opening chapter being devoted to bacteriology, an apology which is no longer necessary in view of the fact that every teacher of the principles of surgery is of opinion that the principles

of bacteriology find an appropriate place in works of this character.

The book is rather loosely written as regards English. We open it at random, and we find on page 94 this: "The exploring needle must be used; it will do no harm to an aneurism if aseptic." Page 111: "Within forty-eight hours as a rule the gangrene has mapped out its area," the meaning of which is evidently that the gangrene has become limited or circumscribed. On page 328 we find: "The treatment of these conditions is by their well-known rules." On page 512: "The commonest seat of a felon is the last digit of a finger because the superficial lymphatics run directly *inward*." (The italics are ours.) Page 513: "Opening a felon is exquisitely painful." We presume to the patient. "In effusions into the knee joint, the fluid is behind the patella, and the bone floats up." On page 514 we are told that "when the big toe is pushed inward by ill-fitting boots, a bunion forms," and we are told on the same page that "a bunion is a bursa due to pressure; it is most commonly found about the metatarso-phalangeal articulation of the great toe, but occasionally over the joint of another toe." "In treating a bunion the patient must wear shoes that are not pointed." Therefore, we are led to infer that if the patient does not treat a bunion, it is immaterial what kind of shoes he wears. Again, we find: "Distention of the entire abdomen and of the flanks, linked with tenesmus," etc.

Some of the teachings are unsound. "For example, on page 619, it is said: "Puncture of the intestine with an aseptic hypodermic needle, introduced obliquely, will relieve gaseous distention." Let any one attempt to relieve gaseous distention in the *post-mortem* room by a single puncture or a half dozen punctures if need be, and he will very speedily ascertain that even in the non-elastic dead intestine the opening soon closes after the needle, and the air can not be easily withdrawn. Moreover, the operation on the living subject is itself dangerous, and a caution should have been given, because if the opening were large enough to allow the passage of air through the intestinal wall, it would be large enough to allow the escape of fecal matter.

We have with regret pointed out these faulty methods of expression in order that they may be corrected in the next edition, as the book has many excellent features and doubtless will reach another edition. We notice, too, that the author has used the old British dosage in his prescriptions.

Army (British) Medical Department Report for the Year 1892.

The British Army Medical Reports have had an interest for medical and sanitary men since the days when E. A. Parkes and his pupil, De Chaumont, edited their appendices which were usually stored with the latest views and experiences on sanitary subjects. The present, the thirty-fourth volume, is constructed on the old and familiar lines,—a statistical report and an appendix. From the former we learn that the strength of the white troops during the year was in round numbers 200,000 men, one-half of whom were at home, the other half abroad. Of the latter 68,000 were in India, nearly 8,000 in Malta, 5,000 in Gibraltar, 3,000 in Egypt, 3,000 also in South Africa, detachments of from 500 to 1,500 in the other colonies and settlements, and a mean strength of about 3,000 at sea in transports. The rate of admission on sick report of the 200,000 men was 10.35 per thousand of strength, the death rate 9.46, the rate of discharge for invalidism 13.26, the non-effective rate or number constantly sick 58.08, and the average duration of each case of sickness 20.6 days. These figures differ but little from the average annual rates of the ten years 1882-91.

The admission, death and non-effective rates of the home stations were much lower than those given above: Admission, 7.61; death, 4.38; non-effective, 42.75. In Canada and Bermuda the records show a gratifying freedom from sickness. Halifax is the only station in Canada now occupied by Imperial troops. In Gibraltar, Malta and Cyprus the rates were much similar to those of the home stations, at other places they were higher: India had the worst record, an admission rate of 15.15, giving 83.88 constantly sick with 17.59 deaths and 12.40 discharges, besides 24.41 sent home as invalids out of every thousand men present with the flag.

The West Indies had 71 constantly sick; Egypt 67; the Straits Settlements 64.55 and China 60.

Enteric fever at the home stations occasioned only 132 cases of sickness or 1.3 per thousand of strength. In the United States Army during the same year we had 3.95, and this was a light record, as the average annual rate of the previous ten years was 5.17. There were 1,650 men of the home force constantly sick with venereal diseases, or 16.46 cases in every thousand men. The rate of admission for these diseases was 201.2; the United States Army rate for the same year was 72.46. Malarial disease, rheumatism, alcoholism, injuries and suicide were less frequent in the British Army than among our troops. We had as many suicides among our 26,000 men as they had in a strength nearly four times as large. Of 68,761 recruits inspected 38.3 per cent. were rejected as compared with 63.8 per cent. in the United States recruiting offices. It must not be supposed from these figures that candidates for enlistment in Britain are finer specimens of physical development than those of this country. The explanation lies in the fact that we have a relatively greater number of candidates to select from and our recruiting officers can therefore decline many men with slight defects that would not prevent their enlistment under other conditions. Nearly 79 per cent. of the accepted British recruits were boys under 21 years of age. Omitting boys under 17 years of age, of whom there were 1,421, the average age of the accepted recruit was only 19.3 years.

There was in Malta, during the year, a decided increase of enteric and Mediterranean fevers. A heavy autumnal rainfall was injurious owing to its having washed impurities into the main drinking water supply; and to this fact an unusual amount of sickness in November and December is said to have been due. During the outbreak all milk was boiled and the water boiled and filtered. The result of this latter expedient is said to have been excellent. Fire-places in barracks are urged as a necessity from December to March, when the dampness and cheerless appearance of the present unheated rooms exercise a depressing influence on the men. In the island of Mauritius the chief general causes militating against the health of the troops are the malarial nature of the climate, the general ignorance and neglect of the simplest rules of sanitation among the civil community of all grades, the impure water supply at Port Louis, the total absence of sewerage and the defective system of hand removal of excreta. At Port Louis the sanitary condition is said to be as bad as it possibly can be. In Ceylon the dry earth system is in use at all stations. Of the 86.76 men constantly sick per thousand of strength in the Bengal command, 25.58 were disabled by venereal diseases, 16.17 by malarial diseases and 4.15 by enteric fever. Of the last there occurred several notable local outbreaks, as at Dagshai, among the young men, fresh from home, of the Argyle and Sutherland Highlanders, where there were 98 cases and 12 deaths. Only such cases as presented unmistakable symptoms of enteric fever were returned under that heading. Of 96 occurring at the same time and place, and diagnosed as simple continued fever, some were prolonged and may have really been enteric fever cases.

The conclusions reached by the medical officer in charge were that the disease was brought by the regiment to Dagshai and spread among the young soldiers and that exposure to the sun, wettings, chills, etc., were exciting causes giving rise to fever and thus predisposing the men to enteric fever when the disease was present. Men in the early stage when suffering from diarrhea before admission to hospital used the latrine nearest to them at the time and thus probably spread the disease from one building to another. Many cases of sore throat and erysipelas occurring at the same time seemed to point to some local insanitary cause believed to be of a miasmatic character, as the site of the post is saturated with sewage.

The medical officer at Merut reports that the cause of enteric fever is as obscure as ever. He is inclined to think that a fever of a prolonged nature, having as its pathognomonic sign ulceration of the small intestines, can be caused without a specific excitant; in fact that youth, indigestion, indigestible food, undue exposure to heat and fatigue, are factors enough in themselves to produce a fever, the nature of which is such that over 25 per cent. of those attacked die. He considers that if the five causes above mentioned were eliminated, with them would go nearly all the cases of the disease we call enteric fever. The medical officers at Lucknow and Quetta are inclined to the fecal dust theory of propagation. The latter says that the atmosphere at his station is very dry, and desiccating dust storms from the west are of frequent occurrence. The filth pits and dump-

ing grounds are to windward of the cantonments and particles of dried refuse are blown across the lines and have every opportunity of obtaining entrance into the food and throats of the inhabitants and becoming a probable source of disease. At Benares the infection in certain of the cases is said to have come from the native quarters outside of the cantonments, as some men admitted for gonorrhoea showed symptoms of enteric fever a few days afterwards. Speaking of the Dagshai outbreak the principal medical officer of the district remarks that the question of the microbe being present in excreta is generally received as certain, and as by burying this the subsoil is contaminated, the necessity of destroying by fire all contents of soldiers' latrines is proved. Experiments were carried out for six months in the camp of the Highland regiments at Umballa, and one incinerator was found sufficient to dispose of the excreta of 1,500 men. He is of opinion that the value of the incinerator can not be over-estimated and strongly recommends that this method of disposal be at once sanctioned, certainly for hill stations and in time for the plains.

At Agra there occurred 391 cases of severe fever, each of which rarely lasted over a week. Patients recovered quickly from its effects. There was no eruption nor any specific symptom, and it could not be classed under any other head than simple continued fever. It began and ended very much like an epidemic and lasted from July to October.

From cholera a total of 134 admissions with 95 deaths was recorded. The difficulty of determining sometimes whence comes the infection is illustrated in a report from Ferozepore. The disease was prevailing in the surrounding villages when:

"On the afternoon of April 21 a man of the Royal Sussex Regiment was admitted into the detention ward of the station hospital, suffering from diarrhea and vomiting. The following morning he appeared so much better that he was moved into one of the ordinary wards, where during the day his attack developed into cholera and proved fatal. On his way to this ward he had been placed (in a dhooly) for a few minutes in another ward while a bed was being prepared for him. Two hours subsequently a patient in this other ward was attacked, as were also five other inmates, and two more were seized in the ward in which the first man had been finally placed. All these cases occurred on the 22d. Next day two more patients in the hospital were attacked, and a third on the 24th. On the 25th a patient in a tent in the hospital compound was taken ill, and on the 26th there were three cases, first a nursing orderly, then a patient in a tent, and a second nursing orderly. The last case of this outbreak occurred on the 28th in a patient in a tent. The medical officer records his opinion that as only two hours elapsed between the placing, for a few minutes, of the first case in a ward, and the commencement of the outbreak in that ward, direct infection could not be ascribed as the cause of the patients in hospital being attacked. The second outbreak occurred on June 19, on which day three men of the Royal Artillery in the Fort were attacked in their barrack. They were treated in the detention room in the Fort, the only available place, which is an end room of the building occupied by married soldiers and their families. The next day a woman living in the adjoining quarters—under the roof there is communication between the rooms—was attacked, and on the same day a case occurred in the tents into which the men of the Royal Artillery had been moved the previous afternoon. On the 21st two more of these men were seized, and on the 22d a patient in the station hospital. On the 26th the last cases of this outbreak took place, viz., an officer living in a private bungalow, the wife of a soldier living in the Ordinance lines, and a man of the Sussex Regiment in a tent near the Fort."

In Bombay, Deesa and Aden one-third of the sickness was due to malarial fevers. The troops at Alexandria and Cairo suffered severely from enteric fever—109 cases with 36 deaths. To the unsanitary condition of the native city and especially of those quarters usually frequented by the men is attributed the origin of the disease at both of these places. The quality of the water at Alexandria is so well recognized that all the drinking water used by the troops is boiled and filtered before use. Some of the men were moved from their barracks into the field under canvas. Following this there was at first a considerable abatement in the epidemic but it did not last long. Every possible sanitary precaution was taken and the greatest care used in the isolation, disinfection and treatment of the cases as they occurred. Many of the cases were of a virulent type terminating in early perforation of the bowel.

In the Appendix, Brigade Surgeon Lieut.-Colonel J. Lan Nutter reviews the chief points of hygiene that have attracted attention during the year, discussing legislative literature, work of societies, special points of hygiene and work in the hygienic laboratory at Netley. Under the second heading, favorable notices are given of Leffmann and Beam's "Analysis of Milk and Milk Products," and of Billings' "Ventilation and Heat." The special points noticed are the filtration of water as presented by Koch in his paper on "Cholera and Water Filtration," and the disposal of sewage by the oxidation effected during electrolysis. In the laboratory at Netley unsuccessful efforts were made to separate organisms pathogenic to man from soil taken from the site of the Aldershot camp, and some experiments were

made to determine the value of the new disinfectant, izal. This is followed by a report on the proceedings of the seventh session of the French Congress of Surgery, April 1893, by Brigade Surgeon W. F. Stevenson. A medical report on the mission of Sir C. Evan-Smith to Fez in 1892, by Surgeon-Captain W. G. McPherson, gives an interesting account of the topography of the country between Tangier, Fez and Rabat with sanitary notes on Fez and its surroundings, and remarks on the population and meteorology of the interior of northern Morocco, and on the diseases and medical customs prevalent among its inhabitants. There are also some minor papers; one on the fevers of Alexandria, another on enteric fever in India, a third on myopia and a fourth on gunshot fracture of the lower jaw. The appendix closes with meteorological data from various stations.

NECROLOGY.

WILLIAM GOODELL, M.D., the eminent gynecologist, who had been in failing health for the last two years, died at his residence in Philadelphia, on Saturday morning, October 27, aged 65 years. Dr. Goodell was the son of the Rev. Wm. Goodell, D.D., of Holden, Mass., and was born on the island of Malta, while his parents were journeying to Turkey, where his father was engaged in missionary work.

In 1849 he entered Williams College, Massachusetts. Graduating three years later, he came to Philadelphia and continued his studies at the Jefferson Medical College, and received his diploma in 1854. The same year Dr. Goodell rejoined his father in Constantinople, and there entered upon the practice of his profession. In 1857 he married, at Smyrna, Asia Minor, Caroline, daughter of the late Judge Thomas S. Bell, of West Chester, Pa., who survives him. In 1861 he returned to America on account of the unsettled condition of political affairs in Turkey, and, locating in West Chester, there commenced practicing medicine in this country.

In 1865, on his appointment as Physician-in-Charge of the Preston Retreat, at Twentieth and Hamilton Streets, he came to reside permanently in Philadelphia, and continued to hold this appointment until his health began to fail.

Soon after coming to Philadelphia he restricted his practice to obstetrics and diseases of women, on the subject of which he was a prolific contributor to this and other medical journals, and was also the author of "Lessons in Gynecology."

In 1870 he was appointed Lecturer on Obstetrics and Diseases of Women at the University of Pennsylvania, and in 1874 Clinical Professor of the University in the Diseases of Women and Children. He was also Honorary Professor of Gynecology of the University, a member of the AMERICAN MEDICAL ASSOCIATION, and the Gynecological Society; also of the State and county medical associations. He was a Fellow of the College of Physicians, and a member for many years of the American Philosophical and American Pathological Societies, and a correspondent of the Boston Gynecological Society, of the London Obstetrical Society and of the Imperial Medical Society of Constantinople. His death is a great loss to the AMERICAN MEDICAL ASSOCIATION.

DUDLEY SHARPE REYNOLDS, Ja., M.D., son of Dr. Dudley S. Reynolds, of Louisville; born at Louisville, Feb. 20, 1873, died from the accidental discharge of a pistol, at Collinsville, Ill., Oct. 22, 1894. He was an unusually promising young man, of brilliant intellectual endowments, and more than the average of educational accomplishments for one of his age. His literary education was obtained in the public schools of Louisville, and in Professor Gooch's Preparatory Institute. He was a member of the class of 1890 at the Louisville High School, after which he entered upon the study of medicine, graduating with creditable distinction in the Hospital College of Medicine, June 21, 1893. He had been traveling in Europe during the summer, and on his return had determined to practice his profession at Collinsville, Ill., where he was engaged to marry the daughter of Mr. Oscar B. Wilson, a prominent citizen of that place. His sudden and tragic death shocked the people of Collinsville, and a wide circle of friends and acquaintances. His remains were conveyed to the home of his father at Third and Chestnut Streets, Louisville, Ky., and laid in their last resting place at 3 o'clock P.M., on October 25.

WILLIAM W. REESE, M.D., of Brooklyn, L. I., died October 20, aged 82 years. He had been suffering for two years or more from interstitial nephritis, upon which pneumonia

supervened about one week before death. He was an ex-Treasurer and ex-President of the Kings County Medical Society. In the Physicians' Mutual Aid Association he was for many years an active office bearer. He was a descendant of the Pennsylvania family of Friends, bearing the name, Reese, and was a worthy representative of the religious brotherhood whose motto has for generations been "Peace and Good Deeds."

V. H. GUR, M.D., of New Lexington, Ohio, October 19.—W. H. EDWARDS, M.D., of Warrior Run, Pa., October 19, aged 25 years.—Solomon W. Davison, M.D., of Rochester, N. Y., October 21, aged 72 years.—O. B. Adams, M.D., formerly of Elgin, Ill., October 14, aged 64 years.

ASSOCIATION NEWS.

Treasurer's Notice.—Members of the ASSOCIATION knowing themselves to be in arrears will please send the amount of their annual subscription to the Treasurer, HENRY P. NEWMAN, M.D., Venetian Building, Chicago, without delay.

The great expense on account of the establishment of the new JOURNAL office, makes it more than ever necessary that our members should be prompt in their response to this notice.

SOCIETY NEWS.

Mississippi Valley Medical Association.—The Secretary of this Association announces the following preliminary program for the twentieth annual meeting in Hot Springs, Ark., Nov. 20, 21, 22 and 23, 1894:

Cases of Traumatic Cataract in Children Treated by Extraction, by J. M. Ball, St. Louis; Toxics, by W. F. Barclay, Pittsburg; The Philosophy of Stimulants, by A. D. Barr, Calamine, Ark.; Squint, with Special Reference to an Operation, by Chas. A. Beard, St. Louis; Conservative Surgery, and What it Means at the Present Time, by A. C. Bernays, St. Louis; The Deeper Inflammations of the Skin, by A. W. Brayton, Indianapolis; Intestinal Indigestion, by A. P. Buchman, Ft. Wayne, Ind.; The Medical Expert Witness, by Robt. M. Campbell, Ashland, Ohio; Some Observations on "Sore Throat" Due to Concretions in the Tonsils, by L. C. Cline, Indianapolis; The Differential Diagnosis of Coma, by W. J. Conklin, Dayton, Ohio; Constipation, by G. J. Cook, Indianapolis; Syphilis, and its Relation to Other Affections, especially those of the Skin, by W. T. Corlett, Cleveland; Surgical Treatment of Uterine Fibroids; Disposal of the Pedicle, by A. H. Cordier, Kansas City; Stab Wound of Pericardium; Resection of Rib; Suture of Pericardium; Recovery, by H. C. Dalton, St. Louis; Surgical Treatment of Trachoma, by D. A. Dean, Pittsburg; Possibilities of Medicine, by J. O. DeCourcy, St. Libory, Ill.; Some New Instruments, and Means of Physical Diagnosis, by Chas. A. Denison, Denver; Quinin in Chorea, by F. R. Fry, St. Louis; Report of a Case of Trephining for Cerebral Clot, with Loss of Vision; Recovery; by J. B. Hamilton, Chicago; Spot Specialism, by C. H. Hughes, St. Louis; The Management and Treatment of Endometritis, and the Prevention of Ovarian and Tubal Diseases, by W. H. Humiston, Cleveland; Functional Stenosis; Its Relation to Malformations, Dislocations and Flexions; and Conditions Characterized by Amenorrhea, Dysmenorrhea and Hyperemias; with a Scientific Rationale in Therapeutics, by G. F. Hulbert, St. Louis; The Neatest Method of Circumcising, by B. Lewis, St. Louis; Colles' Fracture, by J. E. Link, Terre Haute, Ind.; Double Nasal Atresia, Due to Smallpox, by H. W. Loeb, St. Louis; Tubercular Meningitis, by I. N. Love, St. Louis; Physicians' Prescriptions, by S. Loving, Columbus, Ohio; Traumatic Lesions of Cranium and Brain; Report of Clinical Cases, by G. N. Love, Randall, Kan.; Observation on Residual Urine and Remarks on Perineal Section, by G. Frank Lydston, Chicago; Modern Surgical Technique, by H. O. Marey, Boston; Tumors of the Neck, by Donald Muclean, Detroit; Advantages and Disadvantages of Kraske's Operation, by J. M. Mathews, Louisville; Resection of the Knee for Separation of Lower Epiphysis of the Femur; Case of Two Years' Standing, in a Patient 13 Years of Age, by A. H. Meisenbach, St. Louis; Accidents and Injuries from Electric Currents of High Potential, by H. N. Moyer, Chicago; The Mental Symptoms of Cerebral Syphilis; A Clinical Study, by F. P. Norbury, Jacksonville, Ill.; Enlarged Tonsils and Their Treatment, by John North, Toledo, Ohio; My Experience

with Gold as a Therapeutic, by A. Owen, Evansville, Ind.; The Surgical Treatment of Injuries of the Head, by Chas. P. Parker, Cleveland; Headache, by Curran Pope, Louisville; Address on Surgery, by Joseph Ransohoff, Cincinnati; Syphilis, by A. Ravogli, Cincinnati; Reform in the Management of the Insane and the Neurotic Viewed from a Gynecologic Standpoint, by Chas. A. L. Reed, Cincinnati; Retinitis Syphilitica, by D. S. Reynolds, Louisville; The Spine and the Elevator, by B. M. Ricketts, Cincinnati; Infantile Paralysis, by John Ridlon, Chicago; President's Address, by X. C. Scott, Cleveland; Climate and Tuberculosis, by S. R. Solly, Colorado Springs, Colo.; Toxicity in the Production of Nervous Diseases, by A. E. Sterne, Indianapolis; Constipation from a Surgical Standpoint, by Leon Straus, St. Louis; Laparotomy for Pelvic Diseases no Longer Necessary, by R. Stansbury Sutton, Pittsburg; Topical Treatment of the Air Passages; With Exhibition of a New Atomizing Vaporizer, by H. M. Thomas, Chicago; The Importance of Urinalysis in Diagnosis, by A. B. Walker, Canton, Ohio; Reflex Irritation as a Cause of Disease, by E. Walker, Evansville, Ind.; Address on Medicine, by J. T. Whittaker, Cincinnati; Tumor Albus of the Knee Joint, by W. E. Wirt, Cleveland; Influence of Inflammation of the Seminal Vesicles in Maintaining Gleet, W. N. Wishard, Indianapolis; Modern Antiseptic and Aseptic Midwifery in Private Practice, by E. G. Zinke, Cincinnati.

The railroad rates for this meeting will be one fare for the round trip. A special train will leave St. Louis for Hot Springs, Sunday night, November 18, via Iron Mountain Route. A stop of several hours will be made at Little Rock, Ark., on Monday, November 19.

It is requested that all who contemplate making this trip, arrange their plans to join the official train at St. Louis, Sunday night, November 18.

FREDERICK C. WOODBURN, Secretary.

399 College Avenue, Indianapolis.

PUBLIC HEALTH.

To Health Officers.—Boards of Health desiring to communicate information to the Public Health Department of the JOURNAL will please address the EDITOR of the JOURNAL.

The Epidemic Contagious Diseases.—Toward the close of October there was a decline in the incidence of typhoid fever throughout the country, a marked increase in the prevalence of diphtheria and only a slight increase, if any, of smallpox—in fact, except in Milwaukee, this disease has been stationary or slightly declining. In that city, Dr. Wingate, Secretary of the Wisconsin State Board of Health, reports, October 29, the situation "not improved," 71 new cases, with 15 deaths, having occurred during the week, and 151 cases remaining under treatment at that date—71 cases in hospital and 80 at their homes. The opposition to removing patients to the isolation hospital continues active and the warfare on Health Commissioner Kempster is still being carried on. The State Board of Health is prohibited from interfering until this attack ceases, and it is feared now that the disease is so widely and firmly lodged that "it will only cease to exist after it finds no more material to feed on." Elsewhere in the State there has been an outbreak among the Indians on the Oneida Reservation, and there are four cases at Two Rivers; all outbreaks, outside of Milwaukee, are taken charge of, more or less directly, by the State Board of Health, which sees that proper preventive measures are enforced. In Chicago the disease has been practically stationary during the last three months, the number of cases under treatment daily ranging between fifty and eighty; at the close of the month there were seventy-one cases in hospital, whither all patients are at once removed. Dr. Baker, Secretary of the Michigan State Board of Health, reports an aggregate of twenty-nine outbreaks, in twenty-three localities, with 160 cases and thirty deaths, since Jan. 1, 1894. At date of report, October 24, there were thirty-six cases remaining in the State—at Detroit, and in Jackson and Washtenaw Counties. Dr. Baker adds: "In the twenty-nine outbreaks there have been on the average 5.5 cases and one death; in eighteen of the twenty-five outbreaks now over, the infection was restricted to the one house in which it first occurred." Another case developed on the 28th ult. among the employes of the Interior Department at Washington, making a total of seven cases with two deaths thus far reported; the latest victim

was a colored messenger, being the third messenger attacked. The other smallpox localities of the month were Walkerton, Ind., Angola, near Buffalo, N. Y., Newark, N. J., and Port Jervis, N. Y., the latter the most serious. Dr. Benj. Lee, Secretary of the Pennsylvania State Board of Health, reports that, except three cases of smallpox in Philadelphia on the 22d ult., the State was free from the disease. On the whole, the smallpox situation is far from alarming at this date, although there are still occasional importations—two cases being reported October 28, on the steamship *Lucania*, at the port of New York.

Diphtheria has been reported in an epidemic form at localities in Massachusetts, New York, New Jersey, Pennsylvania, Kentucky, Ohio, Indiana, Illinois, Michigan, Wisconsin, Minnesota and Nebraska; and typhoid fever at localities in New York, Pennsylvania, Ohio, Michigan, Wisconsin and Iowa. The area of incidence and the severity of the disease seems to be increasing for diphtheria and decreasing for typhoid.

The Prevention of Diphtheria.—The following is self explanatory, and is furnished for publication by the Health Department, 301 Mott Street, New York.

NEW YORK, Sept. 28, 1894.

CHAS. F. ROBERTS, M.D., Sanitary Superintendent.

Sir:—We desire to direct the attention of the Board of Health to the necessity for the adoption of some more adequate means to prevent the extension of contagious disease in tenement houses and apartment houses, and particularly for the enforcement of isolation of persons sick with these diseases. The methods which have been long employed in the Health Department, *i. e.* frequent visitation and instruction by Department Inspectors, have been found to be only partially effective. It has been the custom for years, in cases of contagious disease, for the Inspectors of the Department to visit the families of the sick persons, inform them as to measures of disinfection and methods of isolation, and at the same time to notify other families in the house, of the existence of a case of contagious disease in a given apartment. This method of giving publicity to the case and of warning other occupants of the house is ineffective in the accomplishment of the desired end; *i. e.*, the complete isolation of the patient and the prevention of further infection. Notifying all the inmates of a large tenement is a very difficult matter, and, if notified, experience has shown that they soon forget the existence of illness in the house. Repeated inquiries have demonstrated the fact that frequently many of the inmates of the house where there is a case of contagious disease do not know of the existence of any sickness.

Further than this, this method fails entirely to protect strangers or visitors who may go to the house or apartment. Ladies in search of servants have been repeatedly found in houses or in apartments where cases of contagious disease were present, and servants who have been living with families where there are cases of contagious disease, on obtaining situations frequently go to their employer's house carrying infection with them; or, when relieved from duty for an afternoon or evening, visit where there are cases of contagious disease and not infrequently carry infection back to the houses in which they are employed. Very commonly, washing or various kinds of sewing is secretly done by other members of the family in apartments where such cases are ill, and the garments thus infected on the premises are later returned to the owners. In small shops, business is sometimes carried on, and in one of several instances recently, a number of cases of diphtheria were directly traced to an infected candy store.

Notifying inmates of the house is ineffectual further, because it has been found that, as a rule, intercourse of families in tenement houses is not with others in the same house but with families which live in other houses, and the latter are entirely unprotected by the methods at present followed.

It has seemed to us after careful consideration of this subject that the desired object would be best obtained by the placarding of apartments in tenement houses where cases of contagious disease exist, and we therefore have the honor to recommend that hereafter the Chief Inspector of Contagious Diseases be authorized, in his discretion, to placard apartments in tenement houses where there are cases of contagious disease. The following considerations may render still more apparent the necessity for this action:

1. Under the present conditions it is impossible to prevent strangers and visitors from entering apartments where there are cases of contagious disease, and they or their clothing thus frequently become infected, and either they contract the disease themselves or they transmit it to

others. These strangers or visitors are usually not aware of the existence of disease in the house or apartment, and unwittingly expose themselves and act as media for the dissemination of the disease. If apartments were placarded, this means of dissemination would be prevented.

2. In diphtheria, as has been repeatedly and abundantly shown by the investigations of this Department, patients are often apparently well long before they are free from the infectious agents, and in spite of repeated warning from Department Inspectors these patients, especially when children, mingle with other children and thus transmit the disease to them. This is one of the most common and important means for the dissemination of diphtheria, and it is of no less importance in scarlet fever and measles, as in the latter diseases desquamation frequently continues many days after the patient has apparently quite recovered.

3. There are at present no means by which other inmates in tenement houses can know when convalescent cases of contagious disease have ceased to be dangerous. They can only be governed by appearances, which, as we have seen, are deceptive. If apartments where cases of contagious disease existed were placarded, isolation would be enforced by the other occupants of the house until the Department Inspectors allowed the placards to be removed.

4. The moral influence of such placards, both upon the inmates of the apartments, the inmates of the house and strangers or visitors to the house would be of as great service in enforcing isolation and preventing extension of disease as the visits and instruction of our inspectors. It has been found impossible, even where daily visits were made by medical inspectors, assisted by the Sanitary Police, to enforce the isolation of children convalescing from diphtheria and scarlet fever after the serious symptoms have disappeared. It is undesirable at such times, unless absolutely required, to remove such patients to the hospital and yet in the eruptive fevers this is the period of the disease when there is greatest danger of transmission to others.

During the last year we have had a serious epidemic of diphtheria to deal with. The number of cases reported weekly during the last months, however, has steadily decreased. The schools have just now opened, and it seems to us that the most strenuous efforts should be made to prevent a new outbreak of the disease or its re-introduction to the schools. This measure would be of undoubted service in accomplishing the desired object.

We would recommend, therefore, that placards should be nailed to the outside doors of the apartments in which cases of contagious disease are present, when in the judgment of the Chief Inspector of Contagious Diseases this course seems to be desirable, and that the placards should bear the following inscription, differing as to the name of disease in question and as to color. The color for diphtheria should be white; for scarlet fever, red; for measles, blue.

DIPHTHERIA.

"All persons not occupants of this apartment are notified of the presence of diphtheria in it, and are warned to avoid entering it until this notice is removed. The persons sick with diphtheria must not leave as long as this notice remains here.

"The removal or defacement of this notice is forbidden.
By order of the Board of Health.

"_____, President.

"_____, Secretary."

For some months in certain classes of tuberculosis the system of placarding apartments has been authorized and employed by the Health Department, and has proven very satisfactory in the attainment of the object desired. The only objection apparently to be urged against this measure is that the inmates of the apartment may object to the publicity thus entailed. This, however, is exactly the object which the measure is justly and properly designed to subvert, and is, in our opinion, the strongest argument in favor of its adoption. Respectfully submitted,

(Signed.) HERMANN M. BIGOS,
Bacteriologist and Director of the Bacteriological Laboratory.

A. H. DOTY,
Chief Inspector of Contagious Diseases.
The above report was approved by the Board of Health of the Health Department of the City of New York at a meeting held on Sept. 28, 1894.

(Signed.) EMMONS CLARK,
Secretary.

Brooklyn Board of Health Regulations Against Diphtheria.—An unusual prevalence, and mortality by diphtheria have vexed

the sanitary officers of Brooklyn. The following circular of information has been prepared for general distribution by the sanitary corps, especially among physicians and afflicted families. It contains reference to the free proffer of bacterial diagnosis, and to the new plant for disinfection:

Diphtheria is a contagious and infectious disease and may be conveyed directly by coughing, spitting, sneezing or kissing, or indirectly by the use of infected articles such as clothing, towels, napkins, handkerchiefs or dishes used by the patient. The germ causing the disease is very resistant and may exist in infected articles for months. When a suspicious case of sore throat occurs in a family, the patient should be isolated, and the family physician or this Department should be notified, when a culture can be taken free of cost, to determine the nature of the case. If it is found to be true diphtheria the isolation should be continued, preferably on the top floor, if possible in a well ventilated and sunny room from which all unnecessary furniture and hangings have been removed. As far as possible the patient should be nursed by one person, and no one but the physician and nurse should be admitted to the sick room.

All clothing that can be washed, which has come in contact with the patient, should be placed by the nurse, or under the direction of the physician, in a solution of corrosive sublimate, two drachms and a teaspoonful of salt to a gallon of warm water in a wooden vessel for one hour. The clothing should then be removed and boiled for one hour in water. It should be remembered that corrosive sublimate is a powerful poison and should be handled with care. Soft rags should be used instead of handkerchiefs for receiving the discharges from the nose and throat and immediately burned after using. Non-metallic vessels used to receive the discharges from the patient should contain some of the above mentioned solution. Children from the infected house should not be allowed to attend schools of any kind, or other gatherings, until the patient has thoroughly recovered and the premises have been disinfected.

In order to determine the time when the patient is free from contagion, secondary cultures from the throat are recommended, as a basis for the final disinfection and raising the quarantine. The usual quarantine can often be shortened by this means. Proper disinfection can best be done by those trained to the work and thoroughly acquainted with the most improved methods. The Department is now in a position to perform such disinfection free of cost. In case of death the body should be completely wrapped in a sheet wet with corrosive sublimate solution.

MISCELLANY.

Dr. Alonzo Garcelon.—A recent letter from Dr. Garcelon gives a pleasant reminder of his restoration to health, and his many friends who were alarmed at his condition on the ASSOCIATION train and at San Francisco will take pleasure in congratulating our venerable ASSOCIATION Fellow, on his recovery.

Medical Congress of Mexico.—The second biennial Medical Congress of Mexico will be held November 5-8, at St. Louis Potosi. Dr. Eduardo Liceaga, President; Dr. Luis Ruiz, Secretary, both of the city of Mexico; Dr. Jesus E. Monjaras, Chairman Local Committee of Arrangements, St. Louis Potosi, Mexico.

The Business Law Weekly.—J. L. Rosenberger, Esq., who for several years furnished the reports of decisions of the Courts for this JOURNAL likes the business of journalism so well that he has established a weekly for the use of business men, which as its name indicates, will give them each week the summary of the decisions bearing upon business affairs. The long experience of Mr. Rosenberger in this particular line, and his journalistic training make it reasonably certain that the *Business Law Weekly* will become an authoritative and successful publication.

Air-Testing in Mines.—An acoustic apparatus, called the "formerophone," has recently been proposed for determining the proportions of gas contamination of subterranean air. The testing is done by organ pipes, one of which is

sounded in the mine air, the other being inclosed in a box containing atmospheric air. The sounds are produced by means of bellows, and can be compared by those having a suitable amount of training in sound reading. It has been noted that the sounds emitted by pipes are affected by the air with which they are fed, so that two pipes having the same normal pitch may be used simultaneously in different media and the results be compared. The standard of comparison is an organ pipe inclosed in an air-tight box containing pure air. The other pipe is fed with the air of the mine or chamber to be tested. The sound thus produced varies from the pure tone of the standard in proportion to the quality and quantity of the gas contained in the air thus fed to the pipe.

Chinese Account of the Origin of the Plague.—Dr. Yersin forwards to *Le Progrès Médical* the following explanation which, he says, is current in Shanghai: The Dowager Empress always has eighteen lamps burning, representing the eighteen provinces of the Chinese Empire. Some time ago one of the lamps burned very poorly, although it received exactly the same treatment as its neighbors. The chief astrologer was consulted and, after carefully examining the case, he announced that this lamp represented the province of Canton and that the province was about to be smitten by a pestilence which would carry off eight-tenths of the population—this was decreed by the God of Sickness. The Empress, much affected by this information, asked if the terrible fate menacing the people of Canton could not be averted. The astrologer answered that the god might be touched by prayers and offerings. These being attended to, the Empress asked what result had been obtained. The chief astrologer then carefully examined the situation anew and declared that the god would be satisfied with a compromise—that he would take four-tenths in human beings and an equal number in rats. This is why rats have suffered equally with the people from the plague in Canton and Hong Kong.

Facetia.—The following are the views of several journalists upon an important medical topic:

A GRIM VIEW OF IT.—The death of an ossified man in Tennessee is reported. He died hard.—*Chicago Tribune*. This is as bad as the man who swallowed a thermometer and died by degrees; it suggests also the case of the consumptive undertaker who died of a coffin.—*Medical Record*. These remind us of a man who choked while eating an apple, and died of applepox.—*National Medical Review*. It was in a St. Louis hotel that a Pike County farmer blew out the gas, and died from gastritis.—*Myer Brothers' Druggist*. Not any worse than the man struck by an engine; verdict died from locomotor attackia.—*Montreal Pharm. Journal*. Still worse the case of that pie-eating dyspeptic of Tiflis, for he died of piemia, superinduced by typhlitis.—*Gaillard's Med. Journal*. The other day a negro in Southern Georgia ate six water-melons. He died of, meloncholia.—*Atlanta Med. and Surg. Journal*. Very good; but have you ever heard of the circus man who was accidentally sat down upon, during a performance, by the largest pachyderm in the menagerie. He died of elephantiasis.—*American Practitioner and News*.

This reminds us of the man who "took the cake." He still lives; a victim to the *cacoethes capiendi*.

Inspection of Bakeries.—A somewhat sensational report has been published in the *New York Press* regarding the unwholesome underground places where bread is made in that city and adjacent cities. Some of the bake-shops are kept tidy and in good repair, says the *Press*, but the rule is the reverse. The remarkable fact is brought into view that the inspection and licensing of these important branches of food preparation have in few cities received any attention, and that few boards of health have any explicit jurisdiction over bake-shops. Now that the attention of sanitarians has been pointedly called to this subject, it is more than probable that special powers and special legislation will be sought. It is worthy of mention that London—the senior in sanitation of all our American communities—has only recently taken up this subject, and better laws are being demanded. Dr. Orr, of London, has expressed the opinion that the outcry against the bake-houses of English cities has been overwrought, for he considers that from the very nature of the business these houses must always be to a certain extent unhealthful. All conditions of unfitness, above the necessary minimum, can be met under the general powers of the Public Health Act and the by-laws governing the County Council (for London) and cognate bodies for the country at large, without the increase of power by new legislation.

The ordinary situation of bakeries, in cellars, can not be regarded as a fortunate one, and it may in the future be found necessary to bring those indispensable works, as well as ice-creameries and the like, up into closer relation with fresh air and sunlight. It is true that the brunt of the daily operations falls in the night, and sunlight is not an essential to the labor and its product, but is highly desirable for the well being of the laborer.

The Horace Wells Anniversary Celebration.—The following circular has been issued: Members are doubtless aware of the action of the American Dental Association at its recent meeting held at Old Point Comfort, Va., with reference to holding a national celebration of the fiftieth anniversary of the discovery of the anesthetic properties of nitrous oxid, by Dr. Horace Wells. The Committee by vote of the American Dental Association, was instructed to secure two papers to be read at the celebration. One upon the "History of Anesthesia," by Prof. Thomas Fillebrown, of Boston; and one on the "Benefits of Anesthesia to Mankind," by Prof. James E. Garretson, of Philadelphia. The Committee was further instructed to arrange for a banquet to follow the meeting, at which distinguished speakers shall make appropriate addresses. A full report of the celebration, including the papers and addresses to be printed and issued, as a permanent souvenir of the occasion. Arrangements have been completed to the extent of securing favorable responses from the essayists named, whose papers are now in course of preparation. The banquet arrangements are also largely completed. To cover the expenses attending the celebration, the fee for admission to the banquet has been placed at \$6. It is necessary that the Committee shall have ample notice of the number who will be in attendance, in order that places may be provided for all who may desire to attend.

Subscriptions will be invited later for the souvenir volume, at a price sufficient to cover the cost of publication.

The celebration will be held in Philadelphia, in Association Hall, Fifteenth and Chestnut Streets, on Tuesday, Dec. 11, 1894, at 2 P.M., and the banquet at the Union League at 6:30, same evening. You are cordially invited to participate in this event, which should enlist the enthusiastic support of every member of our profession. To that end you are requested to send your check and notify the Chairman of the Anesthesia Committee, at the earliest date possible, in order that an official invitation may be sent to you.

It will be proposed at the meeting that subscriptions be invited for a permanent memorial, to take such shape as the meeting shall decide.

J. D. THOMAS, Chairman.

912 Walnut Street, Philadelphia.

Aluminum for Military Uniforms and Equipments.—The weight carried by the German infantry soldier, including emergency rations and 150 cartridges, amounts to 73 pounds, or a little more than half the weight of the average soldier, 143 pounds. The field kit of the Russian infantryman weighs 65 pounds, of the French 63, of the Austrian 63½ and of the Italian 57 pounds. Medical authorities are said by military writers to have proved that a man can not, for any length of time, carry more than one-third of his own weight without impairing his powers of action. Professor Fraentzel, of the Berlin University, in examining a number of men who had fought in the Franco-Prussian war, found many affected with heart disease due to the severe strain of forced marching with the full kit. Influenced evidently by these considerations, the German Emperor directed inquiry to be made to ascertain how the weight of the field kit could be reduced. The experiments were made during the autumn maneuvers of the present year, and as a result it is said that the weight to be carried by the German soldier will hereafter be about 57 pounds. A good deal of this lessened weight is due to the substitution of aluminum for brass or other heavy metals. The aluminum canteen, cup and individual cooking vessel have, according to the notes of our Military Information Bureau, been in use in the German Army since 1893. Aluminum has been adopted for the buttons of the shelter tent and for the sockets of its poles, as also for the boxes to contain the field ration.

A patented alloy of the metal, known as Victoria aluminum, whose component parts, the manufacturer claims, can not be determined by analysis, is said to have a much greater tensile strength than the pure metal and to have a specific gravity of 2.8 to 3.4, according to its hardness, as compared with 2.7, the specific gravity of aluminum. Horse-shoes of this alloy are said to have been found satisfactory, but have not as yet been definitely adopted. Stirrups identical in appearance with the large steel hunting stirrups, stood the

ADDRESS.

CHAIRMAN'S ADDRESS.

Read in the Section on Dental and Oral Surgery at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY M. H. FLETCHER, M.S., M.D., D.D.S.
CINCINNATI, OHIO.

As chairman of the Section, I received from the Secretary of the ASSOCIATION, a circular of information regarding this meeting. Among other items the circular has the following paragraph copied from the By-Laws of the ASSOCIATION:

"The chairman of each Section shall prepare an address on the recent advancements in the branches belonging to his Section, including suggestions in regard to improvements in methods of work, and present the same to the Section over which he presides, on the first day of the annual meeting. The reading of such addresses not to occupy more than forty minutes."

I will gratify you by complying with the last sentence of the By-Law; the others I endeavor to heed.

As to the progress in dentistry,—some points excepted—the name is almost a synonym for advancement, especially in America. The changes which have been made in the past forty years in dentistry must be familiar to all, and if you will recall these changes you will find they relate more largely to the art than to the science of the profession.

An editorial of the *Cosmos* in the last April number says: "In its scientific phase, the growth of dentistry has not kept pace with its development as an art, probably for the simple reason that manual skill is more easily acquired than scientific culture. The disproportionate growth of the dental art, as manifested in the many delicate and precise methods and manipulations which characterize it, is also no doubt largely attributable to the more material fact that the development and exercise of the art is immediately productive of financial return, while the results of the scientific work are seldom or only remotely convertible into money value. "This is particularly the case, when scientific investigation is pursued solely for the purpose of arriving at a knowledge of abstract truth."

It certainly is no discredit that the art has reached so high a state in this country, whether it be from greed of gain, the necessity of bread winning, or the infatuation of invention.

The highest possible attainments in the art of dentistry can not accomplish much without at least some knowledge of the science of the calling. Shakespeare has said: "There was never yet a philosopher that could endure the toothache patiently;" as practitioners of dentistry we all know this to be true. Now is the only relief from this unbearable of maladies, the extraction of the offending organ? To many so-called dentists, I am sorry to say it is. To properly diagnose the cause, and relieve the patient

of pain, requires a knowledge of the laws of health and disease; and these are only acquired by study of the facts brought to light, may be by empiricism, but most likely by the untiring labor of men who have given time, thought and labor to the subject, and in which they are truly interested, and this often means the sacrifice of money or health and perhaps both. A few nights or days do not suffice to bring new truths to light, but years of training are required to establish a habit of scientific thinking.

In the article from the *Cosmos* quoted from above, we read further that: "It is not given to all men to be scientific investigators in the broad sense, but it is after all largely a question of degree, for every one is or should be capable of observation, and the ability to correctly interpret and report the result of such observation is simply a question of practice and training."

An eminent physician who came to me as a patient this day, asked the following very pertinent question: "With all the recent advancements in physiology, pathology and painless surgery, why is it that you dentists have not relieved your specialty of the horrors attending the most frequent operations which you are called upon to perform?" The only answer I could give was that we simply lack the scientific advancement. A recent editorial in one of our most prominent medical journals has the following: "The dentists of America are the best in the world, but they are nevertheless away behind the mark. We appreciate their ingenuity, their skill, their drills and dams, their composite fillings, and artificial teeth; they make the best kind of gold crowns, but do not deserve to wear them; this is because they do not sterilize themselves or teach their patients how to prevent caries. They are wonderful patchers up of things half gone, but do not show how to prevent the going."

"There is hardly a dentist (there are a few) who works in an aseptic way, or uses aseptic instruments; some do not know better, some do not think it necessary. But both are wrong; the one class should learn, the other should think. How many dentists can tell surely when they are dealing with a syphilitic mouth? Yet if such a mouth is being treated, we do not believe that any one would like to be the next patient, though the dentist should wash his hands."

A recent decision in the Supreme Court in the State of Missouri, to the effect that dentists are not exempt from jury duty, as are physicians and surgeons, is another index to the public estimate of our position.

It seems to me it is quite a healthy thing for us "to see ourselves as others see us," after this manner; especially if we wish to improve. And right here I should like to ask a question for each to answer to himself, or to another, and that is, How many

really learned men have we in the profession? We all have the title of Doctor. Definition No. 1 given in the Century Dictionary to the word Doctor, is as follows: "A teacher; an instructor; a learned man; one skilled in a learned profession." Let us answer the question, How many of us deserve this title? How many of us are capable of recognizing a scientific truth, when it presents itself to us? A master of science (which title is given as a synonymous term to that of Doctor) need not necessarily be learned in the dead languages, nor a historian of note, nor even a literary man to any great degree, but he must be a thinker, one familiar with established facts in the sciences, and capable of using such facts; of applying them to the principles involved in the work before him. He must be free from doing a thing in a certain way because some one else does so, unless it appeals to his sense of reasoning as tested by established facts.

Now when we have a *large* proportion of such minds in the ranks of our specialty, instead of a very *small* per cent., such a question as asked by my friend, the doctor, would not be pertinent, nor such editorials as quoted from the *New York Medical News* have any point, but as it is now, they cut deeply, because they strike a defective place, and the future of dentistry, if she hold her own, must progress on a broader line of culture. Then we will *not* be "patchers up of things" to any one, and our specialty will be rid of many of its disagreeable and painful features both to patient and operator.

What is required to be an intelligent specialist, is most beautifully set forth in an address recently delivered before the American Academy of Dental Science in Boston, by the Rev. Reuben Thomas, which is of the more value to us because it does *not* come from one of our own specialty; I would advise its perusal to those of you who have not read it. It is to be found in the last January number of the *International Dental Journal*.

We have here some more wholesome ideas for mental digestion. These intelligent outsiders place us where we rightfully belong, without regard to any opinion, either high or low, which we may hold of ourselves. The reverend gentleman says: "By-and-by a volume will be published, I do not doubt, entitled 'Great Dentists,' as we now have volumes on great surgeons, great lawyers, great divines. But the time has not come for such a volume, as the profession is comparatively new. As a writer in the Encyclopedia Britannica puts it: 'For long, dentistry was practiced to a large extent as a superadded means of livelihood by persons engaged in some other pursuits, and without any professional education whatever. The blacksmith, the barber, the watchmaker, and others of the same class were the dentists of every village and country town; while even in some of our large cities, dentists of the same kind were till lately to be found practicing under the very shadow of our universities and public schools.' These words refer primarily to England, but they sufficiently well fit the past condition of things on this side of the ocean, if the speech of men of 70 years and upward is to be taken as reliable."

We do not have to refer to men of 70 for such things, for within six blocks of my own office, in the midst of an enlightened community of half a million of people, can be found to-day in the window of a barber shop a sign which reads: "Teeth extracted;

twenty-five cents." As a medical relic of the same character, I will state that within three doors of my office, is an old German barber who adds to his income by cupping and leeching, and other cities are probably not different from this.

We have numbers of charlatans in both dentistry and medicine who are little, if any, above these barbers in proper requirements for their profession. But these people must find some patrons, or they would not persist in their willingness to treat them, and the public certainly demands such people or they would not exist. We need an intelligent public to appreciate intelligent specialists; hence, the necessity of the recent discussion, and the suggestions of plans to "educate the public" which have been made in some of our societies and journals. The general public may need some enlightenment on this point; at the same time the more intelligent part of most communities not only values the profession at its true standard, but it distinguishes between practitioners, and places individuals on the proper round of the ladder; and if we wish a higher estimate we must merit it.

The dental ladder may be high or low, but whatever its height it certainly need be higher than it is. I think it is lengthening rapidly in some directions at least, especially as "patchers up of things." In its subdivisions on medicine the Encyclopedia Britannica gives one paragraph to dentistry which is as follows: "Dentistry or odontology is extremely limited in the range of its subject matter; but it affords great opportunity for refinement of technical skill, and it is given up to a dental branch of the profession."

Now all this goes to show that we are looked upon by thinking people as skilled artisans; and that if we are to be regarded as a learned profession, or a specialty of such a profession, we must be able to bear the test which is daily applied to us as a body; and in order to do this we must know all of dentistry, and a great deal more.

Our reverend brother puts these points very nicely; he says: "A learned man in our day, is a man who knows everything of something, and something of everything. Some of his knowledge must be microscopic, but most of the knowledge must be telescopic; he is minutely acquainted with some one thing, and generally acquainted with many things." Now if a learned man is a man who knows everything about some one thing, a learned dentist should be a dentist who knows everything that is knowable about teeth; but in order to do this he must know something about anatomy and physiology and much else besides. For anatomy and physiology are associated with psychology, and mental philosophy generally. He goes on to show what the tendency is, if the mind is not continually exercised in liberal culture. "The mind," he says, "of a specialist has a tendency to conform to the thing about which it is persistently and continually occupied." . . . "So far as his thinking goes, a man is apt to see everything through the spectacles that have invisibly come over his eyes, from the specialty with which he is persistently occupied."

To a mind at all familiar with the laws of mental philosophy this is a potent fact, and true not only of the profession as a whole, but of the specialists in the profession; the artisan through the particular branch of the art in which he is most interested, and the scientist through his special branch. He farther

says: "While, therefore, we pride ourselves on the wonderful advance we have made in dentistry and surgery and other departments of knowledge, and achievements during the last century, there is a necessity for reminding ourselves of the tendency of our age of specialists, to produce men in large numbers who are illustrations of *learned narrowness*; men whose minds are warped, sectarianized, and materialized; men whose world is a very much smaller matter than it would have been if they had given serious heed to other studies than the bread and butter studies of life. Moreover it ought to correct our tendency to conceit and self-congratulations, when we remember that with all our advances there are some things—yes, many things—which animals and even insects can do better than we can do."

You, no doubt, will say by this time that I take an extremely pessimistic view of the profession, advising you first to give more time in perfecting one's self in the speciality, and then saying that this tends to make us examples of "learned narrowness," and so I do, to a certain degree. I am not pessimistic on the subject, but I do say that our egotism and self-congratulations tend not only to make of us a profession of narrow-minded men, but to very greatly retard our progress.

I am fully alive to the fact that dentistry has reached a most remarkable position for a growth of fifty years, and am justly proud of being a member of such a profession, and for this very reason I am anxious that we fully comprehend our exact position, and the dangers ahead, in order that we may progress the more. "Let him who thinketh he standeth take heed lest he fall," is just as applicable to a body of men or a nation as it is to an individual.

Our advancement has been in much the same way as that of many of the arts. Take, for instance, the manufacturing of shoes or watches or the art of printing, the progress and improvement in these and other arts has been just as great in fifty years as that in dentistry, and the real advance in dentistry is only comparable to these arts; excepting in a few points. Other arts like dentistry have their associations for the interchange of ideas and the improvement of the art.

Within dentistry we have had some scientific truths established; for instance, the discovery of the cause of dental caries.

Again, by the combined experience of thousands of men for the past thirty years, the fact has been established that the system will tolerate a pulpless tooth after the pulp cavity and root canal have been obliterated. Again, atavism, and the etiology of the various deformities of the head, face, jaws and teeth have been scientifically studied by the examination and careful records of thousands of skulls and human subjects. There is also a creditable effort now in progress to establish scientifically the cause and proper treatment of pyorrhea alveolaris.

Aside from these few points, and the intelligent discussion of them, and that of the development of tooth structure, I know of nothing that has taken us beyond the advancements made in several of the mechanical arts.

Let some man or men among us formulate a practical plan whereby dental students can be educated to think scientifically, while they are being educated in the mechanical arts of the profession. Let some one rob dentistry of its horrors, by telling us how to

cut sensitive dentine, and insert a permanent stopping without pain; or better, let him give us a practicable prophylactic treatment for dental caries.

Hypnotism may and does accomplish something in the control of pain, but it is not practicable with many operators nor in all cases.

It would seem that the shortest and surest road to these desirable ends is in the proper mental training of the profession. A well balanced mind comes only from broad culture, and not from narrowness of any kind. Sir John Lubbock says: "By concentrating the attention too much on one or two subjects, we defeat our own object." By many, science is considered dry uninteresting work, but this must be only by those who have not tried it or have gotten the wrong conception of it, or a wrong start. I venture the assertion that there are few if any greater enjoyments to the human intellect than the acquisition of new truths. "A cultivated mind," says Mill,—"I do not mean that of a philosopher, but any mind to which the fountains of knowledge have been opened, and which has been taught in any tolerable degree to exercise its faculties—will find sources of inexhaustible interest in all that surrounds it; in the objects of nature, the advancement of art, the imagination of poetry, the incidents of history, the ways and means of mankind, past and present, and their prospects in the future."

This culture may be gotten by constant and persistent effort to comprehend the phenomena and facts by which we are daily surrounded and with which we hourly deal. Lubbock says, again: "The very process of acquiring knowledge is a privilege and a blessing, and if we succeed in gaining the love of learning, the learning itself is sure to follow."

Now when this desire for learning has fastened itself on, a majority of our profession, instead of only a very small number, then we will have more scientific discoveries, and merit the name of a learned profession instead of "patchers up of things." Then will we free our patients from pain, and other disagreeable things. Then we can feel with Bacon: "No pleasure is comparable to the standing upon the vantage ground of truth."

Then, too, as the Rev. Reuben Thomas has put it: "The time will be near at hand when a visit to the dentist will have no more terror in it than a visit to the physician who simply feels your pulse, and looks at your tongue, and asks you the usual questions, and then gives you a bottle of sugar-coated pills."

Let us achieve this end, for it can be done, and the avenues leading thereto will prove to be royal throughout.

DISCUSSION.

Dr. W. J. YOUNGER, San Francisco—The address of the Chairman is not altogether satisfactory because, it seems to me, it does not give dentists credit for what they have done. Its writer does not seem to appreciate to what plane dentistry has attained. There certainly has been a great deal of scientific work in dental circles during the last few years. As an evidence of this, the fact may be cited that the AMERICAN MEDICAL ASSOCIATION has acknowledged dentistry as equal in merit to the other specialties, and has adopted us as a distinct and recognized part of its organization in the formation of this Section. Dr. Fletcher appears not to understand what dentistry has done. I can very well remember when, forty years ago, the condition was as described in the address; but dentistry has lifted itself up, has gone beyond the carpenter and other artisans. We have, for instance, our colleges in which a scientific basis, at least, is laid for the practice of dentistry.

Dr. GILBERT S. DEAN, San Francisco—I do not now care to

discuss the phase of the subject presented by Dr. Younger, but the question of the standing of dentistry should be settled by others rather than by ourselves. There is no question that if we make ourselves a thoroughly scientific body the fact will be recognized. It may take time to accomplish this, but it certainly will come.

DR. L. VAN ORDEN, San Francisco—*I feel that we can not gather all there is in the paper from one reading. In one sense, at least, its writer deserves our thanks. As a profession, we are a little given to self-gratulation. If you recall the progress which has been made in the various arts, you can but see what tremendous strides they also have made. I have been accustomed to accept such statements as the paper refers to, regarding the unprecedented advances in dentistry, and I confess that I am somewhat startled at the possibility that what the paper stated as the actual fact might be so. It is very possible that the paper is correct in its estimate. There is no doubt, however, that the dental profession has a purpose of progress; but unless it is pursued in the spirit suggested by Dr. Fletcher, there will not be much real advancement.*

DR. EUGENE S. TALBOT, Chicago—*It is important that we should recognize the facts as they exist; the more so as the editor of the Dental Cosmos has lately taken up the subject of the scientific position of dentistry. This is a subject of great importance to us, and we have to face it. When we call ourselves a profession we do not know what we do. We are not a profession. Most of what we do is mechanical, and we are nearly to the end of our string in that direction. Take the program of any of the meetings of our State dental societies, and compare it with the program of fifteen years ago, and then say how much better that of to-day is than the older one. As an example, take the program of the Illinois State Dental Society at the last meeting. One of the first things is a paper on amalgam, but it is treated purely from the mechanical standpoint. Not any one knows what amalgam is, whether a chemic compound or a mechanical mixture. We know that it will preserve a soft tooth better than gold, but we do not know why. There is hardly a paper a year on dental subjects which has a bit of science in it; very few with anything new in them. A man can not in a week's time, or after he arrives at a convention, write a paper to be read before it that will contain anything new. That takes years of study. Take the subject of filling teeth with gold. There is nothing new in this line in the papers presented. We have had hardly one in twenty years up to the average of those of forty years ago. In order to improve we must get down to hard work along the lines of original investigation. The English, German and French, as Dr. Kirk says, know what science is. We should take up some subject in which we have an interest, a subject with which we are in love, and follow it steadily. The young man, for instance, should select such a subject, after which the first thing for him to do is to read everything that has been written upon it, digest the knowledge thus gained and write the facts, giving due credit to those from whom they were gained. Then, after a while, he is ready to begin to study it. Lest it be objected that this preparation is unnecessary it is proper to ask, Can you take up the microscope successfully without knowing what others have done with it? It takes years to learn what others have done, preparatory to any effective work, and after that it takes other years to learn something new on the particular subject pursued. I believe it is better to write one paper in ten years which gives something really new and valuable, than to write one every year which is only a rehash of what has been said and done by others.*

DR. C. S. LANE, Oakland, Cal.—*I think that dentists certainly have made creditable advances, and while we may be said to do good patchwork we are something more; are really good tooth doctors. For myself, I am sure that I do more thinking now than formerly, more studying, more doctoring, and I give my patients more instruction in the care of the teeth. The matter of the cleanliness and care of the teeth has received a good deal more attention at the hands of the dentists during the last ten years than previously. We look into cases more carefully than we did, and we save roots, when the crowns can not be preserved, better than we did; we apply medicaments that overcome adverse conditions better than we did. We are saving teeth and roots which were sacrificed then. We ought to be proud of the vigorous growth of our profession; of our progress in inducing great cleanliness. In combating the diseases we are called upon to treat, we are fully as successful as other specialists. A good practice, and one which I am accustomed to pursue is to give patients a little clinic at the chair*

every time they are in it, and I find that I have to tell them over and over again that all our efforts are useless unless they attend carefully to cleanliness.

DR. YOUNGER—*When we look through a window and find a prominent fly-speck upon it, it interferes with our enjoyment of the view presented. So when we put a young man through a course of study and grant him a diploma and then say his work is only on a par with that of a carpenter, it is like a fly-speck on the window. Otherwise, I agree with Dr. Fletcher, and thank him for his paper.*

FIFTY CONSECUTIVE INTRA-PERITONEAL OPERATIONS—ONE DEATH.

BY A. H. CORDIER, M.D.

KANSAS CITY, MO.

Any surgery that involves the handling of, and injury to life-essential organs, must of necessity require more care, judgment and skill than that in localities of less import to healthy and comfortable existence. Of all surgery that of the abdomen and pelvis entails the greatest risk to the life of the patient, hence the birth and existence of abdominal and pelvic surgery as a specialty. That it should be so separated from general surgery is amply proven by the comparative results of the specialist and the general surgeon. This paper is not intended to condemn the work of the general surgeon, neither is it my desire to laud the results of the work of the specialist, only in so far as it is necessary to show that a concentration of one's thoughts and education along a special line must of necessity beget more accurate deductions, and uniformly better results. It is not only necessary that the abdominal surgeon be able to quickly recognize any unlooked-for complications, but equally deft must he be in quickly devising and applying the best method to meet the indications in the case.

In reporting fifty intra-abdominal and pelvic operations with only one death, I anticipate that a selection of cases and a failure to report all deaths will be brought forward by some one. Many of these cases have been operated on in localities where the surroundings were not the best to conduce to a low mortality, yet by the free use of pure boiled water and soap, cleanliness and complete work, I have been enabled to maintain this low mortality. My cases have not been selected, only in so far as my past experience directed me was best for the future of my patient, *i. e.*, no hopelessly malignant cases have been operated on, save one case, at the earnest solicitation of friends and of the patient. An exploratory (?) incision was resorted to, to confirm my unfavorable prognosis, to *their* satisfaction. This case is tabulated because I desire to lay stress on the fact that to me it was not an exploratory incision, (my diagnosis was made prior to the incision) and incidentally to call attention to the fact that too many diagnoses are made only after the abdomen is opened. It does not show a profundity of knowledge to hear an operator and teacher say to his class: "I have here an abdomen, and in the abdomen a tumor. Whether it is from the uterus or the liver it matters not," etc. No opinion is worse judgment than a wrong diagnosis.

Most of my work is done in hospitals where trained abdominal nurses can be in constant attendance, and where my visits may be as frequent as possible. It is far easier to prevent a peritonitis than

to cure it after it has once gained a stronghold. My only death in the series was in a private residence, but it was not due to the surroundings so much as to the condition of my patient at the time of the operation. It requires more time and care on the part of the operator in making and maintaining favorable surroundings in a private residence than in a hospital. I have endeavored to have a trained nurse with all my cases in private houses, yet in some instances the family physician and myself have assumed the whole responsibility. The best results are obtained in hospitals.

The patients have been secluded as much as possible from the meddlesome presence of friends and relatives for several days following the operation.

My patients have in all cases, except the emergency cases, had from three days to a week of preparatory treatment, consisting of dieting, purging with salines, douches, enemas, baths, and as a routine, *tr. nux vomica* in 15 drop doses, three times a day. I do not starve my patients before the operation, but a period of fasting begins on the morning of the day set for the operation. This is kept up for forty-eight hours, or longer, if symptoms of a peritonitis develop, or nausea from the anesthetic persists. If necessary, a nutritious rectal enema is given each four or six hours. This method of nourishing the patient will relieve the vomiting often, and at the same time relieve the intense thirst.

I withhold liquids from the stomach for at least twenty-four hours. This starves the tissues for water, causes the peritoneum to drink up any fluids in its cavity, and thereby diminishes the culture fluid for the growth and multiplication of any microorganisms that may have gained entrance during the operation, from outside sources or by any unavoidable accident liberated during the breaking of a septic cavity during its enucleation. I have avoided raising the temperature of the operating room above a comfortable warmth, (70 to 80 degrees F.) believing as I do that a patient may become much exhausted from a protracted sweat inaugurated in a superheated operating room. I have operated, when possible, in the forenoon. This gives the operator several hours of daylight to see his patient after the operation is completed, and the patient goes on the table soon after a night's rest, and not too long after the beginning of the fasting period. I get along with as few assistants as possible, one usually being all that is necessary to wash and handle the sponges, and assist in the handling of hemostats. No one but myself and this assistant is permitted to touch an article or instrument that is being used in the operation.

I make all my preparations for operation, such as scrubbing the instruments, washing the bowls, etc., and I use my own instrument trays. I have used no antiseptics in my work, but have relied upon thorough cleanliness and pure, boiled, filtered water. I am a firm believer in the bacterial origin of septic processes, but believe that these microorganisms can not exist in dangerous numbers where thorough cleanliness is obtained, and boiled, filtered water freely used.

Visitors at an operation are asked to refrain from talking, and to maintain their positions. This prevents any confusion on the part of the operator from remarks made by onlookers, and causes less dust and other floating particles to be moved about the room and into the field of operation.

In this series I have not used a sponge. The flat gauze pads have been used in each case. They are easily made pure by boiling at the same time with the instruments. I prefer the regular sponge, but too much care and time are required in their preparation. I have used only the purest and strongest Chinese twist for my pedicle ligatures, using the smallest possible strand compatible with safety. In none of my cases have I had cause to regret the use of silk ligatures. In my intestinal sutures and work, the same material has been used. I boil, at each operation, only the amount I anticipate that I will need. A second boiling weakens the silk. Any left over is thrown away. I use silkworm gut sutures for the parietal incision. The same precaution is used here as that observed in the preparation of the silk ligatures. I use very few instruments in my abdominal work. They are always boiled just before using.

Ether has been the anesthetic in most instances, and has not produced any more unpleasant after effects than chloroform. I endeavor to have the anesthesia as short as possible, by having every preparation for the operation completed before the anesthesia is begun.

The abdominal incision is made in the median line, and is as short as is compatible with easy manipulation. A short peritoneal incision minimizes the risk of septic material entering, prevents escape and consequent handling of bowel, and reduces the number of post-operative hernia.

Many of these cases have been pus cases (ovarian abscesses, appendicitis, etc.,) and have required the free use of irrigating fluid—pure, boiled, filtered water. I have used in my irrigations from two to eight gallons of water. In every case where it has been necessary to use irrigation there I have also introduced a drainage tube. The more I use the tube the more am I convinced that it is a life saving device. I never regretted having used the tube, but have had occasions to lament its absence. Even though the doubtful drainage case recovers, the convalescence will be more tardy and less comfortable than if the tube had been used. The vomiting has been more persistent, the bowel less responsive to salines and injections, and the gas pains of greater intensity. If I had to abandon the use of the drainage tube in abdominal surgery, I am sure that the mortality would be increased very much. There is a wrong way and a right way of using and caring for the drainage tube. Those using it correctly will continue to use it. Others will abandon it, and hunt for something new to try.

The after care of my cases has been one of vigilance, that any untoward symptoms might be quickly discovered and early remedied. It is easier to prevent or avert life destroying post-operative complications than it is to cure them when once fully established. It is impossible to give definite rules as to when food and drink should be given these cases. Each case is an individual, and should be treated as such. The judgment and experience of the operator must dictate in each case what course to pursue. It is safe to say that the less fluids and nourishment the patient gets for forty-eight hours, the better will he or she be for this abstinence.

I will endeavor to give a brief summary of the pathology and manner of dealing with individual cases.

The two cases of cholelithiasis presented histories of cystic obstruction, accompanied by the usual recurring painful exacerbations and corresponding interval of comparative ease and comfort. The stones were from the size of a millet seed to that of a filbert, one case having five, and the other some forty odd stones.

The operations were completed at one setting, stitching the gall bladder into the parietal incision, as recommended and practiced by Tait and Price. A rubber drainage tube introduced into the viscus was allowed to remain from two days, in one case, to a week or over in the other. Both continued to discharge more or less bile for several weeks, but ultimately closed, and have remained closed.

My patient on whom I performed the intestinal anastomosis was in a most desperate condition at the time of the operation. No bowel movement for fourteen days, vomiting feces, and in collapse at time of operation. Obstruction due to band across a coil of the ileum, distended gut ruptured above the stricture, feces in peritoneum at time of operation. Lateral anastomosis with the Murphy button. This patient carried the button for one hundred and six days. He has remained perfectly well.

The six ovariectomies were on patients from 22 to 56 years of age, the growths being from the size of a goose egg to that of a good-sized coal hod. Some of the cases were firmly attached to all structures with which they were in contact. Others were very simple, easy operations. Drainage was used where there existed many adhesions, as a precaution against hemorrhage, or part of the contents of the cyst were spilled into the peritoneum during the operation. In two of the cases both ovaries were removed because of evidence of early cystic development.

This young married woman, while shopping, became faint and was taken home in a carriage. A physician was called, and as her general symptoms were those of an early miscarriage, she was so treated for five days. I saw her at this time, and advised an operation. She was bloodless and septic. Operation revealed abdomen full of blood, and a large abscess on one side of the uterus. This was unavoidably ruptured in its removal. Irrigation and drainage failed to save her, as she had a progressive sepsis (true septicemia) at time of operation. Very early surgery would have saved this case also. The tubal rupture had set free more septic material than her weakened and anemic resistance could withstand.

The Tait operations (the removal of healthy appendages) to check the hemorrhage and growth of multinodular uterine fibroids, have been very satisfactory so far. These operations, while usually very simple and easy of performance, are occasionally most difficult to perform, owing to the difficulty in getting the adnexa up into the abdominal incision while ligating. Such was one of my cases. Two easy cases of removal of cirrhotic ovaries for pain *antedating several days the menstrual flow*, are included in my tabulation. In both the cases a varicose state of the Pampiniform plexus was noticed. In both the cases the pains have been relieved, and the results are all that could be desired. This comparatively rare pathologic condition, from its importance, demands more attention from the pathologist and surgeon, even though it be admitted that it is only the result of a chronic interstitial ovaritis, simple or infectious. (Smallpox, etc.)

Four abdominal hysterectomies have been for the removal of non-malignant neoplasms of the uterus. The pedicle has, in each case, been anchored in the lower angle of the incision, the Koeberle sœur-nœud, and wire being used in all. The pedicles have come away within fifteen days, and there have been no fistulæ or herniæ in a single case.

The six vaginal hysterectomies have been performed for malignant disease of cervix in four cases, and for procidentia with suppurating appendages in two. The clamp has been used in each case. No hemorrhage and no untoward results have accompanied the use of the clamps, or followed their removal. The malignant cases have not been far advanced, thus insuring the least risk of recurrence.

Hysteropexy is an operation that, in my experience, is of inestimable value, but we must not lose sight of the fact that, in the majority of these cases, the operation that fixes the uterus to the parietes also breaks up many retro-uterine adhesions, thus liberating other sound imprisoned organs as well as the uterus.

I have used silkworm gut sutures through all the structures, including with the sutures an inch or less of the uterine fundus.

Two of the cases of appendicitis were operations done during the primary attack. Two had had a number of severe spells. The other was a recurring case, with a large walled in abscess. In this case the appendix was found lying loose in the abscess cavity, having sloughed. This case was drained, as were the two cases with recurring histories.

The stabbed wound case demanded an operation to stop bleeding from divided mesenteric vessels, and to remove and clean a portion of the omentum that was protruding and infected.

| | No. of cases. | | Died. | Recovered. | Drainage. | Both sides removed. | One side removed. | Metrostaxis. | Ether. | Chloroform. | Remarks. |

| Exploratory operation (so-called) | 1 | 1 | 1 | 0 | | | | | 1 | | Malignant uterine and omentum. |
| | 50 | 54 | 149 | 26 | 24 | | 9 | 20 | 46 | 4 | |

In five cases of undoubted extra-uterine pregnancy, tubal rupture had taken place in every case before the eleventh week. In one at the end of six weeks. In one case a peritonitis had developed after the rupture, and the case was being treated for typhoid fever. I found in that case universal adhesion of inflammatory mass and placenta, making one of the most desperate cases in the list, yet by complete work, irrigation and drainage, her recovery was complete. The other cases presented nothing of unusual interest, save the one death in my tabulation.

The so-called exploratory incision was to confirm my diagnosis of malignancy, to others interested in the case.

Suppurating and diseased Fallopian tubes and ovaries make up 20 per cent. of all cases. Gonorrhoea and abortions have held first and second places as etiologic factors in the suppurative diseases of the adnexa. In every case both tubes have been found diseased beyond repair, and have been removed. The amount of pus found has varied from a few drops in sealed and strictured tubes to a pint in a large abscess, the walls of which were made up of the remains of the cheesy ovary and its coverings.

Irrigation drainage were practiced in 80 per cent. of these cases, and while the per cent. of recoveries was 100, the two in which no drainage was used would have had a nicer and quicker convalescence had I used drainage. The tube remained in from three to ten days.

ELECTROLYSIS AS A TREATMENT FOR DEVIATIONS, SPURS AND RIDGES OF THE NASAL SEPTUM.

BY WILLIAM L. BALLENGER, M.D.
CHICAGO.

Having seen no contribution from an American observer on the electrolytic destruction of deviations, spurs and ridges of the nasal septum, I offer a report of three cases selected from my private practice.

Mermod, of Switzerland, reported in 1887 excellent results in two cases of chronic rhinitis treated by electrolysis. He limited the application to the mucous membrane. To Dr. Miot, of Paris, however, belongs the honor of recommending electrolysis for the destruction of septal spurs and deviations. In the wake of Dr. Miot, Dr. Garel, of Lyons, reported thirty cases of septal thickening treated by the monopolar method, with success. Drs. Moure and Bergouié still later improved the operative technique of the bipolar method. They claim superior results for their method, and I will briefly outline it here:

Each needle is insulated, except so much of the point as is needed to penetrate the bony growth. The needle connected with the negative pole of the battery is introduced into the spur (or other thickening) in a line with the axis of the nasal fossa, parallel with the septum. The one connected with the positive pole is placed over or above the negative. An important point made by Drs. Moure and Bergouié is not to put the needle too near the base of the deviation, in order to avoid perforation of the septum. The amount of current should vary from eighteen to twenty-five milliampères, according to the volume and density of the growth, and should last from twelve to fifteen minutes. If all conditions are well arranged, a spur or deviation can be removed at a single sitting. Other references might be given.

I do not wish to be understood as advocating electrolysis to the exclusion of other methods. The drill, saw, chisel, galvano-cautery, bistoury, forceps and punches are all useful, indeed indispensable methods of treatment, and electrolysis is also a good method. The judgment of the operator must be exercised in determining the method or methods to be employed in each case individually.

The cases reported below were treated by the monopolar method, with the success narrated with

each case. I have never used the bipolar method, but shall do so in the near future, believing it to be an improvement over the monopolar electrolysis of spurs and deviations of the septum.

Case 1.—Mrs. T., aged 46, consulted me for a painful, dry condition of the pharynx. Upon inspection I found the mucous membrane of the pharynx almost dry, but glazed over with a film of thick pasty mucus. The pain and discomfort were always increased by exertion or emotion of any kind. She had been conscious of the trouble for sixteen years. A large cartilaginous spur projected from the anterior inferior portion of the right side of septum. One of almost equal size was on the left side. Marked hypertrophy of membrane over the middle and inferior turbinates on the left side. Some hypertrophy also existed on the right side, but not nearly so much. I do not intend to review the treatment, except so far as it relates to the destruction of the spurs. On July 2 the spur on the left side was removed with a drill propelled by an electro-motor surgical engine. The hemorrhage, while not so profuse as that attending the operation with the saw, was much more profuse than that attending the operation of electrolysis. On July 15 the spur on the right side was removed by electrolysis, the monopolar method. The membrane over the spur was first cocainized with a 10 per cent. solution of hydrochlorate of cocain applied by laying a pledget of cotton saturated with the solution over the spur. At the end of five minutes the cotton was removed and a gold-plated electrolytic needle was introduced through the spur near its base. This needle was connected with the negative pole of the battery. The patient held the positive pole (a small sponge electrode) in her hand. The galvanic current was gradually turned on until eighteen milliampères of current was passing through the spur. I maintained a close observance of the membrane on the opposite side of the septum, to see if there were bubbles of gas, indicating that the electrolytic effect was penetrating too deep. At the end of fifteen minutes the current was gradually turned off. Three months after the operation by electrolysis, I made an observation and there was no trace of the spur except a smooth base covered by a normal membrane. The wound left after the operation with the drill did not heal so kindly, still a satisfactory result was obtained.

Case 2.—Mr. John M. P., English, aged 28. Without giving a general description of the case I will refer at once to the condition of the septum. There was marked deviation of the septum to the right side, causing partial stenosis. The crest of the deviation was much thickened. The needle was carefully introduced into the bony accretion along the line of the crest, the current being applied as in Case 1. At the end of twenty minutes the needle was removed. The result was not entirely satisfactory, only a portion of the crest being destroyed. One week later the treatment was repeated with complete success.

Case 3.—Mr. W. T. H., age 25. On the right side of septum, extending horizontally a distance of one inch, was a bony ridge causing serious stenosis. The needle was introduced the entire length of the ridge and the current applied as in Case 1. At the end of ten minutes the patient became faint and the current was turned off. The patient was changed from a sitting to a reclining posture and the treatment continued for fifteen minutes, making a total of twenty-five minutes. Upon slight pressure the ridge collapsed, and one month after the operation the septum showed slight evidence of the former existence of the ridge.

No sloughing or other ill effect followed the treatment in either of the cases.

31 Washington Street.

SERIOUS ABDOMINAL CONTUSIONS: SUMMARY AND CONCLUSIONS.

Read at the Annual Meeting of the New York State Medical Association, Oct. 11, 1894.

BY THOMAS H. MANLEY, M.D.
NEW YORK.

1. The abdominal cavity, through its exposed position, is not infrequently the seat of serious injury.
2. Posteriorly, superiorly and laterally it is powerfully supported by the osseous walls of the vertebral

column, the spine and *ossa iliarum*; besides, it derives the powerful auxiliary support of its muscular walls.

3. The abdomen, because of the physical position and function of its anatomic structures is better able to sustain and resist either concussive, percussive or compressive violence than either the cranium or thorax; and hence, of the great cavities, most often escapes the consequences of serious trauma.

4. The gaseous elements which predominate in volume, impart a buoyancy and tympanitic quality to the abdomen, well calculated to neutralize and diffuse the impact of concentrated force.

5. Experimentation on the lower animals and clinical observation with autopsies quite conclusively demonstrate that percussive force, *per se*, is never a cause of vascular or intestinal rupture; but rather that it is caused by the damaged structure or organ being engaged, by the crushing force from before, and the bodies of the vertebral column behind; the promontory of the sacrum, the sharp edge of the superior straight, or the lateral wings of the ilia.

6. The qualities of force commonly sustained by the abdomen, in the order of gravity and frequency, are compressive, percussive and concussive.

7. The symptomatology of abdominal non-penetrating traumatism is extremely vague and indefinite. As a general rule, even in the most serious cases of internal organic injury, the integuments at the seat of injury, bear no trace of damage.

8. This class of injuries jeopardizes life through:

a, hemorrhage from the mesentery, the great blood trunks, or the solid viscera.

b, through septic peritonitis, consecutive to rupture of the intestine, the stomach, gall or urinary bladder, the gall duct, or ureters.

c, through shock, from great violence suddenly applied over the solar or cardiac plexus, though death from this source, without internal tangible lesion, is so rare as to throw a doubt on its possible existence.

9. Sudden and extreme collapse, with well-marked signs of exsanguination, point to free internal hemorrhage; while emesis, intense agonizing pain and tympanitis are quite certain indications of intestinal or vesical rupture.

10. Simple traumatic peritonitis almost invariably succeeds all severe abdominal bruises; the septic, only when there is leakage from the intestinal tract, the gall or urinary bladder. The former type usually running a benign course, and the latter, fatal only in the presence of complications; or when the extent of intestinal perforation is considerable.

11. The treatment of grave abdominal crushes is tentative and radical. The former in all cases attended with great collapse, and others in which we are assured there is no intestinal rupture. Rest and opium must constitute our sheet anchor, with such topical applications as secure the most comfort. Surgical intervention in the way of exploratory incisions into the abdomen is to be resorted to only when symptoms of intestinal rupture are supported by unequivocal symptoms, and all hope of saving life by other measures is lost. Nor shall we operate while our patient is in deep shock. But, nevertheless, desperate and extreme, as this resort must always be regarded, in certain cases it offers the only prospect of saving life. Laparotomy, as a process of effecting hemostasis in hemorrhage following non-penetrating abdominal injuries, should not be permitted.

12. Inasmuch as bruises of the bowel may undergo

sloughing, and cause a consecutive perforation at a distant date it is important, in all severe cases, that the bowel be kept quiescent by a restricted fluid alimentation per rectum; and the body be kept at rest until such adhesive inflammation forms as will effectively seal up threatened breaches.

13. Although there can be no question but serious injury to the organs in these cases often leaves diminished function there is no proof, as far as can be gathered from my own experience, or that of other observers, that hernia is directly induced by contusions of the abdomen.

STIGMATA OF DEGENERACY IN THE ARISTOCRACY AND REGICIDES.

Read in the Section on Neurology and Medical Jurisprudence, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY EUGENE S. TALBOT, M.D., D.D.S.
FELLOW OF THE CHICAGO ACADEMY OF MEDICINE.

A false hypothesis betrays its untruth the further it is traced. If, therefore, the hypothesis of the dental stigmata of degeneracy be untrue, the further this is followed its erroneous nature becomes the more demonstrable. If these stigmata are of value, their existence is the more demonstrable under "the fierce light which beats upon the throne."¹

While degeneracy in kings is, as Dr. Ray remarks, medically no more important than degeneracy in peasants, still sociologically it is far more serious. While there are data denoting the existence of dental and oral stigmata in the Cæsars, the most important illustrative evidence is found in that Portuguese family which has for several centuries richly supplied the thrones and aristocracies of Europe with degenerates. The mother of Pedro I., of Portugal, was the first in whom this degeneracy is decidedly demonstrable. In her, it is, however, the outcome of more than one generation. Pedro the Cruel had irregular epileptic attacks and bad periods of stupidity and inventive malignancy, so often characteristic of epileptics. His son, Fernando I., was an imbecile with prognathous lower jaw and receding forehead. He died without issue. His bastard brother John I., succeeded him. Mentally he much resembled Pedro. From John's marriage with Philippa, daughter of John of Gaunt, came a daughter, Isabella, the mother of Charles the Bold (more properly the Rash) of Burgundy. In Charles the Bold, the jaw defects were noticed, with considerable inventive stupidity and one-sided genius, in marked contrast with the level-headed ability of his father, Philip the Good of Burgundy. Mary, the daughter of Charles the Bold, inherited his jaw, and bequeathed it to her son, the Archduke Philip.

The granddaughter of Pedro the Cruel married the grandson of the bastard brother who succeeded Pedro on the throne; from this union came John II., of Castile; he married Isabella of Portugal, the mother of Queen Isabella of Columbus fame, whose union with Ferdinand founded the Spanish monarchy. Isabella of Portugal become demonstrably insane and so remained for several years until her death. The children of Ferdinand died early with the exception of Joanna who became the wife of the Archduke

¹ A good account of the insanity running through the royal families of Spain may be found in "Ireland's Blot on the Brain." Personal examination of living descendants of the royal families of Spain reveals pronounced stigmata of degeneracy.

Philip. The son of this pair, Charles V., was melancholy, epileptic and spasmodically religious. He had defective teeth; his lower jaw was longer than the upper, which disparity interfered with mastication and made his utterance indistinct. The brother of Charles V. founded the German house of Austria; Maximilian (his son) married Mary, daughter of Charles V. From this taint has proceeded the neurosis still evident in the Austrian and Bavarian royalties. The son of Charles V., Don Carlos, had an imbecile genius, of an asymmetrical frame and with an exaggeration of the jaw deformity of his father; Philip II. had no children by Mary Tudor; his second wife bore him two daughters who introduced fresh taint into the houses of Savoy and Austria. His third wife was his niece, daughter of Maximilian by Mary, Philip's sister. Of the end of this line Macaulay gives the following vivid picture:

"The Prince upon whom so much depended, was the most miserable of human beings. In old times he would have been exposed as soon as he came into the world; and to expose him would have been a kindness. From his birth a blight was on his body and on his mind. With difficulty his almost imperceptible spark of life had been screened and fanned into a live and flickering flame. His childhood, except when he could be rooked and sung into a sickly sleep, was one long piteous wail. Till he was 10 years old his days were passed on the laps of women and he was never once suffered to stand on his rickety legs. None of those tawny little urchins clad in rags stolen from scarecrows, whom Murillo loved to paint, begging or rolling in the sand, owed less to education than this despotic ruler of thirty million subjects. The most important events in the history of his own kingdom, the very names of provinces and cities, which were among his most valuable possessions, were unknown to him. It may as well be doubted whether he was aware that Sicily was an island, that Christopher Columbus had discovered America, or that the English were not Mohammedans. In his youth, however, though too imbecile for study or business, he was not incapable of being amused. He shot, hawked and hunted. He enjoyed with the delight of a true Spaniard, two delightful spectacles, a horse with its bowels gored out and a Jew writhing in the fire. The time came when the mightiest of instincts ordinarily awakens from its repose. It was hoped that the young king would not prove invincible to female attractions, and that he would leave a prince of Asturias to succeed him; a consort was found for him in the royal family of France and her beauty and grace gave him a languid pleasure. He liked to adorn her with jewels, to see her dance, and to tell her what sport he had had with his dogs and his falcons. But it was soon whispered that she was a wife only in name. She died; her place was supplied by a German princess nearly allied to the imperial house. But the second marriage, like the first, proved barren and long before the king had passed the prime of life all the politicians of Europe had begun to take it for granted in all their calculations that he would be the last descendant in the male line of Charles V.

Meanwhile a sullen and abject melancholy took possession of the King's soul. The diversions which had been the serious enjoyment of his youth became distasteful to him. He ceased to find pleasure in his nets and boar spears, in the fandango and the bull fight. Sometimes he shut himself up in an inner chamber from the eyes of his courtiers. Sometimes he loitered alone from sunrise to sunset in the dreary and rugged wilderness, which surrounds the Escorial. The hours which he did not waste in listless indolence were divided between childish sports and childish devotions. He delighted in rare animals and still more in dwarfs. When neither strange beasts nor little men could dispel the black thoughts which gathered in his mind, he repeated aves and credos; he walked in processions; sometimes he starved himself; sometimes he whipped himself. At length a complication of maladies completed the ruin of all his faculties. His stomach failed, nor was this strange, for in him the malformation of the jaw, characteristic of his family, was so serious that he could not masticate his food and he was in the habit of swallowing ollas and sweatmeats in the state in which they were set before him. While suffering from indigestion he was attacked by ague. Every third

day his convulsive tremblings, his dejection, his fits of wandering seemed to indicate the approach of dissolution.

In a very short time the King's malady took a new form. That he was too weak to lift his food to his misshapen mouth, that at 37 he had the bald head and wrinkled face of a man of 70, that his complexion was turning from yellow to green, that he frequently fell down in fits and remained long insensible, these were no longer the worst symptoms of his malady. He had always been afraid of ghosts and demons and it had long been necessary that three friars should watch every night by his restless bed as a guard against hobgoblins. But now he was convinced that he was bewitched; that he was possessed; that there was a devil within him; that there were devils all around him. He was exorcised according to the forms of his church, but this ceremony instead of quieting him scared him out of almost all the little reason that nature had given him. In his misery and despair he was induced to resort to irregular modes of relief. Meanwhile, in this distempered mind of Charles, one mania succeeded another. A longing to pry into those mysteries of the grave from which human beings avert their thoughts had long been hereditary in this house. Joanna, from whom the mental constitution of her posterity seems to have derived a morbid taint, had sat, year after year, by the bed on which lay the ghastly remains of her husband, apparelled in the rich embroidery and the jewels which he had been wont to wear while living. Her son Charles found an eccentric pleasure in celebrating his own obsequies, in putting on his shroud, placing himself in the coffin, covering himself with the pall and lying as one dead till the requiem had been sung and the mourners had departed leaving him alone in the tomb. Philip II. found a similar pleasure in gazing on the huge chest of bronze in which his remains were to be laid, and especially on the skull which encircled with the crown of Spain, grinned at him from the cover. Philip IV., too hankered after burials and burial places, gratified his curiosity by gazing on the remains of his grandfather, the Emperor, and sometimes stretched himself out at full length, like a corpse, in the niche which he had selected for himself in the royal cemetery. To that cemetery his son was now attracted by a strange fascination."

The daughter of Philip IV., of Spain, married Louis XIV. Of her descendant, Louis XV., Carlyle remarks:

"He had always the kingliest abhorrence of death, unlike that praying Duke of Orleans, Egalite's grandfather—for indeed several of them had a touch of madness—who honestly believed there was no death. He started up once upon a time, glowing with sulphurous indignation on his poor secretary, who stumbled on the words: 'The late King of Spain.' 'Late King, Sir?' 'My Lord,' hastily answered the trembling but adroit man of business, 'It's a title they take.' Sometimes Louis IV. would go, or stopping his court carriage, would send into churchyards and ask, 'How many new graves there were to-day?'"

The French descendants of the Spanish line have continued to display the mental defects which led to the expulsion of the Bourbons from the thrones of Europe. The suicide of Crown Prince Rudolph and King Ludwig of Bavaria, and the imbecility of King Otto demonstrates that the taint is still rife. The interesting point in this history is not the long persistence of the neurotic taint, but the persistence of the dental and oral and final stigmata so emphatically as to be recognized by historians.

The following history of Charles VI., of France, has just come to light for the first time and is of unusual interest to us in the present paper:

At the Congress of French-Speaking Alienists, (Report in *Le Progrès Medical*, August 18, 1894) M. August Brachet, former examiner and professor at the Ecole Polytechnique, Laureate of the Institute, read a note entitled: "Concerning the Nature and the Form of the Insanity of Charles VI., of France." The clinical interest is in the richness of the predisposing cause (unique, since it is the only insane individual of whom we have in pathologic documents the history of eighteen direct ancestors) and in a historic point

of view, as regards the capital question of the responsibility of Charles VI. in the remissions of these twenty-eight years of insanity. The history has not been studied by alienists for lack of access to the sources (government archives, chronicles of the times, relations of ambassadors).

Predisposing Cause.—Paternal line (father, Charles V., gouty, cardiac disorder; grandfather, Jean le Bon, arthritic; great-grandfather, Charles of Valois, apoplectic; great-great-grandfather, Philip III., the Hardy, sexual pervert. Maternal line (hitherto unknown to alienists or historians); mother, Jeanne de Bourbon, insane; grandfather, Louis de Bourbon, married the daughter of a lunatic; great-grandfather, Robert de Clermont, traumatic insanity, consecutive to cerebral commotion.

Determining Cause.—Typhoid fever in May, 1392.

Immediate Cause.—Two months later, isolation in the Forest of Mans, Aug. 5, 1392. Insanity for thirty years. Character of the remissions, mental confusion, as might have been expected from the infectious nature of the primary cause. Hence com-

Figure 1.—John II. of Castile.

plete incapacity for government during the forty-eight remissions in these thirty years of insanity.

Conclusion.—Charles VI., insanity of infectious origin in a hereditarily predisposed individual (maternal, vesanic; paternal, arthritic heredity).

I regret that it is impossible to obtain a picture of this monarch because we should, without question, be able to show marked stigmata of the head, face and jaws.

Figure 1.—In John II. of Castile we observe marked stigmata. A receding forehead, small sunken eyes, a long, slender, excessively developed nose, short ram; and long body of the lower jaw and arrest of development of the chin.

Figure 2. Charles the Bold.—The picture of a boy apparently 6 to 8 years of age. While too young to determine the exact stigmata of the entire face, there is a general appearance of hereditary taint with one side of the face lower than the other. Defects in the eye and arrest of the lower jaw.

Figure 3.—The portrait of Pedro I., of Castile, shows a very narrow forehead. Eyes set close together. Long, slender nose. Prominent cheek bones. Arrest of development of the upper jaw and fairly well developed lower jaw.

Figure 4. Ferdinand the Catholic.—Is not unlike the father (Fig. 3). Narrow forehead. Eyes set closer together. Long, slender nose. Cheek bones undeveloped. Arrest of the upper jaw and excessively developed lower jaw.

Figure 5. Charles V.—Illustrates a very deformed face. The forehead broad and low. The eyes wide apart. The left eye higher than the right. The nose long and slender. Cheek bones, bone of the face, and upper jaw arrested in their development. The lower jaw protruding from three-fourths to one inch beyond the upper. Mouth open, owing to excessive development of the ascending rami, and mouth breathing.

Figure 6. Ferdinand of Austria.—Presents marked degeneracy. Long, handle-shaped ears. Narrow forehead. Eyes set close together. Marked deformities of the orbits and eyes. Long, slender nose. Arrest of bones of face and upper jaw. Narrow lower jaw.

Figure 7. Philippe I.—Has a narrow forehead, eyes set wide apart, long slender nose, excessively developed zygomae, arrest of the face at alae of the nose and arrest of upper jaw.

Figure 8. Philippe II.—Shows a long, handle-shaped ear. Full forehead. Left eye smaller than right and irregularly placed in their sockets. Face arrested from superior orbital ridge producing concavity of the face as far down as the cutting edges of the superior teeth. The nose long, slim and sunken. The lower jaw apparently well developed.

Figure 9. Philippe III.—Illustrates a small cranium. Nar-

Figure 2.—Charles the Bold.

row, receding forehead. Eyes set wide apart. Short, stubby nose. Marked arrest of the bones of the face and bridge of the nose, also arrest of the superior maxilla. Marked protrusion of the lower jaw, which may be normal. The apparent protrusion being more noticeable owing to the marked arrest of the bones of the face and superior maxilla.

Figure 10. Philippe IV.—Shows a very striking neurotic face. High, narrow forehead. Although the ear is not shown, with such a long, narrow head we would expect a long, narrow, handle-shaped ear. Eyes set irregularly and close together. The right lower than the left. Long, thin nose. Arrest of the bones of the face and upper jaw. Excessively developed and protruding lower jaw.

Figure 11. Philippe V.—Here is a sensual face. Low, full forehead, eyes set far apart and high in forehead. Long slender nose, high cheek bones and arrest of the upper and lower jaw.

Figure 12. Charles II.—Also illustrates a very neurotic face. Low forehead. Eyes close together. Long, slender nose. Marked arrest of all of the bones of the face and upper jaw, carrying the nose inward. Apparently protruding lower jaw.

Figure 13.—The beautiful face of Catharine d' Aragon displays very little stigmata. All that can be observed is a

fullness at the left superior orbital sides, a long slender nose and arrest of the lower jaw.

Figure 13. Queen Mary of England.—Shows a very striking face. Large, full forehead with excessive development above and to the left of the left eye. Eyes set abnormal and wide apart. Nose short, arrested at bridge, and flat and broad

Figure 3.—Pedro the Cruel.

at alae. Facial bones arrested, carrying the nose inward. Body of lower jaw excessively developed. Chin arrested. While I can not state positively that deformities of the vaults and dental arches are present in all these cases, my experience is that in most cases where there is arrest of bones of the face and upper jaw, we also find V- or saddle-shaped arches.

Figure 4.—Ferdinand the Catholic.

NOTE.—These illustrations are taken from photographs of paintings by famous artists, and were obtained from Sucesor de Laurent, Madrid, Spain.

Stigmata of degeneracy are just as marked in regicides (who represent the canaille, middle class and

aristocracy) and the percentage of deformities as great as in the aristocracy. In an examination of the mental condition of these individuals, while they are not always absolutely insane, as a rule they can not be said to be normal individuals. They can not be classed in

Figure 5.—Charles V.

the same grade; each is a study in itself and no two possess exactly the same peculiarities, yet all are on the verge of insanity. Most of these individuals as will be observed, possess some systematized delusions, and are therefore called paranoiacs. If a

Figure 6.—Ferdinand of Austria.

study of the parentage of each individual could be made, abundant cause would be found in each case for not only their peculiarities, but the marked deformities which exist throughout the entire body showing manifold signs of hereditary taint.

Figure 15.—John James Ankorstrom or Anckerstrom, Swedish gentleman, born 1760, executed 1792. Sworn regicide. Killed Gustavus III., of Sweden, March 16, 1792. No statement about him in Regis' text, only his picture.

Head excessively developed at occipital region. Low receding forehead; arrest of the bridge of the nose; long,

Figure 7.—Philippe I.

slender, aquiline nose; arrest of development of the lower jaw.

Figure 16.—History of Mariotti, as communicated to Dr. Regis by Dr. Deny, of the Bicêtre:

Mariotti is a man aged at present 63 years, who has followed various occupations, and lastly was an employe of the

Figure 8.—Philippe II.

Panama Canal Company. During a month's sojourn in the hospital on account of fever, his daughter died, and this became the starting point of his delusion. He imagined that his daughter had been enticed away, dressed as a man and assassinated. From this time on he had but one object in life; to secure the punishment of her murderer, and repara-

tion for his loss. All his endeavors having failed, he concluded that the chiefs of the Canal Company, M. de Lesseps especially, were endeavoring to suppress the facts, and so one day, receiving no response to his demands, he posted himself where the Minister of Foreign Affairs would pass, and fired a pistol at his carriage. Arrested at once, he de-

Figure 9.—Philippe III.

nied positively any intention of killing the Minister. Nothing would have been more easy, said he, as the carriage was not moving; he did not even aim at it, but fired into the ground. His only idea was to force the government to bring him before the court so that he could obtain justice. He was clearly a paranoiac, one of the persecutory type in which the suf-

Figure 10.—Philippe IV.

ferer, from delusions of persecution, becomes himself a dangerous individual.

Upper part of head very small, tapering from the ears upward. Receding forehead. Excessively developed upper left side of head—arrested right side. Eyes small and sunken. Nose short and thick. Cheek bone excessively developed. Ears long, handle-shaped. Arrested development

of the upper jaw. Arrest of development of right; excessive development left lower jaw.

Figure 17.—Jacques Clement, Jacobin monk. Born at Sorbonne (Diocese of Sens) in 1567; killed Aug. 1, 1589. Typical regicide (religious mysticism). Assassin of Henry III., Aug. 1, 1589. (Knife). (Engraved by Massard from the original in the Library at Blois.)

Figure 11.—Philippe V.

Clement was an ignorant monk, of gross libertine tendencies, excessively bigoted; the mere word "heretic" made him furious; he had hallucinations, as is shown by the following, quoted by Dr. Regis, and given by him as the type of those of the regicide:

"One night, Jacques Clement being in bed, God sent to

Figure 12.—Charles II.

him his angel in a vision, who appeared with a great light and showed him a naked sword with these words: 'Brother Jacques, I am a messenger from Almighty God, who comes to announce to thee that by thee the tyrant of France is to be slain; think, therefore, of the martyr's crown prepared

for thee.' Thus saying, the angel disappeared." (Palma Cayet).

Full, low forehead. Eyes set far apart. Dark brow, excessively developed. Long, slender nose. Arrest of development of lower jaw.

Figure 18.—Francois Ravallac. Domestic, clerk, schoolmaster, etc. Born at Touvres, near Angouleme, in 1578,

Figure 13.—Catharine d' Aragon.

executed May 27, 1610. Type, religious mystic. Assassin of Henry II., May 14, 1610. By a contemporary. (Fac-simile of one of the rarest of the collection of historic engravings.)

"Ravallac, of rather tall stature, powerful and large of limb, cross-eyed, with dark, reddish hair, was a somber melancholic, tormented like Clement with hallucinations. See

Figure 14.—Queen Mary of England.

how he is described by the judge and historian, Matthieu, his contemporary: 'He threw himself into the Monastery of Feuillans, and left it on account of his mental weakness. Those who stayed there have since told me that he was altogether beside himself, and that the word "Huguenot"

turned his madness into fury. His mind was distracted and bigoted, susceptible to every impression. After he returned home he was in prison a year for homicide. He was wayward in the palace, insane in the cloister, and became desperate in the prison, where he had visions and dreams." Regis, "Les Regicides," p. 20.

Long, narrow head. Long, slender nose. Prominent cheek bones. Arrest of development of the bones of the face and upper jaw. Normal lower jaw.

Figure 19.—John Wilkes Booth, the third son of the noted English tragedian, Junius Brutus Booth, born in this country in 1839 and was 26 years old when he shot and killed Abraham Lincoln, President of the United States, April 14, 1865. He was a rank secessionist, and was one of a party of

Figure 15.

Figure 16.

conspirators who had for a long time contemplated the death of the President, but were foiled in every attempt. At last when Lee surrendered and it seemed that the defeat of the Rebel Army was complete, he with others sought to kill the men who were at the head of the government, hoping thereby to paralyze it.

Booth had received from his father, who was himself called by the significant name of Junius Brutus, the name of John Wilkes, in memory of the English politician who, in the reign of George III., had given pretext to the rallying cry of "Wilkes and Liberty." The entire life of Junius Brutus Booth, a genuine lunatic though an actor of genius, was, moreover, only a long succession of eccentricities, impulses and acts of insanity. Among other things, he was a mystic. His belief in the sacred character of the lives of animals was such that he could not bear to see them killed or mal-

Figure 17.

Figure 18.

treated without reason, and that he never ate meat, even forbidding his family to eat it. He was well versed in the knowledge of different religions, giving great importance to the Koran, passages of which he annotated; he read the Talmud in Hebrew and gravely discussed religious mysteries with Catholic priests. He never failed to bow his head in passing a church, he frequented churches of all denominations, participated with fervor in all their ceremonies, scrupulously observed all the practices of devotion, and passed whole hours in prayer. His last words, pronounced in the ear of the ship's steward, his only attendant at the hour of his death, were: "Pray; pray; pray." (Kellogg). Regis, pp. 27 and 28.

It is said of the elder Booth that, one evening while playing Richard III., in the last act, he refused to die (believing

he was the original Richard); he fenced his opponent off the stage through the door into the street. His opponent becoming exhausted from parrying his deadly thrusts called upon the people to interfere.

The photograph from which this picture was taken was obtained by the author in Boston the winter before the mur-

Figure 19.

der, and is an excellent likeness. The stigmata are nicely shown.

The head and forehead are apparently well developed, eyes small and sunken; ears excessively and abnormally developed; nose normal; facial bones and upper jaw arrested; partial V-shaped dental arch; well developed lower jaw.

