PECULIAR PHONETIC SYMBOLS

USED IN THE WRITING OR TRANSLITERATION OF THE DIFFERENT LANGUAGES.

ā, ē, etc.: long vowels; in the Scandinavian languages the accent (*á*, *é*, etc.) is used to denote length.

ą: a nasalized *a*; so used in the transliteration of the Iranian languages.

å: labialized guttural *a* in Swedish.

æ: open *a* of Eng. *hat*, used chiefly in O. Eng.

aí: used in Gothic to denote *e* (open), in distinction from *ái*, the true diphthong.

aú: used in Gothic to denote *o* (open), in distinction from *áu*, the true diphthong.

bh: in Sanskrit a voiced labial aspirate (cf. *ch*).

ƀ: voiced bilabial (or labio-dental?) spirant, used in discussions of Teutonic dialects.

ç: voiceless palatal sibilant, similar to Eng. *sh*, used especially in transliteration of Sanskrit.

č: frequently used, e. g. in Slavonic languages, to denote the sound of Eng. *ch* in *cheek*.

c: voiceless palatal explosive, commonly used in transliteration of Sanskrit and the Iranian languages.

ch: as used in the transliteration of Sanskrit, a voiceless palatal aspirate, an aspirate being an explosive with excess of breath; as used in German grammar, the symbol for a voiceless palatal or guttural spirant.

dh: voiced dental aspirate (cf. *ch*) in Sanskrit.

ḍ: voiced cerebral explosive, so used in transliteration of Sanskrit.

ḍh: voiced cerebral aspirate (cf. *ch*) in Sanskrit.

đ: voiced dental (interdental) spirant, equivalent to Eng. *th* in *then*; so used in the Teutonic and Iranian languages and in phonetic writing.

ë: a short open *e*, used in Teutonic grammar, particularly in writing O. H. G.

e: the short indefinite or "obscure" vowel of Eng. *gardener*; used in the reconstruction of Indo-Eur. forms, and in transliterating the Iranian languages.

gh: in Sanskrit a voiced guttural aspirate (cf. *ch*).

ǥ: voiced velar (back-guttural) explosive, used most frequently in Indo-Eur. reconstructions.

ȝ: voiced guttural (or palatal) spirant, equivalent to Mod. Greek γ, and used in transliteration of Iranian languages and O. Eng.

ḥ: a voiceless breathing, the Sanskrit *visarga*.

hw: a labialized *h*, similar to *wh* in Eng. *what*; used in transliteration of Gothic and the Iranian languages.

ḫ: voiceless guttural (or palatal) spirant, equivalent to German *ch*, and used in transliteration of the Iranian languages.

i̯: the semi-vowel *y*, or consonant form of *i*; used in phonetic writing and reconstructions of Indo-Eur. forms.

j: in the transliteration of Sanskrit and the Iranian languages a voiced palatal explosive; in the Teutonic languages a semi-vowel (= *y*), for which in Indo-Eur. reconstructions *i* is generally used.

jh: in Sanskrit a voiced palatal aspirate (cf. *ch*).

kh: in Sanskrit a voiceless guttural aspirate (cf. *ch*).

ƚ: the guttural ("thick" or "deep") of the Slavonic and some of the Scandinavian languages.

l̥: vowel *l*; used in transliterating Sanskrit, in reconstructing Indo-Eur. forms, and in other phonetic writing.

n̥: nasal vowel; used in reconstruction of Indo-Eur. forms and in phonetic writing.

ṇ: in Sanskrit the cerebral nasal.

ñ: in Sanskrit the guttural nasal (see following).

ŋ: the guttural nasal, equivalent to Eng. *n* in *longer*; used in transliteration of Iranian languages.

ñ: palatal nasal, similar to *gn* in Fr. *regner*; used in transliterating Sanskrit and in phonetic writing.

ö: palatalized *o*; used in German and in phonetic writing.

ǫ: short open *o* in Scandinavian.

ø: short palatalized *o* (ö) in Scandinavian.

ph: in Sanskrit, voiceless labial aspirate (cf. *ch*).

ɋ: voiceless velar (back-guttural) explosive; used in reconstructions of Indo-Eur. forms and in other phonetic writing.

ṛ: vowel *r*; used in transliterating Sanskrit, in reconstructions of Indo-Eur. forms, and in other phonetic writing.

š: voiceless cerebral sibilant, equivalent to Eng. *sh*; used in transliterating the Iranian languages and in phonetic writing.

ṣ: voiceless cerebral spirant; used in transliterating Sanskrit.

th: in Sanskrit a voiceless dental aspirate (cf. *ch*).

ṭh: in Sanskrit a voiceless cerebral aspirate (cf. *ch*).

ṭ: in Sanskrit a voiceless cerebral explosive.

ţ: a form of dental spirant used in transliterating the Iranian languages (represented in Justi's transliteration by ṭ).

þ: voiceless dental (interdental) spirant, equivalent to Eng. *th* in *thin*; used in Teutonic dialects and in phonetic writing.

u̯: consonant form of *u*; used in phonetic writing.

ž: voiced cerebral sibilant, equivalent to *s* in Eng. *pleasure*, and to *j* in Fr. *jardin*; used in Iranian, Slavonic, and in phonetic writing.

ʒ: a symbol frequently used in the writing of O. H. G. to indicate a voiced dental sibilant (Eng. *z*), in distinction from *z* as sign of the affricata (*ts*).

EXPLANATION OF THE SIGNS AND ABBREVIATIONS USED IN THE ETYMOLOGIES.

>, yielding by descent, i. e. under the operation of phonetic law.
<, descended from.
=, borrowed without change from.
: , cognate with.
+, a sign joining the constituent elements of a compound.
*, a sign appended to a word the existence of which is *inferred*.

ablat.	ablative
accus.	accusative
adjec.	adjective
adv.	adverb
cf.	compare
conjunc.	conjunction
deriv. of	derivative of
dimin.	diminutive
fem.	feminine
genit.	genitive
imper.	imperative

KEY TO THE PRONUNCIATION.

aa..... as *a* in *father*, and in the second syllable of *armada*.

aă..... same, but less prolonged, as in the initial syllable of *armada*, *Arditi*, etc.

a..... as final *a* in *armada*, *peninsula*, etc.

ă..... as *a* in *fat*, and *i* in French *fin*.

ay or ā.. as *ay* in *nay*, or as *a* in *fate*.

ăy or *ā*.. same, but less prolonged.

ā..... as *a* in *welfare*.

aw..... as *a* in *fall*, *all*.

ee..... as in *meet*, or as *i* in *machine*.

ĕe..... same, but less prolonged, as final *i* in *Arditi*.

e..... as in *men*, *pet*.

e..... obscure *e*, as in *Bigelow*, and final *e* in *Heine*.

ė..... as in *her*, and *eu* in French *-eur*.

i..... as in *it*, *sin*.

ī..... as in *five*, *swine*.

ĭ..... same, but less prolonged.

ō..... as in *mole*, *sober*.

ō..... same, but less prolonged, as in *sobriety*.

o..... as in *on*, *not*, *pot*.

oo..... as in *fool*, or as *u* in *rule*.

o͝o..... as in *book*, or as *u* in *put*, *pull*.

oi..... as in *noise*, and *oy* in *boy*, or as *eu* in German *Beust*.

ow..... as in *now*, and as *au* in German *haus*.

ö..... as in *Göthe*, and as *eu* in French *neuf*, *Chintreuil*.

ŭ..... as in *but*, *hub*.

ŭ..... obscure *o*, as final *o* in *Compton*.

ü..... as in German *süd*, and as *u* in French *Buzançais*, *vu*.

y or *l*.... see *l* or y.

yu..... as *u* in *mule*.

yŭ..... same, but less prolonged, as in *singular*.

ch..... as in German *ich*.

g..... as in *get*, *give* (never as in gist, congest).

hw..... as *wh* in *which*.

kh..... as *ch* in German *nacht*, *g* in German *tag*, *ch* in Scotch *loch*, and *j* in Spanish *Badajos*, etc.

ṅ..... nasal *n*, as in French *fin*, *Bourbon*, and nasal *m*, as in French *nom*, Portuguese *Sam*.

ñ or n-y.. Spanish *ñ*, as in *cañon*, *piñon*, French and Italian *gn*, etc., as in *Boulogne*.

l or y.... French *l*, liquid or mouillé, as (-i)ll- in French *Baudrillart*, and (*-i*)*l* in *Chintreuil*.

th..... as in *thin*.

th..... as in *though*, *them*, *mother*.

v..... as *w* in German *zwei*, and *b* in Spanish *Cordoba*.

sh..... as in *shine*.

zh..... as *s* in pleasure, and *j* in French *jour*.

All other letters are used with their ordinary English values.

NOTE.

The values of most of the signs used in the above Key are plainly shown by the examples given. But those of ö, ü, *ch*, *kh*, ñ, and *v*, which have no equivalents in English, can not be sufficiently indicated without a brief explanation, which is here given.

ö. The sound represented by this symbol is approximately that of -u- in *hurt* or -e- in *her*, but is materially different from either. It is properly pronounced with the tongue in the position it has when ā is uttered and with the lips in the position assumed in uttering ō.

ü. This vowel is produced with the lips rounded as in uttering oo and with the tongue in the position required in uttering ee, into which sound it is most naturally corrupted.

ch and *kh*. These are both rough breathings or spirants made with considerable force, *ch* being made between the flat of the tongue and the hard palate, and *kh* between the tongue and the soft palate. *ch* approaches in sound to English sh, but is less sibilant and is made further back in the mouth; *kh* is a guttural and has a hawking sound.

l or y. These are both used to represent the sound of French l mouillé, in (-i)ll- and (-i)l, which resembles English -y- in *lawyer*. Final *l*, that is, (-i)l, may be approximated by starting to pronounce lawyer and stopping abruptly with the -y-.

ñ or n-y. The consonants represented by ñ (Spanish ñ, French and Italian gn, etc.) are practically equivalent to English -ni- or -ny- in bunion, bunyon, onion, etc., and, except when final, are represented by n-y. Final ñ, as French -gn(e), may be produced by omitting the sound of -on in the pronunciation of *onion*.

v. This may be pronounced by attempting to utter English v with the use of the lips alone.

See PREFACE (vol. i., p. xli.) and the article PRONUNCIATION OF FOREIGN NAMES.

THE
UNIVERSAL CYCLOPÆDIA.

Raleigh: city; capital of North Carolina and of Wake County; on the Seaboard Air Line and the Southern and Raleigh and Cape Fear railways; 148 miles N. by W. of Wilmington, 286 miles S. S. W. of Washington, D. C. (for location, see map of North Carolina, ref. 2–H). It is in a cotton, corn, and tobacco-growing region, handles about 125,000 bales of cotton annually, and contains large railway-car works and repair-shops, 4 foundries, 3 large planing-mills, 3 cotton-mills, 1 hosiery-mill, 1 knitting-mill, cigar-factory, 2 drug-manufactories, furniture-factory, tobacco-factory, cottonseed-oil mill, 2 clothing-factories, manufactory of steam-engines, agricultural-implement works, 2 ice-factories, and other industries.

Buildings.—The public buildings include the Capitol, in a small park of magnificent oaks; a U. S. Government building (cost $400,000); the State penitentiary (cost over $500,000); one of three State hospitals for the insane; the State Agricultural and Mechanical College (which in 1899 had in all departments 27 professors and instructors and 252 students, a small library, an endowment fund of $125,000, land and buildings valued at $103,054, and an income from all sources of $37,000); the State fair-grounds; State Supreme Court and State library; State museum and hall of history; State arsenal; soldiers' home; Governor's mansion; Methodist orphanage; Catholic orphanage; and State institutions for the white blind and the colored deaf mutes and blind.

Churches and Schools.—There are 16 churches for white people and 12 for colored. The educational institutions include Shaw University for colored males and females (Baptist, opened in 1865), with an agricultural and mechanical, law, medical, and pharmaceal annex; Peace Institute (Presbyterian, chartered in 1857); Baptist Female University (1899); St. Mary's School (Protestant Episcopal, opened in 1842); the Raleigh Male Academy (non-sectarian, opened in 1878); St. Augustine's Normal School and Collegiate Institute (Protestant Episcopal, colored, opened in 1868); Latta University, colored; and 8 public schools (4 white and 4 colored). There are 5 libraries, including the State (founded in 1822), the Olivia Raney Memorial Library, one of the finest in the South, and the Supreme Court (founded in 1812), with an aggregate of over 75,000 volumes.

Public Improvements, etc.—The city has improved water and sewerage systems, gas, electric lights, street-railway, union depot, 4 hotels, many miles of broad paved streets, 2 parks, 4 public squares, 9 public halls, 3 national banks with combined capital of $325,000, 3 State banks with capital of $130,000, 2 trust companies, and 3 daily, 7 weekly, and 2 monthly periodicals. Pop. (1880) 9,265; (1890) 12,678; (1900) 13,643.

JOHN WILBER JENKINS, EDITOR "RALEIGH TIMES."

Raleigh, or **Ralegh**, Sir WALTER: explorer and author; b. at Hayes, parish of East Budleigh, Devonshire, England, in 1552, second son of Walter Raleigh by his wife Catharine (Champernoun), widow of Otho Gilbert; entered at Oriel College, Oxford, about 1568; enrolled himself in a volunteer corps of auxiliaries commanded by his relative, Henry Champernoun, 1569, and passed several years fighting in behalf of the Huguenots in France; served under Sir John Norris, and afterward under the Prince of Orange, in the Netherlands 1576–79. His half-brother, Sir Humphrey Gilbert, having meanwhile obtained from Elizabeth letters patent dated June 11, 1578, empowering him to discover and possess any countries in North America not previously occupied, Raleigh sailed with him for Newfoundland 1579, but was forced by storms (and perhaps by an engagement with a Spanish fleet) to return without having landed in America. He went to Ireland as captain of a company 1580; aided in suppressing the Earl of Desmond's rebellion; was associated with Sir William Morgan in the government of the province of Munster; presented himself at court 1582; obtained the favor of Elizabeth; was employed in confidential negotiations with the French ambassador and the Duke of Anjou; subscribed £2,000 to the second expedition to Newfoundland under Sir Humphrey Gilbert, which resulted in the occupation of that island and the death of Sir Humphrey by shipwreck 1583, and obtained from Elizabeth a new patent for discoveries and colonization in North America, by virtue of which an expedition, headed by Philip Amidas and Arthur Barlow, sailed from England Apr. 13, 1584, and explored Pamlico and Albemarle Sounds in the summer of that year. Their enthusiastic accounts of the newly discovered region being made known to Elizabeth, she bestowed upon it the name of Virginia, and conferred knighthood upon Raleigh 1585, who in the course of the year was made lord warden of the stannaries and seneschal of the counties of Cornwall and Devon; took his seat in Parliament for Devonshire; obtained the passage of a bill confirming his proprietary rights, and dispatched to Virginia an expedition of seven vessels and 108 colonists under Sir Richard Grenville, which made a settlement on Roanoke island. Re-enforcements were sent in the two following years, but the enterprise failed through the capture of two ships by the French, and from mismanagement on the part of the leaders of the colonists, some of whom returned home, and the remainder perished by starvation or massacre; the chief practical result being the introduction of tobacco and potatoes into England. He took an active part in the preparations for repelling the Spanish Armada as captain of the queen's guard, member of the council of war, and lieutenant-general of the forces in Cornwall; commanded a vessel which rendered good service in the actions with the Armada, July, 1588; accompanied Sir Francis Drake in his expedition to Portugal 1589; visited Edmund Spenser at Kilcolman Castle, Ireland, on his return, and in behalf of the poet presented to Elizabeth the first three books of the *Faerie Queene*. In 1590 he equipped a fleet of thirteen vessels, and with Frobisher cruised successfully against Spanish vessels in the West Indies. He was imprisoned for two months in the Tower of London 1592, on account of his secret marriage with Elizabeth Throgmorton, one of the queen's maids of honor, and, being forbidden to present himself at court, he organized an expedition of five vessels, with which he sailed from Plymouth Feb. 9, 1595, explored the coasts of Guiana, and ascended Orinoco river, and on his return published *The Discovery of the Large, Rich, and Beautiful Empire of Guiana* (4to, 1596). He served as rear-admiral at the taking of Cadiz, where he

was wounded, June, 1596; was readmitted at court May, 1597; sailed with the Earl of Essex to the Azores in the same year and took Fayal, but quarreled with his commander and contributed to the ruin of Essex; obtained a grant of the fine manor of Sherborne, Dorsetshire; went as ambassador to the Netherlands 1600; became governor of Jersey 1601; lost favor at court on the accession of James I., was accused of conspiring to raise Lady Arabella Stuart to the throne, committed to the Tower in July, and condemned to death at Winchester, Nov. 17, 1603; suffered confiscation of his estates, which were given to Carr, the new favorite; was kept thirteen years in the Tower, during which time he wrote and published his principal work, *The History of the World* (1614); recovered his liberty, though not his pardon, through the influence of Villiers, Jan. 30, 1616; obtained from James a commission as admiral, and sailed with a fleet of fourteen ships for the discovery of his promised El Dorado in Guiana Mar. 28, 1617; had several engagements with the Spaniards, in one of which he lost his oldest son; lost several vessels, and was foiled in his objects; landed at Plymouth on his return June, 1618; was imprisoned on complaint of the Spanish ambassador, Gondomar, in consequence of his conduct in Guiana, and it having been decided by the judges that the sentence of death pronounced in 1603 was still valid, he was executed at the palace yard, Westminster, Oct. 29, 1618. Raleigh was a man of splendid genius and extensive attainments, wrote many miscellaneous, literary, and political essays, and a few poems of high order. His *Complete Works* were edited at Oxford in 8 vols. (1829). Biographies have been written by William Oldys, Arthur Cayley, P. F. Tytler, James A. St. John, and Edward Edwards, the two latter having appeared almost simultaneously in 1868. Revised by C. K. Adams.

Ral'lidæ [Mod. Lat., named from *Ral'lus*, the typical genus, from the Fr. *râle*, rail. See Rail]: a family of birds including the rails and gallinules. The neck is moderately elongated; the head rather small; the bill more or less elongated, compressed, and with the culmen advancing to a greater or less extent upon the forehead and decurved toward the apex; the nostrils are lateral, rather inferior, and in a membranous groove; the wings moderate and rounded, rather short; the tail rather short, inclined upward, and rounded; the tarsi rather long and slender, and in front covered with transverse scutellæ; the toes three in front, and well developed, the hinder comparatively short and rather elevated; the claws curved and sharp.
Revised by F. A. Lucas.

Ralph, James: poet and pamphleteer; b. in Philadelphia, Pa., about 1698; became a schoolmaster in his native city, where he made some pretensions to literary ability; was an early friend of Benjamin Franklin, with whom he sailed for England 1724, abandoning his wife and child; published in 1728 a poem entitled *Night*, which was sufficiently bad to merit notice by Pope in the *Dunciad*; sought favor with the Whig politicians by writing pamphlets and plays; was patronized by Frederick, Prince of Wales, and received a pension on the accession of George III. D. at Chiswick, Jan. 24, 1762. Author of *Zeuma*, a poem (1729); *The Use and Abuse of Parliaments* (2 vols., 1744); *History of England* (2 vols. folio, 1744–46); and *The Case of Authors by Profession or Trade Stated* (1758). Revised by H. A. Beers.

Rāma: See Rāmāyana.

Ramadan: Arabian form for Ramazan (*q. v.*).

Ra'mah [from Heb. *Rāmāh*, liter., lofty place]: the name of several places in Palestine, two of which are historically interesting and important. One of these, first mentioned in Josh. xviii. 25, and identified by Robinson in 1838, is on the top of a high hill about 5 miles N. of Jerusalem. It belonged to the tribe of Benjamin. The other, where Samuel was born (1 Sam. i. 1), has not yet been identified with certainty.

Rāmā'yana [Sanskr. adjec. *rāmāyaṇa*, concerning Rāma, sc. noun *ākhyāna*, story]: the name of a celebrated poem of ancient India. It is the first great Indic literary or personal epic, as distinguished from the popular epic, exemplified in the *Mahābhārata*. Much critical work is yet to be done ere all the specific problems concerning the genesis of the poem can be solved; but their ultimate solutions are sure to be most illuminating for the student of the genesis of epic poetry. Respecting the general theory of the origin of the poem, see Epic Poetry. The original nucleus of the *Rāmāyana* differs wholly from that of the Mahābhārata (*q. v.*) in two most important respects: First, it is the work of one man; and, second, it is of unitary design and character. The man is called Vālmīki—a fact quite bare of significance, as compared with the fact that he is namable; and whereas the *Bhārata* is inordinately episodical, and is in effect a great cyclopædia of Indic legend, the *Rāmāyana* concerns itself with the legends clustering about the one great name of Rāma.

Vālmīki's material (like that of the *Bhārata*) is truly popular. It consists of the legends of Rāma of the race of Ikshvāku in the land of Kosala. These were the subject of many little epic songs sung by the bards (*sūtas*) at the courts of the Ikshvāku princes. A Brahman, Vālmīki, of pre-eminent poetic gifts, made himself master of these songs, transfused them into a consistent whole, and so created an epos. This was learned by the professional rhapsodists, and by them recited in public. The date of the written redaction we do not know; but it was doubtless made while the institution of wandering minstrels or professional reciters of the poem was still in full vogue, and while their oral traditions of the poem possessed as much authority as the then extant written copies. It is probable that the fixation of the poem in writing took place independently in different localities, and that each of the now extant recensions is an independent reflex of one of the locally or otherwise varying oral traditions.

The most important recensions are three: One is the Bengal recension, edited by Gorresio; and another, the so-called "northern," which has the widest currency, and is the basis of the Bombay editions. The poem, like some mediæval cathedral, has suffered additions and changes at the hands of successive generations, but not in such wise as greatly to obscure its original compass and design. In its present forms the *Rāmāyana* consists of seven books, of which, however, the first and last are doubtless later additions. The seven books contain about 25,000 double verses—say about twice as much as the *Iliad* and *Odyssey* together; but Jacobi believes that a reconstructed text would contain, after casting out all provable additions, some 8,000 or 10,000 double verses.

Story of the Poem (after Monier-Williams).—To Daçaratha, King of Ayodhyā, by his three wives, are born four sons: Rāma, the eldest; and, by Kaikeyī, Bharata. Rāma is taken to the court of King Janaka, and by his strength, shown in bending a wonderful bow, wins for his wife Sītā. He returns, and preparations are made to install him as successor to his father's throne. Kaikeyī now demands of Daçaratha—by way of fulfillment of an old promise that he would grant her any two requests she might make—that Rāma be banished, and her own son Bharata be made king. Rāma dutifully goes into exile with Sītā. The king dies in grief. Bharata goes and proffers Rāma the kingdom, and is refused.

Sītā is carried off by Rāvana, the demon-king of Lankā. The ape Hanumant seeks and finds her. Rāma makes alliance with Sugrīva, king of the apes, and with his aid, and that of Vibhīshana, brother of Rāvana, he invades Rāvana's capital, slays him, and recovers Sītā. He then returns to Ayodhyā and assumes his crown.

Here are two parts fundamentally different. Up to Rāma's refusal of the kingdom all is natural, human, and possible. From the rape of Sītā on, all is unnatural and fantastic to the last degree. This instructive combination is an instance of what has taken place also among other peoples—the mingling of heroic-legendary elements with mythological elements. The first part gives us the story of Rāma as a popular hero; the second blends the conceptions of Rāma the hero with those of Rāma the divinity. As early as the Rig-Veda, Sītā appears as the personified Furrow. She is a genius of the corn-field and wife of the rain-god. The battles of Rāma and Rāvana are only another form of the battles of the rain-god Indra with the demon of drought. What to the nomad herdsman of Vedic times was a penning up of the heavenly waters, that was to the husbandman of epic times a carrying away of the goddess of their corn-fields. Hanumant, son of the wind-god, is a rain-god, the genius of the monsoon, who recovers Sītā, i. e. brings back to life the dead and parched fields.

Place and Date.—The place of the human part of the poem is Kosala, the region about Ayodhyā (Oudh). There is not the slightest allusion to the most important fact in the pre-Christian political history of India, the empire of the great Mauryan dynasty of the neighboring Magadhay, founded by contemporaries of Buddha, nor to its capital, Pātaliputra. In short, the whole political and geographical

background of the poem leads to the conclusion that the date of the original *Rāmāyana* can not be later than the fifth century B. C.

The Bengal recension was published by Gorresio, with Italian translation (12 vols., Paris, 1843–70). The "northern" recension has often been printed in India, especially in Bombay (1854, 1864, 1873, 1888); best and cheapest is the last (of 1888), by K. P. Parab, at the Nirnaya Sāgara Press. There is a good English translation by R. T. H. Griffith (5 vols., London, 1870–74). Excellent epitomes are given by Monier-Williams in his *Indian Epic Poetry*, pp. 60–90, and in his *Indian Wisdom*, pp. 337–361. A critical work is *Das Rāmāyana Geschichte und Inhalt, nebst Concordanz der gedruckten Recensionen*, by Hermann Jacobi (Bonn, 1893). This article endeavors to report some of his best results.

CHARLES R. LANMAN.

Ramazan' [Turk. Pers. *ramazān* = Arab. *ramadān*, name of a month, probably deriv. of *ramad*, be hot]: the Mussulman fast. It is incumbent on every adult believer unless specially exempt, and continues through the entire month of Ramazan, because in that month the Koran was revealed to the Prophet. No food or drink of any sort must enter the mouth from dawn, "from the moment one can distinguish a white hair from a black one," until sunset. One must neither smoke nor inhale perfumes, and must carefully abstain from swallowing his saliva. The Mussulman calendar being lunar, Ramazan in the space of thirty-three years traverses all the seasons. In summer it falls heavy upon the laboring classes; it is, however, observed in general with most accurate fidelity. As far as possible, night and day are made to change places, the mosques remain open all night, and the streets are thronged. It is terminated by the festival of the Kutchuk or Little Bairam, a period of rejoicing.

E. A. GROSVENOR.

Rambouillet, Hôtel de, ō′tel′de-raŭń′boo′yā′: the name generally given to a social circle which gathered around Catherine de Vivonne, Marquise de Rambouillet, and her daughter, Julie d'Angennes, Duchesse de Montausier. Catherine de Vivonne, a daughter of the Marquis of Pisani, French ambassador at Rome, by a Roman lady, was born in 1588 at Rome, and married in 1600 to the Marquis de Rambouillet. Offended by the tone and manners of the French court, she determined to form a court of her own. Her house soon became the place where all who had genius, wit, learning, talent, or taste assembled, and from these reunions originated the French Academy, the highest authority of French literature, and the salons, the most prominent feature of French civilization. The influence of the Hôtel de Rambouillet on conversation and language, manners and morals, was very great, and must, generally speaking, be called highly beneficial; but it occasioned imitations which were merely ridiculous. (See PRÉCIEUSES.) See Röderer, *Histoire de la Société polie en France pendant le 17e Siècle* (1835), and Charles Livet, *Précieux et Précieuses* (1859).

Revised by A. G. CANFIELD.

Rameau, raă′mō′, JEAN PHILIPPE: composer; b. Sept. 25, 1683, at Dijon, France, where his father was an organist; traveled from 1701 to 1717 in Italy and Southern France as violinist in the orchestra of a troupe of strolling actors; was appointed organist successively in Lille, Clermont, and Paris, and published in 1722 his *Traité de l'Harmonie*, in 1726 *Nouveau Système de Musique théorique*, and in 1732 *Dissertation sur les différentes Méthodes d'Accompagnement.* Having acquired by these works a great name as a reformer of theoretical music, he began composing for the stage. In 1732 his opera *Hippolyte et Aricie* had complete success, and he composed about twenty operas and ballets, besides minor pieces of music, which gave him rank beside Lully, who at that time reigned almost absolutely on the stage. D. in Paris, Sept. 12, 1764.

Ramen'ghi, BARTOLOMEO: painter; b. 1484; commonly called *Bagnacavallo*, from a town near Ravenna, where he was born. He was a pupil of Francia. Most of his remaining pictures are in Bologna; in S. Petronio a *Christ on the Cross*, several in fresco in other churches, and *Holy Family* in the Pinacoteca. D. 1542.

Rameses: See RAMSES.

Ram'ie, or **China Grass** [*ramie* is from Malay]: the fiber of *Bœhmeria nivea*, an Asiatic plant of the family *Urticaceæ.* This fiber is stronger than hemp and more durable when woven than linen. The fabric known as grass cloth is made in China from this fiber. Ramie-fiber, superior in quality even to that of Java, has been produced in the southern parts of the U. S. It can be harvested three times a year, producing in all some 1,500 lb. of fully prepared ramie per acre. It is perennial, requires comparatively little labor and attention, has few insect enemies, and stands a rainy season or a drought with little injury. A new process of preparing it for manufacture has been discovered in the U. S.

Rammohun Roy: scholar; b. at Burdwan, Bengal, about 1774; belonged to a wealthy Brahmanical family; studied Sanskrit, Persian, and Arabic; resided for some time in Tibet; edited *The Bengal Herald* in English: was in 1830 sent to the British court from the sovereign of Delhi. D. at Bristol, Sept. 27, 1833. He early renounced the Brahmanical faith. Much attention was attracted in 1820 to his *Precepts of Jesus, the Guide of Peace and Happiness*, published in English, Sanskrit, and Bengalee, and written from a Unitarian standpoint. He founded the BRAHMO SOMAJ (*q. v.*).

Ra'moth Gil'eăd [from Heb. *Rāmōth*, liter., high things, heights + *Gile'adh*, liter., hard, stony region (or hill of witness)]: first mentioned in Deut. iv. 43; a Levitical city and one of the three cities of refuge on the east side of the Jordan (see map of Palestine, ref. 8–F). Ahab, seventh King of Israel, fell in battle there about 897 B. C., and his son Jehoram, ninth King of Israel, was severely wounded there about 884. It is commonly identified with Es-Salt (Arabic adaptation of *Saltus Hieraticus*, sacred forest), about 23 miles N. E. of Jericho, up the wadi Shaib, only 2 or 3 miles from the summit of Jebel Osh'a, the view from which is considered the finest in Palestine. Es-Salt has a population of about 4,000, of whom 500 are Christians. It seems better, however, to identify it with Jal'ud, which is the equivalent of Gilead. It lies about 5 miles N. of Es-Salt.

Rampart: See FORTIFICATION.

Rampur: a native state of India under the protection of the Indian Government; in the Northwest Provinces, between 28° 26′ and 29° 10′ N. lat., and between 78° 54′ and 79° 33′ E. lon. (see map of N. India, ref. 5–E). It is a hot, fertile, and unhealthful region. Area, 945 sq. miles. Pop. (1891) 551,242. Its capital, Rampur, consists mostly of mud huts, and is famous for fine shawls. Pop. (1891) 76,733.

Ramsauer, JEAN: See the Appendix.

Ramsay, ALLAN: poet; b. at Leadhills, Lanarkshire, Scotland, Oct. 15, 1686; was in early life a wigmaker at Edinburgh; afterward became a bookseller, and printed many poems, Scottish and English, usually on "broadsides" or single sheets. He ultimately acquired considerable celebrity, and his bookshop having become a favorite resort of the literary men of Edinburgh, he enlarged his business, becoming a publisher, and started the first circulating library in Scotland. The first collected volume of his poems appeared in 1720; others were soon added, of which the most popular were *The Tea-table Miscellany* (4 vols., 1724), *The Gentle Shepherd, a Scots Pastoral Comedy* (1725), and *A Collection of Thirty Fables* (1730). To him must be credited the preservation of many relics of ancient Scottish literature. In 1724 he published *The Evergreen*, an important collection of old Scotch songs. D. in Edinburgh, Jan. 7, 1758. The best edition of his poetical works is that of George Chalmers (London, 2 vols., 1800; new ed. Paisley, 1874).—His son, ALLAN, b. in Edinburgh in 1713, was an eminent portrait-painter at London; became principal painter to George III. 1767, and was at one time considered (though without reason) a rival of Sir Joshua Reynolds. He figured in literary circles as a friend of Dr. Johnson, and published some pamphlets and essays, chiefly political. D. at Dover, Aug. 10, 1784.

Revised by H. A. BEERS.

Ramsay, Sir ANDREW CROMBIE, LL. D., F. R. S.: geologist; b. in Glasgow, Scotland, Jan. 31, 1814; educated at Glasgow; appointed a member of the Geological Survey of Great Britain 1841; Professor of Geology at University College, London, 1848; lecturer at the Royal School of Mines 1851; was president of the Geological Society of London 1862–63, and of the British Association for the Advancement of Science 1880; became director-general of the Geological Survey 1872; was knighted in 1881. He was the author of numerous memoirs on theoretical questions in geology; of works on the geology of Arran (1841), North Wales (1858), and Switzerland (1860); of *Physical Geology and Geography of Great Britain* (1863); and of a large *Geological Map of England and Wales* (1859). D. Dec. 9, 1891.

Revised by G. K. GILBERT.

Ramsay, David, M. D.: physician and author; b. in Lancaster co., Pa., Apr. 2, 1749; graduated at Princeton 1765; studied medicine at the University of Pennsylvania; settled as a physician at Charleston, S. C., 1773; served in the war of the Revolution as a field-surgeon, participating in the siege of Savannah; was a leading member of the South Carolina Legislature 1776–83, and of the council of safety at Charleston, on the capture of which city he was treated by the British as a hostage and kept eleven months in close confinement in St. Augustine, Fla., 1780–81; was a member of the Continental Congress 1782–84, and again 1785–86; was acting president of Congress during most of the latter period, on account of the sickness of Hancock; published a *History of the Revolution of South Carolina* (2 vols., Trenton, 1785), *History of the American Revolution* (2 vols., Philadelphia, 1789), a *Life of Washington* (New York, 1807), a *History of South Carolina* (Charleston, 1809), and *History of the United States 1607–1808* (3 vols., Philadelphia, 1816–17), besides medical and other essays. His first wife was a daughter of President Witherspoon, of Princeton; his second was Martha, daughter of Henry Laurens, and of her he published a memoir in 1811. During the last fourteen years of his life Dr. Ramsay was a member of the South Carolina Legislature, and for much of the time president of the Senate. D. in Charleston, May 8, 1815.

Ramsay, Francis Munroe: See the Appendix.

Ramsay, William Mitchell, D. C. L.: scholar; b. in Glasgow, Scotland, Mar. 15, 1851; was educated at the Universities of Aberdeen, Oxford, Göttingen, and Berlin; held the traveling studentship of Oxford University in 1879; was fellow of Exeter College in 1882; resided and traveled in Asia Minor 1880–84, and made frequent excursions to that land 1885–91; was Lincoln Professor of Classical Art and Archæology in Oxford 1885; and since 1886 has been Professor of Humanity in Aberdeen University. Dr. Ramsay has published numerous articles in magazines of Europe and the U. S.: *Historical Geography of Asia Minor* (1890); *The Church in the Roman Empire before 170 A. D.* (1893); and *St. Paul's Travels: the Narrative, its Author, and Date*; Morgan lectures in Theological Seminary, Auburn, N. Y. (London, 1895). C. K. Hoyt.

Ram'ses, or **Ram'eses** (Egypt. *Rā-messu*): the name of thirteen Kings of Egypt belonging to the nineteenth and twentieth dynasties. Ramses I., the first king of the nineteenth dynasty, ascended the throne at the close of a period of confusion consequent upon the religious reforms attempted by Khunaten (*q. v.*), during which the Nubians and the Shasu or Eastern nomads had thrown off the yoke of Egypt. All that is known of him is that he waged war in a small way in Nubia, where he left memorial stelæ; that he made a treaty with the Hittites; and that he did some building at Thebes, where he commenced the great hypostyle hall at Karnak. His chief claim to distinction is that he was the father of Seti I., one of the greatest of Egyptian warriors and conquerors, who claimed to have extended his sway till it included all that Thothmes III. had held. Seti thus handed on a united and powerful kingdom to Ramses II., whom he had already associated, in his twelfth year, with himself as king. Ramses II. ruled for sixty-six or sixty-seven years. He was a powerful monarch, a great builder, and a liberal patron. The Greek writers ascribed to him many wonderful deeds under the name of Sesostris, but this name was a sort of conglomerate in which the personalities of several kings were combined, such, e. g., as Usertasen II. of the twelfth, Ramses II. of the nineteenth, and Ramses III. of the twentieth dynasty. The name of Ramses II. is found on monuments or buildings from Beirut to Napata and from one end of Egypt to the other, as well as throughout the length of Nubia. (See Ipsambul.) In many cases, however, his name was inserted in the inscriptions of other kings by a process of usurpation in which he was the worst offender in Egyptian history. His principal residence appears to have been at Tanis, where he erected a granite temple which he adorned with a colossal statue of himself. At Thebes he erected the Ramesseum, besides extending the buildings of his predecessors. He built also at Abydos (see Memnonium), at Memphis, and Heliopolis, besides a multitude of other places. The Ramesseum, a large temple on the W. of the Nile opposite Karnak, was devoted to the worship of the manes of the great Ramses. On its walls were inscribed the accounts of his wars, especially the account of the expedition against the Hittites which is commemorated in the famous poem of Pentaur.

His warlike operations began while he was coregent with Seti I., when he led expeditions into Nubia and Libya. Near Beirut are inscriptions which record his advance to that point in his second and fourth years. In his fifth year he marched against the Hittites, whose principal seat was in the region about Carchemish. With them were allied all the peoples of the entire region. At Kadesh, on the Orontes, battle was joined, and in the conflict Ramses was successful over Mâutenure, the Hittite king, largely by reason of his personal daring and prowess, if we may credit the monumental record. In his eighth year another expedition was undertaken against certain cities in Palestine, Ascalon being the principal place captured. In his twenty-first year Ramses entered into an offensive and defensive alliance with Chetasar, the Hittite king, and to confirm this treaty, which remained in force during the rest of his reign, he took to wife the daughter of the Hittite. In consequence, more intimate relations of friendship and trade were established between Egypt and the East. After a reign of sixty-seven (Josephus, sixty-six) years, Ramses died, and was succeeded by his son Meneptah (Egypt. *Mer-en-Ptah*, beloved of Ptah), who is usually regarded as the Pharaoh of the Exodus, under whom the kingdom rapidly lost prestige.

Ramses III. was the second king of the twentieth dynasty, and ten others bearing the same name followed in immediate succession. The period which preceded the reign of Ramses III. was almost one of anarchy, and in it even a Syrian appears to have succeeded in gaining temporary royal power. During the period following his death the power exercised by the priests was such as to lead to a speedy deterioration of the kingdom, and to a final usurpation of the throne by Her-Hor (*q. v.*), the priest-king. Ramses III. waged war with the Libyans and with his neighbors to the N. E., the Hittites and their allies, while Punt and Ethiopia were forced to pay tribute. His reign was brilliant, and was commemorated on the walls of Ramses's memnonium at Medinet Habu (*q. v.*), at Thebes, which in its various extensions presented the annals of the king. For ethnological purposes its mural decorations, giving life-like portraits of prisoners taken in war, are very valuable. See Petrie's *Racial Types from Egypt* (1887).

The most notable events of the following reigns were the thefts practiced in the necropolis at Thebes and elsewhere, in the times of Ramses IX. and X., which were made the subject of investigations. The results of these inquiries have come down to us, showing the extent of the depredations.

The mummies of the first three Ramses are at the Gîzeh Museum, having been among those found in 1881 near Deir el-Bahri, W. of Thebes. Charles R. Gillett.

Ramses, or **Raamses**: the name given in Ex. i. 11 to one of the "store-cities" built by the Israelites for the Pharaoh of the Oppression, who usually has been identified with the great Ramses II. of the nineteenth dynasty. Its location is unknown, but it was probably a frontier town like Pithom (*q. v.*). By some it is supposed to have been located in the Wadi Tumilat, W. of Pithom, while others identify it with Tanis, which in some inscriptions bears the name Pi-Ramses, dwelling or house of Ramses. C. R. G.

Ramsgate: town; in the county of Kent, England; on the southeast coast of the Isle of Thanet; 72 miles E. by S. of London (see map of England, ref. 12–L). It is an important fishing-station, with a harbor of refuge 51 acres in extent inclosed between two piers. Among its features are an iron promenade-pier, a beautiful Roman Catholic church designed by Pugin, a Benedictine monastery, and a Jewish college. It is much frequented as a watering-place by Londoners. Pop. (1891) 24,676.

Ramus, Petrus (Fr. *Pierre de la Ramée*): humanist and mathematician; b. at Cuth, department of Somme, France, in 1515, in humble circumstances; studied under great difficulties at the University of Paris, and published in 1543 his *Animadversionum in Dialecticam Aristotelis Libri XX.* and *Institutionum Dialecticarum Libri III.*, in which he attacked Aristotle and the scholastic method of philosophizing with great boldness. The university, the Church, the Parliament, took great offense; the books were condemned, and the author forbidden to teach. By the favor of the king he was nevertheless afterward appointed at the university, and continued till his death his opposition against the empty subtleties of the philosophy of his time. Among other works were *Geometria* (1569) and *Scholæ Mathematicæ* (1569). In 1561 he embraced Protestantism,

and was killed in the massacre of St. Bartholomew, Aug. 24, 1572. See Waddington, *Pierre de la Ramée* (Paris, 1855); Lobstein, *Petrus Ramus ats Theolog* (Strassburg, 1878).