(To be continued.)

THE EFFECTS OF MODERN DRESS ON THE HEALTH OF WOMEN.

Read before the Indiana State Medical Society, Indianapolis, Ind.,
May 17, 1894.

BY MARTHA J. SMITH, M.D.

INDIANAPOLIS, IND.

Every woman's dress expresses, not only some of her own individuality, but it expresses even more, her unity with the race; the common history and status of her sex. Of all nations of the earth we suffer most from the cruel tyrannies of dress.

American women are known abroad for two distinguishing traits (besides possibly their beauty and self-reliance), and these are their ill health and extravagant devotion to dress. We strike the sturdy German and English matrons with dismay. Without the trailing skirt of a year ago we were told we were bereft of our grace, our loveliness, our womanliness. Men are excellent theorizers upon the absurdities of modern dress, but when a practical application of their theories is made by their wives and daughters or sisters, few are found brave enough to stand by and encourage them to wear only such garments as are conducive to their health and comfort. Yet what pathetic sentiments they pen upon the physical frailty of women.

The dress adopted by the women of to-day certainly is conducive to the development of many diseases, and proves both a predisposing and exciting cause of them.

Dr. Thomas J. Mays, of Philadelphia, who studied

the types of respiration in eighty-two Indian girls, varying in age from 10 to 20 years who had never worn tight clothing, found the abdominal type of breathing was very marked in every case. He came to the conclusion that the costal type usually observed in civilized women was artificial, and the result of modern dress.

Dr. J. H. Kellogg has since then examined the mode of respiration of several Chinese and Indian women, whose dress does not constrict the waist, and found also the abdominal type of breathing. He found the same in civilized women who wore no corset, and that this type of breathing was prevented by putting on a corset. He produced the costal type of breathing in a man by putting him into a corset.

Hutchinson found the costal type marked in twenty-four girls, whose ages varied from 11 to 14 years, who had never worn a corset or tight clothing around the waist. Gibson states that the difference in the type of breathing begins as early as the tenth year. Reigel asserts much the same thing. It seems there is reason to believe that the costal type of breathing has become established in civilized women, and it has not been proven that it has any injurious effect, but the harm done by tight lacing and tight bands about the waist must be admitted.

Rosenbach says that in a certain number the use of the corset seems to be productive of no ill results, yet this is not the case with the greater number of women. All hollow organs require room for the proper performance of their functions, and this the corset prevents. Especially are they injurious to those who labor with their hands, such as workers with sewing machines, and others who require free bodily action. The first effect of the corset on the muscles of the trunk and abdomen is limited motion. The constant pressure of tight bands and stiff steels debilitates and shrinks the muscles, rendering the flesh flabby, and exaggerating the bony structure in consequence. Entire freedom of action should be given to the chest for the perfect performance of the functions of respiration. Especially is this true at the base of the thorax near the diaphragm. The habit of contracting the body at the waist by tight clothing confines this part as by splints, and as the diaphragm thus contracts, all lateral expansion being prevented, it presses the contents of the abdomen upon the movable uterus, and forces this organ downward, and in addition to this about ten pounds of skirt are bound around the waist by tight bands, and held up by the hips and abdominal walls, which are rendered protuberant by this compression, and at further intervals pressed upon by the stomach. The displacement of the pelvic organs is in this way favored. In estimating the effect of direct pressure upon the position of the uterus, its extreme mobility must be constantly borne in mind.

This is illustrated by examining it by a Sims speculum, when, if the clothing be not loosened around the waist, the cervix is thrown so far back into the hollow of the sacrum as to make its engagement in the field of the instrument often extremely difficult; attention to this point in the arrangement of the patient will at once remove the difficulty.

Another result of this compression is the pressure upon the abdominal vessels, which interferes with the return circulation from the lower half of the body, producing congestions in these regions. The effect

on the muscles of the middle portion of the trunk is to bring on partial atrophy or arrest of development. It has been said that injury caused by tight bands about the waist is avoided by wearing corsets beneath them. You need but a moment's notice to see this can not be true; the bands only help to adjust the steels and bones more closely to the yielding portions of the body. Most women will tell you they do not wear their corsets tight. I have never been able to find one who did, if we accept her own statement. A corset worn ever so loose, the moment the wearer sits the steels incline inward, and pressure begins upon the stomach and diaphragm, which in time shortens the front length of the body from the neck, drawing it downward perceptibly, and ungracefully crowding the bosom upward and abdomen forward and out of place.

The stomach does not have the assistance of the diaphragm to pump lymph out of its walls in digestion. The bile is not removed from the biliary apparatus; the pancreatic juice is not pumped out of the pancreas. The kidneys lie in a state of motionless inactivity until the blood pressure is so great as almost to break through the delicate tubules.

The peristaltic motion of the bowels is impeded, and constipation with indigestion and malnutrition with fecal intoxication results.

W. B. Neffel, of New York, says his experiments on animals have demonstrated that a prolonged compression of the chest and abdomen invariably produces general anemia, serious congestions of the liver and other abdominal and pelvic viscera. The pressure on the cervix uteri when the abdomen is restrained causes it to move backward and forward over the pelvic floor with every respiration.

This is the point, you will remember, most frequently attacked by cancer in women. The uterus is exposed to this downward pressure about fourteen out of every twenty-four hours. The effect of the ends of the stays on the breast is to deform the lacteal tubes, and when they begin to secrete milk a cyst is often formed, which is not easily emptied. This retention often causes abscess of the breast. Cancer of the breast, there is great reason to believe, is often brought about from the irritation of the clothing.

The liver is not only compressed, but often folded upon itself, so that deep furrows are produced in it, and pieces have frequently become detached. Cancer may result from the irritation of the organ in this way. Abnormalities in the form of the liver and lateral distortion of the thorax are very common, and as a result a displacement of the organ or an alteration in form. Sometimes it is found rolled up into a conical mass, but more frequently deeply notched by the turning in of the margin of the ribs.

From its daily occurrence, the tight-laced liver has an importance in diagnosis greater than is otherwise its due. By the narrowing of the base of the thorax, the liver is compressed from side to side, and not infrequently there is produced a series of folds. At the same time, as a consequence of this circular contraction, a part of the right and usually the left lobe also becomes separated by a depression, the depression being sometimes higher or lower, according to the locality of the lacing. These furrows may penetrate deeply into the parenchyma, until only a ligamentous connection remains which allows a free motion of the separated portions. Tight lacing is one of the most frequent causes of abnormal positions

of the liver. The position varying according to the part of the gland which is subjected to the compression.

Frérich says one cause of chronic atrophy of the liver is tight lacing, corresponding to the extent and force of pressure.

Prof. F. Marchand, of Marburg, believes that tight lacing is one of the most frequent causes of the formation of gallstones. The pressure of the border of the ribs upon the liver during the day and at night no pressure, he claims, favors the stagnation of the bile and the formation of concretions in the gall-bladder. It becomes distended during the day and can not empty itself at night. He also states cancer of the liver may arise from this pressure. As a rule the course of the lacing furrow is obliquely across the right lobe of the liver, from which there is a tendency to atrophy of various degrees in the region of the gall-bladder.

It is not infrequent to find the gall-bladder tightly distended and extending far beyond the border of the liver, and in these gall-bladders stones are frequently found. Anything that exerts pressure on the biliary passages, especially the cystic duct, favors the formation of biliary calculi.

Dr. Rotter, of Munich, according to whose researches on gall-stones of 1,034 necropsies, found stones were present in men in 3.9 per cent. of the whole number, and in women 9.9 per cent. In as many as 40 per cent. of the female cases with gall-stones, there were present grooves and constrictions formed by stays.

Schuter found that a lasting compression of the chest would cause albuminuria.

Professor Bouchet draws attention to the fact that pressure of stays on the intercostal spaces in women suffering from intercostal neuralgia may give rise to paroxysms resembling angina pectoris.

It is said the soldiers of Austria were accustomed to retain their trousers about the hips by means of a leather strap; disease of the kidneys increased so alarmingly among them that especial attention was drawn to the subject, and it was decided that the closely buckled band about the loins was the cause of the evil.

Meyer states that tight lacing decidedly manifests an injurious influence on the eye in consequence of congestions resulting from obstructed reflux of blood from the head along the jugular veins.

Probably no other part of the human form except the waist has suffered more abuse and distortion especially among civilized people, than the feet. Many who condemn the Chinese custom of stunting the growth of their women's feet to the extent of practical uselessness deliberately squeeze their own into shoes too small for comfort and grace of movement. Chiropodists tell us the most distressing diseases result from cramping and pressure from badly-made and tight-fitting shoes. Few women are able to poise the body firmly and elegantly because of deformity of the feet, brought about through ignorance of the complex mechanism of these useful members and bungling efforts to improve their natural shape. Corns and bunions are evidence of ill-fitting shoes and shoes worn too tight, and no denial changes the fact. What man or woman can lay claim to fine mental balance who will deliberately stump through life with an ungraceful gait? It is a mistake to suppose the foot can not be clothed elegantly and attractively in any except French heels and pointed toes.

Only look for a moment at the anatomy of the foot and you will see that muscles that are unused remain in an infantile condition. This is illustrated by the arm kept in a sling and unused; it loses strength and at last size. The interference in the function of the muscle may be voluntary or involuntary; the result is the same; atrophy or arrest of development. The nerve which supplies the muscle is unused, and it suffers arrest of development.

If you put the foot of an infant at an early age in a modern shoe, the toes become immobilized and there is restricted motion at the ankle and the muscles in the sole are arrested in their development. The arrested movement of the ankle results in arrest of development in the strong flexors of the foot that are situated in the calf of the leg. The burden of walking is thrown on the muscles of the thigh and back, and they are consequently over-developed. The same thing follows when the well developed and mature foot is irrationally dressed. The imperfection of this organ restrains locomotion; this induces the sedentary habit with malnutrition and either dyspepsia and its concomitant evils or the stealthy onset of obesity, which may be well called the second curse of women. The intravascular and lymph circulation of the foot is much impaired and the bones become either sclerotic or vascular from over dilatation of their vessels when the constriction is removed at night.

The ligaments, too, become degenerated from improper blood nourishment. The plantar fascia is drawn up by the sole or heel of the shoe. A greater strain than normal is thus brought upon it during locomotion and standing.

When the shoe is removed the fascia takes a straight line, the abutments of the arch separate, a greater strain is thus brought on the lower ligaments of the joint and the upper ligaments are loosened.

The upper edge of the bones are crushed together and the pain is unendurable, and tight shoes must be put on to make walking possible. It is not difficult to imagine the pain which attends these changes in healthy bones, if one has ever suffered from a so-called bunion. But the effect on the general health, the spirits, the digestion, the assimilation are conceived with more difficulty.

The habit women have of wearing cotton underwear during the cold season of the year is extremely absurd. Pneumonia, diphtheria, tonsillitis, rheumatism, la grippe, etc., are often contracted in this way. Many women will tell you they can not wear woolen underwear, but the reason they do not wear it is because they fear they will increase their waist measure a fraction of an inch. Many have never seen or heard of the neat-fitting union suit or shirts fastened to a simple waist by two rows of buttons at the bottom.

The custom of wearing mourning is a ridiculous one from every point of view. Cases of melancholy are traceable to wearing heavy crape for mourning. The custom is simply shocking when discussed from either the standpoint of health or fashion. Sorrow should be too sacred for outward display and sign-board advertisement. It has a depressing effect at a time when one needs to rally all one's Christian fortitude and human philosophy to meet life with becoming resignation. We should not despise the charms that dress can give or neglect the adorning of our person, but we should also remember health and comfort are not to be sacrificed.

The dress need not be one so closely resembling that of men as to subject us to the charge of wishing to be men. All I envy in man's apparel is the opportunity for pockets which it affords. These I would like.

Although all men disclaim any preference for an unnaturally small waist, all women persist in believing that a wasp-like appearance, at whatever age and conditions is sure to render them lovelier in the eyes of their admirers. As the struggle to live becomes more intense men will select their wives from the healthy and strong if they are not attracted now by the beautiful and graceful.

Oliver Wendell Holmes has said with characteristic humor that it is impossible to make a perfect human being without beginning several generations before he is born. Men could have a great influence for good in this work if they realized its importance. Women dress not for their own comfort or health of posterity, but to please their brothers, their lovers, their husbands. Women physicians work here at a great disadvantage. With most women, save those in advanced rank of thought, any suggestion in the way of hygiene in dress is immediately branded as dress reform, and straightway the masculine type of radical dress is brandished.

Medicine has become the science of the prevention of disease rather than the cure of it, and it is true that the intelligent application of hygienic measures is supplanting the empirical use of drugs. The physician should give more attention to removing the predisposing as well as the exciting cause of disease, anticipating rather than awaiting the actual presence of sickness. It was not my object in this paper to give examples of dress. I have only tried to give you the effects of modern dress on the health of women.

DISCUSSION.

DR. C. S. BOND, of Richmond—Mr. President, I do not wish this paper to go by without some discussion, because it is of great importance. Yesterday we had a paper on ophthalmia neonatorum, which was considered of such importance as to justify us in pleading with our legislators for protection against some persons who do not pay sufficient attention to that matter; and it might be important to plead still further with this same body to enact a law on the subject of women wearing corsets. It is certainly a bad thing. I do not see why the women do not quit it. The women seem to have this matter in their own hands, one might say, but they tell us the men are inclined to admire a woman who wears a corset. It is foolish in women to court admiration at their own cost. There is no doubt in the world that women would be more gracefully formed, more useful in the lines that they have to pursue, if they did not wear corsets. Every doctor who has much experience in the line of diseases of women sees frequently in his office persons who are suffering more or less from this trouble. All the difficulties that have been so admirably pointed out by the essayist come before us for observation almost every day in one form or other; and it is a matter of great importance, and might easily be remedied without subjecting the women to ungraceful forms. The time will come, probably, when the matter will right itself. I suppose among some of the Chinese and Japanese women to have a large foot would be an unpardonable sin. In this country it seems to be an unpardonable sin among women to have a large waist. The only way is to start a different style. A woman with a waist twice as large as is in vogue, were it not for the style, would be just as much admired. It is only that we have started to admire people in certain directions; so it seems to be a matter of fashion.

DR. J. I. ROOKER, Castleton—Mr. President, this is the thirty-fifth year that I have been attending the State Medical Society, and this is the first time I ever heard a woman take the rostrum and read a paper. The paper was certainly a very good one, and it would be a good thing if we could

get it into the hands of the ladies. I know something about shoes; I think I have made, in my practice of thirty-five years, several thousand dollars on ladies' shoes. Shoes that are nothing but brown paper, and the result is that we have pneumonia. This paper should get into our public schools, and if the doctor would read it to the ladies it would be an excellent thing.

DR. P. McNAB, Indianapolis—Mr. President, I regard this paper as one of the very best and one of the most practical papers we have had during this convention. As a discussion of the question of hygiene it is certainly very fine. I do not want to discuss it at all; I only want to express my admiration of the paper.

DR. JOHN W. HALL, Portland—Mr. President, this is one of the most helpful papers we have had during the convention, and I desire to expressly commend something that will perhaps come to the minds of most members of the society, and that is the most excellent reading of the paper. We could hear it in the back part of the house more clearly than we could hear the majority of papers read by gentlemen. On yesterday we passed a resolution on the subject of nurses looking after the eyes of infants, and recommending that they be fined ten to a hundred dollars if they don't do it properly. It seems to me if we would appoint a commission to get the Legislature to pass a law that women should not wear corsets it would be much more sensible than the resolution passed yesterday. It has been said that men admire women with small waists. I know that sensible men, regardless of the medical profession, don't admire women who wear corsets and have small waists.

DR. WM. FLYNN, Marion—Mr. President, throughout the State of Indiana, in almost every town, are societies composed of women, the object of which is the bettering of their condition, physical as well as moral and mental. Now I think if every doctor here would go home and get the ear of those societies and tell them that at Indianapolis there is a lady who is capable of giving them practical instruction, and have them courteously invite her to read her paper throughout the length and breadth of this State, she can accomplish something. All this jovial talk about the legislature goes for nothing. It strikes me that the best way to get good results is to get the facts in the paper before the people; and I would suggest that physicians—of course not gynecologists, because it would ruin their business—courteously bring up these questions at home, and get Dr. Smith to read this paper.

DR. FLORENCE W. HAYS, Indianapolis—Mr. President, I think the subject-matter is one that has not attracted the attention of the medical profession until recently. Leaders in the dress reform movement have not been doctors, but have been educated, sensible women of the world, who have been hampered somewhat because they have not the requisite knowledge to know and understand the scientific facts. The paper this afternoon would be quite a revelation to a great many of the warmest advocates of dress reform, and in some way it should be brought to their attention. I think physicians owe themselves and society a duty in regard to this matter. They should take a more practical interest in affairs of this sort, and put themselves in line with dress reform and the teaching of physical culture. I think the series of lectures given this winter by some of our Indianapolis physicians before the Y. M. C. A. is a very good start in this direction, and the work should be continued and put on some practical basis, which would include hygiene of dress as well as the matters already discussed. In putting this question before the people directly, however, the trouble would be mostly not with the younger women, but the mothers and dressmakers. The younger women will be found willing enough to make changes that add so much to their comfort. In one of our large institutions of the higher rank in our State, even so long as ten years ago, while I was attending a college myself in which there were some three or four hundred young ladies pursuing the higher branches, fully one-half of those young ladies did not wear corsets through the week and study hours; and since that time the establishment of gymnasiums and the impetus given to outdoor sports of all sorts has, no doubt, lessened even that number.

One of the points not mentioned in the paper is the effect of corsets upon the vocal cords. This is well recognized by all teachers of the voice, both of elocution and of singing; and the rule is that corsets must not be worn during practicing hours. Some of our most talented and beautiful actresses and singers, Ellen Terry and others, abjure corsets altogether. Of course, artistic drapery is the essence of beautiful dress, and this can be easily attained without

corsets; but as to bringing this about in any practical way, no radical immediate changes could be made. Beauty is a very important note to strike in this connection, and should be considered in all methods of reform. I saw in a fashion journal of a recent date a number of illustrations of dresses designed particularly to be worn without corsets. They were models of artistic excellence, and at the same time utility and comfort were much added to; and any changes to be made—of course no radical changes from the method and general appearance of dresses as now worn by women are to be made—must be on the principle of avoiding constrictions and supporting the dress from the shoulders in preference to the waist. In this connection union under suits and skirts fastened to waists with the dress are practical illustrations. When the details are perfected the future woman will be not only beautiful, but healthful.

DR. L. H. DUNNING, of Indianapolis—Mr. President, I do not rise to discuss the subject, but when Dr. Smith read this paper before our county society she gave us in response to questions a very excellent system of arranging clothes. It is a very practical point. Physicians need to advise. Our patients want some guide. If we are going to reform our lady patients we must give them something in place of their corsets, and suggest some improvements. I would ask the Doctor to give us her ideas of what advice we should give our patients when we tell them to take off their corsets.

DR. MARTHA J. SMITH, of Indianapolis—Mr. President, I believe I have nothing further to say, except that as Dr. Dunning has asked me to explain my ideas of dressing I will do so as briefly as possible. Have the dressmaker make a waist of the lining material of the dress, fitted to the form, with no stays at all, finished at the bottom with two rows of buttons, an inch apart, the lower one for the under skirts and the upper one for the dress skirt; or have the dress all made in one piece, such as the Empire or Grecian costume, and then the union suits for underwear. I think this is as simple a dress as any one could have, and it can be made in most any of the modern styles that one wishes. I wish to express my appreciation of the kind words spoken, and I thank you all for your attention.

SELECTIONS.

AN INTRODUCTORY ADDRESS TO THE STUDENTS OF THE MEDICO-CHIRURGICAL COLLEGE.

Delivered Oct. 3, 1894.

BY L. WEBSTER FOX, M.D.

PHILADELPHIA.

PROFESSOR OF OPHTHALMOLOGY IN THE MEDICO-CHIRURGICAL COLLEGE.

A Senator, quite famed for his eloquence, asked a brother Senator, who sat beside him during an introductory debate in Congress to stop and hear him speak. The friend replied: "If you are going to make a speech I would be very glad to listen to it, but if you are going to read one of your infernal compositions I do not propose to stay." By a dispensation of your Faculty, I have been obliged to trespass upon your indulgence this evening, and ask you not to leave the room before my composition is read.

This day marks an epoch in your lives. You have launched your canoe on a stream full of hidden rocks; many snags, much disappointment, and no few hardships will overtake you before you arrive at the great ocean of your professional life, which as yet hides from you those worlds you intend to conquer. You do not here leave behind you your student life,—you have only shunted to another track; you now only concentrate your studies to a more definite purpose. You have elected to master the subtleties of a noble profession, and an inestimable service lures you toward its mastery. You have no doubt decided upon this avocation only after the most careful consideration and thought. Your friends trust you, and we trust you; see therefore to it that you neither disappoint yourselves nor us.

No profession demands more from her students than Medicine. She is a jealous mistress. The midnight oil must be consumed; untiring and unceasing your efforts must be made before you can become proficient in your art. The late Sir Andrew Clark, in an address to a class of medical students, said: "Labor is the life of life. Nature will let no man overwork himself unless he play her false."

The majority of you come from the rural districts, all endowed with strong constitutions, clear heads, and good nerve force. See to it that you do not play your natures false. You will be surrounded by the glitter and glamour of city temptations—fascinating and pleasant as the Lorelei's glance. Some of you may become easy victims to the sorceress. Leave her and turn aside, and stick to your calling. Remember, as Dickens has said: "It is well for a man to respect his own vocation whatever it is." You have more to do than simply to respect your calling. Remember, that, in joining the ranks of the students of the Medico-Chirurgical College, you must respect them. You have also a Faculty to consider, who is closer to you than a parent. But I feel confident, when I look upon the bright, intellectual countenances about me, that the above advice is perforce unnecessary. What a grand thing it is to meet students with a purpose! I see it stamped on all your countenances. I see more; and I hear you utter: "Oh, gentle Faculty, by and through your aid we will win." It is written in letters of burning flame upon all your pennants. You ask, Is it fair that all should be demanded from the student and nothing from your instructors? No; your Faculty have grave responsibilities in directing you in the way you are to acquire the science of the healing art. They have been awake to this fact for a long time. The changes in the policy of the school, the selection of the best teachers in the various departments, the addition of new chairs, the selection of laymen of recognized and superior ability in their respective walks of life, all tend to make this College one of the most scientific and practical in the country. Your College has adopted a course which is out of the beaten track, ambitious outside of the old-fashioned type of college teaching. Your Faculty do not wish to be known as men who simply know their books; they will show you that here you will obtain, not only a safe and sound scientific education in medicine, but also eminently a practical one as well.

"The foundation of our art is knowledge of the material to be worked upon,—the human body. Anatomy to its uttermost details, anatomy naked-eyed and minute, normal and abnormal, healthy and diseased, is the foundation of all good surgery." So said J. Greig Smith, and so says our Nestor of anatomy, Professor Pancoast.

Your teachers of anatomy will lead you on, gradually and pleasantly, through the structure of the human body, which you must know all about. How can you expect to become proficient except you know thoroughly the genesis of your profession? The great Titian was a master at mixing paints before he could produce the matchless gems which are still the admiration of the artistic world. Michael Angelo had to know how to temper his chisel before he aspired to produce that wonderful statue of Moses; Morse, the conductivity of metals before he could send messages with lightning speed to the uttermost parts of the earth. Houston, in connection with his former colleague Thomson, had to produce a dynamo before

they could let loose the Promethean spark that now illuminates this and hundreds of other cities the world over. In all the mechanical arts men must understand the foundation of their calling if they wish to succeed. Is it less to ask you to labor unceasingly to understand the framework, the chemical laboratory, the animated organism, the wonderful handiwork of God,—man?

In the acquirement of your profession you will not so much, as time rolls on, be carried to greater heights, but to broader fields of knowledge; and, at last, when you have filled the cells of your brain with theory, then the practical side of your teaching will be given you,—a knowledge so essential to your success in life. Many of you will elect to become general practitioners. Of what value to you is the knowledge imparted by your professor of anatomy, unless you can appreciate and follow the teaching of an Anders, or the application and technique of surgery as taught by Laplace and Ashton? "What hearing is to the physician, so is touch to the surgeon. It is the intellect which teaches both. So, when the opportunity arises, educate both ear and hand."

In this class we confidently hope to find many young men born to be masters of their art. To such I would say: Though work comes easy, work all the harder; make the talent given you increase and multiply. Though you may have genius, yet patience and hard work are necessary to make even genius fruitful. To those who have not been so well endowed, much may, nevertheless, be accomplished by perseverance. Your Faculty will lend all of you an ever-helping hand. The fable of the victory of the tortoise over the hare should be fresh in your memories. As the masses, your future patients, become more highly educated it behooves you to aspire to a higher grade of intellectuality. We must to-day have physicians who are not only skilled in their profession, but who have a mind sufficiently broad to cope with the living questions of the day. In no time of the world's history are the intelligence and judgment of physicians so largely sought after and so highly esteemed in the important questions as how best to cope with epidemic diseases in densely populated communities. If I may make a criticism, I must say that the preliminary education of the young men who are choosing the medical profession for their life-work has not been as thorough as it should be. In this State it is now necessary to pass two boards of examiners before you can practice medicine. Is this fair under existing laws? I say emphatically, no! The State puts on the restrictions, but does she in like manner give us a preventive? While our commonwealth is doing much to foster education, she is far behind in giving aid to young men who eventually must look after the health of her people. The actual prevention of outbreaks of virulent diseases or of blindness is far cheaper than trying to eradicate such evils after they have become epidemic. But in the meantime where must this aid come from? Clearly, we must look to the men who, in the abundance of their wealth, can afford to build laboratories and found institutions where young men can get this preliminary schooling.

The older countries of Europe are far ahead of us in these matters; their medical chairs are richly endowed by the State, and their occupants do nothing but investigate, analyze, and transmit. If the public wish protection, they must perforce lend us a help-

ing purse. I must quote what one of our leading teachers in medicine says on this subject:¹ "In this country, for the most part, we can not look to the State for endowment for medical education, but we must appeal to private beneficence. A few public-spirited and generous men and women have already given practical proof of their appreciation of these facts. With more general and fuller realization of these needs and present condition of medical education, and the results that can be secured by its liberal endowment, there is every reason to believe that these benefactions will be largely and rapidly increased, and that thereby the condition of medical education in this country shall cease to be a reproach to us."

How can we escape from this reproach? You young men who have not had a college education can now take advantage of your environments. You have arrived at an age when your mind becomes retentive and capable of becoming burnished by attrition. In this large city instructive lectures are given on a variety of intellectual subjects. The Franklin Institute throws her doors open to you all. The Academy of Natural Science in like manner extends a helping hand. The Young Men's Christian Association and our churches, whose pulpits, are filled by the ablest clergy in the land, will also welcome you. Select such plays at our theaters as will rest your mind by the way of diversion. Study not only the words, but the grace and movements of the actors. Remember, it is not fair to yourselves to try to brighten your minds and let your bodies remain awkward and ungainly. Plato said: "That one must form not only a mind, and not only a body, but both a mind and a body, to become a man."

In practical medicine, as in many of the mechanical arts, we need not fear reproach. We have shown the world what we can do; but how much better it would be if our scientific knowledge were equal to our mechanical skill! Then we should have students flocking to America for their medical education, just as we are having students from all over the world flocking to our twin sister, the Philadelphia Dental College, which leads the world to-day in practical dentistry. Handicapped, as we are, we are nevertheless progressing. Your college is heading toward that plane of efficiency which places her in the front rank of medical institutions. Many additions have been made to the corps of instructors. Two new chairs have been added, a chair of physics, and it is with great pride that I revert to the fact that the gentleman who fills that chair is eminent in his department, and honored not only in this country, but throughout the whole scientific world. Gentlemen, it is a rare privilege that you will have the opportunity of listening to such a teacher as Prof. Edwin J. Houston. Another chair which has been added, and which will be of superlative value to you, is that of electro-therapeutics. In Professor Kennelly you have an instructor who is one of the leading masters in this new department of science.

And so I could continue to speak of the other teachers recently added to the College. With such additional advantages, you will continue to keep the olive and the gold² ever bright, ever shining. There are other opportunities given you for advancing yourselves. You have a variety of fraternal associations;

¹ Prof. William H. Welch, M.D., Baltimore, Md.

² College colors.

you will be asked to join quiz classes and societies. Join them, and become active workers. Let the "pride of ambition and the inspiration of generous emulation" help you to individual achievement. Let each week have its review. Not only drive the nail, but clinch it. By this means you will become adepts by asking and answering questions. If you fall below your classmates, their success will be a means of stimulating you to better work. Some of the most pleasing recollections in after-life will be your class-day associations. As you go on from one semester to another, your line of instruction will be in keeping with your progress. Your last two years will find you in the field of practical medicine. I mean by this that you will be given the opportunity of becoming thoroughly acquainted with disease at the bedside. You will learn the technique of surgery, gynecology and obstetrics and in the special departments, such as ophthalmology, otology, and dermatology you will have opportunities unsurpassed. Our large clinics in the various departments warrant me in making this statement.

You are on the verge of a future which will, at the touch of your hand, show mighty developments. Let another Pancoast, Gross, Pasteur, or a Koch be found among your class. "Do what you can in your life; make what you can of your life; but, above all, love the highest and deepest and best that you can." As you stand on the shore of the great ocean before you, do not think that you have no other motive than to acquire sufficient knowledge to enable you to pass your examination and thus get a diploma. Medicine is not a complete science; many changes have taken place in the medical world during the last decade; many more will be unfolded in the next ten years. Look what changes have been produced by the discoveries of Pasteur and Koch! In many diseases the whole line of theory and treatment has been changed. Contrast the surgery of to-day with that of a few years ago! How little is known about contagion! The vast field of preventive medicine is almost entirely unexplored. I feel sure that the day is not far distant when such a chair will become the most important in medical colleges. You, who are inspired, remember that many crowns of laurel await you. You may not acquire wealth in gaining these honors, but you may do more,—you may confer blessings upon your fellow-man. "Who can estimate the money value of the discoveries of Louis Pasteur to humanity?" asks one of our ablest writers. In the opinion of Professor Huxley, these discoveries "have made good the war indemnity of five thousand million francs paid by France to Germany."

Personal habits have much to do in making or unmaking a professional career. Abstain from all unpleasant habits. See that your bodily health is as well looked after as your mental. Young men when they join college classes are sometimes led away by the idea that to chew tobacco, use profane language, and approach the slovenly are passports to manliness. Do not make this mistake. If education refine the mind let your habits refine your body. Remember that, of all men, the medical practitioner should be, above all things, a perfect gentleman.

A Case of Double Penis and Imperforated Anus and Rectum.—

On the night of July 7, I was called to attend Mrs. T. in her sixth confinement, and delivered her of a ten pound boy. The first thing to attract my attention after the child was

delivered was that it had two well developed male organs. Each penis is perfectly formed, situated on a line, one one a little to the left, the other a little to the right of the median line. They are one-quarter or half inch apart. Each organ is as large or perhaps a little larger than usual for an infant and fully up to the standard in every particular. He passes a good stream of urine through each organ at the same time. The urethra bifurcates in the perineal region sending a branch through each penis. The scrotum is divided into three compartments by two raphe; the right and left compartments each contain a testicle, and the middle compartment contains a mass resembling a testicle to the touch. Not thinking of any other malformation, I did not make any further search for anything that night, as I thought the little fellow had enough already to make him famous if he lived. I left the mother and child doing well, and on the following afternoon was consulted by the child's father, who stated that it was nauseated and vomiting occasionally. I suggested that they give it a dose of castor oil, thinking that perhaps its bowels needed to be evacuated. On the next morning I called to see the mother, and upon inquiry, learned that the infant was still nauseated and vomiting. Upon examination, I found the abdomen and

stomach greatly distended, respiration very much accelerated, pulse very rapid, face cyanosed, and the child crying out as if in pain. It strained frequently as if its bowels were acting. I examined further and found an imperforate anus. There was not any rectum. Just a little to the right of the median line was a depression resembling an anus, covered with a subcutaneous areolar tissue. There was not any bulging at this point to indicate a rectum or cul-de-sac inside as is usual in these cases. In the median line was a rather hard gristly substance. While Dr. Cherry administered an anesthetic, I made a crucial incision, as Gross advises in his admirable work on surgery. The incision was extended across the median line into the depression on the right of the median line, and carried upward and backward, going about two and three-quarters or three inches up, when we reached the gut or cul-de-sac. A free incision was made into the cul-de-sac, which was followed by a copious discharge of dark offensive meconium. After this was discharged the distension was diminished greatly relieving the infant, who came out from under the anesthetic all right, and rested well during the night. We advised the administration of a dose or two of oil, which was followed by several discharges from the bowels, after which time the bowels acted regularly.

The mother was instructed to dilate the artificial opening with her index finger, two or three times daily. The parts were kept oiled with carbolyzed oil, and syringed out after

each discharge with carbolized water for two or three weeks. The mother failing to keep up the process of dilating, there was a tendency to close up, and at the expiration of thirty days from the operation, it was necessary to dilate the artificial opening more thoroughly. While my friend, Dr. Wynne, administered an anesthetic I dilated and extended the incisions until we got a good free opening. The mother is keeping up the process of dilating three times a day since then. The bowels act as regularly as any child's, and the process of dilatation does not give the child any pain. It is in perfect health and has been all the time. It is now over three months old and is developing nicely. At the age of thirty days it weighed fourteen pounds, and at the age of sixty days it weighed seventeen pounds. The malformations were photographed at the age of two weeks, and the other photograph was made at the age of three weeks.—(By Dr. J. D. COLE, in *Nashville Medical and Surgical Journal*.)

Kaat, the Indigenous Stimulant of Southern Arabia.—Dr. Zwermer, writing from Sanaa, Yemen, to the *Christian Intelligencer*, brings to notice some facts regarding a plant, whose name is almost unknown outside of southern Arabia. In Yemen, however, it is consumed very largely by the adults of both sexes, and is highly taxed. Not less than one thousand camel-loads are brought from the interior to be disposed of at the Aden markets. It is commonly brought into the market in the form of bundles of green twigs, the leaves of which are chewed by the Arabs who have become familiar in its use. The chosen hour for kaat chewing is the close of the day, and it is a strange sight to the foreigner to see the sober-minded Arabs sitting down in groups for the purpose of a social chew of the leaves of the kaat. The following is the best description thus far given in the journals, of this comparatively unknown substance:

"Kaat (*Celastrus catha edulis*) is a shrub or small tree which grows at an altitude of about five thousand feet in the lower mountains of Yemen, especially on the slopes of Jebel Sobr near Taiz. It is uncertain whether the plant is indigenous, but if introduced into Yemen from Africa it came very early, with coffee, when the Abyssinian conquest caused the fall of the Himyarite empire. Perchance some savant will yet find kaat among the inscriptions on the temple at Mareb, and then there would be no doubt that the Queen of Sheba used it herself!

"Kaat is planted from shoots which are left to grow for three years, and then all the leaves and buds are pulled off except on a few twigs; these develop the following year into juicy shoots which are cut off, tied in bundles, wrapped in grass to preserve their moisture, and sold under the name of *Moubdrreh*. The second crop is of better quality, and is called *Mouthanee*. A small bundle, *kilwet*, sells at Taiz for about 5 cents, and a larger quantity, yet scarcely a handful, called *zirbet*, for 10 cents. Only the leaves and young twigs are masticated, but I have seen the poor glad to pick up even the castaway dry leaves and branches to get what comfort they could out of them. The taste of the leaves is feebly bitter and astringent, very like that of the peach leaf. It has stimulative properties, produces wakefulness, in large quantities hallucination, is said to preserve the teeth, and some use it as an aphrodisiac. All Arabs claim that it gives wonderful power of endurance, and that with their kaat and tobacco they can do without food on long journeys. Every one, young or old, Arab, Jew or Turk, uses it, and many use it in incredible quantities. One soldier told me he spent a rupee a day for his kaat, and the Cadi of Taiz pays \$20 a day for this luxury—his household, however, is as large as the Koran and divorce can make it.

"The Ottoman government receives 25 per cent. customs on the market price of the plant above the land tax on kaat culture. That the total revenue from this source is considerable can be judged from the fact that at Taiz, a town of perhaps five thousand population, all the other taxes are farmed for ten thousand dollars per annum, while the daily sale of kaat amounts to over three hundred dollars!

"Directly opposite my lodging at Taiz was the kaat market, open from early morning, when the fresh bundles came on donkeys and camels, but busiest in the afternoon, for the proper thing is to eat kaat just before sunset, and to invite your guest to chew leaves an hour or two before dinner. The sellers sit in the open air and are mostly women. In their rather picturesque costume, unveiled, (none of the

peasants wear veils in Yemen,) they sit the long day, with a basket of the green luxury before them. Sprinkling their ware from time to time to keep it moist; untying a score of bundles to satisfy some proud epicure who tastes before he takes; haggling over the price of a damaged bundle with some soldier; and again swearing as only Arabs can to the genuineness of the kind in question, for kaat has six distinct flavors and varieties, each with a special name, and alas for the slave who was sent for 'Java' and returns with 'Mocha.'"

SOCIETY PROCEEDINGS.

UTERO-OVARIAN RELATIONS OF EPILEPSY.

DR. THOMAS J. WATKINS—Text-books on nervous diseases say but little in relation to pelvic disease as a cause of epilepsy, although most of them mention pelvic disease as an occasional etiologic factor. Treatises on gynecology seem to avoid the consideration of the symptom which we are discussing. Epileptic convulsions may be divided into idiopathic, reflex and hysteroid or hysteroid-epileptic. The two latter alone interest the gynecologist. Many authors, among them Charcot, Dana and Gowers do not believe hysteroid-epilepsy to be epilepsy, but hysteria. William A. Hammond inclines to the belief that it ought to be considered separately from either epilepsy or hysteria. Hysteroid convulsions may occur in cases subject to attacks of true epilepsy and *vice versa*. It is usually possible to differentiate between true epileptic and hysteroid convulsions. Hysteroid convulsions are of rare occurrence in this country and one seldom meets cases of reflex epilepsy, utero-ovarian in origin. The pelvic conditions which cause epileptic convulsions may be physiologic or pathologic. The physiologic are puberty, menopause, pregnancy and menstruation. The pathologic are disease of the uterus or its appendages. The convulsions may comprise a part or all of the features of true epilepsy. The aura is usually present and often consists of a pain starting from one or both ovaries. Pressure over the ovaries will frequently produce convulsions, and a seizure may often be checked by the same process.

Treatment.—When the convulsions occur with puberty, relief may be obtained by general medication or by such measures as are necessary to establish regular normal menstruation. When occurring at the menopause, general remedial measures are also indicated. When the etiologic factor is pregnancy, the convulsions may be a result of a displaced uterus which will require the usual treatment for this condition. The pregnancy, however, may be normal and it may be necessary to produce an abortion to effect a cure. Dr. Geo. J. Engelmann relates a case of epilepsy occurring during pregnancy relieved by cauterization of the cervix uteri, but later it became necessary to produce abortion to cure the patient. She again became pregnant and the epileptic attacks returned, cauterization of the cervix uteri produced no effect and an abortion had to be induced. Convulsions occurring only at time of menstruation may be due to dysmenorrhea or to the nervous excitability which frequently accompanies this function of the uterus. Relief may be obtained by the employment of general remedies, or by the use of such local measures as may be indicated. Three cases have come under my observation where the uterine appendages were removed to stop menstruation; no relief followed in any of these cases.

Experience has demonstrated that removal of the uterine appendages is usually followed by an excitable condition of the patient at the time of each menstrual period, and this condition usually extends over two, three or more years. From limited observation and from theoretical considerations, it is my belief that removal of normal uterine appendages for relief of epileptic attacks which seem to be apparently dependent upon menstruation is an unjustifiable procedure.

Dr. Polk has recently reported a case in which hysteroid convulsions were limited to the menstrual periods. The uterus was retroverted and the ovaries prolapsed and adherent. He removed the uterus and its appendages with the hope of obviating the distressing symptoms which usually follow the artificially produced menopause. The time intervening since operation was too brief to judge of the ultimate

results. The treatment of convulsions due to, or associated with, utero-ovarian disease can be given in a few words. An epileptic should not be deprived of the treatment of any uterine disease from which she may be suffering, such as laceration of the cervix uteri, endometritis, dislocations, displacements, etc. Relief of these conditions is certain to improve her general health and so benefit the epilepsy, and a cure may result. Dr. Chester Morris, of Philadelphia, reports a case of hystero-epilepsy of fifteen years' duration. The patient had had 651 convulsions, but after the restoration of a retroflexed uterus a cure resulted. Dr. Engelmann relates a case of hystero-epilepsy relieved by treatment of endometritis and erosion of the cervix uteri. Dr. Engelmann believed that the great mass of the symptoms due to pelvic disease depend upon uterine changes and not upon disease of the ovaries. Dr. Graily Hewitt is of the same opinion.

Epileptics afflicted with hydrosalpinx, pyosalpinx, ovarian abscess or ovarian cyst should receive the usual treatment for those conditions regardless of the epileptic convulsions.

Cases are on record where relief of such conditions has resulted in cure. Dr. H. Marion Sims reports seven cases of hystero-epilepsy cured by surgical treatment. Two patients had pathologic ante flexion of the uterus; after relief of the displacement perfect cure resulted. The other five patients suffered from cystic or prolapsed ovaries with enlarged Fallopian tubes and adhesions. In these cases the symptoms permanently disappeared after removal of the appendages. In the majority of Dr. Sims' patients the convulsions were not confined to the time of menstruation. Dr. T. Gaillard Thomas, Dr. Sims and Dr. Pollen have each reported three cases and Dr. Vander Veer six cases cured by removal of the uterine appendages. The improvement in the general condition of the diseased appendages will naturally benefit the epilepsy. It must be remembered, however, that epileptics are often improved like all neurotic patients by the mental effect of gynecologic patients; hence it is possible to value the operation itself too highly.

RHINOLOGIC RELATIONS OF EPILEPSY.

DR. HOMER M. THOMAS—The cases of epilepsy which are of nasal origin are exceedingly rare. If we have a case of epilepsy due to nasal obstruction, the condition would have to be an outgrowth of some specific disease or direct pressure which would produce irritation in the cerebral cortex. Hence if we have a swelling of the cavernous muscular plexus underlying the nasal mucosa, the trigeminal nerve being exposed to friction, this condition can be transmitted through the cerebral cortex, and we may have, through reflex irritation, epilepsy.

The literature of this subject, as far as it relates to rhinologic conditions as causative factors in producing epilepsy is exceedingly meager. As a general proposition, the cases can be classed under two general heads. First, those where there is the presence of a foreign body in the nasal passage, such as a shoe button, or bean or kernel of corn, which are quite frequently passed into the nasal passages by children during play or through curiosity, producing slight attacks simulating epilepsy, purely from the mechanical irritation. Again, we may have deviations of the septum in which there are true hypertrophies, septal excrescences or spurs which produce conditions simulating epilepsy from either mechanical irritation or pressure. In regard to the recorded cases, Hinsdale reports two cases of epilepsy cured by removal of a foreign body from the nose. The first case was a sailor 43 years old, and three months after the operation there had been no return of the fits. The second was a man, 51 years of age; but in this case the convulsions did not ensue until thirteen years after the trauma, and the relationship between cause and effect is therefore very vague. A third case was in a girl, 17 years of age, in whom was found a bean in the nose, which was removed, when the fits entirely ceased. It is not, however, stated for how long a time the patient was under observation.

E. H. Griffin, of New York, reports an interesting case of reflex epilepsy, in which the attacks occurred once or twice a week, accidentally and completely cured by the removal of a shoe-button forming the nucleus of a large rhinolith in the left cavity.

A case of petit mal, with concomitant asthma, is described by W. C. Ayres, of New Orleans, in which relief of septal and turbinate hypertrophies, seated far back, relieved all symptoms.

F. Kjellman reports two interesting cases. The first was that of a school-boy, 12 years of age, who had had spasms for two years, with inability to close the jaws, sometimes asso-

ciated with momentary unconsciousness, which gradually increased in severity. There was found, upon nasal examination a spongy hypertrophy of the mucous membrane of the two inferior turbinated bones. The turbinates were cauterized, but a return of the trouble occurred after repeated cold baths during cold weather. Cauterization of the turbinated bones again caused the disappearance of the untoward symptoms, and the boy remained perfectly well. In this case there was a morbid dilatation of the cavernous vascular plexus underlying the nasal mucosa, through which condition the terminal filaments of the trigeminal nerve were exposed to friction, which condition of irritation was transmitted to the motor centers of the cerebral cortex, and resulting in epilepsy, tonic cramp and occasional loss of consciousness. The second was that of a boy aged 6 years. In the slighter attacks he had spasmodic movements in the left hand and arm, and asthma; in the severer attacks epileptic symptoms appeared, with loss of consciousness and clonic spasms. At the examination Kjellman discovered a moderate diffuse swelling, soft to the touch of a probe, on the right inferior turbinated. Cauterization was not followed by any amelioration of the symptoms. The boy had, for three years past, been addicted to the bad habit of sleeping with his thumb in his mouth, and closing, at the same time, the left nostril with the other fingers. Thus, nasal breathing was obstructed. This case seems, according to the author, to prove: 1, that epileptiform attacks of nasal origin are not always due to an irritation of the nasal ramifications of the trigeminal nerve; 2, that certain cases of so-called epilepsia nostrurna are initiated by an asthmatic attack, and are essentially dependent upon obstructed nasal respiration.

My personal experience with cases of epilepsy in which there were nasal symptoms is confined to one case. A young lady from northern Michigan consulted me for well-defined epilepsy. After thoroughly examining the case, I sent her to my esteemed colleague, Dr. Brower, for the treatment of her epilepsy, while I looked after her nasal and throat relations in the case. This case was one of direct and central epilepsy, but in which there was a persistent chronic catarrh with hypertrophy over the turbinated bones. Cauterization of the surfaces produced some relief; at the same time the patient was taking large doses of the bromids, which I have no doubt had more direct influence on the disease than my local applications. In this case I observed that the prolonged use of the bromids tended to excite nasal inflammation—a Schneiderianitis, which is often a secondary result of the constitutional effect of the bromids, and in specific cases where it is combined with the iodids we get a still more marked inflammatory condition. The disease of epilepsy therefore, as an outgrowth of nasal disease, is rather indefinite and ill-defined except when due to the presence of foreign bodies in the nose, or of septal deviations, or from traumatic causes.

RELATION OF PATHOLOGIC CONDITIONS OF THE RECTUM AND ANUS TO EPILEPSY.

DR. JOSEPH B. BACON—Since it is an admitted fact that the sympathetic nervous system is a very important factor in epilepsy, it would seem that diseases of the rectum must call for careful consideration in the diagnosis and treatment of this neurotic condition. So abundant is the sympathetic nerve tissue supplied to the rectum that we might correctly speak of it as forming one of the layers composing the rectal walls. Another anatomic fact is that at the anal end of the rectum there is an equal excess of spinal nervous tissue, composing an intimate anastomosing of branches of the third, fourth and fifth pairs of sacral nerves, together with the small sciatics. When a part of the body is thus supplied with this unusual amount of vasomotor and sensory nerve tissue, we must expect serious reflex disturbances if that organ becomes the seat of disease.

It is a well-known fact that the reflex centers of the rectum are the last to yield to narcosis, coma or the allied states. It is hence easily irritated and such irritation, if continuous, in cases having an unstable nervous equilibrium could set up and maintain an epileptic habit.

In cases of auto-intoxication, a condition frequently found in epilepsy, hepatic derangement occurs and resulting in portal congestion causes hemorrhoids, hence an epileptic hemorrhoidal state occurs and often precedes the epileptic onset. In all such cases an examination of the rectum is necessary and of value.

When the epileptic habit is once established, any exciting cause will tend to keep up the condition; such as vitiated blood, uterine disease, inadequate elimination from the kidneys, etc., causes which frequently are produced from diseases

of the rectum. Impacted feces, irritable hemorrhoids or ulcer, fistulae, all excite the sympathetic nerves of the rectum; the irritation is carried over the whole system, but especially to the uterus, kidneys and liver. This irritation in the rectum causes a vasomotor disturbance in the kidney, for that organ is almost exclusively supplied with sympathetic nerves; as a result a decreased amount of urine is eliminated, the blood is thus vitiated and causes an irritable condition sufficient to excite the epileptic habit to a renewed attack. Again, the rectal irritation after being reflected to the solar plexus, takes the channel of least resistance and expends its force in producing a vasomotor disturbance of the uterus, a condition frequently observed from rectal disease. Thus the uterus, if primarily the cause of an epileptic habit, is again excited sufficiently to become the reflex center and act as the cause of renewing or continuing the epileptic status.

Much more could be said concerning the rectum from the standpoint of spinal nerve irritations and reflexes. While it is necessary to speak of recto-anal diseases as causes of reflex disturbances, with care, on account of the great amount of abuse and quackery going on at present under the guidance of men who work only for financial gain, yet there is and has for a long time been sufficient exact knowledge concerning the reflex centers of this organ to justify us in claiming that in all cases of epilepsy, if pathologic conditions are found in the rectum they should be if possible removed.

AUTO-INTOXICATION RELATIONS OF EPILEPSY.

DR. W. A. EVANS—The discussion that has preceded what I have to say is conclusive evidence that there is something more to epilepsy than the exciting factors which the various speakers have emphasized. That conditions so diverse and so far removed from each other can produce the same train of symptoms and the same effects can follow treatments so diverse is proof positive that there is a common underlying condition. It is a well recognized fact that every body produces substances that are suicidal or destructive to it. It is a well recognized fact, also, that the human body is no exception to this rule. It is equally a recognized fact that the great eliminative organ of the body is the kidney, and the great eliminative product is the urine. Human urine is toxic under circumstances that can be most accurately computed. Normal urine is toxic. Pathologic urine is likewise toxic. Pathologic urine is frequently less toxic than is normal urine. The morning's urine varies in its toxic properties from that of the night. The urine passed during the night time possesses a preponderance of principle that is convulsive. The urine passed during the day time possesses a preponderance of principle that produces or tends to produce coma. There are several physiologic effects of urine. It depresses temperature; it causes salivation; it causes contraction of the pupil; diuresis; a condition of coma, and a condition of convulsion. These conditions are frequently antidotal each to the other. You can readily understand that the urine containing that principle which causes convulsions can have it greatly modified or curtailed by the presence of the principle which causes coma, and *vice versa*. As a consequence, the amount of effect which we get from the night's urine in the one direction of convulsion is much greater than the amount of effect in the direction of convulsion which we get from twenty-four hours urine. The nature of these various substances are complicated. The substance that we have particularly under consideration to-night is the convulsive, which is perhaps a compound of an inorganic substance, probably a potassium salt, and an organic substance whose nature has not yet been determined.

Féré, in 1890, claimed that he had isolated from the urine a toxin which was purely a convulsive product, and always present in the urine of epileptics. This observation has been confirmed by Raymond and Voisin. Bouchard, to whom the greatest credit is due, has proven the presence of a convulsive agent or agents, but he does not hold that the agency producing epilepsy varies from those present under ordinary circumstances except in degree. A number of observers in this country have extracted from the urine of epileptics an increased amount of the aromatic sulphates, skatol, phenol and indol. They are combinations whose original factors are the products of putrefaction, particularly and not exclusively in the intestinal tract. The observations of these men go to show that there is no one toxin which produces convulsions and which stands in a causative relation towards the convulsions that we term epilepsy, but that in this condition there is an accumulation within the system of the toxins which exist there more or less constantly—so constantly that under our conditions of health we must always call them normal. It has seemed to me that epilepsy is not an

entity; that epilepsy is not a disease, but that it is an expression of conditions. The fundamental condition which should overshadow every other is an accumulation within the body of the products of tissue change which should have been eliminated by some of the excretory organs. We know very well that the organ which should eliminate them is the kidney, but we remember further that their production lies beyond the kidney; that the kidney stands in simply an eliminative relation; beyond that, there are areas which stand in a productive relation; the blood itself, the nervous system, liver and spleen, the muscles and other organs;—and perhaps especially with us, the products of putrefaction within the intestinal tract. Putrefactive products are convulsive. In epilepsy there is this condition of affairs: An accumulation in the system of excretory products poises the organism so delicately that some factor hitherto perhaps not of great importance pushes it over and a cataclysm results. Migraine furnishes a minor parallel, a neuralgia due to an accumulation within the body of products which the kidneys should have eliminated. The urine preceding, during and succeeding an attack is similar to that of the same stages of epilepsy. There is a condition of vasomotor spasm similar to that constituting some of the minor forms of epilepsy.

It is well to bear in mind the fact that, if we are examining for the toxins that are productive of any condition, that they may not be found in the urine prior to the attack in great quantity. The increase of toxin production may be followed by either a decrease or an increase of toxin excretion. But that the increase of production is always in excess of the increase of excretion. It is probable, however, that increased production and decreased excretion seldom go hand in hand for protracted periods, for the results would not be compatible with life. A side-light is thrown by the dramatic picture history of chill in which there is an increased production and a decreased excretion of heat. We must bear in mind, also, that the urine of an attack and the urine following an attack may not give us a toxin in the form in which it circulates in the blood, for the condition of affairs that constitutes an attack represents its partial destruction on the part of the nervous system. A chemic change in the product bringing about the condition of affairs that we know as an epileptic attack. An epileptic attack is followed by the emission of a large quantity of very pale urine which may contain an increased amount of the toxin, but it is more probable that it contains an increased amount of the derivatives of the toxin. I have examined urine within the last few weeks from an epileptic boy, and the following was the condition of affairs: The boy weighed 110 pounds. He was passing in twenty-four hours 270 cubic centimeters of urine, with a specific gravity of 1031; total solids for twenty-four hours, 255 grains. Amount of urea for twenty-four hours 136 grains. There was a very marked increase of the aromatic sulphates. This urine was not taken at the time of the attack, nor immediately after, but it was taken in the interim. There was an especially marked increase of indican. It seemed clear that the boy had a condition of intestinal putrefaction, that his albuminoid foods were not being digested, but were being broken down, putrefying in the intestinal tract; absorption was taking place faster than his kidneys were able to eliminate. At first there was a slight accumulation, after awhile there was such a soaking of his system that it was ready to be pushed over by any factor such as eye-strain, nasal or rectal trouble, or whatever path of conduction in that particular boy might be most out of balance.

In conclusion, permit me to offer the following: Epilepsy is not an entity. Most of the cases are fundamentally due to retention within the body of a toxin or toxins whose most marked characteristic is irritativeness to motor nerve areas. During the interim the excretion of this toxin may be increased or decreased. During the paroxysm and immediately subsequent thereto there is at first an enormous excretion of these substances mostly as ash, and then an enormous production of a narcotic substance which is antidotal to the first cause. The increase in production is most often in the intestinal tract. When saturation has taken place by the excess of addition over subtraction, any added irritation may make the first fulminant.

There are cases in which there is so nearly a balance between addition and subtraction that an occasional "vicarious" diuresis or diarrhea would "strike a balance" were the added factor of a pressure on nerve filaments, in nose or rectum, or elsewhere removed.

SURGICAL RELATIONS OF EPILEPSY.

DR. G. FRANK LYDSTON—Perhaps it is incumbent upon me

to apologize for the paucity of results from the application of various surgical measures in the treatment of epilepsy, and not for our surgical resources, for they are multitudinous. It must be confessed that surgery has accomplished very little in idiopathic epilepsy. I suppose that it would be a fair proposition to say that it is almost time for us to abandon operative measures in this form of the disease. It is unquestionably a fact that most of the brilliant cures reported have relapsed, and that very indefinite results have been obtained from surgical operations in this type of the disease. Anesthesia and the effect of shock probably temporarily inhibit the abnormal cell action characteristic of epilepsy. A brisk spanking might do the same. If the theory of the relation of toxins to epilepsy be right, it is easy to understand the failure of operative procedures in epilepsy of idiopathic or central origin. As far as epilepsy of reflex origin is concerned, it is unquestionably true that operative measures applied sufficiently early—and by that I mean prior to the time when permanent changes in the structure and biochemism of the cerebral cells have occurred—are not only indicated but are likely to bring about excellent results. But even in these cases the effects are in a large proportion of cases only temporary. Nearly every man who has operated for the removal of the supposed reflex cause of the disease, has reported the case so speedily after the operation that most of the recorded cases are valueless. The statistics of operative results in epilepsy in my estimation are about as nearly worthless as any statistics that could be mentioned. You will observe that I am not offering any enthusiastic arguments in favor of surgical interference. Operation in some of these so-called reflex cases undoubtedly temporarily inhibits the morbid cell activity, or whatever you choose to call it, that underlies the manifestations of epilepsy, whatever the source of irritation may be. In some cases of reflex neurosis, we have this temporary inhibition of the epileptic phenomena, and from that the conclusion is arrived at that the supposed source of reflex irritation is really the cause of the disease, when it was merely a coincidence. These coincidences in my opinion explain most of the relapses following apparent cures or temporary relief by operation on the sources of alleged reflex irritation.

Regarding the failure of surgical operations for various forms of reflex neuroses, perhaps it would not be out of place to state that the more brilliant results I have in my operative experience, the more skeptical I become after observing these cases. I remember two cases in point as showing how in reflex neuroses we are very apt to form erroneous opinions. One of these cases my friend Dr. Moyer saw with me. It was one of apparent incipient paraplegia in a young child in which I detected the undoubted cause in an extremely adherent prepuce and phimosis. The suspicion in my mind at the time was that there might be incipient tubercular disease of the spine. The improvement which followed the operation was as marked as one could wish. About three months later the patient had definite signs of disease of the spinal column. I referred the case to Dr. Moyer for consultation, and he confirmed my diagnosis.

This case while perhaps not exactly akin to epilepsy, is germane to the question of reflex neuroses in general. It is probable that epilepsy, when of idiopathic or central origin, depends on varying conditions of the brain and perhaps of the spinal cord. This, in combination with the difficulty of cerebral localization, is perhaps responsible for a great many of our surgical failures. It is true that we find in some cases circumscribed changes that are very marked; but in others, although there is a distinct focus, the pathologic condition is not easy to define even when the brain is exposed by operation. It was Van Gieson, I think, who suggested that an expert microscopist should be present in all operations for epilepsy, in order that a correct diagnosis might be made on the spot. This suggestion is not a practical one perhaps, but it illustrates the difficulty of cerebral localization in these particular cases. While an operation may be done for the removal of the diseased focus, the influence of the morbid process is often so far beyond reach that operation fails. In some of these cases there is a distinct pathologic condition of the cerebral cortex, and the relapse or recurrence after the removal of the condition is usually attributed to the formation of the cicatrix which every one present knows is capable of perpetuating a similar condition of irritation to that produced by the original focus. We know that in certain cases in which epilepsy is due to intracranial conditions, such as internal exostosis, localized pachymeningitis, subdural cysts, and tumors of various kinds, relapse often occurs after the removal of what was undoubtedly the original focus of irritation. This shows plainly that what

ever the source of irritation may be, a profound morbid influence upon the cerebral cortex may remain after the removal of the original exciting cause. The most curable variety of epilepsy is the syphilitic form; when I say the most curable variety, I mean when it is taken sufficiently early. We may, however, remove by proper treatment all evidences of syphilis, and still after a certain length of time epilepsy goes on as if no treatment had been instituted. The results are very little better than we have in the ordinary idiopathic or central form of the disease. A gumma of the brain, which it is reasonable to suppose was the origin of the epilepsy, may have been removed and yet the epilepsy may continue. This, I think, is a fair illustration of the limitations of cerebral surgery in epilepsy.

The relations between the various cerebral centers and ganglia and peripheral muscles are not easily established, but we do know that disease of the cerebral centers will bring about epileptiform referable to the muscles; the exact manner in which it is brought about we do not know. We are apt to be guided in our clinical and surgical deductions for operative interference by the most prominent phenomena that are first observed. The removal of the diseased focus may be ignored, in view of the fact that the initial symptoms described by the patient or observed by the physician may be indicative of disturbance of the center of one or the other extremity. This may lead to erroneous deductions, and a wrong cerebral focus may be excised.

A very interesting field, showing that we are not strictly limited to operative measures in these cases, was recently read by Professor Hadra, of Galveston, Texas, before the Southern Surgical and Gynecological Association. He had been using electricity for the purpose of localization of the focus of irritation, after the removal of a greater or less area of the skull. His observations led him to conclude that the repeated application of the electric current to the diseased focus was likely to be beneficial. He does not say that he has obtained any very striking results; but from a careful perusal of his paper I am inclined to think that the treatment he recommends is at least worthy of further experimentation and trial.

The most fruitful field for surgery in the treatment of epilepsy is its early application in cases of traumatic origin. It is unfortunate, however, that in most cases of traumatic origin the epilepsy does not come on until very late, and by that time certain conditions have arisen which render operation for the removal of the original focus of irritation practically useless. So that if operation in cases of traumatic epilepsy is to be of any value, whatever, it should be done very early. Cases have been reported in which encouraging results have been had, but the principal deduction from the results of the operations is that operative surgery, as far as traumatic epilepsy is concerned, should be chiefly prophylactic. I firmly believe that a great many cases of head injury, followed by epilepsy later in life, might have been prevented by an early operation. I know many physicians who condemn interference with the cranium, unless it is an adult, because of the notion that the young skull is elastic and the brain able to tolerate almost anything short of being run over by the wheels of a locomotive. Nature is therefore relied upon. Particularly is this true where there are no pronounced symptoms of compression. I believe this conservatism is carried too far. I believe that in many cases, even without distinct depression of the skull, epilepsy will develop later on as a consequence of localized pachymeningitis, with or without sclerotic changes in the cerebral cortex. Even when there is no depression, a clot may form which may subsequently undergo transformation into a cyst and produce epilepsy. Spiculae of bone may be driven down upon the brain without serious evidences of injury to the cranium. I believe if more radical surgery was done in head injuries, it would be the means of preventing a great many cases of traumatic epilepsy. With regard to the technique of the operation for epilepsy, the suggestion of Victor Horsley, of operating in two stages is a wise one. Here we expose the brain and tamponade with iodoform gauze. It would seem from the history of the cases reported, in which this method has been followed, that the brain tolerates the pressure of the gauze for a day or two very nicely.

I have here a photograph which was sent to me by my friend, Dr. Bernays, of a case of focal epilepsy involving the right arm in which I saw him remove the thumb, wrist and part of the arm centers. It was as good a demonstration as I have ever seen, both with respect to the focus of irritation and its effect upon the arm, wrist and hand, and also with reference to the effect on the boy after the operation.

was completed. There was a history of slight traumatism and there was a small area of thickening of the cerebral cortex which was removed, involving the centers I have just mentioned. As the patient came out from under the anesthetic he struggled vigorously with all his muscles, with the exception of this member, and that remained perfectly helpless. If an exchange of paralysis for the focal epilepsy was fair, the boy was improved, but the remote results I have not heard. (Here Dr. Lydston passed around a photograph of the boy.)

In conclusion, I will state we have great reason to hope that the therapeutics of epilepsy will be greatly improved, but frankly, I do not believe there is much hope of improvement in the direction of operative measures for the relief of this disease. I am sorry to state this as my conviction, but I believe it is logical.

LARYNGOLOGIC RELATIONS OF EPILEPSY.

DR. EDWARD T. DICKERMAN—Not having any personal experience with this rare form of the disease, I depend entirely upon the literature of the subject. What rôle does the larynx play in epilepsy? This question must be answered under two heads: 1, the part the larynx takes in an attack of epilepsy; 2, the part it plays as an etiologic factor.

Under the first division I will say little, merely mentioning the tickling and burning in the larynx which is often experienced during the aura or prodromal symptoms. The characteristic cry or groan, caused by air being forced through the spasmodically contracted larynx, this spasm of the glottis often causing a sense of distress or choking. During the attack, when vomiting occurs, there is danger of foreign matter entering the larynx, while in an insensible state, choking the patient and sometimes causing death. Following an attack we may have loss of voice for a time, due to the general nervous discharge, inhibiting probably the higher centers of the brain.

Under the second head, What rôle does the larynx play as an etiologic factor, much has been said and little really known. In 1876 Charcot described a case with about the following symptoms: A man in good health is suddenly attacked with tickling and burning in the throat, accompanied by more or less coughing, some dizziness, and falls to the floor unconscious. This lasts from a few seconds to a minute, when consciousness returns without any mental or physical disturbance. This train of symptoms Charcot describes under the name of laryngeal vertigo, and advances the theory that it is analogous to Ménière's disease, and that the superior laryngeal is the centripetal nerve affected. How so clear and acute an observer as Charcot could distinguish a similarity to the distressing symptoms of aural vertigo, with its well-defined symptoms, is not known. Up to date, twenty-one cases have been reported, all but one being males, with an average age of 50 years. Gray reports a case, with a careful *résumé* of the subject, and finding in one of Charcot's cases as well as his own, muscular twitching or spasm, comes to the conclusion that the disease is epileptic in character, and describes it as laryngeal epilepsy.

McBride considers the disease, or at least the loss of consciousness due to a complete spasm of the glottis, causes an increased air pressure in the alveoli of the lungs, preventing the circulation, or interchange of blood in the capillaries, therefore less blood in the left side of the heart. The spasm in the neck and thorax, retarding the blood in the veins, causes a cerebral venous hyperemia, and an arterial ischemia, and thus produces unconsciousness by the disturbance of the blood supply to the higher centers of the brain. McBride cites the well-known experiments of Weber, who with contracted larynx and forced expiration, was able to produce decreased action of the heart, unconsciousness and slight muscular twitching. McBride's experiments were on the same line, with the exception that he used the sphygmograph and found that the ascending line of the tracing was much diminished. This theory, although plausible, does not explain why in tabetic crises and other forms of severe laryngeal spasms, we do not have the same result.

Cases have been reported by Gasquet, Krishaber, Loefferts, McBride, Russell, Masee, Knight, Gleihsman, Dauvan, Lennox Brown, Armstrong, Phillips and Adler, twenty-one in all. Of these, twenty were males, with an average age of 50 years.

Unfortunately, the histories of these cases have not been complete, especially in regard to the nervous history and condition of the patient. Two or three cases, I think, can be thrown out, being cases of syncope due to the violence of the cough, these cases never having another attack. In the majority of the cases, prodromata or tickling or burning in

the larynx were present. In ten cases cough was slight. In two cases cough was spasmodic. Three cases had severe attacks of coughing. In eleven cases no confusion after an attack; one case experienced slight confusion. In four cases congestion of head and face was noted. Spasm of the glottis is recorded in about half the cases. All cases are reported cured by some laryngeal or pharyngeal treatment, either operative or medical.

From the above cited symptoms what deduction can be made? We know that with the epileptic habit present we can have a laryngeal reflex epilepsy, as in the well-known case reported by Summerbrod, in which there was a pronounced epilepsy due to an intra-laryngeal tumor, the attacks ceasing on the removal of the tumor. But here the epileptic habit was established, he having had attacks before which ceased on the removal of a scar from his hand.

1. Given, therefore, the presence of the epileptic habit, we may have epilepsy due to laryngeal irritation.

2. The above cited cases present the cardinal symptoms of the petit mal from the epilepsy that is unconscious with or without muscular spasm.

3. Although the symptoms of epilepsy were cured, the subsequent history is necessary to learn whether the habit remains.

PEDIATRIC RELATIONS OF EPILEPSY.

DR. ROSA ENGELMANN—Epilepsy in its pediatric relations resolves itself into a question of responsibility. The pediatrician is the first consulted relative to eclampsia, one of the most frequent disorders of infancy, childhood and youth. It necessitates great diagnostic acumen to differentiate, and accept or reject, the etiologic factors of this symptom. Chronic organic and acute cerebral and spinal diseases first pass in review. Next comes the functional neuroses from reflex irritations. This category includes the hematogenous auto-intoxications and infections of the chronic and acute general diseases, such as rickets, tuberculosis, syphilis, malaria, scarlatina, diphtheria, pertussis, etc., as well as the ordinarily described excitants, such as colic, teething, worms etc. But even the elimination of these etiologic factors is not decisive, since any one or several of them may become the starting point of a subsequent epileptic cycle.

Youthful nervous tissue from its very immaturity and consequent instability conduces to this deplorable result. Hence the recurrence and the formation of a convulsive habit must be guarded against; for the border line between apparently harmless infantile convulsive attacks and early epileptic attacks is hardly demonstrable. Moreover, the danger of the one developing into the other is imminent. The importance of the early recognition of epilepsy is made evident by Gower's statistics. He states that 5.5 per cent. of epileptic cases develop in the first year, and 12.5 per cent. between the first and fourth years, and that one-fourth of the total number of attacks begin before the tenth year of life. Thus early life, endowed with a mobile and impressionable nervous organization, and subject to constant or repeated reflex irritations, inductive of habit formation is a determinative element in the production of epilepsy.

COLONY TREATMENT OF EPILEPSY.

DR. H. C. B. ALEXANDER—Every defective class has been specialized as to philanthropic treatment with one most unfortunate, most afflicted exception—the epileptic. As Dr. Ewart remarks, they alone have been left to work out their own salvation. Often outcasts from the family, thrust out from the schools, shunned by fellows, refused industrial employment, left to idleness and ignorance, friendless, and drifting at last most likely to the workhouse. They are "not so much born into this world as damned into it." What is to be done with them? The civilized world would cry out if it were proposed to place them in a lethal chamber, but after all would it not be more merciful to kill them thus, instead of allowing them to live from day to day a life of misery and despair? If we grasp the central truth that the child is father to the man, we are masters of the future. The impressions and surroundings of childhood mold character. The slums, the alleys, the evil example of parents, the surroundings of dirt, sloth, idleness and dissipation, the absence of restraint, the want of religious and educational influence are responsible for crime and criminals. Collectively and individually the responsibility rests upon man—he can not shelve it by throwing the blame on heredity. It is for the public to cast an ægis over childhood, and fully to accept the debt and responsibility due to epileptic children. As a good many of these unfortunates are as bright, intelligent, capable of being educated, as well adapted for industrial pursuits as ordinary human beings, the injustice to the

epileptic locked up with the insane becomes apparent. What they require is industrial training combined with medical supervision.

Movements for this much neglected class began with classification of patients in insane hospitals. As these grew in size and the cottage system was adopted, the possibility of separate colonies for epileptics became apparent.

Over forty years ago a clergyman, Mr. Bodt, established a colony at La Force near Lyons, France, which is still in a flourishing state and doing excellent work. A more extensive experiment was made in Germany about twenty-four years ago. Pastor von Bodelschwingle, a Lutheran clergyman, advocated a refuge where these sufferers might be cured, if curable; where they might have a comfortable home if recovery were impossible; where they could develop their mental faculties in the highest degree by acquiring trades or taking part in whatever occupations they might select, finally developing into a community of educated, industrious and contented citizens. He purchased a farm near Bielefeld (Westphalia), and with four epileptics established a colony which gradually expanded. In 1878 it contained 250 epileptics; in 1882, 565, and at the present time considerably over 1,100. During this period 2,407 have been received, and of these 156 recovered, and 450 improved. The colony with its gardens, farms, and cottages is scattered over 320 acres of beautiful woodland and meadows. The chief features in the management are the system of decentralization, the division of the patients, as much as is possible, into small families residing in cottages, the separation of the sexes and of the feeble-minded from those whose mental faculties are more or less normal. To secure a sufficient number of male and female nurses, training schools have been established. The authorities not only have a supply for their own use, but are enabled to send them to distant places.

Making and repairing wearing apparel, knitting fancy work, the laundry, etc., furnish employment for the women, who are also to be seen attending to the gardens. Men have a greater variety of occupation; the printing establishment, book-binding, illuminating picture cards, floriculture, agriculture and fruit raising. There are also a bakery, foundry, tailor and boot shops, dairy and brick-yard. In all, there are over thirty different callings which employ many hands. An orchestra is made up from their own ranks. There is everything to distract the minds of the patients. Every workshop has its mattress ready for use, and there are plenty of willing hands always about to help those who may happen to have a fit. The colony is a hospital for the use of epileptics, and a school for the education of epileptic children, an industrial institute for the adults, and an asylum for those who become insane. The Countess of Meath, speaking of a visit to these colonies, remarks: "Though the men do occasionally hurt themselves in falling, they do not seem to suffer more serious injuries in these workshops, where dangerous tools are about, than if they were employed in an occupation not necessitating their use. And what a blessing must employment be to these poor fellows, giving them the means of forgetting their afflictions and making them realize that they are able to take part in the work going on in the world."

Since the successful establishment of this colony, several similar institutions for epileptics have sprung into existence on the continent. Among these are Rotenburg in Hanover; Maria Hilb near Munster, and Olpe in Westphalia; Alexandra-Kloster at Aix-la-Chapelle, and Rath near Dusseldorf for the Rhenish Province; Neinsted-Thale for Saxony; Tabor near Stettin for Pomerania and Posen; Karlshof near Rastenburg for East and West Prussia; Potsdam for Brandenburg; Haarlem in Holland and Zurich in Switzerland. As might have been anticipated from the altruistic peculiarities of epileptics in insane hospitals, it has been found in these colonies that no harm is done by bringing epileptics into contact with each other. They feel on an equality with their fellows in such a place, losing that sense of isolation and singularity which they can not but observe in the ordinary world as separating them from the rest of mankind. They enjoy caring for each other and being kind and helpful to their fellow sufferers. It has been noted also that the number of seizures almost always diminishes upon entering the new, hopeful, encouraging life together by the busy community.

The movement for epileptic colonization began in the United States in Ohio. At Dr. Peterson's suggestion, Gallipolis was selected. The buildings unfortunately are grouped too closely to subserve best the purposes of an epileptic colony. In California, buildings for the epileptics have been

erected in the grounds of the Home for Feeble-Minded. A law was passed by the Legislature making the State Board of Charities, a commission, to select a site and prepare plans for an institution for epileptics. The law was authoritative in requiring the tract of land secured for the purpose to be 400 acres or more in extent. The whole scheme of building to be arranged on the colony or village plan. It will receive patients next spring.

In Massachusetts there was opened, in 1882, the Hospital Cottages for Children, at Baldwinville. The institution was first organized as a private charity, but is now governed by five trustees appointed by the Governor and fourteen appointed by the corporation. It has been liberally aided by the State. Children under 14 years of age are admitted who are suffering from epileptic or epileptiform seizures; children suffering from nervous disorders, not feeble-minded; children with deformities, diseases of the joints and infantile paralysis; also those needing surgical operations and fitting supports. Sept. 30, 1893, the hospital contained 103 children. The whole number treated during the fifteen previous months was 170, about two-thirds of whom were epileptics.

In Pennsylvania the Elwyn Training School for Feeble-Minded has two buildings for epileptic boys and girls. The Church of St. Clements, Philadelphia, has a small hospital for sane epileptics. The Michigan Legislature has passed a law for training epileptics in separate buildings on the cottage plan. The Minnesota Training School for Feeble-Minded has established an epileptic department with special supervisory care. The King's Daughters of Baltimore, Md., have purchased a small farm and are attempting to establish an epileptic colony. Next to Ohio, New York has manifested most interest in epileptics. New York City long had a special hospital for epileptics and paralytics, and the creation of a State hospital had been urged for nearly twenty years when, in 1891, a law passed for the purpose but was vetoed by the Governor in 1893.

The proportion of epileptics to the general population is about 1 to 650. These figures are, however, merely approximate, but they are under rather than over the mark. If, as justice to an afflicted class and to the community demands, provision be made for this class in Illinois, whose self-respect requires that it lag not behind Ohio and New York, then the estimates should be made on a basis of 2 in 1,000 as a beginning.

The main principles to be observed in the organization of such a colony are, as Drs. Peterson and Ewart have shown,—land, to consist of at least 500 acres, adapted to agriculture and horticulture. This land should be within easy access of a large city, giving a ready market for produce; three small buildings, to be arranged into separate divisions for the male and female patients, each of these divisions to make provision in separate cottages for the insane, the convalescents, the school children, the workers and private patients of the higher classes; every patient, without exception, should be under medical care and there should be a medical man for every 200 patients; an educational building for epileptic children; workshop for adult epileptics, farm buildings, dairy, etc., and a special laboratory for the study of epilepsy by a skilled pathologist.

(To be continued.)

Oleomargarine in the Navy.—In New York, the State Department of Agriculture has supervision of the sale of oleomargarine. A prosecution of a grocer of Brooklyn recently occurred under circumstances going to show that the sailors of the United States Navy regard oleomargarine with favor, as an article of diet. The statement was made in court that so long as this substance looks like butter and does not become rancid the sailors make no inquiry into its origin. He has found that it keeps better in torrid climes, and very few warships go out of port for any southward cruise without a large stock of the imitation butter. While any person may legally keep and sell this substance, if it is labeled and known to be oleomargarine, it is unlawful to sell it as butter. This is State law, and not Federal law. There is no United States law against this sale. Accordingly the defense was entered for the accused grocer that his sales were made in the navy-yard and not in the State of New York. It so happened that the particular sale, in which the grocer was detected by the agents of the State Department, was to fill an order for oleomargarine that he had received from the navy-yard.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00

SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, NOVEMBER 10, 1894.

DIET OF THE PAUPER INSANE OF NEW YORK CITY.

DR. AUSTIN FLINT recently testified before an investigating commission in New York, regarding the relative dietaries of hospitals, asylums and correctional institutions. From 1867 he has been a real or nominal consultant as to the dietaries to the Commissioners of Charities. He testified that he was not called upon very frequently to give advice, and in fact could not name the year of, or occasion for, his last consultation in this capacity. He further testified that his advice was not always followed; for example, the diet tables prepared by him for the insane were not put in use, but the Commissioners, in their wisdom, saw fit to adopt for these demented the tables that had been intended for criminals and workhouse people. The tables, as framed by him, would have given the insane the same dietary as had been arranged for the sick in the hospitals. And he explained his principle of action in this regard in this manner: He felt that a discrimination should be made in favor of the lunatics and the sick, they having been guilty of no crime, so that they should be allowed more food, in these tables, to keep them in the best condition possible, while the criminals were entitled to only such diet as would keep them in a fair condition of physique.

DR. FLINT condemned the use of coffee mixed with chicory, and the boiling of tea for an hour or more could only spoil a good article. He condemned the use of molasses and found that the quantities of butter and fish—three-quarters of an ounce of the former at breakfast and supper, and eight ounces of the latter—were altogether too limited. The quantities of certain important articles, as eggs, butter, fish, were in the city institutions below those in the

tables supplied to the State hospitals for the insane. From this, and other testimony, the discriminations against the city insane have been brought into view. There has been, even, a favoritism displayed toward the criminal demented. The criminal insane of New York City, who are consigned to the State Asylum at Matteawan, have an allowance of \$3.75 per week; while the city charges, guilty of no crime, receive only \$2.73 per week, taking the average of five years. Under the State Commission, no such discrimination is made between the pauper and criminal lunatics, and this has been one of the fortunate results brought about by the legislation of the last three years. The insane of the State of New York have been benefited by the principle of "State care," and New York County may come in under its provisions so soon as the politicians can be induced, or compelled, to relax their hold on the throat of the pauper demented.

A NEW FIELD FOR THE COLLEGE.

The remarkably healthful season of 1894 has given the average doctor plenty of leisure in which to ponder many things. Among them none, probably, has received more attention than the fact that the struggle for medical existence is, year by year, growing sharper and more strenuous. Whether it be that people are becoming more healthy or that the supply of doctors is excessive, the fact remains; and, in either case or both, any new avenue to increased usefulness and consequent increased income must be welcome.

Such an avenue seems to offer in the present period of development of our public health services—National, State, municipal and rural. The amount of work these services already accomplish, even in their relatively inchoate condition, and their beneficial effect upon the public health, can not be over-estimated; indeed, it is not at all unlikely that to their efforts is due some considerable share of the lessening demand for the doctor's services. There is, too, the further consideration that the average practicing physician does, in the aggregate, a vast amount of volunteer sanitary work for which he not only receives no compensation but which, *pro tanto*, reduces his paying practice. To the extent that all this is true there would be a practical as well as poetic justice in securing for the physician a fair proportion of the amount the community saves by being kept well, through improved sanitary conditions and the efforts of preventive medicine, over and above the sum which would otherwise be paid for being treated when sick with preventable disease.

The present outlook offers no immediate remedy for this anomaly—an anomaly which is peculiar to the medical profession whose members after having qualified themselves by years of expensive study for

the treatment of disease, voluntarily and without pecuniary recompense exert themselves to limit and prevent disease. The logic of the situation, however, points to a near future in which the forces of preventive medicine, sanitary administration and public hygiene shall be organized so effectively as to compel recognition by the Nation, the State and the community, and so secure adequate compensation for services now but poorly paid for or wholly unrewarded. As a step to this consummation, the JOURNAL offers for the consideration of the Medical Colleges of the country, the suggestion that the degree of Doctor of Public Health, or its equivalent, be instituted and that provision be made by them for the necessary course of instruction.

Such a degree was first established by the University of Dublin in 1871, when the status of sanitary administration in Great Britain was little if any better than it is in the United States to-day; the example was followed by the Universities of Cambridge and Edinburgh in 1875, and the increasing number and influence of diplomates in Public Health finally led to the recognition of the diploma by an Act of Parliament, which provides that no person shall be appointed medical officer of health in any district unless he is legally qualified to practice medicine, surgery and midwifery; nor in any district of over 50,000 inhabitants unless he is also the holder of a diploma in sanitary science, public health or State medicine. The present effective sanitary administration of that country and the recognized status of its sanitarians, their rewards and honors, are largely due to this degree, voluntarily instituted by a medical college at the instance of the leaders of the medical profession.¹

There can be little question that similar action by our medical schools will produce similar results. Not less in the interest of the development of our sanitary administration than in the practical interests of the profession—in furnishing an assured vocation for a large number of its members—there should be some provision whereby the membership of State and local boards of health, and especially the executive positions of all health organizations, could be filled by men especially fitted and trained for the work, such qualification to be duly attested by the degree of D. P. H.

"IMPEACHING" A HEALTH COMMISSIONER.

The current chapter in the disgraceful history which the city of Milwaukee is making for itself, in connection with the smallpox epidemic, is the "im-

¹ Dr. Charles E. Paget, in a recent presidential address on "Some Imperfections of Public Health Administration," says: "I believe that the University of Dublin even held its first examinations [for the degree of D. P. H.] in 1871, before the passing of the Act which made the appointment of medical officers of health obligatory in England and Wales." He adds, in the same connection, "Let it, therefore, be clearly understood and remembered that this additional impost on medical education was made for the welfare of the country and to the honor of our profession—voluntarily and from high motive, not by legislative decree or in deference to popular demand."—*The Lancet*, Sept. 29, 1894.

peachment" by the City Council of the Commissioner of Health, DR. WALTER KEMPSTER. The JOURNAL has, from time to time, recorded the anti-vaccination and smallpox riots, the lawlessness and bloodshed, which have attended the efforts of the health officers of that city to enforce the public health laws of the State and the municipal sanitary ordinances. The courts have sustained the health authorities in their legal right and duty to enforce vaccination, to remove smallpox patients to isolation hospitals and to erect and maintain such hospitals. These authorities assert that they are powerless to enforce their rights and to discharge their duties because of the hostility of the City Council and have appealed to the State Board of Health for assistance. That body has made an investigation and in its report sustains the Health Department, indorses its action, and recommends to the Governor that military force be employed, if necessary, to enable the Department to cope with the epidemic. GOVERNOR PECK has refused to do this, on the ground that the city has not yet exercised its own authority nor exhausted its own resources. Meanwhile, the disease continues to spread. Less than half the known number of cases are in the isolation hospital, an unknown number are concealed, the deadlock between the City Council and the Department of Health gives no signs of being broken, and a well-informed correspondent of the JOURNAL writes: "The disease has such a start now that I do not look for its speedy termination under any circumstances, and fear that it will only cease to exist after it finds no more material to feed upon."

The attempt to impeach DR. KEMPSTER is based upon charges that undue force was used to remove patients to hospital; that officers of the Department spread contagion by riding in public vehicles; that patients not afflicted with smallpox were taken to the isolation hospital and convalescents discharged while still in a dangerous state; that quarantine was imperfectly maintained and the hospital shamefully mismanaged, etc. Many of the charges are trivial, some notoriously untrue and others susceptible of such explanation as to relieve DR. KEMPSTER of any responsibility for their existence. But even if it were admitted that all the charges were well-founded, that would constitute a sorry defense for the attitude of the City Council of Milwaukee in neglecting to secure first a vigorous enforcement of the existing sanitary ordinances which they are sworn to support, and a proper respect for law and order of which they are supposed to be the guardians.

The investigation of DR. KEMPSTER at the proper time may or may not be justifiable; of that the JOURNAL does not assume to judge. But it is not now the proper time, and never will be, so long as such investigation interferes with or delays the suppression of a loathsome disease whose unrestrained existence and spread menaces other communities and commonwealths.

SANITATION AT THE COMMUNION SERVICE.

The Bedford Avenue Church (Baptist) of Brooklyn, New York, has followed the example of a church in Rochester, in bringing into use individual cups for the communion service. This step has been under consideration for six months, under the lead of the pastor, DR. GUNNING, who is a graduate in medicine. The cups adopted in this instance have a capacity of one-half an ounce, and the wine that will be used will be an unfermented grape-juice. This new arrangement will for a time stand as the ultra-sanitary plan for this act of church ritual. The most weighty argument that has been used for the furtherance of the new plan has been that there seems to be no good and sufficient reason why cleanly people should drink from one common sacramental chalice, any more than the same people should have a repugnance to making use of one common teaspoon, or one common toothbrush.

It may not be easy to bring proof that any given case of disease has been communicated by means of the churchly chalice, but these two congregations, above referred to, are content to serve as pioneers and to give themselves the benefit of the doubt, as against the possible spread of diphtheria, and the like, by the common drinking vessel.

THE ASSOCIATION TREASURER'S NOTICE.

It is extremely gratifying to observe the unanimity and good business sense shown by many members of the ASSOCIATION in paying prompt attention to the notice of the Treasurer. There are, however, many members still in arrears for the annual subscription due last June.

The JOURNAL, grateful for the cordial and kindly responses already made to DOCTOR NEWMAN'S request, yet hopes that the next month may show all membership arrearages paid in full. To that end we earnestly urge those in arrears to make prompt remittance to the Treasurer, in order that the ASSOCIATION treasury may show a handsome balance on the right side of the ledger, and that the JOURNAL may commence the new year with that strength which always accompanies a solid bank account.

CORRESPONDENCE.

The Dispensary Question.

CLEVELAND, OHIO, NOV. 1, 1894.

To the Editor:—I have noticed that our JOURNAL has from time to time denounced the "dispensary abuse," but, on the other hand, I have noticed the apparent apathy of the profession in regard to this question. I would call your attention to the fact that here in Cleveland we have the profession at large agitated over the question of the dispensary abuse, partly brought about by a trial going on between two homeopathic physileans in regard to this dispensary question—the judges in the case being two trustees of their college.

In my own case the trial was before a jury in a justice

court. I sued the defendant for services rendered. The defendant came to the college dispensary looking for the surgeon who treated cripples. On being questioned he asserted a willingness to pay. He stated that he had a correspondence with Columbus, Ohio, parties who would correct the club-feet of his boy for \$500. He stated that \$500 was too much, but that he could pay a reasonable fee. I agreed to do it for a reasonable fee—less than \$500. For personal convenience I very commonly have private patients from in and out of town go to the college building, when a plaster-of-Paris dressing is required, but it is not applied in the presence of the class. This is done at the college instead of my office, on account of having plenty of help at the college, and also that it saves my office from being littered with plaster.

In this case I applied plaster to the child's feet several times at the college building. The operation was performed at University Hospital. The treatment was continued at the defendant's home and my office—lasting in all about four months.

The defendant re-assured me over and over that he would pay, and acknowledged indebtedness in the presence of others. Finally, when I tried to collect my fee he denied indebtedness, claiming that I treated his child as a clinical case before the class. My answer to this was that there was no session of the college and therefore there was no class. I sued for \$262.50. The defendant had paid on account \$5. The jury granted \$143 with interest for three years.

In discussing the "dispensary abuse" there is no chance for argument in regard to the deserving poor—they are never turned away from dispensaries to my knowledge. The question is, Is it right for a dispensary to treat the well-to-do? My argument on the subject is as follows:

I hold that the services of dispensaries are maintained solely for the poor. That, in return for the services rendered, the poor patient may be used for clinical teaching. That the wealthy make donations to the institutions on the representation that the money is to be used in this way. That to obtain donations in the aforesaid manner and then to use the funds so obtained partly for the benefit of the well-to-do, is usually called "*obtaining money under false pretenses*," and is punishable by fine and imprisonment.

But we all know that this abuse exists, and what is the cause? As I see it, the incentive is the inherent selfishness of man; it is largely brought about (especially in the great cities of the East) by the men at the top—those in authority. The professor says to himself: "The larger the clinic, and the more assistants I have, the more important is my position. Then, these middle-class patients do not come from my following—I lose no practice by it." It was from the same motive that one of the Vanderbilts was led to say: "The rights of the public be d—d." In this case it would read: "The rights of the profession be d—d."

The dispensary has no rights in the handling of patients, further than the treatment and clinical use of the poor. It has no moral right to enter into competition with the outside practitioner.

But what about the rights of the dispensary physician? He is in active outside practice and has educated himself for that purpose. He is in open competition with all other practitioners and has a moral right to increase his practice by any honorable means, *i. e.*, in this case to take what additional practice the dispensary may accidentally or incidentally bring him. What right has a dispensary to say that, we, as a dispensary acknowledge that we have no right to this well-to-do patient, but we shall not permit you (the dispensary physician) to treat him? What right has a dispensary to discriminate against their dispensary physicians? Certainly the dispensary would admit the right of some

other doctor (who might be physician to some other dispensary) to have the patient as a private case.

I am willing to abide by any reasonable rule of a dispensary as to the treatment of the poor, but will brook no dictation from any such organization as to whom I shall treat among the well-to-do.

Dr. Bishop, the defendant in the trial between the two homeopathic physicians, sent out a card to the physicians of the city, asking the opinion of the profession in regard to the dispensary abuse. He claims to have over one hundred answers, in which they all denounce the abuse, and agree that dispensaries are solely for the poor, with the privilege of using the patient for teaching purposes.

Respectfully, WM. E. WIRT, M.D.

Priority in Craniotomy and Microcephalus.

GRAND RAPIDS, MICH., NOV. 5, 1894.

To the Editor:—I desire to state through the JOURNAL, that craniotomy for microcephalus is as distinctly American as ovariectomy and several other operations instituted in this country for the benefit of humanity. I take issue with Prof. Carl Beck in his paper published in the JOURNAL October 27, and November 3, on two points: 1, in his statement that Lannelongue of Paris, is the pioneer, if I understand the meaning of this word aright to be the man who moves in first. This point, however, does not afflict me since in point of time the date of my operation obliged him to place me first upon the list of operators. I reported two cases in the same paper dated 1878, which was widely circulated in several countries and severely commented upon by both the medical and secular press. I have operated altogether five times for mental defects, with no deaths. A perusal of my paper will, I think, convince any one that I took care to make a careful diagnosis and that I was at the time conscious of the causes which produce mental imbecility, that my deductions were rational, and that I gave these cases the same careful attention that I give to any case in general practice, for which reason I demur against being set before the profession as an experimenter and human vivisectionist.

Between the years 1876-78, I read several papers upon affections of the brain before the Montreal Academy of Medicine, which were warmly discussed by such men as Dr. R. P. Howard, Dean of the Medical Faculty of McGill College; Dr. Henry Howard, Superintendent of the Long Point Asylum; Dr. Wm. Osler, of Johns Hopkins, Baltimore; Drs. Hingston, Bass, Boddick, Fenwick, and Dr. Casey Wood, now of Chicago; all eminent men in the profession and severe critics, in the presence of whom it is not reasonable to suppose that I would present a radical departure in any department of medicine, as surgery unsupported by an adequate rationale.

Furthermore, I lay claim to the originality of the introduction of veratrum virid and morphia in the treatment of convulsions and puerperal eclampsia, and of pointing out that these symptoms are caused by arterial spasm and anemia of the nerve centers. I tapped the ventricles of the brain at this time, and discovered that sometimes there was no fluid in cases in which I had expected to find an effusion, which led me to the discovery of a distinction between the coma of compression and the coma of irritation, which was published and, as far as I know, has not been noticed by the profession, though the importance of this distinction ought not to allow it to fall into neglect since the latter class of cases are amenable to treatment successfully by medicine, while the former are, for the most part, hopeless, unless we may expect something by surgical interference.

Yours very respectfully,

WILLIAM FULLER, M.D.

Doctor Diet, Doctor Quiet and Doctor Merryman.

CHICAGO, NOV. 2, 1894.

To the Editor:—One of the evening papers of this city, in quoting the well-known sentence at the head of this letter, attributes the saying to Jonathan Swift. Will you kindly state if this is correct, and oblige, yours very truly,

INQUIRER.

ANSWER:—The original is as follows:

*"Si tibi deficient medici, medici tibi fiant,
Hactria: Mens hilaris, requies, moderata dieta."*

This was in the famous "*Flos Medicinæ*" or *Regimen Sanitatis Salerni*, composed in the year 1099 by Johannes de Mediolanus (John of Milan) with the concurrence of the other professors of the celebrated School of Salerno. This book was first translated in English by Paynell in 1579, and later by Dr. Philemon Holland in 1634. Holland's translation of the sentence reads:

"When Physic needs, let these thy doctors bee,
Good dyet, quiet thoughts and heart mirthfull free."

"Mirth," says Burton, 1621 (*Anatomy of Melancholy*) "is one of the three Salernitan doctors, Dr. Merryman, Dr. Diet, Dr. Quiet, which cure all diseases."

Dean Swift was born in 1667 and died in 1745, and if he ever used the expression, was too profound a scholar not to have used it as a quotation.

A Good Word for the Eucalyptus.

CHICAGO, NOV. 5, 1894.

To the Editor:—There may be some foundation for the popular belief that the cultivation of the eucalyptus tree has a salutary influence in antidoting the poison of malaria, though in your editorial in the issue of the JOURNAL of October 27, you discredit it. Our knowledge of the origin and nature of malaria is very vague. I think, however, that rapidly growing vegetation in some way modifies the effects of the poison and renders it less harmful to the human system. I say the human system, for malaria is not observed to have any injurious effect on animals. Perhaps it is assimilated by vegetables in their growth and incorporated into their organized substance. It is likely that all growing vegetation has the same effect.

I lived for a time on the Sangamon "bottoms," when that part of Illinois was newly settled. This was a plain about two miles wide and extending twenty miles from the mouth of the river toward its source. Its elevation was not enough to prevent portions of it from being overflowed when the river was high. It had an alluvial soil of unsurpassed fertility and consequently it produced an enormous vegetable growth. This was then among the most malarious districts in the United States. Agues and other malarial fevers were annually endemic here, from September until the following April. They would then cease until autumn came again. They were not developed when vegetation was in active growth but would return when this process was at rest, yet before the mature vegetation of summer had begun to decay.

Many cases of ill health having an obscure origin and unknown pathology are attributed to malaria, but typical intermittent malarial disease is now but little known in Illinois. I do not think I have seen six cases of shaking ague in Chicago in a quarter of a century. I could find as many in one family at one time on the Sangamon "bottoms" fifty years ago. I am told by physicians practicing in that vicinity that it is not prevalent there now. The amount of vegetable product in Illinois has increased many-fold since its soil has been brought under cultivation. The native grasses would not produce more than one ton of hay to the acre. The cultivation of grasses and cereals has greatly increased this amount, and this may be the reason that malarial diseases are no longer common in Illinois. If this theory is true, the eucalyptus, being a tree of phenomenally rapid growth, should have some protective influence against this class of diseases.

EPHRAIM INGALS, M.D.

34 Throop Street.

ASSOCIATION NEWS.

Treasurer's Notice.—Members of the ASSOCIATION knowing themselves to be in arrears will please send the amount of their annual subscription to the Treasurer, HENRY P. NEWMAN, M.D., Venetian Building, Chicago, without delay.

The great expense on account of the establishment of the new JOURNAL office, makes it more than ever necessary that our members should be prompt in their response to this notice.

SOCIETY NEWS.

Chicago Gynecological Society.—At the sixteenth annual meeting of the Chicago Gynecological Society, held Oct. 19, 1894, the following officers were elected to serve the ensuing year: Dr. Franklin H. Martin, President; Dr. A. J. Foster, First Vice-President; Dr. J. C. Hoag, Second Vice-President; Dr. H. P. Newman, Secretary, and Dr. T. J. Watkins, editor. The retiring President, Dr. Fernand Henrotin, delivered an interesting annual address after which the Society adjourned for the annual banquet. Drs. J. B. Murphy, Health Commissioner Arthur Reynolds, Alex. H. Ferguson, John B. Hamilton and others were guests of the Society.

New York Medico-Legal Society.—*Psychologic Section.*—There will be a meeting of the Psychologic Section of the Medico-Legal Society at the residence of H. W. Mitchell, M.D., 747 Madison Avenue, at 8 o'clock p.m. sharp, on Monday evening, Nov. 12, 1894. The Chairman, Prof. Elliott Coues, of Smithsonian Institute, will preside.

The program is as follows: Opening Address by Prof. Elliott Coues. Subject: "Psychic Research in its Medico-Legal Aspects."

"Hospitals for the Insane and their Management." By Clark Bell, Esq., reviewing the address of S. Weir Mitchell, M.D., before the Medico-Psychologic Society.

Discussion, limited to five minutes each, by the Superintendent of Hospitals for the Insane; Experts; and Assistant Physicians; including Superintendents Page, Harrington, Quimby and Walter Channing, of Mass.; Rohé and C. K. Clarke, of Md.; C. H. Hughes and C. A. Woodson, of Mo.; Clark Gapen and Frank P. Norbury, of Ill.; Blackford, of Va.; F. C. Hoyt and Gershom H. Hill, of Iowa; A. F. Kilbourne, R. M. Phelps and C. K. Bartlett, of Minn.; John Curwen, G. R. Trowbridge, of Pa.; H. A. Buttolph, of N. J.; W. A. Gorton, of R. I.; J. H. McBride, of Wis.; W. B. Fletcher, of Ind.; A. B. Richardson, of Ohio; O. R. Long and C. B. Burr, of Mich.; Jas. T. Steeves, of N. B.; T. J. W. Burgess, of Montreal; E. S. Blanchard, of P. E. Island; R. L. Parsons and W. S. Fleming, of N. Y.; Michael Campbell, of Tenn.; C. P. Bancroft, of N. H.; D. R. Wallace, of Texas, and others.

"Popular Illusions." By J. H. Hyslop, Esq., of Columbia College, New York City.

"The Psychology of a Jury in a Long Trial." By T. D. Crothers, M.D., of Hartford, Conn., Vice-Chairman of Section. Discussion limited to five minutes. Opened by Judge A. S. Dailey.

Report of Committee, by H. W. Mitchell, M.D., Chairman, on Test Experiments in Telepathy and Mind Reading by Miss Maud Lancaster, before the Section.

"Psychologic Experiments and how the Spirits do their Work." By Prof. J. Louis Kellogg, Esq.

Professor Sundeen has been invited to make some experiments.

Report of Executive Committee on new members and other business. Each member of the Section is entitled to bring one guest. Members and others wishing extra admissions will apply to Dr. H. W. Mitchell or the Secretary. Members will please be prompt. Every member of the Society is eligible to membership in this Section on payment of \$1.50 annual dues, which entitles the member to the Bulletin free.

ELLIOTT COUES, Chairman.

CLARK BELL, Vice-Chairman and Secretary.

The Southern Surgical and Gynecological Association.—The seventh annual meeting of the Southern Surgical and Gynecological Association will be held in Charleston, S. C., Nov.

13, 14 and 15, 1894. Members of the medical profession are cordially invited to attend.

The program is as follows: Memorial Address on Dr. Warren Stone. By A. B. Miles, New Orleans, La.; Operation for Complete Perineal Laceration. By Jos. Price, Philadelphia, Pa.; Gonorrhoea in Women. By J. B. S. Holmes, Atlanta, Ga.; Some Cases of Intestinal Obstruction, with Deductions Therefrom. By A. M. Cartledge, Louisville, Ky.; Hernia of the Diaphragm, with Report of a Case. By Floyd W. McRae, Atlanta, Ga.; The Treatment of Sinuses Following Celiotomy. By W. H. Wathen, Louisville, Ky.; The Diagnosis and Treatment of Congenital Cystic Hygroma. By J. A. Goggans, Alexander City, Ala.; Some Complicated Cases of Abdominal Surgery. By J. G. Earnest, Atlanta, Ga.; Early Operation in Appendicitis, with a Case. By J. McF. Gaston, Atlanta, Ga.; Appendicitis. By W. B. Rogers, Memphis, Tenn.; Attention to Women Before and After Labor. By W. G. Bogart, Chattanooga, Tenn.; Plastic Operations for Carcinoma of the Breast. By J. T. Wilson, Sherman, Texas; Gunshot Wound of Spleen, Hemostasis by Deep Suture, Recovery. By L. McLane Tiffany, Baltimore, Md.; Technique of Vesical Drainage. By G. Frank Lydston, Chicago, Ill.; Successful Treatment of a Case of Nævus by Electricity, with Remarks. By William Perrin Nicolson, Atlanta, Ga.; The Use of Electricity in Late Syphilis. By Lewis Wheat, Richmond, Va.; Observations on the Action of Chloroform on the Functions of the Human Brain and Spinal Cord as Witnessed in Extensive Injuries of the Cranium and Brain. By Bedford Brown, Alexandria, Va.; Treatment of Abscess of the Liver. By J. D. S. Davis, Birmingham, Ala.; Puerperal Peritonitis. By V. O. Hardon, Atlanta, Ga.; Treatment of Peritonitis. By Richard Douglas, Nashville, Tenn.; Movable Kidney. By Geo. Ben. Johnston, Richmond, Va.; History of Vaginal Excitiation of the Uterus. By Geo. J. Engelmann, St. Louis, Mo.; The Present Status of Gall-Bladder Surgery. By A. Vander Veer, Albany, N. Y.; Gynecological Surgery away from the Large Cities and Educational Centers. By W. L. Robinson, Danville, Va.; Reminiscences of Dr. J. Marion Sims in Paris. By Edmond Souchon, New Orleans, La.