Rancagua, răăn-kaa'gwăă: city; capital of the province of O'Higgins, Chili; near the river Rapel; 43 miles by rail S. of Santiago (see map of South America, ref. 8–C). It is the center of a rich agricultural district, and is noted as the scene of one of the most important events of the war for independence. The patriot Gen. O'Higgins was besieged here by the Spaniards under Osorio, and help promised by Carrera did not arrive. After two days' battle in the streets (Oct. 1–2, 1814) O'Higgins escaped with only a fragment of his force, leaving the town in ruins. This disaster ended the first republic. Pop. about 8,000. H. H. S.

Rancé, răăń'sā', Dominique Armand Jean Lebouthillier, de: founder of the order of Trappists; b. in Paris, Jan. 9, 1626; enjoyed while yet a boy several large ecclesiastical benefices, and was ordained a priest in 1651, but led, nevertheless, a very dissipated life until in 1660 he gave all his property to the poor, renounced his benefices, and retired to the monastery of La Trappe, of which he became abbot in 1663. He introduced rules of the severest asceticism and founded what was practically a new order. D. Oct. 27, 1700. He wrote *Traité de la Sainteté et des Devoirs de la vie monastique* (1683) and *Relation de la Vie et de la Mort de quelques Religieux de ta Trappe* (4 vols., 1696). See Marsollier, *Vie de Rancé* (1703); Gaillardin, *Trappistes* (1844); Pfannenschmidt, *Geschichte der Trappisten* (1873); and *The Century Magazine* (Aug., 1888).

Randall, Alexander Williams: lawyer and public official; b. at Ames, Montgomery co., N. Y., Oct. 31, 1819; studied law; settled at Waukesha, Wis., 1841; became postmaster of that town and its representative in the Legislature; was judge of the second district 1856; Governor of Wisconsin 1857–61; rendered eminent service in raising volunteers at the beginning of the civil war; minister to Italy 1861–65; Assistant Postmaster-General 1865–66, and Postmaster-General 1866–69, after which he practiced law at Elmira, N. Y. D. at Elmira, July 25, 1872.

Randall, James Ryder: journalist; b. in Baltimore, Md., Jan. 1, 1839; received his education at Georgetown College, D. C. Traveled for his health in South America and subsequently removed to New Orleans, where he was employed on the Sunday *Detta*. His popular Southern war song, *Maryland, my Marytand*, was published in Apr., 1861. Other poems from his pen were *The Sole Sentry*, *Arlington*, and *There's Life in the Old Land Yet*. In 1866 he became editor-in-chief of *The Constitutionalist* at Augusta, Ga., which position he held for many years. Revised by H. A. Beers.

Randall, Samuel Jackson, LL. D.: statesman; b. in Philadelphia, Pa., Oct. 10, 1828. He received an academic education; engaged in mercantile business; and entered political life at an early age. He was a member of the city council for several years; State Senator in 1858–59; elected to Congress as a Democrat in 1862; and by re-elections held his seat till his death, in Washington, D. C., Apr. 13, 1890. For many years he was chairman of the House committee on appropriations and member of the committee on rules. In 1876, 1877, and 1879, he was elected Speaker of the House of Representatives, and in 1883 was defeated. He was widely known as a leader of his party, as a political debater, and as a parliamentarian.

Randolph: town (incorporated in 1793); Norfolk co., Mass.; on the N. Y., N. H. and Hartford Railroad; 15 miles S. of Boston (for location, see map of Massachusetts, ref. 3–I). It contains a public library, founded in 1876 by the heirs of Royal Turner, built of Randolph and Quincy granite, and containing over 13,000 volumes; a high school founded on a bequest by Amasa Stetson; several grammar and primary schools; a savings-bank with deposits of over $1,000,000; a weekly newspaper; and manufactories of boots, shoes, harness, steel-roller forgings, and boxes. Pop. (1880) 4,027: (1890) 3,946; (1900) 3,993.

Editor of "Register and Holbrook News."

Randolph: village (settled in 1820); Cattaraugus co., N. Y.; on the Erie Railroad; 17 miles E. of Jamestown, 52 miles S. of Buffalo (for location, see map of New York, ref. 6–C). It is in an agricultural and dairying region, has manufactories of furniture and prepared paint, and contains five churches, the Chamberlain Institute (Methodist Episcopal, opened in 1849), the Western New York Home for Orphan Children, a State bank with capital of $50,000, and a weekly newspaper. It was settled as a trading-point for lumbermen on the Alleghany river, 6 miles S. Pop. (1880) 1,111; (1890) 1,201; (1900) 1,209.

Randolph: town (comprising the villages of Randolph Center, and North, South, East, and West Randolph); Orange co., Vt.; on a branch of the White river, and on the Central Vermont Railroad; 28 miles S. of Montpelier (for location, see map of Vermont, ref. 5–C). It is in an agricultural region, is the seat of a State normal school, and has 2 Congregational, 2 Methodist Episcopal, 2 Protestant Episcopal, and Baptist, Christian, and Roman Catholic churches, high and graded schools, a national bank with capital of $75,000, a savings-bank, and 2 weekly and 2 monthly periodicals. Of the group of villages West Randolph contains the railway-station, and is the business center. The town has a large farming trade, and manufactures of butter-tubs, screens, lumber, and woodwork. Pop. (1880) 2,910; (1890) 3,232; (1900) 3,141. Editor of "News and Herald."

Randolph, Edmund Jennings: statesman; b. at Williamsburg, Va., Aug. 10, 1753; nephew of Peyton and son of John Randolph, attorney-general of Virgina, a leading royalist; studied law; entered the Continental army at Cambridge as an aide to Gen. Washington Aug., 1775; represented Williamsburg in the Virginia convention of May, 1776; became attorney-general of the State in July; was a delegate to the Continental Congress 1779–83, and to the convention which formed the Federal Constitution 1787; presented to that body the so-called "Virginia plan," but without success; refused to sign the Constitution, though he advocated its ratification in the Virginia convention; was elected Governor of Virginia 1788; was the first attorney-general of the U. S. on the organization of the Federal Government 1789; succeeded Jefferson as Secretary of State 1794, and resigned in Aug., 1795, in consequence of disapproval by his colleagues of his dealings with the minister of the French republic, on which subject he published a *Vindication of Mr. Randotph's Resignation* (Philadelphia, 1795). D. in Frederick co., Va., Sept. 12, 1813. An interesting description of his person, character, and public services was given by William Wirt in his *British Spy*. Also see Conway, *Omitted Chapters of History, disctosed in the Life and Papers of Edmund Randolph* (New York, 1888).

Randolph, John, of Roanoke: statesman; b. at Cawsons, Chesterfield co., Va., June 2, 1773; studied law at Philadelphia under Edmund Randolph; was elected to Congress as a Democrat in 1799, and re-elected, with the exception of two terms, until 1825; was chairman of the committee of ways and means 1801; was the chief manager of the impeachment of Judge Chase 1804; became conspicuous for his wit and eloquence, no less than for the bitterness of his speech and his numerous eccentricities; was prominent as a champion of State-rights and as a partisan of Jefferson's administration until 1806, when he separated from his political associates, opposed the election of Madison, the embargo, and the war with England in 1812, in consequence of which he was defeated in that year in his candidacy for re-election, but was returned at the election of 1814; opposed the Missouri Compromise with great vehemence, fastening upon its Northern supporters the epithet "doughfaces"; visited England in 1822, and again in 1824; sat in the U. S. Senate 1825–27; had a duel with Henry Clay, Apr. 8, 1826, growing out of his denunciation of the political alliance between the latter and J. Q. Adams; supported Gen. Jackson in the election of 1828; sat in the convention of 1829 for revising the constitution of Virginia; went as minister to Russia 1830, but spent most of his time in London; returning in 1831, was again elected to Congress 1832, but before taking his seat died in Philadelphia, Pa., June 24, 1833. He was never married. By his will he emancipated and provided for his slaves, numbering over 300. Several biographies have been published, among which are that by Hugh A. Garland (1850) and that by Henry Adams (1882).

Randolph, Peyton: statesman; b. in Virginia in 1723; graduated at William and Mary College; studied law at the Temple in London; was appointed in 1748 royal attorney-general for Virginia; was elected to the house of burgesses; became chairman of a committee to revise the laws of Virginia; framed the remonstrance of the house of burgesses to the king against the passage of the Stamp Act 1764, but after its passage discountenanced Patrick Henry's celebrated "five resolutions" 1765; resigned the office of attorney-general in 1766, and was Speaker of the house of burgesses for several years thereafter; was chairman of the

committee of vigilance chosen Mar. 10, 1773, and an efficient worker in promoting through correspondence a concert of action with the other colonies; presided over the Virginia convention at Williamsburg, Aug., 1774; was chosen a delegate to the Continental Congress; was first president of that body upon its meeting at Carpenters' Hall, Philadelphia, Sept. 5, 1774, though from ill-health he soon resigned that post; presided over the second Virgina convention at Richmond, Mar. 20, 1775; was again chosen president of the Continental Congress when it reassembled at Philadelphia, May 10, 1775, but resigned May 24, returning to Virginia to preside over the house of burgesses; resumed his seat in Congress a few months later. D. in Philadelphia, Oct. 22, 1775.

Randolph, THOMAS: poet; b. near Daventry, England, in 1605; d. 1635. He was educated at Westminster and at Trinity College, Cambridge, of which he became a fellow. His plays include *Amyntas*, a pastoral comedy, and *The Muses' Looking-glass*, a morality in defense of stage-plays. His best-known poem is his *Ode to Sir Anthony Stafford*. He was a friend and disciple of Ben Jonson. H. A. B.

Randolph-Macon College: an educational institution chartered in 1830 and opened in 1832, endowed and sustained by the Virginia and Baltimore conferences of the Methodist Episcopal Church South. It was first located in Mecklenburg co., Va.; suffered severely during the civil war, and was removed in 1866 to Ashland, Hanover County, and re-endowed.—RANDOLPH-MACON WOMAN'S COLLEGE, Lynchburg, Va., is an endowed institution for women with courses of instruction parallel to those for men at Ashland. It was founded in 1891.—RANDOLPH-MACON ACADEMY, Bedford City, Va., was established in 1889 as a fitting school for the college; and RANDOLPH-MACON ACADEMY, at Front Royal, Va., practically a duplicate of the one at Bedford City, was established in 1891. These institutions are all under one president, and controlled by one board of trustees.

Range-finders and Position-finders: See the Appendix.

Rangoon': chief city of Burma, and third port in importance in British India; on the eastern arm of the Irawadi delta, 20 miles from its mouth (see map of S. India, ref. 4–L). It is in unimpeded connection with the main stream and with the coast, and is accessible for large craft. It is the center of a system of canals, and the terminus for two railways running northward, one to Prome, the other to Mandalay. It is provided with street-cars, fire brigades, and other modern improvements; but is badly built and unsanitary, with the houses often on bamboo piles, and the narrow streets intersected by canals. The teak forests in the region about it and the excellent character of the port early caused the development of a considerable ship-building industry, which has latterly declined. The principal exports are rice, teak, cotton, spices, and skins. Rangoon is the chief port of importation for the trade of Upper Burma and Yunnan. The city has few noteworthy buildings or monuments, but near by is the Shway-Dagôn Pagoda, a massive and imposing structure, with a tower 321 feet high capped by an enormous gilded crown and containing a bell weighing 30 tons. The pagoda is the repository of eight hairs from the head of Gautama Buddha, and is a favorite object of pilgrimage and seat of an annual fair.

Rangoon was in 1753 selected by Alompra as capital of Pegu, and given its present name *Ran-kun*, or "end of the war." Before that it was named after the pagoda, which was built, according to tradition, about 585 B. C. The city was occupied by the British in 1821, but soon returned to the Burmese. It was again taken in 1852, and has since been held by the British. It has prospered under their rule, and the population increased from 25,000 in 1852 to 180,324 in 1891. The city forms a separate administrative district of 22 sq. miles. The population is chiefly Buddhist.

MARK W. HARRINGTON.

Rangpur': district of Bengal, British India; between 25° 16′ and 26° 21′ N., and bounded E. by the Brahmaputra. Area, 3,486 sq. miles. Pop. 2,100,000. The surface is very low, and in the wet season entirely inundated. Cotton does not succeed. Indigo is the principal product; fifty large factories are in operation, M. W. H.

Ran'idæ [Mod. Lat., deriv. of Lat. *ra'na*, frog]: the family of anurous batrachians which contains the true frogs.

Ran'ke, JOHANNES, M. D., Ph. D.: physiologist and anthropologist; b. at Thurnau, Bavaria, Aug. 23, 1836; studied at the Universities of Munich, Tübingen, Berlin, and Paris, graduating M. D. in 1861 at the first named, from which he received Ph. D. in 1882. He was appointed Extraordinary Professor of Physiology in the University of Munich in 1869. He was the co-editor of the *Beiträge zur Anthropologie und Urgeschichte Bayerns* (1877); and has been editor of the *Archiv für Anthropologie* since 1882. His principal work is *Grundzüge der Physiologie des Menschen*.

S. T. ARMSTRONG.

Ranke, LEOPOLD, von: historian; b. at Wiehe, Thuringia, Dec. 21, 1795; studied at Halle and Berlin; was appointed teacher at the gymnasium of Frankfort-on-the-Oder in 1818, and Professor of History at the University of Berlin in 1825. His principal writings are *Geschichte der romanischen und germanischen Völker von 1494–1535* (1824); *Fürsten und Völker von Südeuropa im 16. und 17 Jahrhundert* (1827); *Die serbische Revolution* (1829), one of his most brilliant productions; *Ueber die Verschwörung gegen Venedig im Jahre 1688* (1831); *The Popes of Rome, their Church and State* (3 vols., 1834–37; translated into English by Mrs. Austin in 1840, by Scott in 1846, and by E. Foster in 1848); *History of Germany in the Time of the Reformation* (6 vols., 1839–47; translated into English by Mrs. Austin); *Memoirs of the House of Brandenburg, and History of Prussia during the Seventeenth and Eighteenth Centuries* (3 vols., 1847–48; translated into English by Sir A. Duff Gordon); *Jahrbücher des deutschen Reichs unter dem sächsischen Hause* (3 vols., 1837–40); *Französische Geschichte vornehmlich im 16. und 17. Jahrhundert* (5 vols., 1852–55); *A History of England principally in the Seventeenth Century* (6 vols., 1859–68; English translation 1875); *Geschichte Wallensteins* (1869); *Weltgeschichte* (1881–88). The complete edition of his works comprises forty-seven volumes. His very first productions immediately attracted great attention, both on account of the high merit of their style and composition, and on account of the ingenuity evinced in gathering and sifting the materials. It is also to this latter point that the expression "the school of Ranke" principally refers—to the method of studying history rather than that of writing it. D. in Berlin, May 23, 1886.

Rankine, JOHN: See the Appendix.

Rankine, WILLIAM JOHN MACQUORN: physicist and engineer; b. in Edinburgh, Scotland, July 5, 1820. In his early education his father, a retired lieutenant of the rifle brigade, was his chief instructor. He early displayed fondness for the natural sciences, and was fortunate in having the eminent Prof. J. D. Forbes as his tutor in natural philosophy. To him he dedicated his earliest and a somewhat remarkable paper, advocating the use of cylindrical wheels for railway carriages. Civil engineering naturally attracted his attention, and from 1841 to 1851 he was employed on the railways of Scotland. One of the most noticeable of his physico-mathematical researches was based on an hypothesis of "molecular vortices," by which was deduced the laws of elasticity, and of heat as connected therewith; from this he took at once prominent rank as an original investigator. His theoretical results, conforming closely to those subsequently obtained experimentally by Regnault and Dr. Ure, were in their ultimate form published in *The Philosophical Magazine*, Dec., 1851 (*On the Centrifugal Theory of Elasticity as applied to Gases and Vapors*). Important papers on kindred subjects succeeded this, among which are *On a General Law of the Transformation of Energy* and *Outlines of the Science of Energetics*. In 1855 Rankine became Regius Professor of Civil Engineering and Mechanics in the University of Glasgow. Soon after taking the chair he turned his attention to the production of a series of manuals for engineering students and practical men. D. in Glasgow, Dec. 24, 1872.

Ransom, MATTHEW WHITAKER: U. S. Senator; b. in Warren co., N. C., Oct. 8, 1826; graduated at the University of North Carolina, and admitted to the bar 1847; became a planter and politician; attorney-general of North Carolina 1852–55; member of the Legislature 1858–60; commissioner to the Montgomery convention 1861; entered the Confederate service as lieutenant-colonel; rose to be major-general; surrendered at Appomattox Court-house; elected as a Democrat in Jan., 1872, to the U. S. Senate for the term expiring in 1877; re-elected for 1877–83, 1883–89, and 1889–95; U. S. minister to Mexico Aug. 29, 1895–97.

Ransom, ROBERT: officer; b. in North Carolina, Feb., 1829; graduated at the Military Academy, and promoted brevet second lieutenant of First Dragoons July 1, 1850; became captain First Cavalry Jan., 1861, resigned May 24, 1861, and

joined the Confederate army, in which he became a major-general, serving with distinction throughout the civil war along the seaboard and in the Army of Northern Virginia. After the war he engaged in mercantile pursuits and farming until 1878; was civil engineer in the service of the U. S. on works of river and harbor improvements from 1878 until his death Jan. 14, 1892. JAMES MERCUR.

Ransom, THOMAS EDWARD GREENFIELD: soldier; b. at Norwich, Vt., Nov. 29, 1834; educated at Norwich University, a military institute presided over by his father; became in 1851 a civil engineer; later a real-estate agent at Chicago; raised a company of volunteers in Apr., 1861; elected major of the Eleventh Illinois Volunteers, and lieutenant-colonel of the same regiment on its reorganization in July; distinguished himself in the surprise of Charleston, Mo., on the night of Aug. 19, when he was severely wounded; was at the capture of Fort Henry; made colonel for gallantry in the assault upon Fort Donaldson; distinguished at the battle at Shiloh; became chief of staff to Gen. McClernand and inspector-general of the Army of the Tennessee June, 1862; afterward on Gen. Grant's staff near Vicksburg; appointed brigadier-general to date from Nov., 1862; took part in the Red river campaign, commanding McClernand's corps during that general's illness, and in the Atlanta campaign at the head of a division, and subsequently in command of the Seventeenth Corps. D. at Rome, Ga., Oct. 29, 1864.

Ransome Stone: See STONE.

Ranun'culus [Lat. for a little frog or tadpole, applied to certain plants, probably because they grow where tadpoles abound]: a genus of herbaceous dicotyledons of the CROWFOOT (*q. v.*) family. The flowers, which are mostly yellow, have five sepals, five petals, many stamens, and many separate flattened pistils each with a solitary erect seed. About 200 species are known, widely distributed in all parts of the world, and of these more than one-fourth occur in North America. *R. aconitifolius* and *R. asiaticus* are the ranunculi of gardens, cultivated for their flowers, in which the stamens have been changed to petals. The common buttercups, with bright yellow flowers, are *R. acris* and *R. bulbosus*, naturalized in the U. S. from Europe. Among the common species indigenous to the U. S. are *R. septentrionalis*, with large yellow flowers, *R. sceleratus*, *R. abortivus*, with small yellow flowers, and *R. delphinifolius*, an aquatic with divided leaves and yellow flowers. The common white-flowered aquatic species with dissected leaves has recently been placed in the allied genus *Batrachium* under the name *B. Trichophyllum*. The small-flowered, creeping buttercup, common in wet places, has likewise been removed to an allied genus, *Cyrtorhyncha*, as *C. cymbalaria*. CHARLES E. BESSEY.

Ranvier, rȧȧn'vi-ā', LOUIS, M. D.: pathologist; b. at Lyons, France, in 1835; graduated M. D. from the Paris School of Medicine in 1865; was appointed to the chair of histology in the College of France. Among his works are *Traité technique d'histologie* (Paris, 1875); *Leçons sur l'histologie du système nerveux* (1878); and, with Cornil, *Manuel d'histologie pathologique* (1869–72). S. T. A.

Ranz des Vaches, rȧȧnz'dā-vaash' [Swiss Fr. (: Fr. *rangs des vaches*), liter., rows of cows]: the name of the melodies which the Swiss herdsmen play upon their alp-horn.

Rapallo, CHARLES A.: See the Appendix.

Rape: See JURISPRUDENCE, MEDICAL.

Rape [from Lat. *ra'pa*, beet, turnip]: the *Brassica napus*, a plant of the family *Cruciferæ*, and closely related to the Swedish turnip and colza, from which it may be distinguished most easily by the fact that its young leaves are smooth and glaucous-blue. The navew is of the same species as the rape. Rape is largely raised in Europe for the oil of its seeds. Its stalks are valuable forage, and are good to plow under for manure. Its oil-cake is used as sheep-food and as a fertilizer. The oil is used for machinery, for lighthouse lamps, etc., and the seed is fed to cage-birds. Lately it has been recommended in the U. S. for pasture and as a soiling crop. Revised by L. H. BAILEY.

Raphael [from Heb. *Rĕfāĕl*, God heals, through the Greek Ῥαφάηλ, as the name of a man, 1. Chron. xxvi. 7]: according to the Apocrypha, one of the chief angels. In the book of Tobit he is "one of the angels which present the prayers of the saints" (xii. 15). He binds Asmodeus, accompanies Tobias on his journey, and brings healing to Tobit. A similar *rôle* is attributed to him in the book of Enoch. Raphael binds Azazel, one of the fallen angels, stands near the Eternal One, is the angel of the spirits of men, heals the earth, and "is set over all the diseases and wounds of the children of men" (x. 7; xx. 3; xl. 5; liv. 6; lxxxviii. 1). In Jewish theology Raphael is also one of the chief angels—the patron of the healing art. In the Midrash he is said to have been one of the three angels sent to Abraham. Catholic theology formally accepted him as one of the archangels at the council of Rome (745) and of Aix-la-Chapelle (759). See *The Apocrypha*, ed. Wace (London, 1888, i., p. 171); Brecher, *Das Transcendentale, Magie und magische Heilarten im Talmud* (Vienna, 1850); Hamburger, *Real-Encyct. für Bibel und Talmud* (ii., 966); Weber, *System der Altsynagog. Paläst. Theologie* (Leipzig, 1880, p. 164); Rönsch, *Buch der Jubiläen* (pp. 385, *seq.*). RICHARD GOTTHEIL.

Raphael, or **Raffaello**: the name by which *Raffaello Sanzio*, or *Santi*, the painter, is usually known. He was born at Urbino, Italy, Apr. 6, 1483, and probably received his first instruction in art from his father, Giovanni Santi, who died when he was eleven years of age, leaving him to the care of his uncles. It is uncertain who directed the young Raphael's studies after his father's death to the time he entered Perugino's studio at Perugia about 1500 or a little earlier. Some writers mention Timoteo della Vite, others Signorelli. Perugino's influence is evidently predominant in the first work to which we can fix a date, the *Marriage of the Virgin*, commonly called the *Sposatizio*, painted in 1504, now in the Brera at Milan. At this period of his studies Raphael went to Florence, and the work of the great masters living there became known to him; on his return to Perugia he painted in 1507 the *Entombment* for the Baglioni family. In this picture (now in the Borghese gallery at Rome) he shows the influence of Florentine art. His fame as one of the most promising artists of the day was established, and he was called to Rome by Julius II. to carry out the grand schemes for the decoration of the Vatican in 1508. The hall of the Segnatura was the first committed to him; in this he painted the so-called *Disputa del Sacramento* and the *School of Athens*, besides adorning the vault with allegorical figures. The pope was so well satisfied that he commissioned Raphael to decorate the remaining rooms. The designs were made by Raphael, who painted the most important parts and put in final touches; but he was greatly assisted by Giulio Romano, Francesco Penni, Giovanni da Udine, and Perino del Vaga. The Sala di Costantino was painted after his death by his pupils. Besides the work at the Vatican, Raphael finished other important pictures in the course of twelve years. Of these the principal are the Madonnas *di Foligno*, *del Pesce*, *della Sedia*, *di S. Sisto*, *di Loreto*, *dell' Impannata*, and *La Perla*; the *Santa Cecilia*; *Lo Spasimo*, the *Transfiguration*; the frescoes of the Sibyls in Santa Maria della Pace, the Psyche frescoes, and the *Galatea* in the Farnesina, the cartoons for the Sixtine tapestries, besides innumerable subjects for engraving. Raphael also was distinguished as a portrait-painter. Leo X., who succeeded Julius II. in 1513, continued to treat Raphael with the highest favor. At the death of Bramante, the year following this pope's accession, Raphael became the architect of St. Peter's, and fitted himself by deep study for this new office, to which was added in 1515 that of director of the excavations among the ruins of ancient Rome. His love of antique art led him to pursue with the greatest zeal these fresh researches, but the strain of so much work was too much for his fragile constitution. He caught a fever, and died, after a few days' illness, on Good Friday, Apr. 6, 1520. Raphael received more consideration from his contemporaries than any other artist; he became rich and famous; every honor was showered on him, and he might even have allied himself by marriage with one of the princes of the Church. His death at the early age of thirty-seven made a profound sensation. He was buried with great pomp in the Pantheon. Those who wish to form a true estimate of the genius of Raphael must study his drawings and cartoons, which preserve the essence and spirit of his work, so often lost by re-painting or by his assistant's interpretation in the frescoes and pictures. Among works of reference are Paulus Jovius, *Raphaelis Urbinatis Vita* (in Tiraboschi's *Storia della Lett. ital.* (Florence, 1812, vol. vii.); Rehberg, *Rafael Sanzio aus Urbino* (Munich, 1824); A. Springer, *Raffael und Michelangelo* (2d ed., Leipzig, 1883); I. Eugene Muntz, *Raphael, sa Vie, etc.* (Paris, 1881); Crowe and Cavalcaselle, *Life and Works of Raphael* (1883); Kugler's *Handbook*, ed. by Sir A. Layard (1887). W. J. STILLMAN.

Raphides: See Rhaphides.

Rapidan' River: a stream of Virginia which rises by several head-streams at the base of the Blue Ridge, and flows between Green and Orange Counties on its right, and Madison and Culpeper on its left. Ten miles above Fredericksburg it joins the Rappahannock, after a course of about 80 miles.

Rapid City: city; capital of Pennington co., S. D.; on the Rapid river and the Fremont, Elkhorn, and Mo. Valley Railroad; 45 miles S. E. of Deadwood, about 140 miles W. by S. of Pierre (for location, see map of South Dakota, ref. 7–B). It is in the famous Black Hills; is the seat of the State School of Mines, created by act of the territorial legislature in 1885: and contains 2 national banks with combined capital of $125,000, a State bank with capital of $50,000, and a daily and 5 weekly newspapers. Pop. (1890) 2,128; (1900) 1,342.

Rapid-fire Guns: See Machine and Rapid-fire Guns.

Rapp, George: founder of the sect of Harmonists (*q. v.*); b. at Iptingen, Würtemberg, Germany, Oct., 1770; founded in early manhood a communistic religious association to restore the practices of the primitive Christian Church; came into conflict with the authorities; emigrated to the U. S. in 1803 with a number of his associates; founded the town of Harmony, Butler co., Pa., and later the town of Economy, now Harmony, in Beaver co. D. at Economy Aug. 7, 1847.

Rappahannock River: a stream which rises in the foothills of the Blue Ridge, near the northwest border of Fauquier co., Va., and flows southeast, generally parallel to the Potomac, reaching Chesapeake Bay through a broad estuary. Its largest branch is the Rapidan. At its rapids at Fredericksburg a fine dam affords extensive water-power. Below Fredericksburg it is a noble tidal stream, the navigation of which is important. It is about 250 miles in total length.

Rapto'res, sometimes **Raptatores** [Mod. Lat. pl., from Lat. *raptor*, a robber]: a group, or order, of birds containing the birds of prey, comprising the hawks (*Falconidæ*), owls (*Strigidæ*), secretary-bird (*Gypogeranidæ*), and American vultures (*Cathartidæ*). These last differ from the others in many important particulars, and should, very likely, be placed apart. The *Raptores* are birds of powerful flight, characterized by a hooked, cered beak, and, with few exceptions, powerful feet and sharp, curved claws. The palate is desmognathous, there are two carotids, the oil-gland is present, as are also cæca, except in *Cathartidæ*. The female is generally larger than the male; the young are helpless when hatched. There are about 500 species, distributed throughout the world. Accipitres (*q. v.*) is by many authors restricted to the hawks or diurnal birds of prey. F. A. Lucas.

Raritan River: a river in New Jersey, which rises in two branches in Morris co., flows S. E. through Somerset and Hunterdon Counties, and falls into Raritan Bay at Perth Amboy. It is navigable as far as New Brunswick.

Raschîd: See Haroun al Raschîd.

Rash: a popular name for the acute exanthematous or eruptive diseases, or more frequently for the eruption itself which attends such diseases. Nettle-rash or urticaria, scarlet rash (roseola), and canker-rash (scarlet fever) are the diseases generally called by this name, which, though convenient for nursery use, is of no scientific value.

Rashi [a combination of the initial letters of his title and name]: the celebrated Jewish commentator Rabbi Solomon Ben Isaac; b. at Troyes, in Champagne, France, in 1040. Little is known about his life, except that he studied at the theological schools of Mayence and Worms. He died July 13, 1105. He wrote commentaries on all the books of the Bible except Chronicles; which, though they contain much of the traditional rabbinic exegesis, seek to determine the simple meaning (*Peshat*) of the text. They have been held in the highest esteem not only by Jewish writers, but also by Nicolaus de Lyra, Luther, Sebastian Münster, etc. His commentary on the Pentateuch was the first Hebrew book printed (1475). He also wrote a commentary on twenty-three of the treatises of the Babylonian Talmud, which is printed in every edition of that work. Among his other writings may be mentioned a commentary to *Bereshith Rabba*; *Happardēs*, containing decisions on ritual and legal matters; and a few hymns. In his commentaries Rashi cites a large number of Provençal words which have been collected by Arsène Darmesteter, and which are of value in determining the pronunciation of the particular dialect used by the Jews in that part of Provence. See Zunz, *Zeitschrift für die Wissensch. des Judenthums* (Berlin, 1822, iii., p. 277); Graetz, *History of the Jews* (Philadelphia, 1894, p. 286); Siegfried, *Raschi's Einfluss auf Nicolaus von Lira und Luther* (in Merx, *Archiv*, i., p. 428); Maschkowski, *Raschi's Einfluss auf Nikolaus von Lyra* (in *Zeitschrift für alttest. Wissenschaft*, xi., p. 268); Clément-Mullet, *Documents pour servir à l'histoire de Raschi* (Troyes, 1855); Arsène Darmesteter, *Glosses et Glossaires Hébreux-Français du Moyen Âge* (in *Romania*, i., pp. 146, *seq.*).

Richard Gottheil.

Rask, Rasmus Kristian: scholar; b. at Brændekilde, on the island of Fünen, Denmark, Nov. 22, 1787; studied at the University of Copenhagen. In 1808 he published his *Introduction to the Study of the Icelandic Language*, which, with his edition of the *Eddas* (1818), the first critical and complete one published, forms the foundation for the study of Icelandic literature and language. In 1813 he began his extensive travels. He spent first two years in Iceland, the result of which was his celebrated *Researches concerning the Origin of the Icelandic Language* (1818), which received the gold medal of the Danish Scientific Society, and in which the first observations of the transpositions of sounds in the Teutonic languages were published. He next spent two years in Stockholm, where he published a grammar of the Anglo-Saxon language (1817), translated into English by B. Thorpe (1830), and studied Finnish, and then, in 1817, he proceeded by St. Petersburg, where he remained over a year, studying the Slavonic dialects, to Astrakhan, through Persia, and to India, which he traversed in its whole length from 1820 to 1822, returning home, by Ceylon, in 1823. He brought to Copenhagen a great number of rare Oriental manuscripts, one of the greatest treasures of the Royal Library; but incomparably greater was his working knowledge of most of the languages composing the Indo-European family, from the English to the Mantchu. But his health was broken, and the results of his enormous linguistic acquisitions were fragmentary. He wrote essays on the Zend language, the genuineness of the *Zend-Avesta*, the ancient Egyptian and Hebrew chronology, and published grammars of the Spanish (1824), Frisian (1825), Italian (1827), and English (1832) languages. His richest and most original work is his *Introduction to a Scientific Orthography of the Danish Language* (1826), in which he gave comparative philology a new and powerful impulse, and foreshadowed many ideas later established as truths. He undoubtedly anticipated Grimm in the discovery of the law of the permutation of consonants. D. in Copenhagen, Nov. 14, 1832. *Samlede Afhandlinger* (vols. iii., 1834–38). Revised by D. K. Dodge.

Raskōl'niks [from Russ. *raskolenik'*, schismatic, heretic]: members of the *Raskól'*, or schism, which dates officially from the year 1666. During the long period of the Mongol yoke numerous errors crept into the ritual and liturgical books of the Russian Church. In the seventeenth century, during the reign of Alexis Mikhailovich, the patriarch Nikon introduced numerous reforms, which were met by great opposition. Nikon fell, but the council which deposed him in May, 1667, confirmed his reforms. From that time the schism in the Russian Church became established. The Raskōlniks objected to the alterations in and the printing of the church-books, to the form of the cross, and to various other matters. Thence they took the name of *Staroobryadtsy*, or Old Ritualists (from *stary*, old, and *obryad*, a rite); but, as they professed to be the preservers of old faith, as well as of old rites, they called themselves also *Starovertsy*, or Old Believers (from *vera*, faith). When Peter I. introduced his reforms into Russia the Raskol waxed stronger, its old religious opposition being fortified by a political resistance to the census, to military conscription, to shaving, to giving up the national dress. Peter I. vainly endeavored to crush their opposition. Since his time their treatment has fluctuated. Peter III. was their avowed protector. Catherine II. treated them leniently for a time, granting them the official designation of *Edinovertsy*, or Like-Believers, and allowing them to retain their old ritual. After the insurrection of Pugachef, an outbreak of schismatic and rebellious fury, they met with less favor. Nicholas I. in vain tried severe measures. Toward the end of his reign advances were made to them by the Poles and the Russian socialists, but the only result was the installation in 1846, at Belokrinitsa in Bukovina, of a Raskōlnik metropolitan, Ambrose, formerly Metropolitan of Bosnia. His successor, Cyril, visited Moscow in 1863, and there held

a Raskōlnik council-general; but just then the Polish insurrection broke out, and the Old Believers sent him away and addressed to the throne an assurance of loyal devotion. They were rewarded by tolerant measures, and large concessions were made to them.

Little is known as to the numbers of the Raskōlniks. The official census shows over 1,000,000, but it is said that more than 12,000,000 really exist. They form the most industrious, honest, and sober portion of the Russian community. They belong almost exclusively to Great Russia. Those in Poland, Livonia, Little Russia, and White Russia are all colonists from Great Russia. They evince a truly Russian faculty of organization, forming readily into communities ruled by practical systems of self-government. At a very early period they split into two great bodies—the *Popovtsy*, or Priestly, and the *Bezpopovtsy*, or Priestless (from *bez*, without, and *pop*, a priest). The former were obliged to depend for their priests upon fugitive "popes" from the establishment; the latter dispensed with the services of ecclesiastics, using those of elders instead. For about a century neither body possessed any legalized establishments, but about 1771, after the great plague of Moscow, each branch was allowed to have a cemetery in the capital, and to build there a church and a convent, and these still exist as the headquarters of the Raskol. In addition to these bodies the Raskol comprises the *Dukhovnyie Khristiane* (spiritualist Christians), who are divided into a number of minor sects. Some of these are respectable, such as the *Molokany* (said to be so called from *molokó*, milk, because they do not abstain during fasts from milk and its products) and the *Stundists* (from the German *Stunde*), both of which bodies hold what may perhaps be called Protestant doctrines. The *Dukhobortsy*, or spirit-wrestlers, seem to have been originally harmless mystics, but they afterward changed their character, and were in consequence mostly transferred to the Caucasus. The worst of these sects have either been crushed by the police or are rarely met with, such as the *Detoubytsy*, or child-killers, who put new-born babes to death in order to insure their salvation. One of these sects, that of the *Skoptsy*, or self-mutilators, a set of gloomy fanatics greatly addicted to money-getting, has isolated adherents in all parts of Russia. See the history of the Russian Church by Philaret, translated into German by Blumenthal (2 vols., Frankfort, 1872); Wallace's *Russia* (New York, 1878), pp. 306–324; A. F. Heard, *Russian Church and Russian Dissent* (1887); *The Stundists* (London, 1893).

Raso'res [Mod. Lat., from Lat. *ra'dere*, *ra'sum*, scrape, scratch]: a former group of birds containing originally the fowls and pigeons, and later the fowls alone. See GALLINÆ.

Rasp: See FILE.

Raspberry [obsolete *rasp* (the fruit); cf. Ital. *raspo*, raspberry), connected with verb *raspare*, scratch: Fr. *râper*, a word of Teutonic origin]: a name applied to those species of the rosaceous genus *Rubus*, in which the "fruit" or collection of drupelets falls away, in a thimble-like mass, from the receptacle, leaving the latter on the bush. Raspberries are important fruits in the U. S. Up to about the middle of the nineteenth century the cultivated varieties belonged to the European species, *Rubus idæus*, but very nearly all the varieties grown in the U. S. are offsprings of native species, *R. strigosus*, the wild red, and *R. occidentalis*, the wild black or black-cap. The commonest pure form of the former in cultivation is the Cuthbert. The black species is represented by Gregg, Ohio, and many others. An intermediate class, hybrids between the two, has become prominent, and it now comprises some of the best varieties, of which Shaffer may be taken as a type. This class has been described as a distinct species under the name of *Rubus neglectus*. *Rubus strigosus* is the American representative of *R. idæus*, with which it is very closely allied. The leaves are thinner and the fruit less firm and usually smaller than in the European species, and the calyx is glandular, while the other is not. The canes are also more bristly-hairy, and the fruit does not have the tendency to ripen throughout the season, which is often a marked trait of the European berry. The cultivation of the European varieties is attended with difficulty in the northern parts of the U. S., chiefly because of the severity of the winters. Another species of raspberry, *R. phœnicolasius*, has been introduced from Japan. See WINEBERRY.

The raspberry requires a warm, well-drained, and fertile soil. The chief point to be considered in the growing of the raspberry is the fact that the stem or "cane" bears only one good crop of fruit; therefore the stems are cut away after the fruit is harvested, or at latest before the following summer, and new shoots from the root, which have grown while the others were in fruit, are allowed to take their places. That is, the stems grow one year and bear the next year, after which they are worthless. From two to eight shoots or canes are allowed to grow to each plant, depending upon the age of the plant, strength of the soil, and method of training. The style of pruning and training varies. Red raspberries propagate naturally by suckers or sprouts thrown up from the roots, while the black-caps multiply by means of "tips," or new plants which spring from the tips of the recurving stolon-like canes when these come in contact with the ground. All raspberries are readily multiplied by means of root-cuttings. (See CUTTINGS.) Raspberries are important fruits for evaporating and for making into commercial conserves. There are no special manuals devoted to raspberry-culture in the U. S. L. H. BAILEY.

Rassam, HORMUZD: archæologist; b. of Chaldæan Christian parents at Mosul, Turkey, in 1826. In 1845 he became acquainted with Austen H. Layard, who was then beginning his explorations in Assyrian ruins, and in 1847 he accompanied Mr. Layard to England. In 1864 he was sent by the British Government on a mission to Abyssinia, to secure the release of several Europeans who were held in confinement by King Theodore, but was himself imprisoned by Theodore 1866–68. Rassam's *Narrative of the British Mission to Theodore*, etc. (2 vols., London, 1869), is his chief publication. After the death of George Smith in 1876, Rassam made repeated trips for the British Museum to the Babylonian-Assyrian region, and enriched the museum with many important discoveries. Most notable among these are the bronze gates of Balawat, from the time of Shalmaneser II., 858–824 B. C., and the tablet from the temple of the Sun-god in Sippar, commonly known as the Abu-Habba tablet, recording the restoration of the temple by Nabu-apal-iddin, a contemporary of Shalmaneser II. See T. G. Pinches, *The Bronze Gates discovered by Mr. Rassam at Balawat* (*Transactions of the Society of Biblical Archæology*, vii., 83–118, London, 1882), and *The Bronze Ornaments of the Palace Gates of Balawat*, parts i.–v., published by the Society of Biblical Archæology (London). D. G. LYON.

Ras'tadt or **Rastatt**: town in the grand duchy of Baden, Germany; on the Murg, 3 miles from its junction with the Rhine, and 15 miles S. W. of Carlsruhe (see map of German Empire, ref. 6–D). It is surrounded by fortifications, built in 1840–48 by Austrian engineers as a protection to the northern entrance of the Black Forest. It was the residence of the last margraves of Baden, whose palace (planned after that of Versailles) still exists. In 1714 the treaty which ended the war of the Spanish Succession was signed at Rastadt, and in 1797–99 a congress met which terminated without any result, the event being marked by the assassination of the French plenipotentiaries. Steel wares, tobacco, and beer are manufactured. Pop. (1895) 13,268.

Rat [O. Eng. *ræt*: Germ. *ratte* < O. H. G. *ratto*. The relation to the Romanic word, Fr. *rat*: Ital. *ratto*, is not clear]: any one of the larger species of the family *Muridæ*, the smaller being known as mice. The best known of these are the common brown rat (*Mus decumanus*) and the black rat (*Mus rattus*). The common rat was originally a native of India and Persia, but its present distribution is almost coextensive with that of man. It is generally believed that it extended into Europe about the middle of the eighteenth century, and found its way to America about 1775. It was anticipated in its incursions by the black rat, but its superior strength and aggressiveness have driven that species before it, and have supplanted it in almost all countries. It is very prolific, breeding four or five times during the year, and having about a dozen young each time. It is almost omnivorous, feeding upon grains, vegetables, and meat. The black rat (*Mus rattus*) is smaller than the brown species, and is much more timid. It also was originally peculiar to Asia. With prefixes or qualifying terms the name rat is applied to various other species of *Muridæ* and to rodents of other families. The wood-rats belong to the genus *Neotoma*, the pouched rats or gophers (see GOPHER) to *Geomys* or *Thomomys*, the cotton-rats of the southern parts of the U. S. to *Sigmodon*, the kangaroo-rats (see KANGAROO-RAT) to *Dipodomys*, *Perodipus*, and allied genera, the spiny rats of South America to *Echimys*, and the bamboo-rats of India to *Rhizomys*. Revised by F. A. LUCAS.

Ratafi'a [Fr.; Malay, *araq*, arrack + *tafia*, a spirit distilled from molasses]: a name given to a large class of liqueurs, or sweet alcoholic drinks strongly flavored with aromatics.

Ratel: any one of three carnivorous mammals of the family *Mustelidæ* and genus *Mellivora*, found in Africa and India, known as honey-badgers. The typical species, *M. ratel* or *capensis*, a native of South Africa, has a stout, badger-like body and short tail; its total length is about 3 feet. The back is iron-gray, with a white crown and streak down each side. F. A. L.

Rathbun, Richard: See the Appendix.

Ratich, Wolfgang: See the Appendix.

Ratio [= Lat. *ra'tio*, reckoning, account, calculation, relation, deriv. of *re'ri*, *ra'tus*, reckon, believe, think, judge]: the numerical measure of the relation which one quantity bears to another of the same kind. The only way in which two quantities can be compared is by division. The operation of dividing one quantity by another of the same kind consists in dividing *the number of times* that any assumed unit is contained in the former by *the number of times* the same unit is contained in the latter. The operation of finding a ratio is therefore purely numerical, and the resulting ratio is consequently an abstract number. If the terms of the ratio are commensurable, their ratio is *exact*; if the terms are incommensurable, the expression of their ratio by quotient of two abstract numbers is only *approximate*; but it is to be remarked that the approximation to the true value may be made to any desirable degree of exactness.

Prime and ultimate ratios were used by Newton as the method of analysis in his *Principia*. It is a simplification of the method of exhaustion as used by ancient geometers. To conceive an idea of this method, let us suppose two variable quantities whose values approach each other so that their ratio continually approaches a, and finally differs from a by less than any assignable quantity; then is a the ultimate ratio of the two quantities. Again, if two variable quantities simultaneously approach two other quantities, which on the same hypothesis remain constant, the ultimate ratio of the variable quantities is the same as that of the constant quantities. The ratios are called *prime* or *ultimate*, according as the ratio of the variable quantities is receding from or approaching to the ratio of the constant quantities.
Revised by S. Newcomb.

Rationalism [from Lat. *rationa'lis*, rational, reasonable, deriv. of *ra'tio*, *ra'tionis*, reckoning, thinking, judgment, reason, deriv. of *re'ri*, *ra'tus*, reckon, think, judge]: that tendency in modern thought which claims for the unaided human reason the right of deciding in matters of faith. It asserts the prerogative of the intellect to be supreme arbiter in all departments of revealed truth. It requires certainty as the condition of its favor, and promptly rejects what does not come before it with all the exactness and clearness of a mathematical demonstration. Like naturalism, supernaturalism, and other terms expressive of the relation of reason and faith, the term rationalism was first used in its present sense by the philosopher Kant. The scene where rationalism has exerted its chief sway is Germany. The sources were various, not only embracing different countries, but likewise different departments of investigation. The deism of England, one of the most polished and powerful of all forms of free thought, was industriously propagated in Germany, where the works of Lord Herbert, Hobbes, Shaftesbury, Tindal, Woolston and Wollaston were circulated in the language of the people and read by wide circles. In Holland the philosophy of Descartes and Spinoza was very powerful, and its influence was very decided east of the Rhine, particularly in the universities of Germany. The pantheism of Spinoza was very attractive to many minds, and was regarded as a welcome relief from the cold and heartless banishment of God from his own creation. France, however, was the chief foreign country which contributed to the rise and sway of German rationalism. The influence of Voltaire and the Encyclopædists was very great, and Berlin became as much a home to these men as Paris had ever been. The domestic causes were, first of all, the philosophy of Leibnitz, popularized and simplified by Wolf at Halle University: the destructive theology of Semler; the influence of the skeptical court of Frederick the Great, with its French surroundings; the *Wolfenbüttel Fragments*, published by Lessing; and the *Universal German Library*, issued by Nicolai. Rationalism was in the ascendant in Germany from 1750 to 1800, but with the beginning of the new century it began to lose its hold upon the best minds. Schleiermacher was the transitional theologian from the old rationalistic to the new evangelical faith of Protestant Germany. His *Discourses on Religion: Speeches to its Cultured Despisers* (Eng. trans. London, 1893) diverted public attention from the rationalistic criticism to the necessity of feeling and a sense of dependence on God. Jacobi was really the first to introduce the sense of dependence into the domain of religious philosophy, but Schleiermacher was the first to apply it to the man of general culture. Neander, the Church historian, was the first positive theologian of the so-called "mediatory" school. His historical works breathe a fervent and devout spirit, at the same time that they evince the profound scholarship of the original student. In 1835 a new impulse was given to rationalistic criticism by Strauss's *Life of Jesus* (n. e., Eng. trans. London, 1893)—a work proceeding directly from the Hegelian school. It advocated the mythical origin of the Gospels. This work was promptly replied to by Neander, Ullmann, Tholuck, and many other representatives of evangelical thought. The most recent phase of rationalistic thought is materialistic. The views of Büchner, Carl Vogt, Moleschott, and others have gained a wide influence. Evangelical theology is, however, in the ascendant again in most of the German universities. On the literature of rationalism compare Farrar, *Critical History of Free Thought* (Bampton lectures, 1863); Lecky, *History of the Rise and Influence of the Spirit of Rationalism in Europe* (2 vols., London, 1865); Hurst, *History of Rationalism* (New York, 1865; 9th ed., rev., 1875); Fisher, *Faith and Rationalism* (New York, 1879); Pfleiderer, *The Development of Theology in Germany since Kant* (London, 1890). J. F. Hurst.

Rat'isbon, or **Regensburg**: town of Bavaria; on the right bank of the Danube, opposite the influx of the Regen; 82 miles by rail N. N. E. of Munich (see map of German Empire, ref. 6–F). It is surrounded with walls pierced by six gates, and has a Gothic cathedral begun in 1275, but not finished till the middle of the seventeenth century: a town-house, in which the imperial diet assembled from 1662 to 1806; a magnificent stone bridge over the Danube, 1,100 feet long, connecting the town with the suburb of Stadt-am-Hof; and a monument of Kepler, who was born here. Gold, silver, brass, iron, steel, earthen and porcelain ware, leather, tobacco, and glass are manufactured, and there is an active trade in wheat and salt. Originally a Celtic town, it was made a frontier fortress by the Romans. In 1245 it was made a free imperial city. It was stormed by both the French and the Austrians in 1809, and was ceded to Bavaria in 1810. Pop. (1895) 41,474. See Walhalla.

Rat'itæ [Mod. Lat., liter., fem. plur. of Lat. *rati'tus*, marked with a raft (sc. *a'ves*, birds), deriv. of *ra'tis*, raft]: an order or sub-order of birds, considered by many authorities as a sub-class, contrasting with all the other living forms of the class, and containing the ostriches, cassowaries, and kiwis. It is distinguished, according to Huxley, by the sternum being devoid of a crest, and ossifying only from lateral and paired centers, the parallelism or identity of the long axes of the adjacent parts of the scapula and coracoid, and the non-development of an acromial process to the scapula, and of a clavicular process to the coracoid; the vomer has a broad cleft; the hinder and posterior ends of the palatines and the anterior ones of the pterygoids are very imperfectly or not at all articulated with the basisphenoidal rostrum. It may be further added that in all the living representatives the feathers are characteristic, the barbs being disconnected. The group embraces the largest of birds, all of which are incapable of flight, and progress by running. The species, though comparatively few, represent several well-defined families—viz., *Struthionidæ*, embracing the African ostriches; *Rheidæ*, including the South American ostriches or nandus; *Casuaridæ*, with the cassowaries and emus of the Papuan Archipelago, Australia, etc.; and *Apterygidæ*, including the kiwis of New Zealand; the order was also well represented in former geological epochs, especially in New Zealand, by the gigantic *Dinornithidæ*, which seem to have been destitute of true wings.
Revised by F. A. Lucas.

Raton: town; Colfax co., N. M.; on the Atch., Topeka and S. Fé Railroad; 111 miles N. by E. of Las Vegas (for location, see map of New Mexico, ref. 8–T). It is in a coal-mining region, and contains the machine-shops of the railway company, a national bank with capital of $50,000, and three weekly newspapers. Pop. (1890) 1,255; (1900) 3,540.

Ratram'nus, also called **Bertramus** by an error of copyists: a learned monk of the famous abbey of Corbie, near

Amiens, best known by his treatise *De Corpore et Sanguine Domini*, written to confute the transubstantiation doctrine of Paschasius Radbert (about 844 A. D.). It was translated into German (Zurich, 1532), and has repeatedly appeared in English under the title *The Book of Bertram the Priest, concerning the Body and Blood of Christ in the Sacrament* (London, 1549, 1582, 1623, 1686, 1688, 1832; Baltimore, Md., 1843). He died after 868. His writings occupy about 170 pages in vol. cxxi. of Migne's *Patrologia*.

Revised by S. M. Jackson.

Rattan [from Malay *rōtan*, rattan]: the slender stem of various plants of the genus *Calamus*, many of which are climbers or trailers, often many hundreds of feet in length, others quite short, all having a beautiful head of feathery leaves. *C. viminalis*, *C. rudentum*, *C. rotang*, *C. verus*, *C. scipionum*, and *C. draco* are among the species. The third and the last mentioned yield a part of the dragon's-blood of commerce. The young shoots of some of the species are used as a potherb; some produce good fruits; but the chief use is that of the stalks. From Borneo to Bengal great quantities are gathered for the Chinese, the European, and the American markets. In China mats, sails, and cables are among the articles made from them. In the U. S. they are used in making chairs, baskets, canes, umbrella-ribs, etc., and splinters of rattan are used in carriage-trimming and other ornamental work. Tropical America has numerous rattan-like palms of the genus *Desmoncus*, armed with strong thorns. They are locally used like the true rattans. See Palm Family.

Rattazzi, raăt-taăt'sĕe, Urbano: statesman; b. at Alessandria, Italy, June 29, 1808; studied law at Turin, and began to practice as an advocate at Casale; was elected a member of the Sardinian Parliament in 1848; opposed in the most decided manner the Austrian authority in Italy, and became a member of the cabinet of Gioberti, but retired immediately after the battle of Novara; entered the cabinet of Cavour (1853–58) as Minister of Justice, but resigned on account of his opposition to Cavour's policy of an alliance with France; formed a cabinet in opposition to Ricasoli in 1862, and again in 1867, but held the place only for a few months. D. at Frosinone, June 5, 1873. By the radicals he was accused of being subservient to France; by the clericals of being in compact with Garibaldi; thus his position was often very difficult, but he was a man of eminent ability and in possession of great talent as a speaker.—His wife, Marie Studolmine de Solms, a daughter of the Princess Lætitia Bonaparte, was the author of a biography of Rattazzi, *Rattazzi et son temps* (1881), and other works.

Rattigan, Sir William Henry: See the Appendix.

Rattlesnake: any snake of the family *Crotalidæ* provided with a rattle to the tail. The rattle is composed of articulated horny segments in varying number—from two or three up to thirty or more. The popular belief that the number of segments indicates the age of the animal is erroneous. The species of the group are peculiar to America, and are especially numerous in the arid regions of the southwestern parts of the U. S. According to Prof. Cope, eighteen species and a number of sub-species are found within the limits of the U. S.; of these fifteen belong to the genus *Crotalus*, which has the head covered with small scales, and three to the genus *Crotalophorus*, which has large plates upon the head similar to those of ordinary snakes. The common rattlesnake of the Eastern States is *Crotalus horridus*; in the Southern States, from North Carolina to Florida, *Crotalus adamanteus* is also found. A species of *Crotalophorus* (*C. catenatus*) is also found in the Western States, and extends as far eastward as Western New York, although the other species of the group are confined to the western and southwestern parts of the U. S. The venom of the rattlesnake varies in intensity with the climate, season, and the condition of the animal itself. It is most to be feared in warm weather. See Poison of Serpents.

Revised by F. A. Lucas.

Raumer, row'mer, Friedrich Ludwig Georg, von: historian; b. at Wörlitz, in the duchy of Anhalt, Germany, May 14, 1781; studied law at Berlin, Halle, and Göttingen; received employment in the civil service of the Prussian Government in 1801; appointed Professor of History at Breslau in 1811 and at Berlin in 1819; was a member of the German Parliament at Frankfort in 1848, and afterward of the Prussian upper house. D. in Berlin, June 14, 1873. His principal works are *Geschichte der Hohenstaufen und ihrer Zeit* (6 vols., 1823–25); *Geschichte Europas seit dem Ende des 15. Jahrhunderts* (8 vols., 1832–50); *Briefe aus Frankfurt und Paris 1848–49* (1849); *America and the American People* (2 vols., 1845; translated into English by W. W. Turner); *Vermischte Schriften* (3 vols., 1852–54).

Raumer, Karl Georg, von: geologist; brother of Friedrich Ludwig Georg von Raumer; b. at Wörlitz, Apr. 9, 1783; studied geology at Halle and Göttingen, and at the mining-school of Freiberg under Werner; appointed Professor of Mineralogy in 1811 at Breslau, in 1819 at Halle, and in 1827 at Erlangen, where he died June 2, 1865. Most widely known are his geographical works, *Lehrbuch der allgemeinen Geographie* (1832) and *Beschreibung der Erdoberfläche*, both often reprinted.

Ravaillac, raă'vaă'yaak', François: assassin of Henry IV. of France; b. at Angoulême, department of Charente, France, in 1578; entered the order of the Feuillants, but was expelled as a visionary and fool, and became noted for his fanatical hatred of the Protestants, which feeling by degrees concentrated itself on the person of Henry IV., their former leader. Several times he sought in vain to approach the king; at last he succeeded. On the afternoon of May 14, 1610, the king rode out to pay a visit to Sully, who was sick in bed. In the narrow rue Laferronnerie his coach was stopped for a moment by some heavily laden carts in front of it. Ravaillac jumped up on the hind wheel and plunged a dagger into the heart of the king, who died immediately. The murderer was captured soon after, confessed the crime, and was put to death May 27, having been subjected to cruel tortures without revealing the secret instigators of the deed.

Raven [O. Eng. *hræfn*: O. H. Germ. *hraban* > Mod. Germ. *rabe*. Cf. Lat. *cor'vus*, crow, and Gr. *κόραξ*, raven]: a bird (*Corvus corax*) which differs from the crow chiefly by its larger size and the lanceolate feathers of its chin and throat. It is found over the greater part of the northern division of the Old World, as well as North America, although it is rare on the Atlantic seaboard. It generally associates in pairs, but sometimes is to be seen in small flocks. It builds a rude nest, usually on a cliff, and deposits therein from four to six eggs of a light greenish blue, blotched with brownish spots. It is capable to some extent of mimicking the human voice. It was formerly, and is still by some superstitious persons, looked upon as a bird of evil omen.

Ravenel, Henry William: botanist; b. in St. John's parish, Berkeley co., S. C., May 19, 1814; educated in South Carolina College; planter for twenty years at St. John's, then resided at Aiken, where he died July 17, 1887. He published *Fungi Caroliniani Exsiccati* (500 species, 1853 to 1860) and *Fungi Americani Exsiccati* (800 species, 1878 to 1882), the latter in connection with M. C. Cooke, of England. He published many papers in botanical journals and the *Proceedings* of scientific societies. C. E. B.

Ravenna: city: in Northern Italy, in the province of Ravenna, between the rivers Lamone and Ronco; 44° 24′ N. lat. and 12° 10′ E. lon. (see map of Italy, ref. 3–E). It is connected with the great towns of the Peninsula by rail and with the Adriatic by a canal completed in 1747. Its walls are 3 miles in circumference, with five gates. It stands in a marshy plain over 4 miles from the water, and is one of the most malarial cities of Italy, though anciently it was bathed by the Adriatic and famous for salubrity.

Ravenna is, according to tradition, older than Rome. The Romans subdued it 187 B. C., and Augustus made it the headquarters of the Roman fleet on the Adriatic, constructing the Portus Classis and connecting it with the Po by an inland canal. Honorius abandoned Rome (404), and made Ravenna the capital of the Western Empire, induced thereto by its apparent capability of defense. It was the seat of many important ecclesiastical councils; until 679 its archbishop claimed equality with the pope. Taken by Odoacer, King of the Heruli (476), it was captured from him after a three years' siege by the Ostrogoth Theodoric the Great (493). It then attained so high a degree of splendor as to call itself *Ravenna Felix*. Belisarius took it (538). Narses, another general of Justinian, made it the capital of the exarchate of Ravenna, and it was governed by the Emperors of Constantinople till 752. Then the last exarch was expelled by Atolph, King of the Lombards, himself expelled (755) by Pepin of France, who bestowed the city upon the popes. Nevertheless, it generally adhered to the Ghibellines in the papal wars. It became an independent dukedom (1318); was seized by Venice (1440), whereupon its prosperity rapidly increased. Pope Julius II. regained it (1509).

It continued part of the states of the Church (with the exception of intervals during 1797–1815) until it was incorporated in the kingdom of Italy in 1860.

No Italian city seems more apart from the currents of modern life. Ravenna is not so much a city as a museum. Here better than at Rome may be studied primitive Christian art from the fifth to the ninth century. In the Cathedral of Sant' Urso, partly of the fourth century but reconstructed in the eighteenth, are frescoes by Guido Reni; the original campanile still remains. Close by is the octagonal-domed baptistry of the fourth century, containing the famous fifth century mosaic, representing the baptism of our Saviour in the Jordan. Near the Church of San Francesco, built on the ruins of a temple of Neptune about 450, but completely modernized, is the mausoleum of DANTE ALIGHIERI (*q. v.*), who died at Ravenna in 1321. In SS. Nazario e Celsò, erected (440) in the form of a Latin cross by Placidia, daughter of Theodosius the Great, are the sarcophagi of that empress (d. 450) and of Honorius I. and Constantius III. The round tower of St. Giovanni Battista was constructed in 438. Santo Spirito and Sta. Maria in Cosmedin, embellished with mosaics of the sixth century, were built by Theodoric for the Arian bishops. Sant' Apollinare Nuovo, erected by Theodoric about 500 as the Arian cathedral, is resplendent with mosaics, mostly of the sixth and ninth centuries. San Vitale (consecrated in 547), a work of Justinian, is a partial copy of St. Sophia in Constantinople. Its gorgeous mosaics, admirably preserved, give the whole New Testament story; especially interesting are those of Justinian and his suite, and of his empress Theodora and her retinue. In the Carthusian monastery is the library founded in 1714, with over 50,000 volumes and 700 MSS. Among the latter is an autograph MS. of Dante of the fourteenth century. Half a mile outside the Porta Serrata is the rotonda or mausoleum of Theodoric. The cupola, 36 feet in diameter, and weighing over 200 tons, is hollowed from a single block of stone. Also outside the walls is the imposing Sant' Apollinare in Classe, on the site of a temple of Apollo, dedicated in 549 and restored in 1779, a specimen of the purest early Christian art. Two miles from the city is La Colonna dei Francesi, the square pillar raised in 1557 to commemorate the battle of Ravenna (1512), in which Pope Julius II. was defeated by Gaston de Foix. S. of Ravenna toward Rimini extends the Pineta, the vastest and most ancient pine forest in Italy. It begins not far from Sant' Apollinare in Classe, on the site of the ancient harbor, and stretches 25 miles along the Adriatic, with a breadth of from 1 to 2 miles. Pop. (1881) of city, 18,571; of commune, 60,573. E. A. GROSVENOR.

Ravenna: village (settled in 1799); capital of Portage co., O.; on the Penn., the Erie, and the Pitts. and W. railways; 16 miles E. N. E. of Akron, 38 miles S. E. of Cleveland (for location, see map of Ohio, ref. 3–I). It contains 6 churches, 3 large public schools, a Roman Catholic school, 2 national banks with combined capital of $250,000, gas and electric light plants, water-works system owned by the village, and a semi-weekly and 2 weekly newspapers. The manufactories include glass-works, coach and hearse factory, carbon-works, flour and planing-mills, foundry, machine-shop, novelty-works, large dyeing establishment, 2 brick and tile works, 2 shoe-factories, and basket, chair, sad-iron, and spoke and hub factories. Pop. (1880) 3,255; (1890) 3,417; (1900) 4,003. EDITOR OF "REPUBLICAN."

Ravenscroft, JOHN STARK, D. D.: bishop; b. near Blandford, Prince George co., Va., in 1772; taken to Scotland in infancy; received there a classical education; returned to Virginia 1788; studied at William and Mary College; admitted to the bar, but ultimately studied theology; took orders in the Episcopal Church 1817; a minister in Mecklenburg co., Va., 1817–23, and pastor of churches successively at Raleigh, N. C., and at Williamsburg, Va., when he became Bishop of North Carolina. D. at Raleigh, Mar. 5, 1830. Two volumes of his *Sermons* were edited by Dr. (afterward Bishop) J. M. Wainwright in 1830, preceded by a memoir. See biographical sketches in *American Church Review* and in Batterson's *Sketch-book of the American Episcopate*. Revised by W. S. PERRY.

Ravenstein, ERNEST GEORGE: geographer and statistician; b. at Frankfort-on-the-Main, Germany, Dec. 30, 1834; son of an eminent local geographer and cartographer; educated chiefly in his native town; removed to London about 1852; held an appointment in the intelligence department of the War Office 1855–75; member of the councils of the Royal Geographical and Royal Statistical Societies; founded the German Gymnastic Society 1861, and for ten years was its president; has published *The Russians on the Amur* (London, 1861); *Geographie und Statistik des Britischen Reiches*, in Wappäus's *Handbuch der Geographie* (Leipzig, 1862); *London*, one of Meyer's *Handbooks for Travelers* (1872, subsequent editions); *Cyprus* (London, 1876); *The Laws of Migration* and other papers in *Transactions* of the Royal Geographical and Statistical Societies; *A Handbook of Gymnastics and Athletics* (London, 1864); also a map of Eastern Equatorial Africa (twenty-five sheets), published by the Royal Geographical Society (1882–83); a *Systematic Atlas* for private study and superior schools, fifty-two sheets (London, 1893); a topographical map of England and Wales (1893).

Ravignan, răă'veĕn'yaăń', GUSTAVE XAVIER DELACROIX, de: pulpit orator; b. at Bayonne, France, Dec. 2, 1795. He first studied and practiced law, but in 1822 entered the Jesuit seminary at Montrouge and was ordained priest in 1828. After some years of teaching his talent as orator revealed itself, and in 1836 he succeeded Père Lacordaire at Notre Dame, Paris, where he remained till 1848. He was also an ardent champion of the Jesuits in pamphlets, and active in charitable works and foundations. D. Feb. 26, 1858. See his *Life*, by Père de Pontlevy (2 vols., Paris, 1860; Eng. trans., New York, 1873). A. G. CANFIELD.

Rawal Pindi: a district of British India, in the Northern Punjaub. It lies on the south slopes of the Western Himalayas; is noted for its fertility and salubrity; embraces 4,681 sq. miles, and since the extension of the railway has carried on considerable trade with Afghanistan (see map of North India, ref. 3–C). Pop. over 1,000,000. Its largest town is Rawal Pindi; pop. (1891) 73,460; best known in recent times for the great durbar held there (1885) by the Viceroy of India, in honor of the Amir of Afghanistan.

Revised by C. C. ADAMS.

Rawdon-Hastings, FRANCIS, Marquis of Hastings: soldier and statesman; b. in Ireland, Dec. 7, 1754; was educated at Oxford; entered the army 1771; was sent to America in 1773; was present at the battle of Bunker Hill; became aide-de-camp to Sir Henry Clinton; participated in the battles of Long Island and White Plains and the attacks upon Forts Washington and Clinton; soon afterward raised in New York a corps called the Volunteers of Ireland, of which he took command; distinguished himself at Monmouth; was made general and sent to the Southern States with re-enforcements for Cornwallis 1780; took a prominent part at the battle of Camden Aug. 16; remained in the Carolinas after Cornwallis's return northward; attacked and defeated Gen. Greene at Hobkirk's Hill Apr. 25, 1781; relieved Fort Ninety-six; fortified himself at Orangeburg; incurred much obloquy on account of the execution of Col. Isaac Hayne July 31; sailed for England Aug., 1781; was captured by a French cruiser and taken to Brest; was made Baron Rawdon and aide-de-camp to the king 1783; succeeded his father as Earl of Moira in 1793; was given command of a force of 10,000 men sent to the relief of the Duke of York in Flanders in 1794; was intrusted with the direction of the expedition to Quibéron in 1795; was made lord-lieutenant of Ireland in 1805; made an unsuccessful effort to form a cabinet on the assassination of Mr. Perceval in 1812; was honored with the order of the Garter and appointed Governor-General of British India in 1813; successfully conducted the Nepaul, Pindaree, and Mahratta wars; was created Marquis of Hastings in Dec., 1816; retired from the government of India after a successful administration of nearly ten years in 1823, and became Governor of Malta in 1824. D. on board the Revenge in the Bay of Baia, near Naples, Nov. 28, 1826.

Rawlins: city: capital of Carbon co., Wyo.; on the Union Pac. Railroad; 136 miles W. N. W. of Laramie, 710 miles W. of Omaha (for location, see map of Wyoming, ref. 11–I). It is in a mining and stock-raising region, has an elevation of 6,540 feet above sea-level, and contains a valuable sulphur spring, quarries of limestone and building-stone, a national bank with capital of $75,000, and two weekly newspapers. The city has large trade, especially with Northwest Colorado. Pop. (1880) 1,451; (1890) 2,235; (1900) 2,317.

Rawlins, JOHN AARON: soldier; b. at East Galena, Ill., Feb. 13, 1831; the son of a farmer and charcoal-burner. He had but limited opportunities for obtaining an education, and at the age of twenty he began to attend school; in Nov., 1854, began the study of law, and in 1855 was ad-

mitted to the bar, and began practice in Galena. He won success in his profession, and became a leading Democrat of the Douglas school. On the outbreak of the civil war he favored coercion of the Southern States by force of arms, and a speech made by him at a mass-meeting in Galena induced Capt. Ulysses S. Grant to offer his services to the Government. While engaged in raising a regiment Gen. Grant offered him a position on his staff as assistant adjutant-general, with the rank of captain, which was accepted, and with the exception of two months, during illness, he was with Gen. Grant in all his battles and campaigns until the close of the war. He was advanced in rank until in 1865 he was appointed chief of staff to the lieutenant-general, with rank of brigadier-general U. S. army, and later became brevet major-general. When Gen. Grant was elected President he appointed Gen. Rawlins to a place in his cabinet as Secretary of War. In the few months of his administration he displayed the same executive ability which led to his selection. D. at Washington, D. C., Sept. 6, 1869.

Rawlinson, George: historian; brother of Sir Henry Creswicke Rawlinson; b. at Chadlington, Oxfordshire, England, about 1815; educated at Swansea and at Ealing School; graduated with classical honors at Oxford 1838; became fellow of Exeter College 1840, and Bampton lecturer 1859; elected Camden Professor of Ancient History at Oxford 1861, and appointed canon of Canterbury cathedral Sept., 1872; resigned his professorship in 1889. Author of a number of historical works: *The Five Great Monarchies of the Ancient Eastern World* (4 vols., 1862–67; 2d ed. republished in New York, 1871); *A Manual of Ancient History* (1869); *The Sixth Great Oriental Monarchy, or the Geography, History, and Antiquities of Parthia* (1873); *The Seventh Great Oriental Monarchy, or The Geography, History, and Antiquities of the Sassanian or New Persian Empire, collected and illustrated from Ancient and Modern Sources* (1876); *History of Ancient Egypt* (2 vols., 1881); *Egypt and Babylon* (1885); and a *History of Phœnicia* (1889). Canon Rawlinson contributed largely to the *Speaker's Commentary*, and in connection with his brother and Sir Gardner Wilkinson published a translation of Herodotus (4 vols., 1858–60; 3d ed. 1876), valuable for the notes and illustrations. Revised by W. S. Perry.

Rawlinson, Sir Henry Creswicke, D. C. L.: Orientalist and diplomatist; b. at Chadlington, Oxfordshire, England, in 1810; educated at Ealing School. He entered the Bombay army in 1826, and on account of his knowledge of Oriental languages was sent to Persia Nov., 1833, to aid in the instruction of the army of that country; resided several years at Kermanshaw, near the celebrated rock inscription of Behistun, which he was the first to decipher (1838); sent to Kandahar as political agent 1840; held that capital to its allegiance during the Afghan war; went as political agent to Turkish Arabia 1843; appointed consul at Bagdad Mar., 1844, and consul-general 1851–55; returned to England Feb., 1855; knighted and made a director of the East India Company 1856; member of Parliament 1858; member of the council of India 1858–59; was envoy to Persia 1859–60; again sat in Parliament 1865–68; president of the Royal Geographical Society 1871–73, and again 1875–76, and president of the Society of Biblical Archæology from its foundation in 1873. He translated the Persian text of the inscriptions of Darius, first published in the *Transactions* of the Royal Asiatic Society for 1846; contributed to the same journal many memoirs on the same subject or illustrative of the history and geography of the East; edited (with E. Norris and George Smith) 5 folio vols. of cuneiform inscriptions (1861–70); furnished valuable material to his brother's edition of Herodotus (1858–60), and published a volume of essays on Oriental politics, entitled *England and Russia in the East* (1874). He was nominated vice-president of the Council of India in 1876, and received a baronetcy in 1891. D. in London, Mar. 5, 1895.

Rawlinson, Sir Robert, K. C. B.: civil engineer and sanitarian; b. at Bristol, England, Feb. 28, 1810; in 1831 entered the Liverpool dock engineer's office, and in 1836 was employed on the London and Birmingham Railway under Robert Stephenson. He was then assistant surveyor to the corporation of Liverpool until 1844, when he was made engineer of the Bridgewater Canal. In 1848 he was appointed by the Government an inspector under the Public Health Act, and made the first inspection and the first report at Dover in 1849. His most important work was the devising and establishing a new system of main sewering. In 1855 he was sent as engineer sanitary commissioner to the British army in the Crimea. By the efforts of the commission the monthly percentage of mortality among 4,000 sick soldiers was reduced from 8·61 in March to 1·01 in June. He served on numerous commissions, and was a member of the Army Sanitary committee. He was chief engineering inspector under the local government board, and commissioner under the Rivers Pollution Prevention Act. He was knighted in 1883, and upon his retirement in 1889 received the decoration of K. C. B. He was president of the Institution of Civil Engineers in 1894. D. May 31, 1898.

Ray [viâ O. Fr. from Lat. *ra'ja*, ray, skate]: the vernacular name of species of the family *Raiidæ* and kindred groups. See Raiidæ and Fisheries; also Stingray.

Ray, Isaac, M. D., LL. D.: alienist; b. at Beverly, Mass., Jan. 16, 1807; graduated at the medical department, Harvard University, 1827; began practice of medicine at Portland; removed to Eastport 1829; devoted his attention to the subject of insanity; published *The Medical Jurisprudence of Insanity* (1838; 5th ed. 1871); became superintendent of the State insane asylum at Augusta 1841, and of the Butler Asylum at Providence, R. I., 1845, filling that post until Jan., 1867, after which he settled in Philadelphia, Pa. Author of *Conversations on Animal Economy* (1829), *Education in Relation to the Health of the Brain* (1851), and *Mental Hygiene* (1863), besides many contributions to professional journals and a valuable series of official annual reports. D. in Philadelphia, Mar. 31, 1881.

Revised by S. T. Armstrong.

Ray (sometimes written **Wray**), John, F. R. S.: biologist; b. at Black Notley, near Braintree, Essex, England, Nov. 29, 1627; son of a blacksmith; graduated at Cambridge, where he became a fellow of Trinity College 1649; took orders in the Church of England at the Restoration; resigned his fellowship from conscientious scruples 1662; resided for some years with his friend and pupil, Francis Willughby, at Middleton Hall, Warwickshire, and afterward at his birthplace; devoted himself to botany and zoölogy, making extensive tours with Willughby in Great Britain and on the Continent; became a fellow of the Royal Society 1667; published a *Catalogus Plantarum Angliæ* (1670), the most formal work of the kind which had then appeared; proposed a new system of botanical classification in his *Methodus Plantarum Nova* (1682), which was substantially adopted by Antoine de Jussieu in the next century; edited (with an English translation of the former) the *Ornithologia* and *Historia Piscium* of his friend Willughby, and published his great work, the *Historia Plantarum* (in 3 vols., 1686–1704). He also prepared valuable *Glossaries of North and South Country Words*, which were edited by Rev. Walter W. Skeat, for the English Dialect Society (1874). He also wrote *The Wisdom of God manifested in the Works of the Creation* (1691, often reprinted), and a *Synopsis Methodica Animalium, Quadrupedum et Serpentini Generis Vulgarium* (1693), which gave him a similar rank in the history of zoölogical classification to that he had previously gained in botany. D. at Black Notley, Jan. 17, 1705. The Ray Society, organized in 1844 for the purpose of issuing new editions of rare books on zoölogy and botany, has published thirty sumptuous volumes, two of which (vol. ii. of 1844 and vol. ii. of 1848), devoted to the *Memorials* and *Correspondence* of Ray, were edited by Dr. E. Lankester.

Rayleigh, Lord: physicist. See Strutt, John William.

Raymond, Andrew Van Vranken, D. D.: clergyman and educator; b. at Vischer's Ferry, N. Y., Aug. 8, 1854; educated at Union College and New Brunswick Theological Seminary; pastor of the First Reformed church, Paterson, N. J., 1878–81; of Trinity Reformed church, Plainfield, N. J., 1881–87; of the Fourth Presbyterian church, Albany, N. Y., 1887–94; since 1894 president of Union College, Schenectady, N. Y. C. K. H.

Raymond, Henry Jarvis, LL. D.: journalist; b. at Lima, N. Y., Jan. 24, 1820; graduated with honors at the University of Vermont 1840; wrote for Horace Greeley's *New Yorker* while studying law in New York 1840–41; became assistant editor of *The New York Tribune* on its establishment in Apr., 1841. In 1848 he became office-editor of the New York *Courier and Enquirer*; projected *Harper's Magazine*, for which he wrote the prospectus; was elected to the New York assembly as a Whig 1849; distinguished himself in debate; re-elected 1850; chosen Speaker; devoted

special attention to promoting legislation for the improvement of the school and canal systems; retired from *The Courier and Enquirer* 1850; on Sept. 18, 1851, issued the first number of *The New York Times*. Raymond took an active part in the Baltimore Whig convention of 1852; elected lieutenant-governor of New York 1854; prominent in the organization of the Republican party 1856, having been the author of the *Address to the People* issued by the Pittsburg convention; warmly urged Seward for the presidential nomination 1860, but gave efficient support to Lincoln when nominated and during his administration, though often differing from him on questions of war-policy; elected a member and Speaker of the New York Assembly 1861; presided over the Union convention at Syracuse 1862; defeated by Gov. Morgan in his candidacy for the U. S. Senate 1863; chairman of the New York delegation in the national Republican convention 1864; elected to Congress in 1864, but separated from the majority of his party in that body by giving a partial support to the policy of Johnson; took part in convoking the Philadelphia "Loyalists' convention" of 1866, and wrote its *Address and Declaration of Principles*; refused to be a candidate for re-election to Congress 1866; declined the mission to Austria offered to him in 1867. D. in New York, June 18, 1869. He published a *History of the Administration of President Lincoln* (1864), which in a revised edition was entitled *The Life and Public Services of Abraham Lincoln* (1865), and a few other works.

Raymond, Jerome Hall: See the Appendix.

Raymond, John T. (original name, *John O'Brien*): actor; b. in Buffalo, N. Y., Apr. 5, 1836. He was educated in the common schools; made his first appearance at the Rochester (N. Y.) theater as Lopez in *The Honeymoon*; afterward appeared at Charleston, S. C., as Asa Trenchard in *Our American Cousin*, with Edward Sothern as Lord Dundreary. On July 1, 1867, he played with Sothern the same character in the same piece at the Haymarket theater, London, and afterward made a tour of the British provinces. He returned to the U. S. in the autumn of 1868, and appeared in New York as Toby Twinkle in *All that Glitters is not Gold*. His artistic triumph was achieved in 1874, when he brought out at the Park theater, New York, *The Gilded Age*, founded on Mark Twain's novel. As Col. Mulberry Sellers, he acted with much humor and originality. The piece did not prove popular in England. He appeared on the stage for the last time in Hopkinsville, Ky. D. at Evansville, Ind., Apr. 10, 1887. B. B. Vallentine.

Raymond, Miner, D. D., LL. D.: minister and educator; b. in New York, Aug. 29, 1811; spent childhood and youth in Rensselaerville, N. Y.; studied 1830–34, and taught 1834–41 at Wilbraham Academy, Mass.; joined the New England conference of the Methodist Episcopal Church 1838. He was principal of Wilbraham Academy from 1848 to 1864, then became Professor of Systematic Theology in the Garrett Biblical Institute at Evanston, Ill.; published *Systematic Theology* (3 vols., 1877–79). D. Nov. 25, 1897.

Raymund Lully: See Lul, Raimon.

Raynal, rā′naal′, Guillaume Thomas François: historian; b. at St.-Geniez, department of Aveyron, France, Apr. 12, 1713; studied theology at the college of the Jesuits at Toulouse; entered their order and began to preach, but went in 1747 to Paris, and, enjoying the company of Diderot, Holbach, Helvetius, etc., he entered on an entirely opposite course. Of his numerous historical works, *Histoire du Divorce de Henri VIII. avec Catherine* (1763) attracted some attention, and his *Histoire philosophique et politique des Établissements et du Commerce des Européens dans les Deux-Indes* (first published anonymously in 4 vols., 1770, then in an enlarged edition under his name, 5 vols., 1780) was condemned by the parliament of Paris, and a warrant of arrest issued against the author. He fled to Switzerland, lived subsequently at the court of Frederick II., but was allowed to return to France in 1788; received several marks of distinction from the authorities. D. at Chaillot, near Paris, Mar. 6, 1796. He also wrote *Tableau et Révolutions des Colonies anglaises dans l'Amérique septentrionale* (2 vols., 1781), which was translated into English, and sharply criticised by Thomas Paine.

Raynouard, rā′noo′aar′, François Juste Marie: poet and philologist; b. at Brignolles, Provence, France, Sept. 18, 1761. He was bred a lawyer, elected to the Legislative Assembly in 1791, and was a deputy in 1806 and 1811. His poem, *Socrate dans le temple d'Aglaure* (1803), and his tragedies, *Caton d'Utique* (1794), *Les Templiers* (1805), and *Les États de Blois* (1814), gave him a literary reputation, and he was chosen to the Academy in 1807. He contributed to a better knowledge of the Provençal language by his important works, *Choix de Poésies originales des Troubadours* (6 vols., 1816–21); *Lexique roman, ou Dictionnaire de la Langue des Troubadours* (6 vols., 1838–44); *Grammaire romane* (1816); *Recherches sur l'ancienneté de la langue romane* (1816). D. at Passy, Paris, Oct. 27, 1836. A. G. C.

Razor-clam: the common name of various bivalves of the genus *Solen*, in allusion to the shape of the shell.

Razzionere, Pablo de: See Cespedes.

Ré, rā: an island of France, department of Charente-Inférieure; in the Bay of Biscay, in front of the harbor of La Rochelle. It is 18 miles long, 4 miles broad, treeless, with steep coasts; is strongly fortified, and has about 15,000 inhabitants, who are mostly employed in fisheries, oyster-farming, wine-cultivation, and the manufacture of salt.

Reaction Keys: See Recording Apparatus, Psychological, in the Appendix.

Read, David B.: See the Appendix.

Read, George: jurist; b. in Cecil co., Md., Sept. 18, 1733; became a lawyer at Newcastle, Del., 1754; attorney-general of Delaware and member of the Delaware Legislature for many years; a member of the Continental Congress 1774–77, and a signer of the Declaration of Independence; president of constitutional convention of Delaware 1776; member of the convention that framed the Federal Constitution; appointed judge of appeals 1782; U. S. Senator 1789–93; and chief justice of Delaware from 1793 to his death, Sept. 21, 1798.

Read, John Meredith, Jr.: diplomatist; b. in Philadelphia, Pa., Feb. 21, 1837; graduated at Brown University 1858, and at the Albany law school 1859; adjutant-general of New York during the civil war; published *An Historical Inquiry concerning Hendrick Hudson* (1866); wrote much for periodicals; appointed consul-general at Paris in 1868; acted as consul-general of Germany during the Franco-German war, and afterward for nearly two years directed the consular affairs of that empire, including protection of German subjects and interests during the sieges of Paris; appointed U. S. minister to Greece in 1873, but returned in 1879, the office having been abolished; president of the Social Science Congress at Albany, N. Y., in 1868, and vice-president of the one at Plymouth, England, in 1872. D. Dec. 27, 1896.