President's Address. By C. Kollock, Cheraw, S. C.; Transfusion in the Treatment of Acute Hemorrhage. By T. J. Crofford, Memphis, Tenn.; A Case of Vaginal Hysterectomy for Carcinoma of the Uterus, three days after Parturition. By Geo. H. Noble, Atlanta, Ga.; The Simultaneous Appearance of Cancer in the Breast and Uterus. By James Evans, Florence, S. C.; Something about the Final Condition of the Mouths in Gastro-enterostomies with Specimens. By H. Tuholske, St. Louis, Mo.; Puzzling Point in Labor. By Geo. R. Dean, Spartansburg, S. C.; Supra-pubic Cystotomy compared with Perineal Operations. By C. H. Mastin, Mobile, Ala.; Tracheotomy for Foreign Bodies in the Air Passages. By W. F. Westmoreland, Atlanta, Ga.; Ligation in Continuity with Report of Case 1. Ligation of the External and Internal Carotid Arteries and Internal Jugular Vein. Case 2. Ligation of the External Carotid Artery. By Jno. A. Wyeth, New York; The Placenta—When and How Delivered. By J. B. Murfree, Murfreesboro, Tenn.; Report of Cases of Varicocele Treated by the Open Method and Shortening of the Scrotum. By W. E. Parker, New Orleans, La.; Treatment of Cystitis in the Female. By Hunter McGuire, Richmond, Va.; Hydro-pyonephrosis—Successful Removal of a Forty-pound Tumor of the Kidney. By Jos. Taber Johnson, Washington, D. C.; The Value of Plastic work in intraperitoneal Operations. By J. W. Long, Richmond, Va.; Fibroid Tumor of the Uterus, with Suppurating Ovary Discharging per Rectum. By Rufus B. Hall, Cincinnati, Ohio; Technique of Operations on the Pregnant Uterus. By W. D. Haggard, Nashville, Tenn.; The Relation of Uterine and Ovarian Disease to Insanity. By L. S. McMurtry, Louisville, Ky.; Surgery of the Ureters. By Howard A. Kelly, Baltimore, Md.; Ideal Operation for Varicocele. By G. Frank Lydston, Chicago, Ill.; The Value of Coccygeal and Sacral Resection in the Treatment of Congenital Occlusion of the Rectum. By Rudolph Matas, New Orleans, La.; The Surgical Treatment of Spina Bifida, with an Illustrative Case. By H. O. Marcy, Boston, Mass.; Ligation of the Uterine Arteries in the Treatment of Chronic Metritis. By W. E. B. Davis, Birmingham, Ala.

The officers for the ensuing year are as follows: President, Cornelius Kollock, Cheraw; Vice-President, J. B. S. Holmes, Atlanta; Secretary, William Elias B. Davis, Birmingham; Treasurer, Hardin P. Cochrane, Franklin. Council: Lewis S. McMurtry, Louisville; George J. Engelmann, St. Louis; Hunter McGuire, Richmond; Wm. David Haggard, Nashville; Bedford Brown, Alexandria.

PUBLIC HEALTH.

Epidemic Contagious Diseases.—Both typhoid fever and diphtheria have increased in the number of cases and of localities infected in the States enumerated in last week's issue of the JOURNAL. The smallpox situation remains substantially unchanged—the only feature of note being another introduction of the disease in the ill-fated town of Walkerton, Ind. A cable dispatch of the 3d inst., reports Asiatic cholera alarmingly prevalent at Broussa in Asia Minor, causing considerable apprehension in Constantinople, where the disease has also reappeared in the Scutari barracks.

Bovine Tuberculosis.—Considerable activity is being manifested by the public health authorities in some of the Eastern States in renewed attempts to exterminate tuberculosis in cattle. In New York, recently, thirty tuberculous cows belonging to a choice herd were killed at Elmira, but criticism is made that the Commissioners take such action only upon the request of owners—usually of costly cattle for the protection of the remainder—and that no systematic inspection is made of the common dairy herds, which furnish the milk supply and which are generally kept under conditions that favor the development of the disease. In Massachusetts such a systematic inspection has been begun, with the avowed purpose of examining every cow, bull and calf, beginning at Cape Cod and extending westward until the whole State has been covered; the tuberculin test is employed and every animal that shows the characteristic reaction is to be slaughtered forthwith. On the recommendation of its Sanitary Committee the Philadelphia City Board of Health has also adopted the tuberculin test and, after sixty days' notice, any milk producer supplying the city who fails to furnish a clean bill of health for his dairy—based upon the results of this test—will be liable to have his milk supply rejected as suspicious and its sale prohibited.

Purification of Water.—A great deal has been lately written and published concerning permanganate of potash as a sterilizer of water. MM. Chicandard and Schipiloff assert that its use is simple, rapid, inexpensive and efficient. According to these authors all that is necessary is to add enough of the salt to color the water violet, and then get rid of the excess of potash by adding any harmless organic matter, such as powdered oak-bark, cinchona, kola nut, coffee or licorice. By this method they claim an absolutely innocuous water is obtained, much superior to that furnished by boiling or filtering. M. Coreil, Director of the Toulon laboratory, has completed a long series of experiments to determine the correctness of these assertions, and he claims (*Annales d'Hygiène Publique*), that, so far from confirming these optimistic views, in his opinion this method is open to very grave objections, and reliance upon it may lead to serious consequences during epidemics of typhoid fever or Asiatic cholera. Coreil asserts that the permanganate, in the quantity indicated, does not cause a disappearance of the bacteria in polluted water—only a diminution in their number. He insists that the method shall not be substituted for boiling or sterilization by heat during the prevalence of an epidemic.

Catarrh Remedies said to Contain Cocain.—Dr. R. G. Eccles, of Brooklyn, has contributed to the *Druggists' Circular* some observations as to the dangers arising from the nostrums advertised for the cure of catarrh, due to their contained cocain. He remarks that "the sober second thought has been commended by wise people through all time. When the Birney Catarrhal Powder Company took their second thought they deemed it wise to let their patrons know that they were using cocain every time they blew the Catarrhal Powder into their noses, and began to state this fact on their labels. They certainly could not have done a more discreet thing for themselves nor better for their patrons. This writer has certainly no desire to oppose those who with open eyes walk into a medical danger, but he deems it a duty to the public to point out such danger and then allow each

person to act as he desires." As to the danger, Dr. Eccles writes: "Persistent use will most likely establish a habit as bad or worse than drunkenness; to become a slave to cocain is something terrible. The writer has seen several such wrecks and they are truly objects of pity."

The Lesson of the Plague.—The *Medical Press and Circular* holds that the dangers from the plague can not be considered as having passed by. The disease is still endemic and fatal in Yun-nan and other parts of southern China, and the free inter-communication that exists throughout the Empire makes it important that China shall bestir herself to apply modern scientific methods, both preventive and curative, to the deadly disease. The Hong Kong outbreak has slain its thousands of Chinamen and a few Europeans. It has enforced itself upon the latter who survive, that the Chinese quarters of the treaty port cities are, under their present conditions a source of constant danger. The communism of disease holds sway, and it must be borne in mind that the sanitation of the native sections can not be neglected any more than the best of the town. The habits of the lower orders of the city-dwelling Chinese are filthy in the extreme, and as a consequence they are constantly keeping alive the germs of the filth-diseases, such as cholera, typhoid fever, dysentery, and the plague. This constitutes a standing menace to the Europeans and Americans who must needs reside in China that may well make the future sanitation of all parts of the treaty ports a subject for international discussion.

Cremation Among the Ancient Greeks.—One of the most interesting communications read at the recent Congress of Orientalists at Geneva was, according to *Le Progrès Médical*, that of M. Georges Perrot on "Incineration and Inhumation during the Homeric Epoch." In spite of Schliemann's opinion it is evident that inhumation was the sole mode of sepulture during the Mycenaean period, and it is evident, moreover, that it was never abandoned in Greece, at least among the poorer classes. Cremation could not have been of foreign origin, for it was unknown among the peoples who exerted any influence on Greece. It could only arise from a change in the conception of death. We know that during the primitive epoch, survival in the tomb after death was believed in. Hence the custom of placing familiar objects, such as weapons, vases, etc., along with the body, and of offering sacrifices to nourish the departed. These primitive ideas were modified little by little as experience attested the destruction of the body. Thence arose the idea of Hades, where was sent all that remained of man after death—his image, eidolon, shade. As the destruction of the body was necessary for the entrance of the shade into Hades the rite of incineration was established, not as a substitute for the old custom but as an addition. This is why in the Homeric age the tomb, no longer the perpetual dwelling-place of the dead, was a hillock surmounted by a stela—the last vestige of the former rites. The cult of the dead and the custom of sacrifices on the tombs survived elsewhere. In Continental Greece the usages of the Mycenaean period mostly prevailed, as is shown by the latest excavations at Dipylon near Athens. In this cemetery, where inhumation was long practiced, a characteristic feature is the presence of vases surmounting the tomb, sometimes reaching five feet in height. These recall the drains in the Mycenaean tombs for conducting the libations of blood, wine and milk, provided by the piety of the survivors for the dead.

Hospital vs. Home Mortality of Smallpox.—One of the principal charges upon which the attempted impeachment of the Health Commissioner of Milwaukee is based, is that of maladministration of the isolation hospital. It is admitted by Dr. Kempster that the hospital is and has been greatly overcrowded—upward of seventy patients at times being thrust into quarters intended for only fifty. In fact, it was the attempt to establish another temporary smallpox hospital, to relieve this overcrowding, which led to much of the existing friction. But the effects of the alleged mal-adminis-

tration are not obvious in the records of the epidemic, and from which the following figures are taken:

| | | |
|---|-----|-----|
| Total number cases of smallpox in Milwaukee, January 1 to October 20, inclusive | | 517 |
| Number treated at hospital | 341 | |
| Number treated at home | 176 | 517 |
| Recovered at hospital | 202 | |
| Died at hospital | 78 | |
| Remaining October 20 | 61 | |
| | 341 | |
| Recovered at home | 55 | |
| Died at home | 59 | |
| Remaining October 20 | 62 | |
| | 176 | 517 |

These figures show a mortality of 27.8 per cent. among those removed to and treated in hospital, as against a mortality of 51.7 per cent. among those who resisted removal to hospital and were treated at home. The "mal-administration" which resulted in only 78 deaths instead of 144—which would have been the number under the home mortality rate—can not have been very serious.

NECROLOGY.

HENRY VAN BUREN, M.D., of Chicago, October 28, aged 59.—G. E. Garrett, M.D., of Peoria, Ill., October 29.—William P. Overton, M.D., of Cold Spring Harbor, L. I., October 24, aged 74. He was President of the Queens County Medical Society.—John Jackson, M.D., of Whitewater, Wis., October 20, aged 80.—John Wiggins, M.D., of St. Louis, October 28.—J. C. Jones, M.D., of Wymore, Neb., October 30.—E. J. Hutchinson, M.D., formerly of Bloomington, Ill., died at Lakota, S. D., November 2, aged 50.—James M. Justice, M.D., of Logansport, Ind., November 2, aged 77.

MISCELLANY.

Physicians Living in Chicago.—It is estimated that there are about 3,400 physicians within the corporate city limits of Chicago, embracing a territory of 186½ square miles, and a population in round numbers of 1,625,000 inhabitants.

The German Hospital of Brooklyn.—On October 22, the corner-stone of a future great hospital was laid in Brooklyn, New York. The property covers an entire block and the structure is planned to expend a quarter of a million of dollars. The Mayor of the city presided and a vast concourse of devoted Teutonic friends were present and sang chorals and paraded the streets of the German section.

An Eye to Business.—The medical student of the period is quite up to date. Noting the field for surgical practice opened up by the collision of opposing leagues he, too, is organizing himself for the football fray, *pour encourager les autres*. The Columbia College (N. Y.) Medical Department Football Association has arranged for a game with the team of the Long Island College Hospital, has challenged the Bellevue Hospital College men and is trying to arrange games with the Yale freshmen and the Brooklyn Polytechnic. The Rush Medical College (Chicago) eleven recently trounced their opponents by a score of 36 to 4; and the returns from the medical schools are not all in yet.

Episcopal Hospital of Philadelphia.—A bequest of \$15,000 will soon be paid this hospital, under the will of the late W. V. Lippincott. The same hospital is also residuary legatee. Numerous other institutions receive sums of five thousand dollars or over. Among these are the Memorial Hospital at Roxborough, Home for Crippled Children, Home for Incurables, St. Christopher's Hospital for Children, Kensington Hospital for Women, School for Feeble-Minded Children, Institution for the Deaf and Dumb, besides two or three other asylums for children. If the estate, when divided, reaches a total larger than these primary bequests, the Pennsylvania Hospital for the Sick and Injured and the Pennsylvania Hospital for the Insane will receive each a gift of \$5,000.

Women-Doctors in Turkey.—A late number of the *Revue Bleue* contains an article by C. Chryssafides, in which he argues that the recent imperial irade by which women are allowed to practice medicine in Turkey has political importance of the highest degree. The writer thinks that this concession will meet "a long felt want." We know that Mussulmans are unwilling to allow male physicians to enter the harem; consequently, Moslem women, either through timidity or by order, are forced to resort to female quacks, and only consult skilful practitioners in cases of exceptional gravity. The Sultan's irade will probably change this state of things and assure women-physicians an influential standing in Turkish families—all the more so since Orientals profess great veneration for doctors. Chryssafides has no trouble in proving that at the Ottoman court the doctors of the palace always have been and are at present very influential personages. It follows that not only will doctresses be secure in their practice in Turkey, but they will exercise a great deal of indirect political influence for their respective countries. We may be sure, says the author, that the English and German governments will not neglect this double opportunity very long; and it is not likely, he adds, that the Bible societies will remain inactive either. Russia would seem to have been more astute in this matter; as heretofore noted in the *JOURNAL*, the government has authorized the foundation of a woman's medical college in St. Petersburg, and the reason now given for this action is that women who desire to enter the profession may not have to go to France or Switzerland, "where they are likely to become imbued with nihilistic principles."

A New Mission Hospital Opened in India.—A new institution largely supported by American means has been built at Miraj, about two hundred miles southeast of Bombay. The opening took place last Fourth of July. The walls were hung with the "Stars and Stripes" side by side with banners of the native State and with the British colors, and the presentation ceremony was participated in by Bala Sahib, the Chief of State. The municipal secretary and numerous other visitors of rank were present, some of whom made addresses. One of these was made by an ex-Kharbhari, or Secretary of the State, Mr. Rao Bahadur Sitaram Chitray, a man greatly beloved by his own people and a constant friend of the new undertaking. Some of his expressions are very quaint. He began his remarks by referring to the successful treatment of his own case by the medical missionary. He proceeded as follows: "The surgeon in chief of this hospital is a kind-hearted physician and surgeon, and being a missionary, treats rich and poor alike. His skilful treatment of my case is only an example of the kind and careful treatment given to all who come to him. Since the introduction of the good British rule, great and many are the improvements in this land, but none of these are more useful than the charitable medical hospitals established by Government. It is true that we had a number of good native physicians, but they were available only to the rich, and their knowledge of anatomy and physiology was not to be compared with that of a doctor of the present day. The science of surgery was not known to them. At the present time, therefore, the charitable dispensaries and hospitals in India may be called the greatest boon to the people of all ranks everywhere. This hospital is an example of this, as it will give medical aid to thousands in Miraj and the southern Mahratta country. The climate of Miraj being excellent, the sick will always consider this place a sanatorium, as Dr. Unless understood when he chose this site.

"I have been thanked by the President of the Mission for my interest in its work, but although I have a great personal interest in it, I do not deserve such thanks. These are due only to Bala Sahib, the Chief of Miraj, who is, as we all know, an enlightened prince who takes deep interest in the welfare of his subjects, and has therefore given faithful and kind support to the Mission."

Lay Appreciation of the Doctor's Hard Lot.—In an editorial notice of the addresses delivered at the commencement of the academic year at the various metropolitan medical schools the *Morning Post*, London, October 2, gives some pleasant words appreciative of the hard lot and unremunera-

tive work of the general practitioner which are as applicable in the United States as in the island of Great Britain: "It is a somewhat melancholy thought that men of high ability, of indomitable energy, and of laudable ambition are too often compelled to spend their lives in a constant round of hard work which brings them almost as little pecuniary profit as professional distinction. Such cases are by no means rare, and they do not deserve less sympathy because they are one of the inevitable consequences of the struggle for life under modern conditions. For such men, however, there should be, and doubtless there often is, a very real compensation in the consciousness that the work of the ill-paid general practitioner is neither less honorable nor less useful than that of the most fashionable specialist of the day. It is, indeed, infinitely creditable to the rank and file of the medical profession that they do their work with an amount of zeal and of patience which are matter of common knowledge and universal recognition."

And even the hard lot of the medical student of to-day meets with public appreciation and sympathy: "There are plenty of men yet in practice who can recall the time when the student had, at least before he arrived at the stage of practical work in the wards of the Hospital, very little to do except to study anatomy. Physiology, as a separate branch of study, scarcely existed at all; while the whole enormous modern development of microscope work was absolutely unknown. Naturally the student's life in those days was considerably easier than it is at present, and he was comparatively untroubled by the fear of failure in examinations. We have changed all that now, and, in consequence, the rollicking medical student of tradition has ceased to be a type and figure of the class which he once represented with sufficient accuracy. Is it not, indeed, significant that at one hospital the students should have been warned recently not against idleness, but against excessive study? Mr. Robert Sawyer and Mr. Benjamin Allen might well rub their eyes in profound astonishment if they could hear that—to them—supremely unnecessary admonition."

Abandonment of Fort Supply, Oklahoma.—The post hospital of this military station was closed October 15, last, in accordance with recent orders requiring the abandonment of the post. Camp Supply was established in 1868 as a base of supplies against the hostile Cheyennes and Arapahoes in the Indian Territory. The site selected was a sandy bottom between two creeks, Wolf and Beaver, which by their junction a short distance below, form the north fork of the Canadian River. This, at the time and for several years afterwards, was regarded as a most injudicious selection on account of the malarious surroundings. The country in this vicinity consists of high rolling prairie land with occasional ranges of hills broken by deep ravines in which is a scanty growth of red cedar. Many streams cross the prairie in an eastward course, the bottom lands usually broad sandy tracts whitened with an alkaline efflorescence. The climate was found to be very variable with hot and dry summers and inclement winters, sand storms in the one season and biting northerners in the other. Vegetables were scarce, and all attempts to cultivate them proved unsuccessful on account of the poverty of the sandy soil. Game, however, was plentiful until of late years when it became comparatively scarce. At first the officers of the command were quartered in tents and the men in dugouts, about four feet deep, lined with cottonwood logs which rose three feet above the surface and supported a roof of logs, straw and earth. The next year stockaded quarters were built, but as they were roofed and floored with mud they were as leaky, damp, uncomfortable and almost as unhealthy as the dugouts.

In 1873 new buildings were erected, stockaded walls as before, but with shingle roofs, ridge ventilation and pine flooring. The walls and ceilings of the officers' quarters were lined with canvas which, in the language of an official report, "was nicely whitewashed." The partitions between the rooms were lined with canvas which had the very superior advantage of being altered to suit the taste or convenience of the occupants. The official report already cited spoke of the guard house as holding out but few inducements for men to become inmates of it. The hospital was the best

building at the post. In the course of years, however, the post became much improved in comfort and sanitary condition. Seven sets of company barracks were erected, each 100 by 22 feet, with wings 68 by 22, and a wide veranda along the front. Bathrooms and lavatories in the wings were supplied with hot and cold water. Officers' quarters were two-story frame buildings with many conveniences. A handsome brick guard house was erected recently. At first the water supply was taken from Wolf Creek, the delivery being by barrels in the water wagon; but afterwards spring water was piped into the post from a ravine two miles distant. A dam was built to collect the water and a wire fence put up to exclude cattle. The receiving reservoir had a capacity of 80,000 gallons and the distributing reservoir held 100,000 gallons. The sewers of the post received none of the surface drainage. The level of the subsoil water fluctuated with that of the creeks. The sewerage system consisted of 4 and 8 inch pipes, with automatic ventilating and flushing tanks, the outfall being into Beaver Creek half a mile distant. With the introduction of the spring water the prevalence of malarial diseases has been much lessened, and of late years there has been but little endemic disease. Measles was at one time introduced by recruits from Columbus Barracks, Ohio; but this was the only epidemic disease recorded in the history of the post.

Abandonment of Fort Bowie, Arizona.—Fort Bowie was reported as abandoned, October 22, last, in accordance with existing orders which were cited in the *JOURNAL* of October 6. It is doubtful whether any of the officers or men who formed its garrison during the past thirty-five years will have a single regret that it has passed out of existence. It was situated in a wild rocky gorge through which a road or trail of disintegrated granite led east and west through the Chiricahua Mountains to connect Messilla with Tucson. North and south were the high peaks of the range, Dos Cabezas, Castle Dome, Helen's Dome and Bowie's Peak. In the gorge which is known as Apache Pass, 4,780 feet above the sea-level, are the only springs or water supply for many miles along the trail to the east or west; and in the early days of Arizona Territory these springs were the regular camping ground of war parties of the Apaches from the northern mountains in their frequent descents on the farms and mining settlements of Sonora. The withdrawal of the regular troops from Arizona at the outbreak of the Civil War led these Indians to believe that this was due to the steady hostilities which they had kept up against the United States military posts.

When General Carleton marched his column in 1862 from California to join the Union forces in the East and protect the overland route, his troops had to advance across southern Arizona in detachments of two or three companies, each several days behind the other to be sure of having supplies of water in the various springs and holes known to frontiersmen to lie on the line of march. The Apaches considered this warlike demonstration as directed against themselves and concentrated their forces to defend the pass and force the column back on the Arizona Desert by holding the springs. They succeeded in keeping the troops from the water for two days and might have held their position much longer but for the fact that some pieces of a light battery were brought up and opened on them with shell. This demoralized them and they withdrew into the security of the mountains. Artillery fire was a new and alarming experience to them. Our troops suffered much from want of water during the attack; and Dr. Vittridge, an acting assistant surgeon was wounded. Company G, Fifth California Volunteers, was left as a guard to the springs at this important and dangerous part of the road, and its camp on the summit of a knoll overlooking the water supply became afterwards Fort Bowie. Up to 1868 it was merely a camp of shelter tents and dugouts on the slope of the hill, but the building of a permanent fort was then begun and for several years thereafter the quarters were much superior to those of most of the Arizona posts. All the buildings were of adobe or sun-dried bricks; one-storied, with accommodation for one company of infantry and two troops of cavalry. The water was pumped into reservoirs and distributed by gravity; and the waste water and sewage were carried away by a well laid sewerage system.

All the conditions were healthful at this post; but for many years there was danger in leaving its immediate vicinity, the broken granite rocks and precipitous ravines af-

forded so many lurking places for the hostile Indians. A promising young captain of the Thirty-second Infantry was killed a short distance from his quarters. Even the bears sometimes took part in the war against the intrusive white race. An acting assistant surgeon, *en route* along the gorge to join the post, strayed from his escort a few yards up a side path and came unexpectedly on a bear. The doctor escaped with his life, through the coolness and marksmanship of a soldier of the escort, but he received many bruises and two or three ugly gashes in his thighs. No; there are few persons in the military service of the United States who will heave a sigh on account of the abandonment of Fort Bowie.

Urinary Phosphates in Malaria.—Mm. Picci and Bernasconi have published the results of their examination into the "Elimination of Phosphates in the Urine of Malarial Patients." In the first twenty-four hours of infection, phosphoric acid is more considerable than in normal urine.—*L'Union Medicale*, Oct. 23, 1894.

Small Caliber Rifles.—The Military Information Division of the War Department has issued an interesting pamphlet entitled, "Notes on Organization, Armaments and Military Progress in American and European Armies," in which are given an epitome of the more important foreign military organizations, and a somewhat detailed description of the small arms and side arms in use at home and abroad. Full descriptions are given only in the case of the newer or little known arms, although occasionally the older small arms are also described for purposes of comparison. These have an interest for the military medical man in view of the change that will be produced in the character of war wounds and the alterations that will be necessary in field hospital management.

During the past year there has been continued activity in testing, changing, adopting and manufacturing small caliber rifles. The United States Navy has the smallest of these small calibers, 6 millimeters or .236 inch. Holland and Roumania have the Mannlicher rifle with a caliber of 6.5 millimeters or .256 inch. This is the size, also, of the Krag-Jørgensen rifle of Norway, the Parravecino-Carcano of Italy and the Mondragon of Mexico. The modified Krag-Jørgensen rifle now being issued to the troops of the United States has a caliber of 7.62 millimeters or .30 inch, the same as the Mouzin rifle of Russia. The Lee-Netford adopted last year by England is 7.7 millimeters, or .303 inch; the rifle of the German Experimental Committee 7.9 millimeters, or .311 inch; the French Lebel, the Austrian Mannlicher and the Japanese Murata 8 millimeters or .315 inch. Our naval officers are convinced that their caliber, the smallest of any adopted, is superior to anything larger; and they stopped at that fraction only because of the anticipation that a smaller one would involve too many difficulties in the manufacture of barrels. They say that an approach to a practical point blank, man firing standing, of 725 yards will result from the adoption of their new barrel and its ammunition. The Mondragon rifle, called after its inventor, a major of Mexican artillery, is now being made in Switzerland until the National Army Factory at Molino del Rey is equipped for its manufacture. It is regarded as one of the best of the new rifles. It is capable of three kinds of fire: low fire of from 15 to 20 shots per minute; repeating fire of 40 shots per minute and rapid fire which is said to deliver as many as 80 shot per minute. In addition it claims advantages in simplicity of mechanism and facility in working. Since the war in Chile, the greatest energy has been manifested by the South American republics in arming their troops with the small caliber rifles. The Congressionalists won their decisive battles over Bulmaeceda by the help of the Austrian Mannlicher. A supply of this rifle had been obtained by the presidential government and when the fleet revolted, the revolutionists who went on board took the rifles and issued them to the land forces. These quick firing and wide carrying Mannlichers spread a panic in the ranks of the presidential troops although the latter were better trained soldiers. The Lee-Netford rifle is now in the hands of all British infantry. The Secretary of State, Mr. War, reported in March last in answer to a parliamen-

tary inquiry: "In India there are Lee-Netford rifles for the European troops and in reserve; in the colonies the infantry is armed with them and at home there is an ample supply of arms for the regulars and the militia, and a large reserve in addition."

The effect of the latest small bore projectiles is a matter for the future to decide. Recent experiments (1894) by the medical staff of the German Army, as to the wounds inflicted by the small bore bullet have furnished further proof that, notwithstanding its diminutive size, its effects are highly destructive, owing to its enormous speed of rotation which causes the tissues struck to be torn within a radius of four inches. Up to 660 yards, a bullet striking the head, neck or abdomen means death. From 660 to 1600 yards most serious, and in many cases fatal wounds are certain to be inflicted. Beyond 1,600 yards the injuries caused resemble those inflicted by the round bullets which were in use before 1860.

The United States Ordnance Department is carrying on a series of careful experiments with the Kruka-Hebler tubular bullets, the results of which have not yet been made known. The two causes which influence detrimentally the velocity of bullets are the condensation of the air strata immediately in front and the formation of a vacuum immediately behind the projectile. To obviate these, the tubular bullet was invented which, when made of steel, is said to have an immense range, a flat trajectory and great penetration.

Louisville Notes.

THE CHILDREN'S FREE HOSPITAL.—The first annual report of this most worthy institution was issued in January, 1893. It shows that on Oct. 16, 1890, thirteen public-spirited men and women of this city incorporated themselves as a charitable and benevolent society, under the corporate name of the Children's Free Hospital. Stock was issued, and as soon as \$10,000 was subscribed a very suitable building was purchased and refitted, and the first patient admitted for treatment on Jan. 23, 1892. Many times defeat stared the tireless workers in the face, but they kept on, and now have a most admirably conducted hospital, which is doing a grand work, as a result of their labors. The original cost of the completed building was \$12,547, and the cost of the running expenses averages about \$5,000. The hospital has no regular medical staff; every physician is invited to use the hospital as his assistant in any case, when he requires facilities for the care of the sick, which he can not get in the homes of the patients. The relation of the patient and physician is not altered by the admission to the hospital. Here, as at home, the physician asks whatever assistance he needs. During the year there were treated 155 cases of all kinds. The report for the year 1893 was most encouraging; there were 111 cases treated; of these 88 were discharged, 4 died, and on Jan. 23, 1894, 23 patients remained. The hospital is furnished and paid for, and at present there are ten beds supported by annual subscription. At present, no patients are being received on account of an outbreak of measles which was brought in by one of the children admitted recently. Thus far there have been eleven cases. None of them have been severe and all are convalescing. The hospital has as an adjunct, a splendidly equipped isolating ward in the rear of the place. No contagious diseases are admitted as such, but this ward enables them to handle all cases which may arise.

MORTALITY REPORT.—The mortality report of the city for the week ending November 2, shows a total of thirty-four deaths. Of these, fourteen were male, twenty-six white, twelve married, eleven natives of Louisville, and twenty-three native-born Americans. Pneumonia leads the list with five fatalities. For the month ending November 2 the Health Officer reports a total of 286 deaths, the number of male and female being the same; 218 were white, 78 married, 156 natives of Louisville. Consumption heads the list with forty, old age next with twenty-three, and diphtheria and inanition next with twenty each. There were two homicides and two suicides. This is an unusually heavy death-rate from diphtheria and the end is not yet, as the daily report for Novem-

ber 1 showed two children who died from this trouble. The importance of having a contagious disease act is becoming more and more apparent, and it is earnestly to be hoped that those in charge of it will not let it drop, for it is a question of vital importance to many.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.—Louisville will send quite a delegation to the annual meeting of the Mississippi Valley Medical Association this month at Hot Springs. The meeting bids fair to be one of the most successful that has ever been held.

ACADEMY OF MEDICINE.—The question of an Academy of Medicine for the city is being agitated again upon a somewhat different basis than the one spoken of during the spring, and much is expected of the committee which has charge of the preliminaries. Such an organization is much desired in Louisville. As it is at present there exist several private societies which meet bi-weekly and monthly, and at which the social feature is one of the chief objects, a quite elaborate collation being served at the beginning or completion of the meeting. These societies are limited as to membership and the profession at large are without any society. The Academy will enable all to take part in the discussions, and it is earnestly hoped that this attempt to perfect an organization will prove successful.

Washington Notes.

MEDICAL SOCIETY OF THE DISTRICT.—The Committee on Legislation was directed to take steps to present to Congress a plan for filtration of the Potomac water, used in the District of Columbia. A committee was also appointed to investigate and report the facts connected with the present outbreak of smallpox.

THE WASHINGTON OBSTETRIC AND GYNECOLOGIC SOCIETY.—The two hundred and sixteenth meeting of the Society was held November 2. Dr. W. P. Carr read a paper entitled "Oophorectomy for Fibroid Tumors of the Uterus," and reported several cases so treated. Dr. H. D. Fry presented a specimen of sarcoma of uterus, which he had removed, and also gave the history of a case of ectopic gestation in which his diagnosis was confirmed by a successful operation. The interesting specimens, left tube after rupture, were presented. The fetus was lost in the clots removed from the peritoneal cavity. Dr. H. L. E. Johnson gave the history of a case of multiple fibroma of the uterus, complicated by a large unilocular cyst of the right ovary, and presented the specimen. The vermiform appendix and left ovary and tube were also removed. The patient, aged 52, had flooded for thirty-eight years.

The death of Dr. Goodell, of Philadelphia, an honorary member of the Society, was announced and suitable action taken.

THE WOMAN'S CLINIC.—The annual meeting of the Board of Directors of the Woman's Clinic will be held on the 6th inst., for the election of officers.

SMALLPOX.—One death from smallpox. There were seven cases in this city at the closing of this report. All isolated at the smallpox hospital and due to imported infection.

THE SIBLEY MEMORIAL HOSPITAL.—The Attending and Consulting Staff of the hospital will be announced by the Board of Management on the 5th inst. The physicians connected with the institution vaccinated 2,200 patients during the past week. This was in the nature of emergency work for the Health Department of the city.

THE PUBLIC SERVICES.

Regulations Regarding Consular Bills of Health from Certain Ports in Canada and Mexico.

The Treasury Department has issued the following circular:

TREASURY DEPARTMENT, OFFICE OF THE SECRETARY,

WASHINGTON, D. C., Oct. 17, 1894.

To the Officers of the Treasury Department, Consular Officers, and Others concerned:

The following Act passed both Houses of Congress during the last session, and was approved by the President August 18, 1894:

An Act to amend section two of the Act approved February fifteenth,

eighteen hundred and ninety-three, entitled "An Act granting additional quarantine powers and imposing additional duties upon the Marine Hospital Service."

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That Section two of the Act approved February fifteenth, eighteen hundred and ninety-three, entitled "An Act granting additional quarantine powers and imposing additional duties upon the Marine Hospital Service," is hereby amended by adding to the end of said section the following:

"The provisions of this section shall not apply to vessels plying between foreign ports on or near the frontiers of the United States and parts of the United States adjacent thereto; but the Secretary of the Treasury is hereby authorized, when, in his discretion, it is expedient for the preservation of the public health, to establish regulations governing such vessels."

Under the above Act, vessels plying between Canadian ports on the St. Croix River, the St. Lawrence River, the Niagara River, the Detroit River, Lake St. Clair and St. Clair River and the St. Mary's River, and adjacent ports in the United States on the same waters; also Mexican ports on the Rio Grande River and adjacent ports in the United States, are exempt from the provisions of section 2 of the Act granting additional quarantine powers and imposing additional duties upon the Marine Hospital Service, approved February 15, 1893, which requires vessels clearing from a foreign port for a port in the United States to obtain from the consular officer a bill of health.

During the prevalence of any of the quarantinable diseases at the foreign port of departure, vessels above referred to are hereby required to obtain from the consular officer of the United States, or from the medical officer of the United States, when such officer has been detailed by the President for this purpose, a bill of health, in duplicate, in the form prescribed by the Secretary of the Treasury, Quarantine Regulations of the United States, 1894. J. G. CARLISLE, Secretary.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Oct. 27, 1894, to Nov. 3, 1894.

Major JOHN V. LAUDEBDALE, Surgeon U. S. A., is granted leave of absence for four months, to take effect upon the final abandonment of Ft. Ontario, N. Y.

Major WILLIAM H. GARDNER, Surgeon, so much of the order as assigns him to Ft. Custer, Mont., is revoked.

Capt. ALFRED E. BRADLEY, Asst. Surgeon, so much of the order directing him to report for duty at Ft. Keogh, Mont., is amended as to direct him, upon the abandonment of Ft. Sully, S. D., to report for duty at Ft. Custer, Mont.

Capt. OGDEN RAFFERTY, Asst. Surgeon, so much of the special order as directs him to report to the commanding officer, Presidio of San Francisco, Cal., for duty, is revoked.

Major CLARENCE EWEN, Surgeon, is granted leave of absence for six months, on surgeon's certificate of disability.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending Nov. 3, 1894.

Asst. Surgeon A. W. DUNBAR, ordered to Naval Laboratory and Department of Instruction.

Asst. Surgeon ARNOLD FARENHOLT, detached from Naval Laboratory and Department of Instruction, and ordered to U. S. R. S. "Vermont."

Asst. Surgeon L. W. STONE, detached from U. S. R. S. "Vermont," and placed on waiting orders.

Asst. Surgeon J. S. HOPE, detached from Naval Hospital, Mare Island, Cal., and ordered home.

Surgeon DWIGHT DICKINSON, detached from the U. S. S. "Miantonomoh," and ordered to the U. S. S. "Richmond."

ORIGINAL ARTICLES.

REST IN THE TREATMENT OF DISEASES OF THE HEART.

Read at the Meeting of the Tri-State Medical Society at Jacksonville
Ill., Oct. 2-3, 1894.

BY ROBERT H. BABCOCK, A.M., M.D.

PROFESSOR OF CLINICAL MEDICINE AND DISEASES OF THE CHEST, COLLEGE
OF PHYSICIANS AND SURGEONS, CHICAGO, ILL.

For years it has been my custom, both in practice and in teaching, to insist upon absolute rest in bed in cases of heart disease with destroyed compensation. My opinion was based upon the consideration that the only period of rest enjoyed by the heart was during diastole, and since the heart beats more slowly in a recumbent than in an erect position or during exercise, the diseased heart should be encouraged to beat slowly. Moreover, I was supported in my belief by the statements of such weighty authorities in medicine as Balfour and Liebermeister. The latter has reported an instructive case of a business man who had a serious valvular lesion, and who every now and then overstrained his heart to the point of threatened loss of compensation. He would enter the hospital and after three or four days of treatment and upon relief of his most urgent symptoms would again take to his business, in spite of all Liebermeister could say to the contrary. One day this patient suffered a fracture of the femur, which necessitated rest in bed for six weeks; and Liebermeister stated that this prolonged rest did more for the patient's heart than anything else could have done.

A few years ago a German physician reported a series of cases of valvular disease in which the only treatment employed was rest in bed and the milk diet. The results were highly satisfactory. I am sure that in my own experience I have seen great benefit follow prolonged physical repose. Imagine, then, my surprise recently upon perusing Fraentzel's valuable work on heart disease to run across a very positive statement that he considered absolute physical rest injurious and had seen unmistakable harm result therefrom. This, according to him, is particularly the case in "idiopathic enlargement of the heart," although he denounces absolute rest even in valvular disease. He cites in support of his position the fact that striped muscle degenerates when deprived of the stimulus of exercise, and since the heart muscle is striated, like voluntary muscle fibers, the cardiac muscle will degenerate under prolonged rest. In cases of enlarged hearts, secondary to arterio-sclerosis, the injury has been rapid and unmistakable while there was an evident increase of the atheroma.

Naturally this set me to thinking, and I recalled at least two cases of Fraentzel's "idiopathic enlargement of the heart" both in corpulent men, with large

chests, in which the absolute rest in bed insisted upon was not followed by relief of symptoms. In fact, in both cases, cardiac failure was progressive and more rapid than was expected; death ensuing within three weeks. Having witnessed unmistakable improvement in other cases, and not having attributed the rapid increase of symptoms in the two cases just mentioned to the effect of entire rest, I have been led to question if the positions taken by Liebermeister and Fraentzel may not both be correct. In other words; may not rest be beneficial to some—disastrous to others? Furthermore, is the reason given by Fraentzel the correct one? It seems to me not. The heart muscle, although composed of striated fibers, is not like voluntary muscle, inasmuch as the cardiac muscle can never during life be subjected to absolute inaction. Its contractions are intermittent and unceasing, and therefore in its period of diastole, time is not given for degeneration as in prolonged inaction of a voluntary muscle. It seems to me the injury to the heart results from other causes which lie in the circulation outside of the heart itself. The chief factor in the maintenance of the circulation is the difference between pressures in the aorta and in the two venæ cavæ, that within these great venous trunks being negative. When the left ventricle becomes weakened and dilated, less blood is thrown with each contraction into the aorta, and blood pressure falls; the normal difference between arterial and venous pressure diminishes and the circulation suffers in consequence. If now the patient be put to bed, venous flow is still further retarded in consequence of the cessation of muscular movements on the one hand, and on the other of decreased aspiration of the blood out of the great veins into the thorax, consequent upon more quiet and shallow respiration. Consequently, the work of maintaining the circulation is thrown mainly upon the already weakened heart. It would not be strange under these conditions if the weakened, nay perhaps degenerated cardiac muscle should suffer still more in its integrity. Having, unaided, to pump the blood onward, the heart walls stretch still more, and the condition called by the French, *asystole*, grows more and more apparent.

Furthermore, in cases of arterio-sclerosis, under lessened physical exercise, there is diminished oxidation, together with an increase of these conditions within the venous system, thought by Fraenkel and others to favor the development of atheroma, and hence the marked increase of this vascular change observed by Fraentzel might very well be the case. These conditions appear to me to explain in great part at least the injurious effect of absolute rest in cases of cardiac dilatation without valvular disease, or of general fatty degeneration.

Unquestionably, moderate physical exercise, as quiet walking on level ground, serves as a beneficial

stimulus to the heart muscle, even when diseased. But since this beneficial effect may so easily be counteracted by the increased dilatation, produced by muscular effort, I am of the opinion that a judicious combination of both exercise and rest is indicated in these cases.

Let us now consider the various valvular lesions coming under daily observation, and whether or not there are any conditions rendering Fraentzel's position untenable in these cases. By valvular disease is meant either stenosis of the orifice or insufficiency of the valves. Pathologically these two conditions are probably always united but in varying proportions. Therefore we recognize clinically the preponderating condition and I shall here consider, separately, stenosis and regurgitation. In mitral stenosis there is practically a dam built across the blood stream at the point of the left auriculo-ventricular opening. The blood can not escape from the auricle as rapidly as it is sent into it from the right ventricle. There is permanent congestion back of this pathological obstruction; increased work is thrown upon the left auricle and the right ventricle, which consequently undergo compensatory hypertrophy. So long as the chambers are adequate to increased work the cardiac contractions are slow and the lengthened diastole allows adequate filling of the left ventricle. Moderate muscular effort is unattended by urgent symptoms. So soon as compensation is lost, that is, dilatation preponderates over hypertrophy, cardiac action becomes more rapid, mainly at the expense of diastole, and the weakened right ventricle and left auricle are unable during the shortened diastole to drive sufficient blood through the constricted orifice to adequately fill the left ventricle. This chamber in turn throws a smaller volume of blood into the aorta and arterial pressure falls correspondingly with consequent retardation of the circulation. If, now, rest be prescribed the resulting fall in the rate of cardiac contractions allows more time for the filling of the left ventricle, while at the same time venous blood is forwarded to the heart less rapidly. As a result of these conditions the left ventricle, unimpaired in its contractility, receives and discharges a larger amount of blood into the arterial system. Something like the normal difference between arterial and venous pressure is restored and the circulation correspondingly improved. Thus relieved of strain, opportunity is afforded the heart to respond to proper medication and to regain its lost compensation.

In mitral regurgitation the obstacle to the circulation through the heart is intermittent. With each ventricular systole a portion of the blood intended for the aorta is thrown back into the auricle. This chamber, thus receiving the blood from two directions at once, becomes momentarily surcharged, but the next instant discharges its contents into the ventricle and its distension is relieved. In the stage of destroyed compensation it is important that blood be not forwarded to the heart and lungs with undue rapidity, lest the left auricle be over-distended and its ability to withstand the regurgitant stream be still further impaired. The mitral valves, being incompetent, their place has to be taken by the walls of the left auricle and the mass of blood this chamber contains. If compensation be lost, not only is the regurgitation the greater, but the contractility of the left ventricle is lessened and a proportionally smaller volume of blood is thrown into the aorta. A

fall in arterial pressure and a slowing of the circulation result. If the integrity of the left ventricle be not too greatly impaired, and the rest be not too prolonged the employment of this therapeutic agent, together with cardiac tonics will unload the distended left auricle, augment its power of resisting the regurgitant stream and enable the better filled ventricle to discharge a larger proportion of its contents into the aorta. Moreover, the cessation of muscular movements lessens intra-cardiac blood pressure, which is raised by the constriction of the arterioles lying within the area of the contracted muscles. Peripheral resistance to the outflow from the ventricle is diminished and the degree of regurgitation thereby relatively lessened. For a time, then, absolute rest is beneficial, but if too long maintained again may prove hurtful, through the added work put upon the left ventricle and the consequent increase of the regurgitation.

Consequently, in this form of mitral disease, rest should be employed with more caution than in stenosis. There are conflicting indications for and against rest. It should not be continued beyond relief of the first urgent symptoms. Moderate exercise about the room should then be permitted, at first for a few moments at a time, subsequently for increasing periods. In aortic disease there are still other facts to be considered; loss of compensation does not so much mean retardation of the venous flow and over-distension of the heart, as the danger of sudden diastolic arrest, particularly in aortic regurgitation. The enormously enlarged ventricle throws an abnormally great volume of blood with each systole into the arterial system. If arterial tension be increased, the reflux into the dilated ventricle is correspondingly increased. Muscular effort, however slight, augments blood pressure within the arterial system. Therefore, that our efforts to reestablish compensatory hypertrophy upon the part of the left ventricle may be successful, physical rest should be enjoined in the hope of thereby lessening those conditions that favor regurgitation into and distension of the left ventricle.

Moreover, as Balfour so forcibly states, the distending force of the regurgitant stream is increased in the upright position in accordance with Pascal's law, that the distending force "is equivalent to the weight of a column of blood of the height of the cranium above the heart and of the diameter of the ventricular lumen."

When compensation is destroyed, dilatation is greater, that is, the lumen of the left ventricle is increased and the weight of the distending column corresponds to its enlarged diameter. This consideration alone furnishes sufficient reason for insisting upon the supine position, when the left ventricle has lost its compensation.

I well remember the case of a woman, suffering from general edema from relative insufficiency of the mitral valves, secondary to loss of compensation of a long standing aortic regurgitation, in whom a two weeks' rest in bed, and proper medicinal treatment effected an entire removal of the symptoms. Although repeatedly warned against rising and making sudden effort, she one day left her chair to which she had been allowed cautiously to resort, and stepped forward to open the door in answer to a knock. The next instant she fell dead.

In stenosis of the aortic orifice, compensation fails

when dilatation of the left ventricle surpasses hypertrophy, and the ventricle is no longer able to force its contents past the obstruction. In such an event rest seems to me indicated for two reasons: 1, that the action of the heart may be slowed, thereby time given for the slowly contracting ventricle to discharge more blood into and raise the pressure within the arterial system; and 2, that the stream of blood be not forwarded to the heart under the influence of exercise more rapidly than it can be disposed of by the weakened ventricle.

Such are the considerations which lead me to take exception to the injunction laid down by Fraentzel, against the employment of rest in valvular lesions of the heart. Moreover, they are in accordance with the results of my own experience.

There are still other forms of cardiac disease in which the employment of rest becomes a vital question; of these, fatty degeneration, whether acute or chronic, and parenchymatous degeneration in the course of diphtheria and other infectious diseases are important. If symptoms of cardiac failure are urgent, it seems to me that absolute physical rest can not but be at least temporarily beneficial, although when too prolonged the heart might suffer from the very want of these accessory forces in the circulation furnished by carefully regulated exercise.

Bradycardia, on the other hand, would seem to indicate exercise rather than rest, because of the stimulus to the heart's contractions arising therefrom. Tachycardia of a functional or paroxysmal nature ought theoretically to be favorably affected by the removal of muscular effort, as well as of those emotional disturbances which serve to stimulate cardiac contractions. Heart rest seems imperatively called for, and how can this be accomplished except through a lengthening of the diastole or period of heart repose; and with the slowing down of the heart usually accomplished by bodily quiet, a relative increase in the diastolic period results. Moreover, with the slowing down of the heart, blood pressure within the aorta, which sinks in consequence of the rapid and ineffectual systoles is again raised with corresponding improvement in the circulation. Should the rate of the pulse remain unaffected by absolute physical rest there can be no object in its continuance. In acute affections of the heart, such as simple endocarditis, it seems to me there can be no question as to the beneficial influence of rest in bed.

As Fothergill points out, concerning the use of digitalis, the increased action produced by exercise causes more forcible closure of the valves and thereby subjects them to greater strain; the violence of the inflammatory process is certainly increased and the growth of connective tissue favored. Furthermore, simple endocarditis is observed most frequently with inflammatory rheumatism, and Sibson has shown that, if entire rest be employed during a rheumatic attack, the liability to endocarditis becomes very much less. These considerations are so patent as to make superfluous further remarks upon the beneficial effects of this therapeutic agent.

Although this paper concerns the therapeutic uses of rest in heart disease, a few words may not be amiss upon the kind of exercise to be allowed. This should be moderate, as a rule, in all forms of cardiac disease, however complete the compensation. Although patients with aortic insufficiency are sometimes capable of great muscular effort this is always

dangerous. When compensation has failed or is threatened, exercise for the most part should be limited to short walks upon the level ground. They should never be extended to the production of decided fatigue, and stair climbing should be absolutely interdicted. We have heard much of the Oertel method; but experience has clearly demonstrated that mountain climbing is only admissible before compensation has been lost. Likewise Swedish movements, so highly praised by Fraentzel in some cases, and the light gymnastics forming a part of the Schott method are to be chiefly employed in those cases where compensation is still maintained. Nevertheless, in some instances, Schott's exercises as well as Swedish movements seem to be of positive value in restoring compensation. But if cardiac failure be marked, quiet walking and driving must be absolutely the only exercise permitted, and this should be followed by a short period of bodily rest. Fraentzel never allows his cardiac patients to walk in less than four hours after a meal; a most useful injunction.

Conclusions—1. The position taken by Fraentzel, that rest is injurious in the treatment of all forms of heart disease is untenable, and the reasons he assigns are incorrect.

2. Prolonged rest is detrimental, undoubtedly, in cases of enlargement of the heart without valvular disease, particularly if secondary to arterio-sclerosis, and in cases of fatty or other degeneration of the cardiac muscle.

3. The cause, however, lies in the circulation outside of the heart and not, as stated by Fraentzel, in the liability of cardiac, like striped voluntary muscle, to degenerate as a result of prolonged inaction, since the heart muscle can not during life be subjected to complete repose.

4. When compensation has become destroyed in valvular lesions of the heart, particularly mitral stenosis and aortic incompetence, rest is indicated theoretically and is beneficial in practice.

5. Bradycardia would theoretically contra-indicate prolonged rest.

6. On the other hand, it is called for in paroxysmal tachycardia, but should not be maintained, after having shown its powerlessness to affect the heart rate.

7. Acute inflammatory or degenerative affections of the heart indicate rigid rest in the recumbent position.

Venetian Building.

THE RELATION OF THE STUDY OF PATHOLOGY TO THE HIGHER MEDICAL EDUCATION.

BY J. CLARK STEWART, B.S., M.D.

PROFESSOR OF PATHOLOGY, MEDICAL DEPARTMENT, UNIVERSITY OF MINNESOTA.

In speaking upon this purely scientific subject, I shall try to avoid as far as possible, technical terms and expressions so as to make my remarks intelligible and I hope interesting to our youngest undergraduates, although naturally such a topic appeals more strongly to graduates and advanced students.

Our subject is a most important one and worthy of the most careful consideration, both on account of its intrinsic importance and also on account of the rapid change in medical opinion as to its place in the college curriculum.

To illustrate this latter phase of the subject, let us compare the changes in the teaching of our best colleges since 1880.

Take, for instance, the College of Physicians and Surgeons of New York, a college which then enjoyed and has since maintained a foremost place among our medical colleges by virtue of its high standards and progressive methods. At that time the course in pathology necessary to the degree of M.D. at this college would at the present time seem ridiculous, but it then fairly represented the demands of the most advanced medical educators of that time.

The didactic instruction in pathology was given by the chair of Practice of Medicine, and covered the pathology of those diseases lectured on in the annual course, illustrated at times by the demonstration of fresh and preserved specimens. There were no especial lectures upon pathology, and general pathology was only taught as it came up in relation to other subjects in the course on medicine. There was no obligatory instruction in laboratory work or *post-mortems*.

The passing of the examination in practice of medicine was the only requisite for the degree of M.D. as far as pathology was concerned. However, even at this time the studious undergraduate could secure thorough instruction in pathology at this institution, as first class courses in pathologic histology were given by Dr. T. M. Prudden in the laboratory of the Alumni Association, and frequent *post-mortems* were available at the New York and Bellevue Hospital. How greatly all this has changed can be seen by glancing over the present schedule of the same college.

In the recently established four years' course, there is demanded in addition to attendance upon lectures and *post-mortems* about one hundred hours of laboratory work in pathology; fifty hours in bacteriology and thirty-two hours in clinical microscopy, besides optional courses in pathology, bacteriology and original research. This calls for about eighty hours didactic work and one hundred and eighty hours in the laboratory, which can be supplemented to any extent by any student desiring especial instruction in these subjects.

These changes are still more noticeable in the schedules of some of the other schools, which apparently wish to atone for past laxness by present severity in their demands.

Instances might be multiplied, showing approximately the same changes of schedule in other colleges during the past ten years as those mentioned, but I think this unnecessary as the facts are well known.

In regard to the intrinsic importance of the study of pathology to those who wish anything that can be fitly called a medical education, it is only necessary to consider the importance of the subjects included under this term, pathology.

During the first two years of the medical student's course, his time and attention are largely taken up by those fundamental branches, anatomy and physiology with the related laboratory work in normal histology and embryology, and medical education without a thorough comprehension of these subjects would be indeed a farce. Now what anatomy and physiology are to the foundations of a medical education, so is pathology to the complicated superstructure which modern ideas demand, to complete and adorn the modern physician's education.

The term, pathology, is very comprehensive, combining the morbid counterparts of anatomy, physiology and normal histology with the complicated subject of bacteriology woven in—that is to say, the department of pathology includes morbid anatomy, the gross anatomic changes caused by disease; morbid or pathologic histology, the microscopic changes in the tissues due to injury or disease, including the constitution of neoplasms; morbid physiology, a most important part of the subject and one much neglected, which treats of the alterations of function caused by disease, with their origin and results.

Bacteriology while it may be classed under the general department of hygiene is, I think, more practically and profitably taught in connection with pathology. This subject has become such an important factor in the etiology, prognosis and treatment of disease that its thorough study has become an immense undertaking, and there seems to be a tendency in some quarters to over-rank its importance in the college curriculum, making what is really only a part of pathology greater than the whole, and compelling students to spend much more time on this branch than is really justifiable when its true position is considered.

In addition to these distinct divisions of the general subject, there should be included in this department the subject of clinical or microscopic diagnosis, which covers a grouping together for diagnostic purposes, of the facts and technical methods of pathologic histology, bacteriology and to a certain extent those of chemistry. This work is the connecting link between the laboratory and the clinic, applying the most exact instruments and laboratory methods to the living patient, not infringing on but supplementing the work of the physical diagnostician. After this exposition of the scope of pathology, and remembering the constant progress that is being made by hosts of earnest workers, you can better appreciate its importance as a basis of the higher medical education.

Students, I find, are apt to consider this study as a purely scientific ornament in their college course, as contrasted with the more practical branches dealing directly with the practice of medicine and surgery, and are apt to begrudge the time and hard study needed to master its difficulties.

This is a great mistake which will be fully realized only after graduation, for an intelligent understanding of the etiology, symptoms, prognosis and treatment of most diseases, can only be obtained by thoroughly informing one's self of their pathology.

To be in close touch with the medical spirit of the times, a thorough and exact knowledge of the facts of pathology is absolutely necessary, for one can not read intelligently any number of one of our better medical journals without depending upon his knowledge of both the theory and laboratory methods of this science. To illustrate, let me cite a few cases familiar to many of you, showing the relation of recent pathologic discoveries to practical points in medicine.

First as to etiology: What can be more important than the flood of light shed upon tuberculosis, and the now obsolete scrofula by Koch's discovery of the tubercle bacillus? Our present familiarity with the results of this discovery lead us to forget that thirteen years ago the cause of tuberculosis was unknown. Now we have a sure means of diagnosis in the mi-

croscopic examination of sputum, tissues, etc., and perhaps nearly as reliable a one in subjecting the suspected case to the injection of tuberculin. The use of this product of the growth of the tubercle bacillus as a curative agent in human tuberculosis is at present under a cloud, partly I think, owing to the great lack of good judgment on the part of the general medical public who rushed into its use headlong on all sorts of unsuitable cases, and then rushed into the press to condemn the remedy but not their own folly.

I have not the slightest doubt that tuberculin has proved of the greatest value in many properly selected cases, and believe that in the near future this substance will be so modified and its use so perfected as to furnish us with a most valuable remedy. Tuberculin is now proving to be of great value to the common health by its use as a diagnostic agent in the detection of tuberculosis in cattle. It is used extensively by veterinarians and health officers in the condemnation of tuberculous animals and the results are no longer questioned.

The debt of preventive medicine to Robert Koch can scarcely be over-estimated. The placing of tuberculosis among the infectious diseases, and thus among the preventable, was a tremendous stride forward in the interests of health, although we can not as yet read the full benefit of this discovery because of the lax medical education of the past. Neither the medical nor the general public are as yet thoroughly educated on this subject, and until they are, the more thorough preventive measures can not be put in force.

The problem of the proper sanitary handling of a case of chronic infectious disease often lasting for years, during the greater part of which the victim is able to be about, attend to business, travel in public conveyances and attend places of amusement is truly a difficult one; but with a general knowledge of the facts in the case public sentiment will demand and receive protection.

Every medical man of the present day should be a public educator on all matters pertaining to hygiene, and especially on this subject of the transmission of tuberculosis, and by united action the time will soon come when every consumptive in the land will understand the facts and believe that he is a menace to his friends and the general public through his sputum and excreta, and then at least it is fair to presume that some decided progress will be made in the prevention of tuberculosis.

Another striking instance of the value of pathologic research is seen in the elucidation of the causes of tetanus and lockjaw. The discovery of a bacillus only flourishing when deprived of oxygen and existing in our street dirt and garden soil, explained many facts which had long puzzled the clinicians, and showed clearly how the rusty nail and toy pistol cap could initiate so deadly a disease. The study of this germ and its life habits have again contributed to the prevention of disease by teaching that the open treatment of suspected wounds makes the least favorable conditions for the growth of this germ, which laboratory research has shown can only flourish in the absence of oxygen. Here, again, germ products are of avail in therapy, as Brieger has elaborated a substance for injection which is said to cure tetanus. In general, it may be said that there is a fair prospect of an entirely new therapy coming into

use based wholly on laboratory study of the various pathogenic bacteria, each disease being combated by the use of substances elaborated by the growth of its causative germ, either in the laboratory pure culture or in a suitable animal. To illustrate: Pneumonia has been treated by a substance obtained from the blood of an animal which has just recovered from the disease, the theory being that the injurious effect of the growth of the germ in the body is finally combated by a so-called antitoxin elaborated by the living body, which first checks the growth of the germ, then kills it and so brings the disease to an end. By taking the blood serum from such an animal just convalescent, and injecting it into another suffering with the same disease, the morbid process is quickly brought to an end.

These blood serum and antitoxin methods bid fair to enrich our therapeutic resources greatly, but if their use should ever become general the cause of the higher medical education would be greatly advanced, because as many of these substances are most virulent poisons a false diagnosis might cause very disastrous results, and the general public would have to be a little more careful than they are at present in choosing their medical advisers.

Another important and interesting discovery not in the line of bacteriology is that of the amœba coli with its etiologic relations to hepatic abscess and dysentery. In all medical text-books for years the clinical fact has been stated that abscess in the liver followed certain cases of dysentery, but it was only a few years ago that the laboratory of the Johns Hopkins Hospital furnished the proof that a small animal parasite was the cause of both conditions.

The recent study of the plasmodium malarie has furnished an invaluable means of diagnosis, by the examination of the blood, between typhoid and malarial fevers, and incidentally has made the classic treatment of malaria by quinin, scientific instead of empirical, by showing that very weak solutions of this drug are fatal to the plasmodia.

Illustrations of the debt owed by clinical medicine to pathology are so numerous that a mere enumeration of the non-striking ones would consume all the allotted time; hence I will speak of but two more: 1, as to the terrible disease, diphtheria—you doubtless all know something of this most treacherous disease, and the more experienced have noted the strange variability in its virulence. Laboratory workers have shown much in explanation of these variations. They have demonstrated, first that true diphtheria is due to the Klebs-Löffler bacillus, but that a similar disease clinically indistinguishable may be caused by other bacteria. In general they have shown that the disease caused by the Klebs-Löffler bacillus is more serious than the pseudo-diphtherias and hence to be carefully differentiated from a sanitary standpoint.

As this may be clinically very difficult, and at times impossible, they have carefully elaborated a method of diagnosis by culture which is now in use by the Board of Health of the city of New York. Physicians are furnished with sterilized test-tubes containing swabs, with which they touch the exudate in their patients' throats; replace in the stoppered test tube and return to the Health Department where cultures are rapidly made by bacteriologists and the result reported within twenty-four hours.

This is a very important advance in the interests

of public health, for when properly carried out it insures a two days' quarantine of all suspicious cases, which practically means all sore throats with any form of exudate, as the bacteriologist has proved that true diphtheria may so closely resemble a mild lacunar tonsillitis as to be indistinguishable by the best clinician, although you will still find some of the older if not wiser men at our medical societies who insist "that *they* can always diagnose diphtheria without fail, although they can not teach others how to do it."

Any precautions leading to the early diagnosis, and thus to a limitation of the spread of so fatal a disease are of the greatest value, and it is to be hoped that the near future may see the extension of these methods into our own city.

Another instance, this time in the line of bacterial therapy, but on a different principle from those already mentioned, is the use of the germ and toxins of erysipelas as a curative agent.

The remarkable effect upon various chronic disorders of an attack of accidental erysipelas has been noted for a good many years, and since so much attention has been paid to bacteriology much experimentation has been done in this line, in using the pure culture as a means of mitigating the disease. Local tuberculosis, syphilitic lesions and diphtheria are reported to have been thus cured.

Within the last few years Dr. Coley, of New York, has determined by experiments that an attack of erysipelas has a certain inhibitory or even curative power over malignant tumors, and some of his reported results are truly remarkable. Both carcinomata and sarcomata have shown some favorable results, but, on the whole, the latter seem to be the more favorable subjects for this treatment, which consists of the induction of an artificial erysipelas in the subject of an inoperable malignant tumor, or more recently in the systematic injection of erysipelas toxins, and in favorable cases the growth of the tumor has been checked, or it has become smaller or even disappeared. Scarcely enough time has elapsed since these apparently successful experiments, to prove their permanent value, and the treatment in some cases has been very severe, but remembering the utter helplessness of the surgeon in the case of these inoperable sarcomata, any prospect of help is to be welcomed.

The foregoing illustrations are enough to show you the dependence of all branches of medicine upon the researches of the pathologist, and judging from the past it is probable that each year will materially increase this debt, until some time in the happy future medicine will no longer deserve the reproach of not being an exact science.

As medicine becomes more scientific and more exact, the practitioner will need all the more preparatory study to fit him for its use, and of this study pathology will, I think, necessarily form an ever increasing part.

I have been asked to express my views as to the following practical points:

1. The amount of time necessarily or advisably allotted to pathology in the four years' course.

This, I would answer by the following schedule and comments:

SCHEDULE.

First Year: Lectures, *i. e.*, recitations, demonstrations, etc. Pathology including bacteriology, two hours weekly,

for thirty weeks, sixty hours. Laboratory, pathology and bacteriology, three hours weekly, thirty weeks, ninety hours.

Second Year: Lectures, pathology and bacteriology, one hour weekly, thirty weeks, thirty hours. Laboratory, elective special pathology and bacteriology, three hours weekly, ninety hours. *Post-mortems* two hours weekly throughout the second and third years, 120 hours.

Fourth Year: Lectures, clinical diagnosis, one hour weekly, thirty weeks, thirty hours. Laboratory, elective clinical diagnosis, two hours weekly, twenty weeks, forty hours. Elective special pathology, ninety hours.

Total: Didactic work obligatory, 120 hours.

Laboratory work obligatory, 90 hours.

Laboratory work elective, 220 hours.

Post-mortem work obligatory, 120 hours (estimated).

In this connection, I should like to call your attention to the recommendations of the committee on formulation of a curriculum for the Association of Medical Colleges.

This is that the least amount of instruction that will be accepted as sufficient in colleges of the Association when the four years' course shall have been established shall be twenty-five hours didactic and one hundred and fifty hours laboratory work in bacteriology; fifty hours didactic and one hundred hours laboratory work in pathology.

I think this is giving entirely too much importance to bacteriology in comparison with the remainder of the department of pathology, and too little time to didactic pathology which, however treated is a very comprehensive subject. Very few medical students can afford to devote enough time to bacteriology to become competent practical bacteriologists and those who expect to thoroughly master the subject will need much more than one hundred and fifty hours, while the remainder of the class who merely wish an appreciation of the principles and methods of the science, with the technical skill to avail themselves of its practical diagnostic points, will find a good part of this allotted time really wasted.

I am in favor of giving the most ample time and fullest facilities to the few who really study laboratory bacteriology and pathology, without compelling the rank and file whose ambition is merely to become intelligent and able practitioners to really waste their time in acquiring technical skill of which they will never make use.

In accordance with these views, the schedule just read gives one hundred and twenty hours didactic and ninety hours laboratory work as obligatory, but provides two hundred and twenty hours additional elective laboratory work on the two subjects including clinical diagnosis.

2. To what extent should pathology be taught in the regular course by the instructors in practice and surgery?

This question admits of a good deal of diversity of opinion, but I think it is better to err by sins of commission rather than by those of omission; that is, I think the subject should be gone fully into in connection with both chairs, even at the risk of repetition. I think, however, that instructors in both practice and surgery should confine themselves as closely as possible to gross pathology and pathologic physiology and omit entirely histologic details. Take the subject of tumors, for instance; the lecturer on surgery can, I think, well avoid anything more than a superficial discussion of the theories of tumor formation, and omit entirely all details of their microscopic structure, and yet teach a great deal of their pathology in explaining their clinical and life histories, what malignancy is, the gross peculiarities of

benign and malignant tumors, what cachexia is and how caused by tumor growth; in general, everything relating to the tumor as seen in the patient with the changes caused by its presence. The teacher of pathology can be well restricted in this part of the subject to morbid anatomy and histology; that is the study of the tumor after its removal from the patient supplemented by a careful study of that most important subject, etiology.

The immense amount of work now being done in this department indicates that our ideas on tumor causation may soon undergo revision, and here certainly the pathologist should have first place in teaching the results of microscopic research.

The bacteriology of suppuration should, I think, be taught by the surgeon in the greatest detail, although it will necessarily have to be again gone over in the systematic course. The practical importance of this subject to the surgeon makes it imperative that he devote much time, both to the bacteriologic facts and to their practical application, and it will be a further advantage to the student to view these facts from the standpoints of the chairs of practice and pathology.

The instructor in practice must teach pathology in order to make his subject clear, but as I have already said, I think he can profitably avoid entirely histologic changes and many of the details of the morbid anatomy, concentrating his teaching on what I have included under morbid physiology. One part of this subject seems to be greatly neglected, and that is the connection between the pathologic lesions of a disease and the individual symptoms. Students are apt to memorize a set of lesions and a set of symptoms and not have a very clear idea of the relation between the two.

It is difficult to draw a line between the teachings of the chairs of practice and pathology, so much so that in some of our best schools the entire didactic work of the two subjects is combined. This avoids repetition, but throws an immense amount of work on the chair.

3. To what extent should pathology be taught by the instructors in the special branches?

Here there will not be so much difference of opinion. I think each specialist should teach his students all the necessary pathology of his branch, especially that part of it whose great importance I have emphasized in regard to the teaching of practice, *i. e.*, the relation of the pathologic process to the symptoms.

The work of the various specialists will vary in this respect, as those dealing with the eye and ear and skin treat of subjects seldom taken up in a systematic course in pathology, while the specialist in genito-urinary disease will find renal diseases, at least, very thoroughly gone over both in practice and pathology, while in regard to urethral and prostatic pathology he will have an undivided field.

In closing, I wish to clearly define my position in recommending the making elective of so large a part of the laboratory work. I consider that the whole amount laid out for the four years' course would be of the greatest value to every student, and I should advise all who can possibly do so to take all the elective courses, so shaping them as to best subserve the special aim of each; but my experience in teaching pathology has taught me that all students can not be made into skilful laboratory men; and that

the restriction of the obligatory practical work to the projected ninety hours in the second year will sift out the incapable and idle, and leave the field clear for better work on the part of those who really want it and can take advantage of the increased room and opportunities thus afforded.

One of the advantages claimed for a four years' course, is the greater adaptability to the needs of the individual in allowing more elective work; and I think that in all departments there should be allowed the student the greatest liberty of choice compatible with the requirements of a liberal medical education. The student can not expect to learn everything necessary to the practice of medicine in any medical college, be the course three or four years, but he has a right to demand that the education given him in his college course shall be such as to give him the broadest and most complete foundation for his studies in after life.

STIGMATA OF DEGENERACY IN THE ARISTOCRACY AND REGICIDES.

Read in the Section on Neurology and Medical Jurisprudence, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY EUGENE S. TALBOT, M.D., D.D.S.

FELLOW OF THE CHICAGO ACADEMY OF MEDICINE.

(Concluded from page 716).

Figure 20.—Charles Edward Nobiling. Born at Kolino (Posen), April 10, 1848. Died in the hospital at Berlin, Sept. 10, 1878. Typical (political mystic).

Assault on Emperor William June 2, 1878. Son of a suicide—attempted suicide after his act. Anarchist.

Well developed head and forehead. Small, sunken eyes. Long, slender ears. Arrest of bones of face and of jaw. Well developed nose.

Figure 20.

Figure 21.

Figure 21.—Nicholas Alphonse Aubertin. Inventor. Born July 26, 1835, at Bombas, (Moselle). Sent to the Bicêtre 1888. Attempted to assassinate Jules Ferry, December, 1887.

Persecutory, reasoning paranoiac, without hallucinations, complained of various persons who mixed up in his affairs, to whom he gave his hatred and insults. "But gradually, by a psychologic process, not at all surprising in exalted cases like this, he came to consider himself as personifying France, and making his political enemies those of the state, and conceiving the idea of punishing them. From this on, he was double insane, a persecuted persecutor on his own account, and a mystic fanatic on that of the state. In this state of mind he made a list of sixteen enemies; thirteen private and three public, and having condemned them to penalties to fit their crimes and referring them, as he called it, "to the lottery of summary justice," he drew their names from his hat in order to see with which he should begin. It was the name of Jules Ferry, condemned to death for *lese patrie*, that came first from this strange urn, and Aubertin, as a faithful minister of justice, took it upon himself to carry

out the sentence." The two following were personal enemies condemned "to have their two legs broken at the knees." Each was to have his turn.

Well developed head and forehead. Eyes small and sunken. Nose apparently normal. Upper jaw arrested.

Figure 22.—Jean Passanante; cook. Born at Salvia (Pozzuoli) in 1849. Imprisoned at Porto Ferraja in 1879. Typical regicide (political mystic). Attempted to kill King Humbert Nov. 17, 1879. (From a likeness given by Lombrosa).

"Elder sister had an imbecile son, an albino, a subject of tremor, and of extraordinary ascetic fanaticism; his younger sister had an odd habit of, every evening after finishing her work as a domestic, shutting herself closely up in her chamber and saying her beads and praying aloud; his elder brother, Joseph, was sent to the asylum at Aversa in March, 1887, suffering from systematized religious delu-

Figure 22.

sions. 'Possessed with the idea of elaborating the principle of faith and reforming religion, he become an ascetic lunatic, preacher and prophet.' We see the analogy between the criminal and the lunatic; they are brothers in mysticism. As Dr. Virgilia well says: 'The one in the religious sphere; the other in the political, exhibit the same phenomena.'" Regis, l. c. p. 29.

Figure 23.

There seems to have been a very prominent self feeling, desire of notoriety, etc., in Passanante, and possibly also a touch of religious fanaticism. The Bible was one of his favorite books. Socialist.

According to Virgilia he has become totally demented in prison, has lost all ideas, and lives a purely animal existence or worse; coprophagous.

High, broad forehead. Eyes irregular set. Left smaller than right; left higher than right. Left cheek bone more

prominent and higher than right. Ears long, handle-shaped. Apparent arrest of lower jaw.

Figure 23—Charles J. Guiteau shot President Garfield for the openly avowed reason that he was about to wreck the Republican party, and because the conception leading to the homicide was an inspiration of the Deity. From the evidence presented at the trial, the results of the autopsy and of the microscopic examination, alienists the world over, agree both as to his insanity and its type. Dr. W. W. Ireland is of opinion not only that he was insane but was a primary paranoiac (*primare verrückt*). His ancestry was defective on both sides. The mother suffered from an acute brain disease prior to and at the time of his birth and was for years "a nervous invalid." The father was regarded as a lunatic by clergymen, lawyers and others with whom he came in contact and by the eminent Illinois alienist, Dr. Andrew McFarland. A brother of the father died insane in Bloom-

Figure 24.

Figure 25.

ingdale Insane Hospital. The transcript of his hospital history shows that there was hereditary insanity in the family for generations prior. The homicide's brother showed strange peculiarities; the sister is an hysterico-epileptic and was once adjudged insane in Illinois.

With such a family history, hereditary stigmata are to be expected and defective as is the record these are found. Drs. McLane, Hamilton (called by the State), Spitzka and Kiernan¹ (called by the defense), agree that the skull exhibited decided asymmetry. This, as Kiernan remarks, extending to the face produced what Spitzka called a "lop-sided smile," and also involved the eyes.

Spitzka² lays great stress on the asymmetry of the convo-

Figure 26.

lution in either hemisphere, especially those of the island of Reil. He found in the right side, five fissures and six straight gyri; on the left seven fissures and eight gyri. The right hemisphere was less developed than the left. Dr. Spitzka also states that "aberrations in development of the kind discovered in Guiteau's brain has not yet been found in others than persons of unsound mind," and that "the only finding in the brain of constitutional lunatics of monomaniacal tendencies which promises to establish a relation between the insane and the state of the brain, consists in such architectural anomalies."³

¹ Chicago Medical Review, Dec. 15, 1881.

² American Journal of Neurology and Psychiatry, August, 1882.

³ Ireland, commenting ("Through the Ivory Gate") remarks: "These statements, if they could be proved, would settle the question, but I

The principal lesions found in Guiteau's brain were adhesions of the dura mater to the inner table of the skull along the longitudinal sinus, and adhesion of the dura to the pia mater and to the brain at a spot on the vertex. Other defects were also observed in the brain. Marked asymmetry was also observed in the head and face. Head and forehead fairly well developed; eyes set close together; right apparently higher than left; ears excessively developed; arrest of development at alae of nose; jaws normal. Microscopic examination revealed, in the opinion of Dr. E. O. Shakespeare, an unbiased observer, who made it, such marked evidence of disease and defect as to warrant the opinion that Guiteau was mentally abnormal.

Figure 27.

Figure 24.—Balthasar Gerard. Soldier. Villefranche (Franche Comte) in 1558. Executed July 14, 1584. Typical (religious mystic). Assassin of William of Nassau, July 10, 1584. (Portrait p. Bibl. Nat. Coll. des Estampes).

Premeditated his crime for six years. Probably had accomplices enough. Was rather of the type of Booth with religious fanaticism added. Regis does not say much in regard to him. Was made almost a saint by the Spaniards at the time. From the anesthesia of paranoia suffered torture courageously and was believed by the Dutch to have been aided by the devil.

Figure 28.

Excessively developed head. Small, sunken eyes. Arrest of bones of face and nose. Arrest of upper jaw.

Figure 25.—Aimee Cecile Renault. Born in Paris, 1774. Executed June 17, 1794. Typical (political mystic). Design of assassinating Robespierre. Likeness after Bonneville (Bibl. Nat. Coll. des Estampes).

Believed she ought to give her life for the return of the King.

Excessively developed occipital region. Exceedingly low forehead. Long, narrow ear. Arrest of bones of the nose. Well developed lower jaw.

doubt whether they can be proven." In reply to this remark I should say that there is scarcely a tissue of the body, more especially about the head and neck, but what will show stigmata of degeneracy as a result of arrest of development of the cells of the brain before birth.

Figure 26.—Karl Ludwig Sand. Student. Born at Wonsiedel in 1795; executed May 10, 1820. Typical (political and religious mystic. Assassin of Kotzebue, March 23, 1819. (Bibl. Nat. Coll. des Estampes.)

Meditated his act a long time. Wrote in his journal in 1818: "Lord, strengthen me in the idea I have conceived for the deliverance of humanity by the holy sacrifice of thy son. Make me a Christ for Germany, and make me, like Jesus, brave and patient in suffering." Attempted suicide after his act.

Low forehead. Small, ill-shaped eyes. Well developed nose. Prominent cheek bones. Arrest of development of the upper jaw. Excessive development of lower jaw.

Figure 27.—Jean Louis Verger. Priest. Born at Neuilly-sur-Seine, Aug. 20, 1826. Executed Jan. 20, 1857. Mixed type. (Reasoning mania of persecution, and religious mystic. Assassin of Mgr. Sibour, Jan. 3, 1857. From photograph by favor of M. Lacassagne.)

Figure 29.

Figure 30.

Son of a suicide. Had hereditary insanity. Considered all those he lived with, his *confrères* in particular, as his enemies, accused them of various crimes, and on this account was deprived of his priestly functions. Became clamorous for his rights and persecuted his superiors with his demands. Went into the Church of the Madeleine, with a placard on his breast inscribed: "I was naked, and ye clothed me not; hungry, and ye gave me no meat." Up to this time he was a simple case of persecutory insanity, but now the dogma of the Immaculate Conception was about to be proclaimed by the Pope, and he had a double cause to champion; his own, and that of the Deity. He wrote and spoke violently against the new dogma, and while he anathematized his own enemies he avenged the outraged religion by killing the

Figure 31.

Archbishop of Paris in church, with the significant cry: "No goddesses! no goddesses!" and regretting, he said, only one thing, that he could not go to Rome to strike another and a more illustrious victim. Notwithstanding the ample evidences of his insanity which would be evident to any modern alienist, he was condemned and executed, without any voice but that of his advocate raised in his behalf. Medical science was then nearly forty years behind its present status. Even Lacassagne, who later described his form of insanity so well, had only the year before declared him sane.

Rather low forehead. Small, deep-set eyes. Normal cheek bone. Long, handle-shaped ears. Nose arrested in its development. Arrest of upper jaw. Well developed lower jaw.

Figure 28.—Cotilla Galeote; priest. Born in Spain; condemned to death, but later interred in an asylum. Mixed type (reasoning insanity of persecution—religious mysticism.) Assassin of the Bishop of Madrid, April 18, 1886. (From photograph. Favor of De Lacassagne).

He had been interdicted from office for his eccentricities. Almost an exact repetition of Verger's acts and delusions. His insanity became so manifest after his condemnation that a second medical commission was called to examine him who reported him a lunatic, and he was interred in an asylum.

Full, low forehead. Small eyes. Deep set, and close together. Ear excessively developed. Long slender nose. Arrest of development of bones of face and upper jaw. I was informed, when in Madrid, by a physician that the deformed palate and V-shaped arch had much to do in the sending him to the insane asylum.

Figure 29.

Figure 29.—Louis Pierre Louvel; saddler. Born at Versailles, 1783. Executed June 7, 1820. (Political mystic paranoiac). Assassin of the Duc de Berry, Feb. 13, 1820. Drawn from life, at the Conciergerie).

Had the idea of killing all the Bourbons and chose the Duc de Berry as his first victim. Regis does not give a full account of him.

Low forehead. Eyes long; set far apart. Right lower than left. Long slender nose. Arrest of bones of face and upper jaw. Small lower jaw.

Figure 30.

Figure 30.—Louis Allibraud; clerk. Born at Nimes, May 20, 1810. Executed July 12, 1836. Typical regicide (political mystic). Attempted to kill Louis Phillippe, June 5, 1836.

Impr. Thierry Freres (Bibl. Nat. Coll. des Estampes).

Had had the idea a long time to revenge the death of citizens killed at Lyons. Compared himself to Brutus—his favorite works were those of St. Justin.

Excessively developed occipital region. Low, narrow forehead. Eyes set close together. Long, handle-shaped ears. Long slender nose. Arrest of bones of face and upper jaw. Arrest of development of lower jaw.

Figure 31.—De Paris l'Aine. Guard of the King. Born at Paris, November, 1753. Suicide Jan. 27, 1793. Typical regi-

cide (political mystic). Killed Lepelletier Saint Fargeau, Jan. 20, 1793. Engraved by Brion. (Bibl. Natl. Coll. des Estampes).

Antecedents very little known; all that is known of the immediate reasons for his suicide is what he himself wrote on the back of his commission as Royal Guard, found on his breast after death. My "brevet d'hominem; let no one be disturbed. No one was my accomplice in the fortunate death of the scoundrel, Saint Fargeau. Had he not been at hand I would have done a still better act; I would have freed France of the regicide, the parricide d'Orleans. Let no one worry. All the French are cowards and I say to them:

"Peuple, dont les forfaits gettent partout l'effroi
Avec ealine et plaisir j'abandonne la vie;
Ce n'est que par le mort q'on peut fuir l'enfamill
Q'Impriime sur nos fronts le sang de notre roi.
(“People, whose crimes dismay everywhere bring,
With cajoling and pleasure I quit In life's race;
Since tis only by death we can flee the disgrace
That is stamped on our foreheads in the blood of our king.”)

Figure 32.

Broad, low forehead; eyes small, set close together. Nose excessively developed. Slender cheek bone, well developed. Bones of the four upper and lower jaws arrested.

Figure 32.—Joseph Fieschi. Soldier, spy, draper, conspirator. Born at Murato (Corsica) July 13, 1790; executed Feb. 19, 1836. Exceptional. (Accomplices. Political mystic). Attempted assassination of Louis Phillippe by infernal machine. (From Nature).

Figure 33.

The stigmata of this subject is very noticeable. Head and forehead larger. Depression over each eye. Eyes small. Left lower than right. Nose long and slender. Cheek bones excessively developed. Bones of the face and upper jaw arrested. Receding chin.

Figure 33.—Charlotte Corday (Marie Anne Charlotte Corday). Born July 27 at Legueries (Orne). Executed July 18, 1793. Type, political mystic. Killed Marat, July 13, 1793. On leaving for Paris she gave away whatever she had, retaining only "Plutarch's Lives," in which she could converse to the end with her hero, Brutus. Killed Marat to save the republic. Refused priestly consolation; was "a republican before the revolution."

Low forehead. Eyes small and round. Left eye higher than right. Long, slender nose. Cheek bones round. Arrest of upper jaw. Small, undeveloped chin.

Figure 34.—Cesare Giovanni Santo, an Italian, stabbed President Marie Francois Sadi Carnot, June 24, 1894, at Lyons, to avenge the death of anarchists previously executed by the courts.

Santo was 22 years of age and was born in a province of Milan, Italy. He was sentenced to death August 4, and was beheaded soon after. The assassin was the youngest of six children and the only one of the family who was not well respected, the remainder being hardworking men and women. He left home at the age of 11, and even at that time showed anarchistic principles. His mother was temporarily insane over her son's crime. It is said that the father had epilepsy, which disease was brought on by threats of death by the Austrians while their prisoner in 1848. It is difficult at this period to give any of the facts in regard to family history, or the mental and physical condition of the assassin, since they were not brought out in the trial and no authentic report has been published by physicians. From his photograph he presents the following stigmata:

Head small; forehead low; eyes small, abnormally shaped; ears abnormally developed, long, handle-shaped; nose small at bridge, broad and flat at alae; face, cheeks and superior maxillary undeveloped; lips large; lower jaw apparently normal. From such an ill-looking individual, stigmata of degeneracy of nearly all of the tissues of the body must result.

Figure 35.—Patrick Eugene Joseph Prendergast, 25 years of age, shot and killed Mayor Carter Harrison, of Chicago, Oct. 28, 1893, at his residence, claiming that the Mayor had not given him a certain office which had been promised him. Very little was obtained at his trial in regard to the family history, except that his grandfather was insane. There can be no doubt but that Prendergast was insane, since five experts who were employed by the State to examine him found him, after spending considerable time in making a thorough examination, to be a paranoiac and therefore could not and did not appear for the State, but did appear, without reward for the prisoner.

Prendergast was born in Ireland and came to this country at the age of 5 years. On the witness stand I gave the following testimony: Height five feet, seven inches. Weight 132 pounds; hair red, coarse and stiff; very little upon face. Nose fairly normal, thin at bridge, broad at alae. Ears large and projecting; lobes short and broad; tragus both well developed; helix broad, with typical tubercles at the upper and outer border of the ear. Lips, upper, small and thin; lower excessively developed, more prominent because of undeveloped upper jaw. Face, arrest of development of the bones of the face, especially at the alae of the nose. Zygomatic arches, normal, but appear prominent owing to the arrest of the bones of the face. Lower jaw normal. Forehead receding. Head sunken at the bregma; occipital portion excessively developed; circumference 22.2 inches (57 millimeters); antero-posterior, 7.75 inches (20 millimeters); lateral 6.36 inches (16½ millimeters); lateral index .82; therefore extreme brachycephalic. Feet large; hands normal; fingers long and skinny. Width outside first permanent molar 2.25 inches; width outside second bicuspid, 2 inches; width of vault, 1.25; height of vault .75; antero-posterior, 2.

ARTIFICIAL SELECTION.

Read before the Milwaukee Medical Society, Oct. 9, 1894.

BY W. H. WASHBURN, M.D.

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE IN WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS, ETC., MILWAUKEE, WIS.

It is by natural selection that those most fitted to succeed in the struggle for existence survive and propagate their kind. The familiar example may be cited of the deer which, being the equal of all the other members of the herd in other respects, is less swift of foot, and hence lagging behind his fellows falls a victim to his feline enemy the panther. His untimely death has eliminated him from the problem and made it impossible for him to become the progenitor of a slow-footed race of deer.

The dominant races of men have been evolved by

reason of the operation of the law of natural selection. While we may not at this time care to repeat or emulate the violent acts of our forefathers, by which they over-ran the territories of their less ferocious neighbors, appropriating the land, and in many instances slaughtering entire populations, we must nevertheless recognize the fact that it was by such deeds as these that a superior race of the *genus homo* became possible. With advancing civilization, and with our developing ideas of justice, equity and the brotherhood of man, natural selection has come to play a comparatively subordinate part in the solution of the various problems confronting mankind. In point of fact, as we advance in civilization, we are on every side adopting methods and means of rendering entirely inoperative this great natural law.

The law of nature, as well as the decree of Jehovah seems to be, "in the sweat of thy face shalt thou eat bread," and the law of natural selection if allowed to operate would with promptness eliminate from the problem those who refused to work. The so-called dependent classes, found principally in alms-houses and other charitable institutions, in the large cities begging from door to door, and in the country on the tramp, are representatives of the class who eat bread without having fulfilled the other part of the decree. Starvation is the legitimate end of these people and thus would natural selection solve the problem of the care of the dependent classes. But with the evolution of a superior race of men, we have acquired humanitarian tendencies and an increase in moral and sympathetic feeling, and these qualities in us will not allow us to stand idly by and witness the death of these elements of society by the operation of natural laws. We accordingly establish and maintain institutions for their care at the expense of those other members of society who are better fitted for survival, and in the meantime they are permitted to continue the work of reproduction thus continually replenishing the earth with offspring similarly unfit for survival. Society would probably suffer a greater evil by reason of the outrage to its finer feelings if natural laws were permitted full sway in the solution of this problem, than it now suffers in encouraging the growth of this dependent class. We see, then, in our poor laws and in our charitable institutions agencies which interpose to prevent the full operation of the law of natural selection.

If the trade union enables an incompetent and inferior craftsman to obtain work at current wages, by just so much does it interfere with the operation of the law of natural selection, which would condemn this man to idleness and starvation, or the adoption of a new means of earning a subsistence in some avocation in which he might excel. The natural law being thus rendered to a certain degree inoperative, the average efficiency of the whole class, trade, profession or occupation into which this individual has been foisted and maintained is correspondingly reduced and the tendency is toward deterioration rather than the reverse.

There is probably no agency in operation to-day which is opposing the operation of the law of natural selection more effectively, or I might say as effectively, as the medical profession. In the evolution of medical science we see this influence at work in every direction. I may here advert to the agency of certain disease germs in the work of natural selec-

tion. These germs are in many instances unable to maintain an existence and cause disease except in the tissues of the comparatively unhealthy, and in those certainly they are able to flourish in the greatest exuberance and most often ultimate in death. Were it not the fact that the healthy man is able to successfully resist the invasion of his body by microorganisms, disease would be the rule rather than the contrary. We live at the bottom of an atmosphere which fairly teems with microorganisms of innumerable varieties, many of them being pathogenic. These microorganisms are therefore constantly invading the bodies of men, the healthy among whom react against them so successfully that disease does not always result, while on the other hand the unhealthy are constantly falling victims to their pathogenic influence. In this way it transpires that disease germs, in general, are friends of the human race rather than enemies, rendering efficient aid in eliminating the physically unfit from the problem in the struggle of life. I say, in general, disease germs are friends of the human race, because there are germs that appear to attack with equal facility the vigorous and healthy, as for example those of measles, syphilis and smallpox.

The advances in medical science both preventive and curative which have, within the last thirty or forty years, lessened the prevalence and the mortality of the germ diseases, have enabled those to survive and procreate who under other circumstances would have perished without issue. As a consequence of these advances in medical science, it has resulted that while the mortality per million of population has markedly decreased in the group of diseases caused by microorganisms, it has correspondingly increased in the group of constitutional diseases. In this latter group hereditary predisposition plays an important part, and a survey of vital statistics indicates that there has been an increase in their prevalence and mortality. An increase in diseases of the respiratory organs, of the circulatory organs, also an increased tendency to diseases of the nervous system, suicide and intemperance. Increased mortality from cancer, diabetes, rheumatism, anemia and renal diseases.

In 1850 there were (Holmes, *Medical News*, July 7, 1894) 422 blind persons per million of population, while in 1890 there were 807. In the State of Maine (Haycraft, *British Medical Journal*, Vol. i, p. 404, 1894) there were in 1850, 75 insane persons per million of population, while in 1890 there were 685 per million. In 1838-1840 there were 155 deaths among infants under 1 year old per 1,000 born, whereas in 1890 the proportion had sunk to 142 per 1,000. In the period 1851-1860 the deaths from phthisis in children under 5 years old were in the proportion of 13.05 per 1,000 living, and from hydrocephalus 25.39 per 1,000 living, whereas in the period 1871-1880 the deaths from phthisis had fallen to 7.67 per 1,000 and from hydrocephalus to 19.00 per 1,000 living.

In the meantime, deaths from tuberculous affections other than of the lungs had risen from 19.20 per 1,000 living of the same age to 25.50 per 1,000. (*Journal of the Royal Statistical Society*, March, 1894.)

These few comparisons of mortality rates are sufficient for the purpose, but might readily be added to if time were taken to study the mortality returns of any city or country where trustworthy records are kept. But the physical and moral well being of

society and the advance of civilization is retarded in another conspicuous direction. There was a time in the history of mankind when ability to kill and to successfully rob one's neighbor was necessary to the continued existence of the human race, and it hence resulted that for thousands of years the most daring robbers and homicides were the ones best calculated to survive and leave offspring, but we happily live in a time when mankind has evolved out of this state, and these qualities render the subject out of joint with the times and less able to survive in the struggle of life.

The law of natural selection does come into exercise to a certain degree in the class we are now considering; that is the criminal class. There is a certain economy in vice; that is, vice, like the bacillus in the process of its growth calls into operation agencies which tend to its own extinction. The criminal class is constantly recruited from the non-criminal; the average duration of life among the members of this class is much less than the general average; and they less often leave progeny. Nevertheless, there are numberless instances on record where crime has appeared among large numbers of the descendants of criminal ancestors. Now these descendants as certainly inherited their impulse to vice and crime as the child of phthisical parents inherits its tendency to tuberculous affections and is no more to be blamed in the one case than in the other, and yet society can not be called upon to supinely suffer from the depredations of this class.

Our penal laws are enacted with a view not to the punishment of the criminal, but to the protection of society against his further acts of criminality, and he is accordingly temporarily withdrawn from his accustomed haunts of vice and boarded at the expense of normal man in State institutions. Having served out the term of his sentence here, he returns to society to again engage in criminal enterprises and incidentally in the work of procreation, producing progeny that will in turn prey upon society and require to be imprisoned at society's expense. While it is a fact as already stated that natural selection is coming into play to a certain extent in the elimination of this class of society, it is nevertheless undeniable that it is increasing in numbers to an alarming extent as is shown by prison statistics. (President Brinkerhoff's address at St. Paul Prison Congress, 1894.) Thus in 1850 there was in the United States of America 1 prisoner to every 3,442 of the population, whereas in 1890 the proportion had risen to the enormous ratio of 1 to every 757 of population. These considerations would seem to warrant us in the conclusion that interference with the operation of the law of natural selection, as above indicated, has enabled a physically and morally inferior class of individuals to survive into middle life and become the progenitors of still further degenerate offspring. Thoughtful men are already able to foresee that if this retrogression is not to continue, something will have to be done in the way of artificial selection.

Malthus recognized vice and misery as the most powerful agents in natural selection, and in his famous "Essay on Population," first published in 1798, pointed out a means of greatly reducing the prevalence of vice and misery as a means of natural selection. His plan was to insist strenuously upon the obligation of every man to maintain himself

and his offspring, prohibiting marriage on the part of any man not able to support an average family; that is, himself, wife and five children. I am not aware that the suggestion of Malthus has ever been put into operation anywhere, the argument of his opponents, among whom the clergy have always occupied a prominent place, being, practically, that inasmuch as man is endowed with procreative instincts and capacities he should therefore exercise them, let the consequences be what they may in the direction of bringing into being a race of paupers, criminals, imbeciles or other types of abnormal man.

As the medical profession deals with the physical disorders of the human body and strives to limit their prevalence by the discovery and application of prophylactic measures, the State, that is organized society, dealing with social disorders should equally strive to discover and put into operation efficient measures having in view the prevention of these disorders. Society then, that is the State, should seriously consider the question of supplementing what is still operative in the way of natural selection by artificial selection, and this can be carried out by submitting the members of the classes known as defective, delinquent and dependent, with due discrimination, to the operation of castration. By this operation the individual is at once and forever eliminated from the problem as a possible ancestor of future abnormal men. We are not here interested or concerned as to the future careers of these emasculated elements of society. We are not particularly interested in this respect to know whether the criminal thus treated becomes more docile, law abiding and therefore respectable, or on the other hand becomes more violent, vicious and murderous. This does not appear to me to be pertinent to the issue; if he does thus become more vicious he can be effectually dealt with by sequestration or execution; the question is entirely one of prophylaxis, and there can be no possible question raised as to the effectiveness of the measure in the individual case.

Every individual born into this world has a *right* to *demand* a normal and healthy, mental, moral and physical constitution, and therefore this application of artificial selection in the treatment of not only the delinquent, but also the defective and dependent elements of society will not only protect society, advance civilization and lighten the burden of normal man, but will also prevent suffering, misery and the cruel treatment of unborn millions of abnormal men. It is a measure that is not only merciful to society now but is merciful to future prospective victims, as well as to unborn criminals themselves, and as for the individuals to be operated on, their crimes or defects should be regarded as sufficient justification for the treatment.

It is the rankest kind of folly, not to use a more vigorous term, to suppose that because a man is born with procreative apparatus and instinct that therefore he is to exercise it without regard to the consequences to himself, his offspring or to society at large. This, however, appears to be the philosophy of those who have in the past opposed the theory of Malthus, or rather perhaps, what in their imagination they are pleased to regard as the Malthusian theory. The sooner the folly of this proposition is generally recognized by mankind, and by legislators in particular, the better it will be for the interests of civilization, and I believe that within the lifetime of

many here present, emasculation will be the penalty of certain crimes, if not the recognized treatment of all chronic criminals, and that, with wise discrimination, it will be advantageously applied in the management of the other classes of abnormal man already adverted to; that is, defectives and paupers.

803 Grand Avenue.

THE ANTRUM OF HIGHMORE IN ITS RELATION TO VOCAL RESONANCE.

Read by title in the Section on Oral and Dental Surgery, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY W. XAVIER SUDDUTH, A. M., M.D.

PROFESSOR OF EMBRYOLOGY, PATHOLOGY AND ORAL SURGERY, UNIVERSITY OF MINNESOTA.

Any deviation from certain well-known points of design in the construction of a musical instrument is liable to result in failure. Maker and musician have long vied with each other in their efforts to suggest modifications and improvements without materially altering the original form, which consists of a vibrating body re-inforced by sounding-boards or resonant cavities in endless variety. They are all, however, poor copies of the original instrument, the human harmonium. While musical literature abounds with accurate scientific descriptions of musical instruments in general, next to nothing can be found regarding the science and art of voice melody and oratory, and still less treating of the design of the organs themselves.

The pianist, as he skilfully runs over the keyboard of an instrument, quickly perceives its good or bad points and indicates them with a degree of precision that clearly shows a knowledge of its construction. The expert organist will learnedly discuss the different makes of organs, as he dreamily draws out one step after another until, growing enthusiastic over some special combination of reeds and diapason, he bursts forth into a perfect flood of melody that fairly entrances his listeners and stamps him, not only as a master of technique, but shows his acquaintance with design and construction as well. No one not familiar with the anatomy of an instrument can combine its good points so as to get the best results. The virtuoso as she gracefully fondles a Cremona will expatiate upon the beauty of this or that particular form or make, and many times reveal an acquaintance with the literature upon the subject that is truly refreshing. The knowledge of the value of correct design and construction of musical instruments is not alone confined to professionals, but pervades to a greater or less degree the general public.

The would-be musician, before he commences his musical education, secures the advice of an expert in the selection of an instrument and thus begins his career in an intelligent manner. How marked the contrast in the selection of a "human harmonium" and the education of its possessor. Some one hears a child sing and remarks that it "has a good voice." An instructor is secured and the "cut and try" method of its education begins. No scientific examination of its vocal organs is made to determine their character or condition. Many times a brilliant career is suddenly checked through vicious methods of training by persons ignorant of the physiologic conditions existing in the production of harmony. Oftener

yet no effort is made to ascertain the cause of failure.

If an organ or piano should get out of tune an expert would be sent for at once to set it right, and yet the human vocal organs are as truly musical instruments as they, and as readily amenable to scientific investigation and treatment when out of repair. By aid of a laryngoscope fitted with a small incandescent electric lamp, the posterior nares and vocal cords may be thoroughly examined and all pathologic conditions detected. Not only this, but by using the same light the antrum may be illuminated from within the mouth and its outlines clearly defined, so that any deficiency or abnormal condition may readily be determined.

The vocalist of the future need not remain in ignorance of the condition of his vocal organs. Physical examinations will be made in the beginning, and from time to time, to determine how the cords and membranes are standing the strain of training. The hygiene of the parts will be closely observed and a more rational system of instruction, based upon purely scientific methods, will be adopted. Art has truly been the precursor of science in the education of vocalists, and too much attention has been given to results and too little to the scientific investigation of the causes of success or failure. Experimental methods have prevailed to too great an extent in the past and many pupils have found after years of training that they have mistaken "appreciation for genius" and that, by reason of some physical inadaptability, which might have been known in the beginning of their career, had an expert been consulted, they can never become successful vocalists or orators. No amount of instruction, no matter how competent, can account for physical incapacity in the vocal organs of the pupil, whether due to a congenital deformity or acquired pathologic condition of the cords, or the resonant cavities that make and control harmony.

Study of the anatomy of vocal organs has demonstrated the existence of a definite type, the possession of which is essential to success for soprano and bass singers and orators. If more attention was devoted to the study of the anatomy and physiology of the vocal organs, a better understanding of their functions would prevail and fewer failures would be recorded among vocalists, either in their early training or subsequent career. The widespread ignorance of the subject is deplorable, and in marked contrast with the knowledge that prevails regarding the value of quality and form in musical instruments in general.

Considerable attention has been devoted to phonetics by Alexander Bell and others, but their investigations have been confined largely to speaking rather than to singing and oratory. While it is true that the human voice is capable of wonderful improvement by patient training and that now and then a genius overcomes apparently insurmountable defects and attains unquestioned success, on the other hand it is equally true that another person may have perfect vocal organs and yet make a dismal failure.

The possession of correctly formed vocal organs does not necessarily insure that the possessor will become a successful vocalist under training, any more than that the ownership of the best manufactured musical instrument guarantees the development of artistic technical ability; nevertheless, the possession of a perfect instrument is the first step in attaining perfection either in instrumentation or vocalization although not the *sine qua non* of success.

There are many things other than perfect vocal organs that are essential for a successful vocalist; in passing we may mention artistic temperament, musical ear, pliable muscular system, patient perseverance and good health. These conditions have, however, all been noted more or less frequently in the past, and do not properly come within the scope of this article which is intended to deal with resonant cavities only, and to point out the rôle they play in the production of harmony.

Vocal sounds are generally complex in character and are produced by the passage of the breath over the vocal cords. On the other hand, non-possession of any or all of these militates against successful results under training.

Then, again, the development of pathologic conditions even after a considerable degree of perfection has been acquired is a quite common occurrence. Hypertrophy of the mucous membrane covering the cords, lining the fauces, or oral and nasal cavities, or the accessory resonant cavities themselves may result as the sequelæ of overstrain. Some individuals have what is known as "a catarrhal dyscrasia" and are especially obnoxious to catarrhal inflammations.

Local edema of the pharynx and cords is not uncommon in connection with a weak heart. The lungs may suffer and consumption, asthma, emphysema or pleurisy develop, any one of which would lessen their bellows power. Nasal polypi or hypertrophy of the nasal mucous membrane may occur and lessen, if not entirely shut off, vocal resonance in chronic conditions, and lastly singing in public halls, many times ill ventilated and filled with dust from the incoming audience, tends to irritate the vocal organs and develop a catarrhal condition. The use of alcoholic stimulants so common among certain classes of concert singers, is also ruinous to the voice.