Read, Opie Percival: See the Appendix.

Read, Thomas Buchanan: poet and painter; b. in Chester co., Pa., Mar. 12, 1822; studied sculpture at Cincinnati, but soon turned his attention to painting, which he practiced in New York (1841), and soon afterward at Boston; removed to Philadelphia 1846; went to Florence, Italy, in 1850, and resided there with few intermissions until 1872, when he returned to the U. S. D. in New York, May 11, 1872. Author of *Poems* (1847); *The New Pastoral* (1855); *The Wagoner of the Alleghanies* (1862); and *A Summer Story, Sheridan's Ride and Other Poems* (1867). Among his paintings are the well-known portraits of Mrs. Browning and of Longfellow's children; the portraits illustrating his compilation, *Female Poets of America* (1848); and the painting illustrating his *Sheridan's Ride*.

Reade, Charles: novelist; b. in Ipsden, Oxfordshire, England, in 1814; educated at Magdalen College, Oxford, and graduated 1835; was elected to a Vinerian fellowship at Oxford 1842; was called to the bar at Lincoln's Inn 1843; published in 1852 *Peg Woffington*, a novel which gave him an immediate reputation, and afterward issued many novels and tales, among which are *Christie Johnstone* (1853); *Never Too Late to Mend* (1856); *Love me Little, Love me Long* (1859); *The Cloister and the Hearth* (1861); *Hard Cash* (1863); *Griffith Gaunt* (1866); *Put Yourself in his Place* (1870); *A Terrible Temptation* (1871); *A Woman Hater* (1878); and *The Jilt and Other Tales* (1884). Reade displayed great skill in plot and incident, had a picturesque style, and often wrote with a social or political object in view. Most of his novels were successfully dramatized by himself or by Boucicault, and he wrote several independent plays. He gained some note from his lawsuits on questions connected with the rights of authors and the limits of permissible literary criticism, and from his vigorous advocacy of international copyright with the U. S. D. at Shepherd's Bush, London, Apr. 11, 1884.

Reade, John: See the Appendix.

Reade, William Winwood: nephew of Charles Reade; traveler and novelist; b. at Ipsden, England, in 1839; published several novels, one of which, *The Veil of Isis, or the Mysteries of the Druids* (1861), displayed much ethnological knowledge, combined with a strong anti-theological bias; traveled on the west coast of Africa 1862–63; published on his return *Savage Africa* (1863); made a journey from Sierra Leone to the sources of the Niger 1868–70; published *The Martyrdom of Man* (1872); and *The African Sketch-book* (1873); accompanied the Ashantee expedition as correspondent of *The Times* 1873–74. D. at Wimbledon, Apr. 24, 1875. His latest publications (1875) were *The Story of the Ashantee Campaign* and a novel, *The Outcast.*

Reading, red'ing: town; capital of Berkshire, England; on the Kennet, near its junction with the Thames; 36 miles by rail W. of London (see map of England, ref. 12–I). It contains ruins, surrounded by public gardens, of a Benedictine abbey, founded by Henry I., who was buried there. The abbey was used as a palace by Henry VIII. and his successors until its destruction during the Cromwellian wars. Among modern structures are the Renaissance municipal buildings, containing a free library, science and art schools, etc., the assize courts, and the grammar school (rebuilt 1871). Reading has manufactures of silk, velvet, and ribbons, and has trade in wheat, flour, malt, timber, wool, and cheese. It has a huge biscuit-factory, and adjoining the town is an extensive seed-nursery covering 10,000 acres. Reading is the seat of a suffragan bishopric in the diocese of Oxford, and returns one member to Parliament. Pop. (1891) of municipal borough, 55,752; of parliamentary borough (1901), 72,214.

Reading: town (incorporated in 1644); Middlesex co., Mass.; on the Boston and Maine Railroad; 12 miles N. of Boston, 15 miles S. E. of Lowell (for location, see map of Massachusetts, ref. 2–H). It contains a high school with preparatory college course, a public library (founded in 1868) with over 7,000 volumes, a national bank with capital of $50,000, a savings and co-operative bank, and a weekly newspaper. The town has important manufactures, which include shoes, furniture, machinery, magnetic goods, organ-pipes, and brushes. Pop. (1880) 3,181; (1890) 4,088; (1900) 4,969. Editors of "Chronicle."

Reading: city (founded in 1748, incorporated as a borough in 1783, chartered as a city in 1847); capital of Berks co., Pa.; on the Schuylkill river, the Schuylkill Canal, and the Penn., the Phila. and Reading, and the Wilmington and Northern railways; 54 miles E. by N. of Harrisburg, 58 miles N. W. of Philadelphia (for location, see map of Pennsylvania, ref. 5–I). It is in an agricultural region, has large trade and excellent shipping facilities, and is noted for its manufactures, especially of iron and steel. E. of the city is Mount Penn, and S. of it is the Neversink Mountain. On the summit of the latter are two large hotels. A gravity railway, 8 miles long, has been constructed from the city to the summit of Mt. Penn and around the mountain. The summit is 1,140 feet above sea-level, and is surmounted by a stone tower 50 feet high. At the lower terminus of the railway the city has converted a tract of wild land into a beautiful park. There is another public park, of 50 acres, at the head of Penn Street. Local transit is afforded by trolley cars throughout the city, five electric railways extending into the suburbs, and one crossing the Neversink Mountain to Klapperthal, a large and beautiful park. The city is supplied with water from springs and mountain streams and by pumping from the Maidencreek. There are six reservoirs and over 75 miles of distributing-mains. The water-plant is valued at $1,500,000. There are gas, electric, and steam-heating plants, volunteer fire department with electrical fire-alarm, and six cemeteries. Reading contains 60 churches, a training-school for teachers, a high school for boys and one for girls, 45 public schools, public-school property valued at $535,500, business colleges, 13 private schools, 2 libraries (the Reading, founded in 1808, and the Berks County Law, founded in 1843) containing over 10,000 volumes, 3 opera-houses, 3 hospitals, 3 homes for orphans, 7 national banks with combined capital of $1,450,000, 2 State banks with capital of $225,000, 20 building and savings associations, 4 trust companies, a board of trade, and 6 daily, 1 Sunday, 11 weekly, a bi-weekly, and six monthly periodicals. The census returns of 1890 showed that 434 manufacturing establishments (representing 84 industries) reported. These had a combined capital of $14,718,678, employed 12,976 persons, paid $5,466,923 for wages and $12,014,493 for materials, and had products valued at $20,864,585. The principal industry was the manufacture of iron and steel, which had 11 establishments, combined capital of $4,391,734, and products valued at $7,122,397. Fifteen foundries and machine-shops had capital of $1,833,120, and products valued at $1,769,949. Other important manufactures were hardware, woolen hats, textiles, malt liquors, cigars, hosiery, brass, and planing-mill products. The principal shops of the Philadelphia and Reading Railroad Company are located in the city. In 1894 the assessed valuation was $41,408,805; value of city property, $1,800,000; city debt, $420,000; water debt, $615,500. Pop. (1880) 43,278; (1890) 58,661; (1900) 78,961, with suburbs, 90,000. Jesse G. Hawley, proprietor of "Eagle."

Reagan, John Henninger: U. S. Senator; b. in Sevier co., Tenn., Oct. 8, 1818; settled in Texas during its existence as an independent republic; studied law, became surveyor, judge, member of the Legislature, and colonel of militia; was a member of the U. S. Congress 1857–61; Postmaster-General in the cabinet of the Confederate Government 1861–65, after which he was for some time a prisoner in Fort Warren; M. C. from Texas 1875–85, and re-elected. He was U. S. Senator for 1887–93. He was one of the authors of the Cullom-Reagan Interstate Commerce Act.

Re'al [= Span., deriv. of *real*, royal < Lat. *rega'lis*, royal, whence Eng. *regal* and *royal*]: in Spanish and Portuguese countries, a coin and money of account. The old silver real (the eighth of the *piastre*, *peso*, or dollar) was long a familiarly current coin in the U. S., where it was worth 12½ cents, and bore various popular names. In Spain the real is now about 5 cents. In Portugal 40 reis make one real, but it is never coined. In Spanish America the real has various local values.

Real Estate: See Property.

Real'gar [= Fr., from Span. *rejalgar*, from Arab. *rahj al ghār*, liter., powder of the mine]: mineral disulphide of arsenic, a resinous-looking ruby-red or orange-yellow mass, transparent or translucent, and of conchoidal fracture. It is also called *red orpiment* and *ruby sulphur*. It may be prepared artificially by melting together 1 part of sulphur and 2 parts of arsenious acid, and by melting metallic arsenic with sulphur or orpiment. Realgar is sometimes used as a pigment, though not so much as formerly.

Revised by Ira Remsen.

Realism [from Lat. *rea'lis*, pertaining to things or substances, real, truly existent, deriv. of *res*, thing, affair]: as opposed to nominalism, the doctrine that universals (notions of species and genera, such as *man*, *animal*) have real existences corresponding to them. In the Middle Ages the disputes of the Schoolmen (*q. v.*) over the solution of some questions of Porphyry developed this doctrine into sharp contrast with nominalism. The dispute was not an idle one, but involved the all-important theological and metaphysical question of personal individuality. At an earlier period, Boethius and St. Augustine had been decided Realists; so were all Platonists and Neo-Platonists. In the ninth century John Scotus Erigena and Remigius of Auxerre were Realists, while Rabanus Maurus and Eric of Auxerre indicated nominalistic proclivities. Roscellinus in the eleventh century boldly announced nominalism, and applied it to the Trinity, making three Gods, but no unity. Realism prevailed against him, if not by argument, at least by authority. The great Realists of the eleventh and twelfth centuries were Anselm, William of Champeaux, Gilbertus Porretanus, John of Salisbury; of the thirteenth century, Alexander of Hales, Bonaventura, Albertus Magnus, Thomas Aquinas, and Duns Scotus. Their doctrine was *universalia ante rem* (in God's mind), *in re* (in things), and *post rem* (in man's thought). Although in that age of authority we find most of the Schoolmen adopting and defending tenets with a blind zeal often devoid of any clear understanding, yet to the great thinkers here named must be conceded an insight into the true grounds of this doctrine as held by Plato and Aristotle. That universals are real in a different sense from individual things was held by all true Realists—a point not sufficiently considered by the Nominalists, who objected that one individual can not be predicated of another individual, using in this the very language of Aristotle (*De Cat.*, cap. v.), who carefully distinguishes the reality of universals (δεύτεραι οὐσίαι) from that of individuals (πρῶται οὐσίαι). It was held by Realists that individual things are fleeting and transitory; each thing has its history; it originates in some former thing, runs its course of action and interaction with other things, and finally disappears, giving place to

another, its suceessor. Hence each individual thing is only a momentary phase of some proeess whieh has many potentialities; these potentialities it realizes in the series of individual things, each thing realizing some of them. Thus the process, as embracing the rise and dissolution of many individuals, is generic or a universal; it possesses the potentiality of eaeh thing, and at the same time possesses the reality of eaeh; the reality of each thing is the reality of the universal process which causes it. Inasmuch as it—the process—annuls individual things, and likewise originates them, it includes in itself the total of reality, and is therefore real in a more complete sense than any individual thing. Again, it must be noted that what we call individual things are arbitrarily limited phases of processes. Each individual, so called, is identified by nominalism with only a portion of its history, as it were, for it ean be traeed by degrees back into another thing, in which it originated, and forward into another, in which it finally disappears. Moreover, it is eorrelated in spaee with other things, and it is arbitrary in the Nominalist to assume that he has an individual thing before him when he has only a dependent part of the whole process of interrelated things. Thus the word process, to whieh natural science in our day has arrived (Darwinism teaching that things are to be studied in their history and development, evolution and the correlation of forces being doetrines of the supreme reality of universals in the shape of a law or persistent foree), interprets realism, and reinstates it as a more advanced stage of thinking than nominalism. Realism may be (*a*) psychologieal, holding in regard to artificial things—e. g. table or chair—that the general notion or name conventionally signifies the purpose or design which creates such things, and therefore corresponds to what reality they possess; (*b*) natural, a realism which recognizes the natural objective processes in nature and mind. Mind is considered immortal as individual (not as a thing), for the reason that it is a total process within one reality; each thinking being has potentially in his mind the universal reason, and is able to realize the same by his own activity. In thus realizing his possibilities by culture and education he does not annul his individuality (as the process of forces annuls things), but rather intensifies his conseiousness of self, and deepens his subjeetivity by the same act in whieh he realizes his universality. This doctrine is expressed by Aristotle's "enteleehies." First enteleehy (self-contained being—"End-in-itself"—entire process in one reality) has all the possibilities and the power to develop them, but has not energized as yet (the man as infant or savage); second entelechy has developed its potentialities through self-activity (the man as cultured, civilized, and enlightened).—Realism, as contrasted with idealism in the school of common sense, is the theory that we cognize external objeets by direct perception instead of by means of interposed ideas.

WILLIAM T. HARRIS.

Realism in Fine Art: the art or practiee of expressing the real in contradistinction to the imagined, the ideal, or the traditional. Thus, in the choiee of subject, the representation of a glory of angels may be ealled imaginative or imaginary. The frieze of the Parthenon is a strongly idealized treatment of a procession, very abstract indeed, and not at all a complete statement of the faets. The pieture of a saint with his or her attributes is generally very traditional. In opposition to these, realism would choose religious enthusiasm seen among living and humble people, or a faithful portrait of a military or civic parade, or a sailor risking his life in the way of duty. That is to say, the realist paints what he has seen and known, and whatever ideas of dignity or humility he may wish to convey will be given to the common scenes and the actual persons of his own experience. Apart from the choice of subject, realism chooses a manner of representing men and things which will give them nearly as they are to ordinary human observation. A realistic study of slaves or poverty-stricken peasantry would insist on their dull and fatigued expression, their stooping and often malformed bodies, and their hard and hopeless toil. The same subject, the same scene and incident, might be treated so as to insist upon the close communion with nature, the healthful out-of-door life, the strength of body of both men and women. Also, to come still further away from the mere choice of subject, the peasants or the slaves in the realistic picture will be shown ugly because of monotonous work and poor food, ill-clothed and dirty, unpleasing and even repulsive to look at. The same men and women may be invested with beauty of form and color, and may be so painted and so grouped as to give a very beautiful resulting composition, without obvious and admitted falsehood.

Realism in art is generally assumed to be a debasing theory and practice. The term is more often used in reproach, and applied to artists whose work is not approved. In this there is a constant though unconscious reference to the French term *réalisme*, which is commonly used in this evil sense. Some years ago a photograph from a drawing by Couture was handed about the studios; it represented a student of art seated on a cast of the head of an Apollo and drawing carefully from the head of a large hog, while cabbages and old boots lay about as further models for study. The title written below was *Un Réaliste*, and the idea was, of course, that realism turned away from the highest beauty to see truth in the ugly, or at least the indifferent; but this again is a mere satire of assumed vulgarity in choice of subject; and no one would have been quicker than Thomas Couture to state that choiee of subject has little to do with fine art, and that it would be better to treat a group of swine ideally than a group of men of heroic stature and beauty realistieally. In all the French horror of *le réalisme* there is the assumption that it is in some way opposed to *l'idéal*; that is to say, that realism is the antagonist of idealism. As all artists are in pursuit of the ideal in one form or another, this antagonism can hardly exist to the degree supposed. Rembrandt in his etchings was a realist as to the figures of men and women; he took them as he saw them, ill-grown, ill-nourished, clothed in hideous garments: but in light and shade and the composition of light and shade he was an idealist in the highest sense. The student who compares the *Adam and Eve* of Rembrandt with a photograph or a cast from the Parthenon frieze is free to say, as he is apt to feel, that the one is vulgar realism and the other is noble idealism; but a further consideration brings with it the sense that one is as idealistic as the other—it is only a question what the ideal is.

Again, a landscape painting may show the rocky structure of two low hills on the Newport coast, and the thin bed of morass which fills the hollow between them. It is perfectly traceable how the hills are built up and how they are wearing away; and the bit of swamp which separates them is as obviously there merely because the rock is impervious to water, and holds vegetable mould and pulverized rock together in a soft, spongy, saturated mass, as if we could sound it and take up a shovelful for examination. This treatment of the natural facts with a strong insistence on their true character is certainly realistic; but the means taken to show it are probably very idealistic, probably so because it is unlikely that the whole story would be as clear to the eye of the observer at any one point of the natural landscape as it is made to the student of the picture. The picture as a piece of coloring and line composition is an ideal work, of course, but it will be ideal also in the matter of this insistence on a high and important truth, which truth could only be shown in its fullness by a very decided abandonment of mere copying.

The conclusion is that in fine art there is none of that clear distinction between realism and idealism that is maintained in metaphysics. Idealism is merely the higher realism, the realism of very intelligent and clear-seeing men.

RUSSELL STURGIS.

Reality: the fundamental truth, underlying all things. See METAPHYSICS.

Real Presence (sc. of Christ in the Eucharist), **The Doctrine of the**: part of the professed belief of the Roman Catholic, Greek Catholic, and other ancient Churches. According to it "Christ is contained whole and entire under either species—i. e. that his body, blood, soul, and divinity are given both under the form of bread and under that of wine" (*Addis and Arnold*). In the Anglican Church the real presence is maintained, but so defined as to avoid the imputation of being a belief in the corporal presence—i. e. in "the presence in the holy sacrament of the Lord's Supper of the body and blood of Christ in a corporeal or materially substantive manner" (*Hook*). On the contrary, the real presence is not "to be sought for in the sacrament, but in the worthy receiver of the sacrament" (*Hooker*); but as, "with the natural bread in the sacrament, there is present the spiritual bread which is Christ's body," it is none the less real. See EUCHARIST and TRANSUBSTANTIATION.

Real Property or **Realty**: See PROPERTY.

Reaping and Mowing Machines: machines usually operated by horses, used instead of sickles or scythes in cutting grain and grass. They have many features in common, and are considered together in this article. The first account of reaping-machines is given by Pliny the Elder, A. D. 23, who describes, as used in Gaul, a cart with a series of

FIG. 1.—Reaper used by ancient Gauls.

stationary projecting combs in front (shown in Fig. 1), which cut, or rather tore off, the heads of grain, leaving the straw standing. A machine operating on the same principle of stripping the heads is now in common use in Australia, except that mechanical means are provided for elevating the grain to a threshing and cleaning device and for putting the grain into bags. Pitt made the first English reaping-machine in 1786, and up to 1826 twelve improved or modified machines were brought out by as many inventors in England. Boyce, in 1799, was the first to take out a patent. Up to 1828, however, all these machines were failures, and in 1835 there were only three machines that had succeeded in doing field work. In the U. S. twenty-eight patents were granted on reapers and mowers up to 1835, and over 20,000 have been granted since. Reaping-machines are the product of the combined skill of many inventors. Their essential parts are a cutting apparatus, gathering device, platform, carriers or rakes for elevating or depositing the grain in gavels or in wagons, and a divider for separating the swath to be cut from the grain. Rev. Patrick Bell,

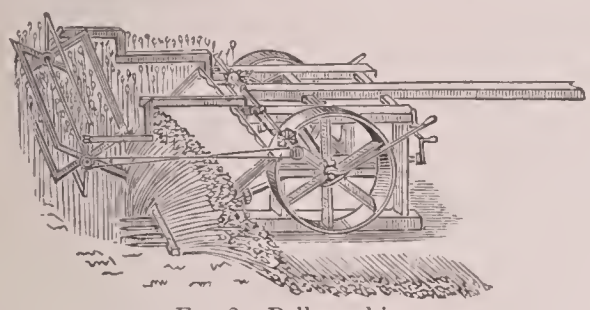

FIG. 2.—Bell machine.

of Scotland, in 1828 and 1829, built a reaping-machine with a reel, and scissors to cut the grain, and an endless carrier

FIG. 3.—The reaper invented and built by Cyrus H. McCormick, Steele's Tavern, Va., 1831.

to receive and deposit it at the side (Fig. 2). It remained unknown until the London Exhibition of 1851, after which it was tried, but failed in the competition with better machines. In 1831 the machine of Cyrus H. McCormick was invented and successfully operated. This machine, for the first time, was an organized instrument, containing practical devices that have been incorporated in every successful reaper made since (Fig. 3). As built and tested in the field in 1831 it contained the reciprocating knife moving through fixed fingers to sever the grain, the platform to receive the grain, the reel to hold the grain for the knife and to incline it upon the platform, and the divider projecting ahead of the knife to separate the grain to be cut from that to be left standing. The horses traveled ahead of

FIG. 4.—The McCormick reaper of 1845. The raker is carried on the machine.

the machine and beside the standing grain. It was mounted upon two wheels, and the motion to move the operating parts was derived from the outer wheel. A raker walked beside the machine and drew the grain from the platform in bundles. Later a stand to support the raker was added (Fig. 4). Obed Hussey, in 1833, invented a vibratory zigzag sickle (Fig. 5), sliding through double finger-guards, which has been very generally adopted. His open-top finger-guard, a valuable feature, was not patented until 1847. In 1845 and 1847 patents were taken out by C. H. McCormick for his inventions. In 1849 Purviance made a movable platform by which the reaper could be converted into a mower. Mr. Dorsey, in 1855, dispensed with the reel and adopted the quadrant-shaped platform, invented by Seymour, and a continuously revolving rake and series of beaters so arranged that, while they and the rakes brought the grain to the cutters and the platform, the rake, instead of rising, followed the cut grain, and deposited it in gavels. In the same year Samuel Johnson, of Brockport, N. Y., made a practical application of the single-arm, vibratory sweep-rake (Fig. 6), and so arranged it and the beaters that they acted either as rakes or beaters at the will of the operator. Sieberling, in 1861, took out patents for a drop which was composed of slats, which deposited the grain at intervals upon the ground immediately behind the cutter bar. His invention was subordinate to prior English patents. In 1865 W. N. Whiteley adapted a revolving and controllable rake to the two-wheeled, jointed-bar machines, substantially as now used on all reapers. In 1868 he invented an automatic open switch for the controllable-reel rakes, as now in gen-

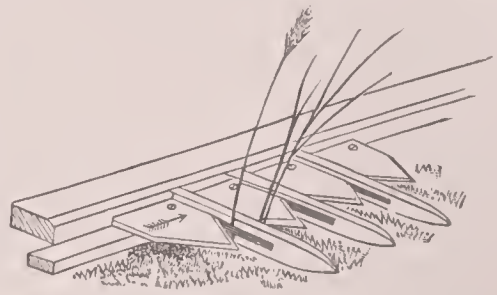

FIG. 5.—Hussey's cutter.

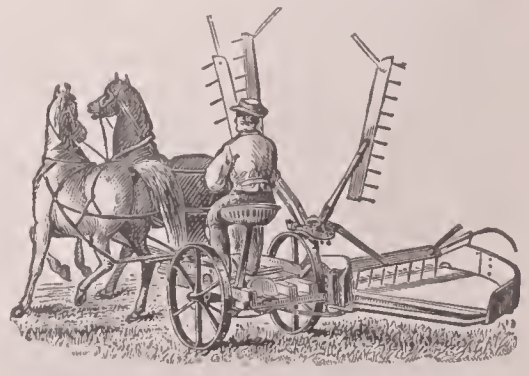

FIG. 6.—Vibratory sweep-rake reaper.

eral use. Several forms of rake, as Wood's chain-rake and Miller's table-rake, have been introduced into the U. S. and other countries. C. W. and W. W. Marsh invented and patented a machine in 1858 in which the cut grain was received on an endless apron and carried thereby to another apron, which elevated the grain to a stand on the machine, where two men, while riding along, bound it into bundles. This machine (Fig. 7) considerably advanced the art of cutting grain. The automatic wire self-binder, marking a progressive step in harvesting machinery, followed the Marsh harvester. The wire bands proved to be objectionable in both wheat and straw. Magnets were required in the mills to remove the pieces of wire from the wheat, and cattle were injured by the wire when eating the straw. Marquis L. Gorham invented a cord-binding attachment which, with various improvements by J. F. Appleby, has been generally adopted by the manufacturers of binders, with one or two notable exceptions. All self-binding machines are now so perfected that they give universal satisfaction. In all this class of machines the grain is delivered by the elevating aprons upon a slanting table, where iron packers work continuously through slots in the table and rake the grain down to the knotter and upon a trip-finger, which automatically sets the knotter in motion when enough grain has accumulated for a bundle. The knot is tied in the cord by a single revolution of a bill-shaped hook with a hinged tongue that is moved by a cam. The self-binder (Fig. 8) has rapidly replaced the self-rake reaper (Fig. 9). Briggs and Carpenter, Feb., 1836, secured patents for a heading-machine; since then over 100 have been granted on these machines, which have proved to be well adapted to cutting large harvests in dry climates. The essential parts are a cutting device from 16 to 20 feet long, mounted upon wheels, a reel, an endless horizontal apron, which carries the severed heads to a second apron, extending 4 to 6 feet at an upward angle, whereby the heads are deposited in a large wagon-box, the side next to the header being low, the opposite side high.

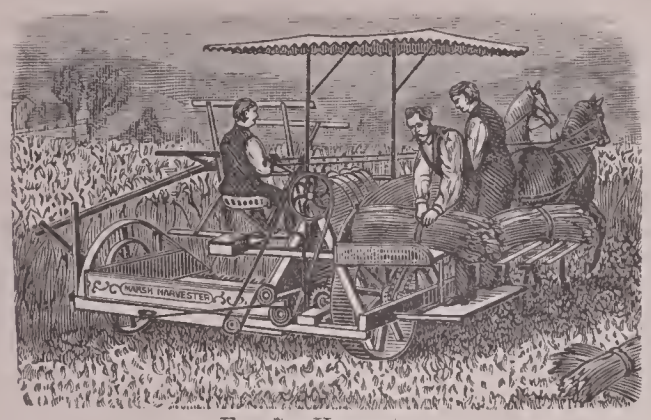

Fig. 7.—Harvester.

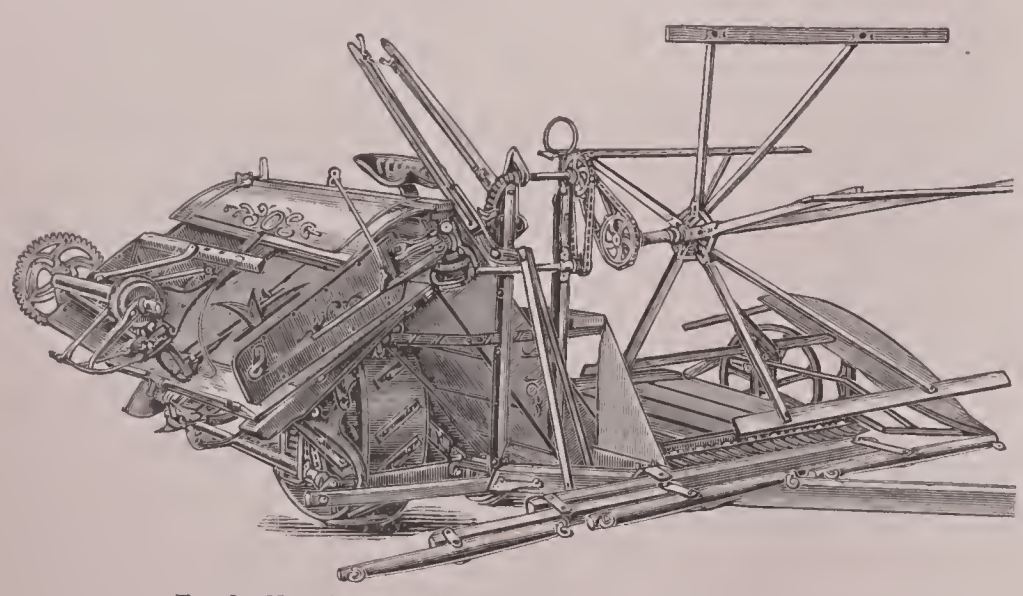

Fig. 8.—New Osborne harvester and binder (the self-binder).

A large, long tongue extends to the rear, supported by a truck, and with wheel-steering device similar to that used on steamboats. Four horses abreast, attached to the tongue near the trucks, push the machine. The cutting device is like that shown in Fig. 10. Six men and ten horses are able to cut and stack the grain from 15 to 30 acres daily. The combined harvester (Fig. 10) unites the header, the thresher and separator, the fanning-mill, the sacker, and straw-carrier in one machine. The large machines are propelled either by a traction-engine or by thirty to thirty-six horses. If steam-power is used, seven men are required; if horse-power, four. Of the combined harvesters 10 per cent. are steam-power, 90 per cent. horse-power. Either will cut from 60 to 125 acres and thresh from 1,700 to 3,000 bush. daily. The average life of one of these harvesters is about eight years if used forty to fifty days each season. From the grain-cradle to the steam-harvester is a long way, yet the larger part of the harvests of the world is secured by the aid of the former, or implements still more primitive.

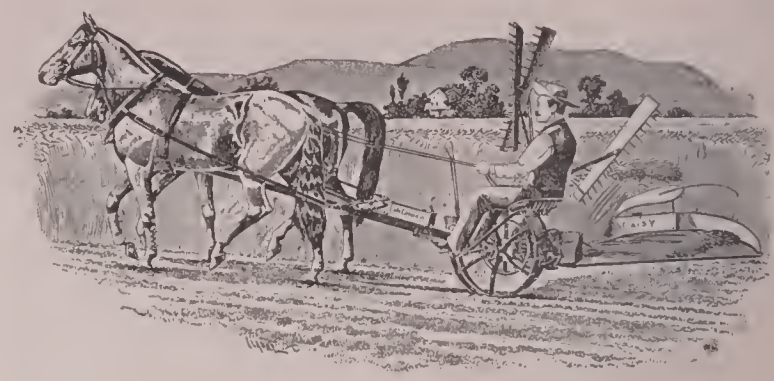

Fig. 9.—A modern self-rake reaper.

Fig. 10.—Combined harvester (shown as at work in the field).

The corn-harvester (Fig. 11) is the greatest improvement in the late inventions of harvesting machinery. It is the binder modified, strengthened, and adapted to the heaviest and most difficult work—that of cutting, elevating, and binding corn 8 to 14 feet high, weighing from 15 to 25 tons per acre.

Simultaneously with the reaper came the mowing-machine. At first it was practically the reaper dismantled of its platform and other parts not needed for cutting grass. As it required a higher speed to cut grass than grain, no satisfactory combined mower was made until a device was invented for changing the knives from a low to a high speed. Separate machines for mowing are now the rule; they are without reels or platforms. The cutter-bar is hinged at the inner end to allow it to follow the inclinations of the ground. Levers are provided for elevating or depressing the cutter-bar and for controlling the dip or angle of the guards and knives. Cyrenus Wheeler produced a successful mower in 1853, which was soon followed by the Buckeye and others, which were modifications of Hussey's and Wheeler's machines. Rear-cut machines were most common prior to 1880; since that time front-cutting machines have come into general use (Fig. 12). In 1870 Rudolph Eichemeyer's oscillating gear mower converted, by means of cams in the main wheels, their rotary motion into reciprocating motion required by the knife, thus obviating the necessity of gear-wheels.

Though efforts to cut grain and grass by machinery in Great Britain antedate those made in America, yet the U. S. so far excels in the construction of harvesting machinery that none of any description is imported. Since 1875, at

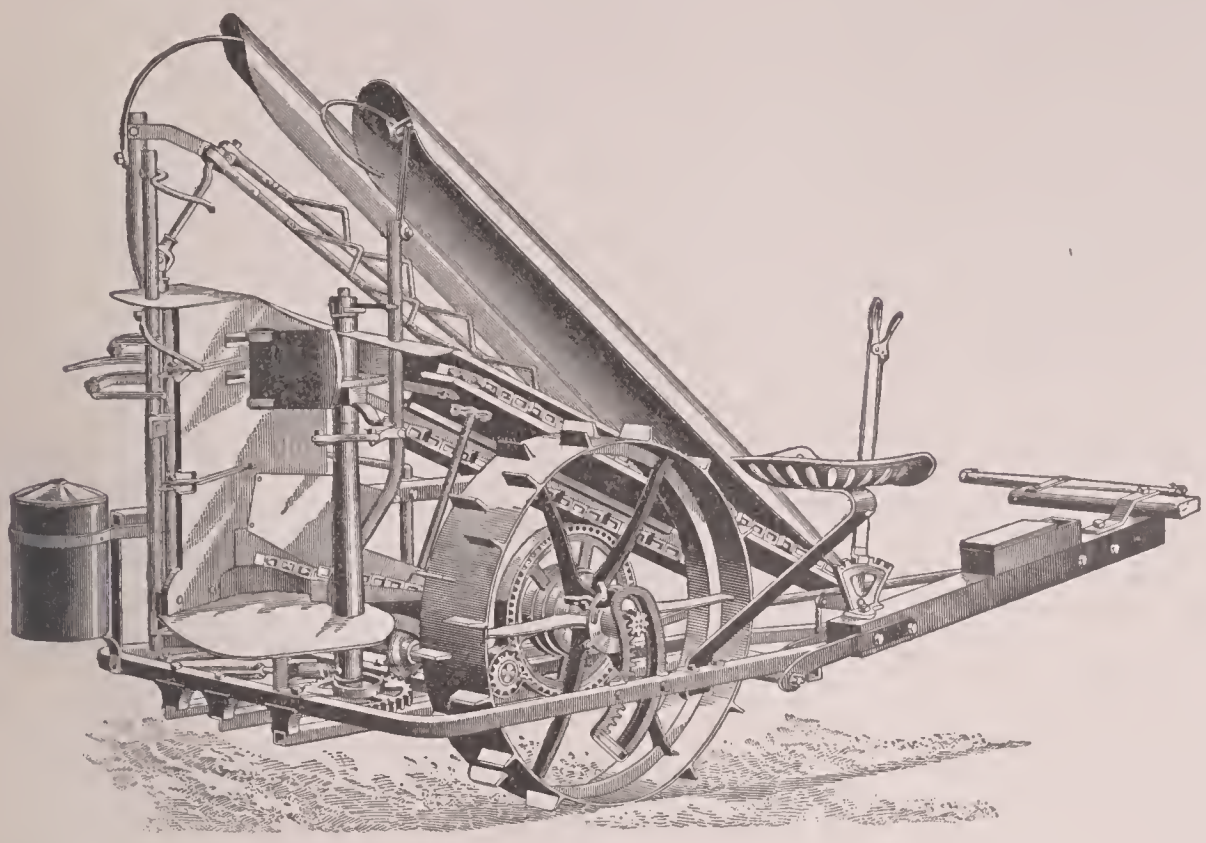

Fig. 11.—Vertical corn-binder.

which date American machines had been fairly perfected, about a dozen large and as many more small establishments have manufactured for home use over 100,000 machines annually, while supplying other nations with the larger share

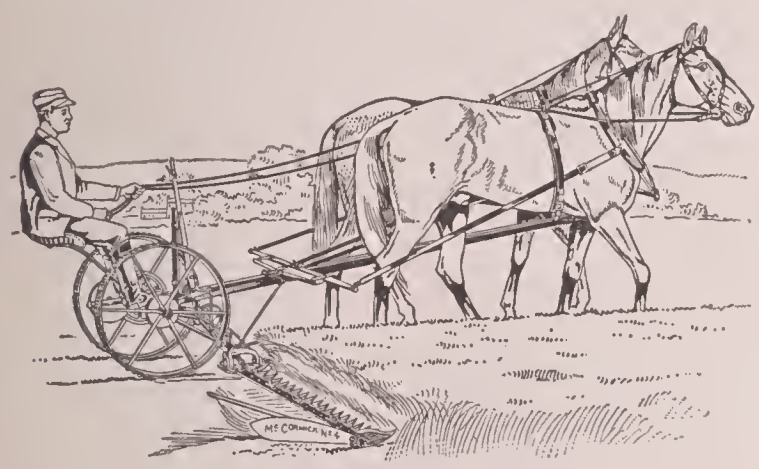

Fig. 12.—Modern mowing-machine.

of their harvesting appliances. The total average number of machines made each year exceeds 300,000. I. P. Roberts.

Reason [M. Eng. *resoun*, from O. Fr. *resoun, raison* > Fr. *raison* < Lat. *ra'tio*, reckoning, thinking, judgment, reason, deriv. of *re'ri, ra'tus*, reckon, calculate, think, judge]: in its first or most general signification, the conscious intelligence of man as contrasted with the instinct of brutes or with the necessitated action of inanimate things. In this sense stress is laid on the ability to adapt means to ends. From it are derived the expressions "reasonable" and "according to reason"—i. e. according to a proper regard for the adaptation to ends; "rational," meaning correct appreciation of this adaptation; "irrational," lacking such appreciation. Its second signification is that of ground—the "reason why anything is or is done." This includes (*a*) the ground as motive of action, (*b*) as efficient cause or sufficient reason. Aristotle's formal cause (*τὸ τί ἦν εἶναι*), the ideal totality of the possibilities of a thing within which exists mutual adaptation of parts, is the distinction upon which rests this and the former use of the term reason. The verb to reason, in the sense of to argue or adduce grounds, and the noun ratiocination come from the second meaning. (See Cause.) The third use of the word is as an equivalent of Aristotle's *νοῦς*: (*a*) *νοῦς ποιητικός, actus purus*, active or divine reason, the thinking occupied with creating and contemplating divine ideas; (*b*) *νοῦς παθητικός*, passive reason, including the activities of the mind in mere feeling or desire, sense-perception, imagination, and reflection. This active reason is nearly what Victor Cousin calls the impersonal reason, that to which "we owe the knowledge of universal and necessary truths, of principles which we all obey and can not but obey"—"the light that lighteth every man that cometh into the world." The fourth meaning of reason is akin to that of active reason, and distinguishes it from understanding. Kant, its author, makes the latter deal exclusively with the results of sense-perception, while reason deals with the supersensuous. With him, reason (*Vernunft*) is not a faculty of cognition, but only "regulative" of the practical conduct of life. Hegel and others restore it to its function of highest faculty of cognition, but preserve its function as practical, inasmuch as they make it to be the recognition of universal and necessary principles, not in a mere abstract sense, but as realized in the institutions of civilization, including under this head family, society, state, art, religion, and science. It is of interest to note that the Germans and English use the word reason (or German *Vernunft*) to mean the higher faculty of cognition, whose object is God or the infinite, and the word intellect, as equivalent to understanding (Germ. *Verstand*), to mean the "mere human" knowing of finite and relative objects; while the Italian philosophers make the intellect (*intelletto*) cognizant of divine things, but the reason (*ragione*) only of the finite.

William T. Harris.

Reasoning: See Logic.

Réaumur, rā'ō'mür', René Antoine Ferchault, de: physicist and naturalist; b. at La Rochelle, France, Feb. 28, 1683; educated in the Jesuits' College at Poitiers; studied law at Bourges; settled in 1703 at Paris; devoted himself with great enthusiasm to the study of natural history, physics, and mathematics; became a member of the Academy in 1708; received a pension of 12,000 livres a year from the Government for his *L'Art de convertir le Fer forgé en Acier* (1722), by which he first made his countrymen acquainted with the art of making steel of iron. D. on his estate, Bermondière, in the province of Maine, Oct. 17, 1757. He is best remembered by the thermometer which is called after his name. (See Thermometry.) Of his works the most remarkable is *Mémoires pour servir à l'Histoire naturelle des Insects* (6 vols., Paris, 1734–42).

Rebec [viâ O. Fr. from Ital. *ribeca, ribeba*, from Arab. *rabāba*, rebec, fiddle with one or two strings]: a musical instrument introduced by the Moors into Spain, whence its use spread over Europe. It was a precursor of the violin, and was of various sizes. From the neck it grew larger until the base was reached. It was played with a bow.

Rebolledo, rā-bōl-yā'dō, Bernadino, de, Count: poet; b. at Leon, Spain, in 1597. From the age of fourteen he was a soldier, serving against the Turks and in Barbary, and afterward during the Thirty Years' war. In 1647 he was ambassador to Denmark, and later to Sweden. He was on intimate terms with Christina of Sweden, and had a part in her conversion. From 1662 he was Minister of State at Madrid, and enjoyed many emoluments and honors. As a poet he strove to keep clear of the eccentricities of Gongorism, but fell into the opposite fault of being prosaic. He published at Antwerp in 1650 a volume of verses entitled *Ocios*; in 1652, at Cologne, a didactic poem called *Selva militar y*

política; a version of the book of Job, called *La constancia victoriosa*, and one of Jeremiah, *Trenos de Jeremias* (both Cologne, 1655). He wrote also a poetical version of the Psalms, a life of Christ in verse, and several ballads and epigrams. D. in Madrid in 1676. His works were printed in three volumes, at Madrid, in 1778. A. R. MARSH.

Récamier, rā'kăă'mi-ā', JEANNE FRANÇOISE JULIE ADELAÏDE BERNARD, Madame: b. at Lyons, France, Dec. 4, 1777; a woman of great charm of person and mind, she married in 1793 Jacques Récamier, a Paris banker, three times her age, and made her house the gathering-place of a group of brilliant personages, among whom Chateaubriand and Ballanche were conspicuous. The reactionary political and religious ideas there current made her the object of Napoleon's displeasure, and in 1811 she was ordered to leave Paris. At the restoration she returned to Paris and established herself modestly in the old Abbaye-aux-Bois, where she again became the center of a brilliant intellectual circle. Her beauty and intelligence gained her many worshipers and suitors, among whom Chateaubriand and Prince August of Prussia are famous. D. May 11, 1849. See Madame Lenormant, *Souvenirs et correspondance tirés des papiers de Madame Récamier* (2 vols., Paris, 1860), and *Madame Récamier, les amis de sa jeunesse* (Paris, 1872), both translated into English by Isaphene M. Luyster (Boston, 1867 and 1879); also Chateaubriand, *Mémoires d'Outre Tombe*, vols. viii.–x. A. G. CANFIELD.