The purest sounds are the vowels repeated in the key of "C" natural, with as little obstruction to the exit of the sound waves as possible. When the key is varied then the modifying influence of the resonant cavities is obstructed. In speaking in an ordinary tone of voice, the sound produced is largely "cordal," but if a special declamatory effort is made, the accessory cavities are called into play and assume an important part, the same as in singing.

The basis of audible vocal sound is found in sound waves set in motion by vibrating vocal cords. The pitch varies in an inverse ratio to the amplitude of the vibrations of the cords, the texture of which has much to do with the quality of the tones produced. Variations in tone are largely under the control of the will of the individual, through which changes in the tension of the vocal cords or alteration in the shape of the soft parts, is accomplished by muscular action. The direction of the sound waves is also altered in a similar manner so as to bring into play the various resonant cavities.

The range of tones produced by the human voice varies greatly in different individuals and even in the same person at different times. It is also susceptible of great cultivation and as high as sixteen harmonies have been noted in the trained voices of some bass singers. Training alone, however, will not account for this high degree of perfection; all the physical conditions must be perfect and the resonant cavities ample and so situated as to be under perfect control.

In rendering ordinary organ music, only a few

pipes and stops are needed, but when it is desired to execute the fugues of Bach or Mendelssohn's sonatas, a largely increased number is required. So also in that degree that the resonant cavities of the human voice are harmoniously developed will it be possible to produce musical tones in variety and perfection. Then, again, even as any variation in the form of the reeds or sounding-board of an instrument will modify the tone produced, so will any change in the form or physical condition of the resonant cavities of the human voice influence its range and quality. Size also seems to have a more or less marked influence, and so far as the writer's observation has gone there appears to be, everything else being equal, a correspondence between the range and perfection of the human voice in speaking and singing, and the capacity of the resonant cavities. Who ever saw a great vocalist or orator with a narrow, pinched face? Are not the distinguishing features of the successful vocalist the possession of a more or less oval and comparatively broad face with a projecting forehead, a strong nose and firm and pointed jaws—all points indicative of large resonant cavities? The breadth of the face gives space for the maxillary sinuses that are located in the superior maxillæ, and a wide nasal cavity also. The prominent forehead permits of a full development of the frontal sinuses. Physical examination of a large number of individuals permits me to say with a considerable degree of positiveness, that there is a correspondence between the breadth of the face and the size of the resonant cavities and that, from a study of the physiognomy alone, a very accurate idea of the possibilities of any given individual as a vocalist may be formed, provided no internal pathologic condition exists, which latter also may be accurately determined by laryngoscopic examination. There is no question in my mind but that there is a type for vocalists and orators, which is indicated by more or less pronounced features. How seldom do we find an accredited successful vocalist with what may be termed a pretty face. It is true that many such persons possess sweet voices, but they invariably lack power.

It is only necessary to call to mind the faces of a few noted vocalists and orators in order to establish the fact that there is a type of physiognomy to which they, in the main, conform. Let me cite a few, taken from "Practical Physiognomy," by Mary Olmstead Stanton:

Annie Louise Cary.—Large mouth, full red lips; full cheeks and short, thick, muscular nose. These points given by Mrs. Stanton for Miss Cary, indicate breadth of forehead with considerable development of the maxillary sinuses. Etelka Gerster.—Dramatic jaw; firm and rounding chin; nose broad and strong; forehead prominent, also cheek bones. Litta (Marie von Elsner).—Full broad face; broad nose and prominent forehead; and so on through the list, which comprises Christine Nilsson, Materna, Scalchi, Thursby, Albani, Patti, Madam Sainton-Dolby, Campanini, Gatty, Huntly and many others. Then for orators we might mention Henry Clay, Henry Ward Beecher, Theodore Tilton, Robert Ingersoll, Daniel Dougherty, Wendell Phillips, John Gough and so on without a single exception, all more or less square-shouldered, broad faced, prominent-featured men with large sinuses.

Then again, certain races also are noted for their melodious voices, whether trained or untrained—their prominent among these may be mentioned the negro

race. The plantation songs are known the world over, not so much for their artistic merit as for their melody. Now, if the physiognomy of the negro is called to mind it will be remembered that it is marked by the very points cited as essential for good vocalists, and they undoubtedly possess large resonant cavities.

The Celtic race, which can be distinguished wherever met by its rich, broad tones, has produced many noted vocalists. Some of our most prominent orators are of Scotch-Irish descent. The "banks and braes" of bonnie Scotland teem with a people noted for their melodious voices. No one can correctly sing "Annie Laurie" or "Auld Lang Syne" who has not Scotch blood in his veins or the Scotch physiognomy. The Norse race also, has many of the points above indicated. Choral associations are quite common among them and the Swedish Nightingale is a marked example of the type.

There are also races and peoples that are marked by a deficiency in their powers of vocalization. The Japanese and Chinese races speak and sing in a monotone with little or no range of the voice. That this is not entirely from choice may be proven by studying their physiognomy. Their faces are narrow and short, their features smooth, their eyes small and their foreheads receding—all points indicating small resonant cavities.

The Indian races of America have comparatively long, narrow faces, more or less depressed in the region of the maxillary sinuses, which gives prominence to the malar or cheek bones and limits the size of the antra. The Indian seldom or never sings, and his war-whoop has little music in it, although sometimes possessing considerable volume.

Brother Jonathan is too young to have acquired a national type, but the people who boast the bluest blood are noted for their pinched physiognomies and high pitched voices.

A study of the face of the Goddess of Liberty, that graces our American dollar, and which may be taken as representing the American type, as far as there is one, reveals the cause of this, as it shows a narrow face, with high arch and a tendency to suppression of the lateral incisors which indicates small or deficient antra.

Then again, temperamental distinctions may be made bearing upon this point. The nervous and bilious temperaments seldom if ever produce noted vocalists or orators. The basal temperament of this class is generally sanguine, although sometimes a sanguo-bilious or nervo-sanguine temperament may be found. These temperaments are to be remarked by broad oval faces, firmly set jaws and a more or less square articulation of the teeth; all points indicating harmonious and full development of the maxillary sinuses. Having considered the resonant cavities of the head in their general relation to the human voice, let us turn our attention for a few moments to them more in detail. Prominent among the accessory nasal cavities is the antrum of Highmore or maxillary sinus. Very little is known of its place in the evolutionary history of man and still less regarding its function.

A considerable experience, personal and clinical, in treating diseased conditions of this cavity has led me to look upon it as an important adjunct to vocalization, adding materially to the quality of the voice and perhaps also to its range.

The antrum of Highmore is situated in the superior maxillary bones on either side of the face, and in some instances penetrates the malar bone, forming an irregular elongated cavity. Its situation in general, may be said to be beneath the orbit and on the outer sides of the nasal fossæ. Its floor rests upon the alveolar process of the superior maxilla, in which latter body are embedded the roots of the superior teeth. Its anterior wall is formed by the facial and its posterior, by the zygomatic process of the superior maxilla. Its roof is formed by the floor of the orbit. Its contour, although varying somewhat in different individuals, is generally pyramidal with its base toward the nasal cavity and its apex pointing toward the malar bone.

The floor is often very uneven on account of the close proximity of the apices of the roots of the teeth, which often show in the cavity as slight elevations covered only by thin layer of bone. In quite a number of skulls examined, the roots of the molar teeth which often show in the cavity as slight elevations covered only by a thin layer of bone. In quite a number of skulls examined, the roots of the molar teeth projected a considerable distance into the cavity, forming hillocks, while in other instances thin bony partitions were observed that divided the cavity more or less completely into compartments. I am not fully satisfied in my own mind as to whether the latter are secondary growth or simply remains of the original bone that was not removed in the hollowing out process which took place in the formation of the cavity.

At birth there is no indication of the antrum, and so far as I know there is no literature treating upon the process of its formation. A few words, therefore, based upon original studies in this direction may not be amiss in treating of this cavity.

In the process of the development of the face at an early stage, only a very thin layer of bone separates the orbital cavity from the nasal fossa. Later, the turbinated bones seem to arise from the inner side of the orbital plate. Soon after this a slight depression appears between the middle and inferior turbinated bones which marks the location of the maxillary sinus. Shortly after birth this depression begins to deepen and advances with the growth of the superior maxillary bones, its final size and contour depending, to a great extent, on the conformation of the superior maxilla, the process of the growth of which is by internal absorption and external deposition of osseous material. The lining membrane of the antrum is analogous and continuous with that of the nasal fossa. The cavity which, at first, is simply a lateral nasal fossa comes finally to be shut off from the main cavity by the turbinated bones and a thin membranous partition through which one and sometimes two openings, the *ostium maxillare*, are found. The secretions from the mucous membrane lining, this sinus are normally discharged through these openings into the nasal cavity. The only other openings through the osseous walls of the antrum, other than those above described are the posterior dental canals, but as these do not penetrate but pass underneath the mucous membrane lining the cavity, they can not properly be said to be openings into the antrum.

The other cavities opening into the nasal fossa are the frontal, sphenoidal and ethmoidal sinuses. The frontal sinuses are situated between the two tables of the frontal bones and open into the nasal fossa

through the infundibulum. They are absent at birth and develop as the individual matures, like the antrum. The sphenoidal sinuses vary considerably in different persons, sometimes reaching considerable magnitude, at other times being absent altogether. When present they show as rounded cavities in the body of the sphenoid bone and have an opening into the superior meatus. The ethmoidal sinuses or cells consist of a series of compartments hollowed out in the ethmoid bone. They are divided into anterior and posterior cells, the anterior of which communicate with each other and open into nasal fossa in the region of the hiatus semilunaris by means of the *ostia ethmoidalia*. Vicarious openings are sometimes found into the frontal sinus and the orbit.

In describing the action of the resonant cavities let us for a moment consider the influence exerted by the nasal cavity in vocalization. "The most prominent function of the nasal fossæ in phonation, is as a resonant cavity to the voice in the production of articulate sounds; a nasal element is present in the utterance of all sounds, whether oral or nasal, and is even more conspicuous by its absence." Bosworth says that: "In cases where the posterior nares are occluded so as to preclude the action of the nasal cavities as resonators the voice is materially modified, and articulation becomes more or less fatiguing." Regarding the influence of the frontal sinuses, Mary Olmstead Stanton, a prominent writer on physiognomy, points out "fullness of forehead," among other facial signs of musical and oratorical capacity, "where is located the frontal sinuses. The fullness at this point shows that the cavities of the sinuses are large and hollow and this peculiarity of formation assists resonance of tone acting on the principle of the drum." She also speaks of "full rounded cheeks" as indicating "bellows power," and although she mentions "prominent malar bones" she fails to connect them with the antrum, but cites them as indicative of "great muscular development" . . . which, she says, is essential to good vocalization."

These two quotations seem to cover the gist of the literature upon the subject of vocal resonance, and although I have made diligent search I have nowhere found any reference to the maxillary sinuses as accessory resonant cavities. It may not be uninteresting in this connection to indicate how I came to attribute to the antrum an important rôle in vocalization.

In treating cases of suppuration of the maxillary sinuses, it has been my practice to trephine the outer plate in the region of the canine fossa. The bone thus removed is never replaced, but the opening is closed by extension of the mucous membrane which forms a membranous covering that remains more or less sensitive for a considerable length of time. This latter special feature enables the patient to detect the least vibration of the air inclosed in the cavity.

The human vocal organs belong to the class of instruments known as "reeds," and the maxillary and frontal sinuses serve to reinforce the tones produced by the vocal cords, even as the sounding-board of the violin and the guitar modify the notes produced by the strings, adding immeasurably to the richness and fullness of the tones produced. No mechanical instrument has ever been invented that can equal the human voice in quality of tone and richness of expression, and it is just these points that the antrum and the other resonant cavities add to it.

It is not necessary for me to enter into the consideration of the laws of acoustics governing the relation of the maxillary sinuses to vocalization; suffice it to say that the direct connection of a sounding-board to an instrument is essential to the re-inforcing of the tones produced. It is not essential that the sounding-board be an open tube. The air within a hollow closed space may be set in vibration by sympathy and serve the same purpose as if it were open at one end. Knudt's experiments have conclusively demonstrated the truth of the above statement.

In the case of the human voice, all the bones of the head vibrate in unison with the vocal cords, and the vibration is carried to all the closed cavities of the head, giving one kind of resonance. The antrum in addition, and by reason of its semi-membranous covering on the nasal side, which has a lower tension than the osseous walls, produces a yet more mellowed tone which is under the control of the will of the individual, who, by changing the direction of the sound waves, can send them over the surface of this membrane, thus securing its modifying effect.

Variations in the quality and register of the human voice are largely the result of physical changes. These are to be remarked in the changes of the voice from infancy to youth and again at full maturity and in old age. The voice varies according to the health of the individual, being stronger in good health and impaired during illness.

Pathologic growths, such as polypi, at times occlude the post-nasal space; hypertrophic rhinitis also acts in the same way to shut off the sound waves from the accessory nasal sinuses giving the voice the so-called nasal twang, which contrary to common understanding, is not a nasal sound but is due to the absence of the nasal influence.

In conclusion, permit me to present the following summary, viz:

That the maxillary sinuses are developed with the growth of the individual after birth.

That in some instances one or both are absent or but slightly developed.

That they have no definite form and vary greatly as to size in different individuals.

That there is a correspondence between the breadth of the face and the size of the antra.

That in some instances they are divided into compartments by osseous walls, which effect resonance.

That they are cavities intimately connected with the nasal fossæ, being separated therefrom, in part at least, by a thin membranous partition.

That the air contained in these cavities vibrates in harmony with the tones produced by the vocal cords.

That this vibration is most appreciable when the tones produced are full of melody, as in certain kinds of church music and negro melodies.

That it is more prominent in singing than in speaking, unless a special declamatory effort is attempted.

That there is a type of individual to which the successful vocalist and orator belongs and which is indicated, among other things, by a considerable but harmonious development of the maxillary sinuses.

That variation in the size and shape of the resonant cavities when present, undoubtedly affects their value as resonators; and

Finally, that certain races, noted for their melodious voices, are distinguished for the conformity of

their physiognomy to the type above given for vocalists.

DISCUSSION.

Dr. TALBOT—I regret Dr. Sudduth's absence, because I like when I attack the position taken by a writer, to have him present to talk back. I take decided issue with the arguments made. Dr. Sudduth has mentioned a number of singers, most of them exceptionally fine artists, who he says all had large features. It is a well-known fact that certain forms of disease are the result of neurologic conditions. Great singers—and this is especially true of those mentioned in the paper—are all geniuses in their way, and genius is now laid down in medicine as a particular form of insanity. A man who is an expert in invention, in art, is suffering from a form of insanity. All his ability runs in one direction. We shall find, if we study the lives of great geniuses, that almost always they are of no account in any other direction than that in which their preëminent genius is acknowledged, this particular faculty having been developed abnormally at the expense of the other parts of the brain, which are accordingly weak. Inherited tendencies have much to do with the result. If the brain develops in only one direction the osseous system has to suffer, and accordingly we find arrested development of different parts of the osseous system. If a large nasal cavity, large antra, and large jaws are due to the fact that the individual began to sing early and in that way developed them, just so we can develop the maxillary system. What effect the antrum has upon the vocal sounds produced I can not see, and I think that if we examine the skulls of noted singers after death the antra will be found much like the antra of others—some one way, some another. Gray says the opening from the antrum into the nares is of the size of a crow's quill. I have seen these openings so large that one could pass in a finger. It is asserted by the laity that individuals with high vaults make the best singers. I doubt it. There is a seeming difficulty in the way because of the contracted jaws found with this type. Dr. Sudduth speaks of roots of teeth extending into the antra. This is very rare, though it is occasionally seen.

Dr. G. S. DEAN—I am not prepared to discuss the paper, but I must say a word. The paper is of great value and touches upon a subject which we, as dentists, ought to know something about. If it is true that the antrum and the cranial sinuses are concerned in voice production generally, we ought to know about it particularly, as we may, in time, learn how to develop the antrum. Dr. Ottolengui tells how he moved the teeth of a public singer and the voice improved. Dr. Sudduth has treated of the voice as a string instrument; I think it is more of the character of an organ pipe. The first principle of sound re-inforced by a column of air is familiar to all. Take a string which by itself can be heard only three feet away; with a sounding board to re-inforce it, its tones will fill the room. The organ pipe is another illustration. Among birds, the owl has large cranial sinuses, but he is not much of a song-bird. So in the animals, the elephant has the largest cranial sinuses of all, yet he has not a very good voice. Dr. Sudduth makes the point that when the nasal passages are closed, as by catarrh, the voice becomes what is called nasal, although it is in reality absence of the nasal quality. As a general principle, the greater the volume of air set in motion by the sound the greater is its volume. The point brought out by Dr. Sudduth, that we as dentists ought to familiarize ourselves with the mechanism of sound is important. For myself, I propose to study the subject presented.

Dr. VAN ORDEN—If the antrum is not for the benefit of the voice, what is it for? It seems to be of little value unless it should be for this, or for helping the nose in blowing. It would seem well worth while our looking into the anatomy of the subject farther than the text-books take us.

On Transmissibility of Cancer from Man to Animals.—M. Boinet, after a long series of experiments on the transmissibility of carcinoma from man to animals, states that after having made repeated inoculations on the rat, the rabbit and the guinea-pig, he concludes that histologic examination of the lesions which resulted does not authorize him to pronounce in favor of such transmission.—*Semaine Medicale*, November 3.

PROGRESSIVE HYPERMETROPIC ASTIGMATISM.

Read before the Chicago Ophthalmological and Otological Society,
Oct. 16, 1894.

BY WM. T. MONTGOMERY, M.D.
CHICAGO.

In his classical work upon accommodation and refraction of the eye, Professor Donders says: "Astigmatism is either congenital or acquired. If it be acquired it is to be looked upon clinically as another form of disease," etc. I think this is the opinion that almost universally prevails with oculists up to the present time, so far as hypermetropic astigmatism is concerned. It is a congenital defect and does not progress or change without traumatism, or the presence of some other disease. Until recently I have accepted this idea without question. It had been my custom in prescribing glasses for the correction of hypermetropic astigmatism, either simple or compound, to assure the patients that they would not have to change their glasses. Within the past few years, a number of cases have come under my observation which have caused me to modify the above statement, and to question whether or not this defect is always congenital and unchangeable. The majority of these cases have been my own, which have returned after periods varying from one to five years, complaining of a recurrence of the symptoms that induced them to seek my advice in the first place. A number have come wearing glasses adjusted by other oculists whose skill I do not question. Of these I have not always been able to learn whether a mydriatic had been used or not. My own patients who have returned for examination, had been fitted under a mydriatic, and usually atrop. sulph. gr. iv to 3i instilled into the eyes twice daily for ten days. I do not claim special skill in adjusting lenses, but do claim to have used ordinary care in this work. My practice has been to examine first with ophthalmoscope, then with test glasses use the mydriatic until the patient could answer promptly as to improvement by a change of .25 in strength, or a turn of 5 degrees in axis of cylinder. If anything has been written upon this subject it has not come under my observation. My object in presenting this short paper is to get an expression from members of this Society upon the question, Does hypermetropic astigmatism increase? My recent experience inclines me strongly to the belief that it does under certain conditions. I shall only present brief notes of three cases, the most striking I have so far observed:

Case 1.—Jerry H., age 17, Irish-American; bookkeeper, residence Chicago, was first examined by me March 18, 1882. Patient states that his sight has always been poor. He has worn glasses for a number of years, but is unable to read or do close work comfortably with any glasses he has tried. Eyes very irritable. V. = 20-80 either eye, and not materially improved by glasses. Atrop. used, but my notes do not show how long. Patient thinks his eyes were under the effect of the medicine about two weeks. Under the mydriatic, R. eye accepts + 3.50 C + 3. cyl. ax. 75°. L. eye + 4. C + 2.50 cyl. ax. 90°. Either eye, V. = 20-60. These lenses enabled the patient to pursue his work as bookkeeper comfortably until April 2, 1886. Eyes have become irritable again, so that he can not do his work. We can not improve upon the old lenses without the use of a mydriatic; a 2 per cent. solution of homatropin is instilled into the eyes at intervals of a few moments until about twelve instillations are made. Waiting forty minutes the eyes accept, R. eye + 3.50 C + 4. cyl. ax. 75°. L. eye + 4 C + 3.50 c. 90°. V. = 20-60.

These lenses were ordered, and served the patient well until April 13, 1891. Now complains that he can not see as

clearly as he could when he began to use the last glasses. Testing his vision, I find it is only 20-80. The lenses are scratched in the center, and I infer that his lowered vision is due to this. As the patient needs new lenses, I decide to make another test, this time without any mydriatic. To my surprise, the patient now accepts R. eye + 3.5 C + 4.50 c. 75. L. eye + 4. C + 4.50 c. 90. V. = 20-4 either eye. These were ordered and are satisfactory. The patient, who is above the average in intelligence, is very much exercised about his eyes, but is reassured by the statement that the defect does not increase in adults, and by the fact that his vision is better now than it has ever been before.

Case 2.—Addie B., age 14, school girl; American; residence, Chicago. Was first seen by me Oct. 5, 1886. Father states that the daughter's eyes have never been strong, but she has been able to get along comfortably with her studies until recently. A few weeks ago, her sight became so blurred and she began to have such severe headache that she was obliged to give up using her eyes for any kind of close work. On examination, eyes free from external inflammation, but very irritable. Ophthalmoscope shows a high degree of hypermetropia, but no attempt is made to measure it on account of the irritable condition of the eyes. The right eye has a circular coloboma of the macula. The center of the coloboma about corresponds to the macula lutea and is about twice the diameter of the optic disc. The edges of the coloboma are clean cut, presenting the appearance as if choroid and retina had been cut out with a circular punch to the sclerotic. A solution of atrop. sulph. gr. iv to 3i was ordered to be instilled into the eyes twice daily. October 15, right eye accepts + 3.50, V. = 20-200; fixation peripheral. Left eye accepts + 5.50 C + 1.25 cyl. ax. 125°. V. = 20-40. The above lenses were ordered to be worn constantly.

Oct. 27, 1888. Patient returned complaining of symptoms similar to those complained of on first visit. She states that the glasses gave complete relief and enable her to go on with her studies until a few weeks ago. Left eye now accepts + 5.50 C + 2.50 cyl. ax. 125°. V. = 20-40. Lens was ordered. Oct. 29, 1889. Patient returned complaining of headache, and irritable eyes again. She states that the glasses ordered one year ago afforded relief until short time ago. Left eye now accepts + 5.50 C + 3.50 cyl. ax. 125°. V. = 20-40. This combination was substituted for the second lens, and I have not seen the patient since. Urged her to call as soon as her eyes began to trouble her again, and I have recently made an effort to find her, so to examine her eyes again, but was unable to do so.

Case 3.—Eddie H.; age 10; pupil; residence, Mendota, Ill. Was first seen by me Oct. 2, 1890. The patient is a robust boy, large for his age. The father stated that the boy has been having headache and trouble with his sight since he first started to school. The headache has become so severe that he was obliged to leave school. An examination of the patient's eyes shows the following manifest defect: R. eye = + 4. C + 1. cyl. ax. 70°. L. eye = + 4. C + 1. cyl. ax. 100-80 either eye. Under homatropin each eye accepts + C + 1. cyl. ax. 90° V. = 20-60. As the ophthalmoscope shows about the same defect, the above lenses were ordered for constant use. April 25, 1892, eighteen months later, the patient returned. The father stated that the glasses gave the boy complete relief for more than a year, but that a few months ago the headaches began to trouble him again and were now as bad as ever. The patient now accepts + 4.50 + 2. cyl. ax. 90° each eye. V. = 20-60. These were ordered and the patient returned home. Sept. 25, 1893, seventeen months later, the patient came back again complaining of return of the headache. As before, the father says that the new glasses gave complete relief for more than a year. The patient at this time accepts + 4.50 C + 2.50 cyl. ax. 90°, each eye. V. = 20-60. These were ordered and worn until Oct. 1894, when the patient returns. The patient now accepts R. eye + 5. C + 2.75 cyl. ax. 90°. L. eye + 5. C + 3. cyl. ax. 90° V. = 20-60. The ophthalmoscope and ophthalmometer shows the same, except the latter instrument shows the axis of astigmatism, R. eye 80° and L. eye 100°, but the patient will not accept the lenses in this position. Indeed, he readily detects a turn of 5 degrees either way from 90 degrees with either eye.

In this case a mydriatic was only used at first examination—homatropin 2 per cent. solution. I do not believe that this drug will completely relax the accommodation in all cases, but when the defect,

shown by the test lenses under it, agrees, as in this case, with the measurements made with the ophthalmoscope, I do not hesitate to prescribe. In four years the astigmatism increased from 1 D. to 2.75 and 3 D., or was it all there in the beginning and has it become manifest on the installment plan? This patient was not especially studious and did not use his eyes more than the average boy at his age.

Case 2, the young girl, was a pupil in the Chicago High School when I first examined her. She was then 14 years old, but small for her age. I did not notice at this time that her eyes were unusually small. At the last examination she was 17 years old and about as large as the average girl at 14. Her eyes are abnormally small in proportion to her size. She was bright intellectually. Said she had been studying hard and hoped to finish at high school that year. In the three years between the first and last examinations, there was an apparent increase of the astigmatism from 1.25 to 3.50 D. I say apparent, though I believe it was a real increase.

In the young man's case the time intervening between the first and last examination was a little over nine years. The apparent increase of the astigmatism was right eye from 3. to 4.50 D. Left eye 2.50 to 4.50 D. The first examination in each of the Cases 1 and 2, was at the age of most rapid development—at the age when the boy and girl are changing into the man and woman. Both had very imperfect eyes, and both were engaged in work requiring long hours at close work. These are the conditions most favorable, it seems to me, for bringing about the change the clinical histories of these patients seem to indicate.

Among several important questions these cases suggest, the most important to my mind is, What effect, if any, had the wearing of glasses upon the increase of the trouble? It has been claimed or suggested by some one that correcting high degrees of hypermetropia in children or young persons may arrest the growth or development of the eyes. If there is any truth in this suggestion, is it not a mistake to adjust lenses to such imperfect eyes? Would it not be better to proscribe books and close work and advise an active out-of-door pursuit?

REPORT ON CAR SANITATION.

BY GRANVILLE P. CONN, M.D.

CONCORD, N. H.

Presented to the American Public Health Association by the Committee on Car Sanitation, at the Twenty-second Annual Meeting, held at Montreal, Canada, Sept. 25-28, 1894.

A report upon this subject must include several topics; for in order to bring before the public a full realization of its importance, we must consider the construction, the heating, lighting and ventilation of coaches, as well as the methods of car cleaning now in use by the management of most roads.

This last is most essential, as it is the first principle of sanitation, without which nothing like a healthy standard can be assumed.

The problem of car sanitation is one of complex character and involves so many mechanical questions, that one can hardly be expected to bring out the whole of the subject in a single paper. I have endeavored to get the opinions on this subject from other members of the committee, but have not succeeded in doing so, as for various reasons the dif-

ferent members have begged to be excused, therefore I have selected from the opinions of sanitarians and practical mechanics, such quotations as seemed to have a concise, practical and unbiased bearing upon the conditions necessary to secure the sanitation of passenger coaches.

In the design of a car for the transportation of people it is important that it be constructed with a view to stability, safety and endurance. It must be constructed with a strength equal to the strain which is expected of it, in order that it may be safe to passenger and employe. This is important, for without strength and capacity for endurance it would be a veritable trap to every one having anything to do with it. It is virtually and for the time being a house on wheels, in which the varying number of people are expected to make their homes for a longer or a shorter period, according to the distance which they may be expected to travel. Therefore, like a house, it should be constructed upon sanitary principles, in which ventilation, heating and such conditions as will allow it to be kept clean are paramount factors in every case. Unless these sanitary principles can be carried out, and made permanent, then this house on wheels becomes unwholesome and unhealthy, and the conditions become favorable to disease, or of disseminating it, should a contagious or infectious malady find a place within its walls. Theoretically speaking, a room or a car into which a large number of people are to assemble should have left out of its construction everything that is calculated to foster or develop disease germs, therefore, the plainer it can be made, the less upholstery, carpets and curtains that are placed within, would seem to be the best calculated for health. Practically, however, the public demand something more than plain walls and plain seats, and forget the conditions necessary for sanitation in their desire for luxury. This is an unfortunate circumstance, but it is necessary to deal with the problem as it exists. Probably cars could be constructed with much less expense on leaving out much of the draperies, etc., that are now considered necessary; but as the public demand the luxurious apartments which we find in all well-appointed cars to-day, we shall be obliged to consider the different classes of coaches just as they now exist on most of our long lines of travel.

Referring to ventilation, it is now twenty years since the State Board of Health of Massachusetts instituted an investigation into the condition of passenger coaches. They found that the atmosphere of the ordinary coach contained from one to six times as much carbonic acid gas as other public assembly rooms, such as churches, theaters and public halls. The same year, 1874, at a meeting of the Master Mechanics' Association, the Master Mechanic of the Boston & Albany and also of the Old Colony Railroad, made a report on that subject. It was taken up by the Association, and considerable discussion followed. Some improvements came from this action, but since that period the progress of ventilation in cars has not been rapid, in fact it can scarcely be said that any improvements have been made. Recently, State legislation has placed the obligation upon the management to use steam heat, therefore, the necessity of further improvements in ventilation has become apparent to every one. In ordinary weather during the winter the problem of how to heat the car with steam and not have it too warm, is far

more difficult in solution than it is to prevent it from becoming too cold. These difficulties are largely due to the fact that the men who have charge of this work are incompetent to carry out the designs of the inventor of steam heat. They have little or no conception of what constitutes good atmosphere in a coach, and they care but little about their work except that the time goes on and they draw their pay. They have no instructor beyond the mechanic who simply shows them how to turn the valves which admit the heat and to shut it off, and the whole problem, as far as they are concerned, is how to keep heat enough in the car to keep it warm. The changing of the atmosphere of the car is of but little moment to them; they are constantly going in and out of the car at every station, and perhaps may be pardoned for not noting the atmospheric condition that obtains throughout the train.

Another fact in car sanitation, and to me, perhaps, the principal one, as it involves every principle of sanitation, is absolute cleanliness. This may be impossible in coaches, yet a near approach to it need not be considered impracticable.

Cleanliness is the first principle in sanitation, whether it be of cars or houses, and seems like a very simple matter. But when we consider that it involves in its principles, cleanliness of atmosphere as well as material, then the problem becomes greater, for in keeping the atmosphere of the car clean, as well as its floor and ceilings, you have arrived at what may be called true sanitation. The problem of keeping a car clean is greatly enhanced by the fact that very many good people allow themselves and their children when riding upon the trains, to become slovenly in their actions, throwing things upon the floor of the car that never would be permitted in an ordinary dwelling house. Why is it that people are so forgetful of good sense and good manners when riding upon trains is past comprehension; yet, we see it every day, and the coaches become excessively filthy from that cause alone. It may not be easy to break up such habits, yet, if the trainmen formed habits of cleanliness in regard to the coaches which are under their care, it would have a very beneficial effect on the passengers. In the Pullman and Wagner coaches, where porters are employed to wait upon passengers and keep the car clean, when the occupants so far forget themselves as to cover the floor or carpet with the refuse of orange, banana or apples, nut shells and other things which render a car unwholesome or unclean, and the porter goes around with his dust-pan and brush cleaning it up; it does not take a great many miles of travel for such people to see the error of their ways and to discontinue them. The same might be true of the ordinary coaches if the brakeman or person in charge should perform the same acts, for people naturally would become ashamed of throwing things upon the floor for another person to clean up in order to render the apartment comfortable.

Little need be said in regard to heating of cars, as that has become a question of legal importance. The accidents by fire became so numerous that the different State Legislatures took it in hand, passed laws doing away with the ordinary stove, and substituting steam heat. Unfortunately, there was no concert of action with different roads in the use of steam heat, as each road experimented for itself, the consequence being there are many different methods

of transmitting steam through the cars. Which of these is the best I am not able to state, but it is to be hoped that some uniform method will be adopted by which all roads will be able to effect interchange of cars, and that the instructions which should be received upon that particular subject, shall be so uniform that there will be no difficulty experienced in keeping cars properly warm and ventilated.

To digress a moment, I would add that it has been found necessary to open schools of instruction in the use of the air-brake, and I am told that old and experienced trainmen after attending these schools have been surprised to find how little they knew of the practical application of what was supposed to be merely an automatic machine. Now this instruction is secured by fitting up a car with all the mechanism of the automatic brake, and having a thorough mechanic for a teacher, and why not combine with that the teaching of car sanitation, to the extent that the trainmen may fully understand how to use such devices as are now found on most passenger coaches?

In regard to the different systems of ventilation, several experimenters and inventors have gotten up systems of their own, had them patented and endeavored to put them on the market. Some of them are very complex and all of them require some knowledge of the subject, else they can not be made useful. All of them involve extra expense in the construction of a car.

The question of how to ventilate a car is one which the mechanic and sanitarian must bring out together. It seems as though it would be quite impossible to invent any system that will change the air of a car while in motion and at the same time be effective while it is standing still. With electrical power it may be possible to place fans in a car, the same as you do in a house, that will be effective when the car is standing still, but when the car is moving the pressure of the atmosphere upon the outside is so great that considerable change will take place inside the car. Then again this pressure of the atmosphere is so different when the car is moving slowly, than it is if the car is moving rapidly, that it brings up another point in the problem of ventilation to be solved by the practical mechanic.

Before the use of the power brake, the duties of the trainmen were almost constant and imperative, but with the advent of the automatic brake his duties were made much lighter and less exacting. It is true that with the introduction of the various improvements that have been or may be instituted, a higher order of intelligence may be required than was necessary to assist in stopping or starting a train, yet that does not prevent the average trainman from doing good work, providing he has proper instruction.

The *Railroad Car Journal* publishes the report of the Committee of the Master Carbuilders' Association, from which I quote at length:

"In all modern systems of ventilation, sanitary engineers endeavor to have a plenum instead of a vacuum, or, in other words, to have a slight excess pressure inside of the building instead of a slight vacuum. With a plenum there can never be any cold drafts or admission of dust, smoke or cinders, for the reason that the pressure would always be driving the air outward through every crack and opening. With a vacuum the reverse is the case, and dust, smoke and cold air will find their way in at every crack. It is very desirable that the windows of passenger cars be so arranged that they can be locked fast in winter time, to prevent one obstinate passenger interfering with the comfort of the whole

car load, but this can only be done when a sufficient supply of fresh air is constantly being furnished to the passenger, comfortably warmed. The opening of the doors at stations is also a great interference with a uniform system of ventilation. This can not be avoided, but the evil effects of it can be largely overcome by building the cars with an inner swinging door. Most of the modern larger passenger cars having smoking rooms, double saloons and heating apartments, can be easily fitted up with a swinging door at the end of the passage in between these compartments, which will act as a kind of air-lock and prevent a good deal of discomfort otherwise unavoidable. A convenient way of arranging the windows so as to avoid the drafts and interference to the comfort of the passengers in the winter time, would be to have the outer sash arranged, as is commonly the case now, with the inner sash arranged so that when lowered they will lock themselves tight and can only be released by a lever at the end of the car, attached to a locking bar running the full length of the car on either side. These windows could be kept raised in summer time, the outer sashes being so that the passengers can raise them or lower them as they please. In the winter time, when these sashes are lowered no window could be raised.

"To summarize, the ideal conditions would be as follows:

"1. The admission of thirty cubic feet per minute per passenger of fresh air, and the carrying off of an equal amount of foul air, summer or winter.

"2. The fresh air so admitted must not be moving at a speed of more than three or four miles per hour in winter time.

"3. Fresh air admitted must be of a temperature in winter time of about 70 degrees Fahr.

"4. Fresh air so admitted in winter time must have added to it a proper degree of moisture for the temperature at which it is admitted, according to the average humidity of the atmosphere, when at 70 degrees in the climate in which the cars are running.

"5. No system of winter ventilation can be more successful unless means for the fresh air supply are provided independently of and separately from the windows and doors, as well as the ventilators for carrying off the foul air.

"6. The fresh warm air should be distributed through as many openings and as low down as it can be conveniently ranged for, and the foul air should be carried off through many small openings in the roof of the car as can conveniently be arranged for in winter.

"7. The ventilation should be entirely independent of the speed of the train and act as well whether the car is standing or running.

"8. The ventilation should be so arranged that there will be a plenum or slight excess of pressure inside the car, so that all drafts will be outward instead of inward, and smoke and dust thus excluded.

"9. It is most desirable that double windows should be used, and so arranged that they can be locked fast in winter time, but readily opened in summer time.

"10. It is most desirable that an inside swinging door be used, so as to form an air-lock or inside vestibule, to prevent the admission of cold air and dust every time the doors to the platforms are opened."

In arriving at these conclusions this Committee had an investigation made under the supervision of an expert, and incorporated into their report something of his work, and the reasons for summarizing such ideal conditions as they have deemed necessary for perfect ventilation.

The Committee add the following:

It may be argued that there is no use for any such system of ventilation as this, that the present arrangements for ventilation of passenger cars are good enough, and that nobody is any the worse for the present state of affairs. To show that this is an entirely wrong position, your Committee had a number of tests made to show the degree of foulness of the air in sleeping cars, and day coaches, which tests have been under the supervision of Mr. Wm. Forsyth of the U. S. & Q., through the kindness of Mr. Rhodes. Pure air contains from three to four parts in ten thousand of carbonic acid, and at 70 degrees Fahr. an average condition of moisture would be from four to five grains of water per cubic foot.

Mr. Angus Smith made a series of careful experiments in air-tight rooms for the purpose of seeing how long healthy people could exist in an atmosphere having an excess of carbonic acid and moisture. As the result of his ex-

periments, it was shown that it was very unwholesome to breathe an atmosphere having more than seven parts in ten thousand of carbonic acid, and that an atmosphere containing ten parts in ten thousand could not be endured by delicate people for long without injury, and that as the presence of an excess of carbonic acid is a direct indication of the presence of microorganisms, commonly called disease germs, the injurious effects are not merely limited to the poisonous influence of carbonic acid, but that the danger of taking organic diseases was very largely increased. It was further shown that the senses are a very unreliable guide in judging of the foulness of the atmosphere, and that people who remained in a room in which the atmosphere had become gradually fouled would hardly notice its foulness, whereas outsiders suddenly coming in would be almost suffocated.

"Microorganisms, or disease germs, are not given off to any harmful extent in the exhalations of healthy human beings, but they are given off in large numbers in the breath and spittle and evaporation from the skin of unhealthy persons. Especially is this the case with people suffering from tuberculosis, whooping cough, fevers and so on, and the disease germs grow and multiply very rapidly in a foul moist atmosphere. To quote a prominent naval surgeon: 'The road is short, straight and sure from vomica and mucous patch to the receptive nidus in another's body. Who that has ever had forced on him an aerial feast of cabbage, onions, garlic, alcohol, tobacco and gastric effluvia of an old debauch, can doubt that aqueous vapor can transport microscopic germs by the same route?' (A. L. Gihon, in an address before the Pan-American Medical Congress in Washington, D. C., 1892.)"

Experiments made in Europe on animals which were inoculated with a preparation from the dust beaten out of the cushions of railroad cars in ordinary service and which cars were not known to have carried sick people, showed that the most of these animals which were inoculated died of violent diseases. Few of them lived long enough to die of tuberculosis—none of them survived. As these microorganisms are in the air and simply settle on the dust, all this goes to show how very necessary indeed it is to carry off the foul air, and that, to quote a Southern physician:

"The movement of vast masses of people annually from one section of this broad country in search of those climatic influences modifying the course and progress of disease, has become, from a sanitarian standpoint, a great unsolved problem, namely, that of accomplishing the proper ventilation of cars by the introduction of pure air, free from dust, cinders, smoke and so on, and at the same time the withdrawal of the impure air arising from the natural emanations of the body, as well as the more serious dangers accruing from chronic or contagious influences."

"In all these devices which depend upon the speed of the train for their action, and where the air intakes surround the stovepipe, every time the car stops the ventilating process ceases and may be reversed; at slow speed it will be almost inoperative.

"Great improvement could, however, be made in the condition of the air in our crowded passenger cars if the trainmen were compelled to pay proper attention to the ventilators; a regular set of instructions should be furnished them for their guidance, and division officers should be instructed to pass through the train at every opportunity and report cases where the ventilators have been neglected and the air is overheated or foul, to the division superintendent for discipline. The men would then soon learn to attend to this part of their duty. Sleeping car companies should have a code of rules printed and posted in the cars, and their porters and conductors should be made to observe such rules. One specially important thing is not to open the ventilators on the windward side of the train, otherwise with drop sash or trailing sash ventilators, down drafts and cross drafts are unavoidable."

The above extracts from the report of the Committee of the Master Car Builders' Association has much to commend itself to our notice, as it comes from the best and most advanced class of practical mechanics. As a rule, such men are not visionary, but reason from cause and effect, therefore their opinions are entitled to our consideration. I under-

stand the report was written by Master Mechanic Sunderson, of the Norfolk and Western Railroad of Virginia; yet when asked his personal opinion of its being practical to carry out such ideas, and use the average trainman to accomplish the work, he remarks in rather a sarcastic manner: "I wonder what the A. R. U., or any other railroad organization, would say if we required our immaculate brakeman to do the chores in the railroad cars?"

Another member of this Committee, when asked if he believed it was possible to carry out such an ideal system as the report would allow the public to expect would be in use in a few years, says: "I would say in answer to your first question that I do not believe, as a railroad mechanic, that it will be possible to introduce and have accepted by railroad managers, the ideal conditions in a passenger car as expressed in the paper that was read on this subject. I do believe that if our trainmen were educated to make better use of our present facilities there would be less complaint. They have been relieved from year to year of their former duties, until they feel that all they need to do is to wear a uniform."—Mr. West, Master Mechanic, N. Y. O. & W. R. R., Middletown, N. Y.

Undoubtedly this is true, and we are all the more ready to believe its truth after having once asked one of these uniformed "Mikados" to ventilate the coach. That look of pity and condescension makes an impression never to be forgotten.

In support of that part of the report which I have quoted—relating to the experiment on animals inoculated with a preparation of dust from passenger coaches—I will give an extract from the report of scientists who have recently conducted a series of experiments, under the direction of the Imperial Board of Health of Germany, as to the danger arising from the dust in railroad carriages. Their results show a decided risk involved in traveling under the present sanitary conditions of coaches:

"The dust was collected in each instance from a square meter of surface, and from forty-five compartments, representing twenty-one carriages. The inoculations were made upon guinea-pigs. Many of them died of various diseases, and the rest were killed. Three only were found to have tuberculosis. The number of bacteria was largest in the fourth-class cars, and grew less with each rise in grade of the compartments. In the fourth-class cars the number was estimated at 12,624 per meter; in the third-class, 5,481; in the second, 4,247; and in the first-class, 2,583. On the seats and upper walls the numbers varied in the four classes from 2,646 to 29, while the roof was almost free. Though the third- and fourth-class carriages were the most infected, it was much easier to clean them, as they could be washed with hot water and soap, which could not be so vigorously applied to the better class carriages owing to the carpetings and upholstery."—(*Boston Medical and Surgical Journal*.)

The following letter written on a trip to the Eastern States, says:

"In our sleeper were three consumptives returning home to die, and that alone was depressing enough, but when, on getting up in the morning, one sees a considerable amount of dry, yellow sputum on one's *vis-a-vis* neighbor's bed-linen, it is neither dainty or reassuring. Morning cogitations, usually so pleasant, are apt to turn to the uncomfortable possibility of all the bedding in the car being subjected from time to time to the same infection, and being probably imperfectly washed or simply rinsed. Then it is impossible to clean the upholstery and carpeting without taking them out of the car, and an infected sleeper should be dangerous, as the continual vibration keeps the dust and bacteria in the air. The space is also necessarily confined. Moreover, travelers are apt to catch cold from drafts and from sleeping close to the windows, thereby rendering the mucous membrane receptive to germ implantation. They order these things better in Europe; on some of the continental lines

special coaches are provided for consumptives, and these are constructed with particular reference to ready cleansing and disinfection at the end of every trip—which, it should be noted, are much shorter than the 'runs' in this country, and the need of precautions is, therefore, and for so much, greater here than abroad."—(Dr. Douglas W. Montgomery's letter to the *Pacific Medical Journal*.)

Dr. S. S. Herrick, of San Francisco, read a paper before the Section on State Medicine, at the meeting of the AMERICAN MEDICAL ASSOCIATION the present year, entitled, "Common Carriers as Disseminators of Contagion."

The writer dwelt particularly on the disposal of the excretion of the people on inland waters and railroad coaches; believing that certain communicable diseases whose contagious properties are discharged from the alimentary canal are liable to reach the alimentary or respiratory tract of other persons not intercepted or destroyed, and cholera, typhoid fever, dysentery, intestinal tuberculosis and other filth diseases are notable in this way.

He says: "Companies who provide meager accommodations for passengers were properly censured, and should be held justly responsible if inadequate remedies were provided for their patrons."

Discussions by Drs. Ruggles and Cochran, Davisson and Stoner, all of whom were in accord with the opinions advanced by Dr. Herrick. These men, who are enthusiastic supporters of preventive medicine, are gentlemen of sound judgment and are not carried away by any desire for notoriety. They believe that State and Federal authorities should be ever on the alert to secure health for the individual, and that it is a duty which they owe to the people of the country to have a watchful care over the transportation company as well as the municipal lines governing health officers.

The *Ohio Medical Journal* says of the prevention of consumption:

"We do not deem it wise or prudent to invade the homes of tuberculous patients for the purpose of securing disinfection or the isolation of the sufferer. The instruction of the patient and his household, by his physician, in the necessity of prophylactic measures, is at present sufficient. But we believe that a vast deal of good might be done by the exercise of strict sanitary measures against the contamination of rooms in hospitals and hotels and the berths in sleeping cars. The most careful cleansing and disinfection of apartments occupied by consumptives should be required before other individuals are permitted to occupy them."

As we have said before, in this report, cleanliness is one of the first principles of sanitation; whether it be a car, a house, an office or a work shop, the same principle holds good. In the construction of coaches for passenger use, something should be done to render the cleansing of the car a matter of small expense, for while in the process of construction, little things might be done that would add to their convenience, healthfulness and cleanliness.

All passenger cars at the present time are constructed with water-closets; the floor of such coaches and a few inches of the side or mop-board should be covered with copper, as an ordinary wooden floor will soon become filthy and can never be made clean. Odors will always be given off from an ordinary board floor whenever the temperature rises to that of summer heat; but if the floor be covered with sheet copper, hot water, dry steam and chemicals may be used, leaving it without any absorbing surface to develop odors which may be latent in cold weather and very active on a hot summer day. If the designer and purchasing agent give attention to this in

first instance, the extra expense will be little or nothing, and will add very much to the efficiency of the car when the rules of sanitation are applied. As cars are now heated with steam direct from the engine, and as these pipes pass through water-closets for the purpose of protecting them against the cold weather, I can see no reason why taps may not be placed in those pipes in the water-closets and used for the purpose of cleaning them with hot steam; and it certainly could not be but very little extra expense at the time of the construction of the car.

Dr. S. S. Herrick, of California, in commenting upon a statute law of that State relating to the maintenance or commitment of a nuisance, remarks:

"Obviously, travelers themselves should not be held responsible for committing a nuisance, so long as transportation companies provide no facilities for obviating the same; and the legislation should be aimed directly at these companies, holding them responsible and requiring them to provide an adequate remedy.

"It is well understood that the law must not ordain what is impracticable, and equally plain that no serious difficulty and expense would be involved in abating such nuisances. No mechanical difficulty exists for a steamboat or a railway coach to have its closet provided with a closed receptacle, having suitable means for deodorizing, disinfecting and ventilating, and for discharging the contents into some proper place at short intervals. The details of a contrivance suited to such a purpose need not here be entered into; they belong to the inventor and mechanic rather than to the sanitarian as such.

"Aside from considerations of health, it seems strange that respect for common decency has not abolished a practice in travel by land which would have brought a blush to common carriers in the good old days of slow coaches. While inventors and builders of palace cars are doing so much for the comfort and convenience of passengers in other respects, they adhere to a form of closet from which travelers must be excluded at the time when it would be most acceptable (halting at large stations), and which scatters filth and disease along the route. It is to be noted that cholera still lingers in Europe, and meanwhile we must not consider ourselves safe here within two weeks' travel by team; while the other filth diseases, like the poor, are always with us.

"In my judgment the time has come for sanitarians to speak plainly and forcibly on the subject, and to demand of legislators a specific remedy which courts will be bound to apply to this class of offenses against health."

I understand several roads are making use of compressed air for the purpose of cleaning the draperies and plush covering of the seats; and that a plant or that purpose can be arranged to be effective, with small expense. If this is true, and I see no reason why it is not, it should generally be used, for thorough cleansing with fresh air would be a most valuable disinfectant.

The vestibule train has become very popular, no one doubts its efficiency as an easy riding coach, and it insures perfect safety in going from car to car, but is an object lesson for the ventilation of cars it becomes a failure, inasmuch as it simply ventilates from one car to the other. Some air will pass into the vestibule section, but as that section has less width than the car itself, the pressure of the atmosphere extending to the car is much more lessened than it is upon the sides of the car itself, therefore but little air is forced in from that section of the construction, as the ventilating property of the vestibule is lost, and aside from that it may be overcome by the extra heat of lighting.

This leads one to consider the lighting of cars. Nearly every large road has been experimenting with different methods of lighting coaches, and car companies like the Pullman and Wagner have done the same.

Whether these experiments have been conducted in the light of sanitation, or as a question of expense may be a matter of doubt, although it is probable that the safety of the car from destruction by fire has entered into the range of experiments. Gas and kerosene lighting, while moderately expensive, are not only dangerous by reason of their possibility of fire, but the extra heat which they occasion in the car in the summer time proves a very serious obstacle to the comfort of the passengers. Then again, the destruction of oxygen by gas or kerosene lighting increases the amount of carbon dioxide in the atmosphere of the car, oftentimes to a dangerous extent, and in that way the health of the passengers is seriously threatened unless there is a large amount of fresh air introduced continuously.

That electric lighting is the ideal of the present time perhaps no one will dispute, unless the expense of the same is taken into account. So far as I can learn, none of the devices for electric lighting have yet been brought down to the maximum of the manager's idea of expense, and therefore, some other method will find favor until the public demand safety in lighting as well as in heating coaches.

It is also well to note that the public are critical regarding the water supply. Some years since, Dr. R. H. Reed of Ohio, in investigating this matter, found that the water-tanks of ordinary coaches, and sometimes those of palace cars were notoriously filthy. The water supply must of necessity depend largely on the character of the supply at given points along the line. When cars are cleansed and the water tanks refilled, the ice supply depends upon the same conditions, but there can be no excuse for filthy tanks any more than in public or private houses. There are enough men employed about the trains to see that every tank is made clean day by day, and not to do so and thereby endanger the health of the traveling public becomes criminal.

In conclusion, I have but little to add, as, until the use of such devices for lighting, heating and ventilating we now have are fully understood and appreciated by the average trainman, who should be held responsible to his superior for the safe condition of his coach from a hygienic and a mechanical point of view, it is useless to assume that a more elaborate mechanism will find favor.

Nothing as yet approaching an automatic system in heating, lighting or ventilating of a car has been placed before the public, but as it is only a comparatively short period since automatic brakes and couplers have been placed upon the market, we may confidently look forward to the time when the public demand for hygienic improvements will evolve from the mind of man, some plan or system to meet the emergencies of the occasion.

In order to do this, effectually, some one connected with the road would have to instruct the employe in the use of hygienic appliances, the same as is now necessary in the use of automatic brakes; and it would seem quite practical that all roads having a surgical department should extend this work into the domain of hygiene, and give the surgeon-in-chief authority to inspect, instruct and to hold responsible such employes as are in any way concerned in maintaining a healthy condition on our trains. The surgeon, more than any other person connected with railroads, appreciates the hygienic condition of the coaches, stations and grounds of our railroads, for

in case of accident he has much to contend with that is unknown to the physician and surgeon called to see those injured in ordinary accidents, and, therefore, will always be on the alert for all sanitary improvements.

However it may be brought about, the employe should be taught how to make the best use of all the devices in use to promote the sanitation of cars; and should be held responsible for any unsanitary conditions arising by reason of his negligence.

SOCIETY PROCEEDINGS.

Chicago Academy of Medicine.

(Continued from page 728.)

MORAL TREATMENT OF EPILEPSY.

DR. H. M. BANNISTER—The subject allotted to me is a limited one. The epileptics we meet with in general practice hardly require any moral treatment. In a few cases moral reform is necessary, and in spite of all we may say of the incurability of epilepsy generally, is sufficient for all purposes. The epilepsy in these cases is only an episode, a result of excesses, sexual, alcoholic, etc., and the epileptic habit not being set up, a moral reform cures the disease. I am satisfied that I have known several such cases.

Moral treatment, properly so-called, is applicable solely to epileptics who have undergone mental deterioration, or who are mentally below par from the beginning. These cases require guidance and control. I shall speak, therefore, of this class; insane or semi-insane epileptics.

It can readily be inferred from what has already been said this evening, that epilepsy is not in itself a disease, but is merely a symptom of cortical irritability. The theory now generally accepted is that epilepsy is primarily a cortical affection; though I do not say that there may not be exceptions, yet that is the rule. When the epileptic lesion, whatever it may be, involves the psychically functioning elements of the cortex so as to bring the subject within the class of which I speak, psychic irritability is the result, and we may say in general terms that irritability is the key-note of the epileptic character. This is the indication for moral treatment, and the reason why in many of these cases it is even more important than medical treatment. Many, even of this class, are insensible to or intolerant of the ordinary remedial agents, and moral treatment is the only practicable resource. This psychic irritability shows itself by its reaction on the physical system, often in a very marked way. It is well known to those who have had to deal with epileptics *en masse*, how readily they react to all sorts of suggestion. It is often observed that one epileptic having a fit in a ward will seem to cause others to have them. The effect of operative procedures on the attacks is also in point. While I have never seen permanently good results follow any operation on old confirmed epileptics, I have seen just as good temporary ones from slight surgical procedures, such as setons, as from the most radical cerebral operations. This fact has been remarked by others, among them Dr. L. C. Gray, of New York.

Hysteria has been mentioned this evening as a complication of epilepsy; the fact is the two conditions continually overlap, and moral treatment is required for both.

Here I may mention another point, in regard to which I think erroneous impressions exist. By many, unconsciousness is made the criterion of epilepsy, in the post and pre-epileptic states, and all that is done by the individual in these conditions is called automatic. If this were true, moral treatment would be useless in these conditions, but according to my observation, and I think this has been extensive, it is not generally true. Often there is not even subsequent amnesia, and I am not prepared to say that consciousness is necessarily or invariably lost in the epileptic attack itself. Even the subjects of epileptic furor are more or less susceptible to prudential considerations. I have often noticed epileptics in that condition avoid attacking other patients who they knew would be likely to do them injury. I have had the testimony of epileptics themselves as to this fact, given in such a way that it could not be doubted. (Here Dr. Bannister narrated an illustrative case.)

This is probably the secret as to how some of these patients are managed outside of asylums; but while intimidations and force fall under the head of moral, or, perhaps we should say, immoral treatment, they would be out of the question in the proper management of these cases.

I have spoken of the epileptic character and said that its key-note was irritability. As ordinarily described in textbooks, it is a very unamiable character. It is admitted however, that there are exceptions, and one Italian author has estimated the proportion of epileptics who are altruistic as about 16 per cent. of the whole number. I should say that under proper conditions and taking account of and providing for the predominant element of irritability, we can find a much larger proportion than that. Many apparently very vicious epileptics, under judicious management and proper conditions, develop many very amiable qualities. An insane or mentally deteriorated epileptic still possesses his natural disposition, *plus* the irritability and the mental weakness. The latter is comparatively unimportant and may even aid in his management; the irritability must be controlled largely by moral measures. I have found it best to treat them as reasonable beings, explaining to them that their physical disease necessitated certain restrictions which had to be enforced. Then by granting them all the privileges I could, consistently, with their welfare and that of others, letting it be understood that it was as a favor, not as a right, I made friends; while the opposite course of giving them liberties as a right, and having to restrict them when they were least fit to be reasoned with, made them vicious and unmanageable.

The very marked religious tendency of epileptics, so often spoken of, and to their disadvantage, may often be utilized as a valuable aid to treatment. They are generally sincere, and their inconsistencies are the result of their irritability and disease. As religion is one of the greatest social forces in the world, it is not hard to see how it may be of advantage here. In individual cases I have seen it of the very greatest value. (An illustrative case was given.)

I believe the colony treatment the best that has yet been devised for a large part of the mentally deteriorated epileptics. They are not wanted in the insane asylums, and there are good reasons for this, both on account of others and themselves. Yet if the colonies are to completely relieve the asylums of this class, there will have to be some restrictive arrangements for a certain proportion that can not safely be let go, at all times, at large.

OPHTHALMOLOGIC RELATIONS OF EPILEPSY.

DR. CASEY A. WOOD—I feel that I ought to confine the few words that I have to say to the ophthalmologic relations of this subject, because during the last few years I have given some attention to them. There is, perhaps, no man in this country who has studied this subject with the fullness which Ranney has, and there is no one who has given us proportionately fewer results than he has in his papers. I have had occasion to operate on a half dozen cases of supposed eye-strain due to inequalities in the action, and alteration in equilibrium of the external ocular muscles, and my conclusions are that any other operation of equal severity would have brought about the apparently beneficial result that I obtained in these cases. Out of this number, there has been one case which up to this time I regard as cured but inasmuch as the case has only been under observation for a year, I perhaps ought to wait longer before deciding positively as to a cure having been effected.

In looking at the literature of operations for idiopathic epilepsy, I find that a great many operations performed on perfectly normal organs have resulted in cures of the disease. I presented this observation in the form of an appendix to my paper, which appeared in the *New York Medical Journal*, and suggested that there should be some regularly instituted operation for the treatment of idiopathic epilepsy. I think if we were to remove small patches of skin from various portions of the body, extending the surgical treatment over six months, that we would get about as good results as from operating on the eye muscles or any other organ of the body. I do not wish to enlarge upon the ophthalmologic part of this debate, but it seems to me that one important point has been overlooked, and that is the possibility of *spontaneous cure* in epilepsy. There are a great many cases mentioned in literature. I have been able to find more cases of spontaneous recovery from idiopathic epilepsy than I have, for instance, from the results of operations of any sort on the eye. I can point out to you cases where people have recovered from idiopathic epilepsy where nothing whatever had been done

or where the last thing done could not have borne any relation to the causation of the epilepsy. I think, also, in this matter of epilepsy, we should regard with a great deal of suspicion any operative procedure, whether on the eye, nose or throat—no matter where it is. I quite agree with Dr. Brower and others in that respect. I have on hand now, a small boy, from whose middle ear I removed a number of granulations nine months ago. The boy up to that time had attacks of epilepsy every two weeks. He has not had any since. Whether it was the moral effect I do not know. The bromids, in this case, have been stopped. I think what Ranney has given us simply points to one great fact; that if we do something for the patient and tell the parents and neighbors that he will probably get well, it will have a marked influence upon the epilepsy, even if it does not entirely cure it.

MEDICINAL TREATMENT.

Dr. DANIEL R. BROWER—To discuss the treatment of epilepsy in ten minutes is certainly a task that I am altogether unable to perform. It has been said by one of the preceding speakers that epilepsy is not an entity; this I indorse. It represents an irritable condition of the cells of the cerebral cortex, and these irritable cells may be thrown into a state of commotion at any point and by any one of the peripheral end organs of the body, and develop an epileptic attack as a result. These patients are intensely emotional; they are, therefore, most susceptible to suggestions, and in estimating the value of any treatment this fact must be borne in mind. I have had sometimes good results in experimenting with these patients, from the simple administration of what was practically nothing, but given with suggestion great results would follow. There is one important point in the treatment to which I wish to call attention, and that is the necessity of treatment of the aura.

These epileptic attacks, I care not what their foundation may be, after a while become purely a matter of habit, and while, as Dr. Lydston has said, we may remove the cause of the disease, the habit goes on. By the successful treatment of the aura, we may sometimes break up the habit. Just how the aura is to be treated depends very largely upon what it is. I have under observation at the present time a young man whose aura begins with a peculiar sensation and twitching of the hand, and pressure made at the wrist or somewhere on the forearm will arrest the progress of the paroxysm. So he carries a stout string about his wrist and jerks it the moment the sensation is felt, and this prevents the development of the paroxysm. A good many of these expedients might be suggested for this purpose. Unfortunately for these patients, a certain proportion of them have no prodromal symptoms, and in such cases treatment before the attack can not be instituted. Medical treatment in the interval between the attacks is then the only indication. And here comes in the question of the possible etiologic factor. What is it that, acting upon the irritable cerebral cells, develops the paroxysm? Every one knows that each case must stand by itself. As regards the importance of the etiologic factor—auto-intoxication—discussed admirably by Dr. Evans, I believe it plays an important part in the development of the paroxysm, and I think it is most important to watch carefully the condition of the gastro-intestinal tract; frequently the best we can do for the patient is to administer gastro-intestinal antiseptics. Unfortunately, as you know, we have no absolutely reliable remedies of this class, but I think excellent results can be obtained by the use of resorcin, beta-naphthol, the sulpho-carbolate of zinc, and salophen. Some one or more of these intestinal antiseptics, either administered separately or in combination, will produce marked improvement in the condition of the intestinal tract, stopping intestinal fermentation, and diminishing the frequency of the epileptic paroxysms. A very good combination, in my judgment, is resorcin with the sulpho-carbolate of zinc. Then another important thing to consider is the necessity of watching renal elimination. I think there is too little attention paid to this. I had an epileptic patient in my office, a man weighing 175 pounds, who only eliminated 400 grains of solid matter from his kidneys during the preceding twenty-four hours. This is a common experience in epilepsy, hence the necessity of some kind of medicine directed to this important function. I think one reason why the formula of Brown-Séguard has benefited so many of these patients is because the iodids and carbonates, renal eliminants, are used with the bromids. Everybody recognizes the value of the bromids, but I am free to confess, the more I have to do with these patients the less confidence I place in these drugs, and I certainly do not

give them in the doses that I formerly did. The mental deterioration from excessive use of the bromids makes the second stage of the epileptic worse than the first. As to the value of the several bromids, my preference is for the bromid of sodium, I presume because I regard it as less destructive to general nutrition or to the muscular tonus of the body than bromid of potassium. I prefer ammonium bromid in the cases of petit mal, and of nocturnal epilepsy. I have had very satisfactory results from a combination of ammonium bromid with antipyrin suggested by Dr. Wood, of Philadelphia. In cases of petit mal and of nocturnal epilepsy, I have used the treatment suggested by Trousseau, that is belladonna or its alkaloid, which I usually combine for this purpose with ammonium bromid.

Chloralamid is a valuable addition to the treatment of epilepsy, especially in the nocturnal form, and in those patients who sleep badly. I prescribe alteratives in addition to the general treatment suggested; I prefer as an alterative the chlorid of gold and sodium. I think there is in epilepsy, not only the condition of cells already mentioned, but also a chronic degeneration of the neuroglia, and this drug, I believe, is of some advantage in interstitial inflammations, not only in the brain but in the spinal cord, in the kidneys and in the liver. It is to a certain extent a cerebral tonic.

Lastly, I use electricity, the galvanic and static. I use galvanic currents of high ampèreage by longitudinal application. The anodal electrode, twenty centimeters in diameter, is applied to the head, and the cathode, ten centimeters square, is applied to the cervical spine. A current of ten to fifteen milliampères is used. These high ampèreage currents have some modifying influence over the irritability of the cortical cells, and inasmuch as such a high ampèreage current must have at least a catalytic, if not an electrolytic effect upon the brain, I believe it does modify the nutrition of the interstitial tissue.

Dr. JAMES G. KIERNAN—Epilepsy illustrates very strikingly the influence of the factor of personal equation, the factor of the moral influence as pointed out by Dr. Bannister, and the factor of the constitutional influence of the operation or the medicinal treatment *per se*, as mentioned by Dr. Wood. With reference to the question of curability, there are several things to be considered. In the first place, it is the grand mal which strikes the majority of people as the great evidence of epilepsy. The average ophthalmologist—although we have had no illustrations from the ophthalmologists this evening on the reflex hypotheses—takes it for granted that when the grand mal disappears the epilepsy is cured. Behind that are hysterical, sensory, mental and petit mal phenomena, and finally, which is ignored in the vast majority of cases, nocturnal epileptic phenomena. Until you can show that every one of these has disappeared, you can not say with any degree of positiveness the patient is cured or even ameliorated, because the grand mal is the smallest part of the problem.

With regard to traumatic epilepsy, I fully agree with Dr. Lydston that the sooner the operation is performed, the less chance will there be of the epileptic habit being formed. I do not believe when the epileptic habit is once established, that you can ever cure, in the true sense of the word, a case of epilepsy; at the same time, I do think every epileptic should have his intestinal canal, his eyes, and every other organ put in shape.

In reference to the point raised by Dr. Evans of auto-intoxication, while I agree with him from many standpoints, I desire to call attention to one fact which he has perhaps unintentionally omitted, that the epileptic status can be best explained along the line which he has stated, and that every investigation along the auto-intoxication line has simply served to corroborate the opinion of Meynert, based on clinical phenomena alone.

I heartily agree with the position taken by Dr. Brown, that the great tendency is to regard epilepsy as the grand mal type and to ignore the sensory phenomena, the aura and other conditions. I remember being in a case once with Mills, of Philadelphia, and Spitzka, of New York, and two European physicians. We were able to make a diagnosis from the evidence in the case that the man had epileptic insanity, but the verdict of the jury was otherwise. The case finally went to the Supreme Court, and the Supreme Court did not agree with the jury because the verdict was against the facts.

With regard to Dr. Moyer's position, that no epileptic should be held responsible who has committed a crime of violence without rational motive, I most heartily agree. I think in the condition of amnesia referred to, where there is general irritability, the epileptic is conscious, but I do not

believe after careful examination of these cases that he is conscious in the other conditions. In dealing with that state I am taking into account a factor which is often ignored. In somnambulism a man may rise in his sleep, may be conscious, may do everything and forget all about it. I do not think, after investigating the condition of epileptics, you can regard their condition as conscious outside of an irritable state with consciousness. We must remember this, that a large number of our acts belong to the subconscious category. We register an immense number of acts without being conscious of it and that registration rises into consciousness and occurs in morbid conditions as a state of delirium. That being the case, it can be seen how many complicated acts can be performed by an epileptic without assuming the condition of amnesia. With regard to the latter condition, I do not think a single attack of that kind is characteristic of epilepsy. We may have temporary amnesia. I can recall instances where I have been awakened, have acted, returned to sleep, and forgotten all about it. I think every one has done the same thing. With regard to the utero-ovarian status of epilepsy, the vast majority of wonderful cures which have been reported by gynecologists are due to a lack of knowledge of epilepsy. Taking into consideration all things, a large proportion of the recoveries from epilepsy reported are simple evidence of lack of knowledge of the ordinary facts of the disease outside of the state of grand mal. While at Ward's Island and the Cook County institution I had chronic epileptics who had been "cured" by all possible procedures. At the Cook County institution, three patients were reported to have been cured by operation, but they were just as bad epileptics as they were before operation. Another case at the Cook County institution was a gentleman who had been "cured" of epilepsy, by trephining, by a French surgeon. You will find a report of the case in 1868 in *Champonniere's Journal de Medecine Pratique*, but the man had epilepsy just as bad in 1884 and 1889 as he had in 1868.

INOCULATION TREATMENT.

DR. A. LAGORIO—My attention was called to the method of inoculation of nervous matter in the treatment of epilepsy about two years ago. It happened this way: A little boy 8 years old was brought to me at the Pasteur Institute in August, 1890, to be treated for a bite inflicted by a supposed rabid dog. The little patient received a full course of anti-hydrophobic fluid inoculations. Twenty-two injections were given in all, during a period of eighteen days. At the time of treatment the boy was rather anemic, poor in health, and had been treated for different ailments since childhood. I did not hear anything of the patient until about a year and a half afterward. To my astonishment I learned from the mother that her son had escaped hydrophobia, that the injections given not only improved his health, but had made him strong and vigorous, but that above all things they had cured him of epilepsy. This surprised me not a little, and I began to investigate the matter. That the boy had been truly suffering from epilepsy was assured me by the family physician, the late Dr. Thuemmer. The epileptic attacks would come on sometimes once a week, and then at other times once every two weeks, or once a month. There was no question about his having had epilepsy, and there is no doubt that from these several inoculations he recovered from the disease. What the causative factor was in curing the boy's epilepsy has always been to me a question—was it the substance which was injected? In my published report of April 12, 1892, I made a brief mention of this case—a copy of it was mailed to the leading medical journals of the country and also to several Pasteur institutes. It naturally aroused considerable interest, and many experimenters at once tried it; and although several of them reported cases, it pained me to notice that all them forgot to mention the source from which they received the inspiration. The object of my reporting the first case on record was not to claim any positive cure for epilepsy, but rather as an incentive to others to try the method and report.

Paul has injected the gray matter of the brain in many patients afflicted with nervous diseases and he has noticed that the vertebral pains and hyperesthesia rapidly disappear after a few hours and that in a locomotor ataxia the fulgurant pains cease, as also the neurasthenic headache and insomnia.

The experiments made by Brown-Séguard, Paul, Babes and others, and their claimed results led Crocq to believe that the effect of these nervous matter injections was due to the phosphorus contained in it, for according to Jolly there is found 2.928 per cent. of phosphorus in the white matter and 1.911 per cent. in the gray.

Crocq therefore instituted a number of experiments in the Hospital Molenbeck Sain-Jean (Bruxelles), with the injections of phosphate of sodium. Two cases of locomotor ataxia, one of chloro-anemia, and one of paralysis agitans were treated and the results were very encouraging indeed. But no beneficial effects can be attained whenever there are present profound lesions in the nerve substance; whenever the disease is essentially functional as in hysteria, chorea and epilepsy some good results can be had.

Colucci and Germano, of Naples, have given us a report of fourteen epileptics treated with the anti-hydrophobic emulsion. They find that this Pasteur fluid has an almost immediate action on the blood vessels. After three or four injections there is noticed a slowing of the pulse, and after a greater number of injections there is a marked irregularity and arrhythmia of all the cardio-vascular apparatus. If the injections are continued, a prostrating effect upon the body follows. The action of this Pasteur fluid is compared by them to such poisons as atropin, muscarin, veratrin, duboisin, etc. Their conclusion was that the Pasteur inoculations had rather increased the intensity of the epileptic attacks, and that such treatment, as a rule, failed in all of them.

I have treated about twenty epileptics with the nervous matter injections. I have abandoned long ago the rabic fluid, and only use the plain nerve matter emulsion. The effects are pronounced indeed. The epileptic seizure soon stops. Is it due to the moral impression or to the tonic effect produced upon the nerve centers? I do hold that such injections act as a most powerful neuro-tonic. Patients who are run down in health, haggard looking, anemic, nervously prostrated will soon improve in strength and health, and their appetite will revive. I will not enter upon the history of all cases, for the short time will not permit it, but will explain in a few words my method of treatment. I always begin with a course of nerve injections—one every day for twenty days, then one on alternate days for two weeks. I then administer bromid of sodium, occasionally, with belladonna and digitalis in small doses for some time to follow, and the results have always pleased me. I have had patients who came saturated with strong bromid mixtures but their attacks would still come. It was only after a course of nervous emulsion injection that they have showed signs of improvement.

This method which I have adopted, I believe is the best I can use in cases of epilepsy. By alternating the treatment, giving the injections first and then follow with a mild bromid medication, we can attain far better results than by administering the bromids alone.

Although I have written to all the patients, I have been unable to receive replies from all, especially from those living out of the city. Four patients living here have faithfully reported occasionally, and the results in these cases are remarkable. A young man began to have epileptic attacks four months after being infected with syphilis in 1890. He took a complete course of anti-syphilitic treatment for many months. He also took bromids *ad nauseam* for the relief of his epilepsy but nothing helped him. He was referred to me and finally submitted to nerve emulsion injections, and then bromid of sodium was given. It is a year and a half since he was treated, and he has had only two attacks during this time. When we consider that previously to the injections he was having two to three attacks a week, we must admit the result is highly promising.

In another case, almost identical with the one reported, and in which I applied the same treatment, nine months have passed without any attacks whatever.

A lady patient began to have epileptic attacks at the age of 6 years, following scarlet fever. These attacks occurred about twice a month. She had taken all sorts of treatment, but of no avail. When she called on me she had marked symptoms of bromidan from the large amount of the bromid salts taken. After the injections her general condition improved and has remained so for five months without a single attack.

Another case of nocturnal epilepsy also reported to me lately that the treatment had improved her wonderfully.

But, gentlemen, we must never be too sanguine, and must not rush into enthusiasm because of any fair or good results that we attain in our method of treatment. This method of nerve injections although in use a short time deserves attention and is worthy of trial. Time, only, will tell whether the results are permanent. I hope the farther we go, the more we will improve the method and the better probably will be our results.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 FIFTH AVENUE, CHICAGO.

SATURDAY, NOVEMBER 17, 1894.

A PLEA FOR BREVITY IN MEDICAL WRITING.

"Therefore, since brevity is the *soul* of wit,
And tediousness, the limbs and outward flourishes,
I will be brief."—*Polonius* in "Hamlet."

Gracefulness and elegance is not given to all alike, nor can every one hope to express himself with perfect propriety and perspicuity; but in the use of the mother tongue all may be able to combine clearness of expression with brevity. This, indeed, is that simple style so much praised and so seldom seen.

A fact stated with simplicity gains in force, while if buried in tropes and figures or in mere words, it has no vigor. Too great attention to ornament destroys the dignity of an article, and is nearly fatal to its authority. One need not reject ornament, but in writing upon scientific subjects ornament must be held subordinate to truth and simplicity. These last are indeed cardinal virtues in the manuscript intended for the medical journals. Let the writer write what he thinks, express what he feels, and record what he observes. Observations of unusual cases are *always* of interest, no matter how they are reported, but even these reports lose none of their interest by being brief.

There is no need to use two words where one will answer the purpose of conveying to the mind of another some new fact, or the thoughts that the knowledge of that fact has evoked, and PROFESSOR EDMUND ANDREWS' article on this subject in this JOURNAL, August 18, 1894, was pointed and timely.

If we thus relegate ornament and redundancy to a subordinate place in medical writing, what shall we say of obscurity, and wrong use of words? While obscurity of meaning most frequently results from incomplete description, it very commonly arises from

redundancy. Delicacy of expression and nicety of shading only come from long practice and study. They are never intuitive; but simplicity may be natural. The wrong use of words comes usually from a lack of study of rhetoric and want of attention to the rules of composition. No one need fear criticism if he will write what he thinks, as he thinks it. He can make the necessary corrections in style afterward. It is the thought—the concept—that is wanted by his fellows, and it is the interchange of conceptions that enlighten minds and raise the average of human knowledge. We can truthfully say that American medical writers are improving year by year, and we have had many American medical men whose writings can not be excelled, but it must be admitted that the average journal article is too long and tedious. The papers of the Surgical Section of the AMERICAN MEDICAL ASSOCIATION, read this year, are much above the average, because CHAIRMAN ROBERTS wisely placed a time limit on each writer when he solicited his paper.

There is an argument for brevity in medical writings, that should appeal even to those who write merely for the sake of writing, found in the well-known fact that wherever the writer of a very long and tiresome paper puts his "conclusions" at the end, in the form of a synopsis or summary, that part is not only read first, but is frequently the *only* part read by anybody except the writer and the proof reader. In such cases the "conclusions" frequently contain about all there is of value in the paper. Short papers are always read, and the great improvement in our medical literature in the past few years, as shown by the pages of the JOURNAL, is doubtless owing to the tendency of the time toward pithy articles. Let us hope that at future meetings the plan of CHAIRMAN ROBERTS may be the rule instead of the exception.

LIABILITY OF DRUGGIST TO PHYSICIAN.

The relation which exists between druggist and physician is one peculiar in its character. What are the legal rights and liabilities thereof, on the druggist's side, furnishes not only to him, but to the physician, an interesting and important subject for contemplation.

As a general proposition, the Supreme Court of Louisiana declares, in the case of *Tarlton v. Lagarde* (decided July, 1894, but just reported in the advance sheets of 16 *Southern Reporter* 180) it can not be conceded that the mere refusal of a druggist to fill prescriptions furnishes any occasion to hold him for damages to the physician who gives the prescription. In many cases the druggist may have the best reason for declining. As a chemist, he may perceive, or have cause to suspect, the physician erred in his prescription. Or the druggist may not have at

hand the ingredients, or he may distrust his ability to prepare the prescription, or other causes may incline the druggist to undertake filling prescriptions.

From the evidence in this case it appears that a druggist declined to prepare two prescriptions. In one a patent medicine formed a component. He seems to have been averse to putting up prescriptions of which this patent medicine formed a part. In his own language as a witness, he was unwilling to take the responsibility of such a prescription, as he was not sure of the composition of the patent medicine.

There was testimony that it was not usual to make a patent medicine a component of a prescription, and there was testimony that it was not infrequent. This difference in the testimony of the physicians who testified, the court thought, deserved some consideration in connection with the unwillingness of the druggist to prepare the prescription,

With reference to the other prescription, which it was contended that the druggist should be made liable because of his refusal to fill, the answer was, that the prescription was not filled for want of the necessary ingredient and other causes. Under these circumstances, the court holds that the druggist was not liable in damages to the physician merely and only because the filling of his prescriptions on these occasions was declined by the druggist, for reasons not at all impugning the physician's capacity. Neither did it believe that the impression arising solely from the exercise of the druggist's right to decline to fill the prescriptions furnished any cause of action.

On the other hand, the court held that the druggist incurred liability by, without the slightest cause, indulging in public expressions tending to create the impression of the physician's incompetency. The slander attributed to the druggist was in the course of a discussion between himself and one of his fellow citizens, begun on the street, and continued in a barber shop. It first began with a request of the druggist for information of the gentleman addressed, formerly a Representative, whether the laws compelled a druggist to fill prescriptions presented to him. The information given on that subject did not suit him; but excited him, and led him to make observations offensive and unjust to the physician, at least in their tendency to affect those who were gathered by the animated and angry discussion, or to whom the observations might be repeated. The druggist, having exercised his privilege of declining to fill the prescriptions, should, for that very reason, have abstained from any comments calculated to convey impressions damaging the physician's character as a professional man. On the contrary, he engaged in a public discussion on the subject of the latter's prescriptions, in which he derided his diploma, and he further commented on one of his prescriptions. For

this the Supreme Court thought that a judgment in favor of the doctor for \$50 was too small, and increased it to \$100.

EXPERIMENTATION ON CONDEMNED CRIMINALS.

Medical history informs us that upwards of nineteen hundred years ago, ERASISTRATUS and others made inquiry into certain anatomic and physiologic questions by means of vivisection. Some two thousand condemned prisoners were dissected alive in the course of those novel and instructive experiments, and now in the nineteenth century comes GOVERNOR FLOWER, of New York, who is said to have granted permission not to destroy, but to save the lives of persons electrocuted.

It appears that under the present law providing for execution by electricity, a clause was included which provides that in all such cases a *post-mortem* examination shall be immediately made. Certain electricians have asserted with much positiveness that it was the necropsy which destroyed the criminal and not the electric current. To settle this question, if authoritatively raised, it has been suggested to his Excellency the GOVERNOR, that proper experiments to determine whether or not these victims of the law could be resuscitated would not only be in the interest of science but in the interest of humanity, for if these persons could be brought to life, many a case of accidental electric stroke might be saved which, under present methods result fatally.

It is stated that the only apparent obstacle is the general theory that when a man is condemned to die by due process of law he must die in fact, and if by a new operation of the electric current, life was restored, the electrocution would have to be done again.

CASTRATION AS A REMEDY FOR ENLARGED PROSTATE.

Women have long had almost a monopoly of the sensation of being unsexed, thanks to the enterprise and valiant skill of the gynecologist; but now the general surgeon, despairing of having castration of men adopted by law as a punishment for crime, has recommended it as a remedy for disease. PROFESSOR RAMM, of Sweden, performed the operation twice in 1893, for enlarged prostate. HAYNES, of Los Angeles, three times; FREMONT SMITH, of St. Augustine, once; WHITE, of Philadelphia, once; C. MANSELL MOULLIN, of London, once. That well-known writer, in the *British Medical Journal* for November 3, advocates the operation in desperate cases, and states that it is invariably followed by disappearance of the enlarged prostate.

The crop of eunuchs, heretofore not very great in this country, may now be expected to increase with surprising rapidity, as our home talent is certainly

not less bold than that of foreign nations, and no matter how dull the practice may become, American surgeons' knives are quite sharp enough to produce any number of *sans testicules* that may be demanded by the fantastic fads of the times.

CORRESPONDENCE.

Was Death the Result of Cocain?

ALBION, MICH., Nov. 9, 1894.

To the Editor:—Oct. 26, 1894, I had occasion to remove a nasal polypus from the left nostril of a lady patient aged 60 years. Less than a year previous I had thoroughly cocainized the anterior and posterior nares upon two occasions, and each time removed a large number of mucoid growths, varying in size from a pea to a walnut, which completely filled the cavities and rendered respiration through the nares impossible. Upon neither of these occasions did she exhibit any toxic symptoms or evidence of shock or prostration. She was a patient of rather a nervous, delicate organization, but without any established history of organic disease. Upon the day mentioned she came to my office, complaining she was again experiencing difficulty in breathing freely through her nose. Examination revealed the presence of a mucous polypus in the left anterior nasal passage. A 4 per cent. solution of cocain was applied by means of a small pledget of absorbent cotton twisted around the thin end of an aluminum applicator, the entire mass being little if any thicker than an ordinary round match. The cocain solution by this means was lightly applied to the base of the growth; no packing of the nostril nor prolonged application was at any time made. After waiting two or three minutes, this same procedure was repeated and then immediately the mucoid growth, as large as a walnut, was removed by the forceps without any difficulty. The resulting hemorrhage was about the average attending these operations. The patient expressed herself as relieved and delighted at the luxury of again having free nasal passages. She vigorously walked to the washstand and thoroughly washed her face and hands, and remained in the waiting room of my office for perhaps ten minutes, occupying an ordinary upright chair. At the end of this time she expressed herself as feeling all right, got into her buggy at the door and was driven to the home of her daughter, a quarter of a mile distant, where she remained about three-quarters of an hour, making no complaints of illness, but expressed a desire to go to her own home, some two miles in the country. Herself and husband entered the buggy, and as he was the subject of senile cataract, as was her usual custom she did the driving. She continued, according to her husband's statement, to talk naturally and rationally, without any complaint of physical ailment. When within a mile of home she suddenly fell forward, gasped a few times and died.

No *post-mortem* was made; hence it is not known whether any organic cardiac lesion existed, but no diagnosis of such condition had been made during life, though during the past four years she had been attended by two physicians besides myself—(a year ago I attended her in an attack of la grippe). The time elapsing between the operation and her death was approximately one hour and a half. Can any connection with the result be traced to encain or the operation?

HENRY DENNY THOMASON, M.D.

Case of Twins; One White, One Black.

WAYNE CO. HOUSE, ELOISE, MICH., Nov. 7, 1894.

To the Editor:—In reply to yours of November 2, I will say

that twins were born, one African and one white child. The colored baby lived. The mother is a light-haired German woman, and I learn from her that the father was "a nigger born in slavery"—probably his father was someslave driver, at least he must have been a white man. "Breeding back," as the horseman says, seems to be applicable in this case.

Yours very truly,

F. B. HEISOROT, Resident Physician.

The First Statue to a Medical Man in the United States.

NEW YORK, Nov. 5, 1894.

To the Editor:—In your editorial of Nov. 3, 1894, you state that the Sims statue is the first public statue erected in the United States to the memory of a medical man. How about the statue of Dr. J. D. Crawford, which for years has stood in the rotunda of the Capitol at Washington, as the discoverer of ether in 1842?

It is a more graceful execution than that of Sims, who is represented with harsh angles without the smoothness and ease of the real Dr. Sims, as his presence graced the parlors, chambers and streets of New York.

If a medallion or monument can be called a statue, then Dr. Ephraim McDowell, of Kentucky, was thus honored.

I am glad to see your notice. The erection of this statue is an unique event and deserves fullest recognition. Few such statues adorn the capitals of Europe. That of Boerhaave, at Leyden, is a remarkably fine one. I am told there is one at Leipsic of another medical man. At Westminster, you see the marble bust of Sir J. Simpson, a fine portrait also; while at Newcastle-on-Tyne there is in one of the Established churches a magnificent full length portrait, in stained glass, occupying a whole large window, of a medical man of that city.

It is too bad that Dr. Rush's statue project languishes. We should prize the memory of such men. But now we have two statues of our professional worthies let us, as we look on or think of them, be inspired to do good work as they did. I thank God that such lives were lived for our encouragement.

Yours truly,

E. CUTTER, M.D.

BOOK NOTICES.

The Physician's Visiting List. (Lindsay and Blakiston's) for 1895.

This well-known and popular visiting list is, as usual, first in the field for the new year. It will be found quite up to date. A dose table has been prepared giving the dosage in the decimal system, also in the old British apothecaries-weights. Those wishing to use the decimal system who have not heretofore used it, will find the table of doses invaluable.

A Manual of the Practice of Medicine. Prepared especially for Students. By A. A. STEVENS, A.M., M.D. Third Edition, revised. Illustrated. Cl., pp. 501. Philadelphia: W. B. Saunders. Chicago: E. H. Colegrove & Co. Price, \$2.50.

This is an excellent manual quite up to date in everything except dosage, clearly written, and in general quite satisfactory. The special pathology is necessarily brief, but it fairly represents the accepted teachings of the day.

Diagnosis, Differential Diagnosis and Treatment of Diseases of the Eye. By A. E. ADAMS, M.D. Cl., pp. 94. New York: G. P. Putnam's Sons. 1894.

Works on diagnosis without regard to size are always valuable, unless they contain positive errors. This little volume seems measurably free from them, and as it consists of tables arranged in parallel columns it will be found very convenient for ready reference.

The Pocket Anatomist. (Founded upon Gray). By C. HENRI LEONARD, A.M., M.D. One hundred and ninety-three illustrations. Eighteenth revised edition, containing Dissection Hints and Visceral Anatomy. Detroit: The Illustrated Medical Journal Co.

This useful pocket book, while intended mainly for students, will be found useful to general practitioners as well, for convenient and ready reference while on their rounds. The paper is poor but the low price at which the book is furnished probably precludes better material.

Essentials of Diseases of the Skin, including the Syphilodermata, arranged in the form of Questions and Answers. Prepared especially for Students of Medicine. By HENRY W. STELLWAGON, M.D., Ph.D. Third edition, revised and enlarged, with seventy-one letter press cuts and fifteen half-tone illustrations. Cl., pp. 270. Philadelphia: W. B. Saunders. Chicago: E. H. Colegrove & Co. Price, \$1.

An excellent book of its class, and one of the few question books that teach nothing to be unlearned afterward. The book is well printed and handsomely illustrated.

The Late Charles Warrington Earle.

A memorial volume to the late Charles Warrington Earle has recently been issued. It contains the memorial addresses of Rev. Frederick A. Noble, D.D., Bishop Samuel Fallows, D.D., William E. Quine, M.D., Henry T. Byford, M.D., and Mrs. George Sherwood. The frontispiece is an excellent steel engraving of Dr. Earle.

These addresses are so elevated in tone, and so touching in style, that it is well to have them preserved in permanent form not only on account of the many virtues and endearing qualities of the subject, but as well for their intrinsic merit.

The Pulse.

This is a handsomely illustrated annual, published by a committee of students of Rush Medical College, which publication the committee assure us will be continued from year to year. It contains a narrative of the college, the professors, ancient and modern, and of many alumni. The work is embellished by many half-tone illustrations, representing the building, the professors, the students, the clinics, and many humorous pictures. The letter press contains beside the heavy literature commemorating the many virtues of the college, specimens of class poetry, and facetiae concerning various members of the class, which doubtless are best appreciated by "those who are in it."

The mechanical part of the book is excellent and, as a whole, it is highly creditable to those concerned in its production.

Essentials of Chemistry and Toxicology. For the Use of Students in Medicine. Twelfth Edition. (Wood's Pocket Manuals.) By R. A. WITTHAUS, A.M., M.D., Professor of Medical Chemistry and Toxicology in the University of Vermont; Member of the Chemical Societies of Paris and Berlin, etc. 32mo, 314 pages, muslin, red edge. Price, \$1.

This little book is a handy volume that may be carried in the pocket. That its teachings are sound is evident from the fact that it has passed through twelve editions. In the present edition, "the part relating to the compounds of oxygen has been in great part re-written and re-arranged to keep pace with the advances in organic chemistry so far as is possible in a work of this character." The orthography adopted by the American Association for the Advancement of Science has been adopted, and it looks a little queer to read of "sulfur" and the like, but as we have already become accustomed to "fluorin," "chlorin," "bromin" and "iodin," the shock is not great. This intensely practical age has little time to waste in writing and printing superfluous letters from mere etymologic reasons.

NECROLOGY.

BENJAMIN McCLUER, M.D., of Dubuque, Iowa, November 4. He was born in Franklinville, N. Y., in 1824 and was graduated from the medical department of Harvard in 1852. He

began the practice of his profession in Holliston, Mass., where he resided for four years. In 1856 he moved to Dubuque engaging in general practice until 1861, when he was appointed surgeon of the Ninth Iowa Infantry. He served during the war with distinction and in 1865 was brevetted Lieutenant-Colonel. In 1866 he returned to Dubuque and resumed practice until 1893, when he retired to private life.—T. M. Ingraham, M.D., of Flatbush, N. Y., November 4, aged 72.—Frank Hartzell, M.D., of Churchtown, Pa., November 4, aged 50.—William A. Thom, M.D., Jr., of Norfolk, Va., November 1. He was an ex-President of the Norfolk Medical Society, and was at the time of his death President of the Society of the Alumni of the University of Virginia. He was for a number of years quarantine officer of Norfolk.—Rodolph B. Shultz, M.D., of Reading, Pa., November 3, aged 34 years. He was graduated from the Jefferson Medical College of Philadelphia and was for several years physician at the County Hospital.—E. B. Forsee, M.D., of St. Joseph, Mo., aged 50 years.—J. H. Davis, M.D., of Waterloo, Wis., October 28. J. R. Coleman, M.D., of Princeton, Ill., November 4, aged 60 years.—C. H. Lovelace, of Dukedom, Tenn., November 7, aged 40 years. He was for many years a member of the ASSOCIATION.—Charles T. Chase, M.D., of Brooklyn, November 8, aged 63 years.—E. B. Elrod, M.D., of Flora, Ill., November 10.—J. S. Geigley, of Canton, Ill., November 2, aged 36.

PUBLIC HEALTH.

Syphilis in Greenland.—Nelms comes to the following conclusions (*Rev. Int. de Bibl. Med.*), on the subject of syphilis in Greenland: 1, a few cases of syphilis occurred in Greenland during the decade 1870-1880; 2, at present there are no cases in that country; 3, the Greenlanders manifest a relative immunity to the disease.

Brewers' Grains and Cow's Milk.—One of the most important problems in the hygiene of infancy is that of the quality of cow's milk, which forms nearly the entire food of many children, and we know that many deaths from atrepsia are due to milk of poor quality. It is generally believed that brewers' grains fed to cows make the milk more abundant but "watery," and that dairymen feed them as an indirect way of watering the milk. In order to elucidate this question M. Garnier undertook a series of researches, the results of which he has communicated to *Les Annales d'Hygiene Publique*. To his mind his investigations prove that grains when mixed with sufficient dry forage to keep animals in good condition may modify or diminish the proportion of fats, but have no marked influence on the quantity of water in the milk.

Protection Against Noxious Animals and Insects.—A new section of the Pasteur Institute, devoted to the experimental study of means of defense against injurious animals and especially insects, is to be founded, according to the *Gazette Medicale de l'Algerie*. It will be under the management of Professor Metchnikoff. This scientist was the first to utilize the parasitism of certain mushrooms for the destruction of insects ravaging them—the *Anisoplia austiaca* and *Celonus punctiventris* by *Isaria destructor*. The station will have for its mission: 1, to collect and maintain cultures of all the pathogenic microbes of insects and injurious animals; 2, to study the conditions of development of these microbes in animals and artificial media; 3, to direct experiments in the field; 4, to supervise and control their application in practice. The section will publish a special bulletin and will have the advice of a number of eminent savants—MM. Giard, Laboulbene, Grandeau, Künckel d' Herculeis and others.

Sewer Discharges of Seaport Towns.—M. Cassedebat, a French army surgeon who has made a special study of potable waters, has been investigating the action of sea-water upon microbes with a view of determining whether the discharge of sewage into the harbors of seaports has any injurious

effect upon the public health. He collected samples of water in the port of Oran, Algeria, at varying distances from the mouths of the sewers, and has discovered that the liquid was so charged with germs that it was not possible to count them until a twentieth dilution was made. The bacteria were most numerous where the water was most tranquil and allowed the germs to be brought to the surface and distributed along the shore, whence they might readily be disseminated by the winds over the city. Nevertheless, sea-water is destructive to microbic life. M. Cassedebat, using tubes of sterilized sea-water, found pus microbes died in from twenty-two to twenty-four days; the pneumococcus in from thirty-five to forty days; the anthrax bacillus in from twenty-one to twenty-four days; and the microbe of typhoid fever after forty-eight hours; the rapid death of the typhoid bacillus is of most interest.

A Health Department Appreciated.—It is so seldom that the lay press gives just recognition to the public health services, that the *JOURNAL* hastens to reproduce the following from the Toronto (Ont.) *Star* of a recent date: "One of the best managed departments in connection with our civic affairs, and the one which gives the best returns for the money expended, is the Health Department." The appropriations and expenditures for sanitary purposes during 1894 are then given in some detail, and the *Star* adds: "For this expenditure the general health of the city is better than ever before. Besides this expenditure, there is a large amount appropriated for building and maintenance of the isolation hospital, but the citizens have the satisfaction of knowing that the city is being so well fortified against epidemic diseases that the danger of a serious outbreak is reduced to a minimum." It may also be noted in this connection that the health departments of some of our large cities—where political corruption is rife and municipal pay-rolls have been overloaded for election purposes—have been recently singled out for honorable mention, because of reduced rather than increased expenditures.

Sanitary and Medical Legislation in New York.—The amendments to the State constitution adopted at the late election in New York make feasible some needed legislative changes in the interest of State medicine in that commonwealth. One amendment strikes out the word "coroners" from the old instrument so that it is now reasonably certain that the forthcoming General Assembly will enact legislation analogous to the Medical Examiner laws of Massachusetts, Connecticut and New Jersey with regard to the inquisition into the causes of sudden or violent deaths and into cases in which there is reason to suspect that death was due to other than natural causes. This amendment has been urged by the New York Academy of Medicine on grounds which may be summed up substantially in the statement that diverse and incongruous functions, requiring an almost impossible combination of expert knowledge, are embodied in the old office of coroner; and that, as a result, society is not adequately protected—its lower classes especially, against the negligence of employers and corporations and all classes in general against crime, by the coroner system. Another amendment abolishes the limitation to \$5,000 of the amount of damages recoverable in case of death by accident; and still another forbids the sale of lands and the cutting of timber in the State forest preserves—a prohibition in the interest of the conservation of the water supplies and the preservation of health resorts.

Epidemic Contagious Diseases.—Smallpox "storm centers" continue at Milwaukee and Chicago, and there is some increase of danger points in other States—New York, New Jersey, Pennsylvania, Ohio, Indiana, Michigan and Iowa. Under date of November 5, Dr. Wingate, Secretary of the Wisconsin State Board of Health, reported 139 cases of smallpox in Milwaukee and 37 cases in seven localities in Milwaukee, Waukesha, Walworth and Manitowoc Counties; during the week ending November 13 there had been reported thirty cases with seven deaths in five localities in four counties, and twenty-three new cases with nine deaths in Milwaukee; Dr. Wingate adds: "This is the smallest number of cases reported from Milwaukee in any one week since August 4; there are now on hand in the city 107 cases (41 in hospital and 66 at home) a decrease of 32 as compared with the week

previous, and of 44 as compared with two weeks ago;" since the outbreak in January last the disease has appeared in forty-seven different localities in Wisconsin, and now exists in Milwaukee, Wauwatosa, South Milwaukee, Greenfield, Franklin, (all in Milwaukee County), Beaver Dam (Dodge County), Muskego (Waukesha County), Spring Prairie (Walworth County) and Two Rivers (Manitowoc County). Except four cases at Sandwich, DeKalb County, on the 14th inst., there is no smallpox reported in Illinois outside of Chicago, where there were on the 13th inst., fifty-seven cases—all in hospital. A dispatch of the 13th says that of the forty-three cases now known to exist in New York City, thirty-two are said to be traceable to the family of a grocer in which there was an unreported case of smallpox some time ago, during the existence of which the shop was kept open, and customers contracted the disease. Whether as a result of the amount of attention given by the public press to the new antitoxin treatment of diphtheria or because the disease is really more prevalent and more virulent than usual, the fact remains that the *JOURNAL* is in receipt of an unusually large number of reports of the prevalence of diphtheria; its incidence seems to be general north of the Ohio River, and in many localities whole families are reported to have been swept off, panic created, schools closed and business suspended. Other dangerous contagious diseases in this country—typhoid fever, scarlatina, etc.—present no features worthy of note. A recent Berlin despatch reports 170 soldiers of one regiment, at Glogau in Prussian Silesia, ill with symptoms of Asiatic cholera and the barracks closed in consequence. Professor Flügge has been sent to determine bacteriologically the exact nature of the disease; several cases of choleraic nature have also been reported at Jaetschau in the same province, but the season is too far advanced to warrant alarm on account of these reports.

Activity Among Health Authorities.—In addition to the actions of the various State Boards of Health and municipal health officers heretofore noted in the *JOURNAL* from time to time, there is manifest at the present time an unusual activity among these bodies which is attracting general interest. As a result of the efforts of the Maryland State Board of Health, a Sanitary League of the health authorities of that State has been organized with Dr. T. W. Simmons, of Washington County, as President; Dr. James F. McShane of Baltimore, Vice-President, and Dr. James A. Steuart, Secretary of the State Board of Health, as Secretary; the League purposes to devote its energies to securing needed sanitary legislation. From Ohio, Dr. C. O. Probst, Secretary of the Ohio State Board of Health, announces the tenth annual meeting of the National Conference of State Boards of Health to be held in Washington, D. C., December 12-15, prox.; Dr. Probst, President of the Conference, will open the discussion on one of the questions propounded by the Michigan State Board of Health. "Is it possible to have united action throughout the country on the prevention and restriction of consumption?" the Ohio Board will offer the following question for discussion by the Conference: "What measures should be taken by State Boards of Health to prevent the conveyance of smallpox contagion by tramps?" and Dr. J. W. Scott, of the Illinois Board, will read a paper on the State control of the production of vaccine virus. The Michigan State Board has prepared a bill, which it will urge at the next session of the Legislature, prohibiting, under severe penalties, the sale of milk from cows affected with tuberculosis; and another, requiring school teachers and professional nurses to possess certificates from reputable physicians, that they are free from tuberculous or other disease communicable to pupils or patients. The Illinois Auxiliary Sanitary Association held a meeting during the week at the State capital, at which Dr. C. N. Metcalf, Secretary of the Indiana State Board, read a paper on the "Best Methods of Sanitary Organization;" Dr. A. K. Reynolds, Health Commissioner of Chicago, on "Needed Public Health Legislation;" Dr. Sarah Hackett Stevenson, of the Illinois State Board, on "School Hygiene;" Dr. Henry B. Baker, Secretary of the Michigan State Board, on "Vital Statistics and the Best Methods for their Collection;" Dr. Adolph Gehrman, Director of the Chicago Municipal Laboratory, on the "Bacteriologic Diagnosis of Diphtheria;" Dr. C. O. Probst, of the Ohio State Board, on the "Restriction and Prevention of the Communicable Diseases."

Among the topics of "Needed Sanitary Legislation," Dr.

Reynolds urges the extension of the burial-permit ordinance to every locality and the adoption of a uniform classification and nomenclature of the causes of death, as essential to a more perfect registration of deaths and their causes—the shifting of the duty of reporting births from the physician or midwife to the parent or householder on whose premises the birth occurs, in order to secure a more perfect registry of births—the compensation of physicians for the notification of contagious diseases, or their relief from this obligation and its imposition upon the householder—the vesting of the control of county charities in a continuing, non-political board of trustees—and the creation of the office of medical examiner to relieve the unqualified political corner of the duty of determining “the cause of death.” In Iowa, during a two-day session, the State Board of Health took action on the subjects of tuberculosis, smallpox, diphtheria, “walking” typhoid, trichinosis and other diseases; tuberculosis was declared to be communicable and as such a quarantinable disease; Professor Bay, the bacteriologist of the Board, in submitting his report of work done in the bacteriologic laboratory, stated that he had, “simultaneously with Dr. Klein in Germany, discovered and identified an unmistakable rod bacillus, constantly found in smallpox and vaccine virus,” and had named it the *Dispora iowaeensis*; “walking cases” of typhoid fever are declared to be as capable of spreading the infection as the bed-fast, and are, consequently, to be subject to the same rules of surveillance, disinfection, etc.; typhoid fever, roseola, chickenpox, mumps and whooping-cough are recommended to be stricken from the list of quarantinable diseases. In Missouri a Sanitary Commission, appointed by Dr. George B. Homan, Health Commissioner of St. Louis, has made an elaborate report on dairy inspection and the regulations necessary to secure a pure milk supply, and the report has been adopted as the basis of legislation to prevent the sale of milk from diseased cows, and from cows within one month before or one week after calving, of milk which coagulates upon boiling, and of milk handled by persons afflicted with or exposed to a communicable disease. From all of which, and much more of a similar character not here noted, it might be inferred that the occupation of the physician will soon be like Othello's.