Recanati, rā-kăă-naa'tĕĕ: town; in the province of Macerata, Italy; on a hill about 900 feet above the sea; 15 miles S. of Ancona (see map of Italy, ref. 4–E). The adjoining country is very productive, the grapes and figs being of the finest quality. The town has a Gothic cathedral dating from the fourteenth century. The Palazzo Comunale has on its façade a bronze representation of the translation of the Holy House to LORETO (*q. v.*). Leopardi was born here, and his monument adorns the principal piazza. Recanati was sacked by the French in 1799. Pop. 5,824. Porto Recanati, 6 miles N. E. on the coast, has 3,040 inhabitants.

Recapture: in international law, the recovery of a captured vessel by a cruiser of the same nation or of an ally. If retaken before any sentence of a prize-court of the captor's sovereign has decided upon the validity of the capture, and thus determined the ownership of the captured vessel, it goes to the owner; after such sentence, if retaken, it goes to the captor. The captor in the first of these two cases is entitled to a reward. (See SALVAGE.) This is the usage in the courts of the U. S., but a majority of the maritime states of Europe, including Great Britain, restore a recaptured ship to the original owner, even after she has been condemned by a prize-court and adjudged to the captor. It would seem that a neutral purchaser for value from the captor might thus lose his property. A French privateer is not compelled to restore a recaptured ship if an enemy has held it twenty-four hours, while a man-of-war must do so. Spain restores a recaptured ship to the neutral unless she is loaded with enemy's property. The amount of salvage payable to the recaptor by an owner differs. In Great Britain and the U. S. the usual rate is one-eighth of the value of ship and cargo, though the latter nation observes reciprocity in the matter, levying the same rate that would be applied to its ships by the state to which the recaptured vessel belongs. France charges one-tenth, but if recapture has taken place within a day only a thirtieth. Spain and Portugal charge one-eighth, but more if the recaptor is a privateer. Denmark and Sweden allow one-third and one-half respectively. The rate may be modified by treaty. Revised by T. S. WOOLSEY.

Receipt [from O. Fr. *recete* < Lat. *recep'tum*, liter., something received, neut. perf. partic. of *reci'pere*, receive]: the transaction by which property is delivered by one to another, or a writing acknowledging such a transaction. It is used in the first sense in the Statute of Frauds. (See FRAUDS, STATUTE OF.) A written receipt is to be distinguished from a RELEASE (*q. v.*) in that it does not destroy a subsisting right, but is merely evidence of a fact, and therefore may be explained or refuted. As it is merely evidence of a fact it is not a CONTRACT (*q. v.*), although the written instrument in which it appears may contain a contract also. A familiar example is a BILL OF LADING (*q. v.*), which sets forth a receipt of certain goods by a carrier and a contract to transport them. It is at times difficult to decide whether a particular instrument is a simple receipt or superadds to this a contract obligation. Even in the latter case the receipt is open to explanation, except in cases where the contradiction of the receipt would work a destruction of the contract. (*Basch* vs. *Humboldt Mutual Insurance Company*, 35 N. J. L. 429.) Whether the person delivering property or making payment pursuant to a legal obligation has the right to a simple receipt has not been settled by the courts, but statutes give such a right in certain cases. FRANCIS M. BURDICK.

Receiver: a person appointed by the court to receive rents, issues or profits of land, or other property which is in question between the parties to a litigation, or which belongs to one who is legally incompetent, as an infant. The appointment of receivers was resorted to by equity tribunals for the purpose of doing justice in cases where the jurisdiction and remedies of the common-law courts were inadequate. The general principles upon which a court of equity acts in appointing and controlling receivers are stated briefly by the U. S. Supreme Court as follows: "A receiver is appointed upon a principle of justice for the benefit of all concerned. Every kind of property of such a nature that, if legal, it might be taken in execution, may, if equitable, be put into his possession. Hence the appointment has been said to be an equitable execution. He is virtually a representative of the court, and of all the parties in interest in the litigation wherein he is appointed. He is required to take possession of property as directed, because it is deemed more for the interests of justice that he should do so than that the property should be in the possession of either of the parties in the litigation. He is not appointed for the benefit of either of the parties, but of all concerned. Money or property in his hands is in *custodia legis*. He has only such power and authority as are given him by the court, and must not exceed the prescribed limits. The court will not allow him to be sued touching the property in his charge, nor for any malfeasance as to the parties or others without its consent; nor will it permit his possession to be disturbed by force nor violence to be offered to his person while in the discharge of his official duties. In such cases the court will vindicate its authority, and, if need be, will punish the offender by fine and imprisonment for contempt." *Davis* vs. *Gray*, 16 Wallace 203.

Whether a receiver should be appointed in a given case is a matter of judicial discretion, which is exercised cautiously by the courts, especially in the case of a CORPORATION (*q. v.*). Modern legislation has given to law-courts authority to employ receivers, and has increased their powers and usefulness. The cases in which receivers are appointed fall into four classes: (1) Where there is no legal owner of the property, as in the case of an intestate's estate, or the owner is legally incompetent to manage it, as in the case of infants and lunatics. In the U. S., statutes often provide for a temporary administrator and give to guardians and committees an authority so wide as to render receivers unnecessary. (2) Where the litigants are legally competent to manage the property, but justice demands that neither party should control it, as in the case of winding up partnership affairs by judicial proceedings, or of the partition of property. (3) Where the legal title is held by one in a fiduciary capacity who is abusing his trust, as in the case of a suit against an executor, or a mortgagor, or of creditors' suits. (4) Where the proper enforcement of a judgment requires a receiver.

Receivers' Certificates.—Courts of equity are accustomed, at present, to authorize the receiver of a railroad company to borrow money for the operation of the road, and to issue therefor certificates which are made a first lien upon the property of the corporation. This extraordinary power is exercised because of the quasi-public character of railroads, and has been denied in the case of a private corporation, whose chief business was mining and selling coal. "A railroad corporation . . . is charged with the duty of operating its road as a public highway. If the company becomes embarrassed and unable to perform that duty the courts, pending proceedings for the sale of the road, will operate it by a receiver, and make the expense incident thereto a first lien. . . . Private corporations owe no duty to the public, and their continued operation is not a matter of public concern." (*Farmers' Loan and Trust Company* vs. *Grape Creek Coal Company*, 50 *Federal Reporter* 481.) Such certificates are non-negotiable securities; they do not pledge the general credit of the maker, but are payable out of a particular fund. Their validity depends upon the order of the court, and even a *bona-fide* purchaser will not be able to enforce them if the order has not been strictly followed in their issue. Their payment is not compelled by a suit at law, but by an order of the court. One who assigns or indorses them does not

incur the obligation of an indorser of negotiable paper, and it has been held that he does not impliedly warrant that they are collectible. If issued below par the holder's recovery upon them is limited to the amount he paid, unless the court authorized their issue or sale at a reasonable discount. (*Union Trust Company* vs. *Illinois Midland Railway*, 117 U. S. 434.) See Beach on *Receivers* (New York, 1887); Kerr on *Receivers* (London, 1891). FRANCIS M. BURDICK.

Recent Period: in geology, a portion of time between the Pleistocene period and historic time, though this portion is usually included in the Pleistocene. During this period the aspects of nature, both as regards the organic and inorganic worlds, have remained essentially the same, but minor changes have been constantly going on that serve well to illustrate and explain the manner in which the globe has been revolutionized in past ages. These changes consist in the elevation and depression of coast-lines, the scooping out of valleys, the draining and filling of lakes, the outbursts of volcanic matter, and the extinction of certain kinds of animal and vegetable life. See CHAMPLAIN EPOCH and PLEISTOCENE PERIOD. Revised by G. K. GILBERT.

Rech'abites: descendants of Rechab, the father or ancestor of Jonadab. They were a branch of the Kenites (1 Chr. ii. 55), who entered Palestine with the Israelites. The Rechabites were strict abstainers from wine, and dwelt in tents (Jer. xxxv.). There is a secret society of total-abstinence men and women in the U. S. and Great Britain known as the Independent Order of the Rechabites.

Recife: See PERNAMBUCO.

Reciprocity: in international law, the condition or relation existing by virtue of a species of treaty or convention between two or more nations, whereby each pledges itself to act in the same manner toward the other or others in reference to a given subject or to given subjects.

Strictly speaking, the stipulations of a reciprocity treaty or convention should be perfectly mutual; but a wider license is permitted in the actual practice, and if the stipulations are for the most part both in quality and quantity mutual, the term is used to denote this general mutuality in the agreements. Furthermore, the stipulations of the treaty or convention may be themselves of a general nature—as, for instance, in the use of what is termed "the most-favored-nation clause" in a treaty, whereby a treaty of reciprocity may be constructed without containing any particular specification of the manner in which the parties to the same shall act toward each other upon the given subject or subjects, but only the general pledge that each will deal with the other in reference to the subjects mentioned as it does or shall with that nation which it favors, or shall favor, most upon the same point or points.

The practice of reciprocity is older than European international law itself. In fact, before the period of the French Revolution of the eighteenth century the greater part of the intercourse of all the European nations was based upon reciprocity treaties and conventions. International law, as a system of principles, was at that period just emerging from the great mass of long-observed reciprocal agreements between nations. The Armed Neutrality of 1780—an agreement entered into by most of the nations of continental Europe, declaring and maintaining that the rule of "free ships, free goods," was a principle of international law independent of treaty or convention and based upon natural right—marks the chronologic point when, in practice, the exceeding importance of reciprocity agreements in international intercourse began to decline. The revolutionary idea at the close of the eighteenth century was to place both constitutional and international law upon the firm basis of natural reason or justice and universal principle, and emancipate them both from the arbitrariness and vacillation of conventional agreement. The famous debate in the French Assembly of 1790 in regard to the abolition of the Droit d'Aubaine presented most clearly a new philosophy of international law on the part of governments, which declared that every nation should accord to every human being, alien or subject, the natural rights of man, and protect him in their enjoyment, independent of any reciprocal agreements with the nation to which the alien belonged. Throughout continental Europe the revolutionary demand was made upon every government for the recognition of this principle, and Europe's political history from then to now is largely the record of its realization.

At the outset the British Government showed little disposition to sympathize with this enthusiastic humanitarian outburst of its revolutionary neighbor across the Channel; but thirteen years before the French movement began, the great economist Adam Smith produced his work upon the *Wealth of Nations*, one of the objects of which was to emancipate trade from the thraldom of reciprocal agreements between governments and place it in the category of the natural rights of man. That the British Government came to the adoption of this view, and assisted, at least, in bringing almost every European government to its recognition and practice, is matter of history. It may therefore be said, in general, that the revolutionary movements and changes at the close of the eighteenth century and the beginning of the nineteenth reduced greatly the part played by the rule of reciprocity in international intercourse, by moving out of its reach a large number of subjects, by far the larger number upon which it had thereto been employed —viz., the universal rights of man as a citizen of the world —and placing them under the protection of principle independent of specific treaty.

Numerous trade arrangements have been entered into by the U. S., as well as by European powers, on the basis of reciprocal or equivalent reductions in the duties on certain articles. By the third section of the act of Congress of 1890 commonly known as the McKinley Act, it was provided that, "with a view to secure reciprocal trade," sugars not above 16 Dutch standard, molasses, coffee, and hides should be admitted into the U. S. free of duty, unless the President "should become satisfied that reciprocal favors were not granted to the products of the United States" in the countries producing those articles. Under this provision arrangements were concluded with Brazil, the Dominican Republic, Honduras, Salvador, Guatemala, Austria-Hungary, Spain (as to Cuba and Porto Rico), the German empire, Nicaragua, and Great Britain (as to British Guiana and certain British West India islands) for the admission into those countries, free or at a reduced rate of duty, of certain articles from the U. S., in consideration of the free admission by the latter of the articles above enumerated. These arrangements were superseded by the tariff act of Aug., 1894, by which the conditions of trade were materially liberalized.

The word reciprocity is also sometimes used as a term of constitutional law to denote, in a confederate or federal state system, the mutuality upon certain subjects which the confederated or federated parts are obligated to observe. For example, in the Constitution of the U. S. it is provided that each State shall give full faith and credit to the acts, records, and judicial proceedings of every other, shall surrender to any other, upon proper and legal demand, fugitives from justice, etc. J. W. BURGESS.

Recitative [from Fr. *récitatif*, from Ital. *recitativo*, deriv. of *recita're*, recite]: in oratorios, operas, etc., a kind of musical reading or declamation resembling ordinary speech in time and accent, but differing from it by a strict adherence to the tones of the musical scale. The recitative is usually confined to such words as pertain to narrative, description, passion, and declamation. In ordinary recitative the rate and style of utterance are chiefly dependent on the discretion of the vocalist, sustained by an accompaniment of only a few plain chords; but in recitative with full accompaniment a more strict observance of musical time is required, although the rhetorical or declamatory character is still to be retained. Revised by DUDLEY BUCK.

Recke, rā'ke, ERNST, von der: poet; b. in Copenhagen, Denmark, Aug. 14, 1848. He is one of the few living Danish romantic poets, and his talent is almost wholly lyric-dramatic. His earliest and most popular poem is the three-act drama *Bertran de Born* (1872), with music by P. Heise, which is frequently performed at the Royal theater. His writings on the art of Danish verse, *Principerne for den danske Verskunst efter dens historiske og systematiske Udvikling* (2 parts, Copenhagen, 1881) and *Dansk Verslære i kortfattet Fremstilling* (Copenhagen, 1885) are of hardly less merit than his original works, and he has also engaged in the orthographical struggle in Denmark. Among his other publications may be mentioned *Lyriske Digte* (1876); *Kong Liuvigild og hans Sönner* (a tragedy, 1878); *Archilochos* (1878); *Knud og Magnus* (a tragedy, 1881); *Smaadigte* (1883); *Blandede Digte* (1890); *Fru Jeanna* (a tragic opera, 1891); *Hertuginden af Burgund* (1891). D. K. DODGE.

Recklinghausen, rek-ling-how'zen, FRIEDRICH DANIEL, von, M. D.: pathologist; b. at Gütersloh, in Westphalia, Dec. 2, 1833; studied medicine from 1852–55 at the Universities

of Bonn, Würzburg, and Berlin, graduating M. D. from the last in 1855; was assistant at the Berlin Pathological Institute from 1858 to 1864; in 1865 was appointed Professor of Pathologieal Anatomy at the University of Königsberg; in 1866 oecupied the same chair at Würzburg; and in 1872 went to the Strassburg university. He has contributed many valuable papers to the literature of pathology. S. T. A.

Reclus, *re-klü'*, Élisée: geographer; b. at Ste.-Foy-la-Grande, department of Gironde, France, Mar. 15, 1830; was edueated in Rhenish Prussia, and studied in Berlin under Karl Ritter; traveled from 1852 to 1857 in England and America, and published after his return to Paris a number of valuable geographieal works, partly in the *Revue des Deux Mondes*, partly in book-form, of which the most prominent are *The Earth* (2 vols., 1867) and *The Ocean, Atmosphere, and Life* (1872; translated into English by B. B. Woodward, New York, 1871 and 1872). His *Nouvelle Géographie universelle*, regarded as the most eomplete geographical survey of the world ever written, occupied him for twenty years (1874–94), and consists of nineteen volumes, of from 700 to 1,000 pages each. Among its illustrations are more than 3,500 maps. Holding extreme democratic views, when the revolution of Mar. 18, 1871, broke out he sided with the Commune, and later was sentenced to death, but upon the appeal of leading scientific men his sentence was eommuted to banishment. For several years thereafter he resided in Italy, the U. S., and elsewhere. Having returned to Paris, however, he again became involved in communistie plots and fled to Switzerland. Though absent, he was senteneed in 1894 to transportation for twenty years.

Revised by C. C. Adams.

Reclus, Paul, M. D.: surgeon; b. at Orthez, Basses-Pyrénées, France, Mar. 17, 1847; studied medicine in Paris, graduating M. D. in 1876; in 1878 passed the *concours* for the hospitals; in 1880 was appointed associate and subsequently full professor of surgery. Among his writings are *Clinique et critique chirurgicales* (Paris, 1884); *Cliniques chirurgicales de l'Hôtel-Dieu* (Paris, 1887). S. T. A.

Recluse [from O. Fr. *reclus* < Lat. *reclu'sus*, shut up (in Mediæv. Lat., a recluse)]: in strict language, a monk or nun who from choice retired from communication even with members of the same order. The secluded person sometimes adopted this life by way of penance, sometimes as a means of spiritual progress. No one could be thus secluded without permission. The door was sealed in the presence of a superior officer, and could be unlocked only by the command of a bishop. The name "recluse" was given to the inmates of Port-Royal, the famous Jansenist retreat in Paris.

Recognition: the feeling of familiarity with which an image or object affects us. We say feeling, since the recognition, in itself, accompanies the act of knowledge in which the object or image is again presented; that is, reproduction is assumed in recognition. This feeling of familiarity is vague and often misplaced, and ordinarily goes unanalyzed. The means by which recognition arises vary as the recognition is of an object or of an image. In the case of the second perception of an object its recognition is probably accomplished by means of an image which is already recognized. We have a comparison between the percept and the image, and feel them the same or similar. This is seen to be the case in frequent instances in everyday life. If we are asked whether an object is the same as one seen before, we often say we do not know, for we do not remember how the former object looked; which means that we are unable to call up and recognize any image with which the object present may be compared. In the case of the recognition of an image such a procedure is impossible. It would presuppose another image still, and so on indefinitely. The question, therefore, is narrowed down to the means by which we recognize a reproduced image.

The recognition of an image depends upon the degree in which its apperceptive relations are re-established. The reproduction of an image consists in the reinstatement of the conditions, physical or mental, of the original perception. Such a reinstatement of the conditions suffices to bring an image back into consciousness; but it is not then necessarily recognized. It is only when some of the mental connections—the relations established among the perceptual elements by appereeptive attention—are again more or less consciously presented that the sense of familiarity is felt. It is necessary that there be some accompanying conscious elements to which the recognized elements are related. Often when an image arises in consciousness we do not recognize it till we bring back some association with it. Often, also, we see a face and in so far recognize it as to feel vaguely familiar with it, while we strive to bring up more of its apperceptive connections in order fully to identify it. This first vague recognition is probably due to the felt beginnings of the revival of the spatial proportions of the face. This is further proved by the fact that percepts which are not related in the first presentation—for example, single isolated sensations, as the stroke of a bell—are not generally recognized. We say of such presentations that there is nothing distinguishing or characteristic about them whereby they should be recognized; but this is only to say that there were no specific points of connection between this image and others, or between the parts which are separately apperceived. As soon as some sign is made of a peculiar kind in connection with the image it is recognized. Experiments by Lehmann on the recognition of differences of color strikingly confirm this view. Different shades of gray, which could not be recognized when seen alone, were recognized when they were given names beforehand, or when a number was attached to each in the first perception. Of nine shades without names or numbers only 46 per cent. gave true recognitions; while the same shades, with numbers, gave 75 per cent. of correct identifications. Here the introduction of a simple *local relation* in the perception gave the necessary clew. Further support is derived from the phenomenon of so-called psychic blindness, deafness, etc.—i. e. recognition is absent in animals deprived of the higher co-ordinating brain-centers.

This view of the case also enables us to take account of the subjective element of recognition, which is often overlooked. There is more in recognition than the sense of familiarity with an image. There is the feeling of ourselves as in familiar circumstances. This feeling of self develops largely in connection with active attention. Attention, however, is the organ of the process of apperception. Consequently, when by reinstatement of this process the fact of recognition is experienced, it carries with it essentially the feeling of an emphasized self: the self of the first apperception is again evident in the self of the reapperception, and the sense of sameness of the apperceptive content really arises with the sense of the sameness of the individual who has it. Recognition of the image, therefore, and sense of personal identity, both rest ultimately in differences in the amount, ease, facility, and good adjustment of the attention.

J. Mark Baldwin.

Recognizance [from O. Fr. *recognoissance* (> Fr. *reconnaissance*), recognition, deriv. of *recognoistre* (> Fr. *reconnaître*), recognize < Lat. *recognoscere*, know again, recognize]: in law, an obligation of record which a man enters into before some court of record, or magistrate duly authorized, with condition to do some particular act, as to appear and answer in criminal proceedings, to prosecute a case or an appeal, to keep the peace, etc. (2 Bl. *Com.*, 341.) The recognizance is an acknowledgment (recognizing) of the existence of a debt or obligation appearing upon the record of the court, and need not be, like a bond, sealed and signed by the party. It is proceeded upon by a writ of *scire facias* or a summons, without the necessity of an action as in the case of a common bond. At common law it is a preferred debt, but in many States of the U. S. the preference has been abolished or modified. See Blackstone's *Commentaries*, and the *American and English Encyclopædia of Law* (under *Recognizance*). F. Sturges Allen.

Rec'ollet Friars and Nuns: a name usually applied to one of the congregations of Franciscans of the strict observance, but sometimes designating reformed bodies of other orders. A congregation of Augustinian Recollets dates from 1530. The Franciscans who bear this name are especially those of the French congregation, founded in 1592 by the Duke of Nevers, Louis de Gonzaga (1539–95).

Reconnaissance [= Fr., liter., recognition, examination, deriv. of *reconnaître*, earlier *reconnoître*, recognize, examine, whence Eng. *reconnoiter*]: a preliminary or rough survey of a portion of country. A civil reconnaissance may be undertaken for the purpose of selecting suitable points for trigonometrical stations preparatory to a geodetic survey; for ascertaining the relative advantages and disadvantages of two or more routes preparatory to locating a line of railway, canal, or aqueduct; or for the purpose of acquiring a general idea of the features of an unexplored country. A military reconnaissance may be undertaken to ascertain the military resources of a tract of country; for determining

the best line of march for an army; or for obtaining information in regard to the military character of a defile, of a crossing, or of a position of defense. The information obtained by a reconnaissance is usually embodied in a map and an accompanying memoir. The map is intended to show the general topographical features of the country examined, and the memoir is designed to supply such information as can not be presented by the map. Both the map and the memoir vary in character according to the object to be attained. In reconnoitering for the purpose of opening or extending a geodetic survey, the most important object is to make a judicious selection of points to be used as points of reference, called triangulation points. These points are to be chosen so that the triangles formed by joining them shall have no very acute angles; and for the primary triangulation the triangles should be as large as possible, their sides gradually increasing in length from the base up to the longest admissible line. In reconnoitering for the location of a railroad the objects to be attained are to find the most direct route between the points to be connected, with the most uniform grades and the least curvature. Attention should also be paid to the facilities for construction and the convenience of operating the road. In locating a line of communication between two points due regard should be paid not only to the accommodation of the inhabitants at the extremities of the line, but also to the convenience of the greatest number of people along the general direction of the route. In reconnoitering for the purpose of determining the prominent features of a country but little known two sets of operations are generally carried on by the same party; a system of astronomical observations for fixing the latitudes and longitudes of the principal points of the country, and a running survey, intended to fill in the geographical outlines. To this class belong the numerous surveys that were made prior to 1870 in the Territories of the U. S. west of the Mississippi river. In reconnoitering for military purposes the general object to be aimed at is to acquire a knowledge of the principal lines of communication, the obstacles which they present to military movements, the character of the roads to be traversed and of the streams to be crossed, the nature of the marshes, swamps, defiles, and mountain-passes, the general resources of the country; in fact, to gather all the information that may be of use to the commanding general. Angles are usually measured with a pocket-sextant or a pocket-compass, distances are determined by estimation or by the time required to traverse them, distant points are laid down by intersection of lines whose directions are determined by the compass, and slopes are judged of by the difficulty of ascending them. In the more extended reconnaissances previously alluded to distances are frequently determined or checked by an odometer, an instrument attached to a wagon-wheel, and so constructed as to record the number of times the wheel revolves in passing over a certain line. The information obtained is recorded in the field, and the principal features of the map are plotted down or sketched as the survey progresses. Photographs taken from elevated points are generally found useful in all kinds of reconnaissance work. See COAST AND GEODETIC SURVEY, SURVEYING, and TOPOGRAPHY. Revised by MANSFIELD MERRIMAN.

Reconstruction: See UNITED STATES (*History*).

Recording Apparatus, Psychological: See Appendix.

Recording of Conveyances: the general practice of keeping a public record of deeds, mortgages, and other documents affecting the title to real estate. This and the legal sanction which supports it are modern and for the most part American additions to the common law of land. It is true that there were a few early attempts to engraft the principle of registration of titles upon the law of real property (as in the Statute of Enrollments, 27 Hen. VIII., cap. 16, A. D. 1535, and the various rules relating to the transfer of copyhold lands), but these attempts were either successfully evaded or of very limited application. The persistent and finally successful struggle of the landowners to secure the right of secret conveyancing, free from the notoriety which attended the common-law modes of alienation as well as from the publicity of registration, forms a long and important chapter in the history of English law. Notwithstanding the numerous practical advantages of a system of recording titles—in facilitating and cheapening the transfer of real property, and preventing vexatious litigations respecting titles—the conservative temper of the English people has thus far successfully resisted every attempt to introduce the practice, and it exists there only in a few counties or parts of counties. Accordingly, the familiar rule, that the purchaser of property buys at his peril (*caveat emptor*), applies to the purchaser of real as well as of personal property. The buyer of land, equally with the vendee of chattels, may, notwithstanding the utmost diligence on his part, find that he has expended his money for a defective title. He buys in reliance upon the *indicia* of ownership and the good faith of the vendor.

In the U. S., on the other hand, although the same rule obtains in the case of chattels (see SALES), the purchaser of real property is protected against latent defects in the title by the recording acts of the several States. These acts (which have also been adopted in Canada) vary somewhat in matters of detail, but their general purport and effect are the same. They all provide that no conveyance or other act affecting the title to lands shall be valid as against a subsequent purchaser in good faith and for a valuable consideration, unless it was made a matter of public record prior to such subsequent conveyance, or at least prior to the recording of such subsequent conveyance. Accordingly, a "search," or examination of the public records, is the invariable preliminary to a conveyance of lands, which is as invariably followed by the prompt recording of the instrument of conveyance. Previous conveyances of the property or incumbrances upon it which are unknown to the purchaser, which are not obvious upon an inspection of the premises, and which do not appear in the records, may be ignored by the intending purchaser. He takes his title free from any defects or claims of which he did not have notice, and if "actual notice" is wanting its place must be supplied by the "constructive notice" afforded by a due and proper record of the previous conveyance or incumbrance. By the system of legislation adopted by all the States an officer is appointed in every county whose duty it is to record all conveyances brought to him in books which are open to the public inspection, and which are provided with alphabetical indexes of the grantors and grantees, mortgagors and mortgagees, etc., so as to facilitate the examination thereof by persons interested. All deeds of conveyance, leases for more than a specified term, mortgages of land, assignments of mortgages, and other muniments of title may be recorded at the instance of the parties holding the same. In order that an instrument may be thus recorded, it is generally made a requisite that the same should have been duly acknowledged by the party executing it before some designated officer, and that this certificate of such acknowledgment should have been attached thereto.

It will be understood from what has been said above that a record is by no means an essential part of a conveyance of land. As between the vendor and vendee of the property, as well as affecting their heirs and devisees, the transaction is complete upon the delivery of the deed. The title passes, as at common law, by the conveyance. It is only innocent purchasers for value, who have been misled in consequence of the secret character of the conveyance, who can impeach the transaction.

From a similar policy to that which has dictated the legislation above described, most of the States have also adopted provisions requiring the filing and recording of chattel mortgages in all cases where the property mortgaged remains in the possession of the mortgagor, and in a few States all sales of goods, if not accompanied by delivery, must also be recorded.

The literature of the subject is extensive. The reader should consult especially Bentham on *Land Transfer Reform*; Brickdale, *Registration of Title to Land*; Jones, *On the Torrens System of Transfer of Land*; Olmsted, *Land Transfer Reform*; Report of New York Commissioners on *Land Transfer* (1886); and the statutes of the several States. GEORGE W. KIRCHWEY.

THE GERMAN SYSTEM of recording transfers and mortgages of realty, and the protection given by the law to those who purchase or lend on the faith of the record, are historically derived, to a large extent, from mediæval customs. At the close of the Middle Ages, however, Roman rules began to prevail (for the chief points of difference, see PROPERTY and MORTGAGE), and the re-establishment and development of the German principles have been effected by modern legislation. Prussia took the first step in 1783; the majority of the other states followed her example during the first half of the nineteenth century; and in connection with the civil code proposed for adoption in the German empire a project has been elaborated for a common system of record-

ing titles. This project is modeled on the Prussian law of May 5, 1872, which will therefore be taken as the basis of the following sketch of the modern German system.

The record (*Grundbuch*) is so arranged that all entries affecting a special parcel of land are made in one "folio." A special folio is regularly assigned, in the cities, to each lot, and in the rural districts to each farm or estate (*Gut*). In the latter case the several fields belonging to the estate are enumerated. The tax-number of each lot or field is given, with its area and its assessed rental value. (The tax-rolls and maps give the metes and bounds of the property as determined by governmental survey.) After the property has thus been described, the remainder of the folio is divided into three parts. In the first are noted all changes of ownership; in the second, all permanent charges upon the land, except taxes; all limitations of the owner's right (see SERVITUDES), and all restrictions upon the owner's power of alienation. In the third part are entered all mortgages, with the amount, the rate of interest, the date of their establishment, and the date at which payment is due. In parallel columns are entered assignments and payments, whether partial or in full.

The record is kept by the court of first instance in each judicial district. Entries are made only by order of the court, and on certain legally specified grounds, of which the most important are contract and judgment. In case of conveyance, the law requires a formal declaration from the recorded owner that he transfers the property to the conveyee and a demand from the conveyee that he be recorded as owner. The declaration and demand may be made in person or by attorney or in writing; but if by attorney or in writing the documents presented to the recording officers must be certified. Similar rules govern other entries based on the contract of the parties. If an entry is demanded on the ground of judgment, the judgment must be authenticated.

The recording officers determine the presence or absence of the grounds on which entries may legally be made, but they do not decide controversies. He who impugns the correctness of an entry already made, or protests against an entry which the recording officers are legally bound to make, must bring action in the proper court; but pending the judicial determination of the controversy, he may save his rights by securing the insertion of a "note" (*Vormerkung*). The same course is open to the person who demands an entry which the recording officers can not legally make until his claim is affirmed by a judgment. The "note" has about the same effect as notice of LIS PENDENS (*q. v.*) in the U. S. Where this safeguard seems insufficient, the court before which the controversy is pending may prohibit alienation, and such prohibition is then placed upon the record.

Effect of the Record.—The record enjoys *publica fides*. It is presumed to be accurate and complete. He who purchases from the recorded owner is therefore owner, unless it can be shown that he knew the record to be erroneous. In like manner, he who has taken a mortgage from the recorded owner, or an assignment of mortgage from the recorded mortgagee, has the rights of a mortgagee, unless it can be shown that he knew the record to be erroneous. Against the assignee of a recorded mortgage no defenses are admissible except those which are indicated on the record and those of which he can be proved to have had knowledge.

Mistakes in the record, it is claimed, are rendered extremely improbable by the rules governing entries. When they can be shown to exist, the record may of course be corrected, but no such correction will be permitted to prejudice the vested rights of third parties. The person who has suffered damage from a mistake in the record has therefore the following additional remedies: (1) An action, based on unjust enrichment (see QUASI-CONTRACT), against the person primarily benefited; (2) a subsidiary claim against the recording officers, when they are chargeable with willful wrong or negligence; and (3) if the recording officers are liable but insolvent, a claim against the State.

Modifications of the Law of Mortgage.—The German system of recording has led to important changes in the whole law of real property, some of which have already been indicated. Special innovations in the law of mortgage are as follows:

(1) *Specialty.*—No lien can be imposed upon the entire estate of a debtor, nor even on all his realty. Judgment liens, for example, can be made effective only by having special mortgages recorded against special pieces of property.

(2) *Owner's Mortgage.*—When the owner of property pays off a mortgage he may elect to have the mortgage assigned to himself. In such case no MERGER (*q. v.*) takes place; the mortgage, whether it remains in the name of the owner or is assigned by him to a third person, retains its validity and its priority.

(3) *Land-debt.*—A lien on the land which operates like a mortgage may be created without any accompanying personal obligation upon the part of the mortgagor. Such a lien the Germans call a "land-debt" (*Grundschuld*). No such defenses as are derived, in the case of the ordinary mortgage (*Hypothek*), from the invalidity of the personal claim can be pleaded against the land-debt, for it is not a collateral but an independent claim. On the other hand, the land-debt is not enforceable against the person who created it except while he holds the land.

(4) *Owner's Land-debt.*—The land-debt may be established in favor of the owner himself. This rule enables the owner of realty to give a second mortgage and at the same time to reserve a first.

(5) *A letter of mortgage* (*Hypothekenbrief*) is an authenticated extract from the record, issued by the recording officers, attesting a particular mortgage, and showing all the facts that are of importance to the holder. In the case of the ordinary mortgage such an extract may be issued with the consent of the mortgagor, and its issue is noted on the record. In the case of the land-debt such an extract is always issued (*Grundschuldbrief*). The purpose of the extract is to facilitate assignment by avoiding the necessity of entering each successive assignment upon the record. Any person who presents the extract and shows that it has come into his hands in the manner provided by law (certified transfer) is entitled to receive interest, and, in case of default, to foreclose. The original creditor, of course, can exercise none of these rights unless he is still in possession of the extract. The extract is thus practically a secondary record, separated from the parent record but enjoying the same *publica fides*. The lien on the land is put into circulation after the fashion of a negotiable instrument. In the case of the land-debt, where most of the defenses available against the ordinary mortgage are excluded, the analogy to commercial paper is particularly obvious, and the German jurists describe the "letter of land-debt" as "a bill of exchange on the land."

It is claimed, and with apparent justice, that the German system makes the ascertainment of title simpler and the security of title greater than any other system yet devised; and that it therefore gives a safer basis to credit than any other system.

See Gide, *Le Régime Hypothécaire en Prusse* (1873); and Achilles, *Grundeigenthum und Hypothekenrecht* (1881).

MUNROE SMITH.

Recoupment [from Fr. *recouper*, cut again, cut off]: a species of defense in actions brought to recover damages for the non-performance of a contract, whereby the defendant alleges that he has himself sustained damages by the plaintiff's breach of the same contract, or by the plaintiff's fraud in procuring him to enter into it, which he seeks to cut off or "recoup" from the amount that would otherwise be recovered against him. The doctrine of recoupment has become established by judicial decision both in England and in the several States of the U. S., although there are some slight differences in the extent to which it has been carried by the various courts. Like the defense of set-off, it is confined to actions upon contract, and must itself arise from contract, but here all resemblance ends. A set-off must be for a debt, a certain fixed sum; recoupment is of damages often entirely unliquidated; a set-off is necessarily a demand arising upon a different contract from the one in suit; recoupment is necessarily of damages arising from a breach of the very same contract sued upon; in set-off the defendant may sometimes recover a balance from the plaintiff; in recoupment this can never be done. Recoupment (as is indicated by the etymology) can strictly be used only as a defense, and can do no more at most than defeat the plaintiff's recovery; even if the defendant's damages should exceed those of the plaintiff, he can have no judgment for such excess. In this last-mentioned particular the doctrine of recoupment has been greatly enlarged by the reformed system of procedure prevailing in the U. S. in many of the States, which permits the defendant by means of a counterclaim to recover an affirmative judgment for damages against the plaintiff when the grounds for such recovery have been established by the proofs. See Sedgwick on the *Measure of Damages*. Revised by F. STURGES ALLEN.

Recovery, Common: a species of common assurance or method of conveying lands, also called *feigned recovery*, formerly used in England as a means of evading the statute *De Donis* (see ENTAIL) and conveying an entailed estate free of the entail, or for enlarging the estate of the tenant in tail to a fee simple, by a secret confidence that the person recovering the estate would reconvey to the party in fee simple. The assurance consisted in a fictitious real action founded on the supposition of an adverse claim, which by the collusion of the owner in tail was carried regularly to a judgment against the owner in tail for the recovery of the land by the demandant or plaintiff. The common recovery was invented by the clergy to evade the statute of MORTMAIN (*q. v.*). Common recoveries were abolished in England in 1833 (3 and 4 Will. IV., c. 84), and a statutory mode of barring entails provided. In the U. S. common recoveries were formerly in use in some States; but they have generally become obsolete where they have not been expressly abolished. See Reeves's *History of the English Law*, and the *Commentaries* of Blackstone, Stephen, and Kent.

Rector: See PARSON.

Rectum, Diseases of [*rectum* is Mod. Lat., liter., the straight intestine (sc. *intesti'num*, intestine), neut. of *rec'tus*, straight]: diseases of the third and last portion of the great intestine, which receives the fæcal matters from the colon, and opens outward by the anus. The rectum in new-born children is in only few cases abnormal. Congenital defects are preternatural narrowness of the anus, imperforate anus, and absence of the anus, with partial or complete non-development of the rectum. In childhood rectal diseases are exceptional; atony and relaxation of its muscular coat may result in obstinate constipation and overloading of the rectum with fæces. Reversely, in strumous and delicate children continued diarrhœa may result in prolapse of the rectum or protrusion, usually of the mucous membrane only, less frequently of the muscular coat. Adults are subject to numerous rectal diseases. Dysentery is not infrequently limited to the rectum. (See DYSENTERY.) Chronic ulcer is a frequent sequel of the destruction of tissues in dysentery; ulcers may also arise from tubercular or syphilitic deposit. Irritable ulcer of the lower end of the rectum, especially just within the sphincter muscle of the anus, is termed a fissure. It causes intense pain when stretched by the passage of fæces, and the dread of suffering causes voluntary inaction of the bowels and habitual constipation. Fissure often can be completely and satisfactorily detected only by use of the rectal speculum, the patient being anæsthetized. Stricture of the rectum is often the result of former dysenteric inflammation, ulceration, sloughing, and the subsequent formation of dense scars of fibrous tissue. It results in obstruction, difficult and small stools, constipation, straining and bearing-down pain in the bowels, loins, and lower region of the back, with general depression of health. Stricture is often the result of cancer of the rectum, when, in addition to the symptoms and signs of stricture, the patient has also the cachectic facial appearance and progressive emaciation of the body indicative of cancer, and intense lancinating pains in the rectum, due to the malignant local growth. Hæmorrhoids or piles (see PILES) are the frequent result of congestions and inflammation of the abundant venous circulation of the rectum and anus. Polypus of the rectum is an attached tumor, originating in a relaxed fold of mucous membrane, or in a hæmorrhoidal mass, or redundant growth following the healing of ulcers; it may grow to such size as to obstruct the bowel, or by the dragging efforts of defecation be protruded from the body. Fistula in ano is the result of abscess adjacent to the lower bowel or verge of the anus, the purulent contents being discharged into the rectum, and leaving an unhealed passage or sinus. There may be an additional sinus opening on the surface without the anus; fistula may also be "blind," or terminating in a *cul-de-sac* adjacent to the bowel, but opening only externally. The origin of fistula is usually piles, constipation, or other disease of the lower rectum. Intense neuralgia of the rectum, though a frequent forerunner of malignant disease, is often present in persons reduced in health or of highly nervous temperament. Pruritus of the anus (obstinate itching) is often associated with constipation, piles, the climacteric period, and old age. Eczema often affects the anus.

Preternatural narrowing of the rectum demands stretching by the fingers, aided by anæsthesia, and the use of rectal sounds. The imperforate anus is to be punctured or incised, and kept open by bougies while healing. Prolapse usually yields to improved diet, tonics, and internal and local use of astringents. Excision of a chronic prolapsed rectum is sometimes demanded. Ulcers may be treated by astringent tonics, but more effectively by local use of suppositories or direct caustic applications through a speculum of considerable size. Fissure may be cured by keeping the bowels habitually open and by local use of anodynes, astringents, and mild caustics. A more certain cure is by rupture of the sphincter ani under anæsthetics, allowing the fissure or ulcer a period of rest. Stricture when not malignant may be relieved by cautious incision and subsequent use of large rectal bougies. The operation endangers peritonitis and portal phlebitis (inflammation of the portal vein), with abscess of the liver. Cancer of the rectum is incurable save by extensive operation, and then only if recognized early and treated in the most radical manner. Much palliation and relief are afforded by operations which are not expected to cure. An artificial anus is often made in the groin, by which, annoying as it is, patients secure much comfort. The intense pain is modified by keeping the bowels open and by local and internal use of anodynes, opium and atropine being most efficacious. For the treatment of fistula in ano and hæmorrhoids, see FISTULA and PILES. Neuralgia, pruritus, and eczema demand local use of anodyne and emollient suppositories and ointments, while the constitution is improved by corrected diet and tonics. It has been recognized that much reflex disturbance in distant parts of the body is caused by irritations arising primarily in the rectum, and the so-called *orificial surgery* is an expression of the fact that the profession is now alive to this possibility.

Revised by R. PARK.

Recurring Decimal: See CIRCULATING DECIMAL.

Recurring Series: a series in which each term is equal to the algebraic sum of the products obtained by multiplying one or more of the preceding terms by certain fixed quantities. These quantities, taken in order, constitute what is called the "scale of the series." The order of a recurring series is determined by the number of terms in its scale. A geometrical progression is a recurring series of the first order. As an illustration of a recurring series of the second order, let us take the equation—

$$\frac{1-x}{1+x+x^2} = 1-2x+x^2+x^3-2x^4+x^5+x^6-2x^7+, \text{ etc.}$$

The second member is a recurring series of the second order, whose scale is $(-x, -x^2)$. Every term after the second may be found by multiplying the preceding term by $-x$, the second preceding one by $-x^2$, and then taking the algebraic sum of the results. Recurring series may be of any order whatever.

Red Bank: town; Monmouth co., N. J.; on the Shrewsbury river, at the head of navigation, and on the Cent. of N. J. and the Penn. railways; 7 miles N. W. of Long Branch, 26 miles S. of New York (for location, see map of New Jersey, ref. 4–E). It has regular steamboat communication with New York, 3 national banks with combined capital of $225,000, a public high school, public library (founded 1884), 2 weekly newspapers, several canning-establishments, and carriage and gold-leaf manufactories. A large trade in oysters and fish is carried on. Pop. (1880) 2,684; (1890) 4,145; (1900) 5,428.

Redbird: See CARDINAL-GROSBEAK.

Red Bluff: city; capital of Tehama co., Cal.; at the head of navigation on the Sacramento river, on the Southern Pac. Railroad; 135 miles N. by W. of Sacramento (for location, see map of California, ref. 4–C). It is in an agricultural, stock-raising, and fruit-growing region; has large lumber and wool interests, and considerable river traffic; and contains a State bank with capital of $300,000, a private bank, and 3 daily and 3 weekly newspapers. Pop. (1880) 2,106; (1890) 2,608; (1900) 2,750.

Redbud: See CERCIS CANADENSIS and JUDAS-TREE.

Red Cedar River: See CEDAR RIVER.

Red Cloud: city; capital of Webster co., Neb.; on the Republican river, and the Chi., Burl. and Quincy Railroad; 28 miles E. of Bloomington, 41 miles S. of Hastings (for location, see map of Nebraska, ref. 11–F). It is in an agricultural and stock-raising region, and contains flour and saw mills, machine-shops, 2 State banks with combined capital of $30,000, and 4 weekly newspapers. Pop. (1880) 677; (1890) 1,839; (1900) 1,554.

Red Cross: the name applied to the international treaty arranged by the Geneva convention of 1864, as well as to the various societies organized to carry out its aims. These center in the cause of humane and merciful treatment of wounded, sick, and dying soldiers in time of war. The Red Cross is the distinctive flag designated in the treaty, by which all hospitals (field or permanent), ambulances, persons, materials, and appliances employed in the relief service are known as such; and whenever the flag is displayed accompanied by the national flag to which the hospital, etc., belongs, it is treated, respected, and protected as neutral. Under the treaty soldiers disabled by wounds or sickness who have fallen into the hands of the enemy may be sent through the lines; if healed in the hands of the enemy and incapable of bearing arms, they must be delivered to the outposts to be sent to their homes, upon request; if capable of further military service, they may be sent to their homes on condition of not again bearing arms during the war. Thus the spirit of the Red Cross treaty makes of a wounded or sick soldier a neutral, a non-combatant. The Red Cross movement is civil in its origin, and the various national committees, societies, or associations organized to carry into effect the objects of the treaty are purely civil. They place themselves in communication with their respective governments, and in time of military activity they co-operate with, and become auxiliaries and aids to, the medical and surgical departments of the armies. In time of peace they variously employ themselves in preparing for emergencies.

At the battle of Solferino, Italy, June 24, 1859, the terrible and needless suffering and loss of life caused by days of neglect to care for the wounded and dying were witnessed by a philanthropic Swiss gentleman, Henri Dunant, of Geneva. He personally aided the insufficient medical forces of the armies, and realizing that such conditions ought not to exist, and need not, if the humanitarian impulse and efforts of the people could prevail, he conceived the idea of pledging the nations of the earth to regard and protect as neutral all sick and wounded combatants, and all persons and means engaged in giving them succor. He elaborated these ideas and feelingly described the scenes on the battlefield in a book which he wrote, *Un Souvenir de Solferino*. The cause was warmly espoused by La Société Genevoise d'Utilité Publique, of which Dunant was a member, and through the co-operation of the Swiss Federal Council an international conference was assembled at Geneva in Oct., 1863. This meeting was attended by delegates from sixteen governments, and continued in session four days. It was followed by a convention, to which all nations were invited to send representatives, and which convened in Geneva, Aug. 8, 1864. Twenty-five delegates representing sixteen governments attended. The session continued until Aug. 22, and culminated in the agreement to nine "articles of the convention for the amelioration of the condition of wounded in armies in the field." These articles were signed by twelve governments before the convention adjourned, and the treaty was left open for the accession of others. The signatory powers have reached forty in number.

The treaty designates "a red cross on a white ground" as the distinctive and uniform flag and arm-badge that shall be adopted for all hospitals, ambulances, and personnel: and provides that it must on all occasions be accompanied by the national flag; also that the delivery thereof (in time of action) shall be left to the military authority. The red cross on a white ground was adopted as a well-merited compliment to the Swiss confederation, whose national flag is the reverse—a white cross on a red ground.

The Geneva conference stipulated that each treaty nation shall have one national committee or society, civil in character and functions, which shall be the medium of communication with its government, and shall alone possess the right to use the red cross, and to authorize its use at its discretion. The national committees are usually composed of the most distinguished philanthropic persons in public and private life, with the chief magistrate or ruler frequently at the head.

To prevent desecration of the insignia by unauthorized use, severe governmental prohibitive measures have very generally been adopted.

A committee at Geneva, Switzerland, of which Gustave Moynier is president, is recognized as the international committee, through which all international communication is had. An international bulletin is published by that committee, and many other national committees publish journals or other literature of their work, which are interchanged. Many of the societies have been permanently endowed with large sums of money. Others receive the direct patronage of their royal heads or members.

Similar articles pertaining to naval warfare were formulated at Paris in 1868, but have not been generally adopted and ratified.

Upon the formation of the American National Red Cross, its president, Miss Clara Barton, perceiving a far wider usefulness for its work by applying it to the relief of great national calamities other than war, such as famine, pestilences, fires, or cyclones, incorporated such a feature into the charter of the association which she formed. The innovation received unanimous sanction by the international and other national committees, and the broader scope thus inaugurated was denominated the "American Amendment." Money, food, clothing, buildings, agricultural implements, seed, and other means aggregating over $1,000,000 in value have been distributed on thirteen fields of relief by the American National Red Cross under the "American Amendment"; notably at Johnstown, Pa., after the flood, in Russia during the famine, and on the South Carolina Sea islands devastated by cyclone and tidal wave. No money estimate can be made of the practical benefits educationally, as particularly exemplified in teaching the colored sufferers on the Carolina islands the advantages of frugality, of concentrated action in reclamation of their ruined lands, and of self-reliance generally. CLARA BARTON.

Redding: city; capital of Shasta co., Cal.; on the Southern Pac. Railroad; 170 miles N. by W. of Sacramento (for location, see map of California, ref. 3–C). It is in an agricultural, lumbering, and mining region, and contains 2 State banks with combined capital of $175,500, and 2 weekly newspapers. Pop. (1880) 600; (1890) 1,821; (1900) 2,946.

Reddle, Raddle, or **Red Chalk**: an argillaceous oxide of iron exported from Germany and England. It is used for carpenter's chalk, for marking sheep, for drawing on paper, and in the case of fine grades for polishing spectacle-lenses.

Redemptionists, called also **Mathurins, Fathers of Mercy**, and **Trinitarians** (*Ordo Sanctissimæ Trinitatis*): a brotherhood of the Roman Catholic Church founded by John de Matha and Felix of Valois at Cerfroi in France for the deliverance of Christian captives in Barbary. It was approved by Innocent III. in 1199.

Redemptorist Fathers, or **Liguorians** (*Congregatio Sanctissimi Redemptoris*): a congregation of missionary priests founded in 1732 by Alfonso de' Liguori at Scala in Italy. They are most numerous in Italy, Austria-Hungary, and the U. S. They devote themselves chiefly to the holding of "missions" for the increase of religious activity among the people. The original rules of the congregation were unusually severe, allowing only sacks of straw for beds, hard bread and soup at table, and imposing long seasons of worship every night, self-flagellations three times a week, and missionary activity among the very poorest classes. In addition to the usual vows of poverty, chastity, and obedience, a fourth vow was enjoined, by which the member was obliged to refuse all honors and benefices outside of the order, except upon the express command of the pope. In course of time, however, the rules have much relaxed. The congregation has twenty houses in the province of Baltimore, and seven in that of St. Louis.

Revised by J. J. KEANE.

Redfield: city; capital of Spink co., S. D.; on the James and Turtle rivers, and the Chi. and N. W. and the Chi., Mil. and St. P. railways; 41 miles S. of Aberdeen, 87 miles N. by W. of Mitchell (for location, see map of South Dakota, ref. 6–F). It is in a wheat and stock-raising region, and contains Redfield College (Congregational, chartered in 1887), a national bank with capital of $50,000, and a monthly and two weekly periodicals. Pop. (1890) 796; (1900) 1,015.

Redfield, WILLIAM C., A. M.: meteorologist; b. at South Farms, near Middletown, Conn., Mar. 26, 1789; was in early life a mechanic; conceived the fundamental idea of his famous "law of storms" as early as 1821; soon afterward established a line of steam towboats on the Hudson; issued many essays and pamphlets in favor of steamboat navigation; was subsequently an active promoter of railways, especially such as would connect the Hudson with the Mississippi; published at different times forty essays upon meteorology; promulgated his *Theory of Storms* in 1831, and his views upon hurricanes in 1833; devoted much attention to

fossil fishes from 1836 onward; was the first president of the American Association for the Advancement of Science 1843. D. in New York, Feb. 12, 1857. See his *Biography*, by Denison Olmsted (1857).

Redgrave, Richard, R. A.: painter; b. in London, England, Apr. 30, 1804; studied at the Royal Academy; became celebrated for his genre-pictures, and subsequently for his landscapes; was head master of the Government school of design; was one of the most efficient promoters of the South Kensington Art Museum, inspector-general of art schools, and surveyor of crown pictures. Author of *An Elementary Manual of Colors* (1863) and (with his brother Samuel) of *A Century of Painters of the English School* (1866). He was one of the art jurors in the Universal Exposition of 1851; was commissioned to superintend the department of English art in the French Universal Exposition of 1855, and selected the English pictures which figured in the British Universal Exposition of 1862. D. Dec. 14, 1888. Among his later pictures are *Sermons in Stones*, *Startled Foresters*, *Tranquil Waters*, *Calling the Sheep to Fold*, and *A Well-spring in the Forest*.

Redia: a trematode embryo produced asexually within a sporocyst. The redia is of worm-like form, and has a mouth, digestive tract, and an aperture for the extrusion of germs formed within it, which may develop into other rediæ or into cercariæ. See Flukeworms and Trematoda.

Redif Pasha: Turkish general; b. 1827. In 1871 he was intrusted with the command of the army sent to Yemen, and afterward employed in the ministry of War at Constantinople. He was actively engaged in the events which brought Murad V. to the throne of the caliphate, and in the Russio-Turkish war of 1877. With the fall of his superior, Abd-ul-Kerīm Pasha, he was banished, first to Lemnos, and then to Rhodes. R. G.

Reding, Aloys, von: patriot; b. in the canton of Schwyz, Switzerland, in 1755; entered the Spanish military service, but returned to Switzerland in 1788 and became captain-general of his native canton. He was a zealous supporter of Swiss independence and the old Federal constitution against the Helvetic republic established through French influence; he repulsed the French republicans at Morgarten Pass in May, 1798, thereby securing an honorable capitulation for his canton. His opposition to the Helvetic government continued, and after the departure of the French he called a meeting of the Federalists at Schwyz, but French interference prevented the re-establishment of the confederation. Reding became chief magistrate of Schwyz in 1803 and again in 1809. D. Feb. 5, 1818.

Red Jacket: village; Houghton co., Mich.; on the Mineral Range Railroad; 12 miles N. of Houghton, the county-seat (for location, see map of Michigan, ref. 1–E). It is in the great Lake Superior mining region, adjoins the celebrated Calumet and Hecla copper mines, and has a weekly newspaper. Pop. (1880) 2,140; (1890) 3,073; (1900) 4,668.

Red Jacket, or **Sagoyewatha**: a chief of the Seneca Indians; b. at Old Castle, near the foot of Seneca Lake, N. Y., in 1751; did not originally rank as a sachem, but obtained that dignity through his activity on the British side in the war of the Revolution, being noted as a swift runner, and especially as an eloquent orator; derived his English name from a richly embroidered scarlet jacket given him by a British officer; opposed the treaty of Fort Stanwix 1784; on the conclusion of the treaty of peace between the U. S. and the Six Nations in 1792, visited President Washington, from whom he received a silver medal; gave in 1810 to an agent of the U. S. Government valuable information upon the hostile plans of the Ohio Indians under Tecumseh; visited Washington on the same subject 1810; was a useful ally of the U. S. during the war on the Niagara frontier 1812–14. His last years were spent on the Seneca reservation near Buffalo, but he lost much of his influence on account of intemperance, and was once degraded from the chieftainship, but soon restored. He was an inveterate opponent of Christianity, of schools, and of missionaries. D. at Seneca Reservation, Jan. 30, 1830. His *Life* was written by William L. Stone (Albany, 1867).

Redlands: town; San Bernardino co., Cal.; on the Southern Cal. and the Southern Pac. railways; 8 miles E. by S. of San Bernardino, the county-seat (for location, see map of California, ref. 12–G). It is in an agricultural, fruit-growing, and mining region, is the center of the orange belt of the State, and contains a national bank with capital of $100,000, 2 State banks with combined capital of $55,000, and a daily and 2 weekly newspapers. Pop. (1890) 1,904; (1900) 4,797. Editors of "Daily Facts."

Red Lead, or **Minium**: See Lead (*Compounds of Lead*).

Red Oak: city (founded in 1857); capital of Montgomery co., Ia.; on the Nishnabatona river, and the Chi., Burl. and Quincy Railroad; 39 miles E. of Plattsmouth, 50 miles S. E. of Council Bluffs (for location, see map of Iowa, ref. 7–E). It is in an agricultural and stock-raising region, and has 12 churches, 5 school-houses, court-house (cost $100,000), 2 national banks, combined capital of $150,000, a State bank, capital of $50,000, and 3 weekly newspapers. Pop. (1880) 3,755; (1890) 3,321; (1900) 4,355. Editor of "Express."

Redoubts: small forts or inclosed works (usually) without flanking defenses, generally auxiliary to some larger work or defensive system. In permanent fortification the term is applied to small works or intrenchments within a larger member—e. g. "redoubt of the demilune," "of the reentrant place of arms," etc. In this latter sense, however, the French more commonly use the word *réduit* (from Fr. *réduire*).

Redpath, James; journalist; b. at Berwick-on-Tweed, England, Aug. 14, 1833; emigrated with his parents to Michigan 1848; became a printer, newspaper correspondent, and editor; was long connected with *The New York Tribune*, for which he reported the border warfare in Kansas 1855–57, and the famine in Ireland 1879–80; visited Haiti; became emigration agent of the Haitian Government in the U. S., and afterward consul at Philadelphia; was a war correspondent during the civil war; became superintendent of education at Charleston, S. C., where he founded schools for negro children and an orphan asylum; established at Boston in 1868 a lyceum bureau; established a newspaper syndicate at Washington, D. C., in 1877; edited for two years a weekly newspaper in New York; assisted Jefferson Davis in preparing his history of the Southern confederacy. He was the author of *The Roving Editor* (1859); *A Handbook to Kansas Territory* (1859); *The Public Life of Capt. John Brown* (1860); *Echoes of Harper's Ferry* (1860); a *Guide to Hayti* (1860); and *Talks about Ireland* (1881). D. in New York, Feb. 10, 1891.
Revised by H. A. Beers.

Red River: the last great tributary of the Mississippi. It derives its name from the color of the sedimentary matter with which it is freighted at all times except during very low water. It takes its rise in the great Staked Plain in the Pan-Handle of Texas, flows eastward, and forms the southern boundary of Oklahoma and Indian Territory. It enters Arkansas, but soon bends abruptly S., and flows through Louisiana to its junction with the Mississippi. Its length, measured roughly from one bend to another, is about 800 miles; including all its windings, the total length is estimated at 1,550 miles. Its source is 2,450 feet above the sea. For about 400 miles it traverses a series of cañons and descends 3·75 feet per mile; thence its grade gradually decreases, and in much of its lower course is scarcely perceptible. Its general grade may be judged from a map showing its windings; where swift, the channel is much straighter than where sluggish.

Area of Basin.—The basin drained by Red river is about 97,000 sq. miles in area. This region is mostly fertile, but presents all degrees of diversity, from the arid and saline plains where the river rises to the rich alluvial lands bordering its lower course.

The navigable channels are as follows: Red river proper in high water, 1,246 miles, and its own tributaries, not including Washita, 700 miles; Washita proper, 600 miles, and its tributaries, 800 miles; the total navigable channels reaching the Mississippi through the mouth of Red river amount to 3,346 miles. Large sums have been expended by the national Government in improving navigation. The appropriations for Red river alone up to 1892 were over $1,500,000.

Timber Rafts.—One of the most interesting features in connection with Red river is its tendency to form immense accumulations of floating timber. The banks of the river, in its middle course, are heavily forested, and during floods vast numbers of trees are swept away and accumulate lower down where the current slackens. These obstructions sometimes increase until rafts many miles long are formed. When undisturbed by man they grow by additions to their up-stream ends, while the logs decay and are washed away at their lower extremities. For this reason the obstructions

slowly move up stream. In 1854 the lower end of such a raft was located at a point 53 miles above Shreveport, La., extended 13 miles up-stream, and was forming at the rate of 1½ to 2 miles a year. It is stated that at an earlier date this raft was 200 miles lower down the river. Vegetation takes root on the older portions of the rafts, and what are termed "floating forests" are formed. In 1873, when a navigable channel was opened in the raft above Shreveport, it was 32 miles long. This great raft, before it was disturbed, formed a dam, which checked the flow of the river, and produced a lake-like expansion from 20 to 30 miles long above it. When a channel was opened through it the water above was lowered 15 feet. In recent years the river has been patrolled by "snag-boats," and thousands of trees, stumps, and other obstructions removed annually.

Owing to the timber-dams formed naturally in Red river, and to the abundant silt deposits left on its immediate banks during high-water stage, natural levees are formed along its borders which deflect tributary streams and frequently cause them to form lakes.

Consult *Physics and Hydraulics of the Mississippi River*, by Humphreys and Abbot (1861), and the Annual Reports of the Chief of Engineers U. S. army. ISRAEL C. RUSSELL.

Red River of the North: a river which rises in Western Minnesota, near the source of the Mississippi, flows northward for 250 miles through the so-called Red river valley, and empties into Lake Winnipeg. Its source is at an elevation of 1,600 feet, where it enters Canada it is 767 feet, and at its mouth 710 feet above the sea. Its drainage area, not including that of the Saskatchewan with which it unites, is between 43,000 and 44,000 sq. miles, of which three-fourths are S. of the U. S.-Canadian boundary. The region it traverses is a nearly level plain, once the bed of Lake Agassiz, and is famed for the abundance and excellence of its wheat harvests. The river has cut a narrow channel from 20 to 50 feet deep through lacustral deposits, and furnishes a typical example of recent drainage on a nearly horizontal, new land area. The river is navigable from its mouth to near its source. During high-water stages it is connected by way of Lakes Traverse and Big Stone with the Mississippi, and steamboats can occasionally pass from the Mississippi to Lake Winnipeg. ISRAEL C. RUSSELL.

Redroot: See CEANOTHUS AMERICANUS.

Red Sea, or **Arabian Gulf**: a long, narrow inlet of the Indian Ocean; between Arabia on the E. and Abyssinia, Nubia, and Egypt on the W.; separated from the Mediterranean by the Isthmus of Suez, which is only 80 miles across, and communicating with the Indian Ocean through the Gulf of Aden and the Strait of Bab-el-Mandeb, which is only 14 miles broad. The entire length of the Red Sea is 1,450 miles; its greatest breadth is 230 miles; its depth varies from 1,054 fathoms in lat. 22° 30′ N. to 3 fathoms in the harbor of Suez. It is called in the Old Testament "the sea of *suph*," a seaweed resembling wool. Why, in later times, it was called the Red Sea, writers are not agreed. Herodotus (*Hist.*, ii., 11) reports "a flow and ebb of the tide every day." Recent scientific surveys have shown a tide of 5 to 7 feet at Suez, but much less to the southward. Much, however, depends upon the strength of the wind, which blows from the S. S. E. from October to May, and is strongest in February; and from the N. W. the rest of the year, and is strongest in June and July. Near its northern extremity the sea forks into two branches—one, the Gulf of Akaba, length 100 miles and breadth 15, occupies a depression which is the continuation southward of the valley of the Jordan and Dead Sea; the other, the Gulf of Suez, length 200, breadth 20 miles. In the Sinaitic isthmus, lying between these arms, is Mt. Sinai. The Israelites (see EXODUS) are supposed to have crossed in April the Gulf of Suez, near the existing town of that name, the sea at that time extending with small depth some 30 miles farther N. On account of the violence of its winds, and the great number of islands, shoals, and coral reefs which lie along its shores, the navigation of the Red Sea has always been considered very difficult; nevertheless, from the very earliest times it has formed one of the commercial highways of the world, being the shortest and most convenient road between Europe and India. After the discovery of the route around the Cape of Good Hope the traffic which first the Egyptians and Phœnicians, and then the Greeks, the Romans, and the Venetians, had carried on with India over the Red Sea, declined greatly, but the construction of the Suez Canal has once more led this commerce back into its old channel.

Red Seaweeds: the *Rhodophyceæ*; a class of aquatic plants (mostly marine) notable for their red or purple color. The many-celled plant-body is of various forms, from a simple flat thallus to a branching, leaf-bearing axis. Sexual reproduction takes place by the fertilization of a carpogone (by non-ciliated antherozoids), this resulting in the growth of carpospores, and sometimes of a pericarp (Fig. 1) also. Asexual reproduction takes place by the germination of tetraspores, which are produced in various places on the plant-body by the subdivision of cells into four parts. The class is equivalent to the *Rhodospermeæ* of many authors, and includes but one order (*Florideæ*).

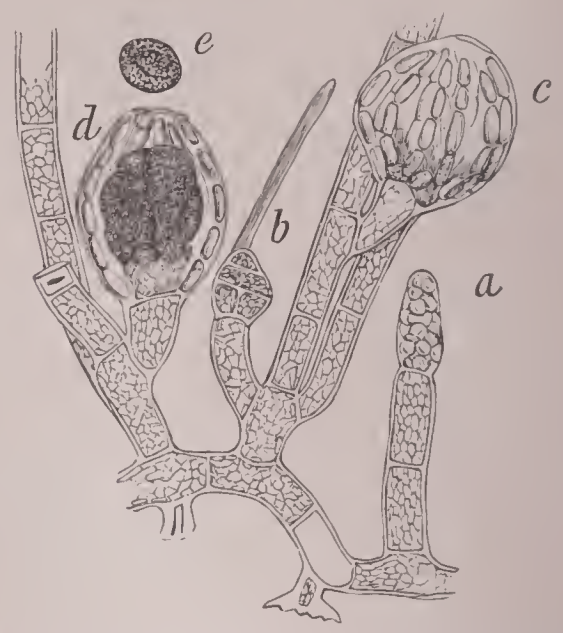

FIG. 1.—A red seaweed (*Lejolisia*): *a*, antherid; *b*, carpogone with slender trichogyne; *c*, sporocarp; *d*, sporocarp in vertical section; *e*, an escaped carpospore. Magnified 150 diameters.

According to Agardh, the known species are between 1,500 and 2,000, widely distributed in all seas, and to a limited extent in fresh water (e. g. species of *Batrachospermum*, *Hildenbrandtia*, *Lemanea*, etc.). The plants are never of large size, rarely attaining a length of more than a few inches, and in some cases they are minute. They are frequently of delicate texture and beautiful outline. The red or purple color is due to the presence in the cells of a soluble substance, phycoerythrin, which hides the chlorophyll. Upon immersion in fresh water the red color of many marine species is discharged, thus disclosing the underlying green.

Agardh has arranged the many families in six groups (which he terms "series") upon characters derived from the structure and development of the spore-fruit (cystocarp). Here only a few general characters will be given, to which there are many exceptions.

Series I. GONGYLOSPERMEÆ. Spore-fruits external or immersed in the substance of the thallus, surrounded by a gelatinous envelope; spores irregularly arranged; plant mostly filamentous, sometimes solid or compressed.

Two families, the *Ceramiaceæ* and the *Cryptonemiaceæ*,

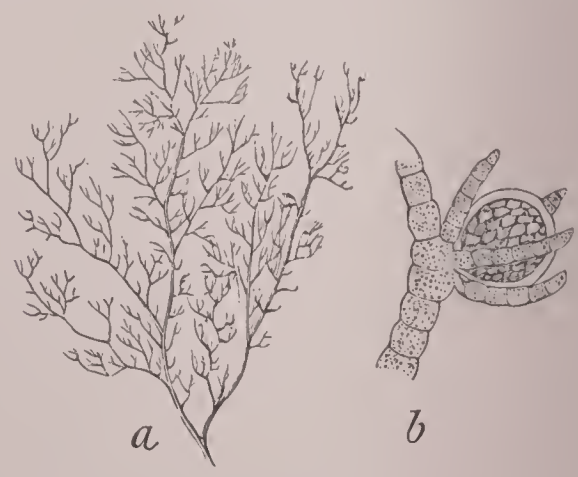

FIG. 2.—*Ceramium rubrum*: *a*, portion of plant; *b*, spore-fruit, magnified.

contain many beautiful species—e. g. *Ceramium rubrum* (Fig. 2), very common along the coasts of the U. S., *Ptilota serrata*, and species of *Griffithsia* and *Callithamnion*, the latter often minute and of great delicacy.

Series II. Cocciospermeæ. Spore-fruits immersed in the swollen thallus forming rounded conceptacles; spores irregularly arranged; plant terete or flattened, fleshy or hardened.

These are usually larger and coarser plants than the preceding, having thick parenchymatous thalli, mostly of a

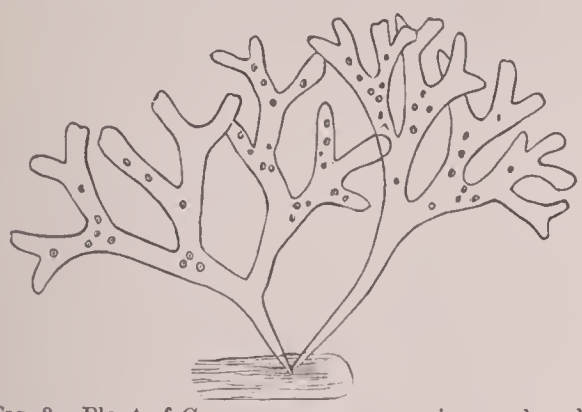

Fig. 3.—Plant of *Gymnogongrus norvegicus*, reduced.

dark-purplish color. *Gymnogongrus norvegicus* (Fig. 3) *Cystoclonium purpurascens*, *Gigartina mamillosa*, and *Chondrus crispus* are common representatives of the principal family *Gigartinaceæ*. The last-named species is the Carrageen (*q. v.*) or Irish moss.

Series III. Nematospermeæ. Spore-fruits external, with a cellular pericarp, or sometimes immersed in the thallus; spores in chains radiating from a central cell; plant filamentous, solid, or membranaceous.

The six families here grouped (*Dudresnayaceæ*, *Dumontiaceæ*, *Spyridiaceæ*, *Areschougiaceæ*, *Champiaceæ*, and

Fig. 4.—*Plocamium coccineum*: *a*, portion of plant; *b*, magnified fragment showing a spore-fruit.

Rhodymeniaceæ) contain many beautiful and interesting species belonging to the genera *Dudresnaya*, *Chylocladia*, *Chrysymenia*, *Rhodymenia*, *Plocamium* (Fig. 4), *Rhodophyllis*, etc. *Rhodymenia palmata* is the Dulse (*q. v.*).

Series IV. Hormospermeæ. Spore-fruits external or immersed, mostly with a pericarp; spores in short chains or single; plant membranaceous. cylindrical, or flattened.

The plants here brought together are apparently but little related. In the *Squamariaceæ* the thallus forms an expanded crust, usually upon other algæ. The *Corallinaceæ* are cylindrical or flattened, mostly jointed, and branching, and like the preceding are covered with a dense layer of lime, which commonly hides their red or purple color. The common coralline, *Corallina officinalis*, is a familiar representative of this family. The *Sphærococcoideæ* include cylindrical or flattened, coarse and cartilaginous plants, while the *Delesseriaceæ* are membranaceous, of delicate texture, and usually rosy-red. One of the prettiest species is *Grinnellia americana* (Fig. 5) of the eastern coast of North America.

Series V. Desmiospermeæ. Spore-fruits external or immersed, mostly with a pericarp; spores borne on central or parietal, simple or branching placentæ; plant filamentous, cylindrical, or compressed.

Five small families are here included (*Helminthocladiaceæ*, *Chætangiaceæ*, *Gelidiaceæ*, *Hypneaceæ*, and *Solieraceæ*). To the first belong the species of *Batrachospermum* (Fig. 6) which are found in fresh-water ponds and streams. *Nemalion multifidum* is a common marine form.

Series VI. Corynospermeæ. Spore-fruits external, with a pericarp; spores borne on a cellular basal placenta; plant filamentous, or solid and cylindrical.

This large group includes five families (*Wrangeliaceæ*, *Spongiocarpeæ*, *Lomentariaceæ*, *Chondriaceæ*, and *Rhodo-*

Fig. 5.—*a*, *Grinnellia americana*, reduced; *b*, spore-fruit, enlarged.

melaceæ). To the first belongs the European *Lejolisia mediterranea* (Fig. 1). The *Spongiocarpeæ* represented by *Polyides rotundus* have cylindrical cartilaginous fronds attached by a disk. The *Lomentariaceæ* have tubular fronds and cystocarps with a basal placenta. The last family (*Rhodomelaceæ*) includes about one-fifth of all the species of red seaweeds. Its important genera are *Dasya* and *Polysiphonia* (Fig. 7). These include many species of great beauty and delicacy.

Fig. 6.—Fragment of *Batrachospermum moniliforme*, enlarged.

Literature.—Agardh, *Species Genera et Ordines Floridearum* (1851–63), *Epicrisis Systematis Floridearum* (1876), *Morphologia Floridearum* (1880); Farlow, *Marine Algæ of New England and Adjacent Coast* (1881); Hauck, *Die Meeresalgen Deutschlands und Oes-*

Fig. 7.—*a*, Portion of plant of *Polysiphonia violacea*, reduced; *b*, enlarged spore-fruits.

terreichs (1885); Harvey, *Phycologia Britannica* (1846–51), *Nereis Boreali-Americana* (1852–58). Charles E. Bessey.

Red Snow: real snow tinted by the presence of *Hæmatococcus lacustris* (or *Protococcus nivalis*), microscopic algæ of the order *Protococcoideæ*. The cells are sub-globose, and about 50 micromillimeters ($\frac{1}{500}$ inch) in diameter. In 1819 Ross found banks of red snow on the eastern shore of Baffin Bay extending for miles, and these were in some parts 12 feet deep. Revised by CHARLES E. BESSEY.

Red Sulphur Springs: magisterial district; Monroe co., W. Va.; on Indian creek and a turnpike 12 miles from Lowell Station on the Ches. and O. Railway; 38 miles S. W. of White Sulphur Springs (for location, see map of West Virginia, ref. 11–G). It is in a beautiful valley of the Alleghany Mountains, is a fashionable watering-place, and is said to contain the only springs of their kind in the country. The water contains phosphorus and a peculiar sulphur compound or gelatinous substance, which is its distinctive feature. The curative properties of the water have been known for more than half a century. Pop. of district (1880) 2,557; (1890) 2,845; (1900) 3,148.

Reductio ad Absurdum: a process of reasoning by which the statement in dispute is made one premise of an argument and an acknowledged truth the other, the conclusion drawn from them being so absurd that the falsity of the premise in dispute must be conceded.

Reduplication: the repetition or doubling of a syllable, a root, or even a complete word, as a method of word-formation. It is a widespread phenomenon of language, and serves a variety of purposes in expression; thus it expresses plurality, reciprocity, repetition, continuousness, intensity, superlative quality, completion, imitation of natural sounds, etc., and is characteristic of nouns as well as verbs. The Indo-European languages abound in traces of an extensive use of this method in the primitive stages of the mother-speech, and cases also occur of its use within the separate history of the languages. (1) The reduplication may consist of the doubling of a root; cf. Lat. *murmur*, a murmuring noise, *querquerus*, shivering cold; Gr. μέρμερος, marvelous, βάρβαρος, unintelligible in speech, ἀλαλά, battle-cry, γάργαρα, muddle. (2) The doubling appears as incomplete, or one syllable of the reduplicated form is weaker than the other; cf. Lat. *quisquiliæ*, scraps, *memor*, mindful, *momordi*, I have bitten; Gr. διδαχή, doctrine, διδάσκω, teach, δέδορκα, I have seen, ὄπωπα, I have seen, πορφύρω, be in movement, γόγγυλος, round, ἀλλήλων, one another, γίγνομαι, become (Lat. *gigno*). (3) A word is doubled; as Lat. *quisquis*, *quidquid*, *quaqua*, *jamjam*, *quamquam*, *quotquot*, *meme*, *sese*; Gr. πάμπαν, πρόπρο, πλέον πλέον, more and more; Sanskr. *áharahar*, day by day, *padé-padē*, step by step. See K. Brugmann's *Compar. Grammar of the Indo-Germanic Languages*, vol. ii., §§ 51–54, 465–476; A. F. Pott, *Doppelung, als eins der wichtigsten Bildungsmittel der Sprachen, beleuchtet aus Sprachen aller Welttheile* (1862). BENJ. IDE WHEELER.

Red Water, or **Black Water**: a disease of cattle, sheep, and goats, characterized by the passage of reddish, brown, or black urine. This disease is most frequently observed among cattle at pasture on low lands, new fields, or soils imperfectly drained. It is thought to be caused by irritating plants which grow in such localities; it may usually be prevented by the amelioration of the soil.

Red Wing: city (founded in 1853); capital of Goodhue co., Minn.; on the Mississippi river at the head of Lake Pepin, and on the Chi., Mil. and St. P., the Duluth, Red Wing and Southern, and the Minneapolis and St. L. railways; 41 miles S. by E. of St. Paul, 63 miles W. N. W. of Winona (for location, see map of Minnesota, ref. 10–F). It is situated on a plain between the river and bluffs that rise to a height of over 300 feet above tide-water, and is one of the most important wheat-shipping points in the U. S. It is substantially built; has water, sewerage, electric-light, and street-railway plants; and contains flour and saw mills, boot and shoe factories, stoneware, sewer-pipe, and lime works, and furniture-factories. There are 14 churches, 4 collegiate institutions, Evangelical Lutheran Seminary (chartered in 1878), State Reform School, Library of the State Board of Health (founded in 1873), a national bank with capital of $100,000, 2 State banks with combined capital of $111,000, a savings-bank, and a daily and 5 weekly newspapers. Pop. (1880) 5,876; (1890) 6,294; (1900) 7,525.

Red-winged Blackbird: See BLACKBIRD.

Redwitz-Schmölz, OSKAR, Freiherr von: poet; b. at Lichtenau, Bavaria, June 28, 1823; studied law at Erlangen and Munich, and later on German philology at Bonn; was for a short time Professor of Literature at the University of Vienna, but resigned his position and devoted himself entirely to literature. He gained a wide reputation by his first work, *Amaranth* (1849), an epic poem written in praise of the Roman Catholic religion, and filled with sentimentality. His later works, *Das Lied vom Neuen Deutschen Reich* (1871), *Odilo* (1878), and his novels *Hermann Stark, deutsches Leben* (1869), *Haus Wartenberg* (1884), and *Hymen* (1887), are the productions of a genuine poet. He died July 16, 1891. JULIUS GOEBEL.

Redwood: the *Sequoia sempervirens*, a noble coniferous timber tree of California, second in size to the *Sequoia gigantea*, or big tree, alone among North American trees. It occurs in great forests upon the coast mountains of California, and often attains a height of 275 feet and a diameter of 15 feet. It is extensively sawn for building purposes. When fresh its wood is of a fine red color, but it slowly fades when exposed to light. (See SEQUOIA.) The redwood sometimes used by dyers is from *Adenanthera pavonina*, a large leguminous East Indian tree.

Redwood City: town (founded in 1849); capital of San Mateo co., Cal.; on Redwood creek, navigable for vessels of light draught to this point, and on the Southern Pac. Railroad; 28 miles S. of San Francisco (for location, see map of California, ref. 8–B). It is in an agricultural, lumbering, and grape-growing region; contains 4 churches, a public school, a State bank with capital of $102,800, and 2 weekly newspapers; and is an important shipping-point for redwood lumber. Pop. (1880) 1,383; (1890) 1,572; (1900) 1,653.
EDITOR OF "TIMES-GAZETTE."

Redwood Falls: city; capital of Redwood co., Minn.; on the Redwood river, and the Chi. and N. W. and the Minneapolis and St. Louis railways; 26 miles N. N. W. of Sleepy Eye Lake, 110 miles S. W. of Minneapolis (for location, see map of Minnesota, ref. 10–C). It is in an agricultural region, and contains Methodist Episcopal, Protestant Episcopal, Presbyterian, Christian, Roman Catholic, and Adventist churches, a handsome graded-school building, county court-house that cost $30,000, 3 State banks with combined capital of $100,000, and 2 weekly newspapers. In the vicinity are mines of coal, gold, and mineral paint. Pop. (1880) 981; (1890) 1,238; (1900) 1,661.
EDITOR OF "GAZETTE."

Reed [O. Eng. *hrēod* : O. H. Germ. *riot* > Mod. Germ. *ried*, reed]: a name proper to certain tall woody grasses smaller than canes and bamboos. The common reed (*Phragmites communis*) of North America, Europe, and Asia is employed on the Eastern continent as thatch, as a material useful in clay walls and floors, etc. The more extensively grown reed of Europe is *Arundo donax*, the woody stems of which are used for a great variety of purposes, especially by the horticulturist and in making musical instruments, fishing-rods, canes, etc. The smaller cane of the U. S. (*Arundinaria tecta*) is often called a reed. Its chief use is in making stems for tobacco-pipes.—REED is also the vibrating tongue or spring, fixed in a narrow slit, which produces musical tones in many wind instruments, such as the melodeon. It was once made of the reed (*Arundo donax*), whence the name. See REED INSTRUMENTS.

Reed, DAVID BOSWELL, M. D.: chemist; b. in Edinburgh, Scotland, in 1805; educated at the High School of Edinburgh, and in medicine at the university of that city, where he was an assistant to Prof. Sir John Leslie; was elected president of the Royal Medical Society and member of the Royal College of Physicians and of the Royal Society of Edinburgh; became instructor in chemistry in the university, teaching that science also to private classes; superintended the improvements in ventilation made in the House of Commons 1836, in the House of Peers 1839, and had charge of the ventilation department in the construction of the new houses of Parliament 1840–45; afterward applied his principles to public buildings in Liverpool and other large cities; visited Russia for a similar purpose; settled in the U. S. 1856; was for some time Professor of Applied Chemistry in the University of Wisconsin; became a resident of St. Paul, Minn.; became medical inspector to the U. S. Sanitary Commission 1863. D. at Washington, D. C., Apr. 5, 1864. He was the author of many books and publications upon chemistry and ventilation.

Reed, Sir EDWARD JAMES, K. C. B.: chief constructor of the British navy; b. at Sheerness, Kent, Sept. 20, 1830;

studied at the School of Mathematics and Naval Construction at Portsmouth; was attached to the dockyard at Sheerness; was afterward editor of *The Mechanics' Magazine*; became secretary of the Institute of Naval Architects. He submitted to the admiralty proposals for reducing the dimensions, cost, and time required for building ironclads, and was soon after appointed chief constructor of the navy. Within three years he designed nearly the whole of the first fleet of ironclads of the British navy. He designed also an ironclad frigate for the Turkish navy, five steam transports of 4,000 tons each for the Indian Government, and numerous smaller vessels. He has also designed armored ships for the German and various other governments. After seven years as chief naval constructor Mr. Reed, who did not approve the construction of rigged seagoing turret ships, found these vessels so much in favor that he resigned his office in June, 1870. In 1874 he was elected to Parliament as a Liberal, and was returned at each election until 1892. He is a member of the council of the Institution of Civil Engineers, having become a member of the institution in 1870. He has been appointed on several Government commissions. In 1878 he was made a Knight Commander of the Bath. He is the author of works on iron ship-building, ironclad ships, and coast defense, and of *Japan, its Histories, Traditions, and Religions* (2 vols., 1880). WILLIAM R. HUTTON.