Statistics of Serum Therapy in Diphtheria.—The following figures, compiled from a lengthy article by Dr. E. Roux, in a recent issue of *Les Nouveaux Remèdes*, form the numerical basis on which rest the claims of serotherapy in diphtheria—the bracketed figures being the JOURNAL corrections of a few minor errors of computation in the original article which do not, however, vitiate the general results: Serum treatment was begun in the Hospital for Sick Children in Paris, Feb. 1, 1894, and continued to July 24; all sick children found in the diphtheria pavilion from day to day were treated with the serum without regard to their condition and without other change in the treatment usually employed, so that the gross results of the months of serum treatment may be compared with those of similar preceding periods; the statistics of the diphtheria service for previous years were furnished by the superintendent and the director of the hospital and supply all the elements necessary for comparison; in addition, the statistics of the Trousseau Hospital for Children, which also has a diphtheria pavilion and in which the serum was not used, furnish another term of comparisons. During the years 1890–1893 inclusive, 3,971 children were admitted to the diphtheria pavilion of the Paris Hospital for Sick Children and of these 2,029 died; the yearly percentages of mortality were: 1890, 55.88; 1891, 52.45; 1892, 47.64; 1893, 48.47—a mean of [51.11] per centum. During the period of serum treatment 448 children were admitted and of these 109 died, or [24.33] per cent. All the conditions being the same, except the addition of the serum to the usual treatment, the difference between these percentages measures the benefits of the antitoxin treatment. During precisely the same period in 1894 there were 520 children admitted to the diphtheria pavilion of the Trousseau, and of these 316 died—a mortality of [60.7] per cent. Obviously, the disease was not of a benign type during this period. Differentiating between the anginas and the tracheotomized croups—the anginas gave a mortality of 33.94 per cent. in 1890, 1891, 1892 and 1893; during the serum treatment period of 1894 the mortality was 12 per cent., but in the Trousseau, where the serum was not used, the mortality was 32 per cent. during the same period. The tracheotomized croups gave a mean mortality of 73.19 per cent. in 1892–93; during the serum period the mortality was 49 per

cent., but during the same period in the Trousseau the mortality was 86 per cent. Dealing only with the cases bacteriologically demonstrated to be true diphtheria—300 in number with 78 deaths,—the mortality was 26 per cent., as against the 50 per cent. mortality of the ante-serum period demonstrated by the researches of MM. Roux and Yersin and MM. Martin and Chaillou. The following table presents an analysis of 169 diphtheric anginas treated by the serum, with 21 deaths—a mortality of 12.4 per cent.:

| | Cases. | Deaths. | Mortality, per cent. |
|--|--------|---------|----------------------|
| Pure diphtheric anginas | 120 | 9 | 9.5 |
| Deduct 7 in hospital less than twenty-four hours | 113 | 2 | 1.7 |
| Anginas with associations | 49 | 12 | 24.2 |
| Deduct 4 in hospital less than twenty-four hours | 45 | 8 | 17.7 |
| Association with the small coccus | 9 | 0 | |
| Association with staphylococci | 5 | 0 | |
| Association with streptococci | 35 | 12 | 34.2 |
| Deduct 4 in hospital less than twenty-four hours | 31 | 8 | 25.8 |

There were 56 deaths in 121 croups operated on—a gross mortality of 46.2 per cent.; deduct 14 who died within 24 hours after entering, leaves 107 operations with 42 deaths—a net mortality of 39.2 per cent.

| | Cases. | Deaths. | Mortality, per cent. |
|--|--------|---------|----------------------|
| Pure diphtheric croups | 49 | 15 | 30.9 |
| Deduct 4 in hospital less than twenty-four hours | 45 | 11 | 24.4 |
| Diphtheric croups with the small coccus | 9 | 1 | [11.1] |
| Diphtheric croups with staphylococcus | 11 | 7 | [63.3] |
| Deduct 3 in hospital less than twenty-four hours | 8 | 4 | 50. |
| Diphtheric croups with streptococcus | 52 | 33 | [63.4] |
| Deduct 7 in hospital less than twenty-four hours | 47 | 26 | 57.7 |

[The deductions in the two foregoing tables are of moribund cases dying in less than twenty-four hours after admission.]

The most important German statistics with which to compare the foregoing are those of Ehrlich, Kossel and Wasserman, who report 220 cases, 168 recoveries, 52 deaths—mortality [30.9] per cent.; among these were 67 tracheotomies with 30 deaths—mortality [44.7] per cent.; in another article Ehrlich and Kossel report 55 new cases—26 tracheotomized with only 8 deaths; they do not state, however, that a bacteriologic examination was made in all cases.

English Expenditures on behalf of Public Health.—The burden of many addresses before sanitary associations and public health meetings in this country has been the impossibility of obtaining appropriations of public money for sanitary purposes. Money is appropriated freely by Congress for the general good in almost every line save in that for the protection of the people against preventable diseases; and the most liberal of our State Legislatures and municipal authorities begin to tighten the purse strings when the needs of boards of health become the subject of consideration. Is it too much to say that, generally, in matters of sanitary progress we are following in the ruts of British sanitation, and about twenty years behind, confined to this rearward position by the backwardness of legislators to give to sanitary propositions the consideration which they should command? When will a President of the American Public Health Association be able in his annual address to “point with pride” to the vast sums expended by his government for the benefit of the public health, as was done by the President of the British Sanitary Institute at the recent meeting in Liverpool? Sir Francis S. Powell, M.P., who delivered the address, restricted himself within the boundaries of public health as affected, in England and Wales, by administration and by law. It was impossible to survey the field without a sense of satisfaction, almost of triumph. The difficulties hindering progress were diminishing both in area and in gravity. Improvement in public health had justified both the cost involved and the labor expended. The Local Government Board had, during the last twenty years, sanctioned a capital expenditure, chiefly for sanitary purposes, of £53,021,334 in urban and of £3,923,270 in rural districts, while, during the same period, local Acts had authorized a further expenditure of £67,335,966; and vital statistics have abundantly proved the wisdom of these expenditures.

During these years a great deal has been accomplished in the United States; but it has been the work of individuals,

mostly members of boards of health and of the Public Health Association, operating within their jurisdictions, removing harmful influences and urging protective measures, renewing their efforts after every defeat with fresh energy, undiminished vigor and full confidence that they will ultimately be successful. To such solid and efficient federal and local support as is given to the health authorities of England, our own vital statistics would respond freely, for few of our urban or rural districts have mortality rates so low as to resist the reducing action of sanitary measures.

SOCIETY NEWS.

Mitchell District Medical Society.—The forty-sixth semi-annual meeting of the Mitchell District Medical Society will be held at Mitchell, Ind., Dec. 27 and 28, 1894. The program is an excellent one and a large attendance is expected.

The Women's Medical Club of Chicago gave their first banquet Wednesday evening, November 14. Gertrude G. Wellington, M.D., was Chairman of the Committee of Arrangements.

The Medical Society of Virginia held its annual meeting in Richmond, October 24. The following officers were elected: President, Robert J. Preston; First Vice-President, Hugh Nelson; Second Vice-President, C. M. Stegeman; Third Vice-President, John Grammer; Recording Secretary, Landon B. Edwards; Corresponding Secretary, J. F. Winn, of Richmond; Treasurer, R. T. Stile.

The American Academy of Railway Surgeons completed its organization at its meeting held in Chicago November 9 and 10, and elected the following officers: President, C. K. Cole, Helena, Mont.; First Vice-President, C. M. Daniels, Buffalo, N. Y.; Second Vice-President, W. H. Elliott, Savannah, Ga.; Secretary, Webb J. Kelly, Galion, Ohio; Treasurer, C. B. Kibley, Corry, Pa.; Editor, R. Harvey Reed, Columbus, Ohio. The next meeting will be held in Chicago, Sept. 12, 13 and 14, 1895.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has by formal vote been selected as the one in which the Transactions will be published. The constitution as adopted limits the membership to 200.

Middle Tennessee Medical Association.—The first regular meeting of the Middle Tennessee Medical Association will be held Nov. 20 and 21, 1894, in the Senate Chamber of the Capitol at Nashville. The Association will be called to order by the President, Dr. J. B. Cowan, Tullahoma, at 12 o'clock. All physicians are most cordially invited to be present.

On August 21 last, a number of the leading physicians of Middle Tennessee, in response to the call of a committee met in Nashville and effected the temporary organization of his Association. Temporary officers were elected and committees appointed, and it was decided that the permanent organization should be formed at the next meeting, the time of which was set for November 13 and 14, but the committees thought best to change the date to November 20 and 21.

It was determined at the preliminary organization, that papers and discussions should be arranged for the forthcoming meeting, and, in carrying out this idea, the Essay Committee has secured a most excellent program. The object of the Association is the advancement of medical knowledge and the promotion of a fraternal feeling in the profession, and it is intended that it shall work in unison with, and not antagonistic to, our State Society.

The Nicholson Hotel will offer reduced rates to its guests. Reduced fare will be given by the railroads, but the manner in which it is given differs in the two roads. Those who intend traveling over the Nashville, Chattanooga & St. Louis railroad must buy the round trip excursion ticket which costs one and one-third of the regular fare, and will be good until November 22. The Louisville & Nashville Road gives the reduction upon the certificate plan. Certificates of purchase of tickets should be secured from the ticket agent when starting, which certificates, when countersigned by the Secretary, will enable the holder thereof to secure return ticket at one-third the regular fare.

The following is the program: **The Climacteric: Its Phenomena and Dangers**, by J. S. Nowlin, Shelbyville. Discussed by A. H. Abernathy, Erin; **Perineal Urethrotomy: Its Indications and Technique**, by James W. Handley, Nashville. Discussed by M. Woodson, Gallatin; **Etiology and Pathology of Vascular Diseases of the Brain**, by J. R. Buist, Nashville. Discussed by W. L. Nichol, Nashville; **Differential Diagnosis and Treatment of Vascular Diseases of the Brain**, by John A. Witherspoon, Nashville. Discussed by John S. Cain, Nashville; **The Use and Abuse of Antipyretics**, by J. W. Waters, Nashville. Discussed by W. C. Bilbro, Murfreesboro; **The Treatment of Pleural Effusions**, by J. B. Murfree, Murfreesboro. Discussed by S. B. Fowler, Gainesboro; **Placenta Previa**, by F. J. Runyan, Clarksville. Discussed by J. Bunyan Stephens, Nashville; **The Methods of Conducting Gynecologic Examinations**, by W. K. Shedd, Williamsport. Discussed by W. D. Haggard, Nashville; **The Prognostic Value of Examinations, Abdominal, Vaginal and Pelvic, Before Labor**, by W. A. H. Coop, Lawrenceburg. Discussed by Thomas Menees, Nashville; **The Prevention and Treatment of Puerperal Mastitis**, by A. J. Swaney, Gallatin. Discussed by B. B. Gracey, Smyrna; **A Clinical Report on Naso-Pharyngeal Reflexes**, by L. B. Graddy, Nashville. Discussed by George H. Price, Nashville; **Differential Diagnosis and Treatment of Conjunctivitis and Inflammations of the Anterior Portions of Uveal Tract**, by G. W. Hale, Nashville. Discussed by T. Hilliard Wood, Nashville; **Is Appendicitis Essentially a Surgical Affection?** by Robert Pillow, Columbia. Discussed by John Wickham, Palmyra; **The Treatment of Severe Typhoid Fever**, by T. H. Marable, Clarksville. Discussed by G. W. Moody, Shelbyville; **Fractures of the Femur**, by Paul F. Eve, Nashville. Discussed by S. C. Bridgewater, Dixon Springs; **The Radical Cure of Inguinal Hernia**, by Charles S. Briggs, Nashville. Discussed by Charles S. Brower, Nashville; **The Significance of the Uric Acid Diathesis**, by J. B. Cowan, Tullahoma. Discussed by William Murrell, Winchester; **A Study of Acute and Chronic Nephritis**, by Hazle Padgett, Columbia. Discussed by N. D. Richardson, Jr., Nashville; **Facial Blemishes**, by C. R. Atchison, Nashville. Discussed by Cranston Nash, Nashville.

HUGH R. MILLER, M.D., Secretary.

MISCELLANY.

The Hard Times.—The funny man of the *Washington Star* says that the times are so hard that his doctor told him that even his blood was impoverished.

Change of Address.—Dr. P. O. Hooper has returned from California, to Little Rock, Ark., and has resumed practice there. Dr. Albert M. Jones to Redlands, Cal., from Eaton, Ohio.

Intubation in Sub-Glottidean Edema.—At the meeting of the Imperio-Royal Society of Physicians held in Vienna October 26, M. Chiari presented a woman 46 years old who had been attacked by stricture of the larynx due to a catarrhal inflammation of the sub-glottidean region. The dyspnea had become very intense, and M. Chiari introduced an O'Dwyer tube No. 4, but the tube was expelled by the patient in a few hours. He then introduced a No. 6 tube which remained in place almost to the next day, and it had a most favorable action on the edema and the dyspnea.—*Semaine Medicale*, November 3.

The Water-Supply at Jerusalem.—The Turkish Ministry of Public Works has determined upon the reconstruction of the ancient water conduits of Jerusalem, dating from the age of King Solomon. By this means it would be possible to convey 2,500 cubic meters of water daily to the Holy City. Of this it is proposed to give 1,000 meters away free of charge to the poor of Jerusalem, the distribution to take place at the Mosque of Omar, the Holy Sepulchre, and other places frequented by pilgrims. The new conduits are to be joined to the ancient aqueducts of Arob, and are to be carried through a tunnel 3,570 meters in length. The total outlay in connection with these works is estimated at 2,000,000 francs.—*The Sanitarian* from *London Standard*.

A Sketch of Dr. Roux.—Dr. Roux has been the assistant of Pasteur for fifteen years. Pasteur himself, who has pushed so far all researches relating to microbes and vaccinating against them, is only a chemist. When he came to study human diseases with his peculiar methods it was necessary that he should have some trained physician to assist him. He applied to Vulpian, who was then at the height of his fame and at the head of the faculty of medicine in Paris. He chose the young Dr. Roux, who was but an unknown student.

Fortunately the student was of the stamp of Pasteur himself. He is capable of working twelve or thirteen hours a day week after week, and he is as curious to know as he is keen in understanding the results of his observation. He has had a great deal to do with all of Pasteur's discoveries, from the vaccine against carbuncles to that against hydrophobia. The discovery of the special poison of the microbe of diphtheria and croup was made by a German professor of Berlin, but he was unable to reduce it to a method of practical vaccination. It is this which has occupied Dr. Roux for the last two years. The 2,500 doctors assembled together in Budapesth from all parts of the world seemed to believe that he has at least been partially successful. This is already a great deal in the disease which has been called the world over the terror of mothers.

In personal appearance Dr. Roux resembles an English Protestant minister more than a French doctor. He is tall, thin, with blond hair, and a small head from which keen eyes look piercingly. He is always dressed with the utmost soberness, wearing no ornament but the rosette of officer of the Legion of Honor, which was given him at the jubilee of Pasteur himself. He looks on strangers with distrust, and the mention that one is a journalist is sufficient for him to wrap himself in icy silence. Some of the Paris journalists have even had a harsher experience at his hands. They have at least learned that the power of his tongue is as great as that of his knives.

He belongs to the vigorous peasant race of Auvergne, where he was the schoolmate of M. Dupuy, the present Prime Minister of France. The latter is full-faced and jovial. There could be no greater contrast between two men, but they are always great friends. Dr. Roux has never married. He lives with his widowed sister, to whose children he gives a parent's attention. Wonders are also told of his charity. It is certain he never tells of it himself—nor apparently of much else that comes his way until it is ready to be of some use.

All last winter his daily visits to the children's hospitals were enough to exhaust the strength of one man. But he was often seen in the remote quarters of Paris at the bedside of little ones down with the terrible disease. Sometimes he has passed the whole night watching them. When the poor parents in the morning asked what they could give him the famous physician darted out of the door and disappeared as if afraid of their thanks. This disinterestedness, which he carries to an extraordinary degree, is known to all his associates of the Institute. He is now the head of the service, but as the Institute is always in want of funds he does not even draw the small salary which is allotted him. His friends say that he belongs to another age, that he knows nothing of money and cares less, and that he has given up his whole existence to serve science and humanity. Among his other good qualities is an absolute devotedness to the person of Pasteur, whom he rightly considers his master. He is one of the best bicyclists in Paris and arrives each morning at the Institute on his wheel.—*Boston Transcript*.

Illinois State Board of Charities.—The following circular has been issued:

CHICAGO, Oct. 22, 1894.

The State of Illinois has about 7,000 insane in public and charitable institutions. Five thousand are cared for in State hospitals; the remaining 2,000 are in hospitals and wards of poor-houses of the counties.

Governor Altgeld decided in 1892 that the existing State hospitals should not be enlarged, but that a new hospital should be built. In order to avail ourselves of the most advanced thought and of recent experience, we beg to address to you the following circular containing a number of questions to which you will be kind enough to give us an answer from your personal experience:

Would you prefer care of the incurable in county asylums and poor-houses at the expense of the counties, to care at the expense of the State, either with more State supervision or with concentration of those patients in State hospitals?

Does the difference in the needs between curable and incurable patients justify the construction of a less expensive hospital for the chronic incurable?

What percentage of patients do you judge fit for work on a farm? (After the plan of Alt-Scherbitz in Germany. First, male; second, female.)

Is a separate institution for epileptics desirable, and to what extent will it relieve the insane hospitals?

Is the Scotch boarding-out system feasible in this country?

Which is, to your knowledge, the best plan for a hospital of a thousand patients?

1. For largely acute cases. (What percentage of those cases would require special medical care and nursing in real hospital wards and watch-wards, after the arrangement of Dr. Scholtz in Bremen, compare *allg. zeitschr. f. Psychiatrie*, Vol. L.)

2. Hospital for chronic patients.

Very truly yours, BOERNE BETTMAN, M. D.,
President Illinois State Board of Charities.

Louisville Notes.

FALLS CITY MEDICAL SOCIETY.—At the regular meeting November 8, the paper of the evening was read by Dr. W. R. Blue, upon "Vegetable Parasitic Diseases of the Skin." Of the different varieties mentioned he said that he had never seen a case of *tenia tonsurans* in an adult. He advised quarantine. Of the thirty-four cases reported the average duration of the treatment with the remedies below was five months. His success was in part due to the regularity and persistence of the treatment. The following was recommended as a routine treatment: First soak the scalp and rub well the affected parts with a 5 per cent. carbolic ointment; shampoo with tr. green soap; paint on the spots a solution of bichlorid of mercury dissolved in tr. benzoin co. of the proportions of 2 or 3 grains to the ounce. Over this is painted flexible collodion. This dressing remains intact for four or five days; it should then be removed and the bichlorid solution re-applied as before. Dr. Butler reported the case of a man brought into the City Hospital with delirium tremens. He was very violent and was put into the cell under the care of an attendant. His hands were confined in a jacket, but while the attendant was gone from the room for something he succeeded in freeing them and when next seen had pulled his tongue out with both hands and had bitten it in two, the severed piece several hours afterward measuring two and three-fourths inches. He had a great deal of hemorrhage which was with difficulty stopped by the application of subsulphate of iron. His pulse grew rapidly weaker and he died a few hours afterward. The interesting part of the case is the fact that the patient could articulate plainly even after his tongue was severed.

THE CITY HOSPITAL.—Several interesting cases have been admitted to this institution during the past month. Three are of particular interest:

Case 1.—A man walked into the hospital saying that he had been cut in a fight. An examination showed the following: A cut in the cervical region of the left side which extended down to the vertebra and cut off a piece of the transverse process, severing one of the arteries; considerable hemorrhage took place from this wound. In the right mid-axillary line, about in the lumbar region, there was a superficial cut four inches long, extending through the skin and fascia. On the left side there was a descending cut which severed the eighth and ninth ribs, cut through the diaphragm into the abdominal cavity, and made a large cut in the spleen. Shortly after, a laparotomy was done, the incision being made in the median line, but no wound of the gut was found. The omentum protruding from the wound in the side was replaced, the cavity flushed, the wound in the spleen packed, a drainage tube inserted and the median wound closed. The patient went on the table in a fairly good condition and remained so until the chloroform was stopped when he began to grow weaker, his pulse rapid and he died thirteen hours after the cut was received.

Case 2.—A penetrating gunshot wound of the abdomen. The wound of entrance was between the seventh and eighth ribs in the post-axillary line. Exploration with the finger showed it to range downward and inward to the liver. Abdominal section was done and the cavity found full of blood, but no wound of the gut was found. The cavity was washed

out and the wound packed. The patient did not rally and died three days later.

Case 3.—Gunshot wound of the abdomen. Ball entered in the left iliac region ranging upward and penetrating the cavity. A laparotomy was done and much blood found in the cavity with a wound of the stomach below the omental attachment near the cardiac end; two penetrating wounds of the transverse colon were also found. The wounds were closed, the cavity flushed and the abdominal incision closed with drainage. There was no shock present but the patient died twenty-four hours afterward.

The report of the hospital for the month past shows an average number of patients in the hospital as 127 per day. There were twenty-one deaths. The average cost of the entire force, including patients, was 80 cents; the average cost per day for the patients' diet was 17½ cents; the average cost of each patient was 50 cents per day.

HEALTH REPORT.—The Health Officer's tabulated report for the week past shows a total of fifty-three deaths. This list includes nine deaths from phthisis, four from pneumonia, and three each from organic disease of the heart, Bright's disease and cerebral meningitis. Three of the deaths occurred at the City Hospital. There were four still births. The Health Officer has had a most excellent ordinance passed for the regulation of the school children as to successful vaccination, by which a complete record of all the children in the city is kept. Details of this will be written in the next letter from your correspondent here.

Washington Notes.

MEDICAL SOCIETY OF THE DISTRICT.—At the Medical Society November 5, Dr. F. B. Bishop read a very instructive essay on electric batteries and some of their distinctive features in the treatment of disease. Dr. Acker presented a patient suffering with scleroderma. Dr. E. F. King presented a specimen of aneurism of the aorta. Dr. A. A. Snyder exhibited some fluid aspirated from a lumbar abscess supposed to be a pyonephrosis.

THE WOMAN'S CLINIC.—The annual meeting was held on the 6th inst. The report of the work for the year was received from the medical staff, and shows a steady increase in the attendance. This hospital is conducted entirely by women physicians and supported by voluntary subscriptions. The election of officers for the ensuing year was postponed to an adjourned meeting to be held two weeks later.

ASSISTANT CHEMIST APPOINTED.—Secretary Morton has appointed Dr. W. G. Brown, Professor of Chemistry in Washington and Lee University, Lexington, Va., First Assistant Chemist of the Division of Chemistry, Department of Agriculture, vice Dr. G. L. Spencer, resigned.

TRAINING SCHOOL FOR MISSIONARIES.—The Washington Order of Deaconesses is extending its work, and now proposes to establish a home and training school in this city for nurses and workers in the missionary field. Articles of incorporation were recently filed by the members of the society with this in view. The new organization will include the Lucy Webb Hayes Deaconess Home, the Sibley Hospital and the Nurses' Training School of the order. It will be known as the National Training School for Missionaries, and will be managed by the members of the Methodist Episcopal Church. The incorporators were Jannett C. Fisk, Elizabeth L. Rust, A. Lewis Clark, Jane Bancroft Robinson, G. McDowell, Hiram Price, Harry L. Roche, B. H. Stinnetz and John F. Hurst.

MARINE-HOSPITAL SERVICES IN WASHINGTON CITY.—Passed assistant Surgeon H. D. Geddings, has been detailed to assist the Health Department during the continuance of smallpox in the District. Surgeon P. H. Bailhache, of the New York Marine-Hospital, has been detailed at Washington in connection with the same service, and has investigated the present outbreak and made a very careful report to the same to the Surgeon-General, whose personal representative he is. The Department has been using its large steam disinfecting chambers at the quarantine station under the direction of the local Health Department.

THE HOMEOPATHIC MEDICAL COLLEGE IN COURT.—In the suit for equity filed Oct. 14, 1893, by the Washington Homeopathic Medical Society, asking for an injunction against the Na-

tional Homeopathic Medical College, the plaintiff on the 9th inst., filed an amendment and supplemental bill.

After reciting the fact of the filing of the original bill the plaintiff states that the defendants were served with process, and although they made emphatic declarations through the public press of their desire to be heard, and to vindicate themselves, they have never answered the bill, and have sought to delay their answer by raising a technical objection to the form of the summons, insisting that the District of Columbia corporation is entitled to sixty days within which to answer, and the defendants have never made the slightest effort to bring the cause to a hearing.

In defiance of the outraged sentiment of all the reputable physicians of the District of Columbia, the bill goes on to say, the defendants, or one of them has during the past year pretended to conduct a homeopathic medical college in which they profess to give instruction in the science of medicine.

The plaintiff claims that the defendants have made no addition to their equipment nor any improvement in the personnel and standing of their so-called faculty; that they succeeded by unscrupulous advertisement in deluding into attendance some persons honestly desirous of obtaining a medical education; that in at least one case it has granted a diploma to a person who has actually studied medicine for not exceeding seven months in the alleged college; that in another case it has granted a diploma to a person who was forced out of a recognized and respectable medical school because of absolute inability to pass any examination, and that the defendants, for the purpose of attracting students, have continued to advertise, as members of the faculty, the names of physicians who had previously positively refused to be identified with the college or to allow their names to be used in connection with it.

The court is asked that the defendants, pending the suit and perpetually may be enjoined from conducting said alleged college.

HEALTH OF THE DISTRICT.—The report of the Health Office for the week ending November 3, is as follows:

| | |
|---|--------|
| Number of deaths (still-births not included): | |
| White | 63 |
| Colored | 62 |
| | — 125 |
| Death rate per 1,000 per annum: | |
| White | 16.8 |
| Colored | 35.8 |
| Total | — 22.8 |
| Death rate per 1,000 per annum for corresponding week last year | 18.4 |
| Still-births: | |
| White | 5 |
| Colored | 8 |
| Total | — 13. |

NEW ORDERS FROM THE HEALTH DEPARTMENT.—The Commissioners, after a lengthy consultation with the Health Officer, approved the following order:

WHEREAS, Smallpox now exists in this District. I therefore direct that parents and guardians shall cause their children and wards to be successfully vaccinated or to be re-vaccinated, except in such cases as have been successfully vaccinated within five years from the date of this order, or as have been protected from infection by a previous attack of smallpox or varioloid.

The late Board of Health, in accordance with an Act entitled "An Act for the prevention of disease in the District of Columbia," passed by the Legislative Assembly of the District, and approved by the Governor June 19, 1872, made the following regulations, among others, in regard to smallpox, and on this the recent order is based:

"Parents and guardians shall cause their children and wards to be vaccinated before they attain the age of 2 years and re-vaccinated whenever the Board of Health shall, after five years from the last vaccination, require it.

"The Board of Health hereby orders and requires the vaccination of all the inhabitants in the District of Columbia, and, whenever, in their opinion, the public health demands it, the re-vaccination of all persons who do not furnish satis-

factory evidence that they have been successfully vaccinated within five years.

"All school trustees, school teachers or others having authority are forbidden to receive into or allow to attend any school, public or private, within the District of Columbia, any pupil not vaccinated, as required by the 'rules and regulations' heretofore made and promulgated by this Board."

The foregoing regulations were legalized by joint resolution of Congress, approved April 24, 1890, and again by an Act of Congress, approved Aug. 7, 1894, which Act provides "that the powers and duties imposed upon the late Board of Health in and by said ordinances are hereby conferred upon the Health Officer of the District."

The drafting of this order was the result of a complaint filed with the Commissioners a few days ago by a parent whose child had been declined re-admission to a public school because of a failure to be vaccinated. They also approved the following:

"That the aforesaid regulations shall apply to all cases of smallpox, varioloid or suspicious cases of disease not distinguished from the aforesaid diseases, provided that the flag or warning placard shall be displayed only upon such premises as are known to be infected with smallpox or varioloid."

SMALLPOX HOSPITAL.—All cases at the hospital are doing well and soon their final disposal will be considered. Dr. Benj. Bell has resigned the position of smallpox inspector, and Dr. L. Elliott has been appointed to fill the vacancy.

Hospital Notes.

THE MEDICO-CHIRURGICAL HOSPITAL OF PHILADELPHIA.—During the month of October, 245 patients attended the eye department of this institution, and 1,225 visits were made by old patients. The prescriptions given for glasses numbered 135. Thirty operations were performed. In the ear department, ninety-five new patients were treated. Fifty-four applied to the throat department. Forty-eight new patients received treatment for nervous diseases and twenty-eight children were prescribed for in the children's department.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Nov. 3, 1894, to Nov. 9, 1894.

Capt. WALTER W. R. FISHER, Asst. Surgeon, will be relieved from duty at Ft. Columbus, N. Y. It., upon the expiration of his present leave of absence, and will report for duty at Ft. Meade, S. Dak., to relieve Capt. NORTON STRONG, Asst. Surgeon. Capt. STRONG, on being relieved by Capt. FISHER, is ordered to Ft. Sheridan, Ill., for duty at that post, relieving First Lieut. GEORGE J. NEWGARDEN, Asst. Surgeon. Lieut. NEWGARDEN, on being relieved by Capt. STRONG, is ordered to Ft. Wayne, Mich., for duty.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending Nov. 10, 1894.

P. A. Surgeon F. J. B. CORDEIRO, from U. S. S. "Adams," home, and granted two months' leave.

Asst. Surgeon L. H. STONE, ordered for examination preliminary to promotion.

Medical Director J. H. CLARKE, Medical Inspector C. H. WHITE, Surgeon T. H. STREETS, P. A. Surgeon A. C. H. RUSSELL, ordered as a Board at Naval Laboratory, Brooklyn, N. Y., to examine candidates for admission to the Medical Corps of the Navy, and for promotion in the Corps.

Marine-Hospital Changes.—Official list of changes of stations and duties of medical officers of the U. S. Marine-Hospital Service, for the six weeks ending Nov. 3, 1894.

Surgeon P. H. BAILHACHE, to report at Bureau for special temporary duty, Oct. 25, 1894.

Surgeon GEORGE PURVIANCE, granted leave of absence for five days each, Oct. 2, 1894, and Oct. 29, 1894.

Surgeon W. H. H. HUTTON, to proceed to Gulf Quarantine Station for temporary duty, Oct. 24, 1894.

Surgeon H. W. SAWTELLE, when relieved from duty at Boston, Mass., to proceed to New Orleans, La., for duty, Oct. 26, 1894.

Surgeon J. M. GASSAWAY, when relieved from duty at New Orleans, La., to proceed to Cairo, Ill., October 27, 1894.

Surgeon FAIRFAX IRWIN, to report at Bureau, Oct. 19, 1894.

Surgeon F. W. MEAD, to proceed to New York, N. Y., for temporary duty, Sept. 24, 1894.

P. A. Surgeon C. E. BANKS, to proceed to Bath, Maine, as inspector, Oct. 20, 1894. Granted leave of absence for three days, Nov. 3, 1894.

P. A. Surgeon C. T. PECKHAM, granted leave of absence for twenty-two days, Oct. 16, 1894.

P. A. Surgeon S. D. BROOKS, to proceed to Saginaw, Mich., as inspector, Oct. 26, 1894.

P. A. Surgeon W. P. MCINTOSH, granted leave of absence, Oct. 9, 1894.

P. A. Surgeon A. H. GLENNAN, granted leave of absence for two days, Sept. 29, 1894. Granted leave of absence for three days, Oct. 21, 1894.

P. A. Surgeon H. D. GEDDINGS, detailed for special duty, to assist the health authorities, District of Columbia, Oct. 27, 1894.

Asst. Surgeon C. H. GARDNER, to proceed to Angel Island Quarantine Station for temporary duty, Oct. 13, 1894.

Asst. Surgeon J. A. NYDEGGER, granted leave of absence for eighteen days, Sept. 24, 1894. Leave of absence extended three days, Oct. 17, 1894.

Asst. Surgeon W. J. S. STEWART, to proceed to Alexandria, Va., as inspector, Oct. 10, 1894. To proceed to Glymont, Md., for special duty Oct. 29, 1894.

Asst. Surgeon EDGAR STRAYER, granted leave of absence for fourteen days, Oct. 24, 1894.

Asst. Surgeon KUPERT BLUM, granted leave of absence for three days Nov. 3, 1894.

Asst. Surgeon SEATON NORMAN, to proceed to New York, N. Y., for temporary duty, Oct. 25, 1894. To rejoin station, Baltimore, Md., Nov. 1894.

Asst. Surgeon E. K. SPRAGUE, granted leave of absence for thirty days Oct. 10, 1894. When relieved from duty at Cairo, Ill., to proceed to Mobile, Ala., for duty, Oct. 29, 1894.

Asst. Surgeon, A. R. THOMAS, to proceed to Cairo, Ill., for temporary duty, Oct. 5, 1894.

Asst. Surgeon J. B. GREENE, to proceed to New York, N. Y., for duty, Oct. 27, 1894.

APPOINTMENT.

JOSEPH B. GREENE, of Alabama, commissioned by the President as an Asst. Surgeon, Oct. 24, 1894.

LETTERS RECEIVED.

ORIGINAL ARTICLES.

AMETROPIA IN MICROSCOPIC WORK.

BY CAPTAIN CHARLES E. WOODRUFF.

ASSISTANT SURGEON U. S. A.
FORT SHERIDAN, ILL.

Every worker with the microscope who has a refractive error which compels him to wear correcting glasses, has probably tried to wear them in his work, but finding them inconvenient has discarded them to discover that the view of the field was apparently just as good without as with them. A moment's consideration of the optical principles of the microscope will show that in cases of myopia, hypermetropia and presbyopia, glasses are totally unnecessary, as every one is probably aware. Only a very slight movement of the fine adjustment is necessary to throw the image to a point where the person can see

distinct vision without glasses when the full accommodation is in play.

If a person with myopia of high degree, say 8 D., uses the microscope, he must have *c* within his far point, approximately within five inches of his eye, *b* must then be brought nearer the eye-piece, by screwing down the microscope so that *a* is nearer to the focus of the objective. The nearer *a* approaches *x* the farther *b* recedes from *x* and *y*, and the more *b* recedes from *y* the nearer *c* approaches the eye-piece.

The normal eye with the accommodation entirely relaxed, or the presbyopic eye which has no power of accommodation whatever, must have the image *b* at the focus *y*, so that *c* may be at infinity, and rays of light from any one point will enter the eye parallel. The hyperopic eye which is also presbyopic will have *b* outside of *y*, so that the image *c* will be at the negative far point behind the observer's head and the rays of light converging. These movements can be

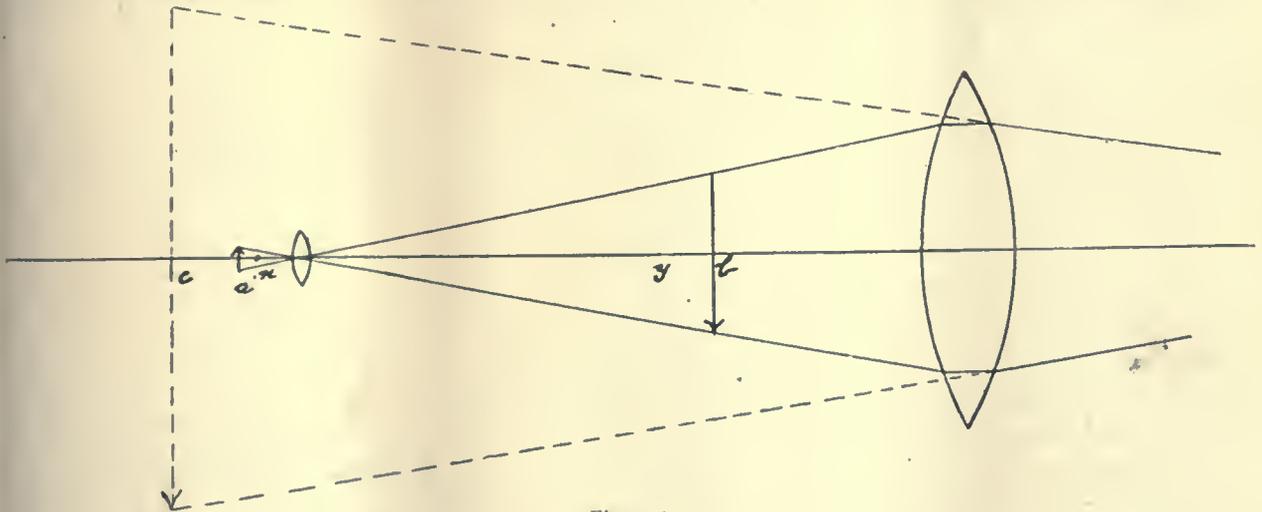

Figure 1.

it clearly. For convenience the eye-piece and objective may each be considered as a single convex lens, and Fig. 1 shows that the objective forms an image *b* just within the focus *y* of the eye-piece, the object *a* being just beyond the focus *x* of the objective.

The eye-piece enlarges the image *b*, throwing it back to *c*, just like a common magnifying glass. Most persons unconsciously use their accommodation while looking through the microscope. Though it is said that the image *c* is usually placed about twelve to fourteen inches from the observer's eye, it is quite probable that the majority of persons by adjusting the instrument cause it to come still nearer; at least as near as the slide. A myopic person brings *c* at least to his far point, and perhaps nearer, so that he exerts his accommodation. The hypermetrope also uses his accommodation and the presbyope may, if he has any power in this direction, but for both, the image can not be brought nearer than the nearest point of dis-

deduced from a study of the elementary rules of optics. For any of the above conditions accommodation is not necessary, as the virtual image can be thrown to the observer's far point, but as already stated most observers do use their accommodation in microscopic work, the image being thrown within their far point.

If the microscope is fixed so that the above myope of 8 D. has a distinct view of the field, let us see what change is necessary in order to give a perfectly clear picture to a person whose refractive error or defect of accommodation renders him unable to see anything nearer than four feet; *c* must now be more than four feet from the eye-piece; to accomplish this *b* must be moved quite near to *y* and for this purpose *a* must be moved farther from *x*, that is, the microscope must be raised from the slide; *b* is so near the focus of the eye-piece that a slight movement to or from the focus, causes *c* to make a very marked movement

from or towards the lens. As b is so much farther away from the objective than a , its position suffers a very marked change for the slightest movement of a towards or from the objective. Consequently the most minute movement of the microscope towards the object, makes a very marked change in the position of c . How slight a movement of the microscope is necessary may be judged from the following approximate estimates. Supposing the instrument is adjusted for the myope of 8 D., the tube is moved upwards by the following turns of the fine adjustment, in order to make clear vision for a person whose nearest point of clear vision is about four feet.

| Objective. | Turns of Fine Adjustment. |
|-----------------------|--|
| 2 inches | About 965 degrees |
| $\frac{3}{4}$ inches | About 180 degrees |
| 1.5 inches | About 10 degrees |
| 1-12 inches immersion | A mere touch, probably less than 3 degrees |

In the high powers the change is very slight, as above figured, because a is so near the focus of the objective, that a tiny movement would send b to infinity.

The actual conditions of the microscope are far too complex even to allude to here, but the above demonstrations, approximate though they be, seem sufficient for the purpose of following out the movements of the image c caused by movements of the objective to or from the object.

Though the number of diameters of enlargement of any combination of lenses, varies according to the distance at which the observer thinks he sees the image, it also varies according to the state of the observer's refraction. The above shows that for the same combination of eye-piece and objective, there is not the same amount of enlargement of the image for the myope as for the hypermetrope. The image c appears slightly larger to the myope and really is larger. As c must be near the eye, b must be much farther from the objective than for the hypermetrope. Moving b from the objective by moving a towards the objective, increases the size of b very markedly, particularly in the higher powers, where the distance of a from the objective is so small in comparison to the distance of b from the objective. To be sure there is less enlargement caused by the eye-piece when c is very near, but the eye-piece has so little influence on the total enlargement as compared with the effect of the objective, that it can safely be discarded in this demonstration. Hence there is a positive advantage in the myope using the microscope without his glasses.

For the astigmatic the conditions are entirely different. *A priori* one would suppose that after focusing the instrument for lines parallel to his axis of greatest refraction, he will not be able to see lines at right angles to these without altering the position of the instrument and throwing the first set out of view. We would judge, then, that the astigmatic observer can not obtain a distinct view of the objects of the field without using a correcting cylinder equal to his own astigmatism, and that unless he does this he will have an erroneous idea of the thickness of the object, from the very fact that he is required to throw the instrument up and down by the fine adjustment in order to see the lines lying in the various angles from his own meridian of least, to that of greatest refraction. This is true to but a limited

extent. In astigmatism of 1 to 2 D., there does not appear to be any appreciable difference in distinctness whether the glasses are used or not, except perhaps in the very lowest objectives. In astigmatism of high degree, say 4 or 5 D., there is a marked indistinctness in using the lowest objectives, but the field becomes clearer with higher powers and with one-fifth or one-eighth objectives it is quite probable that there is an indistinctness only in the very highest grades of astigmatism above 6 or 8 D., forms of the very rarest occurrence.

The reason why the microscope thus corrects the observer's error of astigmatism is probably found in the optical principles by which the microscope is given *penetrating power*. With a good instrument

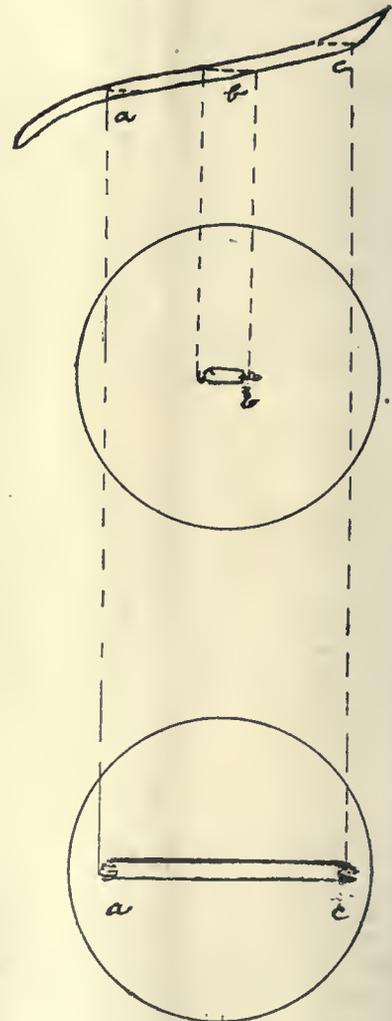

Figure 2.

the field is not a single plane through the object, but includes an appreciable thickness of the object looked at. Everything in this thickness is seen clearly, objects on the bordering planes indistinctly, and those above and below not at all. For instance, in looking at a fiber that is placed obliquely to the axis of a microscope with no penetrating power, we would see only a cross section of the fiber as at b . (Fig. 2.) Owing to the penetrating power we are able to see considerable of the fiber distinctly, say from a to c .

Take a single point of the object looked at, say at a . (Fig. 3.) All the rays from a are brought to a focus at b . Theoretically, there is only one point

where the image is formed, and for our purpose we may consider that there is no spherical or other aberration. At each side of b there are circles of diffusion and each point of light becomes diffused over a circle which increases in size, the farther we remove from b . Now the angle formed at b by the most divergent rays c and d is very small, owing to the great distance of b from the lens in comparison with the diameter of the lens. Hence for a considerable distance on each side of b the circles of diffusion are so small that the retina can not perceive them. Every amateur photographer has noticed that if he uses a diaphragm with a small aperture, there is an appreciable space in which he may move the ground glass of his camera back and forth and still have his scene in accurate focus. In the microscope, objects nearer or further from the lens than a , say a' and a'' and which will be accurately in focus at b' and b'' have circles of diffusion at b that are too small to be seen. The eye-piece forms a clear image of every point in focus theoretically between the two points b' and b'' . Images beyond b' and b'' are blurred as their circles of diffusion are large enough to be seen, and points of light are recognized as circles.

The penetrating power is increased by the fact that

The warped surface of the cornea between the meridians of greatest and least refraction would theoretically prevent clear vision of lines at other angles than the above, but in the milder grades of astigmatism the warping is probably not sufficient to be noticeable, and these lines are clearly seen, as they should be in focus between b' and b'' . Thus it happens that the astigmatic eye has clear vision in the microscope, providing the astigmatism is not very marked, and can be neutralized by the penetrating power of the microscope.

If the astigmatism is so great that the image of the lines in the meridians of least and greatest refraction should be beyond b' and b'' then the eye can not see them without using the fine adjustment and giving the idea of increased depth or thickness to the object observed.

In the two inch objective, there does not seem to be any indistinctness until the astigmatism approaches .25 to .50 D., and for the other objectives the amounts in the table:

| | |
|---------------------------------|--|
| 2 inch | .25 to .50 D |
| $\frac{3}{4}$ inch | .50 to .75 D |
| 1.5 inch | 3.00 D |
| 1-12 inch (immersion) | .8. or 10. D. and probably higher still. |

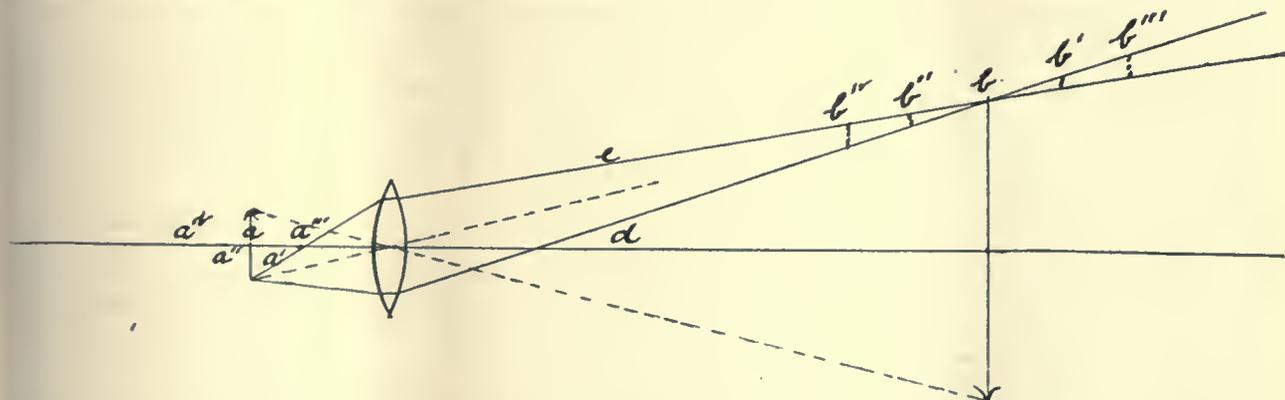

Figure 3.

though the observer's eye is accommodated for the image c (Fig. 1), it can at the same time still see images nearer and farther away than c . This can be explained by considering that the circles of diffusion of these images are too small at c to be noticed. The eye itself has considerable "penetrating power;" that is, if accommodated for a point, say, three feet distant, it can still distinctly see objects much nearer and farther away without altering the accommodation. The point of indistinctness is reached when the circles of diffusion on the retina become large enough to be noticeable or, in other words, when they lay over into adjacent nerve endings.

Now imagine at a , a series of radiating lines like the test card for astigmatism, such as every ophthalmologist uses. They are all in focus at b . An observer with astigmatism who looks at them through the eye-piece, requires the focus of the line parallel to his meridian of greatest refraction to be at b'' so as to be thrown to the far point of his meridian of least refraction. Lines parallel to his meridian of least refraction similarly should be at b' . Though they are both in focus at b , their circles of diffusion are so slight at b' and b'' that when the eye-pieces form images of b' and b'' at the proper points, in front of, and back of c , the eye sees them clearly.

The effect of the microscope in neutralizing the bad vision of the astigmatic increases with the power used, because the higher the power the smaller is the angle at b (Fig. 3) between the most divergent rays c and d , and consequently the greater is the distance between b' and b'' in which the circles of diffusion are too small to be noticeable.

There is a shifting of the apparent depths of lines, so that, though the astigmatic eye sees a field with great clearness, it is not the same field seen by the emmetropic eye. Referring to Fig. 3 again, the emmetropic eye sees all lines in the depth between a' and a'' . Supposing the astigmatic eye should have lines in a certain direction in focus at b' , it is quite evident that it will see all lines in that direction that are in focus anywhere between b and b'' . In other words, lines that are lying in this direction, are seen providing they are at any depth between a and a'' while parallel lines at other depths are invisible. Similarly, lines at right angles to the above are seen clearly if they are at any depth between a and a'' and all others in this direction are invisible.

The figure supposes that the microscope is just sufficient to correct the astigmatism of the observer. If it is more than sufficient, the eye will see the first set of lines if they are at a lower depth than between

a and a'''' that is, some will be below a and some above. Lines at right angles to these will be seen if in a higher layer than a to a'''' . Except for the higher grades of astigmatism, the shifting of the apparent depths of lines at various angles is so trifling that it need not be considered in practical work. In the one-twelfth immersion there is no appreciable change in this respect, even with an astigmatism of 13 D., though there is some interference with clearness. It need be taken into account only in using low powers where a drawing is made of a supposed object of a certain thickness, when what is really drawn consists of intermingled lines from different depths.

The acuity of vision for distant objects suffers a marked diminution as a result of astigmatism. This follows from the peculiar shapes assumed by the circles of diffusion. The expression, "circles of diffusion," is a misnomer here, because *circles* are formed at but one point. The figures are quite complex. A point of light is brought to a focus in a line parallel to the axis of greatest curvature, and at another place in a line perpendicular to the first. Beyond and between these two foci, the diffusion figures are ellipses and at only one point a circle.

Hence it follows that the acuity of vision suffers also in microscopic work, though to a very slight extent. Nevertheless, it is noticeable in high grades of astigmatism, even where there is no apparent shifting of the depths at which objects are seen. Observers with high grades of astigmatism, over 3 or 4 D., are better off if they use a correcting cylinder placed over the eye-piece. Certain microscopists certainly do see and figure most remarkable things that other observers can not succeed in seeing. Much depends on acuity of vision, *i.e.*, a good retina, yet it is safe to say that the frequent accusation of inaccuracy due to errors of refraction of the observers will not hold water, particularly with the higher objectives.

Persons with errors of refraction can therefore assure themselves that no correcting lenses are needed in microscopic work, except perhaps in astigmatism of high grade, and then only when using the lower powers. The spectacles may be discarded for almost all ordinary work. If much astigmatism exists and he desires to picture what the emmetropic eye will see, then the glasses may be used or, better still, a cylindrical glass of proper strength and at proper angle, may be placed on the eye-piece. It is of no consequence whether a convex or a concave cylinder is used.

A convenient method of placing the cylinder over the eye-piece has a soft steel frame, holding the cylinder, and has three soft steel bars to bend over and hold it in place. It was made for me by Meyrowitz, of New York. With its aid, the constant motion of the fine adjustment is less, and there is the absolute certainty that the objects seen in the field are what the emmetrope sees, but as before mentioned it is of no earthly use except: 1, in very high grades of astigmatism; or 2, in moderate grades in using the lower powers. Accurate observation with the higher objectives is compatible with quite a great astigmatic defect.

The spectacle frame prevents the eye being approximated closely to the eye-piece, and therefore restricts the extent of field. Its other inconveniences follow from its obliquity, and therefore its dispersion and reflexion of much of the light coming from the image. The brightness of the field is diminished.

Its obliquity also alters the correcting power of the lenses on well-known principles.

Perhaps observers who wear spectacles may find it comfortable and convenient to use a special contrivance, similar to the bifocal spectacles (Franklin's), but with the lower lens omitted and the upper ones consisting of their usual correcting lenses. They can then look under their lenses when using the microscope.

The writer has tested the vision of an observer who has an astigmatism of 5.00 D. When using the two inch objective there is a marked interference with clearness if the cylindrical spectacles are omitted. A flat circle appears as an oval, and only a portion of the circumference is clear at one adjustment. As the instrument is screwed down, other parts of the circumference come in sight so that this shifting of the apparent depths of parts of the circumference gives the impression that the object seen is of the shape of a circle bent upwards.

In using the $\frac{3}{4}$ objective, there is barely a noticeable indistinctness when he removes his spectacles, but so slight in degree that it would not be noticeable if his attention had not been directed to it. With the $\frac{1}{2}$ objective, there is absolutely no difference in the appearance of the field, whether he looks through his spectacles or not.

The conclusions reached above may also be verified by making the eye ametropic by placing various spherical and cylindrical lenses in front of it, and observing the changes in the appearance of the field if any are noticeable. Such a demonstration is not mathematically exact but it is near enough for practical purposes.

The question of asthenopia resulting from microscopic work is entirely foreign to this paper, but it might be remarked in passing that it is due to bad light, bad position, congestion from constrictions around the neck, the habit of using the accommodation too much and unnecessarily, and to other conditions, but it is *not* due to the observer's errors of refraction. It is intended here, only to call attention to the fact that ametropes have clear vision in using the microscopes without their correcting lenses, and that it is unfair to accuse an observer of incorrect observation because his refraction is not normal.

Prehensile Feet among the Japanese.—The art of "getting there with both feet," which Japan has been illustrating in her treatment of China, seems to be a natural endowment. M. Michaut, the anthropologist, who has been investigating the subject, finds that the Japanese have marvellous address in the use of their feet as means of prehension. These members possess extraordinary mobility; the first metatarsal bone is separated from the second by an interval which may measure from eighteen to twenty millimeters, and the ball of the great toe may be made to touch the two adjoining toes. The Japanese rest on their knees, the feet in forced extension lying on the dorsum inclined inward and crossed one on the other, thus forming a little bench on which the pelvis rests. All the Annamites—the Cochin Chinese, the Tonkinese and the Annamites properly so-called—also have a remarkable separation of the great toe, amounting to from three to five millimeters and prehension also is possible. This can not be attributed to their footwear as might be the case with the Japanese, since the Annamites either go barefoot or wear sandals; nor to adaptation to environment, because they are inhabitants of the plains. History tells us of the kingdom of Gao-Chil, or the people of the "bifurcated toes," who presented this ethnic peculiarity of widely separated great toes in its maximum degree, and examples are still met with—in some families the anomaly being hereditary and descending usually from father to son.

PEDIATRICS AS A SPECIALTY.

CHAIRMAN'S ADDRESS.

Read in the Section on Diseases of Children, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY W. S. CHRISTOPHER, M.D.

PROFESSOR OF DISEASES OF CHILDREN CHICAGO POLICLINIC; PROFESSOR OF PEDIATRICS COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO.

Is disease in children sufficiently distinct from disease in adults to merit separate and special consideration? It is not intended to submit this question to the members of this Section, for doubtless the answer would be unanimously in the affirmative. It is not so certain, however, that the answer would be the same if the question were submitted to the profession at large. Here I can only use it as a text upon which to set forth some of the reasons for our answer.

A few years ago Dr. Goodhart, of London, in his address as Chairman of the Section on Diseases of Children, of the British Medical Association, took the ground that there was no such thing as a specialty of diseases of children. A similar stand is taken by Ewald with reference to "Diseases of the Stomach." With Ewald I can heartily agree; with Goodhart as heartily disagree, and for much the same reasons.

He who looks at a stomach only, does not look far enough, but he who considers a child, has before him a biologic totality, temporary though it be. It is certainly true that many diseases are so nearly alike in both adults and children that a separate consideration of them from the two standpoints leads to little or no additional information, or to any broader conceptions.

It is equally true that to regard the child without reference to the future adult is but partial work. Pediatrics deals not only with the child as an individual, but as an episode in the development of the future adult, and its most comprehensive aim may be expressed as the attempt to control the environment of the child so as to produce the most perfect possible adult. The accomplishment of this object necessarily demands an intimate acquaintance with the pathology of adult life, so that the possible pathology of the particular future adult may be foreseen and the child's environment managed to avoid this as far as possible. But this necessary intimate acquaintance with disease in adults can only be obtained at the bedside. After all, this is only another way of saying that the specialist should develop from the general practitioner, and not attempt to specialize too early. It is sad to see, as I have seen, a skilled ophthalmologist carefully treat a child's eyelids and not realize that the child was seriously ill from pneumonia. Such an instance is no argument against the existence of ophthalmic specialists, but merely a lesson as to the manner in which they should be trained. Specialties dealing with particular organs tend to the development of narrow views in their devotees, for local disease in one part of the body does not preclude the existence of trouble in other parts; and besides, all organs are more or less intimately connected with each other. These facts furnish the grounds for objection to specialists in general, but after all they only furnish objections to individuals and not to the specialties themselves, for no one can contemplate the modern state of such specialties as ophthalmology, neurology, gynecology, laryngology, etc., without a feeling of professional

pride. The remarkable advancement of gynecology in late years has been due, practically, entirely to those who do and think gynecology exclusively. It is certainly, however, too much to expect that the mind, unless it be that of a genius, which is constantly occupied with the study of pus tubes, and laparotomies, and perineorrhaphy, and round ligaments, should have time for the study and advancement of knowledge regarding the changing functions of developing organs, any more than that there should be demanded of it a ready and accurate knowledge of intra-ocular conditions. And yet the diseases of women and children are usually associated, in thought at least, and usually assigned to the same teacher in our medical schools. No man can serve two masters, and in this combination it is not uncommon to find the children sadly neglected.

Pediatrics, as a study, is free from the objections which apply to local specialties. It is limited because it deals only with a portion of the life cycle, but it includes the totality of the individual within that portion. If this be objectionable, so also is the ordinary practice of medicine, which practically today devotes special attention to the phenomena of another portion of the life cycle. It matters not whether the phenomena of childhood be studied by those who also work with adults, or be relegated to others with sufficient interest in children to study them exclusively, provided only that somebody may be interested to do this work. But as the individual who limits himself to particular channels of thought is more apt to gather all that those channels contain, the latter class would probably advance the subject more rapidly.

It can not be too often emphasized that children are not little men and women. The child is an unstable human being, constantly changing; now developing this organ or system with great rapidity, and now that; at one time provided with relatively great heart power, and at another with relatively weak heart; now having kidneys incompetent to do the work thrown upon them by the rapid and undue development of other portions of the organism, and consequently leading to the occurrence of morbid conditions, and later provided with kidneys capable of far greater strain than they are liable to be subjected to for a long time. If the various organs and systems of the child were developed exactly as needed by the remainder of the organism, and in consequence the functions of each were nicely adjusted to the needs of the organism as a whole, all would be well. But this ideal condition is not often seen, and possibly never exists. On the contrary, it is common to note the development of parts by jumps, with a necessary maladjustment of organs and a clashing of functions.

The clashing of functions may be so slight as to lead only to temporary disturbances of no great importance, but it may be so severe as to permanently disable some parts, and determine a *locus minoris resistentiæ* which follows the individual through life, and ultimately cuts short his existence.

Maladjustment of organs may occur not only from irregularity in development, but may be congenital, and is often largely influenced by hereditary tendencies. It may not be improper to mention two quite common types of organic maladjustment. Between seven and ten years of age children frequently increase very rapidly in weight and height. The heart

does not always develop *pari passu*, but from the strains to which it is subjected becomes dilated. It is then noticed that the child seems to be lacking in energy, and is listless, for which outdoor exercise is thoughtlessly advised. What is needed is restriction of exercise until the heart develops to the conditions demanded by the remainder of the organism. Care at the beginning would have prevented the dilatation—carelessness throughout may permanently impair the organ.

In the reptilian stage of its existence, the fetus tends to the formation of a solid urine. In very many instances this tendency remains after birth and shows itself in the well-known uric acid infarction of the kidneys of the newly born. This clashing of functions is disastrous to the unfortunate infant, whose kidneys are but illy adapted to the excretion of a solid urine, and consequently it suffers pain as the sharp crystals make their way through the tubules. The colic of the newly born is frequently due to this cause. As development proceeds, the organs adjust themselves to each other and usually after about three months the colic ceases.

It is not uninteresting in passing to look at some of the means by which nature attempts to protect the infant from this and allied troubles. First, it provides it with that form of food which of all others tends least to the production of uric acid, and then it diminishes the acidity of the urine by diminishing the acidity of the stomach juices, which last is done at some expense to the child, for it probably increases its liability to gastro-intestinal infection. At any rate, it is certain that the infant is more prone than the adult, to gastro-intestinal infection, but possibly it is better, for the race, to kill off some of the infants than to have a community of adults handicapped with Bright's disease. The tendency to excessive uric acid formation is exceedingly common in infancy, and is responsible for many disturbances of the infantile organism, notably often, eczema, which frequently persists or recurs in spite of all treatment until, as the saying goes, "the child outgrows it," which is but another way of saying that in the course of development the offending organs have become adjusted to each other in function.

The references already made to uric acid suggest the extensive and complicated group of conditions which goes to-day by the name of uricacidemia, or the uric acid diathesis. It is not my purpose to discuss with you this subject, or even to give reasons for doubting that uric acid itself is the real toxic agent in many of the conditions usually ascribed to it, but merely to refer to the condition as one of a group of toxemias having a common origin.

In these days of bacteriologic research, it is customary to ascribe nearly all pathologic processes to the action of microorganisms, even assuming, as is done in the "Index Medicus," that cancer is of microbial origin, something as yet very far from proven, and practically holding that all febrile processes originate from like causes. Such assumptions have, it would seem, concentrated too much attention on these etiologic factors, and clouded our perception of others probably equally important and operating in essentially the same way. Certainly, the most common, if not the whole means by which microorganisms produce their effects, are the chemical toxins to which they give rise in the course of their biologic activity. But all cells equally produce chemical

products, some of which are toxic to themselves, and to other cells. And it is quite indifferent whether these cells lead an independent existence as unicellular organisms, or live in permanent juxtaposition to other cells as units of a differentiated tissue with specialized functions. This latter is the condition of the cells which make up the higher animal organisms, and it has long been known that they produce toxins inimical to themselves, and to the organism of which they are elements. Limiting ourselves to man as the animal in which we are most interested, we know that normally he is provided with abundant means for protecting himself against auto-intoxication, but in abnormal conditions this protective apparatus fails and auto-intoxication occurs, and nowhere in the life cycle does auto-intoxication occur in such varied forms, or so commonly, as in childhood. This is partly due to the incompetency of incompletely developed eliminating organs; partly, to the incompetency of incompletely developed organs normally concerned in the transformation of toxins into non-toxins; partly, also, perhaps, to the unusual products produced by incompletely developed organs, or resulting from the maladjustment of correlated organs. This whole wide field of study is practically untouched, but as clinicians we constantly get perplexing glimpses of it.

Among the numerous pediatric problems which should attract the attention of the clinician, there are none more interesting than those presented in the anomalous fevers. Fevers in adults can usually be named; that is to say, they can be traced to definite etiologic conditions, or to morbid processes having a tolerably well-defined and well-known natural history. But this is not true in childhood. It is common to meet in children, fevers of infectious origin, as shown by their simultaneous occurrence in numerous individuals, in a given community, but which do not run courses consistent with the natural history of any of the known and well-defined febrile processes. In the light of present knowledge it is fair to assume that such fevers are caused by various microorganisms, and that those that are caused by a given organism are tolerably constant in their manifestations in different individuals. But largely because they do not have striking and characteristic exanthematous symptoms they have as yet eluded specific clinical classification. Even now, the eruptive disease, rotheln, is so differently described by various writers, that it can hardly be said to have earned yet a definite place in nosology. The undifferentiated fevers afford a magnificent field for clinical observation, particularly at the hands of pediatricians, for it is during childhood that they are most commonly found. At present the best that can be done is to recognize that there does exist a group of undifferentiated fevers, and to avoid forcibly classifying them with known conditions, and giving them names which are not correct.

Time forbids a farther discussion, but in conclusion let me answer the opening question. Disease in children merits special and separate consideration from disease in adults, for the following reasons:

1. Pathogenesis in childhood includes many elements entirely lacking in the adult:
 - a. Undeveloped organs with incomplete functions.
 - b. Irregular development of organs with consequent maladjustment, and clashing of functions.
 - c. Numerous special auto-intoxications.

- d. Different susceptibility to various infections.
- e. Compensatory relations in the child are often peculiar to it, and entirely different from anything found in adult life, e. g., reaction of the stomach and uric acid excretion.
2. Morbid entities of similar causation often present vast clinical differences in the two periods of life, notably, typhoid fever, rheumatism and tuberculosis.
3. Trifling pathologic conditions are more important in childhood, because of the impress which they make on developing organs, and because of their farther reaching influence over the long future life of the individual.
4. The dangerous plasticity of the growing organism also presents therapeutic possibilities not found in the adult, but of vast importance to the future adult.
5. The nutritional problems are numerous and comprehend many factors not to be considered in adults at all.

OVER-FED INFANTS; CAUSE, EFFECT, TREATMENT.

Read in the Section on Diseases of Children, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. A. WORK, M.D.
ELKHART, IND.

We can say properly, that an infant is over-fed when it fails to digest and assimilate the food furnished it. The natural food for the newborn babe, all things being equal, is the food sent with it—the mother's milk—which for the first two or three days after birth seems, to the inexperienced or unthinking mother or nurse very inadequate to the support of the child, but it is all that the little new creature can possibly, with certainty, digest and assimilate. Too often the mischief is played with the child during the initiatory period of its digestion. It is often difficult for the attendants in the nursery to realize or understand the untried weak condition of the whole digestive and correlative systems of the infant. In fact, we must consider that the whole new being with all its varied systems, both anatomic and physiologic is in a primary rudimentary condition. Thus we observe the simplest form of food which is naturally furnished it. Recognizing the foregoing fact we should act intelligently if we are called upon to advise in artificial feeding, and select that food for the unfortunate infant which most nearly simulates the mother's milk. Unless disease is present with the mother, which is transmissible by her milk to the child; we should use our utmost endeavor to have it nurse the mother; as we have the best interests of both mother and child in view.

Some young mothers do not possess the best facilities for furnishing this natural food to their offspring, but there are very few who can not be corrected in this respect by patient persistence. If the nipple is not drawn to dimensions sufficient to allow the babe to nurse well during the first two or three days after parturition, we may have to resort, unfortunately, to artificial feeding; for after lactation proper ensues there is usually such a turgescence of the mamma that satisfactory modification of the nipple then is impossible, and after the usual application of pumps, plasters, and various ointments to remove this gorged condition, the babe is virtually

weaned; and if the child is so fortunate as to get its natural food, unless regular habits of feeding during the initiatory stage are observed, it is in danger, when lactation proper ensues, of over-feeding or being over-fed. There is a great temptation often on the part of the mother, which is largely selfish, to make a breast pump of her child, and thus its stomach is impaired. If normal regular habits as to nursing are well established, on the part of the child, commencing immediately after birth, which habit we know can be attained within seventy-two hours by allowing the child its own undisturbed time to rest or sleep, after first attending to all its needs as to proper cleansing, clothing and food, if it demands it, before tucking it in its little bed in a warm properly ventilated nursery, allowing it to awake by force of hunger, or some other cause peculiar to itself—some dictate of nature. When it awakes give it such care as will make it comfortable for another period of rest, of from two to six hours, then put it to the breast again to its satisfaction. It may nurse itself asleep, then tuck it away again, and so on, and we can truly say it is a natural child, following natural habits of life. And, too, the mother by this habit of the child will find that the supply of food will adjust itself to the needs of the child, and by a little common sense on the part of all concerned in the care of the little one, there will be no danger of over-feeding and bringing on the invariable result, viz., indigestion, bad assimilation and perchance cholera infantum.

The result of over-feeding is the leading factor in the very great mortality in infancy and childhood. It is true that quality of food plays an important part in the ailments of children. Even in considering the zymotic diseases of children, by which diseases so often fond hopes are blighted, we must admit that the mortality is largely due to over-feeding prior to the inception of the disease. The disease is severe or not, according to the fermented condition of contents of the alimentary tract. The decomposed contents of the *primæ viæ* is a fertile field for the rapid propagation of bacilli or disease germs. Thus the severe form of the disease.

The incontrovertible law of cause and effect holds good in the consideration of our subject as well as in all things else with which we have to do. Not long since I was called to the bedside of a child 20 months old, who was feverish, emaciated and debilitated, even to inability to close its eyes; could scarcely utter a cry, had frequent curdy stools and vomited sour curd occasionally. Disease had been denominated cholera infantum. On inquiry of the mother I learned that the child had been sick at intervals for twelve months, and suffered similarly, as at this time. Had employed four physicians during this period; child was weaned from its mother and I learned that she was instructed to give it all the cow's milk it wanted, and whenever it wanted it. The case required but little study to determine a diagnosis; cause, over-feeding; effect, the condition of child as above delineated. Before consenting to treat the case, I had the mother promise to follow my directions strictly. We all know how often a mother's sympathy or affections run away with her judgment and thus our directions are not followed, and the result is not satisfactory to either friends of patient or doctor. I ordered three teaspoonfuls of good fresh cow's milk (cow was in the barn near by)

every three hours, preceded by a weak solution of bicarb. potassium and followed by two or three grains of catalysin and carbon. This treatment was to continue for twelve hours, and if vomiting ceased and stools less frequent, or changed for the better, they were to give four teaspoonfuls at a time, and so on, as the child improved in its digestion and assimilation. We increased the amount of milk until twelve or fifteen drachms were given at a time which was enough to cause the child to improve so that in four days I pronounced it well, and only had to advise temperate feeding.

Over-feeding the infant and the result following *directly*, renders the system less resistant to the diseases of childhood and, in fact, may be a menace to its well being throughout even a long life. On the other hand, if wisdom is used in following the dictates of nature, (as God intended we should) in the feeding of infants, the foundation is laid, physically, for a long and useful life.

DIAGNOSIS OF PNEUMONIA IN CHILDREN.

Read in the Section on Diseases of Children at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY EDWARD H. SMALL, A.M., M.D.

PITTSBURG, PA.

Pneumonia in children may be divided into two classes: croupous pneumonia and broncho-pneumonia. There has been a number of different names given to these two forms, viz., croupous, lobar and fibrinous pneumonia for the first; and catarrhal, lobular or insular pneumonia, bronchitis, capillary bronchitis and broncho-pneumonia for the second. A great deal of confusion has arisen on account of the various names applied to the second class. "Catarrhal" is not altogether correct, for other tissues than mucous membranes are greatly affected. Indeed, Neimyer says: "As no mucous membrane with mucous glands exist in the pulmonary vesicles, the name, catarrhal pneumonia, is not quite applicable to the disease in question." The name "lobular" or "insular" pneumonia "should not be used because it neither includes or suggests the bronchial inflammation which is always present." Neither "capillary bronchitis" nor "bronchiolitis" is an exact term, as inflammation of the capillary bronchi is rarely found without involvement of the lobular structures. "This term would mean a bronchitis which has reached its highest possible development without becoming a broncho-pneumonia—a condition which can not with certainty be recognized by either physical or rational signs." "Broncho-pneumonia" is by far the most descriptive term and the one which should be used.

"Croupous" and "lobar" are sufficiently descriptive. "Fibrinous" is the name the English use.

"Croupous pneumonia is an inflammation involving one or more lobes of the lung, or of both, attended with an exudation into the air-vesicles of the affected part, consisting of coagulable or coagulable fibrin with many red and white blood corpuscles from the surrounding blood vessels."—Pepper.

Broncho-pneumonia is an inflammation of the bronchial lining membrane, which by direct extension involves the connective tissue, bronchioles and air cells, attended with an exudation into the alveoli, principally of desquamated epithelium and leucocytes; or, according to Osler, "an inflammation of

the terminal branches and the air vesicles which make up a pulmonary lobule."

Pneumonia is now considered by most writers a specific infectious disease. The pneumococcus of Fraenkel is the most constant organism to be found, and is the exciting specific cause, although others are often seen in connection with it. This was first discovered through Pasteur in 1881. In 1886 Fraenkel obtained pure cultures of it, settled its specific character and pathogenic action and christened it pneumococcus. This may also be found in human saliva, the pleura, meninges, endocardium, or middle ear. It may invade these parts during a pneumonia, or it may be found in meningitis, pleurisy or otitis media when pneumonia is not present. Netter says it is a reminder of pneumonia, and is met with in persons who have had this disease. In France, bacteriologic investigations in a large number of cases of pneumonia in children showed the presence of the pneumococcus in all cases examined of croupous pneumonia and in 60 per cent. of broncho-pneumonia. It is often very difficult to find it in the latter, on account of its frequent association with other microorganisms.

Croupous pneumonia is almost always a primary affection, occurring at all ages and seasons. It occurs most frequently in the winter and spring, when children are most likely to catch cold. It occurs often in dwellings whose sanitary condition is bad, where there is defective plumbing, in filthy and ill-ventilated tenements, crowded jails and workhouses—these conditions furnish a nidus for the coccus.

Broncho-pneumonia is, on the contrary, a secondary affection. As a rule it is preceded by a bronchitis, and is often a complication or sequela of the infectious fevers: measles, whooping cough, scarlet fever, la grippe or diphtheria. In children it forms the most serious complication of these diseases and often causes more deaths than the fevers themselves. Cases are common after operations on the mouth and nose, after tracheotomy and intubation—the so-called aspiration or deglutition pneumonia, where particles of tissue slip through the larynx into the lungs, and induce such an intense broncho-pneumonia that suppuration, or even gangrene may develop. In infants it may arise from inspiration of the vaginal secretions. The bacillus tuberculosis often causes a fatal form of broncho-pneumonia.

It has been taught by many that croupous pneumonia occurs but rarely in children under three years of age. Jacobi says that about one-third of the cases at this time are croupous. Holt gives a list of 207 cases of pneumonia under three years of age, in which the diagnosis was undoubted, of which 160 or 77.3 per cent. were broncho-pneumonia, 47 or 22.7 per cent. were croupous. Baginski gives 151 cases under three years, with 76.2 per cent. broncho-pneumonia, and 23.8 per cent. croupous. After three years of age the number of cases of croupous pneumonia approach those of broncho-pneumonia.

Croupous pneumonia is a primary disease, coming on suddenly while the child is in good health. Recently I took part in a discussion on pneumonia in children, in which a number of cases of so-called broncho-pneumonia were related, which came on suddenly, without a preceding bronchitis, ran a favorable course of a few days with complete recovery. I think these cases were undoubtedly croupous

pneumonia in which many physicians err in their diagnosis. The first symptoms are cough, pain in the chest, or epigastrium. At the Home for the Friendless we had some twenty cases, in which almost all the children complained of pain in the epigastrium, irrespective of the part of the lung involved. In some children the power of localizing pain seems to be deficient. Then we have drowsiness, lack of appetite, languor, chilliness. The rigor which occurs in adults is rarely seen in children, in place of which there is usually vomiting, or in some, convulsions. (Rusty sputum is rarely seen in children.) Elevated temperature, rapid pulse, and increased respiration soon follow. Often the temperature reaches its highest point in twenty-four hours, 103 to 105 degrees or higher. This keeps up with a slight morning remission for from four to seven days. There is a deep flush on one or both cheeks, some think corresponding to the side involved, and often herpetic eruptions on the lips. The cough continues, but is suppressed as much as possible on account of the pain it causes. The breathing is hurried and the nostrils dilated with each inspiration; the rate may be 40, 60 or 70. The pulse is greatly accelerated; the pulse-respiration ratio is changed from the normal of 1 to $4\frac{1}{2}$ to 1 to 3, or 1 to $2\frac{1}{2}$ or 2. Defervescence takes place in about a week. Usually this is sudden, by crisis. The fall often occurs in twenty-four hours from the highest point to normal or below it. I had a case in which the temperature fell to 96 degrees with good recovery. Holt reports a case in which in fifteen hours there was a fall of $10\frac{1}{2}$ degrees, from 105.5 degrees to 95 degrees, and the next day to 94 degrees, with recovery. Rarely the defervescence is gradual by lysis¹.

Broncho-pneumonia is almost always secondary, following bronchitis. When it sets in there is more fever, the pulse is more rapid, the breathing faster and more labored. The fever is very variable, with no definite curve. It ranges from 102 to 105 degrees or higher. The pulse-respiration ratio is 1 to 2 or 1 to $1\frac{1}{2}$, respiration going to 70, 80, 100 or more. There is great dyspnea, the child fights for breath. There is great dilatation of the *alæ nasi* and retraction of the ribs. The dyspnea is often constant and progressive, and soon signs of deficient aeration, suffused face and bluish finger tips are seen. The child has a most anxious expression and gradually enters upon the most distressing stage of asphyxia. "At first the urgency of the symptoms is marked, but soon the numbing influence of the carbon binoxid on the nerve centers is seen and the child no longer makes strenuous efforts to breathe, the cough subsides and with a gradual increase in lividity, and a drowsy restlessness, the right ventricle becomes more and more distended, the bronchial râles become more liquid as the tubes fill with mucus, and death occurs from heart failure."—Osler. Recovery is gradual, by lysis, and occurs at no definite time—several weeks.

The physical signs in croupous pneumonia are the same as in the adult. They are oftenest at the summits of the lungs. Often these can not well be made out until late, owing to the small amount of the lung involved and to its central position. At first we must depend most upon the general symptoms. The crepitant râle is not so easily made out as in the adult. Bronchial breathing is easily heard during consolidation, especially high in the axilla.

Dullness on percussion will sometimes precede bronchial breathing. Increased vocal resonance and fremitus can generally be made out.

In broncho-pneumonia, fine râles are heard at the bases, or widely spread throughout both lungs. In the first few days percussion resonance may not be impaired, in fact, emphysema may cause hyper-resonance, afterwards areas of impaired resonance or dullness may be found at the bases. Many râles may be heard, chiefly of the fine subcrepitant variety, with sibilant ronchi. At times the careful examiner may make out scattered nodules of consolidation.

So far in this paper, I have endeavored to contrast the two forms of pneumonia in children. I will now recapitulate the chief differences in tabular form:

| CROUPOUS PNEUMONIA. | BRONCHO-PNEUMONIA. |
|---|---|
| Primary disease arising suddenly. | Secondary disease, following a bronchitis. |
| Pneumococcus always present. | Pneumococcus present in 60 per cent. of cases. |
| Temperature of 104 degrees or more in the first twenty-four hours. | Arises more gradually. |
| Definite temperature rate with slight morning remissions. | Temperature of no definite rate. |
| Pulse-respiration ratio of 1 to 3 or 1 to $2\frac{1}{2}$ or 2. | Pulse-respiration ratio of 1 to 2 or 1 to $1\frac{1}{2}$. |
| Respiration rate of 40 to 80. | Respiration rate of 60, 80, 100 or higher, and much more laborious with more dyspnea. |
| Pulse rapid, but soft and full. | Pulse rapid, and often weak and unresisting. |
| Pain severe. | Pain less severe. |
| Flushed cheek. | Lividity of face. |
| Cough frequent, but not constant, and not usually preceding pyrexia. | Cough invariable and usually preceding pyrexia. |
| Not so frequent in children under three years. After the fifth year, uncomplicated pneumonia is generally croupous. | Under three years the ratio is about 4 to 1. |
| Physical signs are mostly confined to one or two lobes of one lung. | Physical signs are heard in both lungs with no definite limitation. |
| Upper lobes most affected. | Posterior inferior lobes most affected. |
| Generally area of consolidation in two or three days. | Only exceptionally are consolidations to be found. |
| Bronchial breathing, fine crepitant râles, bronchophony and increased vocal resonance and fremitus. | Different kind of râles in both lungs and later subcrepitant râles. Although we may have dullness from aggregated affected lobules, we do not have therewith bronchophony and increased vocal resonance and fremitus. |
| Generally ends by crisis in about seven days with good recovery. | Ends by lysis in two or more weeks, with permanent lesions or death. |
| Mortality 5 to 10 per cent. | Mortality 30 to 50 per cent. |

A CASE OF EXOPHTHALMOS IN AN INFANT OF THREE MONTHS.

Read in the Section on Diseases of Children, at the Forty-fifth Annual Meeting of the American Medical Association, held in San Francisco, June 6-8, 1894.

BY HARRIET E. GARRISON, M.D.

DIXON, ILL.

The patient whose case forms the basis of this article, is the elder of twin boys, born June 30, 1893. This was the mother's third confinement. The labor was normal. The delivery of No. 1 was retarded by vertex presentation. He preceded his brother by forty minutes, weighed eight pounds, and No. 2 weighed nine pounds. No. 1 cried lustily and to

all appearances was as strong and vigorous as No. 2. He was warmly wrapped in flannel and placed on his right side. After the third stage of labor was completed, and the mother was made comfortable, as I had but the assistance of an untrained nurse I looked after the children. I found the nurse bathing No. 2, and No. 1 lying as he had been placed at birth, but he had become blue and the extremities cold. In an hour's time by the application of dry heat and hot water internally he had lost the blue color and the hands and feet had become warm. When I saw him twelve hours afterward I could not distinguish him from No. 2, but the attendant said he required more care to keep him warm and comfortable than No. 2, which condition continued. It was two months, August 29, before I again saw the children. Then No. 2 was very sick with cholera infantum. At this time No. 1 weighed nine pounds and No. 2 eleven. On the next day No. 1 showed choleraic symptoms. No. 2 had much the more severe attack of cholera infantum but No. 1 was harder to treat. In a few days No. 2 was rosy and vigorous while No. 1 continued to have gastro-intestinal troubles. September 27 the mother brought the babies to my office. No. 1 was very much emaciated not weighing as much as at birth, but the most marked symptom was the protrusion of the eyeballs—they were apparently being pressed from their sockets. The mother said she had not noticed this condition until a few days previous. At this time I first noticed tachycardia, the pulse ranging at 240 per minute. The next week he was again brought to my office. The protrusion of the eyeballs was not as marked as the week before, but there seemed to be no change in the tachycardia. At this time, the mother thinking No. 1 would not live had them photographed, a copy of which I now present. They are arranged to hide the protrusion of the eyes of No. 1 but it can still be seen. From this time on he continued to improve and in two months the mother told me he weighed fourteen pounds against sixteen for his brother. December 30 the mother again brought him to my office as he had been sleepless, cried a great deal, and his head was hot. He had cut two lower incisor teeth and the upper gums were very red and much swollen. At this time the mother called my attention to the tumultuous heart action. She said she had noticed it for several weeks, sometimes more violent than at others. While in the office the beating was sufficiently violent to shake the clothing over the chest. The pulse rate was now 180 per minute. A careful examination of the heart showed nothing abnormal except the thrilling motion. In January he had a severe attack of la grippe with brain symptoms which continued ten days; pulse 200, temperature 103° F. In the ninth month the pulse was 150, of good volume. The only difference discernible in the twins at this time was the pallor of No. 1 and the staring of the eyes. At the present time in the eleventh month, No. 1 is rosy and hearty looking, has lost the pallor and staring of the eyes, pulse 100, of good quality, creeps actively but does not climb, and stands as much as No. 2. No. 1 weighs nineteen and one-half pounds; No. 2, twenty-one and one-half pounds. No. 1 has all his incisor teeth; No. 2 has six. At this time the children were again photographed. In the photograph the laxness of the muscles of No. 1 is very noticeable as he does not sit nearly as erect as No. 2. His mother tells me his head perspires when he sleeps.

Exophthalmos, Graves' disease, exophthalmic goitre, Basedow's disease, struma exophthalmic, tachycardia strumosa, cardio-thyroid exophthalmus are some of the names which have been applied to this disease—which usually has three prominent symptoms; tachycardia, exophthalmos and goitre.

Graves was the first to distinctly group these symptoms, but gave most prominence to tachycardia and exophthalmos. Then later, Basedow more fully described the symptoms, but made the goitre more prominent. Tachycardia is the first symptom usually observed; the other two varying in different individuals, sometimes the exophthalmos appearing first and sometimes the swelling of the thyroid gland. In this case the exophthalmos was the first symptom noticed. A mild tachycardia very likely existed before the child was brought to me, but the tumultuous heart action was not observed until nearly two months later when the exophthalmos had nearly disappeared, and at no time was any swelling of the

thyroid gland observed. This agrees with a case recorded by Graves in which tachycardia was first noticed, then exophthalmos and two months later the thyroid swelling. Improvement began in my case so soon that the thyroid gland did not become involved.

I have now under my care a girl of 14, with goitre. The pulse is 120 with chlorotic bruit. The murmur is very marked over the carotids and thyroid. The patient's eyes are prominent but not protruding. In another young lady with well marked goitre of right lobe the pulse was never over 120. Exophthalmos came on suddenly while she was being treated for goitre by electricity; the exophthalmos was relieved by treatment but the eyes still looked large. The goitre was but slightly reduced by treatment and is still noticeable at the present time, although she now seems perfectly well and is the mother of several healthy children.

Cause.—There was never any case of goitre among the children's ancestors, therefore, heredity could be excluded. The parents are both large, vigorous and healthy, of German descent. The grandparents are living excepting the paternal grandfather who died of acute pneumonia. The house in which the children live is one of the oldest in this section of the country. It is located on low land near a small stream which at this point is quite sluggish. The difference between the air on the highlands and on the lowlands was very noticeable as I drove down from the surrounding hills in the early morning hours on the day of the children's birth. Although it was very warm June weather the air in the house felt damp and cold, and I directed a fire to be lighted by which the children might be dressed. It is to this unsalubrious situation that I attribute the child's condition; weaker at birth than his brother he could not overcome the unfavorable climatic conditions. Why it should take the form of exophthalmos can perhaps be accounted for by the condition in which the child was an hour after birth. The venous stasis and coldness of the extremities showed a weakness somewhere in the child's system. It could not have been organic heart trouble or it would not have been so quickly relieved by the application of heat. There must have been a weakness of the nerve centers, which control the generation of heat and the vaso-motor nerves. This accounts for the failure of the child to rally from the attack of cholera infantum as this had farther injured the already weak nerve centers. Whether this condition was caused by the pressure on the brain from the vertex presentation or whether it was caused by a defect in nutrition during fetal life, I am not prepared to say.

Treatment.—The child had been taking almost continually, from the time it had the attack of cholera infantum, medicine to assist digestion and to tone up the system. As soon as I saw the child had exophthalmos I gave, in addition to the medicine it was already taking, arseniate of strychnia. A granule containing 1-134 of a grain was dissolved in nine teaspoonfuls of water, and one teaspoonful of this solution was given every six hours. This was given regularly for a long time and was resumed as soon as the brain symptoms of la grippe were controlled. The arseniate is giving as favorable results in the case of chlorosis now under my care. She has been taking it for a month, the pulse rate has decreased to 90 and the goitre is materially reduced. She takes 1-67 of a grain every four hours.

Diet.—The mother having very little breast milk, gave in addition sterilized milk, and as is usually the case, when babies are given the bottle, the children soon became weaned from the breast and the sterilized milk formed the whole diet. After the attack of cholera infantum they were given condensed milk. This agreed perfectly with No. 2, and he has never been under treatment since, but did not agree with No. 1 and he was given, in addition to condensed milk, beef extracts and several infant foods. At the time of the exophthalmos, he was put on peptonized milk for a few days but was soon returned to condensed milk. After the attack of la grippe he was given sterilized milk which at the present time with bread and butter forms the diet. No. 1 consumes double the quantity of milk which No. 2 requires, but does not increase in weight any more rapidly than No. 2.

All the cases of exophthalmos or goitre which have come under my observation before this case, have been in females at puberty or later, for which reason I have always regarded tachycardia, exophthalmos or goitre as being a symptom or symptoms of reflexed nervous origin—the uterus and its appendages being the source of irritation. But since studying this case, I have reached the conclusion that the disease is located in a sympathetic ganglion or ganglia, and the disease of the other organs is due to loss of proper nerve stimulus. And the proper treatment of these conditions is to increase the nutrition of the nerve centers.

DERANGEMENT OF THE KIDNEYS IN LITH-EMIA OF CHILDREN.

Read in the Section on Diseases of Children, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY J. M. G. CARTER, M.D., Sc.D., Ph.D.

WAUKEGAN, ILL.

PROFESSOR OF PREVENTIVE AND CLINICAL MEDICINE IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO; FELLOW OF THE AMERICAN ACADEMY OF MEDICINE, ETC.

One of the most common forms of derangement in the alimentary canal of children is due to the failure of the liver to properly perform its function. This neglect of duty on the part of that important organ permits the accumulation in excess in the blood of glycogen or sugar, uric, oxalic and other acids.

The origin of this trouble is found in improper food in many cases, producing acid digestion. At times, however, the derangement seems to be caused by some nervous influence or an inherited dyscrasia. The condition, whatever its origin, seems to consist in an imperfect digestion of food, or an incomplete oxidation of proteid material by the hepatic cells. An excessive indulgence in sugars, starches, and fats may produce both imperfect digestion and failure on the part of the hepatic cells to completely oxidize the proteids. An acid indigestion is a common result of this indiscretion. Languor, constipation, flatulence and similar symptoms are characteristic of the condition. The skin is sallow or of a peculiar muddy, dingy, unhealthy appearance. The eye is deprived of its normal clearness and, though not tinged with pigment to the extent it is in jaundice, it is dull and characterized by loss of expression. The facial appearance is often listless and uninteresting. The secretions are diminished and digestion is impaired; conditions which may last for weeks or months. A glycosuria may occur in

infants of the first month, and in such children we are likely to meet with lithemia in later life.

Chronic gastritis or gastric irritation and nervous conditions should excite a suspicion of lithemia if the etiology is at all obscure.

When a nervous, fretful, peevish, restless, ailing child, with a voracious or fitful appetite does not yield readily to simple treatment, or is found to have occasional attacks of illness similar to the condition just mentioned, lithemia should be suspected, and a careful examination of the urine made to discover the changes which characterize this disturbance.

If uric acid is not transformed into urea an excess of that acid occurs in the blood and will be excreted by the kidneys. In fact, all acid urine will sooner or later deposit uric acid. Uric acid crystals and urates are sometimes deposited from urine of lithemic children. I should expect that a lithemic child, if this dyscrasia is not corrected, would manifest more serious symptoms of disease in adult life; in England, perhaps gout; and even in America there seems to be a rapid tendency to that popular disease. It must be borne in mind that the continued irritation of the kidneys by the overburdened work of excreting an excess of uric acid for years may be followed by congestion, nephritis and albuminuria. An excess of oxalic acid or oxaluria may likewise be followed by an albuminuria. In such cases there is a high specific gravity of the urine with urates, albumen and casts. These serious cases might be prevented in many instances by a recognition of the lithemia of children and its proper treatment. Along with the intestinal, alimentary and nervous symptoms in such cases will often be found a congestion of the kidneys. The patient desires to urinate frequently, sometimes has a feeling of fullness or distress in the lower dorsal region. Specific gravity generally high, 1020 to 1030; urates, phosphates often and sometimes uric acid, oxalic acid, albumen, or sugar may be present. I have found in some instances a trace of albumen or sugar; and in some I have found indican. I have accepted the presence of indican in obscure cases as indicative of intestinal disease. With the presence of these abnormalities in the urine, ordinarily, there are other symptoms which direct the attention to some derangement of the digestion. The two following cases represent different manifestations of this condition as it has occurred in my experience:

Case 1.—E. P. was a fretful, restless child from birth; sleep disturbed, waking in pain or with some undiscoverable distress many times during the night. Paroxysms occurred every few weeks or months during which the restlessness, wakefulness and peevishness were increased and accompanied by symptoms of acid digestion. The appetite was variable, skin sallow or muddy, the acid urine of high specific gravity and loaded with phosphates and urates. Micturition frequent and often irritating. No albumen or sugar. Tongue slightly coated. Treatment directed to correct the indigestion and eliminate the excessive elements in the urine always relieved the paroxysms. It was seldom necessary to prescribe for the fever which often accompanied these attacks. A permanent cure was produced by regulation of diet and a protracted treatment to correct the morbid condition of the digestive organs.

Case 2.—H. C., 4 years old, frequently has attacks of indigestion and often these verge upon simple continued fever in the persistency of the symptoms and mild fever. The last attack occurred April 15, 1894. Appetite variable. Skin sallow and muddy. Tongue slightly coated, temperature scarcely above normal and pulse only 85 to 90. The patient was peevish, restless, had a constant feeling of fear; and distress in the stomach. Urine 1026, acid, contained a trace

of albumen, urates, phosphates, indican. Urination occurred six to eight times a day. Amount in twenty-four hours eight ounces. Uric acid present, amount not determined. No sugar or bile pigment. The diagnosis was lithemia with congestion of the kidneys. The treatment directed to elimination of retained matters; correction of the indigestion and relief of the deranged kidneys resulted in a cure in two days. There is a persistent custom in this family of feeding the child with sugars, candies, etc., and allowing an uncontrolled appetite to be satisfied at every meal, so that the prospects for a permanent cure are remote.

I may add also that the father is a sufferer from gout. Such cases seldom recover without a complete change of environment. The treatment should be such as will prevent the formation or accumulation of too much acid in the stomach during digestion, and yet will render aid to the embarrassed liver in discharging its functions. The first indication can be met by giving alkalis during or before meals, as bismuth, bicarbonate of soda or lime water; and acids, hydrochloric or aromatic sulphuric, and pepsin after meals. Nitric acid sometimes produces excellent results given an hour and a half before or two and a half or three hours after meals. Theoretically, nitric acid parts with sufficient oxygen to transform uric acid into urea. The phosphate of soda is valuable in many cases. The second indication may be met by giving water between meals. In older children the encouragement of a habit of drinking water an hour before meals and two hours after, will assist in flushing the system, not only relieving the liver but reducing the irritation existing in the kidneys. All treatment should accomplish, or have for its aim, the relief of the kidneys from the excessive work which eventually will lead to permanent trouble if not prevented by the removal of the acid dyscrasia.

Investigations properly directed would undoubtedly show that the increase in the number of cases of Bright's disease which we now meet as compared with the same a few years ago can be attributed in part to the increase of cases of uric acid diathesis and lithemia among children and young people caused by the indigestion of pastries, rich foods, confectioneries, sugars, etc. These conditions are due to the methods of living adopted by families as soon as they attain a degree of wealth that permits such indiscretions; conditions which in many instances might have been corrected in youth. In my experience most of these cases occur in well-to-do families, and it is necessary to give directions curtailing the custom of constantly putting something into the child's stomach. If the cases are infants on the bottle, or young children whose chief diet is milk, it is often necessary to sterilize the milk as that renders its digestibility more nearly like human milk. When such a case occurs in a family where the nervous temperament is prominently developed, I prescribe the syrup of hypophosphites—Churchill's. Ordinarily I prescribe minute doses of calomel and soda or mercury with chalk at the beginning, and have the patient given an alcohol sponge bath morning and evening to be followed byunction with olive or cocoanut oil. These simple remedies with diaphoretics, diuretics and other eliminatives, if needed, will generally be sufficient for the first two or three days. After that I like the effect of aromatic sulphuric or hydrochloric acid (well diluted) half an hour before taking food three or four times a day, and phosphate of soda in 5 to 10 grain doses three times a day until a cure is produced. Seltzer, Buffalo Lithia, Vichy and other mineral

waters have been advised, and should be taken warm and when fasting. The three chief objects to keep in view are: 1, to remove the acid digestion; 2, to regulate the action of the liver; and 3, to relieve the kidneys of their extra work.

SOME REMARKS ON ECZEMA OF CHILDREN.

Read in the Section on Diseases of Children at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY WM. M. HOLTON, M.D.

NEW HARMONY, IND.

Infantile eczema is popularly known as milk crust, tooth rash, moist tetter, etc. The most frequent cause is, probably, a faulty assimilation of food. This may occur from disease or mental distress of the mother. In infants brought up by hand, or "bottle fed," faulty diet may cause gastric disturbance and eczema may result. A scrofulous diathesis is, probably, a predisposing cause. Excessive friction, from too free use of a fine tooth comb or a hard brush to clean the head of dandruff, or excess of either natural or artificial heat may irritate the scalp and produce eczema.

A collection of pimples slightly elevated above the surface is first noticed. The summit of the pimple is usually vesicular, and when broken by scratching, to relieve the intense itching which accompanies the eruption, discharges an irritating fluid, which causes the disease to spread, until not only the entire scalp may be covered, but the ears and face may be involved; indeed, in rare cases, the whole skin may be affected. The secreted fluid at first transparent, becomes opaque, afterwards purulent, and is often stained by blood flowing from lacerations made by the finger nails of the tormented infant. These discharges drying, form thick crusts, covering the diseased parts like a mask and, if the face is much involved, it is disfigured almost beyond recognition. The ears are often thickened, and deep fissures form behind them which almost threaten to detach the ears from the head and are difficult to heal. In the early stages of eczema the child may appear healthy, may even be plump and rosy, but usually the flesh will be less firm than normal and, as the disease advances, slight pallor and an unnatural whiteness of the eye is noticed; later the skin becomes dry, sallow and wrinkled, and the child looks prematurely old.

The mucous membrane of the mouth and nose is often affected, and in severe cases that of the throat and lungs may be involved. Indigestion and diarrhea are frequent complications. The submaxillary and cervical glands often enlarge and suppurate. Wilson, in "Diseases of the Skin," says: "Infantile eczema, when left to itself has no natural tendency to resolution or spontaneous cure. Without treatment it is liable to pass, after protracted suffering, into chronic eczema or, in other words, psoriasis infantalis." Notwithstanding the formidable character of this malady we can promise speedy relief and, in most cases, a permanent cure if proper treatment is adopted and faithfully carried out. Locally, apply an ointment of oxid of zinc, one part to six of simple cerate, or fresh lard; mix well; apply with gentle friction over the entire eruption. Let this remain a week; should it crack and the fluid exude, apply more ointment. After a week, soften the crust with an emulsion of yolk of eggs, cover with

cloths wet with warm water, when the crust can be removed; then continue the ointment as before.

During the time of treatment the use of comb, brush, or of water should be as limited as is practicable. It may be necessary to confine the hands to prevent scratching, but the ointment is soothing, and usually renders restraint unnecessary. As constitutional treatment, $\frac{1}{2}$ grain calomel with 1 or 2 grains of bi-carb. soda, or calcined magnesia, given every night at bed-time is often all that is necessary. A suitable diet should be given, and as relapses are frequent the treatment should be continued for some weeks after the eruption disappears. In obstinate cases, give 2 to 5 drops of Fowler's Solution after each meal. Enlarged glands should be painted with tinct. iodine, and alterative doses of iod. potass, with syrup sarsaparilla compd., given three times a day. These scrofulous cases require protracted treatment, but the result has been, in my experience, satisfactory, and I rely on this treatment with the same confidence that I do on the use of quinin in intermittent fever.

ETIOLOGY AND PROPHYLAXIS OF DIPHTHERIA.

BY B. BECKER, M.D., F.S.Sc., LONDON.
TOLEDO, OHIO.

The Eighth International Congress of Hygiene and Demography, held at Buda-Pesth September 2 to 8, 1894, can be considered as one of the most remarkable and important reunions of representatives of the medical sciences from all countries during the latest times. This can be judged from the reports so far published.

One of the most important proceedings of the Congress was the discussion on the etiology and prophylaxis of diphtheria, which may be shortly related in the following:

Löffler, from Greifswald in Germany, says that diphtheria is produced by a specific bacillus, whose importance is not doubted any more by anybody. As diphtheria we can consider that affection only which is produced by the Löffler bacillus, excluding all similar affections which are caused by other microorganisms. In fact, we often find diseases of the upper air passages, which give the same picture as genuine diphtheria, but which are caused by an infection of streptococci, staphylococci or pneumococci and which, like the genuine diphtheria, can take a benign or a malignant course. The differentiation in diagnosis can only be made by bacteriologic examination, and all the statistics of diphtheria can not have any value as long as this differentiation is not strictly observed.

The course of an epidemic diphtheria depends on different factors: 1, on the quantity and the virulence of the diphtheritic bacilli; 2, on mixed infections by which the virulence of the bacilli is increased, or the organism weakened by the absorption of the products of secretion; 3, on the individual predisposition.

The bacillus of diphtheria is often found in the pharynx or in the nose of healthy individuals, its presence not producing any pathologic symptoms. It produces a disease only in those cases in which it is fixed on the mucous membranes. Lesions of the mucous membrane facilitate this fixation, and atmospheric changes, moist air, etc., seem to favor the de-

velopment of the disease. In the majority of the cases, diphtheria is directly transmitted by contact, by cough, kisses, by hands which are soiled with the fresh secretion, but often also by food, linen, etc., even a long time after the infection.

The patient must be considered as dangerous to others as long as bacilli can be found upon the mucous membrane. Usually they disappear a short time after the healing of the local process, while in certain cases pathogenic bacilli are found in the pharynx and the nose after weeks. Enveloped in organic substances and with the exclusion of light the bacillus can retain its activity for months outside of the organism. Dirt, moist and dark houses therefore favorably affect the conservation of the bacilli and the spreading of the disease. The most favorable condition for such a spreading is found in accumulations of susceptible individuals, as in schools, etc.

As means of prophylaxis are especially recommended:

1. Cleanliness, dryness, ventilation and light of residences.
2. Hygiene of the mouth and nose; repeated gargarisms with solutions of chlorid of sodium, or bicarbonate of soda; cleanliness of teeth, extraction of diseased teeth; removal of hypertrophied tonsils.
3. Cold spongings of the neck.

Every suspicious case should bacteriologically be examined. Every practitioner should receive culture media from drug-stores or health offices to be simply inoculated and sent to the bacteriologic station. The report of all cases of genuine diphtheria, likewise of all suspicious cases, should be obligatory, and all the diphtheritic patients should be isolated. To possibly prevent the spreading of pathogenic germs, local anti-parasitic treatment should be resorted to, if the locality of the disease allows it.

The most effective preventive against the spreading of diphtheria is the prophylactic inoculation of those persons surrounding the patient, especially of the children. Numerous experiments have proven the harmlessness of Behring's curative serum (Heilserum) and its effect as a preventive remedy should be tested liberally in schools and families. Disinfection of the sick room and of all things which have been used by the patient should always be done. Convalescents from diphtheria should not come in contact with healthy people before the absence of the bacillus is proven by bacteriologic examination. In epidemics the laity should be enlightened by public instruction and publications.

Representing the French Committee, Professor Roux, from Paris, offered the following thesis:

1. Diphtheria is a contagious disease; the report of the cases must be obligatory.
2. Diphtheritic patients should be isolated.
3. The health officers have to provide for the proper disinfection of rooms infected by diphtheritic patients, of their clothes, linen and beddings; in short, of everything that has been used by the patients, toys included. During the sickness, the soiled linen, etc., must be disinfected before given out for washing.
4. Carriages, etc., used for the transportation of diphtheritic patients must be disinfected after each use.
5. Children who have had diphtheria should be kept from school until the physician has stated the cure and permitted the return to school.

6. When a pupil of a certain school is taken sick with diphtheria, the rest of the children should be under the observation of a physician for some time. All suspicious cases of angina should be excluded from school immediately. Special care is required for the sisters and brothers of a patient.

Besides these rules to be effected by official ordinance, the following principles should be generally adopted:

1. In order to employ an effective treatment of diphtheria the diagnosis must be made early. The beginning of the disease is insidious in many cases, and it would be overlooked less often by frequently repeated inspection of the child's pharynx. Mothers should make this inspection daily and the children be made used to it from an early age.

2. An early and sure diagnosis of diphtheria can only be made by bacteriologic examination, which therefore should be practiced by every physician.

3. Our knowledge concerning the effect of the anti-diphtheritic serum is of such a kind at present that its prophylactic use can be recommended for children in families with a diphtheritic case.

EMPYEMA OF THE ANTRUM, AND HOW TO TREAT IT.

Read in the Section on Dental and Oral Surgery, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY EUGENE S. TALBOT, M.D.
CHICAGO.

It is not the intention of the author to enter into a minute description of the large number of skulls he has examined in the past few years, but simply to give some of the details of the more marked deformities so that our reasons for certain modes of treatment may be more clearly understood.

Gray says: "The antrum of Highmore or maxillary sinus is a large triangular-shaped cavity, hollowed out of the body of the maxillary bone; its apex directed outward is formed by the malar process, its base by the outer wall of the nose. Its walls are everywhere exceedingly thin; its roof being formed by the orbital plate; its floor by the alveolar process; its anterior wall by the facial and its posterior by the zygomatic surface. This conclusion must have been formed after an examination of very few symmetrical skulls, since the author has been unable to verify this description in all cases after an examination of 6,000 antra.

In order that the cavity may be opened in the proper place and drainage procured, we must possess some idea of its position and shape. I have examined skulls in which the shape of the cavity was just the reverse of that laid down by Gray. In others the antra were almost square with round corners, and still others it was almost impossible to describe, owing to the many deformities assumed.

Septa, bulgings, with corresponding depressions and deformities of adjacent cavities; sometimes the outer wall of the nose will be bent into the antrum from .25 to .33 per cent. of its space and *vice versa*. The size of the cavity also cuts quite a figure in regard to its position and relation to surrounding parts.

In neurosis and degeneracy one antra may develop to such an extent that it will be twice the size of a normal cavity. In such cases it is not uncommon to find the nasal cavities forced to the opposite side,

and the antra of that side only the size of the end of the little finger and situated almost entirely inside the malar process. In such a jaw we should expect to find (in the case of the large antrum) very thin walls as described by Gray, but a far different condition exists upon the opposite side where the antra is very small. Here the walls are thick and a drill would have to pass from one-half to three-fourths of an inch through the alveolar process to reach it at all. Another condition, occasionally observed is, in cases of neurosis and degeneracy, the nasal cavities situated either to the right or left of the face crowd the antrum to one side and bring the floor of the nose directly over the alveolar process; in this case a drill passing through the alveolus would penetrate the nose.

The author has observed two cases where dentists, in attempting to drill through the alveolar process into the antrum with a view of draining it, actually drilled into the floor of the nose. At the time I made the remark that the operator displayed great ignorance in regard to anatomy of the parts. In conversation with specialists on the nose and throat, I have been informed that they have seen similar cases, and I have since learned by observation that we are all liable to the same accident, for the reasons which I have already described. Again, in some cases the antra are almost entirely obliterated. At least only a few cells not unlike the ethmoidal cells are situated at the upper border, while the remainder of the space is filled solid with cancellated bone tissue. Frequently the antra are divided into compartments by bony septa occasionally dividing the cavity into two or more nearly complete cavities. In such abnormal conditions it would be reasonable to suppose that the lowest point in the floor of the antrum would be difficult to find.

The opening into the middle meatus of the nose also varies in size from a crow's quill to a space large enough to admit the end of the little finger.

Difference of opinion exists as to the cause of empyema of this sinus. By some it is believed to be an extension of inflammation of the mucous membrane of the nose due to cold; by others, and especially by dentists to alveolar abscesses. With a view of obtaining some facts in regard to this matter, some years ago I made a special examination of skulls with the following results: Of the 6,000 antra examined, there were 1,274 abscessed molar teeth. Of this number, 76 or about 6 per cent., extended into and apparently discharged into the antrum. Septa were found in 963 cases. In the treatment of 384 cases of pulpless teeth in connection with the superior molars in the past twenty-four years, only four cases of diseased antra were observed. Dr. M. H. Fletcher, of Cincinnati, Ohio, examined 500 skulls or 1,000 antra, in which 252 upper molars had abscesses making 25 per cent. Of the 252 cases, 12 perforated the antra. Dr. Fletcher found, in 224 cases of pulpless molars treated by him, only one case of pus in the antrum. We must conclude, therefore, that diseased antra are rarely due to abscessed teeth. On the other hand, owing to the unstable abnormal development of the bony framework of this cavity which is always found in neurotics and degenerates, we would expect to find inflammation extending from the nasal cavities into the antra, (especially when the openings are large) as a result of cold. Neurotics and degenerates are much more liable to disease, par-

ticularly of the mucous membrane, than those who possess normal development. To drain this cavity, medical men, but more particularly dentists, have been in the habit of extracting teeth or the roots of teeth, and when no teeth are present, drilling through the alveolar process in a perpendicular manner to reach the antrum. As has been shown, the antrum can not always be reached by this procedure. From the extended examinations, made by Dr. M. H. Fletcher and myself, both came to the same conclusion without the other's knowledge, that the best place to open the antrum was at the base of the malar process midway between the root of the second bicuspid and first permanent molar, and illustrated in Fig. 1 B. In such a position the lowest joint in the cav-

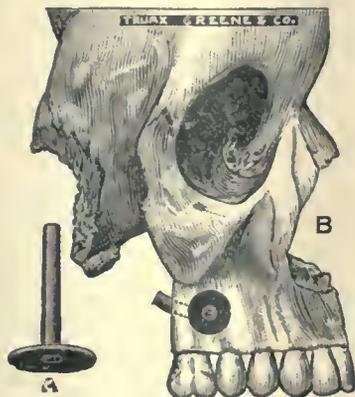

Figure 1.

ity can nearly always be reached and also avoid the possibility of entering the nasal cavity.

One of the great difficulties in treating diseases of the antrum successfully, is to obtain proper drainage after the cavity has been opened. Cotton, ivory and wood are generally used and tubes made of gold and silver. Silver tubes corrode and become very disagreeable, while gold tubes are too expensive. Plugs are of little account because they defeat the object required.

The author has been quite successful with a tube made of hard rubber, as illustrated in Fig. 1 A. They have the advantage over any I have ever used, in that they can be kept in stock at reasonable prices, softened in hot water, and molded to any position required. The flange can be trimmed to any shape

Figure 2.

and degree and the tube cut at any length. The cheek holds it in position, it can be kept perfectly clean and be readily adjusted when the opening is made through the alveolar process and fastened to a tube if necessary.

DISCUSSION.

Dr. YOUNGER—The paper is an excellent one, and I believe the method of opening into the antrum which it describes the best to be found. Two years ago a case came into my hands, in which a tube used to secure drainage from the antrum had been allowed during its removal to slip into the cavity. The patient was a lady 74 years of age. Immediately, though without alarming the patient, an endeavor was made by the surgeon in charge to recover the tube. Chloroform was given, the patient was kept under its influence for two hours, and for an hour and a half the search was kept up, but without avail. Some months later on my

return from a somewhat prolonged absence from the city I was called in, and found the patient much worse and steadily growing feebler. I thought it probable that a part of the tube was still in the antrum but I was unable to find it, although I used cocain, enlarged the opening, and searched for an hour and a half. The operation, however, benefited the patient and for a while she seemed better, but the old symptoms soon returned. I again operated, having in the meantime concluded that the missing tube was behind or over the inferior turbinated bone, and for the purpose of searching for it had a probe made with which I could thoroughly explore every portion of the sinus. The tube was found in fifteen minutes.

DR. DEAN—Was there any local formation of pus or local inflammation, and general rise of temperature?

DR. YOUNGER—We supposed so, on account of the improvement in the patient's condition after the operations.

DR. BOXWILL, Philadelphia—While I have performed many operations about the antrum, I have had but three cases of disease of the antrum which came from the teeth. It is a question how far we, as dentists, may treat antral cases, because they have given so much trouble to the best general surgeons. Much as I love a tooth, and much as I try to save them under almost all circumstances, I think I should prefer, in case of antral trouble, to extract a tooth so as to have plenty of light. It is well not to make unnecessary extra openings in surgical operations; if there is already one, we should try not to make more. After opening the cavity we ought to be able to drain it thoroughly. If this can not be accomplished with cotton then wool may be used, which does very well in many cases. Then, unless there is diseased bone to be removed, we ought to be able to medicate readily.

DR. VAN ORDEN—I have sometimes asked myself if I am always able to recognize antral trouble. In this connection I recall a case in which, if I could get it back into my hands, I should certainly attempt to cure a bad case of nasal catarrh by an operation upon the antrum. At the time this case came to me I treated it, the condition improved, and it was sent to a specialist who didn't seem to pay much attention to it. Dr. Talbot says that only a moderate number of abscesses in the upper jaw complicate the antrum. Would not the engine-point be less painful in operations upon the antrum than the instrument which Dr. Talbot describes, and therefore preferable for use in opening into it?

DR. TALBOT—Yes. The paper stated that the instrument referred to was for the use of physicians and surgeons who do not have the engine.

DR. WALTER F. LEWIS, Oakland, Cal.—Most of the gentlemen present recognize the necessity of having this subject well aired. I move it as the sentiment of the Section that Dr. Talbot's paper should be read before the Dental Congress next week.

The motion was adopted.

DR. TALBOT—I have tried to point out, both in the paper now under discussion and in the remarks which I made upon the chairman's address, that it is only by hard study that dentists can hope to improve the scientific basis of their profession. This paper now under discussion has been eighteen years in preparation, and to reach the deductions stated in it required the examination of over twenty thousand skulls in this country and in Europe. There are facts given in that paper which were never before publicly stated. Dr. Fletcher, as the result of an entirely independent examination, agrees with the conclusion that the antrum can not be depended upon

as to size; that is, whether it is as large as one's little finger or as large as a hen's egg, and extends over to the roof of the mouth can not be determined from appearances. I have seen skulls from which it would have been impossible to extract a tooth on one side of the mouth without going into the floor of the nose. Both myself and Dr. Fletcher reached the conclusion, each without the other's knowledge, that the point named in the paper, between the second bicuspid and first permanent molar, is the proper place to enter the antrum in operating. You must not lose sight of the septum which divides the antrum into two chambers. If you go up into only one antrum, the patient's head should be laid first on one side, then on the other, so as to drain both antra thoroughly. Treatment after opening should be simple. Cleanse out with syringe, using warm water or a weak solution of listerin or boracic acid, or something which will not injure the mucous surface. Many specialists use too strong remedies. Very simple treatment only is needed; cleanse thoroughly with warm water and let nature do the rest.

In reply to queries, Dr. Talbot said that in disease of the antrum the dentist should take entire charge of the case, which he should be competent to treat. I do not consider a man a real dentist who can not do so, though I fear there are comparatively few who are able to treat such cases successfully. I would not attempt to open into the antrum without knowing that it was necessary. I might go so far as to extract a tooth, but should then wait two or three months, if there was any doubt, to give time for a cure of the trouble by nature's help. Then, when sure that it was required, I should make the opening. In mild cases of antral trouble where transmitted light gives no indication I should treat the patient constitutionally, keeping the bowels open and building up with tonics. Ninety-nine out of one hundred such cases are due to inflammation of the mucous membrane, as from the effects of grip or the inhalation of extremely cold air.

DR. C. S. LANE, Oakland—Is the drainage tube a necessity in cases where the antrum is opened? Will it not take care of itself without this aid?

DR. TALBOT—The mucous membrane heals up very quickly in cases where the antrum is opened.

DR. LANE—Some surgeons say that it never heals, and my experience is that unless we do something to assist it, it does not readily heal. The idea advanced by Dr. Talbot seems new and well worth thinking of.

DR. DEAN—By this tube which Dr. Talbot shows, we have practically a valve which prevents the ingress of *débris* from the mouth. I do not feel able to discuss this paper to-day. Ask me a year from now and I may be able to say something upon it.

PYORRHEA ALVEOLARIS.

Read in the Section on Dental and Oral Surgery at the Forty fifth Annual Meeting of the American Medical Association, held at San Francisco, Cal., June 5-8, 1894.

BY W. J. YOUNGER, M.D.
SAN FRANCISCO.

By this name, I mean that condition in which there exist patches of a slate-colored calculus partially or entirely encrusting the roots of the teeth, with the alveolus more or less destroyed and the surrounding gums deep red, retracted and congested—though sometimes attenuated; usually yielding pus at the cervical margin between it and the tooth, but this feature is sometimes absent.

This incrustation is firmly adherent to the cementum, for no pericemental tissue is ever found between it and the cementum. When removed it comes off in scales, leaving the portions of root from which it is detached, clean and white. This is true of the calculus on the shaft of the root, but that which is found around the apex of the fang is very difficult of removal, as it does not scale but has to be dragged off piecemeal or dissolved by chemicals.

This is not in consequence of any difference in the character of the tartar, but in the fact that the apices of the roots are not smooth like the sides and present a roughened surface and therefore a more secure attachment to the calculus.

In consequence of the waste of the bony walls of the socket, when this disease has progressed to any extent the teeth will be found loose and tender on pressure and frequently raised in their sockets or forced out of their position—usually towards the side opposite to the location of the tartar. If the disease is allowed to progress to a conclusion, the teeth will drop, or fall out, in consequence of their attachment to the alveoli being entirely destroyed.

The etiology of this disease is as yet surrounded in mystery, though the professional opinion is strongly drifting into regarding it as of constitutional origin; and the deposit of calculus (which is the bane of the disease and always present, some writers to the contrary notwithstanding) as being of hemorrhagic ori-

gin, due to imperfect nutrition and connected with a gouty diathesis.

That it may be connected with malnutrition may be true, for no organ or tissue can become diseased while it is properly nourished; or that the condition may be aggravated or modified by constitutional disturbance or cachectic state is also palpable; but sufficient proof has not yet been adduced to establish the theory that pyorrhea alveolaris is of constitutional development and especially due to a gouty diathesis.

On the contrary, my experience with this disease (covering a period of over thirty years) has convinced me that it is of purely local origin; and I am very much inclined to the opinion I promulgated some ten or twelve years ago at a session of the California State Dental Association, that it is due to a diseased activity of the pericementum caused by disturbed nutrition or a local irritation, and that instead of bone it produces this disorganized abortion, vulgarly called tartar; itself perishing in the effort by the irritation of its presence.

This is the reason why pericementum is never found under the calculus. And this theory is strengthened by the fact that the constituents of tartar are analogous to that of bone, and why the pericementum is never in contact with the margin of the calculus. For there is always a denuded strip of root between it and the membrane.

While the irritation inducing the formation of this calculus may proceed sometimes from or be caused by the blood (as for instance the impaction of a capillary thrombus) I think it usually due to some irritant acquired from without. For the deposit is first formed near the cervix of the teeth, most frequently upon the approximal surfaces under the lingual margin where food and seed, etc., are most apt to lodge.

It is only in mature life and advanced age that we find it near the ends of the fangs; but in young or old one thing is certain; that between the alveolus and the root there is always free communication between the calculus and the cavity of the mouth. This condition, which in my long experience I have found invariable, shows the probability of some migrating germ or substance from the cavity of the mouth being the original or exciting cause of the mischief.

Now were this disease of constitutional origin there certainly would be many cases in which there would be no lesion whatever between the gum tissue and the neck of the root. The pus seeking egress would pierce the alveolus and the gum just as in alveolar abscess. This would at least go to show that pyorrhea is not always due to an extraneous irritant. But even then it would not prove a constitutional origin and my theory concerning a diseased activity of the pericemental membrane and the lodgment of a capillary thrombus would be a better explanation. Moreover, I have found this disease to exist in an advanced condition, in persons who had always been exempt from any constitutional ailment whatever; who had no gouty or rheumatic diathesis either by inheritance or acquirement (at least had never developed any,) who never had indigestion or any form of dyspepsia, and who had (to use their individual expression, "the stomach of an ostrich" and had never been sick a day in their lives.

It was the consideration of such cases that made me once call pyorrhea alveolaris a "disease of good

health." Another thing that tends to prove the disease is local is the fact that when once it is cured and the gums are made to re-attach themselves the disease does not return to them, no matter what cachectic condition may exist in the system.

As uric acid exists in the blood of the gouty, it is not to be wondered at that in persons of this diathesis, traces of the urates should be found commingled with the calculus of pyorrhea; for any disturbing cause, such as tartar, that induces excitation and flow of blood to a part will almost of necessity acquire a deposit of whatever the blood is freighted with; and therefore the uric acid which Professor Peirce found in some of the calculi and upon which he based his assumption, that the calculus was the result of a gouty condition, was simply the natural outcome of the presence of an over-supply of blood, and had nothing to do with the origin of the calculus.

But the best way to try a theory is to test it clinically; and if, for instance, in pyorrhea alveolaris it is found that the disease can be prevented or cured by constitutional treatment, then we must regard that disease as of constitutional origin. But if, on the other hand, you find a local disturbance or lesion yielding to local treatment, solely, and remaining cured regardless of any systemic pathologic condition, then you may reasonably conclude that this disease is local. And from my experience with pyorrhea alveolaris, I would as soon think it of constitutional origin, as I would that corns, bunions and freckles are of systemic development.

And now to consider some cases in point:

A lady who had a decidedly gouty diathesis, through inheritance (so marked that her finger joints became tender and swollen and the deposit of uric salts was being continually formed in the follicles of her throat) went to a friend of mine, one of the cleverest men in the profession, to have three upper molars, two on the left and one on the right in nearly the last stages of pyorrhea alveolaris, treated and filled. Their roots were so thoroughly incrustated with tartar that they merely hung in their sockets by their apical extremities, and they were all more or less decayed, but especially the right molar, for it had a cavity extending almost to the pulp. She had also suffered for two or three years from frequent attacks of nervous prostration, and the impression commenced to grow that this condition was due, in a measure at least, to the state of her teeth, which in consequence of their looseness and tenderness made it impossible for her to masticate properly.

This gentleman advised her to have these molars drawn immediately for the sake of her health, as he considered it impossible to save them, but as the lady would have to substitute artificial dentures she demurred, and hoping to spur him on to some effort to preserve them she remarked: "I think Dr. Younger could save them!" "Madam," was the retort. "neither Dr. Younger nor God Almighty could save those teeth. They are so loosened by disease, I could pull them out with my fingers!"

The idea that God Almighty should not be able to save them grated on her religious sensibilities, and she determined to wait until my return. I was then on my way home from Berlin, and one of the first persons to consult me on my arrival was this same lady. Having made a specialty of just such cases, I commenced treating her, ignorant of the judgment that had been passed upon the teeth by my esteemed colleague. She feared to tell me until the cure was effected, lest it might prejudice my efforts. In six weeks the teeth were firm and the alveolar tissue strongly adherent throughout their full extent, certainly around the cervices.

It is now nearly four years since the cure was completed, and though the finger joints still swell and become tender and the uric incrustations still form in her throat, the teeth have had no return of the trouble; they are perfectly rigid in their sockets, and

there is nothing in their appearance, nor in that of the enviroing gums, which would suggest the lesion which had been so nearly fatal to their existence. Now no constitutional treatment was made, the success being due entirely to local applications.

Some eight or nine years ago, at a meeting of the State Association, the subject of pyorrhea was in discussion and there was an almost unanimous opinion expressed that this disease could not be cured and that the cures I mentioned could not have been "true pyorrhea." While I was on my feet arguing this, Dr. Cummings of this city came to me, saying: "Can you cure me?" and opened wide his jaws. His teeth were all loose, the swollen gums had retracted from around the roots for an eighth of an inch, and pus was flowing at the slightest touch. I replied: "Yes, if you will permit me to clinic on you before these gentlemen, and prove to them how wrong they are." I then called the attention of the convention to the condition of Dr. Cummings' mouth and asked them to tell me what the matter was. With one accord, they said, "pyorrhea." "Bad case?" "Yes, a very bad case." "Now, gentlemen," I said; "the proof of the pudding is in the eating. I will treat Dr. Cummings before you, and at our next session you will see whether pyorrhea can be cured or not."

I gave the Doctor half a dozen treatments, all local, and the disease quickly yielded; and though eight or nine years have passed since then, there has been no return of the disease, and the teeth and gums are firm and sound.

A few years ago, I commenced treating a gentleman of mature years for pyorrhea. He was also being treated for gout. The pyorrhea was on a fair way to cure, when one fine morning he told me that his physician had informed him that my local treatment could not possibly save his teeth; that the disease in his gums was the result of gout, and had to be treated constitutionally. He therefore dropped me and stuck to his physician; who was a very learned man with a microscope. The result was he was relieved of his gout, also of his teeth, for under the "constitutional treatment" they all dropped out! Had he stuck to me, alone, he would have had his gout, but he would also have had his teeth. He should have stayed by both of us, and now he would have his teeth and be minus his gout.

It is a fortunate circumstance that a knowledge of the etiology of pyorrhea alveolaris is not a necessary factor for its cure. There are few lesions in surgical pathology simpler of treatment than this same disease; the most essential requisite being skill and manipulative dexterity, in order to secure the thorough removal of the calculus and the perfect cleansing of the root. The elimination of every particle of tartar is a *sine qua non* to success. Unless this is done perfectly and absolutely, the disturbing cause of the disease will not be eradicated and it will in time return.

The return of the disease that so many complain of is due very often to the fact that the complete removal of the tartar has not been accomplished, and that the surface of the roots has not been thoroughly cleansed. The appreciation of tartar, however, is not always easy and it requires a certain sensibility in the fingers not common to all persons.

It is that touch which makes one violinist superior to another in the development of the tone of his instrument. This is the reason why so many have failed to discover tartar when it existed, and why it has led them to suppose that either the tartar had been completely removed or that the pyorrhea existed without the tartar. There is, besides the sense of

feeling, an acuteness of hearing by which one can recognize by sound, as the instrument passes over the root, whether it is the substance of the root or an incrustation.

But before the removal of the tartar is attempted, the mouth and crevices and the little pockets containing the tartar and the calculus itself, should be thoroughly sterilized. I prefer the bichlorid of mercury, 1 to 1000. It should be used warm, at least that portion that is injected around the necks of the sensitive teeth, in order to prevent the pain that cold applications are almost certain to produce. The sterilization is necessary to prevent the absorption of septic matter, as the gum is almost certain to be abraded by the instruments used to remove the tartar. For the same reason the instruments should be thoroughly sterilized. The water used as the menstruum for the sterilizers should have been subjected to distillation; otherwise the organic matter and chemicals which are apt to be in ordinary water may be sufficient to decompose or to modify the strength of the sterilizing agent and so negative its action. But, by all means, be sure and sterilize the instruments! Keep them continually in the antiseptic fluid while laid out for use.

When removing the calculus, begin with one tooth and *stay* by it, until all of the tartar is removed, even if it takes the full time of the sitting. And as fast as the tartar is scaled off, wash it out with the warm fluid by syringing with delicate platinum pointed syringes. If this is not done, minute pieces of the tartar will adhere to the raw surface of the gum, keep up an irritation, and prevent the healing process from being established. It is well, when the pockets are very deep, to insert a little lactic acid to dissolve the diseased edge of the alveolus and any minute fragment of tartar which may have escaped the instrument.

The root being thoroughly cleansed, and the *débris* washed out of the pocket, a little tincture of iodine may be dropped into it, or else a solution of chlorid of zinc, three and one-half drachms to the pint of water, to stimulate its contraction and the production of granulations, and to induce the attachment of the alveolar tissue and gums to the root. If this does not take place, then rub quickly with a little wad of cotton saturated with liquor ammonia, washing out immediately with warm water. This ammonia is to remove the mucous membrane from the healed and therefore unattachable surface of the gums; and the water, to wash it off before its escharotic action can be established. By this means a healthy granulating surface is formed, contraction stimulated, and attachment to the clean surface of the root induced. In case the gum should remain flabby, inactive and indolent, then acupuncture should be resorted to. This can be done by rapidly piercing the gum with a sterilized needle. When the amount of the deposit is so great that the alveolar septa have been destroyed, pass a threaded needle through the gums and between the roots of the teeth and approximate them by tying them as nearly together as can be done, without the use of much force. If too much force is used the thread will cut through the gums.

In the case of one lady of 55, the accumulation of tartar was so great that the septa of both gum and alveoli from the first bicuspid of one side to the first of the other were destroyed, and the labial and lingual walls of gums simply leaned against the teeth when the mouth was in repose,

but left them instantly when the tongue or lips moved. For instance, when the lower lip was pushed down, all the wall of the gum upon its aspect went forward with it, leaving the roots of the teeth entirely denuded of gum upon their front. When the tongue was raised or retracted, the gum upon that side moved away also, leaving bare the teeth upon the lingual surface. And when the tartar was removed the separated teeth leaned in every direction.

I gave the gums the ammonia treatment; held them in position by means of ligatures through the interdental spaces; kept the mouth in an aseptic condition by the repeated use of the sublimate, every two hours. In a couple of weeks I had the gratification to see the spaces filled with granulations as high as the margins and firmly binding the two layers of gum into one continuous mass.

This case was reported to the State Dental Association and to the Surgical Section of the Ninth International Medical Congress in Berlin.

The reason for treating the teeth one by one—that is, completing the removal of the tartar and all that has to be done, at one sitting, is that the process of healing should not be interfered with after it has commenced, and also because there is the object of getting, so far as possible, the benefit of healing by first intention.

By the subsequent use of antiseptic washes, until the healing process was entirely accomplished, I have succeeded in curing the most desperate cases of pyorrhea alveolaris, and of restoring to perfect use, teeth that have been for years worse than worthless.

There is only one condition in which I have found failure, and that is where there is a dead pulp in connection with an incrustated apex. This condition is found almost exclusively in the palatal root of the superior molar, and the difficulty in the way of a cure is due, not so much to the tenacity or quality of the tartar, as it is to the septic condition of the substance of the fang, the putrescence of the pulp having invaded tubuli and canaliculi and destroyed beyond hope of restoration the vitality of its tissue, and thereby its ability to re-form attachment.

As the diseased pulp is usually confined to the palatal root—that in the buccal being usually healthy—my treatment in these cases has been to open into these roots, remove their pulps, fill them and amputate the palatal; then grind away enough of the articulating surface of the crown, immediately over the removed root, in order to bring the pressure in the effort of mastication upon the buccal roots. By these means, these teeth can be made comfortable and serviceable for years, if not for a lifetime.

In eleven cases of pyorrhea reported by Dr. C. N. Peirce and Dr. Albert Brubaker, wherein they sought to establish their theory that uric salts were found in the incrustations of what they call "true pyorrhea," in but five of these eleven cases were they able to discover traces of uric salts. Now, although exceptions are said to prove the rule, where the exceptions are more numerous than the rule sought to be established, the exceptions govern the rule. Therefore, the cases decided by Drs. Peirce and Brubaker are not sufficient to establish a theory on which to base their assumption and their conclusion.

There can be no local lesion or irritation which is not more or less affected by the state of the system, that when vitiated will prevent the healing of an otherwise simple sore which under normal conditions would yield readily to local applications.

Dr. Brubaker makes a statement that the deposit of uric salts upon the end of the roots is being "continually renewed." One would infer from the term

"renewed" that the deposit is absorbed and more salt re-deposited; but as such a statement would be absurd he can not possibly mean that. The only inference to be drawn then, is that if the deposit is removed by instruments or chemicals, a fresh deposit of the uric salts would take place, and thus a source of irritation would be continually kept up. Now both Drs. Peirce and Brubaker claim that this condition only takes place in the apex of the fang; but why should it be limited to the apex of the fang? The same exact tissue surrounds the sides of the roots as that which envelops the end. Then why limit this particular action to this particular locality?

The fact is that, when a deposit incrusts the entire end of a root, the irritation set up by its presence results in the death of the pulp, and this condition with the greater vascular activity set up by the propinquity of the calculus to the larger blood vessels entering the foramen of the apex causes in a greater degree a deposit of any salt the blood is freighted with. Therefore, in the few cases in which an examination revealed the presence of the urates such a presence was but a natural conclusion, and the only wonder is that the salts were not found in the entire eleven cases cited instead of only in five.

I do not know why it is that Dr. Peirce calls that condition, only, where the calcic formation surrounds the apex of a root, "true pyorrhea alveolaris." This condition exists so rarely when compared with what he calls pyalogenic calcic pericementitis (but what is known to the profession as pyorrhea alveolaris) that it reminds one of a fanciful name given by early settlers to a certain region in this State, "Strawberry Valley," for the reason that there were no strawberries in the valley! If he wished to make a distinction between the calcic formation on the shaft of the fang and that of the apex he should have left that general condition known as the "true pyorrhea" and given a name to the special condition.

But why is it that this special condition exists almost, if not entirely, on the palatal root of the first superior molar? It is easy to be seen from the fact that the palatal root of the first molar spreads more than that of the multi-rooted teeth. That the tissue over them is more attenuated than it is over the roots of the other teeth, and that they are therefore more affected by thermal changes than the other roots; that the pressure of the tongue and the superimposed food is greater upon these roots; in fact, that the impact of food is stronger on these roots than on any other. They are, therefore, more exposed to changes and vicissitudes than the buccal roots of the same teeth; or of the roots of any of the other teeth. That is the reason why we so often find these roots more denuded and exposed than the other roots, and why the pulps in these roots are more susceptible, in consequence, to abnormal changes and death.

In concluding this paper, perhaps it would be well for me to summarize the arguments for and against the theory of pyorrhea alveolaris being due to constitutional diathesis. The arguments in favor of pyorrhea alveolaris being of constitutional origin are what?

1. That it is found in persons afflicted with gouty diathesis.

2. That traces of uric salts are found in the calculus of some of the people afflicted with the gouty diathesis.

3. That the condition of irritation in the gums and

around the roots, and the discharge of pus, are modified by constitutional treatment.

In opposition to this we find:

1. That pyorrhea is found in persons having no constitutional cachexia or diathesis.

2. That if it were of constitutional origin it would be found in all, or at least in nearly all cases having the gouty disposition.

3. That the amelioration of the irritation by constitutional treatment is what would occur in any local irritation when the system would be placed in a healthy condition.

4. That if it were of gouty diathesis the deposits from the saliva would also be impregnated with these urates.

5. That, if it were of constitutional origin, constitutional treatment would be necessary for its cure; but, instead, local treatment is found sufficient for its complete eradication, notwithstanding the constitutional ailment is continued in undiminished force.

6. In all cases of pyorrhea alveolaris we find a connection between the calculus and the cavity of the mouth, which would not necessarily be so if it were the result of a constitutional pathologic state.

Besides these points, Dr. Van Woert asserts that the disease is communicable by infected instruments which, if true, would prove a very strong argument against the theory of constitutional development.

DISCUSSION.

DR. C. S. LANE, Oakland—These papers are of great interest to those of us who are in active practice, meeting with cases of the characters described every day, and studying to overcome the conditions as we find them. The difference in the positions taken by the writers is an evidence that great minds do not always see things in the same light. One thing that strikes me practically in this disease, is that in some cases I can overcome the condition by local treatment; by a thorough removal of the deposit the way is paved for a thorough cure. In some instances the cure is not so thorough. I have always striven to be very careful in the local treatment of this disease, and yet I find some cases where I can not put a stop to the suppuration, more especially in diabetic patients. I have now one case under treatment which has been in my hands over three years; I have carefully watched the reported discussions on this disease by the leading practitioners, and though I have tried everything that has been suggested I have been unable to arrest the progress of the disease; so that I can not think in this case the cause can be considered due to local conditions, or that its persistence is due to any lack of proper sanitary conditions or local surgical treatment. Many cases of pyorrhea alveolaris can be treated locally successfully, but there are others, especially among patients with diabetic troubles, for the cure of which you have to go farther than merely local treatment.

DR. YOUNG—A case which occurred lately in my practice is called to mind by the remarks of Dr. Lane. A lady, in an anemic state, presented just before an expected six weeks' banishment from the pleasures of the world, with pockets discharging pus around several of the teeth. On careful examination a slight rim of tartar was found near the alveolar process, the disease having progressed on one of the teeth to within an eighth of an inch of the apex. This tooth was so loose that every breath waved it to and fro. I spent one and one-half hours on each tooth, carefully removing every trace of the deposit, and the disease was cured. I used iodine in the treatment. One thing to be borne in mind in the local treatment of these cases is that plenty of time must be taken to each tooth; otherwise you will fail. I think that in the disinclination to do this is the cause of failure frequently. Then again you must have the natural touch that will enable you to know absolutely when the removal of the deposit is accomplished. I know of no other reason why I am successful in the treatment of these cases than the possession of this touch and the taking of the necessary time to do the work thoroughly. You all know me, and you know that I am honest in the opinions I express, and that I take the ground I do, only

because I believe it will be for the benefit of the profession. One reason why I have given the clinical treatment of pyorrhea alveolaris in detail is because I believe the cure is to be found in the careful manipulation of the instrument point, rather than in high scientific theories. I have also received letters from different places, among them Bombay and Krakow, asking how I treat pyorrhea, and this seemed a fitting opportunity to give a general reply.

Dr. JOHN C. MCCOY, Santa Ana—How do you keep patients still for one and one-half hours?

Dr. YOUNGER—By not hurting them. I obtund the sensibility of the tissues so as to cause only the minimum of pain.

Dr. RUSSELL H. COOL, Oakland—I have seen Dr. Younger operate, and his fingers are certainly sensitive. As he says, the proper removal of the deposit in pyorrhea alveolaris requires delicacy of touch; the deposits are tenacious, and you must take whatever time is necessary to remove them. I thought it impossible years ago to cure this disease by local treatment alone, but I have seen cases so cured by Dr. Younger. He mentions warm water in his description of the treatment. He should have said hot—at least as warm as the patient can bear, in connection with the bichlorid. Pyorrhea does not spring up in a night, and I have noticed in young patients, especially, you will find a single pocket, to dislodge the deposit from which requires but little pushing. If neglected, however, we find it spread from this incipency till it involves several teeth. The successful man is he who treats the disease in its incipency without waiting till diabetes is established and the man is on the verge of the grave. You sometimes find in these cases a little abscessed cavity along the course of the pocket. A surgical opening will give room to medicate and treat this.

Dr. I. N. DEMAREST, Santiago, Chili, was here introduced to the Section, but he excused himself from making any remarks).

Dr. G. S. DEAN, San Francisco—I would like to ask a question. Dr. Younger and Cool, and perhaps Dr. Dunbar also, have referred to the occurrence of an abscess between the gingival border and the apical space. Do they mean an actual abscess?

Dr. R. H. COOL—I meant a sinus containing pus. In one case which I recall at the moment, there was such a sinus on the labial surface of one of the teeth. By cutting through the alveolar plate, I opened into it and then treated the same as any other abscess.

Dr. DEAN—I want to call for more testimony. Abscesses which are not apical, we may perhaps call gingival abscesses.

Dr. EUGENE S. TALBOT, Chicago—We have heard both sides of this question—the local and the general—in the papers which have been read, neither of which, however, classified the various forms of pyorrhea alveolaris. I have certainly seen three different conditions which properly come under this name. First, there is the local deposit from the salivary glands; then the serumal deposit directly from the capillaries; and last, a condition which I must say is constitutional, because there is no deposit whatever. I can't harmonize this last with Dr. Younger's conclusions; I don't care if he don't hurt the patient, and no matter if he does take one and one-half hours to each tooth. Take a case of serumal tartar. If Dr. Younger can remove all the deposit, I can not. I don't even know when it is all removed. Take a mouth in which there is a set of good sound teeth, but in which this disease has affected the second molar to within one-eighth of an inch of the apex, the tooth being in consequence quite loose, while others are just beginning to become loose, from the effects of serumal tartar. We will clean that loose tooth thoroughly. We find the ends of the roots exposed and the tooth itself held in the process by one root only. We clean the teeth as well as we can, and in one month's time the patient comes back with the tartar extended all around the mouth. If we remove that loose tooth, treat as before, and watch the case, we can save the other teeth; but as long as that loose tooth remains in the mouth it forms a nidus or rallying place for the destructive forces. I have had that experience over and over again. In the third condition to which I have referred there is no deposit. I have seen cases of this kind where the teeth were loose, and I tell patients from the start that nothing can be done by local measures, and I simply treat them constitutionally. They become built up and the trouble abates; then they stay away for three months and come back all run down with the old condition renewed. I have had other cases where the condition was inherited—not the pyorrhea but a

predisposing condition of the system which was handed down from generation to generation. As long as we practice dentistry as we do to-day, we give evidence that we don't know the principles underlying this disease. We have to get a better knowledge of it. I believe pyorrhea alveolaris is a constitutional disorder, and that it is not due to uric acid in the system, but that the liver is the cause of it and we have to get down to treating that before we can master this disease. It arises from an inherited condition of the liver and not until we know more about the treatment of the liver than we now do shall we know how to really cure pyorrhea.

Dr. YOUNGER—Dr. Talbot asserts that we are as ignorant about pyorrhea alveolaris to-day as we were twenty-five years ago. I would like to know what is known in medicine about for instance, the function of the spleen. I would like to know what the medical profession has taught us about the origin of disease. I think we do know a great deal more about pyorrhea than we did, and that we are able to treat it better.

Dr. BONWILL—I don't like to repeat here what I have just said before the Odontological Society of Pennsylvania where the subject was recently discussed. The majority of dentists don't know how to treat pyorrhea alveolaris. I stated my ideas two years ago in combating the idea of a calcic diathesis being the cause. I agree with Dr. Younger in everything he says, but I go a step further than he does. Dr. Younger looks at the matter in a common sense light. Nothing shows more plainly the uselessness of the dental profession as an appendage to the medical than this one subject. Dr. Younger sees a phenomenon—tartar on the roots of the teeth, which is the true cause of pyorrhea. I have had forty years' experience in the practice of dentistry, and I should be ashamed to have a case of pyorrhea in a mouth of which I had entire control, because I would say it was my fault. In forty years' practice I have not a single case of a regular patient of mine that had pyorrhea. There must be perfect cleanliness. Dentists too often neglect this first important requisite of cleansing the teeth and keeping them clean. The first thing to do before daring to touch a tooth to operate upon it is to see that the mouth is clean. Half of my cases of this disease are the failures of other men. I recall at the moment the case of a patient who came to me after he had been to a number of medical men who told him he would lose all his teeth. Three of them were in fact so far gone that they had to be extracted, but the others were saved. If you cleanse these teeth one by one, take away all the dead tissue the same as Dr. Younger does, cut off the superabundant gum, and cleanse thoroughly they will get well. I have never yet in forty years given a patient constitutional treatment for this trouble. If, after having put the teeth in proper condition you teach patients proper habits with regard to their teeth, there will be no return of the disease. I cleanse the whole upper set if it is at all affected, at once, even if it takes the whole day; cut out the superabundant gum, and don't meddle with nature after giving her a chance to do the work of repair. The gums will again hug up to the teeth. For treatment, there is nothing better than creosote and I now use carbolic acid and not diluted. I attribute much of the cause of pyorrhea to bad dentistry. In almost every mouth under the regular care of the dentist you find that teeth have been extracted in early life; or that that they are cut apart on the approximal surface and filled with flat filling, cutting away the gum to make room. Overhanging fillings at the cervix, amalgam fillings that their author ought to be ashamed of, crude and rough as they are—will destroy the membranes around any tooth. Gold crowns which are not fitted properly or finished fine at the edges are also factors in this disease. Then the rubber dam must be tied on or held up beyond the gum margin, and is another cause of trouble at the cervix. There are many other causes which may help to originate this disease, but those I have mentioned are enough to give my ideas. I am a crank on articulation, for instance. If there is anything which helps out in these cases it is seeing that the articulation is correct. I always take an impression and then knowing the law of articulation, with a little study I can see just where to touch the teeth and correct any deficiency. I am against the principle of the so-called gummy diathesis, and in treating teeth I never cut away too much, but rather too little.

PREVENTION OF DIPHTHERIA FROM THE STANDPOINT OF THE HEALTH OFFICER.

Read in the Section on State Medicine, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY U. O. B. WINGATE, M.D., M.M.S.S.

PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM AND HYGIENE, WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS; EX-HEALTH COMMISSIONER, MILWAUKEE; SECRETARY WISCONSIN STATE BOARD OF HEALTH, MILWAUKEE, WIS.

In presenting this short paper I do not claim to offer anything original or new, but merely to give the results of my observations and suggest points that may be profitably discussed.

Prevalence.—The wide-spread and variable prevalence of diphtheria is of great interest to the health officer. Rural statistics avail us nothing in this country, as a rule, but statistics of death from this disease in our larger cities are fairly reliable. There is one feature, however, that has not yet generally entered into our statistics that may modify them somewhat, that is, the prevalence of croup and what proportion of cases of so-called membranous croup are cases of diphtheria. The recent researches of Dr. H. M. Biggs, of New York, which show that nearly 80 per cent. of cases of so-called membranous croup were found to be cases of true diphtheria by a bacteriologic examination, are of great importance to the health officer and demand a most earnest and careful consideration. I believe all cases of croup presenting exudation in the throat should be treated by the health officer as true diphtheria, unless a bacteriologic examination proves it to be non-diphtheritic. This would seem to be, in our present state of knowledge, the only safe procedure, for certainly if there be a doubt in regard to the care and treatment of infectious diseases the public should have the benefit of it.

The following is a table showing the per cent. of deaths from diphtheria, on the estimated population during the years 1892 and 1893, as officially received from a few of our larger cities in this country:

| | 1892 | | 1893 | |
|-------------------------|------|--|------|--|
| New York | 0.08 | | 0.10 | |
| Chicago | .07 | | .06 | |
| Philadelphia | .13 | | .08 | |
| Brooklyn | .08 | | .06 | |
| St. Louis | .04 | | .04 | |
| Boston | .09 | | .10 | |
| Baltimore | .08 | | .04 | |
| San Francisco | .07 | | .05 | |
| Cincinnati | .09 | | .05 | |
| Buffalo | .06 | | .05 | |
| Cleveland | .07 | | .04 | |
| Washington | .07 | | .04 | |
| Pittsburg | .11 | | .06 | |
| Milwaukee | .16 | | .08 | |
| New Orleans | .02 | | .03 | |

It will be observed, by this table, that in 1892 the largest death rate from this disease in fifteen of our largest cities was in Milwaukee, Philadelphia and Pittsburg, being .16, .13 and .11 respectively; and the smallest rate for the same year was in New Orleans, St. Louis and Buffalo, being .02, .04 and .06 respectively. While in 1893, the largest rate was in New York, Boston and Milwaukee, being .10, .10 and .08 respectively; and the smallest rate being in New Orleans, Washington, Cleveland, Baltimore and St. Louis, being .03, .04, .04, .04 and .04 respectively. These figures are approximately correct.

Etiology.—That the Klebs-Löffler bacillus and its products cause all the pathologic phenomena connected with diphtheria there seems to be no reasonable doubt at the present time, but the origin of this

bacillus and its habits are matters far from being settled, and these questions bear a very important relation to the etiology of this disease. Whether the bacillus originates *de-novo*, or whether it is a product of evolution from other forms of life, whether it can live in the soil in its true state, or is capable of taking on a form of existence non-pathogenic or saprophytic for an indefinite period of time, and then under certain favorable circumstances is capable of developing into pathogenic qualities, are questions yet to be solved. Quite an extensive experience with this disease, both as a practicing physician and as a health officer in a city which at times has led all other cities in this country in the large number of cases of diphtheria, leads me to observe that it is favored by cold, damp, cloudy weather; that it is more active in winter than in summer; that it is favored by damp dark cellars and poorly drained soil; that in certain conditions of soil and weather it seems to remain dormant for an indefinite period of time, and under more favorable conditions such as cold, cloudy, damp but not too wet weather, it becomes active; that sunlight, good air, good drainage and plenty of snow in its season, very materially lessen its ravages. There is much, however, to be learned concerning the true nature and habits of this bacillus, and this is a difficult matter to study, for nature's laboratory, in which these bacilli operate, is far different from any constructed by man.

That defective plumbing may be an indirect cause there seems to be no reason to doubt, but I have found no evidence that the bacillus is carried in the escaping sewer air; it is more probable that the effect of inhaling these sewer air debilitates the system and renders the powers of resistance less, thereby favoring the infection of diphtheria, as well as any and all other infectious diseases.

Periodicity.—Hirsch has called attention to the possible cyclical character of the epidemicity of this disease, though the cycles have extended over periods of various lengths, many of them only a few years, others lasting several decades. In the city where I reside, the two periods of greatest prevalence of the disease that have existed since records have been kept were about ten years apart, these periods lasting about two years each; at other times, although the disease has been constantly present the number of cases has been comparatively low.

Modes of Dissemination.—The means of disseminating this disease are many; from person to person by means of infected clothing of all kinds, furniture, rooms, books, papers, foods, drinks (especially milk), milk tickets, money, domestic animals, such as dogs, cats, birds, etc., and at school from everything with which the child may come in contact, as almost everything conceivable may, under certain circumstances, become infected. There is no evidence that the disease can be disseminated by the air for more than a very few feet; it is usually necessary to come in actual contact with the bacillus at its lodging place in order to become infected, and unless it is propelled for some little distance by the patient in coughing, it is rarely taken through the medium of the atmosphere.

Stage of Incubation.—The stage of incubation is usually short, not longer than two or three days; it may vary, however, being modified by the virulence or activity of the bacilli and the powers of resistance offered by the patient.

Prevention and Control of Epidemics.—In ordinary communities the health officer must first have great legal powers and they must be executed if he is going to contend with this disease; he must also have the hearty coöperation of all physicians in the vicinity. Without these two requisites he is absolutely powerless. The education of the people in the importance of sanitary matters is an admirable requisition but it will not be sufficient alone, in our day and time, to cope with epidemics of disease of any kind. The importance of law and the coöperation of physicians can not be too highly appreciated by members of our own profession. Our medical schools need to impress this more emphatically on the minds of medical students.

Cases must be isolated early and long, and to do this in most families where the disease prevails, the cases must be reported to the health officers early. Every city and town should provide means for a bacteriologic examination in any and all cases where there can be a question of doubt about the diagnosis, and this is often the case.

Every city and town should also be provided with an isolation hospital, or an isolation ward in a hospital to which every case can be removed, if possible, and isolated from all other cases and placed under the charge of nurses trained in the care of infectious diseases. By these means a better chance of recovery is gained by the patient and the danger of spreading the disease is reduced to a minimum. These facts should be taught the people by the physicians in such earnestness that they can not fail to learn the lesson. These hospitals should not be pest-houses nor disgraced by that name. Under modern scientific medical knowledge we have no longer any use for a pest-house and one should not be tolerated in any civilized community. With the antiseptic and aseptic care of all patients with diphtheria, as carried out by modern trained nurses under the direction of competent physicians, in properly constructed isolated hospitals, the control of the infection is absolute. A case of diphtheria early diagnosed and removed to an isolation hospital, and kept there until fully recovered, or until he dies, and the body properly disposed of, and the house and infected articles in the house early and properly disinfected, or destroyed by fire if of little or no value, will prevent a spread of diphtheria as effectually and surely as a problem can be solved in mathematics; but the details in each case must be correctly observed to arrive at a successful result. Where a large number of cases exist in a community the same principles hold good, but it becomes a more complicated problem.

Isolation and disinfection are the key-notes of the prevention and spread of diphtheria, but the details of these two important measures must be as fully understood, and their importance as fully realized, in order to be successful, as the principles of asepsis in surgery.

Having isolated the patient and thoroughly disinfected all apartments and articles infected, and having cared for the case in the most approved manner known to modern trained nursing, there is one matter often lost sight of, that is, keeping the patient isolated long enough. It is well known that the bacilli of this disease may exist in the posterior nares and pharynx for a long time after all traces of exudation have disappeared, and it is decidedly unsafe

to discharge patients from isolation until the mucous membrane is entirely healthy and has been thoroughly disinfected for several days after all appearance of a diseased condition has subsided.

No case, however light, should be discharged from isolation for at least four weeks from the time of the commencement of the disease, and no child should be allowed to attend school or mingle with other children until the expiration of six weeks from the commencement of the last case in a house, in case of recovery, and in many instances a much longer period of time should be observed. In case of death, the body should be wrapped in a sheet wet in a proper disinfectant and immediately hermetically sealed, and should be prohibited from transportation, but should be buried or cremated within twelve hours after death, after which all apartments and articles infected should be thoroughly disinfected, and those of the family exposed should not be relieved from quarantine for at least seven days after the disposal of the body and disinfection. This rule should also apply to all persons exposed to a case of diphtheria before thorough isolation and disinfection, whether isolated at home or removed to a hospital.

By such measures only can we expect to control the ravages of this disease, and it will require a realizing sense of the importance of such measures on the part of the health officer, as well as courage and efficient police powers and police force, at times, to carry out such provisions successfully.

REMARKS ON ONE HUNDRED ABDOMINAL SECTIONS.

BY BYRON ROBINSON.

CHICAGO.

The typical "control" laparotomy is prepared for three days by administering salts and calomel, until a dozen bowel movements are produced or until the bile glistens in the stool. The patients should then rest in bed and be given no purgatives. This will allow the fermenting gas to escape and when the abdomen is opened on the fifth day the intestines will be collapsed like ribbons. Such a course of preparatory treatment is wise as it stimulates all the alimentary glands to the highest stage of depletion. The pores of the skin are opened and stimulated to secretion by daily baths. At the time of the operation all the secretive tissue is at its highest tension and the depleting avenues are all washed out and open. Pure ether was used as an anesthetic in about 90 per cent. of cases and though it may be followed by bronchitis and nephritis, yet it is in my opinion safer than chloroform, which kills outright by acting on the heart or respiratory centers. No cases were selected or refused. The operations were the following:

1. Removal of the tubes and ovaries.
2. Abdominal hysterectomy.
3. Vaginal hysterectomy.
4. Appendicitis.
5. Hernia.
6. Colotomy.
7. Post-peritoneal abscess.
8. Ectopic pregnancy.
9. Tubercular peritonitis.

There were six deaths in the one hundred cases. One died fifty-two hours after the removal of the sixty pound tumor, from shock and sepsis. One died on the fifth day from pulmonary embolus. One died

from shock by removing a large ovarian carcinoma, ten hours after the operation. One died from urinary suppression beginning on the fourth day after the operation. One died an hour after operation from hemorrhage previous to operation. She had ruptured tubal pregnancy and about four quarts of blood were turned out of the abdominal cavity. The sixth died after the use of the Murphy button. The autopsy revealed one large and two small perforations at the side of the button.

The standard for the operation is the urea. The patient on entering the hospital is ordered to have the urine examined three times, eight hours apart. The urea runs from four to eleven grains to the ounce. I think it is unsafe to operate with less than 5 grains of urea to the ounce. Tests of urine were made for albumen and sugar, but less importance was attached to them. I generally prepare the hands by careful washing for an hour before the operation—say thirty minutes the night before and thirty minutes just before the operation. I wash them in turpentine and alcohol. I note the hand preparation, for I work in *post-mortems* and abdominal operative courses on the cadaver every month in the year. I often scrub my hands an hour previous to the operation and I do not know that I have ever infected a patient. Several years ago I was a pupil of Prof. Karl Braun's first assistant, who worked continually on the cadaver and in abdominal sections and obstetrics, and I never knew him to infect a patient. He scrubbed his hands, however, less than I do. I do not use bichlorid on my hands (unless I have been to a virulent pus case) because it desquamates the epithelium, and makes them so rough that I can not scrub them clean. Hot water, soap, turpentine and alcohol have proved sufficient. I have discarded sea sponges for safety and use now only pieces of gauze. During the last part of the series I make the incision slightly to one side of the linea alba, and I think the union is better and stronger. I now close the abdominal incision with silkworm gut. The suture passes through the whole abdominal wall about four stitches to the inch. I leave the sutures in for three or four weeks. Wounds do not heal very well inside of three weeks. We used the drain tube in all pus cases and in most with extensive adhesions. In short, we used the drain tubes when we were in doubt. We use the tube from a few hours to several days. We are gradually limiting the use of the drain tube. We are also gradually limiting the use of irrigating the peritoneal cavity. The sutures we use in the abdominal cavity are silk and kangaroo tendon and linen thread (Barbour's No. 40).

In the after treatment of laparotomy, half the battle is with the intestines. Gas begins to pass in ordinary cases some fifteen hours after the operation, but we generally begin to give Mg. So, 3i and Hg, Cl, grs. ii, alternating every two hours in the early part of the third day until the bowels move. The patient is given a rectal enema on the second day. If gas does not pass on the second or third day, tympanitis arises, which is a kind of incipient peritonitis. It is intestinal paralysis which if allowed to progress ends in peritonitis. But a bowel movement subsides the tympanitis and hence a purgative is a prophylaxis in peritonitis. From our present knowledge we must look on post-operative tympanitis as incipient peritonitis. We give hot fluid drinks from one-half to two ounces an hour as soon as the patient desires them. If the patient vomits the drinks are discontinued. No

ice or cold fluids are allowed as they encourage thirst. Peritoneal sections give rise to a raging thirst and hot water slakes it better than any kind of drink. Besides water is a natural diuretic; it quiets the patient's stomach and nerves and fills the vessels with fluid. For pain we occasionally give one-sixteenth of a grain of morphin from two to four times in the first thirty-six hours. Several years ago while a pupil of Mr. Tait, the first time I saw him do a laparotomy he ordered his assistant to give the patient a hypodermic of morphin immediately after the operation and this practice he frequently repeated. Opium has its place in laparotomy. Rest and ease are superior to pain which can be judicially controlled by morphin injected under the skin. But in all the after-treatment the judicious use of salts (Mg. So₄) is the most effective. When tympanitis (incipient peritonitis) arises, it then becomes a race between bowel movements and death. If the salts irritate intestinal peristalsis they win the subject.

The post-operative sequelæ are of significant importance. There were two hernias; one occurred in the abdominal wound of a woman on whom I had performed a vaginal hysterectomy (for cancer) and some ten months after abdominal section for a parovarian tumor. The hernia became apparent some eight months after the last operation. It was about the size of an apple. I think the cancerous cachexia explains the deficient union of the abdominal wound. This woman died twenty-two months after the vaginal hysterectomy, from a return of the malignant growth.

The second hernia appeared in a woman of about 60, on whom I assisted Dr. Lucy Waite to perform abdominal hysterectomy for a large fibroid. The operation was started as a vaginal hysterectomy, and as it was found impossible to get the uterus through the vagina it was finished per abdominal section. She made a beautiful recovery and remained in the hospital a month. All wounds appeared satisfactorily healed when she left. Some ten months after she left the hospital I heard that she was in a hospital suffering with abdominal and vaginal hernia. Some dozen fistulæ appeared in the abdominal wounds. Nearly all healed in a few weeks or months. One fistula appeared a year after the operation and is still existing. One fistula lasted a year, and I then pulled out a ligature. So far as I know, 2 abdominal fistulæ still exist out of the 100 cases. At the bottom of the two fistulæ I think, there lies a ligature infected with gonorrhœa. As regards stitch abscesses perhaps ten occurred. Nearly all were in cases of severe pyosalpinx, where pus flowed over the wounds and the temperature was high. But four of them, I think, occurred directly from the use of impure boracic acid. In a series of twenty cases, I covered the whole wound with boracic acid. It dries the wound and induces healing. To our surprise four of these cases had stitch abscesses where we knew of no wound infection. Boracic acid is a common commercial article and may be put up by ordinary laborers. The varying price will indicate this. We now use simply boiled gauze on the wound and remove the sutures three weeks after the operation. In one case the tubes were tied and left *in situ*. In this case uterine hemorrhage came on a year after. In another case, after the removal of an enormous pyosalpinx and the other appendages, quite severe monthly hemorrhages have occurred for thirteen months but in the fourteenth

month I again operated, removing a parovarian cyst which induced the hemorrhage. For over a year we have followed the method of not only removing the appendages, but in twenty-six cases have tied the uterine artery which courses along the side of the uterus down as far as the cervix. Three ligatures are applied to the artery from the fundus to the junction of the neck and body. It has proved safe to tie off that much of blood supply. This operation I introduced two years ago, and it has proved a very efficient one; *a*, in immediately stopping menstruation; *b*, in reducing the myomatous growths of the uterus; *c*, in checking uterine hemorrhages; and *d*, it raises the uterus high up in the pelvis by shortening the broad ligaments.

In one case operated upon by Dr. Lucy Waite, a recto-vaginal fistula lasted about a week. In one of my own cases a recto-vaginal fistula remained in a cancerous rectum. In another case not belonging to us, cancer followed in the abdominal wound. In both these last cases, Dr. Joseph B. Bacon and myself performed inguinal colotomy with much relief to the patient. Three cases were tubercular peritonitis and were wonderfully improved by exploration and drainage. Two cases proved to be large cancers of the pylorus and cardiac end. They were simply exploratory.

As regards the removal of the appendages the operation was generally performed on account of the following connected pathologic condition viz: Endometritis plus metritis, plus endosalpingitis, plus ovaritis, plus as much peritonitis as was involved by the infection. Such a condition is founded on a progressive infectious invasion from vulva to peritoneum. My opinion is that these persistent diseases are chiefly of gonorrheal origin. In these cases the infection spreads over the endometrium, next along the rich and luxuriant folds of the endosalpinx to the ovary where the infection finds a home in the germinal epithelium of the ovary and the glandular epithelium of the membrana granulosa. Finally, the invasive infection irritates into peritonitis a limited field where exudates, adhesions and bands permanently remain. The class of women suffering from the above progressive, infectious catarrhal diseases have leucorrhoea, large metritic uteri, which if not fixed by adhesions lie at the mouth of the vagina from relaxed and edematous supports. The tubes are crooked, convoluted and spiral, fixed here and there by adhesions. The tubes may be cystic or thickened by old chronic inflammation. The ovary is generally saturated through and through with infection.

The Graaffian follicles are pathogenic, degenerate, distended. The exudates, adhesions and bands which almost all start from the mouth of the Fallopian tube show different ages by their different stages of formation. Such women are nearly always helplessly sterile; they have painful menstruation, indigestion, anemia and neurosis. Neuralgia and headaches frequently arise. Distant disturbances from reflex irritation are constant. These patients are far better off with the appendages removed. If the Fallopian tubes are closed by allowing a few fimbriae to remain outside, as the peritoneum closed up at the outer end the patient had continual exacerbation or recurrent pelvic peritonitis. If the fimbriae of the tubes were entirely turned back into the tubal lumen before the tubal end was sealed, the woman would not suffer from recurrent attacks. In such cases the whole of the fimbriae lay neatly folded up like the petals of

a rose. The terrible persistence of the disease indicates to me a gonorrheal origin.

In the cases of removal of the appendages we had a hematocele in about 8 per cent. of cases. It generally arose as follows: We pay no attention to menstruation as far as regards operation. When the operation was performed at the menstruation, the hematocele might appear inside of a week. But if the operation was performed midway between menstrual times the hematocele would likely appear with the next menstrual period. The hematocele was apt to appear when the ligature was thrown around a broad ligament with a large and congested plexus pampiniforms. It occurred, the most frequently in the younger women. Two typical cases arose, in a girl of 15 and one of 19 years of age. The hematocele often produced intense pain for two to five days from pressure. To these patients we gave hypodermics of 1-16 grain of morphin several times in twenty-four hours. When it began to absorb it disappeared quickly. I have sometimes wondered whether such swellings might not be exudates from infection in the ligature, or introduced, but I am inclined now to favor the idea of blood extravasation from the plexus pampiniforms. Mr. Tait had some 12 per cent. of hematocele cases while I was his pupil. Vaginal hysterectomy was only performed once for malignancy. The malignant growth had invaded the broad ligament and was perceptible to the touch. Much warm discussion took place as to whether the growth in this uterus was cancer or sarcoma. However, after more extended microscopic labors on it, Dr. Angear pronounced it cancer. The patient lived comfortably for about eighteen months and died twenty-two months after the operation.

Abdominal hysterectomy was done three times by myself, with the Kleeburg elastic ligature, and Dr. Waite once extirpated the entire uterus for myoma. Of all the methods of abdominal hysterectomy, I think that of applying an elastic ligature around the stumps in the lower angle of the wound is the safest for the immediate safety of life. Byford's method of turning the stump into the vagina acts well but requires longer time. Total or partial extirpation of the uterus will no doubt be the future method. The cases must be judged individually and the life of the patient must be the foremost thought of the operator.

In appendicitis, the majority of cases were done on suppurating cases, and we made an incision far out to the lateral side of the right iliac fossa, just to the inner edge of the iliac crest, and allowed the pus to escape without attempting to break up the adhesions and search for the appendix. We drain with a bent rubber tube. No recurrent attack arose in such cases in two years. In other cases of relapsing appendicitis we make the same incision but extirpated the appendix. In pus cases of appendicitis, I am in favor of the incision close to the iliac crest, of not searching for the appendix, of little irrigation and rubber tube drainage and attempting to keep out of the general peritoneal cavity. The operation in circumscribed pus cases will simply be opening an abscess.

In recurrent cases of appendicitis I am in favor of removing the appendix, deliberately putting the patient to bed, preparing him and then taking out the vestigial remnant. Appendicitis is a grave disease of modern recognition, demanding skill in abdominal surgery to manage it successfully. Amateur

surgery in appendicitis is dangerous. Infection among the small intestines is almost always fatal as the infection travels so rapidly that peritonitis—the process which attempts to save life—can not arise.

In women, so far as my work in autopsies are concerned, the appendix lies over the brim of the pelvic in over 25 per cent. of cases. Hence appendicitis is relatively safer in woman than in man, for the pelvis tolerates much peritonitis or rather infection. Also there is no doubt that much interchange of infectious disease occurs between the appendix and appendages.

The cases of hernia have been inguinal and femoral. The inguinal hernia operation in man was performed by free incisions from the external to internal ring, whence the incision was carried an inch higher up or farther out from the intestinal ring toward the iliac spine. The cord was well lifted up and out, while the posterior part of the inguinal canal was carefully restored with Marcy's kangaroo tendon. Layer by layer, the parts of the abdominal wall were carefully sutured by the buried tendon. The cord was finally buried by suturing the skin superficial and deep fascia over it. When finished, the spermatic cord entered a new canal as near the anterior superior spine as its length would permit. It then passed through the abdominal wall under the deep fascia whence it deflected toward the pubic spine, lying between the deep abdominal fascia and the aponeurosis of the external oblique.

The principle underlying the operation is: *a*, the restoring the obliquity of the inguinal canal (Marcy); *b*, the formation of a new canal for the cord (Bassini and Halstead). The abdominal wall posterior to the cord was united by kangaroo tendon of Marcy. It was permanently buried. But the skin and fascia anterior to the cord was united by silkworm gut.

The plan of the femoral hernia we adopted to some extent from Fabricius. The incision was begun at the pubic spine and extended outward perpendicularly to the long axis of the body. The incision extended from the pubic spine to the outer edge of the sartorius muscle. The first landmark to gain was Gimbernat's ligament. This was slightly cut to allow reduction and proper manipulation of the sac. The vein, artery and nerve are then forcibly pushed and drawn toward the iliac spine, and now the lower edge of Poupart's ligament is depressed and sutured to the fascia on the front surface of the pectineus muscle and to the periosteum. After the pectineal fascia is incised it is turned toward Poupart's ligament. The suturing of the lower edge of Poupart's ligament to the turned up edge of the pectineal fascia is then carried on from the pubic spine as far outward as one feels it is safe to push the vein and artery. Slowly we are pushing the vein and artery farther out toward the spine and following it with the deep suturing. This really makes a new canal and closes and fortifies the old one. We use Marcy's kangaroo tendon. The skin is closed by silkworm gut. How far we can safely push the vein and artery toward the iliac spine is the chief question in this operation. We were afraid of edema of the lower limb from compression of the femoral vein, but Fabricius says we need not be alarmed by that consequence. However, we find that we can push the vein and artery farther toward the iliac spine than was thought at first.

The second ectopic pregnancy case had a tempera-

ture of 106.5. Her pulse was about 160. She had a severe chill and I diagnosed rupture in the pelvis. In this case she had had a tubal pregnancy which ruptured and remained in *statu quo*. A few months subsequent to the tubal rupture she became pregnant in the uterus and an abortion occurred. This fresh uterine abortion exacerbated the old tubal trouble which ruptured. She recovered slowly and to-day, fifteen months after, she has a fistula.

The third one of ectopic pregnancy was a young woman. At the operation she had a temperature of 103 and a pulse of 150. She recovered well.

The fourth case was a woman about 37, who had been in bed eleven weeks after rupture. Her pelvis was full of consecutive layers of blood clots due to recurrent attacks. She recovered slowly but well.

The colotomy performed on two of the patients by Dr. Joseph B. Bacon and myself was done on the left side. The sigmoid flexure was drawn out and well pulled down, so as to avoid subsequent prolapse. Two threads of silkworm or silver wire were passed from one edge of the wound to the other, under the gut, and through the mesentery. It was well lightened. Then the peritoneum was carefully sutured to the gut wall so as to entirely shut off the general peritoneal cavity. The gut was opened from three to five days after the operation. Wonderful relief from pain occurred to the patients who had colotomy done for malignant rectal trouble. Besides it checked the growth of the disease to turn the fecal channel in another direction.

The case of post-peritoneal abscess was operated on by Dr. Waite, and drained through the abdominal wound. A history of five years previously having had an abscess on the backbone probably explained the post-peritoneal abscess as being metastatic.

In this series of 100 cases, Dr. Lucy Waite performed 18 of the operations, but as I assisted her in every case I include them in the report.

During the time that the above series of sections were being performed, I supervised quite a number of amateur surgeons in performing various kinds of abdominal sections not included here. I was impressed with two points by the amateur operator. The first was a lack of knowledge as to the landmarks of visceral disease. They seemed not to have been taught where it is possible that tumors and inflammation are liable to arise. The second impression was that the surgeon lacked systematic methods of examining the viscera after the abdomen had been opened. The surgeon would introduce the hand and pass it around the abdominal cavity without definite views of anatomy and pathology.

As far as regards the chief pathologic landmarks of visceral disease and the systematic anatomic manipulation of the same, there is no wonder that amateur and general surgeons show lack of knowledge in abdominal pathology, and sad need of abdominal anatomy, when no college can be pointed to as possessing a chair of one or both. In every college there should be a chair of abdominal or visceral pathology and a chair of visceral anatomy; besides every student who intends to do abdominal surgery should be put through a prescribed course of experiments on the viscera of animals. During several years of teaching of the anatomy and pathology of the abdomen, I evolved the following table which suggests landmarks of anatomy and pathology in the abdomen:

| | | |
|-------------------------------------|--|---|
| Landmarks in Gynecology | <ul style="list-style-type: none"> a. Anatomy. b. Menstruation. c. Labor. d. Abortion. e. Gonorrhoea. f. Tumors. | <ul style="list-style-type: none"> age. regularity. quantity. pain. |
| Landmarks in the Digestive Tract. | <ul style="list-style-type: none"> a. Mouth. b. Cardiac orifice. c. Pylorus. d. Ileo-cecal valve. e. Anus. | |
| Landmarks in the Digestive Tract. | <ul style="list-style-type: none"> a. Hepatic. b. Splenic. c. Sigmoid. | |
| Landmarks in Peritonitis. | <ul style="list-style-type: none"> a. Mouths of Fallopian tubes. b. Hernial orifices. c. Appendix. d. Gall-bladder. e. Sigmoid flexure. f. Splenic flexure. g. Hepatic flexure. h. Accidental. | |
| Landmarks in Surgical Localization. | <ul style="list-style-type: none"> a. Uterus. b. Cecum. c. Colon. { sacrali coli. { tenia coli. d. Sigmoid flexure. e. Pylorus. | |

A few valuable generalizations aid in analyzing when making a differential diagnosis. It may be noticed that the sphincters are liable to disease on account of: *a*, periodical action function; *b*, delicate nerve apparatus; *c*, complicated and varied blood supply; *d*, extensive lymphatic system; that malignancy is their chief disease and anatomy shows definite localized fixation of sphincters. It may be observed that the flexures are quite fixed and that they are liable, first, to non-malignant; and second, to malignant disease. In regard to peritonitis, there are three notorious regions, viz., pelvic, appendicular and that of the gall-bladder. In these three regions the peritoneum tolerates much infection and inflammation. These regions for ages have learned to cope with inflammation. Remember, that peritonitis tends to save life by throwing out barriers of exudate, preventing infectious invasion while it is infection which tends to kill. Note, also, that outside of the great peritonitic regions (pelvic, appendicular and gall bladder) that infection or so-called peritonitis is very fatal, *e. g.*, among the small intestines.

As to surgical localization it simply involves the anatomy. On opening the abdomen the first organ to locate is the uterus; 2, especially important in localizing landmarks is the cecum; 3, the colon is of some significance, while the sigmoid (fourth) and the pylorus, (fifth) is of less importance. None but the intestinal surgeon realizes the all-important localization of the cecum, which gives an easy clue to the rest of the digestive tract. Amateur and general surgeons should realize the difficulty in diagnosing abdominal tumors, especially on the right side. If one opens a cadaver, a silver dollar may be so placed as to touch: *a*, the pylorus; *b*, the gall bladder; *c*, the supra-renal capsule; *d*, the kidney; *e*, the head of the pancreas; and *f*, the hepatic colonic flexure. Thus six organs, within touch of a silver dollar, might give origin to a tumor in the right portion of the abdomen. On the left side, the cardiac end of the stomach, tail of the pancreas, spleen and splenic flexure of the colon presents similar close complica-

tions. In visceral disease it is well to remember that probability is the rule of life. On account of the scarcity of material and the rarity of practical teaching in visceral anatomy, besides the limited knowledge gained by observing, always, at an abdominal section, by those not having the privilege of manipulating and seeing the viscera, amateur abdominal surgery is, frequently unfortunate, unsatisfactory in results and too often disastrous. It is the opinion of the writer, from ten years of special observation in abdominal work, that young physicians should be impressed with the fact that more personal study, experiment and especial training should be experienced before practice is applied to human subjects.

LESSONS LEARNED FROM ONE HUNDRED ABDOMINAL SECTIONS.

1. That chloroform kills outright by affecting the heart or respiratory center.
2. That ether may be followed by bronchitis and nephritis (immediate or remote).
3. That opening the peritoneum produces a raging thirst which can be slaked by one-half to two ounces of hot fluid an hour. Ice is dangerous and cold water should not be used after abdominal section.
4. That saline purgatives are prophylactic against incipient peritonitis. General peritonitis once established is practically an incurable disease.
5. That it is infection that tends to destroy life, while peritonitis tends to save life by throwing out exudates to prevent the invasion of infection. Local peritonitis is nature's method of repair.
6. That the three great regions of peritonitis are: *a*, the pelvic; *b*, appendicular; *c*, the region of the gall bladder. They resist the invasion of infection and tolerate it markedly.
7. That infection among the small intestines is very fatal, from inability to produce peritonitic exudates to circumscribe the infection.
8. That gonorrhoea is the cause and sustaining factor of the majority of persistent tubo-ovarian diseases or pelvic peritonitis.
9. That gonorrhoeal appendages are apt to infect ligatures which may suppurate and produce a fistula from one month to one year after the operation.
10. That post-operative hernia of the abdominal wound is liable to occur in malignant or aged cases. That advanced, malignant visceral disease should not be molested.
11. That irrigation and drainage of the peritoneal cavity should be limited—irrigation quite limited and drainage to hemorrhage and pus cases.
12. That the Trendelenberg position enables one to do more perfect work by seeing with the eyes and giving wider space for manipulation.
13. That suppurating appendicitis can be radically cured (for two years at least) by an incision close to the right iliac fossa, allowing the pus to escape and not searching for the appendix. The incision can profitably be made close to the iliac spine.
14. That in woman the appendix is in the pelvis in one-third of the cases and tubo-ovarian and appendicular disease may each be derived from the other.
15. That inguinal hernia can be radically cured by restoring the obliquity of the inguinal canal, and removing the spermatic cord into a new canal. (Marcy, Bassini and Halstead).
16. That femoral hernia can be radically cured by

displacing the femoral vein and artery toward the iliac spine, and suturing the lower border of the Poupart's ligament to the pectineal fascia—making a new canal for the vein and artery. (Fabricius.)

17. That tying off the appendages and then ligating the uterine artery as it courses along the uterus as far down as the cervix: *a*, quickly stops menstruation; *b*, checks hemorrhage in the uterine myoma; *c*, it atrophies uterine tumors by cutting off the blood stream; *d*, by ligating the whole broad ligament low down with locked stitches the retroverted uterus can be well elevated; and *e*, by ligating the nourishing nerves, atrophy of the genitals will ensue.

18. That the fimbriated end of the Fallopian tube closes in two ways during the course of disease: *a*, in one case (disastrous); the tubal fimbriæ are only partially turned back into the tubal lumen, leaving infected fimbriæ both in the tubal lumen and in the peritoneal cavity—such cases are constantly liable to recurrent infection and exacerbation because the mucal fimbriæ serve as a home for the germs; *b*, the other (favorable) method is where all the fimbriæ of the tube are turned back into the tubal lumen, where they lie coiled up like the petals of a rose.

19. The very severe forms of menstrual neurosis can be cured (for two years) by removing the uterine appendages close to the uterus. Bleeding myoma is also in some cases cured by the same process.

20. But in re-operating on abdominal cases (one ten months, the other fourteen, after) for parovarian cysts, the viscera are found surrounded by various degrees of adhesions. The fourteen months' case possessed dense and extensive adhesions. I proved the same fact on scores of dogs' viscera several years ago.

21. That parovarian cysts are the most liable to recur in 100 cases of abdominal section.

22. That abdominal fistula is apt to arise immediately after the operation and continue for some weeks to eighteen months. Also that some fistulæ arise from two to six months after the operation and continue for eighteen months.

23. That urea is the best standard for safe laparotomy, as far as regards the kidney. When the woman came to the hospital the urea varied from five grains to twelve grains to the ounce, but in a few days it would become about eight grains to the ounce. Not so much notice is paid to albumen or sugar.

24. That in ruptured ectopic pregnancy there is surgical hope, though the temperature is nearly 107 and the pulse 160.

25. Every case of abdominal section should be in bed at least three weeks.

SOCIETY NEWS.

Southern Illinois Medical Association.—The twentieth semi-annual meeting of the Southern Illinois Medical Association was held November 15 and 16 in Duquoin, and was called to order at 10:30 A.M., by President Dr. McKenzie. There were about 25 members present out of a total membership of 100. The address of welcome was delivered by Dr. L. Dyer, and Prof. C. W. Harris, responded to by Dr. Mitchell, of Carbondale. There were ten papers read: "Criminal Responsibility as Related to Insanity." "Duties of Physicians." "Bacteriology." "Fracture of Femur Treated by Hodgen's Splint."

"Whisky in Medicine." "Effects of Alcohol on the Human System." "Phlegmasia Dolens." "Fever, Causes and Treatment." "Diseases of Children—also Case of Wound of Abdomen." "Necrologist's Report." "Cases of Nephritis with Extensive Edema and Necrosis of Lower Jaw." Dr. G. N. Kreider, Treasurer of the Illinois State Medical Society and Dr. Mudd, of St. Louis, were present by invitation. Dr. Corr, first Vice-President of the Illinois State Medical Society, was present as fraternal delegate. All these gentlemen were accorded the courtesies of the Association. Dr. Corr presented the fraternal greetings of Dr. D. R. Brower, President of the Illinois State Medical Association, who urged a more hearty support of the State Society. Drs. Kreider and Corr were accorded the privilege of presenting the claims of the Illinois State Medical Society in that it needed increased numbers and annual dues to support the Legislative Committee in its charitable and scientific work. The Association adjourned at 3:30 P.M. on the 16th inst., to meet in Carbondale, May 15 and 16, 1895.

Chicago Ophthalmological and Otological Society.—Regular meeting, postponed one week, was held at the Saratoga Hotel, Oct. 16, 1894, Dr. Hotz in the chair. There were eighteen members and visitors in attendance. Minutes of last meeting were read and approved.

The application of Dr. T. Faith was received and referred to the Committee on Membership.

Dr. Hotz reported that Dr. Meyer would read three papers before the Society if agreeable:

1. "Recent Views on Histology of Nervous System."
2. "Minute Anatomy of Optic Nerve Tracts."
3. "Review of Researches of Hinschen and Others."

On Dr. MONTGOMERY'S motion, the President was requested to invite Dr. Meyer to deliver these three essays and the Secretary was instructed to present Dr. Meyer with \$50 as an honorarium.

On Dr. BETTMAN'S motion, the Secretary was instructed to levy an assessment of \$2 on each member.

Dr. Hotz reported a case of skin grafting for pterygium. The patient, 30 years old, had four operations performed before consulting Dr. Hotz but without much improvement. The pterygium extended to center of cornea and was very thick. In November, 1893, Dr. Hotz did the ordinary operation, but the pterygium returned in a few months. Sept. 5, 1894, dissected back the conjunctiva as far as the caruncle, a space ten mm. long and six mm. wide. Over this surface a piece of skin, taken from behind the ear, 4x4 mm. was grafted. A larger piece could not be used because in adduction the graft was pushed over the cornea. It healed nicely but even this small piece has been pushed slightly over the cornea.

Dr. BETTMAN showed a case of skin grafting for symblepharon. The eye was destroyed by lime and very extensive adhesions took place. After enucleation, pieces of skin were implanted and the patient can now wear an artificial eye comfortably.

Dr. WILLIAMS had found that although the gain seemed great from grafts for a few months, yet the grafts were very apt to shrink to almost nothing in time.

Dr. MONTGOMERY also spoke of having had such experiences and quoted cases in illustration.

Dr. BEARD thought that most cases required repeated operation before the final result was obtained. He had operated on one case four times already and expected to do more.

Dr. COLEMAN transplanted skin in one eye and mucous membrane in the other. Both did well but the skin gave the better result.

Dr. BETTMAN said that it was important to remove all cicatricial tissue from the wound before the skin is grafted, and thought poor results were often due to neglect of this precaution.

Dr. BEARD prefers mucous membrane to skin in plastic

operations on the conjunctiva because he had a case in which the skin graft caused an ulcer. He removed the skin, put in mucous membrane and the ulcer got well.

Dr. HORTZ prefers skin grafts on lid border and never had any trouble with them. Takes skin from behind ear in narrow wedge-shaped strips.

Dr. WILDER spoke of a case which had been operated on sixteen times for entropion but always relapsed. Dr. W. thought it was because the grafts were not rigid enough and he transplanted a graft from the hypothenar eminence with good results. He showed some beautiful preparations hardened in formaldehyde. He used a 5 per cent. solution and the eyes were hard in two days. Specimens retain their transparency and colors with this preparation.

Dr. MONTGOMERY read a paper on increase of astigmatism and reported cases.

Dr. COLEMAN said that Gould asserts that correcting full error will favor the increase of hyperopia.

Dr. JONES said that a relaxed hypertrophied ciliary muscle would cause apparent increase.
Society adjourned by limitation.

C. P. PINCKARD, Secretary.

The Board of Medical Examiners, representing the Medical Society of the State of Pennsylvania, held their fall examinations in Philadelphia, October 16, 17, 18 and 19. Thirty-three applicants were examined and four failed to receive the average of .75. H. G. McCormick, of Williamsport, is President of the Society, and W. S. Foster, of Pittsburg, Secretary.

The following questions were asked:

CHEMISTRY.

1. What is a salt? 2. What is an atom, a molecule and an element? 3. Describe nitrogen, naming its oxygen compounds and its relations to atmospheric air. 4. Describe the properties of ozone and its influence on respiration. 5. How do you determine the quantity of urea in a given specimen of urine? 6. Describe an alkaloid, naming two examples. 7. What are the physical properties of bromid, iodine and chlorin? 8. Differentiate between an acid and an alkali. 9. What is the atomic theory? 10. What is the difference between mechanical mixture and chemical union?

ANATOMY.

1. What forms the external malleolus? 2. Describe the ovaries. 3. How do arteries and capillaries differ? 4. Describe one of the vertebrae. 5. What vessels and nerves are contained in the popliteal space? 6. Describe the position of the palmar arterial arches. 7. What blood vessels pass to and from the liver? 8. Describe the pyloric orifice of the stomach. 9. What tissues of the abdominal wall are divided in the operation for appendicitis? 10. Give the distribution of the third cranial nerve.

PHYSIOLOGY AND PATHOLOGY.

1. What are the functions of the stomach? 2. Explain how the normal cardiac sounds are produced. 3. Describe the phenomenon of urinary secretion and excretion. 4. Give the principal functions of the cerebellum. 5. What system of nerves regulates arterial tension? Explain the qualities of the normal pulse.

1. What pathologic changes in the arteries usually precede aneurism? 2. What is the pathology, so far as known, of pernicious anemia? 3. Describe the pathologic processes of dry and moist gangrene. 4. Explain fatty metamorphosis and describe the process as it occurs in the heart. 5. Describe the difference characterizing the pathologic changes of croupous and catarrhal pneumonia.

THERAPEUTICS, MATERIA MEDICA AND PRACTICE.

1. Describe the symptoms and treatment of croupous pneumonia. 2. Give the prognosis and treatment of idiopathic erysipelas. 3. Describe the symptoms and treatment of measles. 4. Describe the treatment of ophthalmia neonatorum. 5. Give the prognosis and treatment of locomotor ataxia (tabes dorsalis). 6. Describe the physiologic action of arsenic, and name three indications for its use. 7. Describe the physiologic action of opium. 8. Describe the dietetic and hygienic treatment of typhoid fever. 9. Give the indications for the therapeutic use of quinia sulphate. 10. Name three conditions wherein and the reasons why ver-

trum viride is contra-indicated. 11. Name three indications for the use of belladonna. 12. Describe how belladonna acts when used, as stated in answer to question No. 11. 13. What condition of the eye contra-indicates the use of mydriatics? 14. Describe vasomotor depressants, with an example. 15. Describe and give the indications for the uses of cardiac sedatives, with an example.

OBSTETRICS.

1. What are the earliest probable signs of pregnancy, and their relative value? 2. Describe the causes, symptoms and treatment of abortion. 3. Describe the mechanism of normal labor, L. O. A. position of vertex. 4. Describe the causes, symptoms and treatment of eclampsia. 5. What are the dangers of the puerperium, and how may they be avoided? 6. Describe the process of delivering the placenta. 7. Give the diagnosis and treatment of placenta prævia. 8. Give the treatment of *post-partem* hemorrhage. Give in detail the proper care of the new-born. 10. What are the uses and dangers of ergot in obstetric practice?

SURGERY.

1. What are the principal points in the diagnosis, prophylaxis and treatment of pyemia and septicemia? 2. How would you expose the brachial artery for ligation at the middle of the arm? 3. Give a concise description of rupture of the perineum and treatment. 4. What are the indications for the use of a drainage tube? 5. Describe the predisposing and exciting causes and symptoms of carcinoma of the breast; also give treatment. 6. Describe any one of the several dislocations of the shoulder joint, and mode of reduction. 7. What are the rules for the administration of ether and chloroform as anesthetics, with contra-indications? 8. Describe the kinds of fistulæ-in-ano; give the symptoms and treatment. 9. Describe the symptoms and treatment of a Colle's fracture. 10. Describe the symptoms and treatment of the several forms of gangrene.

DIAGNOSIS AND HYGIENE.

1. Differentiate between coma and syncope. 2. Describe the physical signs of simple ascites and those of ovarian dropsy. 3. Differentiate between compression of the brain from injury and the phenomena of alcoholism. 4. Differentiate between the early eruption of syphilis and measles. 5. Differentiate between thrombosis and embolism. 6. Describe the proper methods for lighting and ventilating school rooms. 7. What are the proper methods for disposing of excrement and garbage in cities? 8. What is the difference between disinfectants and germicides, and how do they severally act in preventing the spread of contagious and infectious materials? 9. What climatic factors should govern in selecting a proper health resort for consumptives in the primary stage of the disease? 10. What is meant by quarantine, and when and how should it be enforced?

NECROLOGY.

CHARLES T. CHASE, M.D., of Brooklyn, died November 5, aged 63 years, the cause of his death having been chronic interstitial nephritis. He was a well-known practitioner of forty years standing in Brooklyn, and the son of that eminent surgeon, Dr. Charles Chase, of the United States Navy. The junior Dr. Chase had a predilection for surgery, having had experience both in the naval and volunteer army corps as a commissioned surgeon during the War of the Rebellion. About eleven years ago he lost his eyesight, and retired from practice.—Timothy M. Ingraham, M.D., of Flatbush, New York, died Nov. 11, 1894, aged 73. He was a graduate in medicine from the old "Woodstock School," or Vermont Medical College, taking his degree fifty years ago. For many years he had an almost exclusive ride in the town of Flatbush (now a ward of Brooklyn). He was a member of the Kings County Medical Society, having been an officer-bearer therein. A widow and twelve children survive him. His final malady was an attack of apoplexy of short duration.—Henry W. Allen, M.D., of Milwaukee, November 9, aged 31.—Carter Higgins, M.D., of Peru, Ind., November 14.—O. B. Reed, M.D., of Lenox, Mich., November 8, aged 90.—E. B. Elrod, M.D., of Flora, Mo., November 8.—George Wilson, M.D., of Dubois, Pa., November 8, aged 80.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, NOVEMBER 24, 1894.

MEDICINE IN ANCIENT ROME.

The old Romans had a great contempt for doctors. Up to the end of the Empire no proof of qualifications, neither diploma or other guaranty, was required from those practicing medicine. According to TIBERIUS every man ought to be his own physician after 30. It was the father of the family who treated his wife, his children, his slaves. CATO has left in his *De Re Rustica* the receipts which he used for half a century in the treatment of his two wives, his daughter-in-law, his daughter, his slaves, his cattle and himself. *Callage* was the basis of his therapeutics—good, both internally and externally, it cured all diseases; it was emetic and purgative, diuretic and diaphoretic. Aided by magic formulæ, such as: "*Daries, dardaries, artataries,*" it caused nasal polypi to be expelled and reduced dislocations.

The Greeks introduced a less primitive therapeutics into Rome. The first Greek physician was ARCHEGATOS, who had his office in the crossroads of Acilius; and here, in which were combined a consulting room, drug store and hospital, he gave consultations, dressed wounds, prepared medicines and had some beds for cases of grave diseases or severe operations. Later on, the people resorted to the doctors' offices, as they did to the barber shops, for gossip, lounging and novelty.

The ancient Romans disliked bathing as much as—according to *La Médecine Moderne*—do the Italians of to-day; that journal, from which this gossip is gleaned, says that, "according to recent statistics the modern Italian takes a bath on the average once in two years." In the time of CATO, according to SENECA, the Romans bathed their arms and legs every day, but ablu- tion of the whole body was indulged in only once in

eight days. The craze for *thermæ*, of which ASCLEPIADES was the originator, was of later date; he was the first to treat fevers by cold baths. Under AUGUSTUS cold baths had great popularity, owing to ANTONIUS MUSA, who cured the Emperor by their use; it is true it is claimed he killed MARCELLUS—the "*Tu Marcellus eris*" of Virgil—by the same treatment.

Greek medicine held undisputed sway under the CÆSARS; only Greek terms were used and pills became *catapotia*, liniments *acopa* and *malagmata*. Each physician had some special drug which he carried about with him and which was, of course, superior to the "other fellows," and the more mysterious the name the more potent the drug; such were *Athamasia*, the immortal; *Ambrosia*, the divine; *Panacea*, the all-curer, and *Theriaka*, which ANDROMACHE, the physician of NERO invented and described in a Greek elegiac poem. It had 600 ingredients, the basis being viper's flesh, and cured every disease; the Emperor took a pill of it every morning before breakfast. It had a prodigious success and outlasted the invasions of the barbarians and the flight of the centuries, so that even at the end of the eighteenth century, according to BOILEU, the patients in the hospital of Montpellier took a bolus of theriaka every evening, as NERO had taken his every morning eighteen hundred years before.

Fees were not neglected; under AUGUSTUS the court physician had an income of 200,000 sesterces—about \$10,000. STERTININUS gave up a practice of \$24,000 to become court physician; CRINUS, of Markilles, left \$400,000 to his native town. The patients who contributed to these fortunes avenged themselves by epigrams. "CHARIDEMMUS," says MARTIAL, "knows very well that his wife is the mistress of his physician. But what would you have? He wishes to die a natural death, peacefully and without fever." "FABULA has quit her husband to follow a lover, whom she pays. That is not astonishing—she is the daughter of SOTA, a physician." "Yesterday ANDRAGORAS felt very well; he bathed and supped joyously with his friends. This morning they found him dead in his bed. What could have caused this sudden death? He saw HERMOCRATES, his physician, in a dream."

DIPHThERIA AND THE ANTITOXIN.

Almost without exception the European governments have either indorsed the ROUX-BEHRING treatment of diphtheria by the antitoxin serum or have authorized its study by their medical or public health services. The latest is that of Turkey, which, by command of the Sultan, has despatched a special commission, consisting of Drs. MAHMOUD BEY, MUNIR BEY and DJELAL BEY, to the Pasteur Institute, with instructions to learn the mode of preparation of the serum and the technique of its use; on their

return they are to establish a laboratory in Constantinople for the preparation of the antitoxin.

Favorable clinical reports of its use multiply in the pages of the British and continental journals and an occasional report, also favorable, finds its way into an American periodical here and there. But a very large number, probably a majority, of the profession in this country still look askance at the claims made for the new remedy.

This somewhat remarkable conservatism is due to two obvious causes—the first, and probably the most potent, is the want of a sufficient supply of the serum to make individual tests; and the second, the haunting memory of the tuberculin failure. Municipal and individual initiative is already at work to remove the first obstacle, but the JOURNAL awaits the opportunity to announce that the National medical services have taken steps to set at rest the doubt as to the claimed value of the new treatment.

It is surely within the scope of the authority of the heads of the Army and Navy Medical Corps and of the Marine-Hospital Service to cause an investigation to be made for this purpose, and all of these services contain men abundantly qualified to conduct such an investigation and to make a report which would be accepted as authoritative and conclusive by the profession. It may be, however, that they are awaiting instructions from Congress.

THE UNRESTRICTED SALE OF POISONS.

This periodical has frequently invited public attention to the necessity of legislation placing some restrictions on the sale of poisons and articles containing poisonous substances.

The daily press contains regularly, every day, accounts of persons slain through accident or design, by some poisonous drug.

The abuse of the unrestricted privilege calls loudly for reform, and past experience has shown that the medical profession is the only one at all likely to bring the matter to public attention. When the general public becomes fully aroused on this question, public sentiment will force the law-making bodies to pass the necessary enactment.

Let our medical societies take the matter up and begin the systematic collection of facts bearing on the question. When the facts are gathered and properly formulated let the voice of the medical society be heard in no uncertain tone. A profession which has done so much for the prevention of disease and the prolongation of human life, will be listened to by Legislatures whenever it has undoubted statistics to prove its assertions. Nothing, however, is ever likely to be done so long as our request is based on assertion only. We must collect and furnish facts in order to succeed, and we may as well close this statement by that other which has been repeatedly made in these columns: *Let us have a Department of Public Health with a Cabinet officer at its head.*

THE RETURNS ARE IN.

We note with pleasure that the Fourth Indiana District has retired the Hon. W. S. HOLMAN from further service in Congress from that district, and that this eminent statesman after the fourth of March next will have opportunity to practice that "economy" he has so long preached, in rural retreat. The medical services dependent on congressional appropriations will not after this session have to contend against his antagonism. *Laus Deo!*

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

This flourishing medical organization held its annual meeting this week at Hot Springs, Ark., under the Presidency of X. C. SCOTT, M.D., of Cleveland. We expect a full report of the meeting, for the next week's issue. The attendance was larger than usual, and the St. Louis special train, as usually happens with everything managed by the editor of the St. Louis *Medical Mirror*, was successful in all particulars.

CORRESPONDENCE.

Statues to Medical Men.

PARKERSBURG, W. VA., NOV. 19, 1894.

To the Editor:—Dr. E. Cutter, in his note in the JOURNAL of November 17, trusting to his memory, falls into an error in writing of a statue to Dr. J. D. Crawford, the discoverer of ether in 1842. It was Dr. Crawford W. Long, of Madison County, Georgia, who first used ether as an anesthetic in 1842, and who neglected to make his discovery known to the world until 1849. I doubt whether there is a statue to his memory in the rotunda at Washington.

Probably the statue in the rotunda is in honor of W. Harris Crawford, one of Georgia's most distinguished citizens, who was Senator, Minister to France, Secretary of War and Treasury, and nominee for President in the congressional caucus with Jackson, Clay and Adams; at which time Adams was elected.

These statues are there by action of the National Congress, inviting the States, through their Legislatures, to place there statues of two of their distinguished citizens, and they are mostly statues of statesmen and politicians.

I have no list of those who have been thus honored, so that the above, relative to a statue to Crawford is based on recollection. If Sims' statue is the first, it is to be hoped that it will not be the last, although it accords more with the spirit of our profession to erect memorials to our departed worthies in some other manner, viz.: a memorial hospital ward, or an endowed professorship, etc.

The centennial of Jenner's discovery is nearly here. In the century just passed has his memory been thus honored?

Respectfully, W. H. SHARP, M.D.

Laryngeal Epilepsy.

CHICAGO, ILL., NOV. 16, 1894.

To the Editor:—In the society proceedings of the Chicago Academy of Medicine, as published in the JOURNAL of November 10, on page 727, there appears an article by Dr. Edward T. Dickerman on "Laryngologic Relations of Epilepsy." In this article the Doctor states that "up to date, twenty-one cases have been reported," etc. I wish to state

that the Doctor may be able to add one to the list if he will look up the JOURNAL of June 3, 1893, page 604, and find "A Case of Laryngeal Epilepsy." Respectfully,

JOHN KERHER, M.D.

BOOK NOTICES.

The Weekly Medical Review. Pocket Reference Book and Visiting List, perpetual. St. Louis: J. H. Chambers & Co. 1895. Price, \$1.

This excellent visiting list is formed on the usual lines, containing tables of reference and blank spaces for call list and records.

Physician's Complete Account Book. Arranged by J. MARSHALL HAWKES, M.D., and R. HARLAN HAWKES, M.D. New York (56 Reade Street): Peckham, Little & Co. Price \$3.

This is a simple and convenient account book for physicians, having blank spaces properly ruled for the keeping of accounts and explanatory memoranda connected therewith.

Local Anesthetics and Cocaine Analgesia; Their Uses and Limitations. By THOMAS H. MANLEY, A.M., M.D. Cl., pp. 177. St. Louis: J. H. Chambers & Co. 1894. Price, \$1.50

The author has attempted in a fairly satisfactory way to give the indications and method of cocaineization as an analgesic. He states as a distinctive difference between anesthesia and analgesia that "a local anesthetic of an intense frigorific character produces chemical changes, and temporarily destroys all sense, but an analgesic only affects the pain sense, and in no manner induces chemical changes, or endangers the vitality of the tissues." The book is timely and instructive.

A Synopsis of the Practice of Medicine for Practitioners and Students. By WM. BLAIR STEWART, A.M., M.D. Svo., cl., pp. 433. Price, \$2.75. New York: E. B. Treat (5 Cooper Union). 1894.

This book as its title indicates, summarizes in a careful and useful manner the existing practice. The treatment recommended is sound and in accordance with the latest approved teachings. In typhoid fever, for example, while the author distinctly asserts that there is no specific, he favors antiseptic medication, commending for that purpose the sulpho-carbolyte of zinc, salol and beta-naphthol. In dosage the old apothecaries system is followed.

Transactions of the Ophthalmological Section of the AMERICAN MEDICAL ASSOCIATION at the Forty-fifth Annual Meeting held at San Francisco, June 5-8, 1894. Cl., pp. 216. Chicago: American Medical Association Press. 1894. Price \$1. Postage free.

There are one hundred and ninety-six members of the Ophthalmology Section of the AMERICAN MEDICAL ASSOCIATION, and for their convenience they directed the reprinting of this "Book of the Section." The papers have all been printed in the JOURNAL, and the volume was edited by the Section Secretary, Dr. L. H. Taylor.

A Dictionary of Medicine; including General Pathology, General Therapeutics, Hygiene, and the Diseases of Women and Children. Edited by RICHARD QUAIN, Bart., M.D., LL.D., assisted by FREDERICK THOMAS ROBERTS, M.D., and J. MITCHELL BRUCE, M.A., M.D. With an American appendix by Samuel Treat Armstrong, M.D., Ph.D. New edition, revised throughout and enlarged. Vol. I, Abdomen-Lysis; Vol. II, Maclocheilia-Zyme. New York: D. Appleton and Company. 1894.

The well-known "Quain's Dictionary of Medicine" has now grown into two volumes, each as large as its portly predecessor, while the type remains as small as before. This is a dictionary of medicine alphabetically arranged, in which each subject is discussed according to the editor's estimate of its importance. There are so many collaborators that the great task of revision has been made lighter for the editors. The editor of the American Appendix has introduced some new medical terms, made a few cross references, added

one or two articles on peculiarly American topics and has given much needed information on the American mineral springs—this last topic is one that has heretofore received much less attention than it deserved.

International Clinics; a Quarterly of Clinical Lectures on Medicine, Neurology, Surgery, Genito-urinary Surgery, Gynecology, Obstetrics, Ophthalmology, Laryngology, Pharyngology, Rhinology, Otology and Dermatology. By Professors and Lecturers in the leading medical colleges of the United States, Germany, France, Great Britain and Canada. Edited by JUDSON DALAND, M.D., J. MITCHELL BRUCE, M.D., and DAVID W. FINLAY, M.D. Vol. III. Fourth series. Philadelphia: J. B. Lippincott Company. 1894.

The present volume of this interesting series is not less instructive than its predecessors, and the growing interest taken in these publications by the profession in general shows that they are yearly more and more appreciated. The editors and publishers have spared no pains to give the "Clinics" an attractive setting.

Medical Jurisprudence, Forensic Medicine and Toxicology. By R. A. WITTHAUS, A.M., M.D., and TRACY C. BECKER, A.B., LL.B., with the collaboration of twenty others. Volume II. Cl., pp. 751. New York: William Wood & Company. 1894.

We noticed this book *in extenso* when we received the first volume (see JOURNAL, March 10, 1894) and we are able to renew the favorable opinion then expressed, concerning the work. The present volume contains a chapter on "Examination of Blood and other Stains," and "Examination of Hair," by Edward S. Wood, M.D.; on "Abortion and Infanticide," by J. Chalmers Cameron, M.D.; "Determination of Survivorship," by T. C. Becker, Esq., and J. Parmenter, Esq.; "When Medical Examination of the Living is Permitted or Required by Courts of Law," by T. C. Becker; "Pregnancy, Labor and the Puerperal State," by J. Clifton Edgar, M.D.; "Sexual Incapacity," by I. C. Rosse, M.D.; "Rape," by J. C. Edgar and J. C. Johnston; "Unnatural Crimes," by Irving C. Rosse; "Railway Injuries," by W. B. Outten, M.D., and "Simulated Diseases," by W. Thornton Parker, M.D. The work concludes with a table of cases by the legal authors and by the medical authors respectively. The index is separate for each volume.

The completion of this work enriches the library of forensic medicine in a marked degree, and it will be referred to with pleasure by all wishing information on the subject.

Practical Urinalysis and Urinary Diagnosis: A Manual for the Use of Physicians, Surgeons and Students. By CHAS. W. PURNY, M.D., Professor of Urology and Urinary Diagnosis at the Chicago Post-Graduate Medical School. With numerous illustrations, including photo-engravings and colored plates. In one crown octavo volume, 360 pages, in extra cloth, \$2.50 net. Philadelphia: The F. A. Davis Co., Publishers (1914 and 1916 Cherry Street).

The author has long been known as an authority on diseases of the kidneys. He has shown much originality of research, and his results have added much to the knowledge of the subject. The present book is in two parts, whereof the first is divided into eight sections and is devoted to "Analysis of Urine;" and the second has three divisions and is devoted to "Urinary Diagnosis." There is an appendix on the "Examination of Urine for Life Insurance."

The book is concisely written and will add new laurels to the already established fame of the author. The author's habitual conservatism is well shown on page 268 where in writing of the "Diagnosis of Renal Tuberculosis" he says: "It is safer, therefore, when suspected, but not found by direct examination, to resort to cultures in gelatin in the usual manner and the inoculation of animals."

To the practitioner and as well to the clinician, this book must prove invaluable for the extent of information contained in its pages, and its practical character. There is little of the compiler but more of the author visible in the pages of the work, which we can not too highly commend.

A Practical Manual of Mental Medicine. By DR. E. RÉGIS, with a preface by M. BENJAMIN BALL. Second edition, thoroughly revised and largely re-written. Authorized translation by H. M. Bannister, A.M., M.D., with an introduction by the author. Cl., pp. 692. Utica, N. Y.: Press of American Journal of Insanity. 1894.