Reed, HENRY: scholar; grandson of Col. Joseph Reed; b. in Philadelphia, Pa., July 11, 1808; graduated at the University of Pennsylvania 1825; was admitted to the bar 1829; was appointed in 1831 Assistant Professor of English Literature and also of Moral Philosophy in the University of Pennsylvania, and in 1835 Professor of Rhetoric and English Literature; married a granddaughter of Bishop White; wrote the *Life* of his grandfather for Sparks's *American Biography*; edited with valuable prefaces and notes Wordsworth's *Poetical Works* (1837); Arnold's *Lectures on Modern History* (1845); Alexander Reed's *Dictionary of the English Language* (1845); Lord Mahon's *History of England* (1849), and other works, and contributed essays and reviews to several literary periodicals. On his return from a visit to Europe he was lost in the steamer Arctic, Sept. 27, 1854. His brother, William B. Reed, edited his *Lectures on English Literature* (1855), to which he prefixed a biographical sketch, *Lectures on English History as Illustrated by Shakspeare's Chronicle Plays* (1855), and *Lectures on the English Poets* (1857), all republished in England.

Reed, HUGH: See the Appendix.

Reed, JOSEPH: patriot; b. at Trenton, N. J., Aug. 27, 1741; graduated at Princeton 1757; studied law in England 1763–65; became deputy secretary of New Jersey 1767; settled at Philadelphia 1771; was a member of the committee of correspondence 1774; president of the first provincial convention of Pennsylvania Jan., 1775; delegate to the Continental Congress in May; served as a volunteer at the battles of Brandywine, Germantown, and Monmouth; was elected to Congress Sept., 1777; signed the Articles of Confederation in 1778; was elected president of the supreme executive council of Pennsylvania; was an earnest opponent of slavery and of the proprietary system of government; visited England for his health in 1784, but without beneficial result. D. in Philadelphia, Mar. 5, 1785.

Reed, THOMAS BRACKETT: party leader; b. at Portland, Me., Oct. 18, 1839; graduated at Bowdoin College, Maine, in 1860; was acting assistant paymaster in the U. S. navy 1864–65; was admitted to the bar in 1865, and commenced practice at Portland; was member of the Maine House of Representatives 1868–69, and of State Senate in 1870; attorney-general of Maine 1870–72; city solicitor of Portland 1874–77; and Representative from Maine in Congress since that time. He was elected Speaker of the House of Representatives Dec. 2, 1889, and soon entered on a course that provoked bitter opposition, but resulted in revolutionizing the parliamentary procedure of the House. He insisted on counting as present those members who in order to prevent a quorum refused to vote. His rulings were sustained, and the principle was embodied in the new rules adopted Feb. 14, 1890. Dec. 2, 1895, and Mar. 15, 1897, he again became Speaker. F. M. C.

Reedbird: See BOBOLINK.

Reed City: village; Osceola co., Mich.; on Hersey creek, and the Flint and Père Mar. and the Gr. Rapids and Ind. railways; 4 miles N. W. of Hersey and 69 miles N. of Grand Rapids (for location, see map of Michigan, ref. 5–H). It is in an agricultural region; has excellent water-power, several mills, and important manufactories; and contains a national bank with capital of $50,000, and two weekly newspapers. Pop. (1880) 1,091; (1890) 1,776; (1900) 2,051.

Reed Instruments: the generic name of a large class of musical instruments, of which the melodeon, the harmonium, and reed-organs are the most important. The tone of these instruments is produced by means of a thin tongue of wood or metal lying within or over an aperture (technically called a *reed*), and vibrated by means of a current of air. Instruments of this class were found among the Chinese several hundred years ago, but most of them are comparatively modern inventions. The first reed-organs were constructed in the U. S. about 1818; they were improved in 1821, 1825, and 1835, since which time the modifications have been too numerous for separate mention. The accordion was invented in Germany about 1829; the harmonium, first constructed in France soon afterward, was later much improved by the introduction of the exhaust bellows, and the bending and twisting of the tongue of the reed, termed voicing, was developed. These two improvements have been the main features which have wrought such changes in the modern reed-organ.

Reedsburg: city; Sauk co., Wis.; on the Baraboo river, and the Chicago and N. W. Railway; 15 miles W. N. W. of Baraboo, the county-seat; 32 miles W. of Portage (for location, see map of Wisconsin, ref. 6–D). It is an important hop, potato, and hog market; has flour, saw, and woolen mills, machine-shops, and other manufactories; and contains waterworks, two electric-light plants, a State bank with capital of $30,000, a private bank, and two weekly newspapers. Pop. (1880) 1,331; (1890) 1,737; (1900) 2,225.
EDITOR OF "FREE PRESS."

Reefs, Coral: See CORAL ISLANDS AND CORAL REEFS.

Ree Indians: a tribe of CADDOAN INDIANS (*q. v.*).

Rees, JOHN KROM, A. M., E. M.: astronomer; b. in New York, Oct. 27, 1851; graduated from Columbia College 1872, and School of Mines 1875; appointed Professor of Mathematics and Astronomy at Washington University, St. Louis, Mo., 1876; director of the observatory and Adjunct Professor of Practical Astronomy and Geodesy at Columbia College, New York, 1881, and managing editor of *The School of Mines Quarterly* 1884; Professor of Geodesy and Practical Astronomy and director of the observatory, Columbia College, New York, Oct. 1, 1884, and has published *Report on Total Solar Eclipse* (July, 1878); *International Time System* (1882); *Observations of the Transit of Venus, Dec. 6, 1882, made at Columbia College Observatory, Standard Time* (1884), etc.

Reeve, TAPPING, LL. D.: jurist; b. at Brookhaven, L. I., in Oct., 1744; graduated at Princeton 1763; began to practice law at Litchfield, Conn., 1772, and opened there in 1784 a law school, long the only institution of the kind in the U. S., which he conducted alone until 1798, and with Judge James Gould until 1820. He was a stanch Federalist in politics; was judge of the Supreme Court of Connecticut 1788–1814, and originated the movement for more equitable legislation concerning the property of married women. D. at Litchfield, Dec. 13, 1823. Author of *The Law of Baron and Femme, of Parent and Child, of Guardian and Ward, of Master and Servant*, etc. (New Haven, 1816; 4th ed. 1888), and of *A Treatise on the Law of Descents in the Several United States of America* (New York, 1825).
Revised by F. STURGES ALLEN.

Reeves, JOHN: law-writer; b. in London in 1752; studied law and was admitted to the bar; was appointed commissioner in bankruptcy 1783; chief justice of Newfoundland 1790; clerk to the bureau of commerce and of the colonies in 1792, and afterward superintendent of foreign affairs. He was inspired with a bitter hatred of republican institutions, and organized an anti-republican and an anti-French society. He advanced in a brochure the statement that the monarchy had no need of the assembly of the legislative chamber, and was denounced in Parliament for this, and tried before a jury, which acquitted him but denounced his opinions (1795). After the death of Pitt, who was his protector, Reeves retired upon a large pension. D. in London in 1829. He wrote a *History of the English Law from the Time of the Romans to the End of the Reign of Elizabeth* (American ed., 5 vols. 8vo., Philadelphia, 1880), a *History of the Law of Shipping and Navigation* (London, 1792), and a *History of the Government of Newfoundland* (1793), besides minor works. F. STURGES ALLEN.

Reeves, John Sims: singer: b. at Shooter's Hill, in Kent, England, in Oct., 1822; son of the organist of the village church. At eight years of age young Reeves could read any music at sight. At the age of fourteen he himself became the organist and the choir-master of the village church. Under Calcott and Cramer and other masters he became proficient in harmony and counterpoint. Under the name of "Johnson," at Newcastle-on-Tyne, he made his first real public appearance in June, 1839, singing the part of the Gypsy Boy in *Guy Mannering*. His voice at this time was looked upon as barytone, and it was not until 1847 that he sang as a tenor. After studying in Paris and in Milan he made his Italian *début* at La Scala Opera-house, Milan. He appeared, Dec. 6, 1847, at Drury Lane, London, as Edgardo in *Lucia di Lammermoor*, and was enthusiastically received. In 1848 he was engaged with the company at her Majesty's theatre, London, but owing to a dispute with the management appeared but once. He then attempted sacred music, with which his fame and memory must always be associated. Singing in *Judas Maccabæus* at Exeter Hall he astonished the critics, who had not suspected his versatility. He afterward devoted himself entirely to concerts, sacred and secular. In July, 1892, he retired from the stage and accepted a professorship in the Guildhall School of Music, London. D. Oct. 25, 1900. B. B. Vallentine.

Re-exchange: in the usual application of the term, the loss resulting from dishonor of a bill in a country different from that in which it was drawn or indorsed. (Chalmers's *Bills of Exchange*, 4th ed. 193.) A New York merchant wishes to pay a debt in London. He buys a bill on London; it is dishonored at maturity; he is entitled to the amount of money called for by the bill in London; he would not be indemnified by recovering in New York the amount of the bill with interest and protest fees; he has a right to draw in London a re-draft on the drawer or indorser in New York for an amount which will put him at once in possession of the money called for and promised to him by the original bill: this re-draft is called re-exchange. It will include not only the sum promised by the original bill, but the exchange on New York, the interest, and necessary expenses of the transaction. (*Suse* vs. *Pompe*, 8 Common Bench, N. S. 538; *Bank* vs. *U. S.*, 2 Howard 737.) Although this re-exchange bill is seldom drawn, the right to draw it fixes the damages recoverable by the holder in case of the dishonor of the original bill, unless the terms of the bill limit the damages, or a statute prescribes them. (See N. Y. Revised Statutes, 8th ed., p. 2501; Mass. Public Statutes of 1882, ch. 77.) The term re-exchange is used to signify, also, the loss on a particular transaction occasioned by the exchange being adverse, and the course of exchange itself. For further information, see Chalmers's *Bills of Exchange*, 4th ed., p. 194; Daniels, *Negotiable Instruments*, ch. xlv.

Francis M. Burdick.

Referendum [Lat., neut. of *referendus*, gerundive of *referre*, refer]: the practice of submitting legislative measures to the voters for ratification. It is observed in Switzerland, and favored by many political writers in the U. S., Great Britain, and Belgium. See Law-making, Methods of (*Switzerland*).

Reflecting Circle: an astronomical instrument for measuring angles by the reflection of light from two plane mirrors which it carries. It differs from the sextant chiefly in having an entire circle. See Sextant.

Reflection [from Lat. *reflec'tere*, reflect; *re-*, back + *flectere*, bend, turn]: the act of the mind whereby it examines itself or looks upon its own states as its objects. It is one of the most unique activities of the mental life. It is different from simple consciousness, in that in the latter there is no such thing as self-examination, and no act of setting up a conscious relation between the subject, or thinker, and the object, or what he thinks about. Reflection in its full sense seems to characterize man alone in the range of animal life; although wherever there is the beginning of the notion of self, there is also probably the beginning of this function of thinking about self which constitutes reflection.

This mental act is the great resource of self-observation and analysis, upon which the psychologist depends for most of his information. As a method, its use is called "introspection." In philosophy, reflection has always been the function upon which idealistic thought has based itself; for there is in nature nowhere else than in consciousness the fact of one kind of event setting itself over against another and criticising it. The inference is that this relation can not be accounted for in terms of the play of objective forces in nature, and so must be an ultimate kind of activity or reality. The theory of reflection is closely allied to that of Judgment and Knowledge (*qq. v.*). J. Mark Baldwin.

Reflection of Light: that bending which occurs in the path of a light ray when it is turned back from a surface upon which it falls. When a light-ray falls upon an unpolished surface, it is irregularly reflected or scattered in consequence of the different inclinations of the innumerable facets of which such surfaces are composed, as may be seen under the microscope. Non-luminous bodies are made visible by the scattering of light from their surfaces. When a ray falls upon a perfectly smooth surface, it is regularly reflected, and a virtual image of the illuminating body is seen behind the reflecting surface. Most surfaces which reflect regularly also reflect irregularly to some extent. The two portions of a reflected light-ray, before and after bending, are called respectively the incident and reflected ray. If a perpendicular or normal be erected to the reflecting surface at the point of incidence, the angles made with this normal by the incident and reflected ray are called the angles of incidence and reflection. The law of reflection is: *The angles of incidence and reflection are equal, and the incident and reflected rays and the normal lie in one plane.*

From the law of reflection it is evident that all rays diverging from a point and reflected from a plane surface appear to emanate from another point situated at the other side of the surface, and at an equal distance from it. Hence when an object is placed in front of a plane mirror the apparent image is of the same form and magnitude and at an equal distance from the other side of the mirror; but all the parts are reversed, like the negative of a photograph, the right hand of the object appearing on the left in the image and *vice versa*. For parabolic reflection, see Lighthouse (*Lighthouse Illumination*).

The intensity of reflected light varies with the nature and the position of the reflecting surface, the reflecting powers of various substances being greater for small angles of incidence than for large ones, and depending upon the index of refraction between the surface and the medium in which the light is traveling. See Refraction.

The phenomenon of reflection takes place equally with ether vibrations of all kinds, such as those of radiant heat and electro-magnetic undulations, and its laws are the same as in the case of light. Revised by R. A. Roberts.

Reflex Action [*reflex* is from Lat. *reflexus*, perf. partic. of *reflec'tere*, bend or turn back; *re-*, back + *flectere*, turn]: direct response of the nervous system to external stimulation—for example, the winking of the eyes when an object approaches, moving when tickled, etc. These actions are contrasted in physiology and psychology with "voluntary actions," those which owe part of their stimulus at least to central processes. Reflex actions are regular, definite, beyond control, inherited, and presided over by the lower centers of the brain and spinal cord. J. M. B.

Reformation: the name usually given to the religious revolution of the sixteenth century which divided the Western Church into the two sections known as Protestant and Roman Catholic. This movement was not an isolated event, but was closely connected with the intellectual and social changes which marked the transition from the Middle Ages to the modern era of civilization. It was also long in preparation. The disaffection with the hierarchy which disclosed itself in the rise of sects like the Waldenses, and within the Church in the reforming councils of the fifteenth century held at Pisa, Constance, and Basel; the rise of radical reformers, "forerunners" of Protestantism, as Wickliffe and others; the spiritual doctrine of the Mystics; political opposition to the Roman see, dating from the old contests of the empire with the pope; and especially the influence of the revival of learning in promoting general culture, in hastening the downfall of scholastic theology, and in producing a diligent study of the Bible and of Christian antiquity—these are antecedents of Protestantism which deserve special mention. Under this last head the work of Erasmus is very important. Protestantism, as a religious system, had two main principles—viz., the exclusive authority of the Bible as the rule of faith, as opposed to the normative authority of the pope or the Church—a principle that involves the right of private judgment; and the doctrine of justification by faith alone, in contradistinction to salvation

by works or human merit. Protestantism claimed for the individual a direct access to the blessings of the gospel, without the mediatorial intervention of the Church or priesthood. In opposition to the doctrine of a particular priesthood, it asserted the universal priesthood of Christian believers.

I. *The Reformation in Germany.*—The movement began in 1517 by the posting of the theses of Martin Luther, an Augustinian monk and a professor in the University of Wittenberg, who attacked the sale of indulgences, which in the hands of Tetzel and others was a source of flagrant abuses. Universal strife was kindled in consequence. Luther was excommunicated by Pope Leo X. in 1520, but he publicly burned the papal bull, with the book of canon law, which was almost equally obnoxious to him. By preaching and by numerous publications, with the aid of Melanchthon and other coadjutors, he gained numerous supporters among all classes. Political opposition to the encroachments of Rome seconded his efforts. At the Diet of Worms in 1521, however, he was put under the ban of the empire. Among his varied labors which contributed to build up his cause one of the most important was his translation of the Scriptures. His adherents were too powerful to be suppressed. The electors of Saxony were his stanchest friends. At the Diet of Spires in 1529, when a majority declared against the Reformation, the "Protest" which gave rise to the name "Protestants" was signed by the Elector of Saxony, the Margrave of Brandenburg, the Duke of Brunswick-Lüneburg, the Landgrave of Hesse, the Prince of Anhalt, together with fourteen cities, including Nuremberg, Strassburg, and Constance. At the Diet of Augsburg in 1530, in the presence of Charles V., the Protestants presented their famous Confession, but a decree was passed condemning their cause. The menace involved in this decree led to the formation of the Protestant Smalcaldic League. The execution of the Augsburg decree by Charles V. was long prevented by political complications, which often proved helpful to Protestantism. Especially was this true of the rivalship of Charles V. and Francis I. At length, in 1546, after the death of Luther, the Smalcaldic war broke out, which resulted disastrously for the party of reform, but their cause was restored after Maurice, Duke of Saxony, turned against the emperor. The Peace of Augsburg (1555) was a virtual acknowledgment of defeat on the part of the emperor, and secured to Protestantism a legal recognition. After the terrible Thirty Years' war in the seventeenth century the Treaty of Westphalia (1648) once more established the legal privileges of Protestantism as one of the religions of the German empire. The final result was that Northern Germany was mostly Protestant, while Southern Germany, after the Catholic reaction and the labors of the Jesuits, became predominantly Roman Catholic. See GERMAN THEOLOGY.

II. *The Reformation in (German) Switzerland.*—The leader of the Protestant movement here was Ulrich Zwingli, who became pastor at Zurich in 1519. Imbued with the Erasmian culture, but a robust and fervent advocate of the distinctive doctrines of the Reformation, he was chiefly instrumental in inducing the city of Zurich to abolish the old system and become a separate Protestant Church (1524). Public disputations, as well as sermons from the pulpit, and books and pamphlets, were agencies employed in Switzerland, as elsewhere, for the dissemination of the Reformed doctrine. Basel (1529), Berne (1528), St. Gall (1528), and Schaffhausen (1529) followed the example of Zurich. The ecclesiastical revolution was also a political one; the movement for reform in the Church was identified with republican principles and patriotic efforts for the improvement of public morals, and in opposition to the corrupting foreign influence which had drawn the Swiss away from their homes to serve as mercenary soldiers. As the consequence of dissensions between the Protestants and Catholic cantons, war broke out, and Zwingli himself fell in battle in 1531. The cause of Protestantism received a severe blow by its defeat in this struggle, but afterward, in a great degree, recovered its fortunes, especially after Geneva espoused the Reformed faith. The Zwinglians differed from the Lutherans on the doctrine of the Lord's Supper, the former considering it a mnemonic or memorial feast, intended to call vividly to mind the Saviour's death; the latter holding that while transubstantiation is to be denied, Christ is actually received in the sacrament, even by the unbelieving communicant. The division occasioned by this controversy, and by the vehement repugnance of Luther to the Zwinglian opinions, divided and weakened the Protestant power at a critical epoch.

III. *The Reformation in the Scandinavian Kingdoms.*—Protestantism spread northward, largely through the influence of Germans and of preachers sent forth from the great Protestant seminary of Wittenberg. Christian II., King of Denmark, first favored Protestantism, but afterward drew back from its support. Under Frederick I. (1523–33), by whom he was supplanted, the Reformation extended itself, and it acquired a legal establishment in Denmark under Christian III. The Lutheran doctrine and a constitution with bishops or superintendents, which Luther had approved, were accepted. Protestantism was introduced into Norway in 1537 in connection with the subjection of the country to Denmark. The Reformed doctrine was first preached in Sweden in 1519; it was favored by Gustavus Vasa (1523–60), and was formally adopted at the Diet of Westerås in 1527. The ecclesiastical property fell for the most part into the possession of the nobles. Subsequent efforts to restore Roman Catholicism proved abortive.

IV. *The Reformation in Slavonic Countries.*—Lutheranism was favorably viewed by the Hussites of Bohemia. Protestantism was strongly established in that country. The refusal of its adherents to join Ferdinand of Austria in the Smalcaldic war brought upon them, especially after the defeat of the Protestants at Mühlberg, severe persecution. Toleration was continued only to the anti-Lutheran Hussites. Lutheranism early spread into Polish Prussia and Livonia, also into Poland. In this last country dissension broke out between the Lutherans and Calvinists, and further division was occasioned by the introduction of Unitarianism, which gained many adherents among the higher classes. The various evangelical parties formed a union of Sandomir in 1572. Sigismund II., the king, was favorable to the Reformed doctrine.

V. *The Reformation in Hungary.*—Numerous Germans were settled in this country, who brought in the Lutheran faith, and were aided in diffusing it by the Bohemian Brethren and by Waldenses. The new faith made rapid progress, especially in the cities and among the nobles. But the civil wars that arose, coupled with the doctrinal contests between Lutherans (mostly Germans) and Calvinists (mostly Magyars), checked its growth. It remained strong, however, until it was weakened and reduced by the labors of the Jesuits and the measures of the Catholic reaction.

VI. *The Reformation in Geneva.*—The pioneer in the work of introducing Protestantism into Geneva was William Farel, a Frenchman, who preceded Calvin, and by whose influence Calvin was induced to establish himself there (1536). The Bishop of Geneva had been expelled and Protestantism legally accepted in 1535. The intellectual vigor, fine scholarship, and indomitable energy of Calvin, in connection with his systematic organizing genius, caused his name to become familiar and his influence to be powerfully felt, not only within the walls of the city, where his tenets were accepted, and where his will became, after long struggles with adversaries, predominant, but also in other countries, especially in France, his native land. He took the leading part in shaping the civil and ecclesiastical institutions of Geneva. His doctrine upon the Lord's Supper was intermediate between that of Zwingli and the theory of Luther, but it was one which the Zwinglian churches could accept. The two streams of Swiss Protestantism gradually mingled in one. Calvin asserted likewise the divine predestination and election—a doctrine on which the Reformers were at first united—in terms which went beyond the view which the Lutherans were inclined to adopt. His doctrine of the Lord's Supper and of election or divine "sovereignty" became the distinguishing features of Calvinism—a system which was defined with great clearness in Calvin's *Institutes of Theology*. These tenets, associated with the Presbyterian polity, which Calvin also founded at Geneva, were accepted by the Protestants of France, Scotland, Holland, and other countries. Thus Protestants were divided under two great classes—the Lutherans and "the Reformed," this last term being specially applied to the adherents of the Swiss type of the Reformation. Numerous foreigners—most of them exiled from other countries for their faith—resorted to Geneva, many of whom were naturalized, and many others, having been instructed by Calvin, returned as missionaries to their own homes. Geneva became to the Romanic countries and to the lands which received Calvinism what Wittenberg was to the disciples of Luther and Melanchthon. The principal leader there, after Calvin, was his accomplished pupil, Beza.

VII. *The Reformation in France.*—A class of mysties, of whom Lefèvre was the most conspicuous, and among whom were Margaret, sister of Francis I. and Queen of Navarre, and Briçonnet, Bishop of Meaux, sympathized with the doctrine of justification by faith, though they were not averse to the traditional doctrine of the sacraments. Humanism was favorable to reform, and Francis I., who was proud of being styled the "father of letters," encouraged innovation up to a certain degree, when his interests prompted him to lend it assistance. On other occasions he was a cruel persecutor of Protestantism at home, even when, out of hostility to the emperor, he was giving help to Lutheranism in Germany. His vacillation was productive of great mischief. Yet Protestantism, mainly from the influence of Calvin and of Geneva, gained a foothold in France in his reign. His successor, Henry II., was inimical to the Reformed faith, especially after the Treaty of Cateau-Cambrésis with Spain. Nevertheless, Protestantism in his reign made great progress. In 1558 it was estimated that there were 2,000 places of Reformed worship scattered over France, and congregations numbering 400,000 organized after the German pattern. In 1559 they ventured to hold a general synod in Paris. The Huguenots, as they were called, became, by the force of circumstances, a political party. The family of Guise gained such ascendency in the Government during the reign of the young Francis II., and eventually under Charles IX., as to come into inevitable conflict with the great houses of Bourbon and Châtillon, and at the same time the Guises set themselves up as intolerant champions of the old religion. The consequence was that the political and religious elements of opposition coalesced. The Protestants found leaders in Condé and Coligny, who adopted their faith, and the latter of whom honored it by a signally pure and elevated career. Anthony of Navarre first espoused, but finally deserted, the Protestant cause. His heroic wife, Jeanne d'Albret, the mother of Henry IV., was their steadfast defender. The history of the Reformation in France would include a full narrative of the civil wars. The edict of St.-Germain in 1562 granted a measure of toleration to the Huguenots; but the massacre of Vassy shortly after opened the long and bloody struggle which went on, with intervals of peace, down to the accession of Henry IV. and the Edict of Nantes (1598). The massacre of St. Bartholomew in 1572, when Coligny and thousands of his coreligionists were slaughtered, was due to Catherine de Médicis as its main contriver, and sprang out of the mingled motives of political, religious, and personal hostility. The Huguenots were always a minority of the nation, but, besides the nobles who were attached to their side, they comprised a multitude of the sober and intelligent middle classes and of the inhabitants of towns. The Edict of Nantes, following upon the abjuration of Henry IV., reduced them to the condition of a stationary or declining party, but one furnished as a means of defense with political privileges of an extraordinary character, which they continued to hold until the time of Richelieu. There were times in the course of the sixteenth century when the Protestant cause seemed likely to triumph in France. Its failure to achieve the victory in that country was the tragic event of the Reformation.

VIII. *The Reformation in the Netherlands.*—The inhabitants of the Low Countries were highly prosperous and intelligent. The contiguity of the country to Germany and France facilitated the incoming of Protestant opinions. Merchants and emigrants brought them over from England. In 1523 two persons were put to death at Brussels as heretics—an event that called forth a stirring hymn from the pen of Luther. The persecuting edicts of Charles V. led to the destruction of a great number of Protestants in the Netherlands. Grotius makes the whole number who perished in this reign 100,000—probably an exaggerated estimate. Philip II., who was unpopular in this part of his dominions, set about the strict enforcement of the laws against heresy. The cruelties of the Inquisition, in connection with the evident purpose to destroy the liberties of the country and subject it to Spanish absolutism, provoked armed resistance. The hero of the great revolt, which was a struggle for political and religious freedom, was William of Orange. In the course of the protracted conflict a Protestant state grew up in the north under the lead of Orange, while the southern provinces finally submitted to Spain and retained the old form of religion. The Dutch republic confronted the whole power of Spain and achieved its independence. At first, Lutheranism had been introduced into Holland, but the Calvinistic type of doctrine and polity prevailed, and was incorporated in the ecclesiastical institutions of the country. The *Confessio Belgica* was composed in 1561, and was revised and adopted by a synod at Antwerp in 1566.

IX. *The Reformation in England and Scotland.*—The Lollards, a remnant of the followers of Wickliffe, were numerous in England at the beginning of the sixteenth century among the lower classes. The revival of learning prepared the ground for ecclesiastical change. The friends of the "new learning" had a spirited contest with the devotees of scholasticism. More, Colet, and Erasmus during his stay in England, exerted themselves in behalf of letters and against superstition. The writings of Luther found readers, especially among young men at the universities. Tyndale's translation of the Bible was eagerly perused, notwithstanding the efforts of the authorities to suppress it, and the martyrdom of its author. The Reformation in England had two distinct sources, which at times worked in conjunction with one another. The first was the moral and religious feeling, which was enlisted in favor of the Protestant movement. The second was the *quasi* political opposition to the foreign rule of the papacy, which was re-enforced by the difficulties encountered by Henry VIII. in attempting to procure a divorce from Catharine of Aragon. The reluctance of Clement VII. to comply with the king's petition moved Henry to reduce the power of the clergy and to oblige them to declare him the head of the Church of England. Finally, he cut the knot by marrying Anne Boleyn without the papal permission in 1532. This was followed by the Act of Supremacy, which put an end to papal authority in England. In 1536 followed the act for abolishing the monasteries and confiscating their property. The king still professed the Catholic dogmas. There was a Protestant and a Catholic party in the Church, the leader of the former being Cranmer, Archbishop of Canterbury, a man of pure and upright intentions, but of a timid nature. The Protestants were led in the council by Thomas Cromwell, the king's vicegerent in ecclesiastical affairs. The Ten Articles (1536) were, on the whole, favorable to the Protestant side; but the bitter matrimonial experiences of the king, taken in connection with the Catholic rebellion in the North, led to the issuing of the Six Articles (1539), which were more in the Roman Catholic interest; and the same circumstances caused the fall of Cromwell (1540). Cranmer was saved from the vengeance of the opposing faction by the king's personal favor. On the death of Henry VIII. and the accession of young Edward VI. (1547) the Protestant party obtained complete control. In his brief reign, under the auspices of Cranmer and his associates, the Protestant Church of England received its constitution, liturgy, and creed. Evangelical theologians from the Continent filled the chairs of theology in the universities. Under Mary (1553–58), the successor of Edward, the old order of things, the papal supremacy included, was restored. Her matrimonial connection with Philip II. and subservience to Spain, and the popular sympathy excited by the martyrdom of Cranmer, Ridley, Latimer, and others, prepared the nation for the restoration of Protestantism under the auspices of Elizabeth, in 1558. During her long reign the Protestant religion took firm root in English soil. The defeat of the Spanish Armada (1588) rendered it certain that the authority of the papacy could not be reinstated by foreign intervention. The conservatism of Elizabeth in matters of religion provoked into activity the Puritan sentiment, which was anxious to assimilate English Protestantism to that of the Continent, where numerous English exiles had lived during the preceding reign. The Puritans likewise demanded a greater independence for the Church in relation to the state than the Tudor love of power and a widespread feeling of repugnance to ecclesiastical control would allow. The result was the division of the Church of England into two great parties whose contests fill many a page of English history for the century that followed the accession of Elizabeth.

In Scotland, at the outbreaking of the Reformation, the clergy were ignorant and vicious, and the Church was in possession of a great portion of the landed property of the kingdom. The evangelical doctrine, of which John Knox was the most effective apostle, gained a lodgment in the hearts of the people, and the co-operation of the nobles was founded partly in religious conviction and partly in the desire to appropriate to themselves the property of the Church. Protestantism in the Calvinistic and Presbyterian

form was legally established by an act of the Scottish Parliament in 1560. The events of the reign of Mary Stuart proved that the new faith was too deeply rooted in the hearts of the middle class of the Scottish nation to be dislodged. The Presbyterian system was fully established in 1592.

X. *The Reformation in Italy and Spain.*—Protestantism in these countries had several peculiar characteristics. Its disciples were confined to the higher, cultivated classes, and the Reformed faith took no root among the people at large. Protestantism was also a thing of degrees. Many held the doctrine of justification in the sense of the Reformers, but felt little repugnance for the old view of the sacraments and the hierarchical government of the Church. The societies of professed Protestants were secret. In Italy there was a widespread desire of Church reform, in which eminent Catholics—such as Caraffa, Contarini, and other members of the Oratory of Divine Love participated. Some of them were subsequently leaders of the Catholic reaction, which aimed at the purification of morals and discipline, but at the same time crushed dissent and schism with an iron hand. In Naples, Venice, Florence, and other cities there were Protestant churches. Eminent preachers like Ochino and theologians like Peter Martyr privately espoused the Protestant faith. These were driven into exile, and Protestantism was extirpated in Italy by the instrumentality of the Inquisition, the *Index Expurgatorius*, and the other agencies of the strict and ascetic party which gained the ascendency in the Church, and which suppressed also the moderate evangelical Catholics of the school of Contarini. In Spain there were Protestant churches at Seville and Valladolid. The writings of Luther and of other Reformers were secretly introduced into the kingdom, as they were in large numbers into Italy; but in Spain also the Inquisition, with its *autos-da-fé* (1559–60), did its work thoroughly.

Literature.—The history of the Reformation occupies, of course, a large space in the general histories of the Church. Of these we may specify Gieseler's, Schaff's, and (on the Roman Catholic side) Alzog's and Döllinger's works. Of the numerous separate writings on the Reformation as a whole, the author would refer to his own work, *The Reformation*; Häusser's *History of the Period of the Reformation* (in an Eng. trans., 1874), which is instructive upon the general course of events; d'Aubigné's well-known history, written by an ardent Protestant; Beard's *The Reformation of the Sixteenth Century*, etc. (1883); Seebohm's *Era of the Protestant Revolution* (1874), a brief work. In the first rank of authorities is the series of histories of the papacy and of England, France, and Germany in the sixteenth and seventeenth centuries, by Ranke. On the Roman Catholic (Ultramontane) side the most noted recent work is Janssen's *Gesch. d. deutschen Volkes seit dem Ausgang des Mittelalters* (5 vols., 1876–86). The literature relating to the Reformation in each of the several countries is copious. George P. Fisher.

Reformatories: See Prison Discipline.

Reformed Church in the United States: the ecclesiastical body which was formerly known as the German Reformed Church, historically derived from the Reformed Churches of Switzerland and Germany. It may accordingly be regarded as the American representative of the oldest of the series of national churches which spring from the great religious movement in the sixteenth century, of which Zwingli and Calvin were the most prominent leaders. In its early European history its most important centers were Zurich, Geneva, and Heidelberg. The union of the churches of Zurich and Geneva was effected by the adoption of the *Consensus Tigurinus* in 1549. In 1559 the Palatinate of the Rhine passed over from the Lutheran to the Reformed Church, and its example was soon followed by several other German principalities. At the direction of the Elector Frederick III., Zacharias Ursinus and Caspar Olevianus prepared the Heidelberg Catechism, which was published in 1563. This catechism was recognized by the Church in Switzerland, and became a common bond of union for the Reformed churches along the whole course of the Rhine from its source to the ocean. It is Christological in its character, giving full expression to Calvin's doctrine of the spiritual real presence, and teaching the doctrine of election, but omitting all reference to an eternal decree of reprobation. The Heidelberg Catechism is the only confession of faith which is formally recognized as of binding authority by the Reformed Church in the U. S.

The American history of the German branch of the Reformed Church may be regarded as consisting of five plainly marked periods.

1. *The Preliminary Period* (1709–47).—Though there were members of the German Reformed Church in the U. S. at an earlier period, it was not until about 1709 that they emigrated to that country in large numbers. In that year John Frederick Hager was ordained in London for service "among the Palatines, New York." During this period the most eminent man was the Rev. John Philip Boehm, who began to preach in what is now Montgomery co., Pa., at least as early as 1720. George Michael Weiss founded the Reformed Church of Philadelphia in 1727. Churches were founded in isolated settlements from New York to South Carolina, but they were most numerous in Pennsylvania. An attempt was made to unite them by means of an organization known as The Congregation of God in the Spirit, but it proved a failure. The churches were very poor, and appealed for aid to the Church of Holland.

2. *The Period of the Coetus* (1747–93).—Michael Schlatter (1716–90) was a native of Switzerland, but had been sent to America in 1746, with the rank of missionary superintendent, to organize the Reformed churches. In 1747 he succeeded in establishing an ecclesiastical body, which was known as the Coetus. It was in all respects like a synod, except that its decisions were not final until they had been approved by the synods of Holland. His visit to Europe in 1751 resulted in the collection of the sum of £12,000, which was invested for the benefit of the German Reformed churches in Pennsylvania. On his return to America in the following year he was accompanied by six young ministers, of whom Stoy and Otterbein became eminent. From the fund collected in Europe the Reformed ministers in Pennsylvania received an annual stipend. There were many independent ministers, of whom the most eminent was Dr. John Joachim Zubly, of Georgia.

3. *The First Period of the Synod* (1793–1825).—The connection with Holland, which had been at first a blessing, became an intolerable burden, and in 1793 the Coetus resolved itself into a synod. This ended the period of dependence. The Church was thrown on its own resources, and met with many discouragements. In some congregations the change of language from German to English induced protracted conflicts. There was a great lack of ministers, and most of the churches in New York, New Jersey, and South Carolina were gradually alienated. It was in the main a period of disintegration, but in its later years the fruits of a new life began to appear. Sunday-schools were introduced, and the work of missions begun. In 1824 the Classis of Western Pennsylvania resolved itself into the Synod of Ohio. The "mother synod" in 1825 numbered 22 ministers and 23,291 members.

4. *The Founding of Literary and Theological Institutions* (1825–63).—A theological seminary was founded at Carlisle, Pa., in 1825. It was removed to York, Pa., in 1829, and thence to Mercersburg, Pa., in 1837. Marshall College was founded at the latter place in 1835. The two institutions were under the same general management, and the little village of Mercersburg became an important literary center. It gave its name to a system of teaching which was known as Mercersburg theology. The professors in the Theological Seminary at Mercersburg at different times were the Rev. Drs. Lewis Mayer, Frederick A. Rauch, John Williamson Nevin, Philip Schaff, Bernard C. Wolff, Henry Harbaugh, E. E. Higbee, and Emanuel V. Gerhart. It was here that Rauch wrote his *Psychology*, Nevin published his *Mystical Presence*, and Schaff began his series of Church histories. In 1853 Marshall College was removed from Mercersburg to Lancaster, and united with Franklin College, which had been founded at that place as early as 1787. The united institution is known as Franklin and Marshall College. Other literary and theological institutions of the Reformed Church are Heidelberg University, Tiffin, O., founded in 1850; Ursinus College, Collegeville, Pa.; Catawba College, Newton, N. C.; Calvin College, Cleveland, O.; and the German Mission House, near Sheboygan, Wis.

5. *The Period of the General Synod.*—In 1863 the two existing synods united in the organization of a general synod. In the same year the tercentenary of the Heidelberg Catechism was celebrated, and several important volumes were published. For some years there were serious conflicts concerning liturgical worship, but these were concluded by the adoption of a *Directory of Worship*. In 1893 the Church appropriately commemorated the centennial anniversary of the organization of its oldest synod.

The Reformed Church in the U. S. publishes 29 periodicals, of which 23 are English and 6 German. It is actively engaged in the work of missions, and has been especially interested in the evangelization of Japan. In the U. S. it has found an extensive field for missionary labor among immigrants from Germany and Switzerland. Several Hungarian churches have recently been founded. The Church sustains four orphanages and a home for deaconesses.

The following are the statistics for 1900: Ministers, 1,075; congregations, 1,677; communicant members, 240,130; benevolent contributions, $630,454. See PRESBYTERIAN CHURCH.

JOSEPH HENRY DUBBS.

Reformed Church of America: a religious denomination known prior to 1867 as the Reformed Protestant Dutch Church in North America, a name which exactly described it, as *Protestant vs.* Roman; *Reformed*—i. e. Calvinistic in doctrine and non-prelatical in order; *Dutch*, as descended from Holland and inheriting its religious type.

1. *Origin and History.*—The first settlers in New Amsterdam brought with them the schoolmaster and the visitor of the sick, and in 1628 a church organization was formed. The emigration from Holland followed the Raritan, the Hudson, and the Mohawk rivers and their affluents, and at first was considerable, but after the English conquest in 1664 fell off rapidly. Still, the Hollanders held the ground they had taken, and everywhere multiplied ministers and churches. Their subsequent growth was hindered by three great causes—too great tardiness in relinquishing the Dutch language in public worship; a bitter controversy among themselves on the question whether they should act independently of the mother-Church in supplying their pulpits; and the waste of the Revolutionary war, whose chief scenes of conflict in the Middle States lay in the territory occupied by the Dutch; but after the return of peace the denomination consolidated its institutions and set to work repairing the desolations of the past. It increased its funds for educational purposes, enlarged its corps of theological professors, prosecuted in various directions missionary enterprises at home, and also engaged in the same work abroad—at first, in connection with other denominations, afterward independently. It numbers (1900) 643 churches, 715 ministers, and 124,248 communicants, who are organized into 34 classes, 4 particular synods, and 1 general synod. The strength of the denomination lies at the East, but seven classes have been formed among the many thousands of Hollanders who have settled in various Western States from Michigan and Illinois to the Dakotas.

2. *Doctrine and Worship.*—The Church is eminently confessional. It owns five creeds—the Apostles', the Nicene, the (so-called) Athanasian, the Belgic Confession, and the Canons of Dordrecht. It requires the Heidelberg Catechism to be taught in families and schools, and also to be regularly explained from the pulpit on the Lord's Day. A short compendium of this catechism is the standard of doctrine for all who seek full communion; and ministers are required to pledge themselves in writing not to promulgate any change of views they may make without previously consulting the classis to which they belong. There is a Liturgy, which is mostly optional, but the forms for the administration of the sacraments, of ordination, and of church discipline are of imperative obligation. No psalmody may be used unless it has been approved by the General Synod.

3. *Polity.*—The affairs of each congregation are managed by a consistory, consisting of elders and deacons chosen for two years, but in such a way that only half go out of office at once. The elders, with the pastor, receive and dismiss members and exercise discipline; the deacons have charge of the alms. Both together are trustees of the church, hold its property, and call its minister. Ex-members of this body constitute what is called the "great consistory," who may be summoned to give advice when necessary. The minister and one elder from each congregation in a certain district constitute a classis, which supervises spiritual matters in that district. Four ministers and four elders from each classis in a larger district make a particular synod, with similar powers, and representatives from each classis, proportioned in numbers to the size of the classis, constitute the General Synod, which has supervision of the whole, and is a court of the last resort in judicial cases.

Educational and other Institutions.—Rutgers College (1770), New Jersey, Hope College (1865), Michigan, Northwestern Academy, Orange City, Ia. (1883), and Pleasant Prairie College, German Valley, Ill. (1893), are controlled by members of this Church, but are unsectarian in teaching and influence. The chief theological seminary, at New Brunswick, N. J., has five professors and a library of over 40,000 volumes. There are two others—one at Holland, Mich., the other at Palmaner, India—each with three professors and a respectable library. Foreign missions are maintained in Japan, China (Amoy), India (Madura), and Arabia. There are 23 ordained missionaries, 55 churches, 6,226 communicants, and an annual outlay of about $112,000. The board of domestic missions aids in sustaining over 150 churches and expends about $65,000 yearly. The board of education aids over 100 students in preparing for the ministry and expends $30,000 yearly. A board of publication, organized in 1854, besides other good work, issues two monthly journals. The salient characteristics of the Church are zeal for doctrine, order, and a learned ministry, unyielding attachment to its own views and usages, and a large charity for all other Christians.