The first edition of this work was crowned by the Faculty of Medicine of Paris, and received the Chateauvillard Prize of 1886. In 1891 the author revised the second edition, and now it has been translated by Dr. Bannister and published by Dr. Alder Blumer, who conceived the idea of having the printing done at the Utica Asylum by his patients. "It is assuredly," says Régis, "the first work treating of mental alienation, written by an alienist, translated by an alienist, and under the direction of an alienist, printed and bound by the insane."

The translator says: "It is a rather remarkable, and perhaps not altogether a creditable fact, that up to the present we have had no English translation of any modern standard French work on mental diseases and their treatment. No apology, therefore, seems necessary for having endeavored to present to American readers the work of Dr. Régis which is, as it is considered in France, a model of its kind." The translator and the publisher have each done their work well, and the book will, we feel sure, be warmly welcomed by the American medical profession.

Chorea and Choreiform Affections. By WILLIAM OSLER, M.D. Philadelphia: P. Blakiston, Son & Co. 1894. Price \$2.

This book, which is gracefully dedicated to Dr. W. R. Gowers, of London, represents "in an expanded form, the lectures on chorea which appeared in the *Medical News*, 1887," and from studies of the case books of the Infirmary for Diseases of the Nervous System in Philadelphia. Facing the title page the author has placed two quotations, one from Bouteille (1810), the translation of which is as follows: "All is extraordinary in this disease; its name is ridiculous, its symptoms singular, its character equivocal, its cause unknown, its treatment problematical."

The author says in the introduction: "In the whole range of medical terminology there is no such *olla podrida* as chorea, which for a century has served as a sort of nosologic pot into which authors have cast, indiscriminately, affections characterized by irregular purposeless movements. With muscular disorder as the salient feature, as the generic character of chorea, there have been scores of specific designations, indicating the quality of the movement, the locality involved, etc. In Foster's Dictionary, ninety-four of these sub-varieties are named."

Our author does very much in this monograph to clear the obscurity in classification, but Bouteille's pessimistic view of the therapeutics of chorea is as nearly true now as when written eighty-four years ago.

The charming style and pleasant method of Dr. Osler make everything he writes entertaining and agreeable, as well as instructive, and this book is no exception to the rule.

The Proceedings of the Fourth Annual Meeting of the Association of Military Surgeons of the United States. Held at Washington, D. C., on May 1, 2 and 3, 1894. Pp. 712. Cloth.

The transactions of this Association have grown from a small volume to a large one, and with that growth there is a corresponding increase in the value of the papers presented. The proceedings of the Association occupy the first place in the volume, after which the papers and discussions follow.

The President's annual address by Professor Senn, was one of those scholarly productions characteristic of that author, on "Abdominal Surgery on the Battle-field." He commends laparotomy for the treatment of internal hemorrhage and dangerous abdominal wounds. The "first aid"

should consist in compression over the injured part and auto-transfusion by circular constriction at the base of one or more extremities; the treatment should be prompt; patient at once removed to field hospital, which should be fully equipped. After opening abdomen, temporary compression of aorta should be resorted to if there is much hemorrhage. Venous hemorrhage to be arrested by sponge tampon. Wounds of liver and pancreas should be treated by suture, tampon or actual cautery. Wounds of spleen or kidney may require removal. Wounds of the stomach should be treated the same as wounds of the intestines.

There are many excellent papers in the volume of which a full *résumé* was given by a very competent hand, in this JOURNAL. The volume is well printed on good paper.

A Clinical Manual of Diseases of the Eye, Including a Sketch of Its Anatomy. By D. B. ST. JOHN ROOSA, M.D., LL.D. Octavo. 650 pages, 178 engravings in the text, nearly all original, two full-page chromo-lithographic plates, and a full-page black plate. Bound in muslin at \$5.50, and in sheep at \$6.50. New York: Wm. Wood & Company. 1894.

The author says in his preface that the work was not written because he "supposed that there were not already in the English tongue many excellent treatises on diseases of the eye. It is presented to the profession because I have not deemed that the debt I owe to it could be even approximately satisfied, nor my own reputation as a teacher, whatever that may be, justly settled, unless I presented in a permanent and accessible form some of the results, with their personal coloring, of my long experience both in the hospital and private practice in ophthalmic disease and therapeutics."

Dr. Roosa has properly judged that the "personal coloring" given to the topics of which he treats, will give his book a wide interest. The opinions of one with such vast opportunities for observation, in this country and in Europe, and of such extensive personal experience can not be a matter of indifference to ophthalmologists, and there is no question of the success of the book.

We note with pleasure the wise conservatism of the author in regard to the use of glasses and muscle cutting. Of school children and their eyes, the author says: "These so-called advances in the methods of teaching, involve excessive use of the eyes under sometimes very unfavorable conditions, that is to say, over desks of inappropriate height for the scholars, in rooms poorly lighted, with air that is sometimes foul for hours. Children are given too many studies to work out at home. It is idle to think that any science can combat such conditions as these. The conditions themselves must be changed, or we shall find a race of myopes and asthenopes growing up where formerly we had strong-eyed people."

The publishers have done their work well and the large clear type gives pleasant evidence that in the making of this book they have profited by Dr. Roosa's dictum that "books should always be well printed." (Page 439.)

Heart Studies, Chiefly Clinical. I. The Pulse Sensations; a Study in Tactile Sphygmology. By WM. EWART, M.D. Cantab., F.R.C.P. Lond., etc., etc. With nearly 200 illustrations. Cl., pp. 486. London: Ballière, Tindall and Cox. 1894. Price, \$1.50.

It is refreshing amid the dreary mass of compilations coming to the reviewer's table and books for the issue of which there can be no possible excuse, to meet with a book which displays so much original work and original thought and it will be found no less interesting to the physiologist than to the clinician. The author thus divides his work into seven parts. The first is preceded by the Introduction which contains two chapters: I, "Tactile Sphygmology and Instrumental Sphygmology: a Retrospect. II, "The Sphygmograph and the Finger; Cause of the Lack of Coöperation

between the two Methods." Part I is "General Notions on Pulse, Artery and Tension," and consists of four chapters, viz: I, "What is meant by the Pulse." II, "The Arterial Walls Their Elastic and Muscular Functions." III, "The Arterial Channel Arteries viewed in their Continuity—Pressure Changes and Pulsable Systolic Changes in Arteries." IV, "Elementary Notions of Arterial Tension and Arterial Blood Pressure." Part 2, contains four chapters, viz: I, "Anatomical Details in Connection with the Radial Pulse." II, "The Relations of the Radial Artery to the Pressure of the Finger variously applied to the Pulse." III, "The Finger as an Organ of Touch, and the mode of using it to the Pulse." IV, "Elementary Tactile Observations." Part 3 is on "The Rudiments of Tactile Analysis of the Pulse," and contains nine chapters viz: I and II, "Preliminary Explanations." III, "The Tactile Exploration of the Pulse Wave." IV, "The Ictus." V, "The Fundamental Pressure-Experiments conducted with a Single Finger." VI, "The Pulse Sensations when Two or more Fingers are used." VII, "The Proximal, Distal and Intermediate Ictus: Their Direction and Relative Time." VIII, "Modifications of the Pulse caused by Compression of the Artery, or induced by Posture." IX, "The Elementary Study of the Anastomatic Pulse." Part 4 contains fourteen chapters on the wave theory; and the instrumental study of the pulse wave. Part 5 has seventeen chapters of tactile studies. Part 6 has four chapters on the observations and theories of Henry Fouquet, and Part 7 has three chapters giving an epitome of the book, and its final conclusions. The frontispiece is an excellent engraving of Henri Fouquet, who was one of the Faculty of Medicine of Montpellier (1767), and is admitted by our author to be the father of modern tactile sphygmology. "He was the first," says the author, "and he remains the only observer who has bequeathed to us the picture of his own personal tactile judgments."

The book under consideration is one of the most original of the year, and deserves a place in the library of every studious physician and surgeon.

PUBLIC HEALTH.

Test for Well Contamination.—The *Journal d'Hygiène* suggests a simple method of determining whether a privy vault communicates with a well of drinking water. Pour into the vault about a pint of a solution of fluorescin—250 grams to 1,000 grams of water. In a very short time, if any communication exists, the well water will be colored a deep red.

Cremation in France.—Judging from the records of the crematory in Père Lachaise, cremation seems to meet with little favor in France. The crematory was established in 1889, but since then only 810 bodies have been incinerated therein. However, the number is slowly increasing from year to year, as the following figures show: 1889, 49; 1890, 121; 1891, 134; 1892, 159; 1893, 199; 1894, including July, 148.

Microbes on Books and Tickets.—In his inaugural thesis (St. Petersburg, 1894), M. Trouskoliavski gives the results of his bacteriologic study of books used by hospital patients and of hospital visitors' tickets, as sources of microbial contagion. Microbiologic examination of newly-printed tickets and books revealed no microbes, but a similar examination of tickets that had been used, and of books that had been read by patients, showed an average of forty-three bacteria to the square centimeter. While many of these are innocuous, some pathogenic bacteria are found—streptococci, tubercle bacilli, etc.—and, affixed to the paper surface, these microbes are found to retain their morbid potency for a long time. Placed on dry sterilized paper, Trouskollavski demonstrated that the comma bacillus remains virulent for from five to

fourteen days; the bacillus typhosus for sixty-three days; the Löffler bacillus for thirty-eight days; and the streptococcus for ninety-eight days. The author dwells upon the danger of turning the leaves of such books by moistening the finger or thumb with saliva—but it is a question whether it is worth while to safeguard those who indulge in such a practice under any circumstances.

A Model Quarantine Station.—The Italian Government has just completed and put into commission a model quarantine station at Syracuse in Sicily. An island in the harbor of Syracuse has been taken for the station, which is built on the site of an old fort of the period of Viceroy Don Garcia de Toledo—the latter half of the sixteenth century. The building, over the gateway to which is the inscription "*Salus populi suprema lex*," is described as divided into two parts—on one side a hospital, provided with every modern appliance to secure pure air, proper drainage and the prevention of contagion; on the other the disinfecting rooms. There are a dead-house for the *post-mortems*, a crematory, and a columbarium for the ashes of cremated bodies. Passengers and crews of vessels from suspected ports—mainly of the East—will be taken into the disrobing rooms, one for each sex; there disrobed and their clothing sent through a hatchway to the disinfecting chambers; after thorough bathing they will pass into the dressing rooms, there to await their disinfected clothing, which, meanwhile, has been subjected to a heat of 120 degrees centigrade. Baggage is treated in the same manner and subsequently both persons and baggage—to which access is freely had—are kept under surveillance for the incubative period of the suspected disease. The provision by which is tested the freedom of the baggage from danger of carrying contagion to the point of ultimate destination, is worthy of note.

Does Prevention Prevent?—One of the most distinguished of American physicians is quoted, in a recent uncontradicted newspaper interview, as saying: "In this category [of dangerous contagious diseases] may be included those diseases that the sanitarians are pleased to call 'preventable diseases!' I have yet to find the preventive or any man who has yet found it." Since the eminent speaker then went on almost immediately to controvert his own statement—by attributing the present surpassingly healthful condition of the city which is honored by his residence to a recent municipal scrubbing up and thorough cleansing—he furnished the antidote to whatever of harm his, no doubt inadvertent, sneer at the sanitarians might otherwise have caused among a public which is justly accustomed to receive his utterances as authoritative and final. There is thus little need for referring to the matter save that—by what our colleague of the *Medical Record* styles "a fortuitous combination of items"—the next article which fell under the eye of the JOURNAL described the methods of prevention of the preventable diseases in the *Hospice des Enfants Assistés* or Foundlings' Home of Paris. These methods are too well known to the readers of the JOURNAL to require repetition; but the answer to the query, "Does prevention prevent?"—could not well be given more conclusively than in the simple historical fact that this institution—until within the last two years the greatest clinical field in the world for the study of measles and diphtheria, which had literally raged as epidemics within its walls for more than a quarter of a century causing a frightful mortality—is now deserted by the students of these diseases because they no longer occur among its inmates. Granted the employment of the preventive, there can be no doubt that prevention does prevent what sanitarians call "the preventable diseases."

An International Bureau of Hygiene.—Dr. Zanni, of Constantinople, has submitted to the editor of the *Medical Press* a series of suggestions for the creation of a Central International Bureau of Hygiene with national branches—each branch to be provided with the necessary appliances and

A Practical Manual of Mental Medicine. By DR. E. RÉGIS, with a preface by M. BENJAMIN BALL. Second edition, thoroughly revised and largely re-written. Authorized translation by H. M. Bannister, A.M., M.D., with an introduction by the author. Cl., pp. 692. Utica, N. Y.: Press of American Journal of Insanity. 1894.

The first edition of this work was crowned by the Faculty of Medicine of Paris, and received the Chateauvillard Prize of 1886. In 1891 the author revised the second edition, and now it has been translated by Dr. Bannister and published by Dr. Alder Blumer, who conceived the idea of having the printing done at the Utica Asylum by his patients. "It is assuredly," says Régis, "the first work treating of mental alienation, written by an alienist, translated by an alienist, and under the direction of an alienist, printed and bound by the insane."

The translator says: "It is a rather remarkable, and perhaps not altogether a creditable fact, that up to the present we have had no English translation of any modern standard French work on mental diseases and their treatment. No apology, therefore, seems necessary for having endeavored to present to American readers the work of Dr. Régis which is, as it is considered in France, a model of its kind." The translator and the publisher have each done their work well, and the book will, we feel sure, be warmly welcomed by the American medical profession.

Chorea and Choreiform Affections. By WILLIAM OSLER, M.D. Philadelphia: P. Blakiston, Son & Co. 1894. Price \$2.

This book, which is gracefully dedicated to Dr. W. R. Gowers, of London, represents "in an expanded form, the lectures on chorea which appeared in the *Medical News*, 1887," and from studies of the case books of the Infirmary for Diseases of the Nervous System in Philadelphia. Facing the title page the author has placed two quotations, one from Bouteille (1810), the translation of which is as follows: "All is extraordinary in this disease; its name is ridiculous, its symptoms singular, its character equivocal, its cause unknown, its treatment problematical."

The author says in the introduction: "In the whole range of medical terminology there is no such *olla podrida* as chorea, which for a century has served as a sort of nosologic pot into which authors have cast, indiscriminately, affections characterized by irregular purposeless movements. With muscular disorder as the salient feature, as the generic character of chorea, there have been scores of specific designations, indicating the quality of the movement, the locality involved, etc. In Foster's Dictionary, ninety-four of these sub-varieties are named."

Our author does very much in this monograph to clear the obscurity in classification, but Bouteille's pessimistic view of the therapeutics of chorea is as nearly true now as when written eighty-four years ago.

The charming style and pleasant method of Dr. Osler make everything he writes entertaining and agreeable, as well as instructive, and this book is no exception to the rule.

The Proceedings of the Fourth Annual Meeting of the Association of Military Surgeons of the United States. Held at Washington, D. C., on May 1, 2 and 3, 1894. Pp. 712. Cloth.

The transactions of this Association have grown from a small volume to a large one, and with that growth there is a corresponding increase in the value of the papers presented. The proceedings of the Association occupy the first place in the volume, after which the papers and discussions follow.

The President's annual address by Professor Senn, was one of those scholarly productions characteristic of that author, on "Abdominal Surgery on the Battle-field." He commends laparotomy for the treatment of internal hemorrhage and dangerous abdominal wounds. The "first aid"

should consist in compression over the injured part and auto-transfusion by circular constriction at the base of one or more extremities; the treatment should be prompt; patient at once removed to field hospital, which should be fully equipped. After opening abdomen, temporary compression of aorta should be resorted to if there is much hemorrhage. Venous hemorrhage to be arrested by sponge tampon. Wounds of liver and pancreas should be treated by suture, tampon or actual cautery. Wounds of spleen or kidney may require removal. Wounds of the stomach should be treated the same as wounds of the intestines.

There are many excellent papers in the volume of which a full *résumé* was given by a very competent hand, in this JOURNAL. The volume is well printed on good paper.

A Clinical Manual of Diseases of the Eye, Including a Sketch of Its Anatomy. By D. B. ST. JOHN ROOSA, M.D., LL.D. Octavo, 650 pages, 178 engravings in the text, nearly all original, two full-page chromo-lithographic plates, and a full-page black plate. Bound in muslin at \$5.50, and in sheep at \$6.50. New York: Wm. Wood & Company. 1894.

The author says in his preface that the work was not written because he "supposed that there were not already in the English tongue many excellent treatises on diseases of the eye. It is presented to the profession because I have not deemed that the debt I owe to it could be even approximately satisfied, nor my own reputation as a teacher, whatever that may be, justly settled, unless I presented in a permanent and accessible form some of the results, with their personal coloring, of my long experience both in the hospital and private practice in ophthalmic disease and therapeutics."

Dr. Roosa has properly judged that the "personal coloring" given to the topics of which he treats, will give his book a wide interest. The opinions of one with such vast opportunities for observation, in this country and in Europe, and of such extensive personal experience can not be a matter of indifference to ophthalmologists, and there is no question of the success of the book.

We note with pleasure the wise conservatism of the author in regard to the use of glasses and muscle cutting. Of school children and their eyes, the author says: "These so-called advances in the methods of teaching, involve excessive use of the eyes under sometimes very unfavorable conditions, that is to say, over desks of inappropriate height for the scholars, in rooms poorly lighted, with air that is sometimes foul for hours. Children are given too many studies to work out at home. It is idle to think that any science can combat such conditions as these. The conditions themselves must be changed, or we shall find a race of myopes and asthenopes growing up where formerly we had strong-eyed people."

The publishers have done their work well and the large clear type gives pleasant evidence that in the making of this book they have profited by Dr. Roosa's dictum that "books should always be well printed." (Page 439.)

Heart Studies, Chiefly Clinical. I. The Pulse Sensations; a Study in Tactile Sphygmology. By WM. EWART, M.D., Cantab., F.R.C.P. Lond., etc., etc. With nearly 200 illustrations. Cl., pp. 486. London: Ballière, Tindall and Cox. 1894. Price, \$1.50.

It is refreshing amid the dreary mass of compilations coming to the reviewer's table and books for the issue of which there can be no possible excuse, to meet with a book which displays so much original work and original thought, and it will be found no less interesting to the physiologist than to the clinician. The author thus divides his work into seven parts. The first is preceded by the Introduction which contains two chapters: I, "Tactile Sphygmology and Instrumental Sphygmology: a Retrospect. II, "The Sphygmograph and the Finger; Cause of the Lack of Coöperation

between the two Methods." Part 1 is "General Notions on Pulse, Artery and Tension," and consists of four chapters, viz: I, "What is meant by the Pulse." II, "The Arterial Walls Their Elastic and Muscular Functions. III, "The Arterial Channel Arteries viewed in their Continuity—Pressure Changes and Pulsable Systolic Changes in Arteries." IV, "Elementary Notions of Arterial Tension and Arterial Blood Pressure." Part 2, contains four chapters, viz: I, Anatomical Details in Connection with the Radial Pulse." II, "The Relations of the Radial Artery to the Pressure of the Finger variously applied to the Pulse." III, "The Finger as an Organ of Touch, and the mode of using it to the Pulse." IV, "Elementary Tactile Observations." Part 3 is on "The Rudiments of Tactile Analysis of the Pulse," and contains nine chapters viz: I and II, "Preliminary Explanations." III, "The Tactile Exploration of the Pulse Wave." IV, "The Ictus. V, "The Fundamental Pressure-Experiments conducted with a Single Finger." VI, "The Pulse Sensations when Two or more Fingers are used." VII, "The Proximal, Distal and Intermediate Ictus: Their Direction and Relative Time." VIII, "Modifications of the Pulse caused by Compression of the Artery, or induced by Posture." IX, "The Elementary Study of the Anastomatic Pulse." Part 4 contains fourteen chapters on the wave theory; and the instrumental study of the pulse wave. Part 5 has seventeen chapters of tactile studies. Part 6 has four chapters on the observations and theories of Henry Fouquet, and Part 7 has three chapters giving an epitome of the book, and its final conclusions. The frontispiece is an excellent engraving of Henri Fouquet, who was one of the Faculty of Medicine of Montpellier (1767), and is admitted by our author to be the father of modern tactile sphygmology. "He was the first," says the author, "and he remains the only observer who has bequeathed to us the picture of his own personal tactile judgments."

The book under consideration is one of the most original of the year, and deserves a place in the library of every studious physician and surgeon.

PUBLIC HEALTH.

Test for Well Contamination.—The *Journal d'Hygiène* suggests a simple method of determining whether a privy vault communicates with a well of drinking water. Pour into the vault about a pint of a solution of fluorescein—250 grams to 1,000 grams of water. In a very short time, if any communication exists, the well water will be colored a deep red.

Cremation in France.—Judging from the records of the crematory in Père Lachaise, cremation seems to meet with little favor in France. The crematory was established in 1880, but since then only 810 bodies have been incinerated herein. However, the number is slowly increasing from year to year, as the following figures show: 1880, 49; 1890, 21; 1891, 134; 1892, 159; 1893, 199; 1894, including July, 148.

Microbes on Books and Tickets.—In his inaugural thesis (St. Petersburg, 1894), M. Trouskoliavski gives the results of his bacteriologic study of books used by hospital patients and of hospital visitors' tickets, as sources of microbial contagion. Microbiologic examination of newly-printed tickets and books revealed no microbes, but a similar examination of tickets that had been used, and of books that had been read by patients, showed an average of forty-three bacteria to the square centimeter. While many of these are innocuous, some pathogenic bacteria are found—streptococci, tubercle bacilli, etc.,—and, affixed to the paper surface, these microbes are found to retain their morbid potency for a long time. Placed on dry sterilized paper, Trouskoliavski demonstrated that the comma bacillus remains virulent for from five to

fourteen days; the bacillus typhosus for sixty-three days; the Löffler bacillus for thirty-eight days; and the streptococcus for ninety-eight days. The author dwells upon the danger of turning the leaves of such books by moistening the finger or thumb with saliva—but it is a question whether it is worth while to safeguard those who indulge in such a practice under any circumstances.

A Model Quarantine Station.—The Italian Government has just completed and put into commission a model quarantine station at Syracuse in Sicily. An island in the harbor of Syracuse has been taken for the station, which is built on the site of an old fort of the period of Viceroy Don Garcia de Toledo—the latter half of the sixteenth century. The building, over the gateway to which is the inscription "*Salus populi suprema lex*," is described as divided into two parts—on one side a hospital, provided with every modern appliance to secure pure air, proper drainage and the prevention of contagion; on the other the disinfecting rooms. There are a dead-house for the *post-mortems*, a crematory, and a columbarium for the ashes of cremated bodies. Passengers and crews of vessels from suspected ports—mainly of the East—will be taken into the disrobing rooms, one for each sex; there disrobed and their clothing sent through a hatchway to the disinfecting chambers; after thorough bathing they will pass into the dressing rooms, there to await their disinfected clothing, which, meanwhile, has been subjected to a heat of 120 degrees centigrade. Baggage is treated in the same manner and subsequently both persons and baggage—to which access is freely had—are kept under surveillance for the incubative period of the suspected disease. The provision by which is tested the freedom of the baggage from danger of carrying contagion to the point of ultimate destination, is worthy of note.

Does Prevention Prevent?—One of the most distinguished of American physicians is quoted, in a recent uncontradicted newspaper interview, as saying: "In this category [of dangerous contagious diseases] may be included those diseases that the sanitarians are pleased to call 'preventable diseases!' I have yet to find the preventive or any man who has yet found it." Since the eminent speaker then went on almost immediately to controvert his own statement—by attributing the present surpassingly healthful condition of the city which is honored by his residence to a recent municipal scrubbing up and thorough cleansing—he furnished the antidote to whatever of harm his, no doubt inadvertent, sneer at the sanitarians might otherwise have caused among a public which is justly accustomed to receive his utterances as authoritative and final. There is thus little need for referring to the matter save that—by what our colleague of the *Medical Record* styles "a fortuitous combination of items"—the next article which fell under the eye of the *JOURNAL* described the methods of prevention of the preventable diseases in the *Hospice des Enfants Assistés* or Foundlings' Home of Paris. These methods are too well known to the readers of the *JOURNAL* to require repetition; but the answer to the query, "Does prevention prevent?"—could not well be given more conclusively than in the simple historical fact that this institution—until within the last two years the greatest clinical field in the world for the study of measles and diphtheria, which had literally raged as epidemics within its walls for more than a quarter of a century causing a frightful mortality—is now deserted by the students of these diseases because they no longer occur among its inmates. Granted the employment of the preventive, there can be no doubt that prevention does prevent what sanitarians call "the preventable diseases."

An International Bureau of Hygiene.—Dr. Zauni, of Constantinople, has submitted to the editor of the *Medical Press* a series of suggestions for the creation of a Central International Bureau of Hygiene with national branches—each branch to be provided with the necessary appliances and

personnel for studying the sources of disease, its development and spread, with especial reference to the prevention of epidemics; the funds necessary for the maintenance of the Central Bureau to be raised by fees for sanitary passports for travelers and by taxes on transport companies and on cattle in transit. The functions of the Bureau, which it is proposed to locate permanently at Berne or Brussels, include the execution of the resolutions adopted by the successive Congresses of Hygiene and the bringing of "the sanitary authorities of the various countries in close and constant communication, its proceedings being embodied in a monthly journal *ad hoc*." At this distance the scheme seems very vague if not visionary. It is not apparent, from the summary of suggestions as published, what authority the Central Bureau or any of the national branches would have to compel travelers to take its sanitary passports or to exact fees therefor, or to levy taxes as indicated; still less what power it could exert to enforce the resolutions adopted by the International Congress. Nor does the *Press* seem at all sanguine of the realization of Dr. Zanni's project, although it has a motive for desiring it which sanitarians in this country can, happily, only partly appreciate. That motive is sufficiently indicated in the following comment: "One of the first steps [of the Central International Bureau] would be to compile rules for the organization of sanitary congresses, international and national, with a view to restricting membership to persons duly qualified to take part in the deliberations and to shut out the troublesome contingent of picnic members whose idea of hygiene is 'high jinks.' Then, and only then, will the decisions arrived at by the members in solemn conclave assembled have weight and value. A sanitary congress must be a meeting of experts and not an aggregation of faddists and rank outsiders, if it is to command the respect of governments and peoples, and the first duty of the International Bureau, if ever it comes into existence, will be to legislate accordingly."

Epidemic Contagious Diseases.—Diphtheria and scarlet fever have both markedly increased during the past week; isolation hospitals have been opened in many localities in consequence and some are already overcrowded; this has been the case for some time in Boston, where it is reported that three or four cots are placed in the private rooms intended for only one patient each and new admissions are refused daily. The first shipment of antitoxin, manufactured in this country, was recently made by Dr. Paul Gibier, Director of the Pasteur Institute in New York, to the Board of Health of New Orleans, where diphtheria has been "raging" for more than a month; a subsequent shipment was made to Toronto. A public subscription has been started by the press of New Orleans for the purchase of the serum and the establishment of a laboratory for its production. Consul-General Charles DeKay reports from Berlin that the demand for the remedy is so great that the hospitals could not be supplied recently, notwithstanding forty horses are used for its production in one establishment alone; as a result the hospital mortality of children under 4, which had been reduced to 11 per cent. in September, rose to 60 per cent. in October.—After repeated contradictory statements in the newspapers for and against the oyster industry, Dr. C. A. Lindsley, Secretary of the Connecticut State Board of Health, reports as the result of his investigation of the recent outbreak of illness among the students of the Wesleyan College at Middletown, that the disease is unquestionably typhoid fever, caused by eating oysters taken near the outlet of a sewer in the Quinnipiac River; twenty cases resulted among those who partook of these infected oysters, including a student from Yale and one from Amherst; two of the Wesleyan students are dead and three of the surviving eighteen are critically ill.—The anticipated recrudescence of smallpox to epidemic proportions with the advent of cold weather has not thus far materialized; the number of cases in Milwaukee

and Chicago remains about stationary; on the 20th inst. there were 106 cases in the former city as against 107 one week previous and 58 in Chicago as against 57 one week previous. The cases traced to the concealed case in the grocer's shop in New York, reported in last week's *JOURNAL*, have given some trouble, by causing a second crop, but the health authorities believe they have now run them all down and that further spread from this source is unlikely. The situation at present speaks well for our municipal sanitary administrations in dealing with this disease under the many handicaps of concealment of cases, opposition to vaccination and resistance to necessary measures of restriction and suppression. An object-lesson in these difficulties is furnished in the story of a recent introduction of the disease into the town of Deerfield, Ohio. A "faith-curer," named Hazzard, while in New York, visited a smallpox patient and treated the case by the "faith cure" methods; returning to Deerfield he promptly developed a well-marked attack of variola, but concealed his condition and refused medical attendance until an unknown number of persons had been exposed.

MISCELLANY.

Change of Address.—Dr. H. A. Kelly has removed to 1406 Eutaw Place, Baltimore, Md.

Progressive Astigmatism.—By an inadvertence which we regret, the Table of Contents last week failed to include the excellent paper of Dr. W. T. Montgomery, of Chicago, on "Progressive Astigmatism."

Appointments.—Dr. A. M. Hurd, for the past year First Assistant Physician of the Buffalo State Hospital has been appointed Superintendent of that institution.

Dr. Augustus H. Buckmaster, has accepted the Chair of Practice of Medicine in the University of Virginia.

New Antidote for Prussic Acid.—M. Johann Antal, a Hungarian chemist, has produced a new compound—the nitrate of cobalt—which is claimed to be a very efficacious antidote in cases of poisoning by cyanid of potash or prussic acid. Used first experimentally with animals, it has been since employed in upward of forty cases of accidental poisoning by the cyanid, and always with success.

Another "Gold Cure" Victim.—An inquest, resulting in a verdict of "death from alcoholism," was held in Chicago on the 12th inst. The victim—a commercial traveler named Dresser—was discharged "cured" from a Keeley Institute about three years since and, for a time, was one of the "star" cures. This makes the sixth or seventh "post" held in that city, within a few months, on "graduates of the gold cure." It might be worth while to gather up the statistics of this kind for the country at large.

Cigarette-Roller's Cramp.—To the already long list of professional palsies—the writers', pianists', typists', milkers', *et al.*,—is now to be added the cigarette-rollers' cramp. It is reported to be very frequent in Spain and to be appearing in France. After a few months work the girls, who roll the cigarettes in those countries, are obliged to cease their occupation—sometimes permanently. They experience intense pain in the joints of their hands and fingers and are often unable for some time to approximate the thumb and index finger.

Honors for Dr. Yersin.—The nomination of Dr. Yersin, Colonial Medical Officer of the second class, to the rank of Chevalier of the Legion of Honor is announced in the official journal of France. After acting as Professor Roux's assistant at the Pasteur Institute for four years, Dr. Yersin proceeded to Hong Kong under a commission from the Minister for the Colonies. His labors there during the plague and in connection with the discovery of the microbe of the pest are well known.

Bequests to Hospitals.—Under the will of the late Edwin J. Leisenring the following named institutions have been remembered with special bequests: The Pennsylvania Hospital of Philadelphia and St. Luke's Hospital of South Bethlehem. They will each receive \$10,000.

Leprosy among African Natives.—A writer in the *Illustrated Africa* states that he has had experience with one hundred cases of leprosy among African negroes, and they were all among males with one exception. The greater degree of cleanliness among African women than among the males is a point of marked difference. The men are too busy to go to the stream and wash. The women need to go to the water daily for their culinary and other purposes, so that it is easy for them to step into the stream before filling their waterpots. Hence at the expense of large average outlay of time in bathing the female is comparatively exempt. The writer finds that fish is an article of diet with many of these African races. The element of heredity does not appear to prevail in their etiology, but the testimony on nice points of this nature is not always accessible, and much that is attempted to be given is unintelligent and unreliable.

Deaver Home for Consumptives.—Under the auspices of the Bishop and Chapter of the Episcopal diocese of Colorado, a home for consumptives is in a fair way to be established in Denver, to which physicians may send their patients in modest circumstances who would be benefited by residence in that climate. The establishment will consist of three separate buildings, one to be occupied exclusively by men, one exclusively by women and the third by mothers with their sons, husbands with their wives and brothers with their sisters, at a cost of \$5 per week for each person—this charge covering board, lodging and medical attendance. It is hoped by this semi-charity to make the climatic advantages of Colorado available to a class of consumptives who are now debarred by reason of the cost of living in Denver and vicinity. There will be accommodations for 216 patients; the medical attendant will be Dr. Samuel A. Fisk, a graduate of Yale and of the Harvard Medical School; the Rev. Frederick W. Oates, rector of All Saints' Church in Denver, will have the direct management and is now in New York securing the necessary funds—to which one lady has subscribed the entire amount requisite to erect the main central building and another lady and a gentlemen have contributed the sum necessary for one of the two other buildings.

Domestic Medicine in the Tennessee Mountains.—A writer in the *Independent*, recruiting in Cloudland, Eastern Tennessee, gives a sketch of the indigenous resources of the hardy mountaineers of that section, when they happen to think that they are not so robust as usual. There is a great paucity of medical diplomas in that section, and principally for the very good reasons that there are neither ill-health or filthy lucre in paying quantities. The writer is a clergyman, and seems to be greatly amused at the many uses to which the ground-hog is put *post-mortem* by the mountain-people. The reference to phthisis, in the paragraph given below, must be held to refer to the few imported cases that reach that country, and not to cases originating therein; the latter are almost, if not entirely, unknown.

In the helplessness of cultivated communities the family doctor is indispensable. But the natural man finds it easy to doctor himself. With 'balsam juice,' the resinous deposit on the bark of *Abies Fraseri*, he cures nearly everything, both outside and inside. The virtues of sarsaparilla and ginseng (the *Aralias*) are understood. Said a mighty Nimrod: 'Ef er hev side pleurisy, an' yer side is swole up es big es yer and, put ground-hog ile on it three nights right hand-unnin.' (And here is *Actomys montan* once more.) Slippery elm (*Ulmus fulva*) helps a bad throat. 'Ramp' (*Allium tricoccum*), though fatal to milk and butter, relieves phthisis. The woods are full of poultices and bitter tonics. Armed with his knife, our mountaineer is capable of heroic surgery, both for his neighbors and himself. Unfortunately, he is apt to have an exaggerated estimate of the medical virtues of 'corn juice,' which too frequently flows from a moonlight ill."

Hospital Notes.

THE CHAMBERS STREET HOSPITAL, NEW YORK.—This emergency institution in New York City is no more. The last patients were discharged or removed on the 7th inst. A new House of Relief has been established at Nos. 67 and 69 Hudson Street, and is now conducted as a branch of the New York Hospital. It is appointed and equipped with all the best modern improvements and is the equal of any institution of its kind in the world, inclusive of an ambulance station especially designed for emergency work.

Washington Notes.

THE DISTRICT MEDICAL SOCIETY.—At the regular meeting of the Society held on the 14th inst., Dr. Henry A. Robbins read a very elaborate essay on syphilis, and Dr. J. W. Bovee presented the specimens and read the history of a case of dermoid cyst, pyosalpinx and double ovarian abscess.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—The two hundred and seventeenth meeting of the Society was held on the 16th inst. Dr. H. D. Fry gave the history of a successful case of Cæsarean section and presented the mother and child. He also gave the history of a case of symphyseotomy, and presented the patient who has made a perfect recovery. The regular paper of the evening was read by Dr. Wm. M. Sprigg, entitled a "Case of Double Vagina and Uterus." Dr. W. P. Carr related the history of a case of double uterus with unilateral pregnancy and removal of decomposed fetus and secundines. A very full discussion followed on the different subjects and was participated in by a large number of the members.

SMALLPOX.—There are five new cases of smallpox in the District this week—all traced to the first case (the Coston child). One of the five was not detected until it had recovered and infected three persons in the family in which it occurred and the convalescent had left the city, visited Gainsville, Nacooche, Winder and Athens, Ga. The patient is now believed to be on the return trip home. A lady friend after exposure in the same family is visiting Augusta, Ga. The health officer there has been notified by telegraph. A volunteer nurse at the hospital contracted the disease and died on the 19th inst.

DEATH FROM HYDROPHOBIA.—The four-year-old daughter of F. G. McDermatt residing in Georgetown, D. C., was bitten by a strange dog, about nine weeks ago. The wound was treated by a regular physician and healed promptly. All fears of hydrophobia were at rest until the 11th inst., when she was taken violently ill with rabies, and died in agony on the 14th. A dog which was bitten at the same time has since developed the disease.

THE HOME FOR INCURABLES.—This worthy institution which is more of a necessity than a hospital, and as usual with charitable institutions is very short of funds, has decided to hold a tea in the near future. After years of usefulness they find themselves possessed of forty inmates to cure and \$2.48 in the treasury. Congress makes no appropriation for this hospital and they care for helpless and hopelessly diseased persons hailing from every section of the United States.

Louisville Notes.

FALLS CITY MEDICAL SOCIETY.—Dr. Frank reported the case of a woman upon whom a double ovariectomy had been done, and in whom there developed a fecal fistula seven weeks after the operation. Through this fistula only a few particles of fecal matter passed, but a great deal of gas, and later, seven lumbricoides worms made their exit from the bowel through the fistula. Four months after the operation a subsequent operation was done for the closure of the fistula. The case was reported because of the unusual interest attached to it on account of the passage of the worms from the bowel through the fistula.

ACADEMY OF MEDICINE.—As previously reported through these columns, a society of this name was formed at the meeting held on the evening of the 10th inst. The former effort proved unsuccessful on account of the financial question. After much discussion it was decided that it would not be successful if the Academy met in rented quarters, so the only plan which suggested itself as feasible was to procure from thirty doctors \$300 each, in \$100 yearly payments, with which the building suitable for the purpose was to be purchased and furnished. Many meetings looking to an organization were held, and all but one or two of the requisite number of subscribers secured; a constitution was adopted and all seemed well until the advent of summer, when the enthusiasm died out and the matter was dropped. The meeting held on the 10th inst. was for the purpose of endeavoring to rescue the Academy, and as the other efforts had failed it was decided to raise only sufficient funds to rent a suitable hall and to furnish it. Temporary officers were elected to serve until January 1, as follows: President, Dr. T. L. McDermott; Vice-President, Dr. F. C. Simpson; Secretary, Dr. J. L. Howard; Treasurer, Dr. J. M. Ray. A commodious hall has been rented in the Columbia Building on the sixth floor; it will soon be furnished, and it is to be hoped that the profession at large will take an active interest in the movement.

VACCINATION LAW.—The following is a copy of the letter sent by the Health Officer to the superintendents and teachers of the schools of the city:

"Your attention is called to Sec. 42, P. 673 of the City Code, viz: No principal of any school, and no principal or teacher of any private, sectarian or other school, shall admit to any such school such child or minor who shall not have been vaccinated, etc." and "That every person being the guardian or having the care, custody or control of any minor or other individual, except such as have had smallpox or varioloid, shall cause and procure such minor or individual to be so promptly, frequently and effectively vaccinated that such minor or individual shall not take or be liable to take the smallpox. Any person violating this section shall be liable to a fine in the city court of not less than \$10 nor more than \$20, and shall also be liable to a like fine for every ten days thereafter they shall delay having the operation of vaccination performed."

FOOTBALL.—A serious accident occurred in a game between the Louisville Male High School and the Manual Training School last week. One of the players on the former team sustained a fracture of both bones of one of his legs while on the bottom of a pile of players in a scrimmage. He was removed from the field and a substitute played in his place. The other injuries sustained by the players were trivial.

JOHN N. NORTON MEMORIAL INFIRMARY.—One of the most valuable as well as deserving institutions of this city is the John N. Norton Memorial Infirmary. This infirmary (or hospital) owes its name to a former and much beloved clergyman of the Protestant Episcopal Church in this city, whose widow made a large contribution to it, and by means of this and other but smaller contributions, sufficient means were accumulated to justify the erection of the handsome and spacious four-story building upon the purchased lot at the corner of Third and Oak Streets, one of the most beautiful and quiet residence locations in the city.

The infirmary was first opened for business in the month of December, 1885, since which period it has been liberally patronized by the sick and afflicted, not only of this city and State, but its influence for good has been felt in several other States from which many patients have been sent to the infirmary for treatment.

The furnishings of apartments, laundry, kitchen, offices and operating rooms have been thorough and in the best manner, and these details of arrangement have been made with a completeness that compares most favorably with older and richer establishments; the appointment of the patients' rooms is even luxurious.

The skilful architecture of the building secures perfect ventilation in all its parts and affords ample light to every department. Each has an attractive outlook, and a cheerful view of agreeable surroundings. There is electric communication between all parts of the house and speaking tubes on each floor. There is also a fire alarm in the building. Open fires are used in the patients' rooms and the halls are thoroughly warmed by an approved heating apparatus.

The managers have been most fortunate in securing the

services of Miss N. Gillette, of New York, as Superintendent. Her training and experience have been in the best schools and hospitals, and she has sustained the reputation of her former employments. Attached to the infirmary is an efficient corps of trained nurses. In addition to their usual duties at the infirmary, nurses have from time to time been supplied to patients at their homes. In connection with the infirmary the management maintains a training school for nurses; the pupils are under the instruction of the superintendent and have the advantage of practical experience in all the details of nursing the sick, and in addition to this have a regular course of lectures delivered to them by a staff of physicians and surgeons of the city.

The infirmary is conducted by a board of lady managers duly elected by the vestries of the various Protestant Episcopal Churches of the city, but it is non-sectarian in its management, its doors are open equally alike to persons of all creeds or of no creed whatever, and it is the privilege of patients to employ whatever physician or clergyman they may prefer, uninfluenced by the managers.

The prices for board and rooms are considered low as compared with similar institutions in other cities.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Nov. 10, 1894, to Nov. 16, 1894.

Capt. BENJAMIN L. TEN EYCK, Asst. Surgeon, granted leave of absence for one month.

First Lieut. FRANCIS A. WINTER, Asst. Surgeon, leave of absence granted in S. O. 71, Dept. of Texas, July 25, 1894, is extended one month. By direction of the Secretary of War.

Capt. EUGENE L. SWIFT, Asst. Surgeon, leave of absence granted in S. O. 147, Dept. of Dakota, Oct. 11, 1894, is extended one month. By direction of the Secretary of War.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending Nov. 17, 1894.

Medical Inspector J. M. FLINT, detached from the U. S. S. "Baltimore," home and three months' leave.

Surgeon C. U. GRAVATT, ordered to the U. S. S. "Charleston," per steamer Dec. 4, 1894.

Surgeon J. A. HAWKE, detached from the U. S. S. "Charleston," and to the U. S. S. "Baltimore."

Asst. Surgeon J. S. HOPE, ordered to the U. S. R. S. "Franklin."

Asst. Surgeon W. H. BARNUM, detached from U. S. R. S. "Franklin," and to the New York Navy Yard.

P. A. Surgeon M. F. GATES, ordered to the U. S. R. S. "Richmond."

Medical Inspector G. R. BRUSH, ordered before Retiring Board at New York, Nov. 17, 1894.

Surgeon L. G. HENBERGER, detached from Marine Rendezvous, and continue special duty in New York.

Surgeon J. M. STEELE, detached from League Island Navy Yard, and to Marine Rendezvous, New York.

P. A. Surgeon W. H. RUSH, detached from Naval Academy, and to the League Island Navy Yard.

P. A. Surgeon A. M. D. MCCORMICK, ordered to the Naval Academy, Annapolis, Md.

ORIGINAL ARTICLES.

THE DEFECTIVE CLASSES AND LEGISLATION FOR THE PREVENTION OF BLINDNESS.

Read before the Bureau County (Ill.) Medical Society.

BY BOERNE BETTMAN, M.D.

Professor of Ophthalmology in the Chicago Post-Graduate Medical School; Oculist and Aurist to the Michael Reese and German Hospitals; Attending Surgeon to the Illinois Charity Eye and Ear Infirmary; Professor of Ophthalmology and Otology in the College of Physicians and Surgeons, Chicago; President Illinois State Board of Charities.

I do not intend to enter into a discussion of some abstruse medical problem, neither do I contemplate engaging your attention with a learned dissertation on any particular subject. I desire merely to touch upon the A, B, C, of sociology, as far as it pertains to the care and improvement of the so-called defective classes. Later on, I will deal more at length with the subject which lies nearest my heart, the blind, and determine why there are so many of these afflicted beings in the world and how we can prevent this sad misfortune. Under the term, "defective classes," we commonly understand all those individuals who, either owing to some physical infirmity or mental defect, are rendered unable to take up the battle of life on an equal footing with the remainder of mankind. They are handicapped in the struggle for existence. Under this category we must place the deaf and dumb, the blind, the feeble-minded, the insane, the epileptics, and the decrepit paupers. Again, we possess in our midst an ever-increasing set of individuals whose minds are so warped that they have lost all regard for law and order, who will not follow the path of rectitude, to whom the sense of right and wrong is a minus quantity. I refer to the criminal classes commonly termed prisoners. As civilization progresses and the demands and ambitions of society increase, so does the struggle for bread and the luxuries of this world. It is a question of the "survival of the fittest." We are governed by the same laws which control plant and lower animal life. The stronger succeed and come to the top, the weaker succumb and are pushed to the wall. But we differ from the animal in recognizing the debilities, the weaknesses of our fellow-men, and in founding for them institutions where the necessary provisions are made to better their condition. Thus we erect asylums or rather hospitals for the care and treatment of the insane, build schools for the education of the deaf, dumb and blind. We care for our paupers in county almshouses, and we place the offenders of society behind lock and bars. Thus society performs its duty by providing for those who owing to their defects either can not keep apace with it, or who attempt to overthrow its organization or sap at its foundations by preying upon it.

It is well my friends that we always have the poor with us. Their very presence and the demands made

upon us by the weak are in one respect a blessing to mankind. They assist in educating the better nature of man, in lessening the innate selfishness and in one word, in developing and broadening those nobler instincts which we term human. They are constantly teaching us another lesson by which we should profit. Their very existence is the result of violations of the laws of nature, the results of moral wrongs and lethargy of society at large. Their number is constantly increasing owing partly to lack of education, partly to lack of proper State legislation, partly to immigration and last but not least to the lax manner in which our laws are enforced, or rather not carried into execution. You will be surprised to learn what a tale of woe our eleventh census recites in relation to crime and pauperism. One of its disclosures is the disproportionate increase of these classes. In 1850 there was one criminal to 3,500 of the population; in 1890 we have the appalling figures presented to us of 1 to 786.5 of the inhabitants of our country. Just think of this alarming and menacing increase—445 per cent. in forty years, while the population has increased but 170 per cent. If this rate of development continues will there soon be any honest people residing in this, our glorious prosperous country?

Henry M. Boies, in his recent book on "Prisoners and Paupers" shows that this alarming state of affairs does not exist in the other civilized nations. We are a prosperous nation in every respect, not only in the production of wheat, corn and cotton, but even in the raising of criminals. Again, I repeat, what a wonderful booming people we are! In England, criminal convictions have fallen from 15,033 in 1868 to 9,348 in 1889. In Scotland, from 2,490 to 1,723 for the same years, and in Ireland from 3,084 in 1870 to 1,225 in 1890. The population has fairly increased in these countries during the periods mentioned. The number of imprisonments in France has increased but threefold in half a century, but we beat them all. Let us be happy; we always lead in everything. To be just, it is not more than fair to state that exceptional conditions exist in our midst, to account for this excessive disproportion between what Mr. Boies calls the worthy and the unworthy in our citizenship. I have briefly stated the causes of our affliction, but will still add another factor enumerated by the author just quoted: Our colored population numbering 7,470,040 souls (one-eighth or 1.35 per cent. of our total population) contribute one-third of the convict class. Freed from the burdens of slavery and ignorance, subjected to degradations, hemmed in by prejudice, they have been placed at a terrible disadvantage which, to a certain extent, will account for a large percentage of defectives found among them. We must not lose sight of the unrestricted immigration. Twenty per cent. of our population is composed of foreigners of the first and sec-

ond generation. They furnish more than half of the inmates of our reformatories, over one-third of our convicts and nearly three-fifths of all the paupers in our almshouses. Do not these facts verify what I have stated before? Do they not demonstrate that our educational facilities are faulty? Do they not verify beyond a shadow of a doubt that we have entered into a condition of repose and tranquillity akin to the twenty years' slumber of Rip Van Winkle? Do they not indicate that we have closed our eyes to the dangers of unrestricted immigration? Are we going to uphold this glorious Union; will we continue to welcome with open arms into "the land of the free and home of the brave" a horde of foreign, pauperized, benighted individuals? Or will we open our eyes to the calamities which threaten us? Will we endeavor to profit by the experiences of recent years? Will we heed in time the lessons these statistics teach, and enact and enforce wise laws which will result in the establishment of a better humanity, of a higher civilization?

Now, what is the State of Illinois doing to control the class of individuals we are discussing? The census of 1890 shows that we are taking care of, educating and controlling:

| | |
|-------------------------|--------|
| Insane | 6,638 |
| Idiots | 5,249 |
| Deaf and dumb | 2,564 |
| Blind | 2,834 |
| Paupers | 5,395 |
| Prisoners | 3,936 |
| Total | 26,616 |

I have not enumerated the epileptics, the inmates of reformatory and industrial schools, but the above numbers will suffice to show that we are burdened with a heavy load. Besides the abnormal numbers of our community we minister to the care of our worthy brethren, the old soldiers and their orphans. Their fair name must not be tarnished by classifying them at all, except for statistical purposes. To them we owe a debt of gratitude. We are their debtors a thousand times over. It is our bounden duty to mitigate the sufferings of our noble veterans, to lavish comforts upon them, to free them from cares and to surround them with the comforts and luxuries of life. These services we perform with a feeling of pleasure. The children of the dead heroes are our wards. How grateful is the State to bestow a loving and watchful care over their lives.

To provide for this large diversified class of beings intrusted to its care, the State has erected and conducts a great number of institutions. Five insane asylums with over five thousand inmates, patients, are found in various sections of our prairie State; one at Kankakee, one at Elgin, one at Jacksonville, another at Anna and the fifth for insane criminals at Chester. A home for feeble-minded children accomodating over five hundred children is located at Lincoln. The soldiers' orphans' home having, possibly, four hundred inmates was built at Normal in 1867, and the soldiers' and sailors' home at Quincy in 1885. Since 1892, a home for juvenile female offenders was organized, and it is temporarily located in Chicago. A similar institution for boys, the State reform school, has its home in Pontiac. Two more worthy institutions, the institution for the blind and that for the deaf and dumb are carrying on their noble work at Jacksonville. The evil-doers and offenders of our laws are confined in two peniten-

tiaries, the Southern and Joliet prisons. All these institutions are taken care of by the State; the almshouses, jails and numerous reformatories by the counties and private corporations. All these State charitable institutions, conducted by superintendents with an army of employes, and controlled by boards of trustees, are under the absolute supervision of a board of commissioners appointed by the Governor, and called the State Board of Charities. This board consists of five members, whose duties are to audit the accounts of these numerous charities four times a year; to sign orders on the treasury for all moneys expended by them, to exercise an ever watchful control on the welfare and treatment of the State's wards; to suggest innovations and improvements in the running of the institutions; to plan a wise policy for the solution of social problems which are constantly confronting us; to educate themselves through reading and attendance at conventions of national boards, in order to be enabled to give the State the best services it can demand from conscientious, honorable human beings. And how large an appropriation do you think the last Legislature assigned to this Board for expenses it incurs to perform its multitudinous duties? The magnificent sum of \$3,000! Just think of it! Three thousand dollars for the secretary's and clerk's salary, for office expenses and for the traveling expenses of its commissioners.

The State demands that these institutions be visited a certain number of times a year and appropriates a beggarly sum of \$3,000. The State Board of Health, which is to control and look after the health of the entire community; to keep out smallpox, cholera, scarlet fever; to perfect our water supply, and prevent typhoid fever, and perform a thousand and one duties is also richly compensated. Its appropriation is \$9,000, but it also has a contingent fund of \$10,000 to draw on, in case some terrible epidemic should attack us. The Board of Live Stock Commissioners receive \$15,000 per annum and a contingent fund of \$25,000. But you must remember it is far more important to raise a fine herd of sheep or cattle than a brood of children. It is far wiser to show fat, sleek oxen and cows at the State Fair than to save men and women from the ravages of cholera, smallpox and typhoid fever, to prevent crime, to restore lunatics to their normal condition. The Fish Commissioners receive \$10,000 a year, so that our ponds and rivers may be well filled with the finny tribe to induce boys to play "hookey" and break the Sabbath. I will not mention what the warehouse commission and the geological museum and other organizations receive. It will suffice to say that two bodies, the Board of Charities and the Board of Health, probably, if I do say it myself, the two most important boards in the State, get for this reason the smallest appropriation of all. Is it not strange that in this, the nineteenth century, the breeding of cattle and fish is regarded as of greater value than the education and reform of human beings and the preservation of good health? Does this not indicate the trend of human effort, especially marked in our country, the scramble after the almighty dollar? Every effort, all our energies are devoted to the accumulation of gold at the expense of vitality. Our legislators having more knowledge and inclination for strictly commercial pursuits are ready to sustain and richly endow such organizations, which stimulate and

improve trade, while movements which tend toward research and investigation, the objects of which are entirely beneficiary, and which enrich society at large, which make the life we live more beautiful and refreshing, are either ignored or provided for with such scanty means that work of real value can not be undertaken.

I do not wish to convey the idea that the State does not expend large sums of money for the care of its defective classes, but what I do mean to say, and that emphatically is, that after the institutions are built and manned, the State does not provide sufficient funds for the organization of a capable board of supervisors, whose duties it should be to introduce ways and means by which a large part of this wealth could be saved or expended for wiser purposes, who could introduce methods by which much of the misery now housed in our institutes could be prevented. I hear you say to yourselves, Can insanity be prevented? Can pauperism be avoided? Can you put a "for rent" sign on our prisons? Do you mean to say that children need not become deaf and dumb, and can you prevent blindness? To all these questions I answer, yes, to a large degree. But it would take too long to enter into a detailed description of this immense subject, the study of prevention. I will, however, as an example of preventive methods, indicate to you how a large percentage of blindness can be avoided. I will inform you how from 25 to 40 per cent. of the inmates of our blind asylums would at the present day be useful and contented individuals, would be in possession of an important sense, if the matter had been seriously considered by our law-makers years ago. In order to discuss this question intelligently, let us first discover to what percentage blindness exists in this country, and then what leads to this affliction. By turning to the last census, that of 1890, we learn that there were in that year, 50,411 blind in the United States—806 blind to every 1,000,000 of the population. In 1850 there were but 9,794—422 to every 1,000,000 of the population, which was then 23,194,896, and in 1890 62,622,250. So that although the total population in forty years has not increased threefold, the number of blind is more than five times greater. The State of Illinois in 1850 contained only 264 sightless beings, 310 to 1,000,000. In 1890 the number was swelled to 2,834—741 to 1,000,000 inhabitants. Our blind asylum at Jacksonville has cost the State up to 1892, \$1,156,690.25. A great deal of money you will say. I agree with you. It was well spent, however. For a number of years we have been taking excellent care of those who, literally speaking, grope their way in darkness. But would it not have been more humane to have saved for 25 per cent. of them their vision? How much better they could have paddled their own canoe and selected a path more suitable and genial. And one-quarter of the total sum, almost three hundred thousand dollars could have been expended for some other necessary object, and the 25 per cent. of blind would now be useful citizens, earning livelihoods tilling the soil and assisting in the work of the world. Before trying to prevent blindness we must know what produces it, otherwise our efforts will be unavailing.

It has taken us years and years to discover the cause of diphtheria, and it is only a few years ago that we succeeded, and only recently the papers were

proclaiming to the world the cure and possible prevention of this dreaded malady. You all have heard by this time of Professor Behring and his wonderful antitoxin.

For years and years, oculists have noted down those diseases which produce or are followed by destruction of vision. They have been tabulated under various headings. That inventory of misery has been most perfectly arranged by Professor Magnus. In an examination of 2,528 cases of double-sided blindness he found that 3.77 per cent. were born thus; 66.5 per cent. lost their eyes through primary diseases of these organs; 10.7 per cent. were caused by injuries, and 19 per cent. were due to diseases of the body as, for instance, affections of the brain which secondarily destroyed the sight. In looking over these accurate tables we will come to the conclusion that a certain amount of blindness will always exist. We probably will not be able to prevent children from being born blind. Possibly, if human beings could be subjected to the same routine of breeding we employ with cattle, a certain percentage even of these cases, congenital blind, would not occur. We can not prevent all accidents, although safeguards can be taken to reduce the percentage of loss of vision due to these causes. Thus working men engaged in factories and foundries have been advised to guard their eyes against flying bits of iron and steel, by wearing protective mica goggles. Neither can we as yet entirely insure the eyes against the ravages of small-pox, meningitis, etc. The best field, therefore, for the introduction of preventive measures is offered by that chapter dealing with so-called idiopathic diseases of the eyeball, that class of diseases which produce 66 per cent. of blindness. Let us give it closer attention and we will discover that there exist two ailments which are largely responsible for the malady we want to prevent. I refer to granulated lids and ophthalmia of new-born babes. Granulated lids can be prevented by exercising proper care and precautions against infection, and even when present can readily be cured without causing serious results, if such cases are properly handled.

I will, however, speak only of the second category of cases, ophthalmia of new-born children. Different authorities claim from 25 to 50 per cent. of blindness is due to this disease alone. Thus Reinhardt found 30.33 per cent. in a material of 2,165 individual inmates of twenty-two blind asylums. Claisse, of Paris, 46 per cent.; Katz, of Berlin, 41 per cent., and Magnus, of Breslau, 34 per cent. What is ophthalmia neonatorum, which means purulent eye affection of new-born children? It is an inflammation of the inner surface of the lids of babes, coming on two or three days after birth and is caused by infectious matter lodging in the eyes while the newcomer is being ushered into this world. Can this be prevented, and if so, how? Every physician has heard of the prophylactic measures of Hausmann and Credé. The first aims to render the tract through which the child passes absolutely clean (aseptic) by ordering antiseptic douches. The latter, Credé, makes the germs which have lodged between the lids of the child's eyes innocuous, destroys them, by dropping into the conjunctival sac a 2 per cent. solution of nitrate of silver. Statistics gleaned from the largest hospitals in the world have proved effectually that these methods will abort, check or rather positively prevent the disease in nearly all cases. Before Credé's

method was introduced in Leipsic the disease appeared in over 6 per cent. of all obstetrical cases; after its thorough introduction the percentage was reduced to a fraction of 1 per cent. Here is a simple remedy which, if carried out, will prevent at least 25 per cent. of blindness. Professor Fuchs in his work on "Prevention of Blindness" tabulates a list of thousands of cases of births, illustrating the prophylactic effects of various remedies, but he finds none so efficacious to prevent blennorrhœa neonatorum as Credé's method. Dr. Lucien Howe, of Buffalo, collected two groups of cases; in the one 8,798 cases, no precautions were employed; in the second group, 8,574 cases, a single drop of a 2 per cent. solution of nitrate of silver was instilled between the lids. In the former the cases of blennorrhœa reached 8.66 per cent.; in the latter it was reduced to 0.656 per cent.

I could, if necessary, multiply these statistics of the preventive powers of a 2 per cent. solution of nitrate of silver, but those I have already mentioned will answer to impress upon you its usefulness, and the necessity of its general introduction. Now that I have shown its great importance it may be well to dwell, if only for a moment, upon its method of application. Immediately after birth the infant's eyes are cleansed with a dry cloth and all secretions adherent to the face and eyebrows are carefully removed. The lids are then separated and a single drop of a 2 per cent. solution of nitrate of silver, that is ten grains to the ounce, is instilled into the eye. In order to obtain a single drop only, Credé advises the employment of a glass rod which is to be dipped into the silver solution and only one drop allowed to adhere to its end. If, however, these safeguards should fail in some cases, or perhaps have not been employed and the ophthalmia should make its appearance, it can be cured in fully 99 per cent. of all cases, if the proper remedies are immediately applied. This disease calls for prompt and immediate action; delay of a few hours is often dangerous and may result in ulceration of the front of the eye and subsequent loss of vision. The physician has at his command powerful and adequate remedies to guard against complications and insure a cure in the great majority of cases.

But what has all this to do with legislation for the prevention of blindness, you will say. If these methods are so efficient, as you assert, and are practiced by all conscientious physicians, why does the disease still occur? What need to introduce laws when physicians graduated from reputable schools of medicine have it in their power to eliminate from our records all traces of this malady? Your questions are timely and pertinent and they can be readily answered by in turn putting a question to you. Are all obstetrical cases conducted by physicians? No. Unfortunately, no. Of the 28,743 births recorded in Cook County last year more than half were reported by midwives. The last official register of midwives of this State contains a list of 1,152. Of these, 700 are located in the city of Chicago. They are not acquainted with the latest researches in medicine. How should they be? The majority of them are ignorant. Their services are ordinarily called for by the poor and benighted. Their very existence is a reminder of olden times when physicians were scarce and the population scattered. In those days it was necessary to have at hand individuals who at least could attend to emergencies, quasi physicians who, owing to a limited experience could perform certain duties better

at least than the laity. In Germany to this very day, the barber acts as dentist in many villages. But as the science of dentistry increases, people are not so willing to have their teeth jerked out by the barber, but prefer to consult educated physicians, dentists, who frequently fill and save teeth which the knight of the razor would have unfeelingly sacrificed. The same is true of the midwife. Her services are no longer essential as formerly. But it would be difficult to convince the community at large of her indispensability, and as long as we must have her with us, let us at least educate her or place such restrictions upon her that she can not do any harm. We practitioners, and especially we oculists, are acquainted with her ministrations to the poor afflicted infants. The usual popular remedies such as milk, camomile tea, and other worthless noxious remedies are applied to the suppurating lids of the inflamed eyes, and only after valuable time has been lost the physician is called in; usually he finds that the disease which has been sadly neglected has made such serious inroads on the eyes of the infants that all hope of restoring vision has vanished. Again, if their education were sufficiently advanced to enforce antiseptic measures before parturition the results might not be so sad.

This State does not exercise sufficient control over midwives. It should demand a stringent examination on the points just elucidated, before a certificate is issued. I have learned on inquiry at the office of the State Board of Health that such questions, having a bearing on the subject under discussion, have up to the present time never been asked. I requested that the matter be brought to the attention of the Commissioners of Health, and have the satisfaction of knowing that this defect, at least, will soon be remedied. But a stronger action than this should be taken; we should subject the midwife to the action of the law if she does not perform her duty. We must insist that inflammation of the child's eyes be treated by a competent physician, by a man versed in sciences, by an individual who by virtue of his education and studies is the only reliable one to perform such services. A carpenter is not an architect, a bookseller is not necessarily a writer of prose and poetry. A blacksmith is not a veterinary surgeon, a midwife is not an oculist. We often make the barber, blacksmith, and carpenter act as doctors when we put them in a jury box and let them decide the mental condition of a person said to be insane. Do not regard these words as an attack against the midwife personally. It is not her fault if the State does not give her the opportunity of perfecting herself in her business. I can hardly call it a profession. It is not her fault if she is not instructed properly and makes use of the opportunities afforded her to earn an honest penny. It is the system I attack, a system which permits ignorance and superficiality to strut unhindered throughout the land. This indifference to high requirements is met with in nearly all branches of industry and learning. The days of apprenticeship have unfortunately passed. Would that they would soon return and with them the feeling of security and of labor honestly performed. In not all cases is the loss of the child's eyes due to the attendant midwife; often ignorance and penury of the parents is the promoting cause. Frequently they will not listen to the nurse, but will insist upon the use of home remedies, or anxious to save the doctor's

fee defer calling him until the chances of curing the disease and saving the eyes have passed. Sometimes, although I am happy to say rarely, the physician himself is to blame in not calling to his assistance the aid of an expert. How can we save the innocent child from the dangers which threaten it at the very outset of its career? Or, as Dr. Howe in his address, read at the forty-fourth annual meeting of the AMERICAN MEDICAL ASSOCIATION, says: "What means can be adopted to bring these children as soon as possible to the notice of a competent physician? Education of the laity is useless; urging the nurses, professional or others, is equally insufficient. It remains only to place the responsibility at once where it belongs by imposing upon such persons a severe penalty. The surest and best means of accomplishing this is undoubtedly by legislation."

Again, he says: "A question might arise as to what advantage it is to oblige nurses and midwives to report a disease of which a certain class of so-called doctors are almost as ignorant as the nurses themselves. The answer to this is threefold:

"1. The nurse is made to appreciate her responsibility, not only in that case, but in others, and to know that the condition indicated by redness and discharge is not anything to be trifled with.

"2. The parents also become alarmed when they know the disease is sufficiently serious to be the subject of special legislation, so that in choosing a practitioner they select with more than ordinary care. Finally, as for the physician himself, if he accepts the case he feels that he must understand it thoroughly, and he will be apt to look it up with considerable care in text-books, and treat it intelligently. Above all, if he fails to do that, the parents have a responsible individual against whom they can with perfect justice enter a suit for malpractice, and if he has proved himself incompetent he not only suffers the penalty which a law has provided for him, but one such case would be an example to him and to other practitioners in the community in which it occurred."

The older European countries have long ago recognized the seriousness of ophthalmia of the new-born and have adopted measures which have borne bountiful fruit. Switzerland, as early as 1865, made it obligatory on the part of the nurse to call the parent's attention to the necessity of calling in a physician in case ophthalmia made its appearance. If the parents refuse, it is her duty to immediately inform the authorities. In that country, parents are forced to meet their obligations to their innocent children. When parents are so ignorant that they know not how to provide for their offspring, the State should be given authority to supply the brain material they lack. If the child becomes blind it is a burden to society, and society has the same right individuals have, to enforce the first law of nature, and that is self-protection. The working of this law in Switzerland is exemplified by the statement of Professor Horner, made some years ago, to the fact that not a single case of blindness due to ophthalmia of the newborn had applied for admission in the blind asylum of Zurich since 1865. In Havre, France, every case of birth must be immediately registered at the city hall and the parents are handed or sent a small pamphlet informing them of the dangers of the disease we are discussing, and containing a brief summary of the methods to be enforced for the pre-

vention and cure of this disease. Other communities of France take still greater pains to imbue the public with their humanitarian ideas. When applicants for matrimony receive a license they are at the same time presented with a pamphlet similar to the one just referred to. These references will indicate to you the importance European nations attach to this subject. Prussia, Bavaria, Saxony, Wurtemberg, Austria, France, and other countries have, years ago, recognized the value of prophylactic measures and have, through proper legislation, bettered the condition of mankind and saved the State millions upon millions of dollars. What have we done in America in this regard? We did not profit by the experience of older nations until 1890. Twenty-five years after the little republic of Switzerland enacted its law, the great State of New York passed through both houses of the Legislature an Act for the Prevention of Blindness, which reads as follows:

SECTION 1.—Should any midwife or nurse having charge of an infant in this State, notice that one or both eyes of such infant are inflamed or reddened at any time within two weeks after its birth, it shall be the duty of such midwife or nurse having charge of such infant, to report the fact in writing, within six hours, to the Health Officer or some legally qualified practitioner of medicine of the city, town or district, in which the parents of the infant reside.

SEC. 2.—Any failure to comply with the provisions of this act, shall be punishable by a fine not to exceed one hundred dollars, or imprisonment not to exceed six months or both.

SEC. 3.—This act shall take effect on the first of September, eighteen hundred and ninety.

Maine followed suit in 1891, and omitted in its law the word, *notice*, in Section 1, in order to defeat any evasion of the spirit of the law which the word, *notice*, might give rise to.

Last year, in 1893, the State of Rhode Island also came into the line of States who have an eye to the welfare of its citizens. Maryland only lately, a few months ago if I am correctly informed, adopted the measures we hope to enact at the next meeting of the Legislature. The attempt was made two years ago but failed. I have in my hands a copy of the bill presented in February, 1893. It reads as follows:

28th Assembly. SENATE—No. 140. February, 1893.

A BILL

For an Act for the Prevention of Blindness.

SECTION 1.—Be it enacted by the People of the State of Illinois represented in the General Assembly, Should any accoucheur, midwife or nurse having charge of an infant in this State notice that one or both eyes of such infant are inflamed or reddened at any time within two weeks after its birth, it shall be the duty of such accoucheur, midwife or nurse, so having charge of such infant to report the fact in writing within six hours to the Health Officer of the city, town, village, district or precinct or some legally qualified available practitioner of medicine.

SEC. 2.—Any failure to comply with the provisions of this act shall be punished by a fine not to exceed one hundred dollars, or imprisonment in the county jail not to exceed six months, or both.

SEC. 3.—It shall be the duty of the State's Attorney of the county in which the parents of such infant reside, to institute and conduct such prosecutions in the name of the people of the State of Illinois upon complaint made to him by any person interested.

The bill must not be ignored a second time. The great State of Illinois which has been the champion of so many worthy enterprises can not afford to disgrace itself in the eyes of the civilized world.

There is no political question at issue here; it should appeal to the democrat as well as to the republican; to the populist as well as to the prohibitionist. Possibly it will find especial favor with the lat-

ter, because it is a prohibitive measure. There is no money in it for the doctor, because no physician exists who is not willing at all times to answer the call of charity. And if the parents live in larger cities, their babe can always demand the service of the county physician or others engaged in hospitals and dispensaries. The midwife is not affected by the contemplated law, at least not in a monetary way. It is entirely and absolutely humanitarian in its effect. Nobody but the child and society are to derive profit through its passage.

Let me call your attention to an argument for its passage which will appeal to many. If one-third of the blindness in this country which is due to blennorrhoea neonatorum could have been prevented, we would now count among our normal wage-earners 17,000 more individuals. Suppose the daily earning of each amounted to \$2 per day or \$600 per year, for the entire number the sum total would be \$10,200,000. In other words the country loses \$10,200,000 yearly by the affliction of 17,000 citizens, and the country would also save one-third the amount now expended for their maintenance. I am not able to describe the happiness, the untold pleasures and joys these 17,000 would experience if their vision were restored.

You, as physicians, assembled here, must utilize your knowledge of a noble science by spreading useful information among the people at large. You know that "an ounce of prevention is worth more than a pound of cure." You know that the science of hygiene has made enormous progress during the last twenty years. You know that we are now able to resist the inroads of epidemics and many contagious diseases. By your teachings and your influence in the community you can do much to popularize this one branch of hygiene. You, citizens, by the power of the ballot can send to the assembly halls such representatives as will carry out the duties you impose upon them. You, legislators and senators, if you are broad-minded and abreast of the times, if you are willing to study and improve social conditions, will not fail at the next meeting of our legislative body to pass an Act for the Prevention of Blindness.

NEEDED SANITARY LEGISLATION.

Read before the Illinois State Board of Health Auxillary Association at Springfield, Ill., Nov. 13, 1894.

BY ARTHUR R REYNOLDS, M.D.
HEALTH COMMISSIONER OF CHICAGO.

In offering these remarks as to needed legislation in the interests of the public health, I follow some indications suggested as much by observation in my practice as by experience in my official position. In Chicago, where is concentrated more than one-third of the population of the State of Illinois, many of the defects and inadequacies of existing health laws are more apparent than in smaller communities; evils that are scarcely felt in the rural districts, and only slightly in smaller municipalities, strongly impress themselves upon us.

I shall, however, confine myself to a few subjects in regard to which it seems to me some general legislation, applicable to the whole State, is needed or would, at least, be advisable. Even if the necessity therefor seems the greater in such a center of population as Chicago and is hardly felt in many other localities, it does not follow that these latter would

not be greatly benefited by a reform in some particulars.

VITAL STATISTICS.

Among the more important of these subjects is the question of vital statistics. For many reasons the desirability of a correct registration of deaths and their causes and of births is obvious and, to some extent, has been recognized. Illinois has in its statutes certain provisions for the securing of reports of births and deaths; but in practice these are far from being satisfactorily obeyed.

In the city of Chicago and in other Illinois towns of considerable size, deaths are probably more fully reported than they are in the State generally, and the same may, presumably, be said as to the registration of births. The completeness of the latter, however, is not so easily guaranteed, and evasions of the law are undoubtedly more numerous than in the case of deaths. The causes of this defect are recognized in the legislation of some States where the registration is more accurate and elaborate than with us, and where it may be considered a measurable success; for example, in Connecticut—one of the few States of the Union whose statistics are quoted as of some value in this respect. There, no penalty is imposed upon the physician who fails to report a death, for the reason that no burial or disposal of a body can take place without the certificate of the attending physician or that of the official medical examiner. A penalty is, however, attached to the failure to report a birth within a certain specified time while, on the other hand, a small fee is paid by the town for every such report. The town clerk is the registrar, and this insures a fairly correct return in the rural districts, since the territory is usually small, the population not dense and the concealment of a birth hardly a possibility.

Under our system of deputizing this duty to the county clerks, without even a nominal compensation to the reporting physician or midwife, there is no possibility of so immediate an oversight, and the chances for defects in the records are multiplied. There is no doubt that births go unreported to a very large extent in all parts of the State, and this is also true as to deaths, except in the cities and towns which enforce the burial permit ordinance of the State Board of Health or its equivalent.

The advantages and needs of accurate birth registration are daily demonstrated in the experience of the Health Department of the city of Chicago; questions are constantly arising which can not always be answered for the lack of it. This is not a matter of merely scientific interest; it is a practical one, and I think it should be impressed upon our legislators that what we ask in this direction is not solely in the interests of State medicine or of sanitary administration. As a matter of fact, while these interests are of importance to us, the full and authentic record of births is of greater and growing importance to the public.

There is hardly a relation in life, from the cradle to the grave, in which such a record may not prove to be of the greatest value. For example, in the matter of descent; in the relations of guardians and wards; in the disabilities of minors; in the administration of estates; the settlement of insurance and pensions; the requirements of foreign countries in matters of residence, marriage and legacies; in marriage in our own country; in voting and in jury and

militia service; in the right to admission and practice in the professions and to many public offices; in the enforcement of laws relating to education and to child labor, as well as to various matters in the criminal code—the irresponsibility of children under 10 for crime or misdemeanor, the determination of the “age of consent,” etc. As the country becomes more densely settled and the struggle for existence sharper, many of these matters, which have hitherto been of minor significance, will take on a deeper meaning and acquire greater importance.

To illustrate some of these points I may cite an instance or two under my own observation as Commissioner of Health. A German woman, who had recently lost her husband, applied at the office for a certificate of the birth of one of her children; her brother in Breslau, also recently deceased, had left her youngest child, named after the uncle, a remembrance in his will. A certificate of the child's birth was necessary. Records of births are not kept in the Health Department, but in the office of the county clerk to which the woman was directed. Fortunately, the birth had been recorded and a certificate of the record, duly attested by the German consul, was prepared, forwarded to Breslau and in due time the poor woman received the amount of the legacy, \$360—no doubt a godsend to her. In another case a Frenchman applied for similar evidence of a birth several years previously—exact date not known; the first search proved fruitless, and the man then endeavored to find the midwife who had attended, but she had removed to Kankakee soon after the birth and had been dead two years. Another application and search unearthed a volume of records antedating the present Registrar's term and the record was found. Other cases have come to my knowledge in which the record of birth had been neglected and other evidence had to be procured; protracted delay was caused and some of these cases are not yet settled, because of inability to comply with the legal requirements as to proof of birth. The United States pension office is especially strict as to this proof in the case of a pensioner's children—payments to whom cease at 16 years of age, which makes the date of birth important.

It is true that in this country the “best attainable evidence” is accepted in the absence of the official record. But in foreign countries they are much more exacting than we are as to the “best attainable evidence,” and to obtain such evidence, outside the official records, entails delay, labor and expense.

The best evidence, the most accessible and the most uniformly accepted, is that furnished by the registry of birth in the records of the officer legally authorized to make and keep such records. Dr. Neely, the Registrar of Vital Statistics for Cook County, tells me he furnishes an average of about one thousand certificates a year based upon his records, and these certificates are final and conclusive as to the facts. But a very large number of applications for these certificates can not be supplied because the birth was not recorded and other evidence must be hunted up.

Efforts to secure the registration of births in this State have thus far met with very little success. Thus, in the Report on the Vital Statistics of Illinois for 1886—which I believe is the latest on the subject published by the State Board of Health—the birth-rate for the whole State figures out, according to the

tables, only 17 per 1,000 and it was only 25 per 1,000 for Cook County and 31 for Chicago.

I may be allowed to dwell a little in detail upon Cook County since I am more familiar with it than with any other county of the State, and also because its vital statistics strikingly illustrate the defective birth registration outside the larger cities.

In 1886 the population of Cook County—assuming it to have been the mean of the figures of the Federal census of 1880 and of that of 1890—was 899,700, and the births registered in the county clerk's office numbered 22,779—a birthrate of 25 for every 1,000 of the population. (For convenience I use generally the nearest full figures, omitting the decimals; the exact figures of the birthrate just cited would be 25.31, but 25 is near enough for practical purposes; if it were 26.60 we should call it 26). The birthrate for the whole county, Chicago included, was as I have just said, 25 for every 1,000. But 703,817 of the total population resided within the Chicago city limits, and of the total 22,779 all but 940, or 21,839, belonged to Chicago—making the birthrate of the city for 1886, 31 for every 1,000, while that of the rest of the county was less than half of 1 for every 1,000.

Although this birthrate for the city was undoubtedly too low it apparently fell off still more in the census year 1890. For that year the population of the county was 1,191,922 (United States census) and the number of births registered was 24,217, giving a birth rate of a fraction less than 13 per 1,000. The population of the city was 1,008,576 and the registered births 23,219—a rate of 23 per 1,000 as against 31 per 1,000 in 1886. In the rest of the county, with a population of 183,346, the number of births registered was 998—a gain of nearly 30 per cent. over 1886, as compared with the population, but still giving the absurd birthrate of less than 1 in 1,000.

It should be explained that the apparent loss of population in the rest of the county outside of Chicago—195,900 in 1886, and only 183,346 four years later, is due to the fact that considerable territory was annexed to Chicago during the period. The population was not lost; it was only transferred to Chicago. This transfer unquestionably had much to do with the apparent reduction of the Chicago birthrate, since it is not likely that the mere change of boundary lines effected any change in the customs of the doctors and midwives or of the people; if they failed to report births before, they would be apt to continue to do so after annexation, at least for a time. As the area thus annexed embraced nearly 140 square miles with a population in 1890 of more than 250,000 of those who, in 1886, returned births at a rate of less than one half of 1 per 1,000, this fact is quite sufficient to account for the apparent falling off in the Chicago rate in 1890.

Dr. Neely tells me that in his opinion about 40 per cent. of the births in the whole county—Chicago included—are not reported. On this estimate of deficiency the birthrate would be about 34 per 1,000 for the county in 1890. But this is assuredly too low. Dr. John S. Billings fixes the true birthrate of the whole country at 36 per 1,000, and there is no reason to believe that the mothers of the great State of Illinois fall below the general average of mothers in other States.

Dr. Neely is probably more nearly correct when he estimates the deficiency in the county outside of Chicago at 75 per cent. which would make the Chi-

Chicago deficiency that much proportionately less. If we deduct this excess of deficiency from the Chicago returns, it would enable us to fix the true birthrate of the city at 38.7 per 1,000. When we take into consideration the fact that the average birthrate of a number of representative foreign cities, including those of Great Britain, Germany, Russia and other continental countries, is a little more than 39 per 1,000; that the birthrate of Moscow is 41.5, of Berlin 42.6, of Alexandria in Egypt 45, and of Montreal 47.6 per 1,000; and that Dr. Tracy, Registrar of Vital Statistics for New York City, basing his estimate on the marriage ratio, fixes the birthrate of that city at nearly 38 per 1,000, it will be seen that Dr. Neely's long experience and observation have enabled him to approximate very closely to the standard of deficiency in the returns.

The composite of the foreign cities referred to may be taken as fairly representative of the cosmopolitan character of the population of Chicago, and there is no obvious reason why the Chicago birthrate should not be at least as high as their average, when we take into account the virile character of its population, the large proportion of the nubile age period and the conditions of living—comfort, food, habitations, clothing, etc.

Let me return for a moment to the contrast between the birth returns of a large city and those of the rural districts as illustrated in Chicago and Cook County. The rates per thousand have already shown this in the mass, but Dr. Neely tells me there are localities in the county, outside of the city, in which, according to his records, there can be no children living under 8 years of age, unless they have been brought in after birth; even in the town of Evanston, with 12,000 population, there has been no baby born to his official knowledge within the past three years—if we exclude the volunteer statement of a woman who recently visited the Registrar's office to secure the record of the births of her four children in that seat of learning and abode of the virtues.

What is true of Cook County is true, also, of the other counties of the State—differing only in degree. Thus, referring again to the 1886 tables of the State Board of Health, we find that Jersey, Pulaski, Putnam, Stark and Wayne Counties reported 60 births or less in each county, which would indicate about 4 births to every 1,000 of population. In Wayne County, according to this report, they have only two babies and a little piece of one every year among every thousand people living in that otherwise fertile and prolific region.

On the other hand, in some counties, such as Adams, Kane, LaSalle, McLean, Madison, Peoria, St. Clair, Sangamon and Will, which contain large towns and are pretty well settled, a much better proportion is reported. This group had, in the year of the report, 1886, an aggregate of 546,000 population and returned 7,629 births, giving a rate of 14 per 1,000. In St. Clair County the rate was 19; in McLean, 18; in LaSalle, 16; in Kane, 16; in Adams, 14; and in Peoria 13 per 1,000. Only in Madison, where the rate was 11, in Sangamon with a rate of 10, and in Will with a rate of only 7 per 1,000, did the returns from this group fall below those of Cook, in 1890, when it was less than 13.

If we were to take these figures as representing the actual facts we should have to look forward to the speedy extinction of our rural population, the

stock to which we look to make up for the degenerative influences of urban life and tendencies. The natural and inevitable interpretation of these figures is that applied to the boy's historic conundrum,—“they haven't the truth in them.”

What is the use of depending for accurate statistics of births on a penalty applied only to the physician for non-reporting them, when in some sections half, and in all regions an appreciable proportion of them, never come under his professional observation? The only way to make the penalty effective would be to apply it to the parents and to the householders where the birth occurs, and to make it still more effective in the rural districts the first and direct registration should be one of the duties of the town clerk or supervisor, he to report to the county clerk, or directly to the State Board of Health, thus securing a narrowed responsibility and a more practicable supervision as well as facilitating the detection and location of errors. Some such provisions as these have often been advocated by the State Board of Health but have not yet become laws.

In the registration of deaths the results are much more satisfactory. In one of the recent reports of the State Board of Health it is estimated that 80 per cent. of all physicians in the State now report deaths and their causes, which would imply that at least 80 per cent. of the total deaths in the State are recorded. In towns and cities where the burial permit ordinance is in force, substantially all deaths are accounted for, and the only suggestions of amendment in the registration of deaths and their causes which I have to offer are: 1, the enactment of a law extending the provisions of this ordinance to all cemeteries and burial places throughout the State; 2, that such law should require that the certificate of the cause of death, on which the permit is based, should be examined by a medical man competent to judge of the sufficiency of the cause specified; and, lastly, the adoption of a uniform classification and nomenclature of the causes of death.

With these amendments the medical profession, health officers and the public at large would, in a short time, be able to determine whether a given deathrate in a community was excessive or not, and what disease or diseases caused such excess. With this knowledge the health officer could intelligently investigate the causes and if found to be due to insanitary conditions it would be more easy to enlist the interest and coöperation of the public to secure their correction. It is not enough to preach sanitation in the abstract—to talk about the importance of good drainage, pure water, ventilation and the rest of it. To get the public to understand these matters we must be able to give them object lessons, to furnish facts and figures in the same way we would do in any other business in which we desired their attention and interest. When we can put our fingers on an excess of deaths from consumption, or typhoid fever, or diphtheria, or among infants and children in a given locality, as compared with other places, and show that the excess is caused by defective drainage, or polluted water, or imperfect or improper disposal of filth, or a bad milk supply, we will have gone far toward securing a correction of the defects and evils, and thus reducing the deathrate—which means protecting both the health and the pockets of the people.

To do this, we must have as nearly perfect a regis-

tration of deaths and their causes as possible—a system covering the whole State and a classification and nomenclature uniform in every locality.

CONTAGIOUS DISEASES.

I confess that I am somewhat at a loss what to say, or rather what to recommend—there is so much that could be said—on the subject of the notification of contagious diseases. It is of the first importance that the health officer should be promptly informed of the occurrence of any disease that is liable to spread by contagion, or whose extension may be prevented by sanitary measures. Without such information, cases of contagious disease may exist uncontrolled until they have sown the seeds of an epidemic; when, if the earliest cases were brought to the attention of the health officer, the outbreak might be limited to them or to those already exposed. Where such notification is made, there is overwhelming evidence of the efficiency of recognized measures of restriction and suppression, in averting epidemics and in confining cases of contagious disease to those first attacked or to the premises first infected. That the suppression of such information vastly increases the difficulties of the health officer is well known to all of us, but most seriously to those who are called on to administer the sanitary affairs of large communities, where it is a physical impossibility to have personal and direct cognizance of every one who is sick and the character of the sickness. And yet the health officer—whose first information of the existence of a contagious disease is, only too frequently, the receipt of a certificate of death from such disease—is held responsible by the press and the public for every epidemic outbreak.

I do not mean to say that this is not to some extent justifiable. I suppose that is what the health officer is for—to prevent epidemics and to reduce the volume of preventable sickness and the number of premature deaths. But we should not be asked to make bricks without straw, nor to perform the impossible—for that is what it amounts to when we are expected to prevent an epidemic, while the baser elements of the community conspire to suppress the knowledge of cases until these have multiplied so much that their concealment is no longer possible, and then the outbreak is beyond speedy control.

There is nothing, as I understand, in the statutes requiring physicians to give notice of cases of contagious disease in their practice. It is true that, under the authority conferred on the State Board of Health in the second section of the Act of 1877,—"to make such rules and regulations . . . as they may from time to time deem necessary for the preservation or improvement of public health"—the Board has promulgated its School Vaccination Orders and its Rules and Regulations for the Prevention and Suppression of the Epidemic and Malignant Diseases, which rules and regulations require physicians to give such notice and which, we are told by the Board, "have the weight and authority of law." That is to say, they have the weight and authority of the law on which they are based but no more; and as here is no penalty provided in that law for its neglect or violation, the notification of cases and enforcement of the rules and regulations depend on the sense of duty and the personal influence of the health officer—his tact, energy, courage and ability to persuade the people of his community to help him

to protect them from contagion and infection, or at least to allow him to do so.

In some cities and towns there are ordinances requiring attending physicians to report to the health authorities all cases of these diseases occurring in their practice, and penalties are provided for neglect to report. But neither are such ordinances effective in securing the necessary notification. In my report for 1893 I have touched upon this subject in the following passage:

"Section 2029, of the Municipal Code of Chicago, directs that 'every physician shall report to the Commissioner of Health, in writing, every person having a contagious or infectious disease that he has prescribed for or attended for the first time since having such disease, during any part of the preceding twenty-four hours.' The object of this requirement is, obviously, to secure prompt notification of the existence of contagious or infectious diseases, to the end that the Department may take the necessary action to prevent any spread of contagion or infection, and to remedy any conditions upon which such diseases may depend.

"But it is a requirement directly in the interest of the public, and not at all, or only remotely, in the interest of the physician, who is called upon to fill out a blank with date, disease, location of case by number, street and ward, name of patient, age, nativity, color, sex, date of attack, length of time in the city, his own name and address, and a statement as to whether the patient attends a school or kindergarten. He is not only required to do this without compensation for the time spent in ascertaining facts of personal and social history, etc., that have no bearing on his treatment of the case—with which alone he is concerned—but he frequently incurs the hostility of the family and friends, who object to the publicity which follows the report, and thereby suffers in his practice.

"That there should be some opposition to the requirement is only natural, and it can not be said to be unreasonable; the Commissioner has, therefore, modified the previous practice of the Department, which has been to prosecute physicians failing to comply. But in order to secure without friction the information so necessary to the usefulness of the Department and to the public welfare, the following appeal to the profession was made:

CITY OF CHICAGO, DEPARTMENT OF HEALTH.

May 16, 1893.

Dear Doctor:—As Commissioner of Health, I realize that the only persons in the community who give intelligent and systematic attention to the prevention of disease are the medical practitioners. Physicians devote from one-eighth to one-third of their time, their strength and their talent to charity, in caring for those who are unable to pay, and I sympathize with them when a law requires from them a service without remuneration, in reporting to the Health Department all contagious diseases occurring in their practice. Being unable to offer any remedy at present, I must appeal to the self-sacrificial spirit of the profession to be faithful in this particular, and to aid in the important work of isolating all such cases, and as far as possible, destroying the germs of infection.

In contagious diseases where warning cards are posted, the Department will lend every aid possible as to their prompt removal, when the physician in attendance guarantees that all danger of contagion is passed.

In addition to reporting the usual contagious diseases, I

desire you to report cases of typhoid fever, so that our inspectors can investigate the sanitary surroundings. Cards will not be posted in typhoid fever.

If I can receive the needed aid from the medical profession, this Department of the city government will be enabled to give to the profession and the public important facts concerning the large mortality from diseases that are, in a great measure, preventable.

ARTHUR R. REYNOLDS, M.D.,
Commissioner of Health.

Before occupying my present position I was engaged in active practice, and I know from experience both sides of this question and appreciate its difficulties. It is argued that the physician—in the interest of the public welfare—should perform this labor without compensation and incur the risks of the odium which attaches to the informer in any shape, because “he holds a license to practice medicine from the State, which, in a measure, protects him from unlawful competition.” The lawyer holds a similar license and is similarly protected from unlawful competition. But what would be said of the proposition to enact a law or ordinance requiring that every lawyer—in the interest of the public welfare—shall report to the Superintendent of Police, in writing, every criminal that he has advised in his professional capacity within twenty-four hours after having given such advice, under penalty of a fine of \$10 for each and every failure to so report? The one proposition is as reasonable and defensible as the other. The ordinance should either be amended so that the physician might receive proper compensation for his time and labor in making these reports; or it should be repealed, so that the profession might be relieved of the constructive charge that many of its members are chronic violators and defiers of the law.

I see no good reason why the householder, in whose family or upon whose premises a case of the dangerous contagious diseases occurs, should not be required to make this report. The notification is in his interest and in that of his neighbors, and it seems only common justice that the responsibility should be placed where the benefit accrues.

This is a subject to which I hope the delegates to the Convention will give their serious consideration.

NEEDED LEGISLATION FOR COUNTY CHARITIES.

I shall touch briefly on only two other points that have occurred to me. And first concerning the legislation which seems necessary for a decent, humane and economical administration of our county charities.

From the various biennial reports of our State Board of Charities, and from some of the annuals of the State Board of Health, a record could be compiled of mismanagement, wasteful and fraudulent expenditure, of cruelties, abuses and scandals in the county treatment of paupers and those most pitiable of God's creatures—the indigent insane. I speak now more particularly of Cook County, whereof I know personally; but, according to these reports, similar conditions exist, only in lesser degree, in many other parts of the State. Cook County maintains a hospital for the insane, second in point of magnitude to but one of the State institutions for similar purposes and ranking, in that respect, with the larger asylums of the whole country. If these reports referred to be true, its history, from its inception, has been a series

of scandals covering every manner of corrupt jobs and jobberies in construction, repairs and maintenance and in the purchase of supplies of every description; these scandals embracing medical and surgical incompetence, brutality of nurses and attendants, and immoralities of employes. The cause is not far to seek. As has been repeatedly pointed out by investigating committees, by State officers, and by the medical profession, it is the system which is at fault. It is a system which has set at naught the best efforts of the few competent and self-sacrificing individuals who have, from time to time, been connected with the institution and who have sought in vain to correct its abuses and to carry out reforms. The county poor-house, the insane asylum and the county hospital are all under the immediate control of the board of county commissioners. If the commissioners were of the best material in the community—as they sometimes are—the term of office is too short (it is now but two years and recently was only one year) to enable a board, so frequently changed, to effect any reform or to establish the principles upon which the administration of the county institutions should be conducted.

The remedy for these abuses would seem to lie in legislation, vesting the supervision and control of such charities in a board of trustees, appointed by the courts, or by the Governor on the recommendation of the courts, or in any other manner which should secure a representative non-political body of citizens, recognized as interested and versed in charitable and penological administration—the functions of the county commissioners to be limited to the fiscal affairs of the institutions, the making of appropriations, the auditing of accounts, fixing of salaries, etc., in the same manner as they are now related to the coroner's and other county offices. It is needless to say that the composition of this board should be continuous and permanent, the term of appointment long, and the yearly changes limited in number, so as to profit by the accumulated experience of members.

While I have treated specifically of the needs of Cook County such legislation would be applicable to the whole State, and in this connection the Wisconsin system of county provision for the insane may be profitably considered. In that State, I understand that insane asylums of a certain capacity may be established by any county or by two or more counties acting jointly, and receive a certain proportion of their support from the State. They are under the supervision of a board of trustees appointed in part by the county board and in part by the Governor; there is a medical superintendent in charge, and the institution is subject to direct State oversight, either through the State Board of Charities or the Lunacy Commission. Under a similar provision in this State, such asylums might be established by the larger counties or those containing the larger centers of population to which the waifs and public charges naturally gravitate, and which now are, in fact, bearing the burdens shirked by smaller communities. They would not be so expensive to maintain as the present institutions, while in every other respect they would certainly be far more desirable.

It should be said that the strictures upon the management of the Cook County insane asylum and the poor farm do not apply in the same degree to the county hospital—thanks to the influence exerted by

the medical profession of the city and county through the medical and surgical staffs of that institution. There is, however, great room for improvement even in the hospital management; but I do not feel sure of the remedy other than through the creation of a permanent responsible board of trustees to supersede the control of its administration by a frequently changing political body.

THE CORONER SYSTEM.

As to my final point, it may be aptly noted that New York has now an opportunity of getting rid of her antiquated coroner system which, like our own, is a survival of the old English form when the coroner or "crownor" was, as the name implies, a royal officer, with many and incongruous functions. Efforts to abolish "crownor's quest law" in that State have been hitherto frustrated by its recognition in the constitution. The amendments to that instrument which were adopted at the recent election include one which strikes out all reference to the office and the officer, and there is little doubt that the forthcoming session of the General Assembly of that State will enact legislation divorcing the medical functions of the office from its other uses—political or what not.

The duties of the coroner as an inquisitor into the causes of death, where death is the result of violence or where there is reason to suspect that death is due to other than natural causes, demand the qualifications of an expert anatomist, pathologist and toxicologist; while his other functions require an expert knowledge of law—a combination which may be found in one and the same person about as often as one meets with a white blackbird. Judging from the Report of Coroners' Inquests for 1885, in the Eighth Annual of the State Board of Health, there was once such an ideal coroner in Illinois—Dr. Alexander Woods, of St. Clair County, and there may have been others; but none of them seems to have been able to secure any needed changes in the legislation concerning this office.

It is not necessary to dwell on the defects and abuses of the present system. The incumbent is frequently neither physician nor lawyer; too often only a cheap politician, readily approachable by employers and corporations—railroad, mining and other—seeking to evade responsibility for deaths due to their negligence. It is a fortunate chance and not a necessary result of the system when the office is as acceptably filled, both as to coroner and coroner's physician, as it is at present in Cook County and, I have no doubt, in other counties of the State. But even where the integrity of the elective coroner and his general intelligence are admitted, he is handicapped in many ways under the present system. The average coroner's jury is proverbially ignorant—a facile tool for any unscrupulous limb-o'-the-law; and its verdict has without doubt allowed many a criminal to go unwhipt of justice, or defrauded the widow and orphan of righteous compensation for the death of the bread-winner. Then, too, cases often occur where prolonged and costly criminal trials ending, not unfrequently in a miscarriage of justice, could have been avoided had the inquest been conducted and the autopsy performed with the necessary skill and intelligence.

To sum up in a single sentence: The present coroner system in this State does not adequately defend

the interests of the poorer classes in particular, against negligence, nor properly protect the public in general, as against crime.

I think this Convention should not adjourn until it has provided some means, either through a committee or otherwise, by which a suitable bill may be presented to the next Legislature, framed substantially on the lines of the Massachusetts Medical Examiner law of 1877 and its subsequent amendments. It is possible that some defects have been disclosed in the practical operation of the Massachusetts law and that there are improvements in the analogous legislation of Connecticut and New Jersey, as well as in the proposed New York bill. But Dr. Samuel W. Abbott, the able Secretary of the Massachusetts State Board of Health, writing in 1893, says the system "has now been in successful operation nearly sixteen years, and it is safe to say that no return to the coroner system will ever be made in Massachusetts. . . . It is a sufficient comment upon this law that more than eighteen thousand cases of sudden, suspicious and violent deaths have been investigated under its authority in a far more satisfactory, intelligent and economical manner than could have been possible under the old régime."

One fact alone should have great weight with our legislators, as it undoubtedly will with the tax-paying public, to-wit, that a careful comparison of the cost of the coroner system in Massachusetts during the three years prior to the Act of 1877, with the cost of the Medical Examiner system during the next three years showed a decided reduction in expenses, and recent statistics show a lessening cost of about 2 per cent. per annum for each case under the new system. The tax-payer at least will appreciate this.

And after all, it is, as I have previously intimated, the tax-payer and the general public who will settle the question of what and how much legislation we shall have. If we can show them that what we ask is really in their interest and for their benefit, and will base our arguments on sound business principles, put forth in plain English, I doubt not that their representatives in the General Assembly will be prompt to embody their wishes in practical, common-sense and efficient legislation for the further protection of the lives and health of the citizens of a State which is destined to be, in the near future, the foremost in the Union.

Is it too much to claim that the work of this Convention here assembled, and of the individual delegates, each in his own locality, may be no insignificant factors in the realization of that destiny?

THE DISEASE OF INEBRIETY.

ITS STUDY FROM THE STANDPOINT OF THE EXPERIENCE OF AMERICAN PHYSICIANS OF EMINENCE WHO HAVE WORKED IN THIS FIELD OF RESEARCH.

BY EDWARD C. MANN, M.D.
NEW YORK CITY.

Dr. Wm. C. Wey, of Elmira, N. Y., the President of the New York State Medical Society in 1871 thus expressed himself in a paper on "Inebriety by Inheritance:" "Latterly, as men of science have more closely interrogated the antecedents of inebriety, it has been found to bear such a striking resemblance to the characteristics of mental disease as to possess

a claim to be regarded as influenced and governed by the same general laws that bear upon the 'art and mystery' of insanity, to use a phrase employed by Dr. Blandford in his recent lecture on that subject. The transmitted tendency to inebriety has been observed by every intelligent physician of experience in the practice of his profession. As individuals are oftentimes unwilling to acknowledge the existence of insanity in the family line, so is the occurrence of inebriety equally concealed or positively denied. The impression is well-nigh universal, that inebriety is a voluntary surrender of the mind and body to the gratifying of sensual indulgence and that a determined effort to reform must of necessity lead to the abandonment of the habit of drinking. This is the belief as well as the language of the temperance lecturer, who holds up the pledge as the sign and seal of redemption from a self-imposed propensity. It is also the stereotyped teaching of the pulpit, which inveighs against inebriety as a crime akin to arson and perjury, which should not be excused or palliated or compromised, but punished by rigid enactments of law. It is the theory of another class that inebriety is simply "inefficiency of the intellectual force," to be charged to weakened will power, which resolution, strength and sincere desire of improvement may at any time elevate into healthy and well ordered exercise.

Higher authority than any mentioned, even the authority of the law, declares the commission of offenses while under the influence of liquor to be properly punishable, because the offender, though rendered temporarily insane by indulgence, voluntarily suffered himself to be brought to that state. In the eye of the law one view is taken of inebriety, and in the judgment of science another. We should consider that at one period the law, not as discriminating as now, assumed the entire custody of the insane, whose restraint and confinement, even in cages and with chains was considered necessary, not for improvement and restoration to mental health, but as a means of punishment and for the protection of society. Pathology, in the day alluded to, laid no claim to correct knowledge of mental maladies. They were grouped under a strong but virtually meaningless expression, "visitation of God." This phrase, while it is to be commended as acknowledging the dignity and attributes of the Creator and Judge of men, served for centuries as a means of begging the question of insanity, precisely as in our day the theory of self-imposed indulgence in alcoholic and other stimulants is stubbornly believed by the people.

The special treatment of the inebriate, through the accessories of hospitals and modern appliances, though no longer new and untried as an experiment, is far from being generally appreciated or understood. This statement applies to the profession in part and to the people at large. It applies to the profession because the study of inebriety as a disease and not as a moral lapse, has been superficially considered. In the all-absorbing duties in which we are engaged from day to day, it is difficult to bring the mind to consider a new and unfamiliar principle in medical science, especially if all our previous mental training, influenced by the traditions of the past, conspires to cast distrust and unbelief on the proposed system. A few in our profession share the impression to which I have referred, of antagonism to the doctrine of restoration of the inebriate through the

agencies of isolation and treatment. The question is asked, What do you treat? A habit independent of control; a disordered mind and a perverted will; or a diseased body, whose crowning honor, the brain, is the seat and center of pathologic change? The proper and successful treatment of inebriety includes all these conditions and much besides. The habit of indulgence in stimulants, as we view inebriety, is only the fruit or development of a series of morbid physical phenomena, in which the mind as well as the corporeal structure is implicated. I expect to be understood as referring to confirmed inebriety, whether leading to habitual intemperance or to occasional and prolonged drunkenness.

Inebriety being accepted as a physical disorder, many of whose forms and features are no longer equivocal but well settled and understood, it becomes us to look back on the train of morbid phenomena by which it has been fostered and developed, and endeavor to analyze its near and remote causes. Conspicuously in this connection comes the consideration of inherited tendency, etc.

Dr. Wey says, in speaking of statistical detail: "I would like to dwell upon the influence of nationality in conducing to inebriety, and show the effects of mixed and unmixed races in conspiring to its production. Our population is of such a composite character that this feature of the subject is in itself a vast study. A significant feature in this connection, which I am not prepared to explain, refers to the exemption of the Jews in this country, and perhaps in other countries, from the influences of inebriety. This is not an accidental circumstance; facts appertaining to vital science can never be reckoned accidental. It is doubtless in accordance with some fixed and immutable law, such as illustrates the entire history of that wonderful people. Information so minute, should be obtained in every case of inebriety admitted to public and private institutions for treatment, as it will show the nativity not only of the patient but of his ancestors, as far as that information can be procured. In this manner, after a time, such deductions may be made as will reveal an interesting chapter in the history yet to be compiled of inebriety in the United States. Information of this character may exercise an important influence in ultimate legislation affecting the welfare of the inebriate, when efforts are made to induce State aid in establishing asylums for their cure, and laws are modified or enacted to secure to them additional advantages and protection. Having faith in statistics, I would cause them to tend to the enlightenment of this whole subject with cumulative and effective power.

"I would interrogate facts and indications in one connection after another, so as to compel them to reveal all that can be told of the special bearings of mental, physical and moral agencies on inebriety. This involves a wide range of inquiry. It extends beyond the dogma of inherited tendency and embraces the entire field of physiologic, pathologic and psychologic investigation. The importance of such particular scrutiny is shown, if proof were necessary, in the declaration lately made from a reliable source: 'In America, considerably more than one-half of the adult population use either tea, coffee or tobacco. A majority of the remainder use alcohol in one or more of its various preparations. Most of the small remaining minority are included among the

not inconsiderable number of those who use opium habitually, and few of us can not count on our fingers all the persons we know to be total abstainers from each one of the stimuli we have named.¹

"The question of the successful treatment of inebriety hinges on the simple fact of *re-formation*—re-formation of the mind and will as well as of the corporeal man generally. It requires a nice and delicate, even a minute analysis of the nearly innumerable cases that incline to the production of inebriety, to be able to perfect a system for its radical treatment. It can not be successfully, that is scientifically treated, until it is thoroughly understood. Inebriety in its component parts needs to be so nicely fitted and adjusted, before it can be put together and perfected into a system of scientific proportions, that its sharp angles and obliquities must be toned down and subjected to the proof and trial of unflinching and convincing tests. Less than this, neither the profession nor intelligent people will indorse or accept. This minute and exhaustive investigation of the subject I heartily commend to the specialists before me, whose lives are devoted to its consideration. You will pardon me for speaking thus plainly. I have a desire which is shared by the best men in the profession to witness the history and management of inebriety placed on the footing of scientific truth and accuracy which illustrates the principles and treatment of insanity. This latter position is one of authoritative science.

"May we not trace a parallel between the early and specific treatment of insanity and inebriety, and show that equally favorable results may be expected in the latter infirmity, when subjected to prompt and intelligent oversight and care in a place provided for that purpose? It is waste of time and opportunity, as we have been forced so many times to confess, to treat inebriety as we would treat a self-limited disease, in the seclusion of the patient's home. To be successfully, that is radically reached and overcome, alcoholism or drunkenness must be brought under hospital restraint and supervision in the forming stages of the disease. The truth of this declaration may seem so apparent that it is trite and commonplace to allude to it. And yet, because it is not heeded and observed by inebriates and their friends, the former are held longer under the dominion of alcohol, and are in danger of reaching an irremediable stage of the affection, while the latter become disappointed and discouraged and are disposed to condemn a system which gives so little hope of relief, etc. Inherited inebriety particularly, and acquired inebriety in special instances, which goes on rapidly or slowly to death from ordinary physical disorganization or from self-imposition, does not necessarily, and I speak reverently on the subject, bring the victims within the limits of moral accountability, any more than the acts of those who are clearly and incontestably declared to be wholly insane."

Dr. Willard Parker, of New York, in an address in 1871 on "What Science and the Inebriate Asylums have taught us," spoke as follows: "In the last half of the nineteenth century, the attention of the medical profession has been directed to the inebriate; it has sought to determine his true status, to decide whether he is a moral delinquent or the subject of disease, or both, and if his case, like insanity, be curable. In order to answer the question, nine or ten institutions or asylums, public or private, have

been established in five of the States, and for the last thirteen years the case of the inebriate has been studied with scientific care. As it was with the insane, so now it is with the inebriate; the asylum is the school in which knowledge is to be acquired for the enlightenment of the medical profession, the information of the public mind, and for the guidance to a better system of legal enactments upon the subject, with these results: 1, the nature of alcohol has been examined, in order to determine its true character; and 2, its influences upon the animal economy have been studied.

"What, then, is alcohol? Is it food? Food is that which repairs some waste of the system. We can repair that only which exists. New in the human system there are water, fat, starch and sugar, nitrogenous substances, iron, sulphur, phosphorus, animal quinin, as claimed by Bence Jones, sodium, potassium, chlorin, etc.; but no alcohol is found. It has no analogue in the system, hence there is nothing which it can repair, and it can not therefore be ranked as food of any kind, but it is, out and out, a *foreign substance*.

"Is alcohol a poison? I reply, yes; it answers to the description of poison. It possesses an inherent deleterious property, which, when introduced into the system, destroys life, and it has its place with arsenic, prussic acid, opium, etc. Like these, it is to be employed as a medicine and has its true position in works on materia medica. It is, therefore, both a poison and a medicine. In this last capacity it has, like opium or arsenic, its definite characteristics and in some cases as a medicine it is indispensable. But has it no place at the table or in our bills of fare, either in distilled or fermented liquors? In certain cases these are useful, but it is when they are used by the feeble or aged, and then they should be taken as condiments and only *with* the food, and in such measure as not to be felt beyond the stomach. In small quantities, wines, etc., *stimulate*, and if not enough be taken to coagulate the pepsin and the albumen in the food, they in proper cases promote digestion and thus help to repair the system. But whenever more is taken into the stomach with the food than is demanded, it passes into the circulation, disturbs the action of the heart, flushes the face, and confuses the brain. When so much fermented or distilled liquor is taken into the system that the functions of the organism are disturbed, then positive harm has been produced; in one word the system has been so far *poisoned*. An irritation has been set up in place of the desired healthful stimulation of the stomach.

"There are appetites implanted in the system, and when wisely managed they help to keep the system in a healthful condition. They express themselves in hunger and thirst, while the cravings of the system for alcohol, opium, hasheesh, etc., are the result of disease in the organism, more or less marked, depending upon the gravity of the lesion of nerve and tissue. The condition of the inebriate is abnormal; he is in a state of unrest throughout the whole system, and the urgency for relief is so great that the will has not the power to resist. What is denominated appetite, therefore, is a state of suffering dependent upon disease, as in colic or pleurisy, and the craving and demand for relief are beyond the power of the will. These, then, are the effects of alcohol beyond the point where it is useful:

¹ The Nation.

"1. To induce a diseased condition of the nerves, which is manifested by the general symptoms of depraved appetite.

"2. Entering the circulation unchanged, it impairs the vitality of the blood. Careful examinations of the blood have been made, to determine what becomes of alcohol when taken into the system. When more is taken than can be employed as a condiment or tonic, it passes into the blood and circulates in all parts of the body, deranging the action of the heart and capillaries, confusing the brain and impairing the vital force. It has been settled also by science that alcohol undergoes no change in the blood, but that it exists there as a foreign substance, like a mote in the eye. And what is denominated stimulation is irritation; and the excitement caused by the effort to throw off the irritating substance wastes the energy and life of the system. After alcohol has produced disease of the stomach and the depraved appetite it next expends its force upon the neighboring organs, inducing disease of the liver and dropsy or Bright's disease, both of which are fatal to health if not to life. The brain, also, although farther from the stomach, is often diseased in function and at a later period, in structure.

"There are those who boast of the amount they can drink, if the spirit only be *pure*, without suffering from inebriation. Such persons do not understand that alcohol, however pure, is in itself a poison, and that they are in much greater danger than those who complain that when they drink it 'flies to the head.' This last class are more likely to be restrained from the indulgence, when the consequences may be so serious or disgraceful. Not only do special organs become involved through the effects of the poison, but the whole living organism is impaired and life is cut short. It has been demonstrated on all sides, at the forge, in the workshop, in the field, on the march, in the Arctic region and in the torrid zone, in physical and in intellectual labor, that the spirit drinker fails to cope with the temperate man. It has been ascertained that a young man at 20, who is strictly temperate, has before him as his average of life, forty-four years and two months. On the other hand, the young man who poisons his system by drink, can look for an average of life of only fifteen years and six months.

"Lastly, in referring to the action of alcohol, we must not omit to speak of the condition of the offspring of the inebriate. The inheritance is a bad one; a tendency to the disease of the parent is induced, as strong, if not stronger, than that of consumption, cancer or gout. And with this tendency he must wage perpetual war or he becomes a drunkard. The tendency referred to has its origin in the nervous system. The unfortunate children of the inebriate come into the world with a defective organization of the nerves, which ranges from the inherited tendency, through all grades to idiocy.

"Such are some of the effects of alcohol upon man. We have stated that the inebriate asylum is a school in which drunkenness is studied and treated. It is now proved to be a *disease* and to be curable. We have learned that there are different classes of patients, whose condition varies like their family history. There is one class composed of those who had healthy and temperate parents, and who have had the advantages of education. They first began drinking socially, and have indulged more and more fre-

quently, until disease, as manifested by the depraved appetite, is established in the system. This class, incurred guilt, or in other words, sinned in the beginning, by violating the laws of the system, just as the over-eater sins against his stomach and suffers from dyspepsia; or the over-worker sins against his brain and induces paralysis or insanity. A large proportion of this class can be cured at an asylum and the time required for that cure will depend upon the duration of the disease and the amount of organic lesion which exists.

"The second class is made up of those who are descended from a drinking stock. They have inherited a tendency or predisposition, have less guilt to answer for than the first class; are less curable, or if apparently cured, are in more danger of a relapse. With this class an irresistible craving occurs in paroxysms, and if they can be shielded for the time from the means of indulgence, they are safe until the occurrence of another paroxysm. There are nations or large communities with whom this fearful tendency to drink is an inheritance, as we have seen, to the perversion of their whole character.

"The third class is composed mostly of young persons who are depraved in all their instincts, and who do not desire either reformation or improvement. They are not subjects for the ordinary asylum, and in time wise legislation will cause provision to be made for them that the community may be protected against their irresponsibility and lawlessness. Asylums have taught us that inebriety is curable; that the depraved appetite is overcome, as the diseased condition on which it depends is removed, and in many cases the cure is radical and permanent. When this whole subject shall be better understood, it will be a wise provision that the children in our schools be taught the character of alcohol and kindred poisons, that they may learn the danger of indulgence and the wisdom of resisting the first temptation as their only sure protection. Thus in time would grow up a public sentiment which would banish from common use the worst of all scourges of the human race."

Dr. Joseph Parrish, President of the American Association for the Cure of Inebriates, in speaking of intemperance as a disease, said: "The testimony has been so profuse and authoritative on the subject during the past few years that I need not repeat it. I must be allowed, however, to refer to the recent action of the British Medical Association at its meeting in 1875 at Edinburgh, as the latest declaration of a public character that has come to my notice. The subject was introduced by Dr. Alex. Peddie, whose name and distinguished position are recognized here as elsewhere. He has drawn the line so distinctly that I prefer to quote his own language as transmitted to me by a friend who participated in the discussion. Dr. Peddie said, in speaking of that class of inebriates who are popularly recognized as "habitual drunkards."

"1. They were those who inherited the propensity for drink.

"2. Those who evinced it as the chief manifestation of some form of cerebral disease.

"3. Those who were affected with it as the result of injury to the head, severe fever or other wasting bodily ailment, mental shock, heavy grief or reverse of fortune, and, indeed, causes similar to those antecedent some other insanities.

"4. Those who acquired it through a course of vicious indulgences in stimulants.

"The distinguishing features of the malady,' continues Dr. Peddie, 'are total loss of self-respect and self-control, under an overwhelming craving for alcoholic drinks, with little or no palatal relish, which must be gratified at any cost, utterly regardless of honor or truth, and in fact unaffected by appeals to reason, self-interest, tears of affection or any suggestions of duty to God or man.'"

Dr. J. P. Boddington also read a paper on the same subject, and said: "That the medical opinion of Great Britain was in favor of legislation providing for the medical care of inebriates." Sir Robert Christison, who has occupied, as you know, the Chairs of Medical Jurisprudence and *Materia Medica* in the University of Edinburgh, as well as other distinguished positions, spoke at length and said, "that the professors of metaphysics, of moral philosophy, of political economy and of what he considered of more importance, the professor of Scotch law, and the Dean of the Faculty of Advocates, had joined with him and others in a representation to the Home Secretary in favor of Parliamentary action in behalf of this class of persons."

You will be gratified to learn, also, that Dr. Lyon Playfair, so widely and favorably known, participated in this discussion and said, that as a member of the House of Commons, he had gone into the "Committee on Habitual Drunkards" in an extremely doubtful state of mind, his feelings, indeed, being hostile to the proposition to legislate in favor of inebriate asylums, but on listening to the testimony before the Committee and referring especially to the evidence offered by the members of this Association, he "was led to a different conclusion, and signed the Report," which was presented to the Commons in this behalf. The result of this debate was the adoption by acclamation of a resolution, which reads thus:

"That excessive intemperance is, in many cases, a symptom of a special form of insanity which requires special treatment, with a view, first to the recovery of those affected, and second, to the protection and advantage of them, and of society. That in the present state of the law such treatment is not attainable, and that it is desirable that equal provision should be made to render it attainable."

Intemperance is evidently diminishing with the advance of the amenities of civilized life. Like other survivals of the ages of animalism it is gradually disappearing. There are several reasons for this. With the culture of the aesthetic tastes—the love of the refined and beautiful—comes the appreciation of these qualities in each other. Men affiliate and combine on the grounds of a common taste, and as the culture of art and refinement in general advances, vulgarity and excess are disallowed; the inferior passions being remanded to their proper places. Religious obligations and the conventional sentiment of refined society, all move side by side with the aesthetic qualities, and men grow into moderation and self-control by the civilizing forces which multiply as we advance. This is one reason. Another may be found in a wonderful physical fact, which has its basis in the law of heredity, and by which we are enabled to obtain more positive knowledge concerning the disease we are considering, and act with more intelligence toward preventing it. It is known that that form of drunkenness which is commonly called periodical, but more properly paroxysmal, is almost always the result of a peculiar inherited pre-

disposition. I might quote authority upon authority in confirmation of this now generally accepted doctrine; but the quotation already made from Dr. Peddie is typical of medical sentiment generally, and is sufficient. The point to which I wish to call your attention specially, is that this form of drunkenness has its period of termination, as well as of recurrence. It either discharges itself, or is deflected from its course into a different mode of manifestation. It has its climacteric period also, and I ask my brethren to note this period. In my experience it is somewhere between 40 and 50 years of age, and I believe more people recover from this form of inebriety at this period of life than any other. They recover by the discharge or exhaustion of the propensity to drink. If, however, there is simply a deflection of the impulse, they may degenerate into some form of chronic alcoholism, and in consequence, fail in the offices of progeniture, and thus save the future from the degree of blight that might otherwise be inflicted.

It may be asked, Why has not this law been operative in the past, and why are not its effects visible in the present generation? The answer is, that there can be no doubt we are realizing the effect of it, and that one of the effects is the peculiarity of this particular paroxysmal form of drunkenness. *Delirium tremens* and *mania-a-potu* were much more common a generation back than now. Indeed, they may almost be said, at this day, to be rare, in comparison with their former frequency. The tendency to them appears to have deviated into what is nowadays called dipsomania, and from this defection there seem to be divergences into the various forms of chronic alcoholism, which, after a while, may so far lose their course and be divested of their characteristics as to be undistinguishable, except in the general features of paralysis, apoplexy, dementia and so on.

I do not know that this feature of the subject has been observed by you, but I can not but believe there is force in it, and I commend it to you as at least worthy of thought and investigation. Let me re-state it: Dipsomania is a comparatively new form of disease, a deviation from *mania-a-potu*, taking a more chronic and obstinate form. It has increased and the former diminished. The tendency of dipsomania is to chronic alcoholism, as manifested in permanent lesions of brain and ganglionic structure, and resulting in incurable nervous disorders. The modification of nervous susceptibility in persons inheriting this tendency, predisposes them when under the influence of liquor, to more positive damage, although it may not appear in such acute and violent forms. If it be admitted that there has been a decided modification of the vice of drunkenness by the improving influence of intelligence, refinement and virtue—and that the criminal view of the subject is being better understood and distinguished from its other aspects, and we have to do with it more as a disease, is there not good reason to hope for better results in the future?

Sanitary boards, as they are constituted in our chief cities, tell us not a little about preventable diseases, and propose various means of prevention, and success seems to attend their efforts in proportion as the people appreciate and apply the recommendations of such boards. When inebriety shall be classified with other diseases, and boards of health and commissioners of hospitals and charities shall act upon this fact, in the same spirit and with the same

efficiency that they do with regard to other disorders, there will doubtless be a corresponding improvement in the habits and lives of the people. Did it ever occur to you that one of the strongest reasons why the people should turn their attention to the disease—aspect of intemperance—is found in the fact that temperance societies, churches, laws, family warnings and all the social and domestic influences that have been brought to bear on the inebriate have failed to accomplish the good that has been expected of them? Surely, if this was a question merely of repentance and reform, the multiplied and influential means of the family, the church, and the pledge—the watchings, the followings, the beseechings, the prayers, the warnings, all would have produced much more fruit than yet has been gathered from these sources.

Can there be such a force in a mere habit, such allurements in a single vice, as to be able to withstand all the earnest and persistent labor that has been organized against it? For it must be remembered that the efforts in this matter have been specific. The counteractions against intemperance have been direct, positive, continued and well-organized. The pulpit, the press, the platform, the school, the family, have each represented organized forces against this evil, and yet the testimony is that it has increased. What a libel this fact would be upon the heart-lore of domestic life, upon the verity and earnestness of Christian doctrine, upon the better instincts of humanity itself, but for the fact that these well-meant and honest efforts have not been directed in the proper line of approach to the evil. A poison that lurks in the blood has no antidote in appeals to the moral sense. A neurosis that inheres in the being can not be driven away by rhetoric. A proclivity that is enfibred with human structure, can not be untwined by argument. These are facts which may not have been admitted, because not thought of, but nevertheless, they are just the facts which have obstructed the progress of what men call the temperance reform. It is said that the well-known John B. Gough declared in a public lecture that out of 500,000 persons who up to that time had signed the total abstinence pledge in America, 300,000 had violated it, and that Dr. Chambers on hearing it exclaimed: "Truly, what an outburst of nature!" While Mr. Gough on this occasion exhibited his candor, it is certain that his distinguished listener gave evidence of his deep knowledge of mankind.

In an address on "The Classification and Treatment of Inebriates," Dr. Parrish said: "I think none of us, who have given careful thought to the specialty we represent, can have failed to observe three classes of inebriates, each of which is capable of an extended and common sub-division, as follows: 1, professional debauchees, whose purposes in life seem to be limited to the gratification of appetites or passions; and who, yielding to such gratification, have not only become confirmed inebriates, but have fallen into other excesses of a more vicious character; 2, those, who without a decided intention to do wrong, and without any abiding purpose to do right, are the victims of their own moral weakness, or of the cupidity or recklessness of others; 3, those who are earnest in their desire to live soberly and righteously, and anxious to avail themselves of every means offered by others for their recovery; who are

capable of estimating their danger and possess the courage to confront and antagonize it."

(To be continued.)

TURKISH BATH IN AMERICA.

An Anniversary Address on Baths, Delivered at the Sanitarium
Oct. 6, 1894.

BY CHARLES H. SHEPARD, M.D.
SUPERINTENDENT SANITARIUM, BROOKLYN, N. Y.

It is with no small measure of gratification that I greet you upon this, the thirtieth anniversary of the opening of the Turkish bath in this country. The old song had it that, "We are living in a grand and awful time!" These words were never more true than they are now. Between 1861, the beginning of our civil war, and 1893, the epoch of the Columbian Exposition, what a revelation the years have brought! The wonderful development of every department of knowledge, of all the resources of the country, have given a continual impetus to every element of progress, and all the refinements of civilization. Pre-eminent among these stands the Turkish bath. It is ennobled by a history which reaches back of records into tradition. During all that time the perfection of the bath was in exact proportion to the civilization of the country in which it was used. Throughout antiquity, moral purity was signified by purification of the body; even baptism is symbolic of the bath. Cleanliness was made a virtue among the pagans, but because great license of manners prevailed at the public baths, many historical Christians condemned cleanliness of person, and taught that the longer one went without washing the fitter one was for the kingdom of heaven. St. Athanasius relates with enthusiasm how St. Anthony, the patriarch of monachism, had never, in extreme old age, been guilty of washing his feet.

In primitive ages, superstition readily centered about thermal springs, as if they were the manifestations of some supernatural power, and through the teachings of their priest physicians, they came to be considered sacred, as though presided over by some particular divinity, and later came temples, erected beside or inclosing the springs. The prevailing habit of thought was to attribute all bodily infirmities to the malign influence of some divinity, so for relief, the people sought the interposition of supernatural power; hence thermal springs were dedicated to some god, principally to Hercules, as the god of strength. The Romans also consecrated their thermal springs to some deity, and their priest physicians introduced a ritual to be observed in making use of the waters. Homer relates that the hot bath was used among the Greeks more than three thousand years ago, and it was in all essentials similar to that now popularly known as the Turkish bath. The baths were common throughout Rome and her colonies, for wherever Rome bore her civilization the bath accompanied her. In time a lavish luxury prevailed in the erection and embellishment of the Roman baths, which increased with the growing wealth of the city. To immortalize themselves the emperors built baths which were the grandest constructions that architectural genius ever created. The Augustan age was an epoch conspicuous for the development of sanitary measures for the promotion of public health; and officers of high dignity were appointed

for the management of the baths. The area embraced by one of these immense establishments was equal to the space included in twenty-five ordinary city blocks, or about one mile in circumference. The largest was constructed by Diocletian, and capable of accommodating 18,000 bathers at one time. The Pantheon, now serving as a church of modern Rome, was originally built as a vestibule to the baths of Agrippa.

Ample opportunities have been afforded for acquiring a thorough knowledge of Roman customs in this respect, notably through the excavations at Pompeii, between the years 1824 and 1825, wherein complete sets of public baths in a good state of preservation, were laid open. In the historical novel, "The Last Days of Pompeii," Glaucus is made to exclaim: "Well! Let us to the baths! Blest be he who invented baths!" "But tell me, Glaucus, are the baths at Rome really so magnificent?" Glaucus turned and recognized Diomed and, suppressing a smile, replied: "Imagine all Pompeii converted into baths, and then you will form some notion of the size of the Imperial Thermae of Rome, but a notion of the size only. Imagine every entertainment for mind and body, enumerate all the gymnastic games that our fathers have invented, repeat all the books that Italy and Greece have produced, suppose places for these games, admirers for all these works; add to these baths of the vastest size, the most complicated construction; intersperse the whole with gardens, theaters, porticos and schools; suppose in one word, a city of the gods, composed of but palaces and public edifices, and you may form some faint idea of the glories of the great Thermae of Imperial Rome."

In the reign of Tiberius there were nearly nine hundred public and private baths in Rome alone, while the villas and the homes of the rich were provided with costly bathing apartments. Previous to his time the diseases of civilization were scarcely known among this people, but after the conquests of the Romans extended beyond Greece and over Asia and Africa, sources of unbounded wealth and luxury were opened to them, and the refinements and corruptions of a higher civilization changed the aspects of Roman life. In the seventh century Alexandria rivaled Rome in the splendor of its public edifices as well as in the number of its magnificent baths, of which there were 4,000 when the city was taken by the Moslems. The Turk having a keen relish for all that could minister to tasteful enjoyment, adopted the baths, and it is reported that when the great library was burned the books supplied the baths with fuel for six months.

Sources of the decline of the baths are traced to the establishment of Christianity at Rome, because the baths were looked upon as heathen temples, and the thermal springs being dedicated to heathen deities they were abandoned by the Christians and the use of the waters held to be sinful. The removal of the seat of empire from Rome to Constantinople, which followed the conversion of Constantine, deprived the baths of the imperial patronage necessary to sustain them; and the irruptions of the Northern nations are partly responsible for the destruction of many of the baths. Throughout Western Europe the very knowledge of them was obliterated for some fourteen hundred years, though the baths survived in other lands. At Constantinople the Greeks preserved them, and the Turks, after acquiring that

city, soon learned to appreciate them as an invaluable sanitary institution, whence comes the present name, Turkish bath.

Through the energy and perseverance of David Urquhart the Turkish bath was introduced to modern civilization. While a member of the British embassy at Constantinople he became enamored with Turkish life and customs. Already the author of several books, he then wrote one entitled, "The Pillars of Hercules," in which was embodied a chapter dilating upon the virtues of the Turkish bath, and relating the advantages that would accrue to his own countrymen by the adoption of the bath as a habit. Some years afterward he came in contact with Dr. Richard Barter, who was conducting a water cure in the south of Ireland. Mr. Urquhart gave Dr. Barter his book, the perusal of which convinced the Doctor that it was the one thing needed to make his institution complete, and soon these men constructed the first Turkish bath of modern times at St. Anne's hill, within a mile of Blarney Castle. After that Dr. Barter established several baths in different parts of Ireland, and Mr. Urquhart promoted the erection of a bath in Jermyn Street, London, which is to-day a monument to his ability and foresight. Charles Bartholomew was also an early friend of the bath, and, by Mr. Urquhart's encouragement was instrumental in establishing a number of baths in England. To-day the Turkish bath is an established and popular institution throughout great Britain.

Erasmus Wilson highly indorsed the bath in a book published more than twenty-five years ago. Sir John Fife, Senior Surgeon to the Newcastle Infirmary, introduced the bath to that institution, and edited the *Turkish Bath Manual*, an authority on the bath. Sir Benjamin W. Richardson testified to the importance of the bath, and the broad field that was open to the practitioner in the treatment of disease, particularly of rheumatism. Sir Edwin Chadwick, the greatest sanitarian that England has produced, personally gave me his hearty indorsement of the bath in 1865.

About the year 1860, Christopher Oscanyon, a representative Turk, attempted to introduce the bath in New York City and obtained the support of a number of prominent New Yorkers, but for some reason the enterprise was never developed. Soon after a small hot air bathroom was opened in Boston. It was called a Turkish bath, but never outgrew its original limits and had but a short existence. It was reserved for the home city of Brooklyn to make manifest the possibilities and luxuries of the genuine Turkish bath.

My attention was directed to the bath through the kindness of Samuel R. Wells who, in 1861 was traveling through Great Britain. He forwarded to me a number of pamphlets upon the subject, among them the chapter upon the bath from the "Pillars of Hercules." These immediately aroused my enthusiasm for a Turkish bath. I had long held in favor the hygienic method of treating disease, and this way of accomplishing the result seemed the very perfection of all treatment. With the practical knowledge of the virtues of the bath came a constantly increasing desire to be able to demonstrate to the world the power of the Turkish bath as a remedial agent, as well as the immense benefits to be derived from its adoption as a habit of the people, fully recognizing the fact that its most desirable and useful depart-

ment of service would be that of preventive medicine. In May 1863, I began on a small scale, and under many discouragements from my friends, the construction of the first Turkish bath. Not having any model from which to work, the process was necessarily slow, and much time was consumed in experiments, not alone with the bath itself, but also upon myself, friends and patients, in testing its practical workings. It was not until October 6 of that year that it was opened to the public. On that day but one bather came and he had left his home, without letting his wife know where he had gone. It was not till four days after that four bathers came. One of those I had waylaid in the street and brought in by dint of persuasion. To the credit of the bath, however, it may be said that he and his whole family were frequent bathers thereafter. After an interval of six days two bathers appeared, both ladies. Two days after came one gentleman, and so on, for about a month before there was a uniformity of daily baths.

The first month we gave about 50 baths, the second 100, the third 150, the fourth nearly 200, thus gaining ground by slow degrees. The first year we gave over 2,000 baths, the second year about 4,000, the third year nearly 6,000. About the middle of the fourth year our facilities were increased and we gave over 10,000 baths, the fifth year over 15,000. At present, in spite of the many large baths that have been constructed in Brooklyn, New York and many other cities, we are giving over 20,000 baths yearly.

One naturally would suppose that the medical profession would be among the first to welcome such a powerful aid as the Turkish bath, but such has not been the fact. This profession, as a body, has never given it much encouragement. Individuals alone excepted, they have waited for the people to demonstrate its value and to commend its use. Years ago an English physician said: "The public in this matter, is far ahead of the medical profession." As none but those who had traveled abroad knew anything about the bath, or had even taken one, it was sometimes very difficult to induce a person to enter its precincts. One professor in a medical college said he would not go inside the hot room for \$50. Another on entering said he hoped he would not be incapacitated from calling on his patients the next day. Such was the nervous dread of the process by those who knew nothing of it. In fact it has been more difficult to convince the physicians than the layman of the value of the bath. With a few highly honorable exceptions, and in spite of a multitude of witnesses, those who control medical teaching and practice go on in the same old fashion, and are likely so to continue until an enlightened public opinion shall command the new and better way. To the people at large we are indebted for the success of the bath. While physicians believe too little, among the laymen there is sometimes the most unbounded faith in its power, as was shown by a man coming all the way from Chicago expecting to be cured of a severe attack of rheumatism by one bath.

The universal use of the bath during thousands of years in every part of the civilized world furnishes a stronger proof of its value than would any mere reasoning. If we would have our people powerful and progressive as a nation, we must necessarily look first to their physical welfare. We should at least in this nineteenth century be as wise as were the Romans. It is an encouraging fact that preven-

tive medicine is constantly growing in the estimation of the medical world. The prevention of disease is a thousandfold more desirable than its cure. It will need but a generation to blot out many diseases and, through sanitary science, put a new and cleaner face upon mother earth herself. The dawn of the era of cleanliness has set in. Unfortunate is the person who can not enjoy a Turkish bath, for it evidences an abnormal condition of the system. With most such cases the shortest road to restoration would be through a wise and persistent use of the bath. Daily I see persons borne down by unnecessary suffering who, by a timely use of the bath and a slight deviation in their habits, would not only be saved this suffering, but they would place themselves upon a higher plane of health. Every man, woman and child would be the better for a Turkish bath once a week during his or her entire life. The young would develop more perfectly, growing straight, strong and handsome, the middle-aged would have less sickness and suffering, and increase in years imperceptibly, while the aged would grow old gracefully, because saved many of the discomforts of advanced years. There is no more important factor in personal hygiene. With complete external cleanliness come purity and perfect circulation of the blood, and the best conditions of health follow as a natural sequence. Thus prolonged life and a larger degree of comfort during life are secured. This desirable habit should be concomitant with obedience to physiologic laws. Indulgence in stimulants and narcotics, or any form of what is called high living, can never be made compatible with a clean life. A few generations living in the better way would bring about a higher standard of health and a new order of life. Twenty-six years ago to-day, upon a similar occasion in this room, I made a short address and closed with this wish: "May Brooklyn, one of the pleasantest cities in which to live, soon have the most magnificent Turkish bath in the world." By no means shall any exertions on my part be relaxed until this is an accomplished fact.

A CASE OF PRIMARY (?) LARYNGEAL DIPHTHERIA, TREATED WITH BEHRING'S ANTITOXIN.

BY EDWIN J. KUH, M.D.

CHICAGO.

Freda H., a robust girl, aged 7 years, complained of hoarseness on November 6, and remained indoors without symptoms of fever until November 11. On that day she took to her bed, and Dr. F. W. Mercer saw her for the first time. On the same afternoon I saw her in consultation with Dr. Mercer. During the day the temperature had ranged at slightly over 102 degrees. The fauces were entirely free, with the exception of a small, white, loose deposit on both tonsils, which was easily brushed away with cotton mounted on a probe. The child was hoarse and the larynx somewhat stenotic. No retraction of chest upon inspiration. Bronchitis in larger tubes. Examination of the larynx was very unsatisfactory, because of an unusually depressed epiglottis, and the child's intolerance of laryngoscopic examination.

The next morning, November 12, she coughed up a piece of membrane two inches in length, one-half an inch in width, and one millimeter in thickness. Laryngeal respiration was but slightly improved, and shortly after became very difficult. Temperature about as before, but pulse rate as high as 165. I saw her the same afternoon with Dr. Mercer, and injected ten cubic centimeters of Behring's antitoxin No. 2. A few hours afterward Dr. W. K. Jaques intubated. Cultures taken from the larynx showed the presence of Löffler's bacilli.

On the morning of November 13 the temperature reached 104½, the pulse rate was not lower, and the lungs were covered with fine crepitant râles.

This rapid inception of broncho-pneumonia led to a fatal issue at midnight of the same day. We could not observe that the injection of antitoxin had made any impression whatsoever on pulse or temperature of the child.

This unfortunate case must, however, not be considered as evidence against the efficacy of Behring's remedy, as the result was evidently clouded by the complication. The child did not die of diphtheria but of broncho-pneumonia.

1104 Columbus Memorial Building.

SOME OF THE CAUSES OF THERAPEUTIC UNCERTAINTY IN THE TREATMENT OF CHILDREN.

Read in the Section on Diseases of Children at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY A. C. COTTON, M.D.
CHICAGO.

The limited time for the presentation of this subject prevents more than passing mention of a few of the many causes that tend to increase the uncertainty of our results in the treatment of sick children.

One frequent cause of failure, faulty diagnosis, whether due to a lack of appreciation of the physiologic peculiarities incident to this stage of development, or to insufficient care in ascertaining the pathologic condition and history, we will dismiss with the mere mention; and, although in the practice of medicine, two negatives *may* make an affirmative, we will relegate the use of wrong remedial agents to the company of wrong diagnoses.

A most common cause of therapeutic uncertainty is our forgetfulness of the difference between the actions of remedies in infant and adult organisms; or rather, shall I say, because we have never learned those physiologic actions in children. As students of materia medica we have learned some few facts and theories concerning the physiologic action of certain remedies in such and such doses in adults. As practitioners of medicine we attempt to apply this knowledge, after subjecting it to a sort of mathematical shrinking and crimping process, to the relief of diseased conditions in children. Are we not guilty of studying backwards? The age \div (age + 12) = a suit of clothes made for the man, with the pants and sleeves turned up to fit the boy. "Rules for determining dose for age," "relative toleration of drugs by adults and children," are expressions that must cause the thoughtful practitioner to blush, unless he admits that he treats a woman not as a woman but as a she man. If we must have a standard of physiologic action of drugs and remedial agents and a standard posologic table, by all means let us adopt the infant; and in accordance with the mathematical idea use the sign of multiplication rather than that of division. However, the absurdity of applying our knowledge of the action of remedies in the adult organism to a physiologic entity so totally different as that of the child, is as apparent as the practice is common. Wrong habits of thought lead to wrong methods of practice. We administer larger doses of calomel, castor oil, etc., as evacuants or eliminants, for the reason that a largely over-worked glandular system is at fault, not because the patient is a child. We recognize an unstable nervous system as easily affected by neurotics and narcotics, and exhibit strychnia, and opium, with caution, but not

because it is a child. The mydriatics as respiratory sustainers may be indicated in full doses in enfeebled respiration, not because children tolerate well belladonna, hyoscyamus and stramonium.

Rapid changes in the histologic structure of the digestive tube cause extreme susceptibility to gastrointestinal irritants, too large doses of medicine producing shock, irritation or over-stimulation followed by depression. Hence small doses at short intervals are advised, or some other route to the interstitial circulation is sought, as, by medicated inunctions, etc. "Age and weight," forsooth! It is the *condition* that should determine our posology. No "royal road" is found or "therapeutics made easy" by such attempts at classification. Let us discard all such "rule of thumb" methods and dignify, not cheapen, our great art by careful painstaking application of our treatment to the especial requirements of each individual case.

Perhaps the most prevalent cause of uncertainty in our therapeutics is the almost universal ignorance or indifference as to *what the patient actually takes in the guise of medicine*. The physician may be never so careful in his diagnosis, unremitting and self-sacrificing in his attendance upon the little sufferer, elaborately scientific in his therapy as expressed in his written order for remedial agents, and then—what? Indolence, ignorance, or habit? What strange apathy, what paresis has chained the faculties and judgment of this erstwhile astute practitioner? Like the ambitious marksman with years of training and finished weapon, who, facing the target, its center the goal of his ambition, shoots into the empty air and trusts to—luck. Is it strange that he marvels at the uncertainty of therapeutics and perhaps joins the popular throng of those who descant loudly upon the inefficacy of drugs? "Throw physic to the dogs," aye, as you throw it to your little patients and the canine mortality will be greatly increased.

What avails care in diagnosis and skill in prescribing, if the prescription is left to the druggist whose shelves are filled with preparations, respectable in name to be sure, but in fact rendered inert or positively harmful from adulteration, decomposition, degeneration, contamination or which, by chemic changes and bacteriologic cultures, produce substances totally different from the active principle of the drug from which the preparation derives its name? With this in mind enter some pharmacy (?) and interrogate the shelves, and tell me if you do not find tincture of belladonna from leaves which vary 200 per cent. in atropin, tinctures of nux vomica of uncertain strength, lactucarium absolutely inert from want of care or knowledge in the gathering or preparing, lacto-peptin which is but a poor saccharated pepsin, wines of colchicum and ipecac inert from age because unstable, cascara adulterated with aloes, rhubarb with turmeric, santonin with boric acid, potassium bromid with sodium chlorid, aqua calcis showing film and precipitate, ergot inert, old spirits of nitre which has become something else, spirits of mindererus which absorbing ammonia from the air, has become alkalin and inert, oilum morrhue with cotton-seed oil, and old unstable emulsions of no one knows what? Do you not also find agents rendered dangerous because irritating or poisonous to the digestive tract? as, cream of tartar adulterated with gypsum, chalk or alum; ginger with cayenne pepper; bismuth sub-nitrate containing arsenic; sulphurous

acid, kept too long exposed to air, oxidized to sulphuric acid; dilute phosphoric acid developing fungi; Fowler's solution with fungi, oxidizing and precipitating arsenic; syrup of the iodid of iron brown with oxidation and the liberated iodine; the same irritating free iodine in old syrup of hydroiodic acid; and everywhere syrups; and again more syrups, medicinal syrups, the enshrined idol of the pharmacist, the *bete noire* of the therapist. Unstable, fermenting from sub-saturation, re-crystallizing and precipitating from super-saturation. Frequently incompatible with its medicinal agent as syrup of ipecac, and frequently rendered innocent of the medicinal agent by the fermentation process or the subsequent boiling to which the druggist resorts rather than throw the stuff away. But in whatever form, medicated or unmedicated, fermenting or sterilized, always unfit for the stomachs of our little patients.

A reconstructive as lacto-phosphate of calcium, defeats its purpose by interfering with digestion when given in the popular syrups; and the use of syrup of calcium as an antacid needs no comment.

Now you have come to the shelves of large bottles, half filled with the sheet-anchors of pediatric pharmacology. Are they not carminative, antispasmodic, anodyne, analgesic, astringent, calmative, antipyretic and stable because antizymotic? You look closely at those fragrant, pleasant aromatic waters. Old are they and filled with algæ and fungi, and rapidly becoming inert or even dangerous. Now with your microscope can you distinguish these bacteria, with which the aqua cinnamoni swarms, from Koch's comma bacilli? and do they not almost always induce choleraic diarrhea? and was not this same aqua cinnamoni a leading ingredient in the *mistura cretæ* with which you dosed your little patients for whom you wrote so many certificates of death from "cholera infantum?" Therapeutic uncertainties indeed!

This interrogation might be continued indefinitely; but for want of space I have mentioned only a few of the preparations most commonly employed in the treatment of children. Omitting the uncleanness of the clerk, the mortar, pestle, graduate, tile, spatula, bottle, stopper and vehicle; in fact, in the entire prescription nothing submitted to any sterilizing agency excepting, perhaps, the sealing wax which graces the outside of the cork. Likewise the absence of care at the bedside; the medicine glass, the spoon, the diluent, no thought of sterilization. The operative surgeon tells us that up to the last decade he killed a large percentage of his patients by introducing poisons into their systems, although his pharmacopœia contained but one principal agent, viz., cold steel. Those were the days, aye, centuries of surgical uncertainties. Now he boils his steel and, presto, an era of precision and certainty.

Let us go back to the drug-store. Ask the soda-water artist if he keeps in stock surgical supplies. What is the inventory? Sponges, catheters, bougies, bandages, lint, sutures, ligatures, drainage tubing, poultices, plush-lined cases of ebony-handled instruments, adhesive and court plasters and pots upon pots of ointments, salves, cerates and lotions. Yes, he keeps them all. Why? No surgeon will buy them. The surgeon who now introduces poisonous microbes with his trocar frankly calls it man-slaughter. The physician employing a teaspoon calls it "therapeutic uncertainties." To the tearful, despairing parent, "your child is in the hands of God," says the phy-

sician. "The patient is in *my* hands," says the surgeon. Shall we wonder if the surgeon is deified?

Wherein lies this difference? Scientific knowledge is common property, but the courage of the surgeon first rose to meet the demand for results. With one stroke he swept from the shelves of pharmacy all the rancid pots of unguents, cerates, salves and embrocations, substituting cosmolin. To the further demand for certainties he rose and took a mighty oath, before which that of Hippocrates pales into insignificance: "I will introduce into the system of my patient nothing but what I know to be innocuous." "Surgical cleanliness" became the watchword, and he made it his religion. If conventionalities and the wisdom of the ages stood in the way, so much the worse for the conventionalities. All the old and much admired stock of instruments, appliances and dressings had to go. Hospitals were torn down, operating rooms constructed, time-honored customs abandoned, nursing sisterhoods ignored, politics and sectarian bigotry defied, in the name of "surgical cleanliness." To secure this, the surgeon prepared his dressings, cleansed his patient, and sterilized his instruments with his own hands. "Let me have control of everything that touches this patient and I will assume all responsibility." The king himself may not approach the operating table. "Here, I am king." And what are the results? Surgical certainties.

Now what do we, as therapists, lack? The knowledge, the courage or the energy? We have the knowledge. "But," says a struggling practitioner, "we are not paid for this work." Nor was the surgeon until he did it; and the splendid results made rational the magnificent fee. Two operations a day are enough for any surgeon; the physician is never satisfied with fewer patients than a score. Many patients, smaller fee, poorer work. Is a life more valuable saved by surgical than by therapeutic skill? Is relief from pain less grateful when obtained through the physician's anodyne rather than the surgeon's knife?

The time is ripe for a long stride forward in pediatric therapeutics. The prevailing belief that the physician can do but little to control the course of disease in children must be positively and emphatically refuted by definite results. The physician must compel respect for his art, and compliance with his requirements, by painstaking, exhaustive diagnosis and elaborate care in the details of his management and treatment of every case. Parents must be shown the wicked folly of using the doctor and his "nasty medicine" as a bugbear with which to coerce refractory children in health, and taught that in sickness he must be allowed absolute control of the patient and every detail of the treatment. A trained and experienced nurse must be made an important factor in every possible instance. The plea of lack of time to attend to details must be regarded as an admission on the part of the physician that he has no right to undertake the case. The objection to expense must be considered an admission that the life is of little value to the parent. Absolute certainty as to what is administered, how and when, based upon an accurate diagnosis, is the only road to certainty in therapeutics, even if we have to prepare and carry our remedies to the bedside and administer with our own hands. Have we the energy to carry out our convictions? Have we the *courage*?

PERSISTENT VITALITY.

Read in the Section on Dental and Oral Surgery, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY F. O. JACOBS, M.D.
SAN FRANCISCO, CAL.

The interest that has lately been created in the operations of replantation, transplantation, etc., has raised the question among dentists as to whether a tissue will survive after having been removed from its natural position and again replaced, or after having been removed, can it again be transplanted to another individual without suffering death? And if so what time may elapse between the two operations? And if it should be determined that such operations were possible, what tissues are the most favorable to such operations? Or, in other words, and more briefly, is there such a thing as persistent vitality?

In surgical operations, just as in every other department of science, we are constantly meeting with surprises. What had been classed with the impossible yesterday is the practicable operation of to-day, and we are constantly being driven back to first principles to account for some unexpected results.

This subject involved the broad question, What are the conditions which produce death, and what conditions are required to support life? Can we lay down any law or rules that will hold good in all cases? At first we meet with so many seeming contradictions that we are discouraged in the attempt. We are prone to think that one form of life is something entirely different from another, and the rules that would apply to one will not apply to another. While we find, in general, that living organisms may exist only in an atmosphere or medium containing more or less free oxygen, some one comes along and tells you he knows of certain forms of life that can exist in an atmosphere of carbonic acid, drawing all its oxygen from its food. Another must have a medium of salt water; another must exist in fresh water; others still can not be immersed in water, but for a few moments without suffering death. Some organisms are able to withstand extreme changes of moisture or temperature. Some animal forms and also plants may be deprived entirely of their moisture; completely dried up, so that vital functions are entirely suspended until moisture is again restored. Some may be frozen in cakes of ice or raised to a temperature near the boiling point of water, without any other effect than to suspend functional activity for the time being.

Among the more highly specialized organisms the amputation of a member or organ generally produces death in the parts so treated, or in the entire organism, owing to which organ or part is separated from the body. But in the more simple forms amputation of a part only produces a new animal. A remarkable example of this is found in the fresh water hydra. This animal consists of a tube, one end of which is modified into a foot, the other is furnished with arms. The entire animal is of but one tissue. If an arm is amputated it immediately grows into a new hydra. The animal may be cut into several pieces, with the result of producing as many animals instead of death. One might think it was possessed of remarkable tenacity of life, but these animals are as easily killed as any. Turn the animal inside out, it immediately makes an effort to right itself. Should

it fail, it dies. Deprive it of moisture and it dies.

Why should the cutting of an animal in pieces only have the effect of multiplication and simply depriving it of moisture produce death? Exactly the reverse of some other plants or animals. The explanation is probably this: Its stricture is that of large delicate cells, very soft, which are easily broken up by desiccation, so that by depriving it of moisture its structure is destroyed; death is naturally the result. Cutting it in pieces only multiplies it, because it is composed of but one tissue throughout, capable of performing the same functions. Hence a piece, if separated from the remainder of the animal, is not dependent upon it to perform any of the functions necessary to support life. Reversing destroys its life because the cells on the inside of the tube are so modified as to perform the functions of assimilating food; while the outer cells are for the protection of the inner. When the animal is reversed neither of these sets of cells are in a position to perform their natural functions, therefore death is the result.

Now, there are other plants and animals of which the reverse is true, which if deprived of their moisture simply remain inactive until the proper quantity of moisture is restored, when they resume their normal functions. In their case the cell structure is a strong firm tissue, which is not broken up by desiccation. Depriving the living matter or protoplasm within of its moisture is not a chemical, but a physical change. Chemical action, oxidation, etc., goes on extremely slow, if at all, until the proper conditions are again restored for the performance of its natural functions. The living matter within the cells is a chemic compound, the exact chemic nature of which is not known, but its constituent elements are known. It is extremely unstable, being constantly acted upon by free oxygen; on the one hand it must be constantly taking up the proper material, on the other to preserve the equilibrium in its chemic nature. Its affinity for water is great and its activity depends upon the presence of water; the more water it is able to absorb the more active it becomes. In the absence of that element activity ceases until moisture is restored unless some chemic change takes place, when it is no longer protoplasm. As it does not form compounds with other substances without losing its identity, differing in the least from itself in chemic nature a living tissue is never attached to a dead one or to other substances. Hence, when a living tissue is found attached to another, supposed to be a dead one, it must be considered evidence that the tissue supposed to be dead is at least possessed of a low degree of vitality.

What has been said of protoplasm is true of it wherever found, for living matter is the same thing wherever found. The different modes of death cited above are due to the difference in the structure of the tissue it inhabits. Where the tissue is composed of firm hard cell walls it is much more able to endure desiccation. Where an organ is composed of a similar tissue throughout its entire body, separating it into pieces only multiplies it.

One of the present methods of skin grafting, scraping the epithelial cells from the surface of the skin on to the part to be engrafted, is a case where a tissue or cells of formed tissue is engrafted on to another tissue, forming a union and a new tissue; transplanting.

Now, if a tissue can be transplanted from one

place or location to another, some time must elapse between the two operations. It then becomes a question how long will a tissue endure between the two operations, and what tissues are most favorable to such operations? How long could the scrapings of epithelial cells be preserved before transplanting, or how much time might elapse between the operation of extracting and of transplanting a tooth? The evidence furnished by such operations is conclusive that it is much greater than any of us have supposed. Bone may be engrafted from one animal to another, even chips of bone may be placed in the wound and a new tissue formed around it.—("American Text-Book of Surgery.")

Why may not a tooth be successfully transplanted? Its structure is not changed by extracting, and decomposition is less likely to set in than in any other tissue of the body.

The above illustration may seem to be far-fetched, but not so. Much of what we have yet to learn in physiology must be drawn from the study of minute and simply formed organisms. The facts to which I have called your attention will show that death implies a chemic change, and without that there is no death.

It also shows that the tissues that are best suited to transplanting, replanting, etc., are hard, firm and simple structured tissues, like the skin, the teeth and bone. Those less suited for such operations are of delicate cell walls and soft loose structure that will easily collapse when removed from its normal position and by loss of moisture.

The success that has been met with in transplanting such tissues fully confirms the above conclusion.

DISCUSSION.

DR. YOUNGER—I am glad that so able a microscopist as Dr. Jacobs is able to substantiate opinions which I have held and advocated for years. Although they were at first denied they are now, I believe, being looked upon with more favor. Dr. Barrett has confessed that he is a convert; Professor Wyeth and Professor Leconte have expressed their belief in persistent vitality; and now we have Dr. Jacobs, who was formerly opposed to the idea, testifying to its truth. He has stated the doctrine better than I can. I told Professor Garetson that the operation of implantation was a success, and that he would have to acknowledge it some time or other.

DR. DUNBAR—Like many others, I am waiting for more definite proofs on the point, though I think Dr. Younger is entitled to credit for the manner in which he has stood up for this theory. I don't think I can add anything to the presentation of the subject which has been made.

DR. JACOBS—The subject has not been sufficiently discussed for me to say much in reply. What I intended to show was that living matter, no matter in what form it is found, acts the same under similar conditions. If a bone or a tooth persists longer than muscle, it is because of the difference in structure. I attempted to show by plants and other animal tissues that where they withstood desiccation it was because of their strong cell structure. The resurrection plant, as is probably known to all of you may be laid away for years, for an indefinite period, and then if supplied with moisture it begins to grow. This is not because of a difference in its protoplasm, but because of its structure. It has been simply dormant; there has been no change in its living matter. Because the living matter in the tooth is found in a little thread protected by strong walls, it has not much chance of destructive changes; consequently why should it not be restored when placed where it can be nourished?

DR. YOUNGER—One of the best proofs of persistent vitality is the return of sensibility to an implanted tooth, even after it has been a long while out of the mouth before being implanted.

DR. DUNBAR—Is your confidence in persistent vitality such that you would leave a desiccated pulp in place in a tooth you intended to implant?

DR. YOUNGER—I remove the pulp as a rule, because I am not sure there is not some dead tissue in it, but the fibrilla

of the pulp in the dentinal canaliculi are left, and that is where the vitality may be re-awakened. (Dr. Younger here related the first instance in which he observed the principle which he calls persistent vitality.)

DR. TALBOT—I have reported a case which appeared to proceed on the same plan which Dr. Younger has demonstrated. It has already gone the rounds of the journals without a satisfactory explanation having been offered. It seems to substantiate Dr. Younger's idea.

DR. W. L. CAVELL, San Francisco—Related the case of a patient, now a lad of 16 who about two years ago, while playing at school had the two superior centrals knocked out. The teeth were replanted on the following day by a dentist with the ordinary antiseptic precautions, but the apical foramina were not closed, being left in the natural condition. During my senior term at the college, the patient was given to me to be treated for a cleft palate, when a medium-sized cavity was found on the mesial surface, midway between cutting edge and cervix of the left central. In preparing the cavity I opened into the pulp-chamber which I supposed had been filled. A hemorrhage sufficient to fill the cavity and allow of a drop to fall upon the dam followed the opening into the chamber by the bur. After assuaging the hemorrhage I capped the tissue in the ordinary way and inserted a gold filling. The tissue in the pulp-chamber was found on examination to be highly vascular, sensitive to the touch, but thermal changes caused no inconvenience. The tooth was not sensitive to the bur or on application of ice. The edges of the cavity were zigzag.

DR. DUNBAR—I gave it as my opinion that in the case of all replanted teeth there is an effort on the part of nature to remove the replanted tissue. I believed that ultimately all these teeth would be exfoliated with absorbed roots; and I gave it as my opinion that in those cases which were accounted successful probably one-half or more of the root was absorbed and the place of the absorbed structure filled with hypertrophied tissues. But I do not think that any harm is done by the treatment. Dr. Talbot's case was a very remarkable one. I was interested in a paper by Dr. Henry Chase many years ago on dental circulation. It would be interesting to know just where the exchange of pabulum took place in this case. I have taken the view that a tooth is doubly nourished,—from the pulp and from the pericementum. All dentists who have had experience in replantation or transplantation know that the tooth changes color in forty-eight hours, which is due to the moisture which it absorbs, as there is no circulation of blood in the tooth. I recall the case of a butcher who broke a bicuspid, in which the tubuli were injected; they were clearly colored by the hematin of the blood. Although there is no circulation of blood in the tooth, there is a movement of the blood plasma from the foramen and the pericementum, and by osmosis there is an interchange between the two, and I have had a theory that this interchange took place in the interglobular layer. I have had no demonstration of this, but it is a plausible explanation. With reference to Dr. Talbot's case, I can not see how a dead tooth would be affected in the way described, though in a case of immediate extirpation of the pulp it could readily occur; but that is contradicted by the fact that in all the cases of implantation I have had, the pericementum is dissolved away, and on percussion there is an absence of the springiness characteristic of normal teeth. If the pericementum is gone, where does the tooth get its nourishment from?

DR. YOUNGER—The tooth referred to by Dr. Jacobs split, and when I got another suitable tooth to take its place I attempted to extract it whole, but an implanted tooth is very difficult of extraction, as any one who has tried it will testify, and this one pulled apart. Dr. Jacobs, upon examining it under the microscope, said that it had true pericemental tissue clinging to it.

DR. JACOBS—I expected to read my paper yesterday, and I then had sections from these specimens with me. I will bring them to-morrow. I agree with Dr. Dunbar that there is no true circulation of the blood in teeth, except as he said where the apex is not so thoroughly calcified, but the circulation there is exactly the same as in plants. It is always up, never down. Osmotic action proceeds from above and below. In the absorption of implanted teeth I hold that the process is occasioned by lack of nourishment. Such a tooth has no pulp, from which the principal part of the nourishment of a tooth comes, and when the pulp is gone not enough pabulum is received to keep the tooth in health.

DR. TALBOT read a request for the members of the Section to assemble with the other delegates to-morrow at 1 o'clock in front of the Mint to have a photograph taken.

SOCIETY PROCEEDINGS.

Mississippi Valley Medical Association.

Abstract of the Proceedings of the Twentieth Annual Meeting, held at Hot Springs, Ark., Nov. 20-23, 1894.

FIRST DAY—MORNING SESSION.

The Association convened in the large dining room of the Eastman Hotel, and was called to order at 11 o'clock by the Chairman of the Committee of Arrangements, Dr. Thomas E. Holland, of Hot Springs.

Prayer was offered by Rev. Joseph A. Dickson.

An Address of Welcome on behalf of the State was delivered by Governor Geo. W. Fishback. Hon. W. H. Martin, of Hot Springs, followed with an Address of Welcome on behalf of the citizens of Hot Springs. These addresses were excellent, well delivered and warmly applauded.

After the reading of the reports of the Secretary and Treasurer, the President, Dr. X. C. Scott, of Cleveland, Ohio, delivered his Address.

PRESIDENT SCOTT referred to Hot Springs as a desirable place for the meeting. All medical associations should be founded and carried on for the purpose of elevating the profession, and producing a beneficial influence upon its members, and also that they may meet face to face and thus learn to know each other personally and better. They should elevate personal character, afford protection to professional interests and advance personal attainments. He urged upon the Association the importance of issuing, if possible, an annual volume of Transactions, which he thought could be easily done with the annual dues at \$3. To be successful, the financial affairs of the Association must be conducted with the same careful and rigid supervision that pertains to any private business. The membership was not as large as it should be. He urged that each member go home from the meeting determined to bring with him next year one or more members. If this was done there would be no longer a complaint of paucity of members.

The holding of the annual meetings in different parts of the Mississippi Valley was to be commended, for by so doing we increase our membership and spread wide the good work done by the Association. He thought the idea of reading all papers before the general body would afford larger audiences, create more interesting and better discussions, and consequently result in a maximum good to a larger number of members.

Since the last meeting some of the States have passed excellent laws governing the practice of medicine, surgery, and midwifery, but he was sorry to announce that in other States where it had been attempted to pass similar laws they had failed from the want of enactment.

At the conclusion of the President's Address, a committee of five was appointed to consider the suggestions contained therein and to report at a subsequent session. On motion, the Association adjourned until 2 P.M.

FIRST DAY—AFTERNOON SESSION.

The first paper read at this session was by the Hon. W. S. KERR, of Mansfield, Ohio, entitled

SOME OBSERVATIONS ON THE RIGHTS AND DUTIES OF MEDICAL WITNESSES.

The paper dealt with the rights of physicians and surgeons when subpoenaed as expert witnesses, and with the duties incumbent upon them as members of a learned and honorable profession when they are called upon to testify as medical experts. The weight of expert medical evidence depends upon two qualities: 1, the skill, learning and experience of the witness; and, 2, his honesty. The latter quality can be and should be alike in all. The former, in the

nature of things, must vary and differ in degrees almost infinite in number. A physician whose practice has been confined to the small towns or the country could not be an Ericsson, nor one of three years' experience an Agnew. But all are admitted to testify to those things which they have studied and practiced, and the course of truth and justice demands that, according to their lights, they should testify the truth, the whole truth and nothing but the truth. The evidence of an expert should be compensated for commensurate with its value. In criminal cases the amount should be fixed by the court; in civil, by agreement between the expert and the party calling him. The medical expert should never have his opinions for sale. Fidelity to his profession and its great principles should be his pole star. Medicine is the greatest of the professions. It deals with life and health, the dearest possessions of this sphere. Its members have ornamented the most exalted stations, and in its daily work, without herald or drum beat, it modestly performs its great task in life.

The author then quoted the opinions of several distinguished judges and lawyers regarding the importance of medical expert testimony.

DR. EMORY LANPHEAR, of St. Louis, followed with a paper entitled,

BONE AND JOINT TUBERCULOSIS THE FUTURE FIELD OF LITIGATION AGAINST RAILWAYS.

He submitted the following conclusions:

1. Pott's disease, hip joint disease, white swelling, and most chronic joint affections are tuberculous, and that "scrofula" has no existence, being an attenuated tuberculosis.

2. The family history is unimportant, as tuberculosis is always acquired—never inherited. The presence of tuberculosis in the family simply gives a better opportunity for infection.

3. Infection may occur in very early life. The germs lie dormant for many years in the lymph glands, and local tuberculosis only develops after an accident.

4. An injury to a bone or joint must be slight in order to cause tuberculosis. If severe, the resultant inflammation or hypernutrition is not favorable to the proliferation of the bacilli.

5. An injury *alone* can never produce tuberculosis. The bacillus must always be present in the system, or introduced into a wound at the site of injury.

6. *Per contra*, bone or joint tuberculosis would never develop without a slight local injury.

7. If, after the railroad accident, falls, wrenches or other accidents may possibly have occurred, the local trouble may be due to them as well as the railway injury. There must be a direct sequence to attribute the disease to the local injury.

Dr. ROBERT H. BABCOCK, of Chicago, made some remarks on "Enlargement of the Heart without Valvular Disease, with Especial Reference to Treatment."

The author said that idiopathic enlargement of the heart, as Fraentzel designates it, affecting primarily the left ventricle, is due primarily to prolonged high arterial tension, and this increase of arterial tension may be secondary to 1, cirrhosis of the kidneys; 2, chronic arterio-sclerosis; 3, congenital narrowing of the arterial system; and 4, some obscure condition probably dependent upon defective assimilation and elimination, which is not fully understood, connected probably with the circulation in the blood of toxins. The author wished to be understood as speaking of idiopathic enlargement of the heart without valvular lesions. Prolonged high arterial tension he considered the chief factor concerned in the production of this form of enlargement of the heart. The enlargement may involve either the right side or the left side of the heart or both. A case was reported in which the enlargement was primarily of the left ventricle, and the enlargement which existed on the right side of the heart was probably secondary to the dilatation which had taken place of the left ventricle. Prolonged high arterial tension, when independent of organic disease of the kidneys or blood vessels, seems to be due to what the Germans call *luxus consumption*. It is observed in

individuals who belong to the better class, who are more or less sedentary in occupation, who are hearty feeders, and oftentimes great diners-out. The treatment was divided into, first, the treatment of the stage of loss of compensation in which the heart is at first broken down in its resistance. Rest is the important factor along with cardiac stimulants and the administration of remedies calculated to decrease the high arterial tension. The patients usually present themselves with dyspnea, cough, and frothy expectoration, and an extremely rapid and feeble pulse, with all the evidences of cardiac dilatation. The first indication, therefore, is to relieve the over-distended left ventricle and to whip the heart on to increased vigor or contraction. Hydragogue cathartics are therefore indicated from the first, since their action is to lessen arterial tension, and by preference the author uses one of the mercurials, since the effect of calomel or blue mass is to lessen arterial tension even before its effects are manifested on the intestines, and this is followed by a saline. Digitalis, strophanthus, and their congeners are not suitable to the cases in the stage of loss of compensation, since the effect of digitalis, and to a less degree strophanthus, is to increase the resistance within the arterial system, and thereby increase the strain, already too much for the impaired right ventricle. It is preferable to administer an arterial stimulant rather than one of the so-called cardiac tonics. Under the effect of rest and cardiac stimulants, improvement in the condition is generally manifested speedily.

The author then referred to the Schott method of treating these cases, which consists of baths and gymnastic exercises. He stated that the treatment had been used in Germany for more than ten years. A combined course of baths and gymnastics is given for an interval of from perhaps seven or eight weeks. He considers this method of treatment suitable to all forms of chronic cardiac disease, excepting those in which heightened arterial tension would be disastrous, as in widespread and extreme chronic arterio-sclerosis, aneurism of the aorta or other large vessels, or cardiac aneurism.

DR. W. T. BAIRD, of Dallas, Texas, read a paper entitled "Oxygen as a Heart Tonic and Some of the Benefits which may be Derived from its Use as Such."

DR. W. H. DALY, of Pittsburg, Pennsylvania, followed with a paper entitled

MALARIA A WATER-BORNE DISEASE.

The author said in summing up the evidence in a given case of so-called malaria, it is important to remember that the water vehicles of malaria may include contaminated land water, taken into the stomach on the stalks of celery or on the leaves of lettuce, or it may find its vehicle in the rinsing of milk cans with malaria water or in the adulteration of milk with contaminated water containing the Laveran germ; the cistern water stored under the earth may be easily contaminated by the earth water containing the germ, if the cistern itself is cracked or otherwise inefficient. The fact that the patient has drunk at all of suspected water, even but once, ought to be taken into consideration, as the single draught of contaminated water may have contained all the necessary germs for the infection of the blood and the production of the fever. The author defined his position on this question by quoting from an article, published in the *Medical Record*, of Sept. 15, 1894, wherein he says: "Twenty years' observations and studies on this subject and investigations made in various districts from Manitoba to Louisiana, and all along the southern coast of the Atlantic Ocean, and of Cuba, Yucatan and other districts in Mexico, lead the writer to the conclusion, that so-called malarial disease is not easily, if at all, contracted by inhaling so-called malaria or bad air of the low, swampy or new lands, but it is distinctly, if not *almost exclusively* due to drinking the water that has come in contact with and become infected by the malarial germs or infusoria that exist in the earth and waters of the swamp and low lands. This germ does not ordinarily, if at all, float in the air during the day or does it easily find a vehicle in the fog or vapors of the night."

The author then quoted at length the contributions of Laveran and others, to show that malaria is a water-borne disease.

THE INFLUENCE OF EARLY TREATMENT ON THE LATE MANIFESTATIONS OF SYPHILIS.

This paper was read by DR. A. RAVOGLI, of Cincinnati. The author said that syphilis must be seriously treated, and the opinion of letting it take its own course is a heresy condemned by experience. Mercury is the true antitoxin

for this disease. It is necessary in instituting treatment to take under consideration the general condition of the patient, his habits, his general health, his surroundings, etc., which have great influence in the toleration of the medicine. The author believes that early, well-directed treatment of syphilis will prevent tertiary symptoms. Mercury can be administered either by the stomach, by subcutaneous injections, by inunctions or by baths. The selection of the method should rest on the good judgment of the physician.

SECOND DAY—MORNING SESSION.

DR. A. P. BUCHMAN, of Fort Wayne, Ind., read a paper on
INTESTINAL INDIGESTION.

Intestinal putrefaction is in its incipient stages not due to a pathologic condition of the tube below the stomach and duodenum, but is dependent solely upon errors of gastric and pyloric digestive processes. Excess of food ingested will universally induce such putrefactive processes, which in infancy and childhood are exhibited in the bowel diseases of early life and can with reasonable certainty be differentiated from deflections by other causes, by the odor and appearance of the dejecta. This phase of intestinal indigestion is due to the primary action of certain bacteria on albumen and albumenoid substances which have slipped past the duodenal gateway without receiving the vito-chemical touch necessary to render them harmless, is intermittent and transient and of little consequence until by constant repetition it becomes a menace to the general organism. The toxic elements generated in this process sooner or later render glandular and cell environments of the intestinal tube altogether unhealthful. The air patients breathe, the water they drink, and the food they eat are charged with a miasm which absolutely forbids a healthy reaction, hence most complicated and decidedly serious pathologic conditions arise. The author said another chief source of intestinal indigestion arises from the inability of the tube below the pylorus to successfully cope with the relatively enormous quantities of carbo-hydrates and hydro-carbons that are daily and continually ingested.

In the second stage of intestinal indigestion the whole lining membrane of the intestine is thoroughly catarrhal, its epithelial investment is no longer capable of performing its allotted work with any sort of regularity and normality. The villi are practically paralyzed and entirely cease selective absorption. The whole glandular structure is undergoing degenerative and thickening processes; the ileo-cecal valve is paralyzed, the cecal end of the colon now fails in its peristaltic movements, the valvular opening to the appendix is permanently relaxed, admitting into the tube whatever may be in the vicinity of its mouth, hence the frequency of appendicitis. The colon becomes thickened throughout its entire structure; the colonic valves become lengthened and thickened. The further changes that take place in intestinal indigestion were pointed out by the essayist. In the third stage we have a large grouping of diseases which, when studied from this point of view arrange themselves in most orderly sequence around their cause. They mainly consist in such forms of pathologic action as result in speedy dissolution, as, for instance, hasty consumption of the lungs, the forms of Bright's disease that run a rapid and fatal course and consumption of the mesenteric glands. Many, if not all, of the rapidly fatal diseases of the nervous system belong to this grouping. In conclusion, the author said that any form of treatment instituted for the relief and cure of intestinal indigestion must necessarily include a careful consideration of the stomach and colon; that very little, if any, amelioration of symptoms will result unless they are both rationally included. Inasmuch as the colon is within easy reach via the rectum, it is the author's experience that colonic baths properly medicated are immensely useful in the general treatment and care of patients suffering with intestinal indigestion.

DR. J. E. WOODBRIDGE, of Youngstown, Ohio, read a paper entitled "Typhoid Fever can be Aborted; another Year's Work with no Death and no Failure in Evidence."

This paper was in the nature of a supplement to the author's previous contributions on this subject which have been published in medical journals, and with which a great many members of the profession are familiar. It will appear in an early issue of this journal.

DR. HENRY SUMMA, of St. Louis, read a paper entitled "Ox-Gall in the Treatment of Typhoid Fever." The author highly recommended its use in this disease, and has obtained excellent results with it.

(To be continued.)

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, DECEMBER 1, 1894.

THE SCIENTIFIC DEPARTMENTS OF OUR DRUG
MANUFACTORIES.

The times have changed in America when the pharmacist was simply the importer, perhaps part owner of the ship which brought his cargoes to our shore. He has now become not only a merchant, but a manufacturer; not only a manufacturer, but a scientific producer, and in the particular realm of science to which he devotes himself, he has few superiors in practical chemistry. We might, however, say the same of many other leading industries. Indeed, it is the tendency of the time that directness, simplicity and economy govern all manufacturing establishments. Even the beer breweries now employ expert chemists who test the various productions, estimate the value of the hops, and malt, govern temperatures, and give directions as to the length of time to be occupied by given processes. The chemic laboratories attached to the establishments of manufacturing pharmacists, have grown to be very extensive, very complete, and give employment to the highest order of attainment. It is natural, then, that men engaged in such pursuits should seek some outlet through which the world must become familiar with their studies, investigations and results. This has led to somewhat irregular or rather desultory methods of establishing quasi-medical journals or tracts of uncertain publication, and various papers which, excellent in themselves, have fallen short of the mark and failed to reach those for whom they were intended by their being handicapped with the suspicion of commercial interest.

The time has come, however, when the vast stock of chemic and pharmaceutical knowledge stored in these great laboratories must be made available to the American medical profession.

DR. SQUIBB, of Brooklyn, New York, well known as a manufacturing chemist of note, several years ago pointed out the way whereby the experiments made in his laboratory could become the property of the profession. SQUIBB's Ephemeris was the result, and it at once took a high rank in the profession, and we have not learned that the sale of the products of the laboratory of DR. SQUIBB has been in any way hampered or lessened by his giving in scientific form not only the means whereby these different products can be tested and their purity established, but the formulæ whereby they were best prepared. Therein lies a lesson for other manufacturers who have large establishments and even greater facilities for work of the highest value to the dispensing pharmacist and practicing physician. Let us have more scientific productions from the great laboratories of our manufacturing chemists. Let them publish their methods, the scientific experiments which they make, and when they have attained clear and definite results let them be boldly stated. Not only will they gain in the opinion of the medical profession, but it is more than probable that the value of a scientific name will be appreciated by the profession in such a manner as to make it pecuniarily profitable not only to issue ephemerides, but regular working bulletins and monographs. Some of the manufacturing establishments in Europe have been pursuing this course for some time, and we understand that from time to time some of our own manufacturers have published occasional monographs or "working bulletins," but the systematic output, if we might term it, of the scientific investigations conducted under the direction of our leading firms has not, we believe, been at any time regularly or completely carried out.

This result, we trust, will shortly be accomplished, and it is probable that with its accomplishment there will come the end of that series of products classed under the name of "secret preparations," which have in the past given rise to so many controversies, and such wide differences of opinion between the medical profession which should be working for the common unity of the profession. If it be urged that a large number of these manufacturers are engaged in general trade, and that therefore they do not become personally responsible for the character and chemic purity of every product shipped from their establishments, it may be answered that the division of their establishments into general and scientific departments, so that any products bearing the label of the scientific department would at once be *prima facie* evidence of its purity, and in this case the objection would fall to the ground. There would be no question in the mind of any of the members of our profession if at the head of each scientific department so created, a well-known scientific man were placed, in order that there would be a definite responsibility for any statement made by him.

THE DEGREE OF D. P. H.

The JOURNAL is gratified to learn that at least one medical college has already taken steps looking to the establishment of a course leading to the degree of Doctor of Public Health—as suggested editorially in these pages last month.¹ The institution is prosperous, well equipped and ranks in the higher class of the four-year medical schools in one of the important centers of medical education. The JOURNAL will give publicity to its announcement as soon as the details of the course in sanitary science and State medicine are perfected.

Meanwhile, in order to facilitate the establishment of similar courses by other institutions, the following summary of the requirements for this degree exacted by the General Medical Council of the United Kingdom is offered. These requirements are based, as stated in the previous article, on the provisions of the Local Government Act of 1888—to-wit, that no person shall be appointed medical officer of health in any district unless he is legally qualified to practice medicine, surgery and midwifery; nor in any district of over fifty thousand inhabitants unless he is also the holder of a diploma in sanitary science, public health or State medicine. It is with the latter of these provisions that the General Medical Council is empowered to deal. In December, 1893, it declared with reference to those who begin the study of sanitary science after January 1 of the present year, that it will not consider the prescribed diploma deserving of recognition in the Medical Register—without which it is valueless as a qualification for the appointment—unless it has been granted “under such conditions of education and examination as to insure (in the judgment of the Council) the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health.”

The conditions of such education and examination required by the Council are in substance, as follows: 1, no candidate for the degree of Doctor of Public Health shall be eligible for examination in sanitary science, public health or State medicine until he has spent at least one year in the study of these subjects *after* he has become a legally qualified practitioner of medicine, surgery and midwifery; 2, six months of this period must have been spent in study in some approved laboratory in which is given practical instruction in chemistry, bacteriology and the pathology of the animal diseases transmissible to man; 3, another period of six months, or its equivalent, must have been spent in the practical study of out-door sanitary work; 4, satisfactory evidence of compliance with these conditions—as well, also, as evidence that he has attended the clinical practice of a hospital for infectious diseases—must be presented to the

examiners, who shall be men specially qualified to conduct such examinations. The examinations extend over not less than four days, one of which is devoted to practical laboratory work and one to the investigation of and report upon subjects within the special out-door duties of a medical officer of health.

The foregoing summary embraces only those points of the English system likely to be available for adoption in this country, but sufficiently indicates the essentials of a thoroughly practical course for an American degree of D. P. H.

A BROAD FIELD OF INQUIRY.

Some months ago two leading teachers of the faculty of the medical college at ——— refused to sign the diplomas of four medical students, because they were known to be beer drinkers, and had been intoxicated during the lecture term. They had passed all the examinations with credit, and fulfilled all other requirements, and two of them had been cautioned by a professor in regard to drinking, the previous year. The majority of the faculty were disposed to grant them diplomas, on their promises of change, and by signing the pledge. The minority refused stoutly, and the matter was deferred. Recently, this has become a serious question; some influential friends of two of these students demand a final decision by the faculty. Several exciting meetings have been held, and the authorities are almost equally divided. It is held that these students are still drinking, and will disgrace the college which grants them diplomas. On the other side the drinking is doubted, and the past drinking is affirmed to be only the reckless overflow of generous convivial spirits, that will subside when engaged in active life work.

The defenders of the students refer to several members of the faculty who are moderate drinkers, and urge that these students should not suffer because of the narrow, fanatical views of persons whose habits differ. The battle is still going on, and it is needless to add that several good men are greatly excited over the issue of this case.

In another part of the country the same questions recently came to public notice in this way: Two medical men appointed by the Legislature on a very important medical commission, were rejected by the Governor. The surprise and disappointment roused a bitter feeling, which since the late election has brought out an explanation concerning the reasons for this rejection. The capability and respectability of these men were affirmed, but their habits of moderate and occasional intoxication were considered dangerous weaknesses, of which designing men might take advantage. The Governor declared that as the report of this commission would decide very influential interests he was not willing to have any one whose judgment might be influenced by spirits.

¹ “A New Field for the College,” JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, NOV. 10, 1894; p. 529.

Still another bitter disappointment is made public in an Eastern college town. A young physician of superior talents who has been an assistant, and has been acting professor in an important chair that is vacant, finds himself put aside and another man placed above him. His superior endowments and training, with influential friends, are ignored, and an inferior man given the honors. The usual wild protests and indignation bring out the reason that he is a wine drinker and has been seen intoxicated at the club. This opens up a bitter field of personalities, and newspaper war of letters.

These incidents are significant of a change in public opinion, and a sharp tendency to make an issue of questions that would have been passed over in silence a few years ago. The capacity or incapacity of a moderate or excessive user of spirits attracts attention and is discussed seriously in cases where the question of brain vigor and health is involved. Business and practical men approach this question without any sentiment, and demand the facts sustained and confirmed by common experience.

The medical profession have a great duty here which they have much neglected. The disputed questions concerning alcohol are purely medical fields of study, and yet the profession has scarcely been heard as either pioneers, students or teachers along this line. In the place of scientific study, two great parties are battling each other; one of wild-eyed emotional reformers who denounce alcohol in every way, and the other party who support it and extol its value as a food, medicine, and beverage. The profession stand aloof—indifferent, or tacitly support either one side or the other. In reality, no topic in modern science is more vital and more intimately associated with disease and the sanitary interests of the community. The physician who is looking round for new fields of study and research will find vast undiscovered stretches of country awaiting the explorer along this line. The strangest and most significant fact of all is, that public opinion is far in advance of the physician in interest in this subject, and in some respects in knowledge concerning it.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

In a narrow valley at the southern extremity of the Ozark Mountains, the annual meeting of the Mississippi Valley Medical Association was held. The town of Hot Springs is now said to have about 17,000 inhabitants. It does not seem to contain one-half so many, because the valley turns and winds among the high hills in such a manner that but a small portion of it is visible at a time. The climate was all that an enthusiast of Hot Springs could desire; sunny sky, balmy air, and distant haze on the mountains; and the excellent hotel accommodations contributed to make the environment very pleasant.

Many professional men were attracted to this meeting in order to see the place to which they had often sent patients, that they might have a more intimate and personal knowledge of this great sanitarium of the Mississippi Valley. They found that its virtues had not been exaggerated, and here was a young city filled with energetic and enterprising citizens in marked contrast to the towns and villages the traveler passed through in order to reach it. The citizens with large-hearted hospitality threw open their doors to the incoming visitors, and endeavored to the best of their ability, and with great success, to convince them of the superior qualities of the Arkansas Hygeia.

The attendance at the meeting was larger than that of last year, and we learn the registration numbered about two hundred. The scientific character of the papers was all that could be desired from such an assemblage, and PRESIDENT SCOTT with excellent tact, kept them well at work. We shall have many of the papers printed in full in the JOURNAL, and of the others we will have, as appears elsewhere, a full abstract of the meeting.

The banquet on Thursday evening was held under the guidance of that inimitable Toastmaster, DR. I. N. LOVE, of St. Louis. It was elaborate and well attended; but if we were allowed to criticise we should say that its sweetness was too long drawn out, as it not only lasted into the "wee sma' hours," but also into the larger hours of the morning. Business over, the Association adjourned, but some of the members still lingered to refresh themselves with the pleasant waters of the springs, and to rest a little from the arduous character of their labors. Altogether it may be said that the visit to the Hot Springs, of the Mississippi Valley Medical Association is one long to be remembered, and marked in the history of the Association with a white stone. The next meeting will be held at Detroit under the presidency of DR. WISHART, of Indianapolis.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

The seventh annual meeting of this Association was held in Charleston, S. C., November 13-15, under the presidency of DR. C. KOLLOCK. There was an average attendance, and the program heretofore published in the JOURNAL was closely adhered to. The papers read were of a high character, and the discussions which followed were spirited. The JOURNAL will endeavor to publish a full abstract of the proceedings in a subsequent issue. The Association adjourned after having elected DR. L. McLANE TIFFANY, of Baltimore, as President, and DR. W. E. B. DAVIS, of Birmingham, Alabama, Secretary. The Association selected Washington, D. C., as its next place of meeting, and the time the second Tuesday in November, 1895.

CORRESPONDENCE.

LETTER FROM BERLIN.

BERLIN, Nov. 10, 1894.

To the Editor:—I arrived in Germany on the 24th ult., and stopped for a short time in Bremen and Hamburg before coming to this city.

Through the kindness of Dr. Dunbar, Director of the Hygienic Institute in Hamburg, formerly an American citizen but now a German subject, I was introduced to Dr. Schede, a pupil of Volkmann, and Oberorzh of the New Eppendorf General Hospital—a new hospital of 1,800 beds, constructed on the pavilion plan, situated in Eppendorf, a suburb of Hamburg. The operating room is well arranged as to light and all the conveniences for modern surgical operations.

Dr. Schede courteously showed me over the buildings and invited my attention to many of his cases, the number and variety of which gave evidence of the vast amount of material that might be utilized in clinics. And yet Hamburg, a city of more than half a million inhabitants, has no medical school to make good use of this abundant material for instruction.

I saw Dr. Schede do an operation, original with himself, for the radical cure of varicose veins of the lower extremity, which deserves notice. He makes an incision from four to six inches below the knee around the entire circumference of the leg, dividing skin, fascia and all the superficial veins down to the muscles—as if he were about to make a circular amputation of the leg. The cut ends of the veins are then picked up, both above and below, tied with catgut and the wound closed. He informed me that he had performed this operation thirty or forty times, and in every case, without exception, with a satisfactory result.

The antitoxin treatment of diphtheria still excites the greatest interest here, and it would seem to an impartial observer that the efficacy of the remedy has been established beyond controversy, both French and German authorities agreeing that the mortality has been reduced from 50 or 60 per cent. to 10 or 12 per cent., and it is claimed that the mortality would be even less were the remedy always resorted to in time. Opinion is divided as to whether Behring or Roux deserves the credit for the introduction of this remedy, but I am informed that the man who first established the principle of this particular line of treatment is a young man, little known, namely Dr. Nuttall, an American, formerly assistant to Professor Welch at Johns Hopkins, but now attached to the Hygienic Institute in this city. The results of his experiments and the principle thereby established were set forth in a thesis which was afterward published, presented when he applied for his degree at Göttingen University some four years ago.

The following is a short sketch of the method of preparing the antitoxin:

1. PREPARATION OF THE TOXIN.—A pure culture of the diphtheria bacillus is made in bouillon, its growth being forced or hastened by maintaining a temperature of 37 degrees C.,—in Germany for eight days, while in France they take three weeks and use Fernbach's flasks which expose a larger surface of the culture to the air. The strength of the toxin is increased by hastening the growth of the bacillus.

2. SEPARATION OF THE TOXIN.—The toxin is separated from the bacillus by means of a Pasteur or Chamberland filter. The unit of strength is obtained by experiments on guinea pigs—one-tenth of a cubic centimeter should kill a 500 gram guinea pig with diphtheritic paralysis in twenty-four or thirty-six hours.

3. IMMUNIZING THE ANIMAL.—Half a cubic centimeter of the toxin is injected subcutaneously into the horse selected

for the purpose and the effects carefully watched. The fever, edema, and loss of appetite which result, usually pass off in a week, when the second injection, one cubic centimeter is given and the same precautions observed as before. The injections are continued at intervals of about a week, depending on the reaction produced, increasing the quantity to 1½, 2½, 5, 10, 15, 20, 25, 30, 35, 45, 50, 60, 100 cubic centimeters, until, at the end of three months, usually, the animal can stand a dose of 250 cubic centimeters without reaction. He is then in proper condition for furnishing serum.

4. PREPARATION OF THE SERUM.—About six liters of blood are taken from the jugular vein of the horse about once a month. The blood is allowed to stand in a cool place till coagulation takes place and the serum is separated simply by siphoning. The serum will keep in sterilized flasks in a cool place six or eight months. Aronson, of this city, adds tri-cresol in the proportion of six-tenths of 1 per cent. in order to preserve it. The horse is kept immunized by injections of sixty cubic centimeters of the toxin every other day, but no injection is given for five days preceding a bleeding. In preparing the horse, if the first injection of toxin should prove too strong, the next dose is not diminished in quantity but its strength is weakened by the addition of Graw's solution, one-third, to the next two or three doses.

A strong serum is made by *intravenous* injection of 250 cubic centimeters to 300 cubic centimeters just after a bleeding, to be repeated as may be necessary until there is no longer reaction. This method is very dangerous to the horse.

5. ADMINISTRATION OF THE SERUM.—This is done by means of a large hypodermic syringe, inserting the needle beneath the skin of the abdomen, in doses of twenty to forty cubic centimeters to a child 5 or 6 years old, to be repeated if necessary in twenty-four to forty-eight hours or even in less time in severe cases. No bad effects have been observed from very large doses. The good effects are apparent usually in less than twelve hours, and consist in lowered temperature (when it has been elevated), improvement in the pulse, and in the general condition of the patient. It is said that every case of pure diphtheria can be cured if this remedy be used within two days after the onset of the disease.

I am indebted to Passed Assistant Surgeon J. J. Kinyoun, M. H. S., for material assistance in collecting these facts concerning this antitoxin, especially the French methods—Dr. Kinyoun having been with Roux in Paris where he had every opportunity for observing his methods.

Very respectfully,

GEORGE TULLY VAUGHAN,
Passed Assistant Surgeon M. H. S.

Private Homes for Old People.

HARTFORD, CONN., November, 1894.

To the Editor:—Some time ago I was asked to find a home for a worn-out physician who through death and changes was left alone in the world. He had a small income, and desired to go away among strangers where the past would be forgotten. I found the various old peoples' homes managed by churches and corporations, objectionable in many ways and lacking in the personality and sympathy so essential to many persons who have been active workers. The sanitariums and hospitals failed in this and other respects, and were neither cheerful or comfortable in their set rules and formalities. Private families who could furnish the proper accommodations could not receive single cases unless the prices paid were remunerative. This poor old physician was forced to enter a sanitarium, where he soon after died, neglected and alone.

The same question has occurred again, and I have found what appears to be a real want, that has not been recognized

practically. This is, briefly, an intermediate home for old people between the corporate and charity institutions and the private family. A suitable residence where all the comforts of rooms, surroundings, diet, seclusion, sympathetic personal care, and also medical attention when required, can be combined for a limited number of cases. Elderly people who from various causes are unable to command the quiet and seclusion of a home, and who would be better away from their former scenes, and have means to pay a moderate sum for this service, are to be found in almost every community. Old peoples' homes and other institutions bring them into a degree of prominence and subject to rules and regulations that are often irksome and unpleasant, such as the separation of a man and wife, and refusal to see friends except at stated times, and the imposing on them of certain perfunctory duties that break in on the cherished quiet and rest desired. Acting on my suggestion, a gentleman who has had several years' experience in the care of old people, has established a home of this character which will be opened January 1, at Ballston Springs, New York. Having made inquiries of the personal details of this work, I am sure it will be of interest to the profession and especially those who, like myself, have been advised concerning homes for old people, to give some of the facts.

Ballston Springs is a tree-embowered village in a valley five miles from Saratoga, and on the same mineral springs belt. Over fifty mineral springs of widely different values are located here. Invalids from all parts of the country live here for the sake of the waters which are free to all. The climate is very dry and bracing, being in the lower Adirondack snow belt, and mostly free from sleet storms and fogs. This town is nearly a hundred and fifty years old, and all the surroundings of good society and churches, with fine water supply and excellent drainage are exceptionally good. A large spacious residence near several springs is being fitted up for a small number of elderly people with the special object of furnishing a quiet congenial home, where personal interest and sympathy, with watchful care and attention are constantly at command. Medical supervision and nursing together with every other means, will be combined to make this a most delightful harbor for anchorage during the afternoon and sundown of life.

While I have no pecuniary interest in this home, I will answer with pleasure all inquiries relating to it, and give any information possible to any one who may be interested.

T. D. CROTHERS, M.D.

New and Important Pharmaceutic Product.

NEW YORK, November, 1894.

To the Editor:—On July 28, last, we presented to the members of the medical profession through the columns of the JOURNAL, a new brain and nerve tissue chemie food. The glycerio-acid phosphate, the formula of which is almost identical with that of the lecithin of the brain cell and nerve tissue, C₄₄ H₉₀ NPO₉; and which furnishes the proper chemie nerve cell and nerve tissue food to the vesicular neurine of the brain where nervous force is generated, and to the tubular or fibrous neurine which conducts it. In answer to numerous inquiries and requests for samples I have sent to all who requested it, a sample of this nerve food with the result that it is now in successful use in many of our hospitals with good clinical results.

For many years I have felt the necessity for a preparation of the hypophosphites, combined with iron, quinia and strychnia, which would not precipitate and which did not require to be kept in a cave or dark place during the warm months of the year. I desired a preparation which should be much richer in the hypophosphites than any I could obtain in the drug stores, and one which should also contain

a more decided dose of iron, quinia and strychnia, to act as a stimulant tonic and reconstructive in all tuberculous, strumous and wasting diseases and during convalescence from grippe and other infectious complaints, and which would be a powerful therapeutic agent to stimulate the general nutrition by means of its action on the nervous system. This, I think from my own experience clinically, I have perfectly succeeded in doing, as the glycerid of the hypophosphites comp. has a powerful stimulative action on the nutrition of all the organs, and this stimulant and tonic effect arises in a special stimulative action on the nervous system. It stimulates appetite and digestion, patients gain in weight and general appearance, and all report a feeling of invigoration from its use.

Each fluid ounce contains:

| | | |
|----------------------------------|----------------|-----|
| Hypophos. soda | | |
| Hypophos. lime | | |
| Hypophos. potass | ãã grs. iv ss. | 26 |
| Hypophos. iron | | |
| Hypophos. quinia, pure | ãã grs. iv. | 24 |
| Hypophos. strychnia | grs. 4-60. | 004 |

Dose from one to two teaspoonfuls in a wineglass of cold water before or with meals.

There is no possibility either of precipitation or of decomposition in this solution. It keeps indefinitely. A sample for physicians' use will be sent upon application to the author, at 305 West Eighty-sixth Street, near West End Avenue, New York.

Very respectfully,
E. C. MANN, M.D.

ASSOCIATION NEWS.

Photographs of Members.—Members of the ASSOCIATION are respectfully requested to send a recent photograph of themselves to the JOURNAL. In so doing please write plainly the name and age of sender and date of photograph.

The Department of Public Health.—The following circular has been issued by Chairman Cochran:

MONTGOMERY, ALA., Nov. 22, 1894.

Dear Doctor:—You are doubtless familiar with the effort which the AMERICAN MEDICAL ASSOCIATION is making to secure the enactment by the Congress of the United States of the bill now pending to create a Department and Secretary of Public Health. The great importance of the proposed legislation to the medical profession and to the people of the country is too evident to require argument. The only thing we need to discuss is how to secure for the bill the favorable consideration of the members of Congress. To this end this circular letter is addressed to the officers of State and other medical societies and associations with the urgent request that such officers will promptly appeal to the members of their societies and associations to write to their members of Congress, in both Houses, requesting them to give their support and their votes in aid of the passage of the bill referred to. If all the doctors in all the States take part in a movement of this sort, and would keep it up for a few years, there can be no doubt that success would soon crown our efforts. Let no one consider his influence of little consequence, but let every one write promptly. Such a storm of letters would batter down all opposition.

Every one who receives a copy of this letter will please enter into correspondence with the Chairman of the Committee. Very respectfully,

(Signed.) JEROME COCHRAN, M.D., Chairman.
C. G. COMEGYS, M.D.,
N. S. DAVIS, M.D.,
J. C. CULBERTSON, M.D.,
CHAS. DENISON, M.D.,
U. O. B. WINGATE, M.D.,
W. B. ATKINSON, M.D.,
LISTON H. MONTGOMERY, M.D., Committee.

SOCIETY NEWS.

Chicago Ophthalmological and Otolological Society.—The regular meeting of the Chicago Ophthalmological and Otolological Society was held at the Schiller Building, May 8, 1894, Dr. Hotz in chair. There were twenty-one members in attendance. On Dr. Gardiner's motion the reading of the minutes of the last meeting was omitted. Drs. Ada Phelps and F. H. Weir were elected members. On Dr. Colburn's motion the President was instructed to make arrangements with Dr. Meyer to read a paper before the Society on the "Relations of the Cranial Nerves to the Eye."

Dr. Horz reported a case of deep cupping of both nerves. Mr. M., aged 37, when 5 years old was struck in the O. S. with the end of a stick; the eye was red and painful for a few days only but the vision has never been as good as O. D. since. V. O. S. gradually grew worse and for several years there has been perception of light only. About three years ago he discovered a scotoma in O. D., one inch to right and one-half inch below fixation point at two feet distance. This blind spot has not changed since then but he thinks the V. O. S. has diminished in the last six months. Never any headache, or full feeling or dull pain about O. D.; no rainbow colors; no periodic obscurations. O. S. perception of light in lower temporal field only; tension normal; pupil dilated but responds feebly to light; normal anterior chamber; media clear; deep excavation amounting to 11 D.; size of vessels normal; no pulsation. O. D. V = 20-40 not improved by glasses; tension normal; pupil active; anterior chamber normal; excavation = 8.50 D.; vessels normal; no pulsation; field of vision for white normal; color fields much contracted.

Dr. FISHER showed a case similar to Dr. Hotz: Mrs. W., aged 55, has had no pain or headache; tension normal; V. O. D. = 20-120; V. O. S. = nil; excavation + 5 D. O. D., 6 D. O. S.; veins slightly enlarged; has had trachoma for many years.

Dr. COLEMAN reported: Mrs. C., aged 77, first noticed one month ago that she could not see to read with O. S.; could read ordinary type at that time c. O. D.; some discomfort of late in O. D.; V. O. D. = 6-12 c. + 1.50 D., V. O. S. fingers at eight feet; O. O. lens shows few opaque lines in lower third; tension normal; total deep cupping of disc; gray-white atrophy; O. S. tension normal; cupping and atrophy of disc; cornea, iris and pupil normal O. U.; fields contracted for color and form.

Dr. GRADLE reported a similar case, but the cupping only in one eye with the other normal. The tension was usually normal but was slightly + at times and Dr. Gradle made an iridectomy. The subjective symptoms disappeared but the vision was not improved.

Dr. BEARD thought that extra ocular pressure of the lids in Dr. Fisher's case might have caused the cupping. He had two patients with similar cupping which might be caused by the pressure of their lids trying to overcome an Hm. astig.

Dr. TILLEY mentioned two cases of deep physiologic cupping which resembled glaucomatous.

Dr. WILLIAMS thought the contraction of the color fields in Dr. Hotz's case quite characteristic of atrophy. He showed several beautiful sections and photographs of normal and glaucomatous nerves.

Dr. FAITH reported a case of purulent ophthalmia, caused by the discharge from a suppurating middle ear.

Dr. WILLIAMS said he had examined the discharge from many purulent eyes and sometimes found no gonococci.

Dr. WILDER said that sometimes some cases were caused by other bacteria than the gonococcus.

Dr. GRADLE spoke of three cases of paralysis of the cervical sympathetic, one-sided, that he had had in the past two years. There was incomplete ptosis and contracted pupil but no redness or sweating of the face. None of the cases improved or got worse.

Dr. COLEMAN reported a case of diplopia where the muscles balanced. It was due to the persistence of the perception of objects not in focus.

Dr. Hotz had a similar case.

On motion the Society adjourned.

C. P. PINCKARD, Secretary.

103 State Street.

NECROLOGY.

FRANK L. SIM, M.D., died at his residence in Memphis, Tenn., Nov. 23, 1894. He had been in failing health for several months and his death was probably due to malignant disease of the stomach and liver. Dr. Sim was born in Golconda, Ill., April 29, 1834. His literary education was received at Hanover College, Indiana. He graduated from the medical department of the University of Louisville in 1855, and a year later received an *ad eundem* degree in the Pennsylvania Medical College. Returning home in the spring of 1857, he practiced medicine with his father till 1861, when he left that part of the country and shortly afterward entered the Confederate service as a contract surgeon in the army, then stationed at Columbus, Ky. After a satisfactory examination he applied for a commission, but while awaiting the same he was ordered to Memphis with a boat-load of soldiers sick with measles. Circumstances induced him to locate in Memphis, where he has ever since devoted himself to the practice of his profession. He remained at his post of duty during the dark days of Memphis in the various epidemics of cholera and yellow fever. In 1882, Dr. Sim became the editor of the *Mississippi Valley Medical Monthly*, but afterward changed to the *Memphis Medical Monthly*, under which name he has continued its editor and publisher. Dr. Sim at the time of his death was Professor of the Principles and Practice of Medicine in the Memphis Hospital Medical College and was Dean of the Faculty. He was a member of the AMERICAN MEDICAL ASSOCIATION, British Medical Association, American Public Health Association, ex-President of American Medical Editors Association, Memphis Medical Society, and at the time of his death was President of the Tennessee State Medical Society, and also a member of the State Board of Health. As a teacher, Dr. Sim was painstaking and popular, as a writer clear and vigorous, as a man the soul of honor and integrity, and as a practitioner he stood well with his professional colleagues and enjoyed the confidence of a large clientele.

JOHN DEXHEIMER, M.D., of Brooklyn, died November 11, aged 36 years. He was of German family, but was himself born in this country. He was a graduate in medicine from the New York University, in the class of 1882. He was an inmate of St. Catharine's Hospital for a short time previous to his death. His fatal malady was multiple neuritis.

WILLIAM P. OVERTON, M.D., of Cold Spring Harbor, L. I., New York, died October 24, aged 74 years. He was a graduate from the New York University Medical School in 1841. He practiced in Brooklyn for a number of years, but in "the sixties" he removed to the above named town. He had been President of the County Medical Society and Coroner for three or more terms in Suffolk County. He leaves a widow and one son. His final ailment was Bright's disease of the kidneys.

PUBLIC HEALTH.

Sulphite Works from a Sanitary Standpoint.—Rodling has recently investigated the large sulphite works at Gysinge in Sweden and reports (*Rev. Int. de Bibl. Méd.*) that the waste products cause 12.09 milligrams of various substances per liter to be discharged into the canal below the works. Of these, sulphuric acid, free or combined with calcium, forms 0.18 mgm.; SO₂, 0.06 mgm.; SO₂ in organic combination, 1.83 mgms.; calcic oxid, 1.10 mgms.; and organic substances, 8.92 mgms. When the contents of the bake-ovens are emptied—three times a day—the SO₂ in the atmosphere is raised to about 0.04, but this causes no inconvenience to those accus-

tomed to it; a prolonged stay in the vicinity of the ovens, however, is insupportable, because the SO_2 in their vicinity is increased to 0.1. Traces of sulphurous acid were found in the snow which had laid about the works for four days. Neither the fish in the Dal below the point of discharge of the canal from the factory, nor the surrounding vegetation, seems to suffer from the sulphite works.

Increase of Smallpox.—Toward the close of November there was an increase of the number of cases of smallpox in localities previously infected, and a number of newly-infected localities were first reported. The disease, however, seems to be kept fairly well in hand wherever the health authorities are duly notified. On the 26th there were 106 cases in Milwaukee and 64 in Chicago. Infected persons escaping from these cities continue to carry the contagion into other localities; a passenger from Chicago on a Grand Trunk train was found on his arrival at Mitchell, Ontario, November 24, to be suffering from the disease; and a family which broke quarantine at Milwaukee and went to Sandwich, Ill., caused an outbreak at the latter place, resulting in a large number of cases and two deaths up to the 26th ult.

Microscopy of Factory Dust.—The noxious effects of factory dust are due—apart from bacilli—either to its chemie composition or to its structure. As to structure, the most injurious forms are those of irregular shape, and the smaller these are the farther they penetrate the bronchi and the more intense and disastrous their action. The following varieties of factory dust are, according to *Le Revue d'Hygiene*, to be considered very dangerous: 1, metallic; 2, some kinds of stone dust; 3, dust of animal origin, such as shell, horn and whale-bone; 4, all kinds of wood dust; 5, dust of vegetable origin—principally jute; 6, dust from animal fiber, except that of wool and silk factories; 7, dust of flouring mills and tanneries under certain conditions and for the workmen who are constantly exposed; and, lastly, 8, the dust of rag shops and that from carpet beating. The study of the effects of these various forms leads to the practical suggestions that fans should be employed to keep the air of shops and factories as free from dust as possible and that, in certain industries the workmen should be furnished with suitable ventilating masks.

A Dangerous Coloring Agent.—Chromate of lead is still largely used for coloring purposes, in spite of the discovery of numerous artificial yellows whose varied tints, as well as "fastness" on exposure to light, leave nothing to be desired in this respect. In the region around Lyons especially, great use is made of this agent and Roubaix and Rouen still use it to some extent. For some years past severe cases of plumbism have been observed in the spinning factories where cotton dyed while floating is wound. The Hygienic Council of the department of the Rhone instructed M. Cazeneuve to investigate the subject, and in his report he concludes that while lead chromate may still be tolerated for dyeing cotton cloth "in piece," for linings, etc., its use for dyeing thread for any purpose should be proscribed absolutely. On account of the "stiffening" and glazing to which it is subjected, piece cotton colored with the chromate gives off no dust, either in its preparation or in making up. M. Cazeneuve hopes that the prohibition, which has been ordered in the department of the Rhone, will be extended to the whole of France.

Cholera Precantions.—The recrudescence of cholera in some parts of Turkey and in Silesia in the early part of November—noted in the *JOURNAL* of the 10th ult.—seems to have convinced the health authorities of Europe that the dangers of the past season are to be repeated next year. At a recent meeting of the German Society of Public Health, Professor

Koch said: "I scarcely think that the cholera, extended as it is in Russia, will quite disappear from that country next year. It will probably last a few years more and again spread to other countries." Referring to the exposed condition of Germany, lying in the center of Europe, he said that its invasion by cholera, when the disease exists in other European countries, can not be prevented and that all efforts must be directed to making it harmless when it does appear. *Per contra*, disinfecting stations have been established on the Russo-German frontier at Bajohren, Edytkuhnen, Prostken, Illowa and Ottlotschin—through which all Russian emigrants must pass before entering German territory. While the direct effect will be to protect Germany their establishment is due to the immigration laws of this country; all Russian emigrants are examined at these stations, and those afflicted with contagious diseases, or who are found to be such as would be debarred from landing in the United States, are turned back and not allowed to pass. The stations have been established by the North German Lloyd and the Hamburg-American steamship lines.