LITERATURE.—Demarest, *History and Characteristics of the Reformed Dutch Church* (2d ed. 1889); Corwin, *Manual* (3d ed. 1879).

T. W. CHAMBERS.

Reformed Church of Scotland: See SCOTLAND, CHURCH OF.

Reformed Episcopal Church: a religious body founded Dec. 2, 1873, by a few clergymen and laymen who left the Protestant Episcopal Church of the U. S. under the leadership of the Right Rev. George David Cummins, D. D. Unwilling longer to share responsibility for what he believed to be the Romeward tendencies of that church, he resigned his bishopric in it, and and was chosen the first presiding bishop of the new Church under the following resolution: "That we, whose names are appended to the call for this meeting as presented by Bishop Cummins, do here and now, in humble reliance upon Almighty God, organize ourselves into a Church, to be known by the style and title of 'The Reformed Episcopal Church,' in conformity with the following declaration of principles, and with the Right Rev. George David Cummins, D. D., as our presiding bishop:

"I. The Reformed Episcopal Church, holding 'the faith once delivered unto the saints,' declares its belief in the Holy Scriptures of the Old and New Testaments, as the Word of God, and the sole rule of faith and practice; in the creed 'commonly called the Apostles' Creed'; in the divine institution of the sacraments of baptism and the Lord's Supper; and in the doctrines of grace substantially as they are set forth in the Thirty-nine Articles of Religion.

"II. This Church recognizes and adheres to episcopacy, not as of divine right, but as a very ancient and desirable form of Church polity.

"III. This Church, retaining a liturgy which shall not be imperative or repressive of freedom in prayer, accepts the Book of Common Prayer as it was revised, proposed, and recommended for use by the General Convention of the Protestant Episcopal Church, A. D. 1785, reserving full liberty to alter, abridge, enlarge, and amend the same, as may seem most conducive to the edification of the people, 'provided that the substance of the faith be kept entire.'

"IV. This Church condemns and rejects the following erroneous and strange doctrines as contrary to God's Word:

"(1) That the Church of Christ exists only in one order or form of ecclesiastical polity.

"(2) That Christian ministers are 'priests' in another sense than that in which all believers are 'a royal priesthood.'

"(3) That the Lord's Table is an altar on which the oblation of the body and blood of Christ is offered anew to the Father.

"(4) That the presence of Christ in the Lord's Supper is a presence in the elements of bread and wine.

"(5) That regeneration is inseparably connected with baptism."

At its General Council in New York in May, 1874, it revised the Prayer-book of 1785 to meet the needs of the changed times, but without making any variations of principles or doctrines. The use of the Prayer-book was made obligatory at Sunday morning services and optional at other times. At the same time it adopted its first constitution and canons. At its third General Council at Chicago a year later it adopted its Articles of Religion, based substantially upon the Thirty-nine Articles of the Church of England.

The Reformed Episcopal Church is governed by a general council, its president being the presiding bishop for the time being, meeting annually, biennially, or triennially as

ordered at each session. This council has supervision and control of all Reformed Episcopal parishes in America, which are subordinately grouped into the following divisions, named in the order of their organization: The First Synod of Canada; the Missionary Jurisdiction of the Pacific; the Synod of New York and Philadelphia; the Missionary Jurisdiction of the South; the Special Missionary Jurisdiction of the South (consisting of congregations composed of colored persons); the Missionary Jurisdiction of the West and Northwest; and the Synod of Chicago. This Church was also planted in England in 1877, and its churches in Great Britain were under the control of its General Council until May, 1883, when they were, by resolution of the council, given a separate and independent existence under the title of the General Synod of Great Britain and Ireland. This body in 1894 was merged with the "Reformed Church of England" under the name of "The Reformed Episcopal Church in the United Kingdom of Great Britain and Ireland, otherwise called The Reformed Church of England."

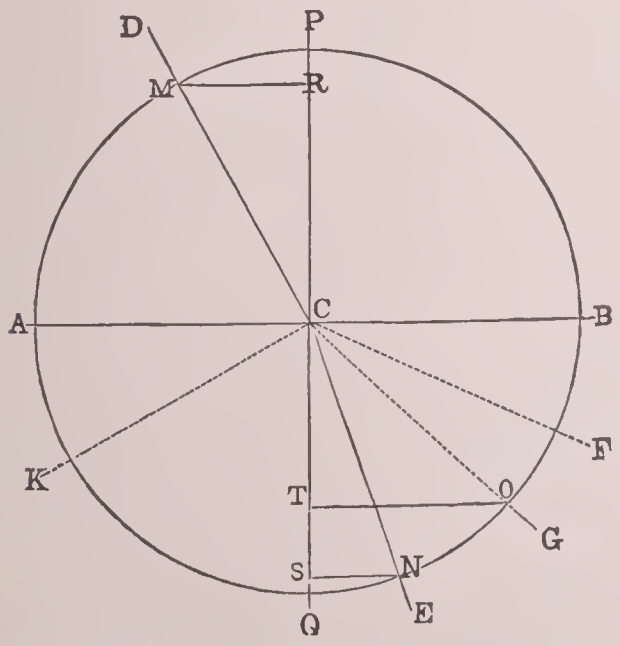
Bishop Cummins was the presiding bishop of this Church until his death June 26, 1876. Since that time the office has been filled by election at each General Council. The young Church had its first five years of life during the unexampled and long-continued financial depression which begun in 1872, but its development was steady and rapid during ten years. Since that time its growth has been more in internal strength and solidity than in extension. As shown by the reports to the General Council at its session in June, 1894, there were in the U. S. 112 churches and missions; 8 bishops: 90 presbyters; 18 deacons; 10,655 communicants; 12,873 Sunday-school scholars, officers, and teachers; $181,150 total annual contributions, of which $123,050 were for current expenses; 102 church buildings and chapels and 11 rectories, all valued at $1,533,017; a theological seminary, value $90,000; a Home for Aged and Disabled Clergymen, value, $8,000; 2 church extension trust funds, $400,000, making a total of $2,031,017. In 1900 there were 104 churches, and 9,743 communicants. CHARLES D. KELLOGG.

Reformed Presbyterians: a religious body in Scotland and the U. S., often called COVENANTERS or CAMERONIANS (*qq. v.*), originating in 1680. They hold that a church member may not take an oath of allegiance to any government that fails to acknowledge the kingly authority of Christ, nor vote for any officer who must take such an oath. A Reformed Presbytery was organized in North America in 1774. In 1782 it united with the Associate Presbyteries of Pennsylvania and New York. Hence arose the bodies of Reformed and Associate Reformed Presbyterians now existing. For an account of these movements in their order, with statistics for 1894, see PRESBYTERIAN CHURCH.

Revised by W. J. BEECHER.

Refraction [from Lat. *refrin'gere*, *refrac'tum*, break up, (in Mod. Lat.) refract; *re-*, again + *fran'gere*, break: Eng. *break*]: the change of direction in light, sound, heat, and similar waves on passing from one medium into another.

REFRACTION OF LIGHT.—The deflection of a light-ray. When a ray of light falls obliquely upon the surface of a transparent medium, a portion of it is reflected (see REFLECTION); the remaining portion enters the medium, is bent aside at its point of entrance, but after that pursues a straight path through the transparent body. In the simplest case of refraction there is only one ray; but in double refraction the intromitted light breaks up into two rays. In simple refraction the deflection of the ray is governed by fixed laws, and the amount of the bending is invariable for each refractive medium. These laws may be best explained through the figure. Let B A be the upper surface of a refractive medium denser than air. At C draw P Q perpendicular to B A, and let the incident ray D C meet B A in C. The medium below C being denser than the air above it, the ray D C is bent toward P Q, making D C E the refracted ray, P C D the angle of incidence, and Q C E the angle of refraction. To determine the amount of the deflection, about C as a center, describe a circumference cutting the incident and refracted rays in M and N, from which points draw M R and N S perpendicular to P Q. M R is the sine of the angle of incidence, and N S the sine of the angle of refraction. The law of refraction, called Snell's law, is that for each refracting medium the sines of these angles bear to each other an invariable ratio, while the incident and refracted rays and the normal lie in one plane. The *index of refraction* is the numerical expression for the ratio of the sines. When a light-ray passes from air into water, for instance, the proportion of the sines is very nearly that of 4 to 3. The refractive index is therefore in this case expressed by the fraction $\frac{4}{3}$, or more exactly by the decimal 1·335. Experiment shows that if the ray passes from the more refractive medium, water, into the less refractive, air, the deflection will be from the normal P Q, and the refractive index will be nearly $\frac{3}{4}$, the reciprocal of the index of the reverse case. The ray on entering the more refractive medium is bent toward the normal, and in entering the less refractive medium is bent from the normal by the same amount; the ray can therefore always return by the path of its arrival, the refractive index being in the one case the reciprocal of what it is in the other.



Looking at the figure, it will be seen that any ray, however oblique, which falls upon A B from the air above will be refracted toward P Q. The reverse is not, however, invariably true. If a ray passes upward through the water, at certain angles refraction is impossible. Let the ray G C, following the law of the sines, just graze the surface of the water B A after being refracted from P Q; then any ray which enters the water between G and B from the direction F, as F C, can not be refracted; for the portion after bending at its proper angle would be within the water, where no change of direction would be possible. The ray which can not be refracted is therefore totally reflected. The critical angle at which total reflection begins is evidently such that its sine equals the reciprocal of the index of refraction. Total reflection at times causes the bottoms of very shallow ponds to be invisible to an eye at a certain angle from them. Every ray of scattered light, by which objects upon the bottom would become visible, reaches the surface of the water at an angle of total reflection, can not emerge, and is turned downward again.

The variation in the refractive indices of different media shows that bodies have different capacities of receiving light through their bounding surfaces. This fact, according to the wave theory, results from the slower propagation of the luminiferous ether-vibrations in the denser medium. Optical density, however, does not necessarily coincide with density of mass. Bisulphide of carbon (CS_2) is lighter than crown glass, but has a greater index of refraction for each kind of light. The velocity of propagation varies inversely as the refractive index, and it is an important mathematical property of the propagation of light that, when a ray passes from one point to another through any number of different media, the time of transmission between the two points is the least possible.

From the law of refraction it is manifest that when a ray passes through a medium with parallel faces, as a pane of window-glass, its course after emergence is parallel to the original direction. All the rays which go to make up the image upon the eye of an object so viewed, therefore, assume their relative positions, and the proportions are perfect, though the whole object is slightly displaced, the amount of displacement being dependent upon the thickness of the glass. An object viewed through imperfect glass, where the faces are not strictly parallel, has its proportions altered, because the emergent rays which go to form it are not parallel, but diverge, or converge, or cross each other, at all sorts of angles. It will be found that the distortion be-

comes more striking as the eye recedes from the glass, the divergencies being more noticeable at a distance. Most optical instruments are dependent upon refraction, and are constructed in accordance with its laws. See ABERRATION, LENS, MICROSCOPE, and TELESCOPE. For the different refrangibilities of each colored ray in the spectrum, see ABERRATION, INTERFERENCE, LENS, LIQUIDS, SPECTRUM. For the history of discovery, see OPTICS. Revised by R. A. ROBERTS.

Double Refraction.—That particular case of refraction in which a ray of light on entering a medium is divided into two rays. One of these, called the ordinary ray, is propagated in accordance with Snell's law. The other, called the extraordinary ray, is propagated in accordance with a much more complex law, which was first shown by Huyghens in 1690 to be a necessary consequence of the assumption that the luminiferous ether in the medium is unequally elastic in two directions, each perpendicular to the other. The phenomena of double refraction are seen to the best advantage in the mineral calcite, a crystalline variety of calcium carbonate. (See OPTICS.) In other double refracting bodies the separation of the two rays is not wide enough to be easily perceptible, but by special contrivances (see POLARIZATION) they may be made to interfere, and many of the most brilliant color effects are thus attained. By such means it has been ascertained that the property of double refraction is exceedingly common in transparent media, being absent only from those homogeneous bodies which are uniform in density, non-crystalline, or isometrically crystallized. (See CRYSTALLOGRAPHY and MINERALOGY.) The two beams are always polarized, the plane of polarization of one being perpendicular to that of the other, except in the case when they coincide in the direction of the principal optical axis of the crystal. In calcite this direction is equally inclined to the three faces whose intersection forms an obtuse triedral angle. The widest separation of beams is in a plane perpendicular to this axial direction. Under this special condition each ray is propagated in accordance with Snell's law, the index of refraction of the ordinary ray being 1·658 for monochromatic yellow light (D line), while that of the extraordinary ray is 1·486. Since the velocity of propagation varies inversely as the index of refraction, the velocity of the ordinary ray is not quite nine-tenths of that of the extraordinary at maximum separation. In the case of quartz under similar conditions the velocity of the ordinary ray slightly exceeds that of the extraordinary. On this basis double refracting crystals are divided into two classes, negative and positive, calcite being a typical example of the negative and quartz of the positive. Calcite and quartz, moreover, have each but a single axis, along which there is no double refraction, while in many other crystals, such as niter, there are two such directions. On this basis, therefore, crystals are still further divided into two classes—uniaxial and biaxial. It was shown by Fresnel that in transmission through biaxial crystals both rays fail to meet the requirements of Snell's law; each therefore may be properly called extraordinary. In certain varieties of mineral, such as mica, some specimens are found to be uniaxial and others biaxial.

For Huyghens's determination of the direction of either ray in a double refracting medium, see POLARIZATION.

Index of Refraction.—The constant ratio of the sine of the angle of incidence to the sine of the angle of refraction when a ray of homogeneous light passes through the bounding surface between two media. Thus if a ray of monochromatic yellow light (D line) at a temperature of 15°C. pass from a vacuum into water at an incident angle of 60°, the angle of refraction will be found to be 40° 29′. The index of refraction, n, under these conditions is

$$n = \frac{\sin 60^\circ\ 00'}{\sin 40^\circ\ 29'} = 1{\cdot}3339.$$

If the first of these media be air instead of a vacuum, since the index of refraction of air is 1·000294, the relative index of refraction of water with respect to air is found by dividing the former result by the latter, giving 1·3335. Since ordinary measurements are made in air rather than in a vacuum the refractive index referred to a vacuum is usually called the absolute index by way of distinction.

The index of refraction affords a convenient means of comparing the refracting powers of different media. For the indices of refraction of different kinds of glass and several liquids, see LENS and LIQUIDS. For a full table of refractive indices for various media, the reader is referred to Landolt and Börnstein's *Physikalisch-Chemische Tabellen* 2d ed., pp. 384 to 447). W. LE CONTE STEVENS.

REFRACTION OF SOUND.—The change in direction of sound-waves on passing from one medium into another. A beam of sound—regarded as any very small segment of an advancing spherical wave-front—moves normally in a radial line, but it is bent from its rectilinear course whenever it undergoes an unequal acceleration or retardation, necessarily turning toward the side of least velocity and from the side of greatest velocity. In other words, the direction of acoustic impulse is always *perpendicular* to the wave-front of sound, whether it continues as an expanding spherical surface, or, by reason of unequal velocity, becomes in any way deformed.

There are four ways in which sound-waves may be subjected to an unequal disturbance of velocity, and the sound-beams become thereby refracted: 1. By variation of *elasticity* in the medium. If the density be unchanged, the velocity of sound varies directly as the square root of the elasticity. 2. By variation of *density* in the medium. If the elasticity remain unchanged, the velocity varies inversely as the square root of the density. 3. By variation of motion, or *current*, in the medium. Sound traveling with the wind is propagated a little more rapidly than against the wind. 4. By variation of *temperature* in the medium. If other elements remain unchanged, the velocity of sound in air varies directly as the square root of the absolute temperature. The effect of heat on a gas is to increase its elasticity if confined, and to diminish its density if unconfined; in either case equally it accelerates the velocity of propagation.

(1) Perhaps the only practical example of acoustic refraction by differences of *elasticity* is furnished by the passage of sound from water into air or from air into water. Sound moves more swiftly through liquids (and still more so through solids), not in consequence of their greater density, but in opposition to their density, and by virtue of their far greater energy of resilience or elasticity, measured in intensity, not in quantity. The concentric sound-waves sent upward by a submarine explosion to the level surface of the water there suffer a large amount of internal reflection, with a reverse curvature, giving the sound-beams the same amount of divergence downward that they previously had upward. A portion of each of the sound-waves, however (with greatly diminished amplitude of vibration), is propagated into the air. These have their convex fronts very much flattened, by reason of being reduced to less than one-fourth of their previous velocity. The radii of these deformed surfaces, representing the directions of the sound-rays, are thus bent or refracted upward (or toward the vertical) at the surface of the air, and have a focus of divergence much more distant than the position of the origin of the sound-waves. In the case of an aërial sound, as the discharge of a gun, the descending sound-waves are largely reflected upward from the surface of the water; but a small portion of the impulse passing this plane, the convex wave-fronts, acquiring suddenly more than four times their previous velocity, are hurried into greatly increased convexity, and the sound-rays are refracted toward the horizon, with a divergence representing a much lower or nearer focus than the origin of the sound. Those sound-rays which by refraction would coincide with the horizontal plane or water-surface would necessarily suffer total reflection.

(2) The refraction of sound resulting from differences of *density* was first demonstrated by Carl Sondhauss in 1852 by means of a convex lens of carbonic-acid gas confined in an envelope of collodion film. The ticking of a watch was heard, with the lens interposed, most distinctly at a focal point where it could not be heard on the removal of the lens. (*Poggendorffs Annalen*, 1852, lxxxv., 381.) In this case the wave-front on entering the convex surface of the lens is so far retarded by the denser gas (commencing at the axis of the lens) as to have a concave form impressed upon it, and on emerging from the second surface of the lens in reversed order becomes still more concave by being accelerated first at the outer annulus. The normals of these concave waves converge to a focal point.

(3) The refraction of sound by inequality of *wind* was first suggested by Prof. Stokes in 1857. Winds, being ordinarily more retarded near the earth than aloft, would act unequally upon the concentric sound-waves advancing against them, by retarding the upper portion of the wave-fronts more than the lower portion. Being thus tilted backward more and more as they advanced against the wind, these wave-fronts would have their lines of impulse, representing the acoustic beams, bent gradually upward from the surface, so as to leave a sound-shadow at no great distance on a plane. On the con-

trary, sound-waves advancing in the direction of the wind would, for the same cause, have their fronts more tipped forward above than below, and the line of acoustic effect would be bent downward, bringing continuously some of the upper sound-beams to the observer's ear at great distances. This explains why sounds are usually heard with so much better effect and to so much greater distance in the direction of the wind than in opposition to it. In those exceptional cases where the upper wind is moving with less velocity than the lower wind, sound will be heard to a greater distance against the wind.

(4) The refraction of sound from differences of *temperature* was first pointed out in 1874 by Prof. Reynolds, who showed that during the heat of a still summer's day, when the lower air had a higher temperature than the upper air, loud sounds could be heard to but short distances, but that in the evening, when the lower air became cooler, the same sounds were heard distinctly several times the former distance. (*Proceed. Roy. Soc.*, 1874.) The difference of sound-velocity due to the temperature is about 1 foot for 1° F. Hence when the lower strata of air are the warmest (as is usually the case), the advancing wave-fronts are accelerated below, causing the sound-beams to curve upward, as in the case of adverse winds. This explains why the sound of waterfalls is heard so much farther and more distinctly at night than during the day, even in the most silent of rural districts. When the lower strata of air are colder than the upper (as more rarely occurs), the advancing sound-waves are tipped forward above, bending downward the sound-beams, and thus greatly favoring audibility at a distance. This explains the facility with which sounds can sometimes be heard to unusual distances in Arctic regions. See Acoustics.

Revised by W. Le Conte Stevens.

Refrigerants [from Lat. *refri'gerans*, *refrigeran'tis*, pres. partic. of *refrigera're*, cool off again, make cool; *re-*, again + *frigera're*, to cool, deriv. of *fri'gus*, coldness, cold]: a term sometimes used in medicine to designate collectively certain medicines given in fever which produce a grateful feeling of relief from the distress of the febrile symptoms. Such are cooling drinks in general—solutions of potassium salts, as the citrate or nitrate; effervescing draughts, acid mixtures, and solutions of purgative salts. The term has no proper scientific signification.

Refrigerating Processes: the means of producing artificial cold by machinery for the purpose of cooling the interior of buildings to a temperature below that of their natural surroundings. Such processes consist in the application of heat through the medium of steam to cause a series of operations with one of the following substances: (1) Air; (2) sulphuric ether; (3) methylic ether; (4) sulphur dioxide; (5) chymogene, a distillate of petroleum; (6) carbonic acid; (7) anhydrous ammonia, the substance most extensively employed in commercial refrigeration; (8) water. The first six of these substances are available for refrigerating purposes only by means of what is termed the compression system, but the last two may be utilized either by a compression system or what is termed the absorption system.

Compression System, Brine Circulation.—Fig. 1 illustrates the essential features of a compression system for a cold-storage warehouse. D is a gas compressing-pump, driven by any form of steam-engine. E is a nest of pipe connecting with the outlet from the compressing-pump, which is kept drenched or surrounded with cold water at about 60° F., constituting the condenser. A is a closed tank connecting with the outlet from the condenser, constituting the liquid ammonia reservoir. C is a nest of pipe immersed in a bath of brine or other fluid, non-congealable at the lowest desired temperature, constituting the cooler. One end of this nest of pipe connects with the reservoir A by means of a valve, B, termed the expansion-cock, and the other end connects with the inlet, or suction end, of the compressing-pump. H represents cold-storage chambers or rooms having insulated walls, within which it is desired to maintain a low temperature by circulating cold brine through the nests of pipe F. This is accomplished by means of the brine-pump P, which draws brine from the bottom of the bath and forces it through the pipes *b*, whence it returns to the top of the bath, or brine-tank.

The operation of the apparatus is then as follows: The expansion-cock being closed, a tank of liquid anhydrous ammonia is connected so as to discharge into the cooler, and the compressing-pump is operated so as to prevent the accumulation of more than the desired pressure—say, 19 lb. above the atmosphere—in the cooler. The tank of liquid anhydrous ammonia in the condition in which it is received from the manufacturing chemists is at the temperature of the atmosphere—say, 70° F. At this temperature the ammonia can exist as a liquid only when it is under a pressure of about 115 lb. per square inch above the atmosphere. The ammonia therefore flows from the tank into the cooler; but in the latter the pressure is only 19 lb., and at this pressure the ammonia can not exist as a liquid unless its temperature is about 5° F., which is the boiling-point corresponding to the pressure. Hence, as its temperature on entering the cooler is about 70°, it is in the condition of a liquid heated above the boiling-point due to its pressure. Vaporization will therefore occur until the latent heat of the portion vaporized equals the heat represented by the difference between 70° and 5°, when the ammonia will have cooled itself to the latter temperature. About 10 per cent. of the weight of ammonia will have vaporized as a consequence of the fall of temperature, or, in technical terms, 10 per cent. of the ammonia is vaporized by free expan-

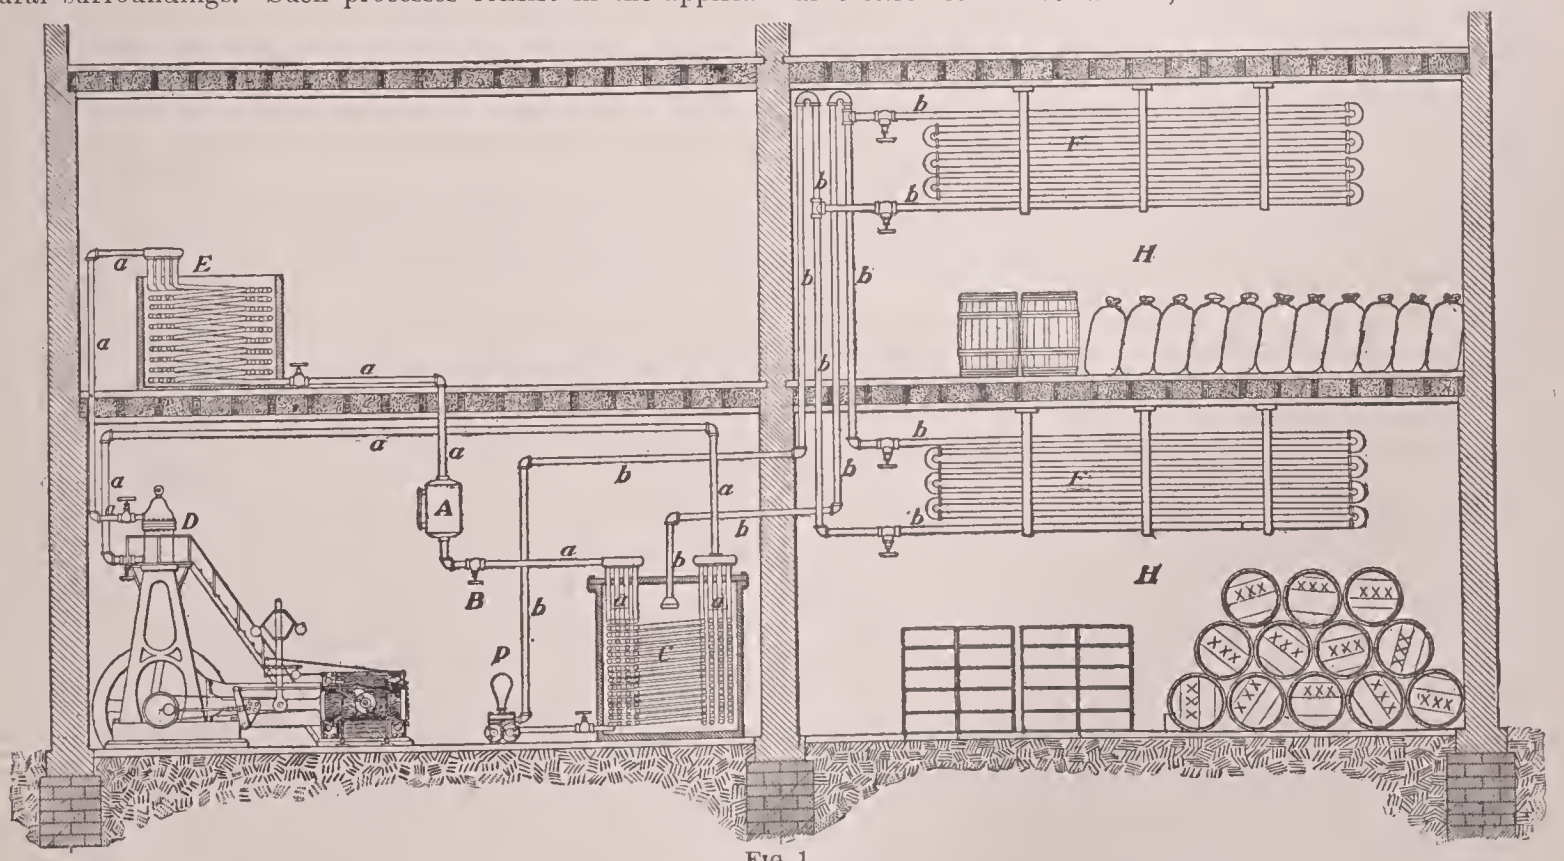


Fig. 1.

sion. Ninety per cent. of the ammonia is therefore in the liquid state when it has attained the temperature of ebullition corresponding to the pressure existing in the cooler, and if no heat could be supplied from surrounding bodies it would remain liquid; but it is practically in direct contact with the brine, whose temperature is so much higher than that of the ammonia that the latter must receive heat from the brine, and, as the compression-pump by its suction prevents the pressure in the cooler from increasing, the effect of the heat received will be to evaporate the liquid ammonia without increasing its temperature. The brine may therefore be cooled by an amount equivalent to the latent heat of 90 per cent. of the total ammonia introduced into the cooler. All of the ammonia is not, however, allowed to vaporize in the cooler in some types of compression-machines, while in other systems particular care is taken to insure its complete vaporization. This difference of treatment gives rise to two classes of apparatus, one known as the wet or cold compression and the other the dry-compression type. In either case all of the ammonia is drawn into the compressing-pump, which forces it into the condenser, where sufficient ammonia is gradually accumulated to cause the pressure to equal that at which it will be liquefied, by means of the cooling water with which the condenser is supplied. When a sufficient amount has liquefied to fill the reservoir A to the desired extent, as shown by a gauge-glass attached to it, the charging of fresh ammonia to the cooler is discontinued, and the expansion-cock B is opened so that liquid ammonia flows into the cooler from the reservoir A at the same rate as the latter receives ammonia from the condenser. This ammonia undergoes free expansion and evaporation in the cooler, and the operations are then continuous, the temperature of the brine gradually approaching that corresponding to the boiling-point of ammonia at the pressure maintained in the cooler by the suction of the pump. When the desired brine temperature is reached its circulation through the cold-storage rooms is commenced. Generally the brine returns to the tank, after passing through the storage-rooms, at about 6° higher temperature than that at which it leaves the tank, and its mean temperature is from 6° to 16° higher than the boiling-point of the ammonia corresponding to the suction-pressure, according to the efficiency and extent of the pipe-surface in the brine-tank. The mean temperature of the brine is about 6° less than that of the storage-space required to be cooled. For the storage of beer a temperature of about 36° F. is required, and this is therefore afforded with a pressure of about 28 lb. above the atmosphere in the cooler. Slaughter-houses require about 25° F. in their storage-rooms, which may be afforded by about 24 lb. suction or cooler pressure; while for the storage of fish, requiring a temperature of about 0° F., a suction-pressure of about 5 lb. above the atmosphere must be used.

Air and Chloride of Calcium Circulating Systems.—Instead of brine chloride of calcium is used as a circulating medium, first, because the corrosion of iron pipes is thought to be less by its use than with brine, and, second, because at temperatures approaching 0° F. brine, unless made from the best qualities of rock-salt, is liable to partly congeal, whereas chloride of calcium is perfectly fluid at temperatures considerably below zero. In cold-storage practice at Boston air from centrifugal fans is blown over the surfaces of the cooler, and by a system of wooden conduits is circulated through storage-chambers. Pipes in the storage-chambers are thus avoided. The expenses of such a system are possibly a little greater than that of a brine system, but by its use a storage-chamber freshly filled with material can be more quickly cooled to a given temperature than by either a brine or a direct-expansion system.

Direct-expansion Compression Systems.—If instead of using cold brine in the pipes in the storage-chambers the liquid ammonia is circulated through them, we have what is called a direct-expansion system. The storage-chamber piping then constitutes the cooler. If it is desired to refrigerate spaces at long distances from the compressor, this system is necessary, as the liquid ammonia from the condenser can be conveyed to an expansion-cock at any point without the expensive insulation necessary on conduits for cold brine. In St. Louis and Denver, for example, areas of half a mile radius are successfully refrigerated by ammonia conveyed in underground pipes. Where, however, the refrigeration is confined to a part of a building near by or containing the compressor, the use of brine is by many regarded as a desirable safeguard against damage of stored material by the accidental escape of ammonia from the circulating pipes, notwithstanding the fact that the cost for piping is less for the direct-expansion system, and that it saves in cost of operation to the extent of most of the power consumed by the brine-circulating pump, and by permitting the suction-pressure to be from 5 to 10 lb. higher to secure a given temperature in a storage-space than is possible with brine as a medium of transmission between the ammonia and the material to be cooled.

"Wet" versus "Dry" Compression System.—In the wet system, which is known also as the Linde system, the presence of some liquid ammonia in the compression-cylinder limits the highest temperature in the latter to about the boiling-point, corresponding to the highest pressure produced by compression, whereas with the dry system the maximum temperature in the compressing-cylinder is upward of 100° F. higher. If the compressing-cylinder was absolutely non-conducting, the wet process should be more economical than the dry method, but the influence of the cylinder-walls appears, by tests, to make the two systems practically equal in economy. See the table near the end of this article.

Ammonia-absorption System.—If instead of being drawn into the compressing-pump the ammonia gas leaving the cooler is led into contact with hydrate of ammonia surrounded by a bath of cooling water, it may be dissolved or absorbed by the hydrate as rapidly as it would enter the cylinder of a compressing-pump. The resulting hydrate of ammonia being then withdrawn by an ordinary pump from the vessel, called the absorber, in which the absorption has occurred, and forced into a still or closed vessel containing a steam-coil, the ammonia absorbed may be distilled from the hydrate as a gas at the same pressure which could be given it by the compressing-pump—that is, the liquefying pressure corresponding to the temperature of the cooling water available for the condenser, the hydrate resulting from the distillation being meanwhile returned to the absorber to react upon more gas from the cooler. The distilled gas being led to a condenser produces liquefied anhydrous ammonia, which can be used through an expansion-cock and cooler like that coming from a condenser of a compression system. Such a series of operations constitutes the ammonia-absorption system. In other words, for the compressing-pump, with its steam-engine in a compression system, there is substituted a vessel called an absorber, a common liquid-pump, and a steam-still. All the other elements, namely, the condenser, liquid-ammonia reservoir, expansion-cock, and cooler, Fig. 1, are identical for the two systems.

A section of a leading absorption refrigerating-machine is given in Fig. 2. G is the still or generator containing the steam-coil *c*, which is supplied with steam by pipe *c* and drained by a steam-trap, I. The distilled gas leaves the generator at J after passing over the baffle, or separating-plates K, to be freed of entrained water. It then passes to the condenser E, which is in two sections, arranged so that water-vapor condensed in the part L can be drained back to the generator. The hydrate or weak liquor resulting from the distillation sinks by its increase of specific gravity to the bottom of the generator, and thence passes by the pipe *a* to the absorber D to reunite with gas entering the latter by the pipe *d* from the cooler C. Simultaneously the recharged hydrate or strong liquor from the absorber is delivered to the generator by the pump P and pipe *e*. In the vessel called the interchanger the weak liquor at about 270° gives up heat to the strong liquor, which leaves the absorber at about 130°. The cooling water which is supplied to the condenser E acts afterward to cool the absorber, the chemical union of the gas and weak liquor being accompanied with generation of heat. A is the liquid-ammonia reservoir, B the expansion-cock, and C the cooler and brine-tank.

All the above remarks regarding the brine, chloride of calcium, air, or the direct-expansion methods of circulation apply as well to the absorption as to the compression system.

Ammonia Compression versus Absorption System.—If a compression system is driven by an ordinary non-condensing Corliss engine affording an indicated horse-power with 3 lb. of fuel, tests of performance show that its economy of fuel is about equal to the best absorption systems when the efficiency of the boiler is equivalent to the evaporation of 11·1 lb. of water per pound of combustible from and at 212° F., and the suction-pressure is about 20 lb. above the atmosphere—that is, when the temperature of the material to be refrigerated is required to be about 20° F. For higher temperatures or higher suction-pressures the compression-machine is superior in economy of fuel, but for lower tempera-

tures theory indicates that the absorption-machine affords the better economy, unless the compression system employs multiple-expansion condensing-engines. Tests indicate that the compression system requires less cooling water than the best absorption systems, apparently because the ammonia leaving the still or generator can not be entirely freed from entrained water or its vapor.

Water, sulphuric ether, sulphur dioxide, carbonic acid, methylic ether, and chymogene can be used in compression systems like those described above for anhydrous ammonia. In the case of water, temperatures in the cooler less than 32° F. require the absolute suction-pressure to be less than ·08 lb. per square inch, or within about ·16 inch of mercury of a perfect vacuum. The fuel required for a given refrigerating effect is about 20 per cent. more than for ammonia, but the dimensions of the compressing-cylinder must be upward of 150 times that required for ammonia. The use of water in a compression system is therefore impracticable, except for making artificial ice very quickly, as explained under Ice-making (*q. v.*). Sulphuric ether was the first substance practically applied to refrigeration by the compressing system. It affords 5° F. in the cooler when the absolute suction-pressure is 1·7 lb. per square inch, and the condenser-pressure, for ordinary temperatures of cooling water, about 8 lb. absolute. The economy of fuel would be nearly equal to that with ammonia, but the volume of the compressing-cylinder must be upward of seventeen times that required for ammonia. The use of ether is therefore obsolete. Sulphur dioxide affords a temperature of 5° F. in the cooler, with about 12 lb. absolute suction-pressure, and about 50 lb. absolute condenser-pressure. Its economy is practically identical with that of ammonia, but the compressing-cylinder must be about three times greater in volume than with the latter substance. Refrigerating-machines using sulphur dioxide are still manufactured to a limited extent in the U. S., where they are known as the Pictet system. The same system in Europe uses a mixture of sulphur dioxide and about 3 per cent. of carbonic acid, which forms what is known as the Pictet fluid. The latter's pressure and density for a given temperature are about 25 per cent. greater than those of sulphur dioxide, but the fuel economy resulting from its use is not sensibly different. Carbonic acid affords 5° F. in the cooler with an absolute suction-pressure of 342 lb. and a condenser-pressure of about 900 lb. per square inch. The fuel required for a given refrigerating effect is about 50 per cent. more than for ammonia, but the volume of the compressing-cylinder is only about one-fourth that required for ammonia. Carbonic acid is as yet in use to a limited extent, but its relatively greater compactness and inoffensive character are leading to its recommendation for service on ships where economy of space is necessary. Nothing very definite is known regarding the application of methylic ether and the petroleum product chymogene in practical refrigerating service. A few machines have been operated with these substances, but they are not now utilized. The physical properties of both of these substances would afford about the same economy of fuel for refrigerating purposes as is available for ammonia. The dimensions of the compressing-

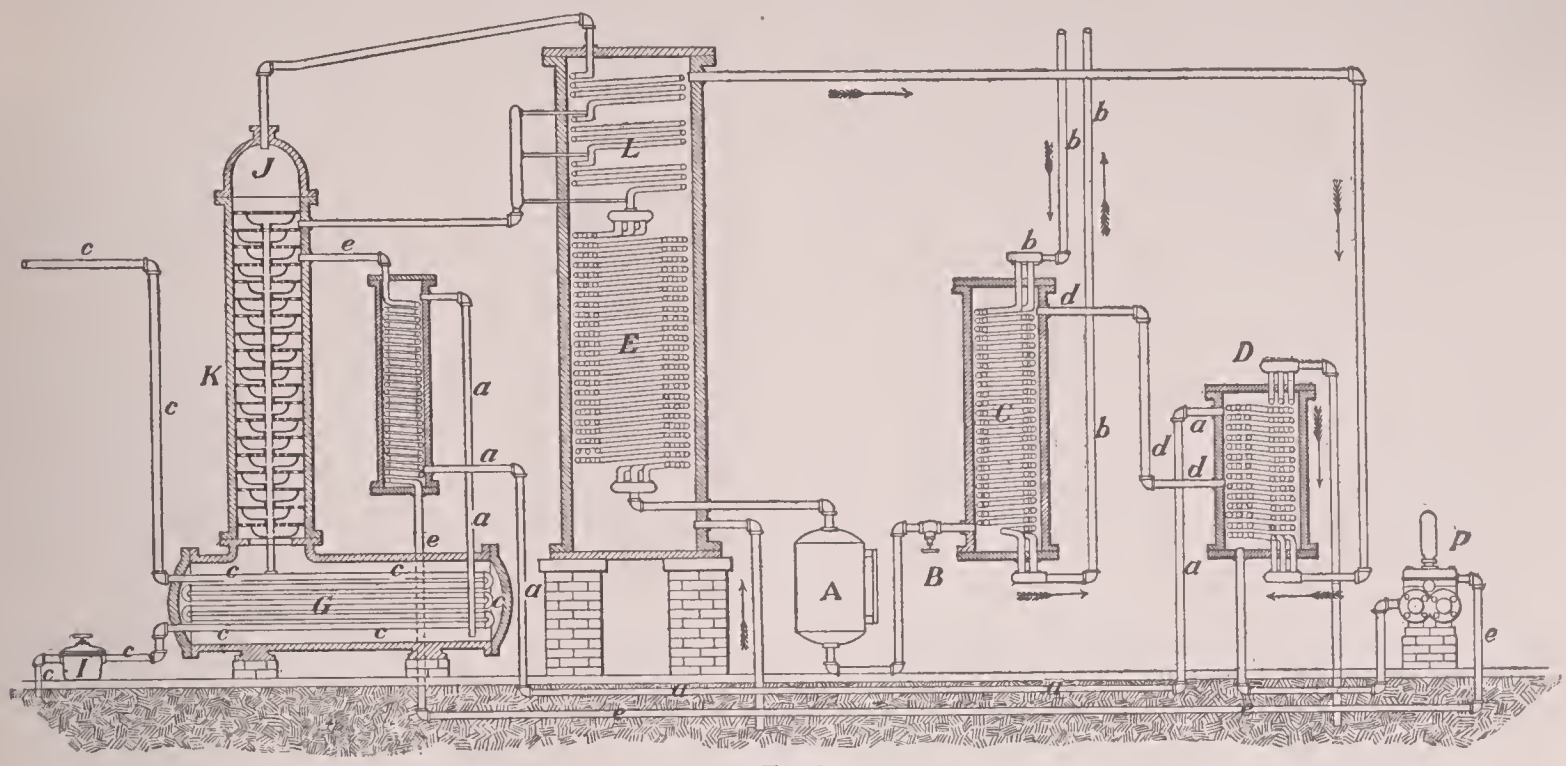

Fig. 2.

pumps would probably be for chymogene intermediate between sulphuric ether and sulphur dioxide, and for methylic ether intermediate between sulphur dioxide and ammonia. Atmospheric air used as a refrigerating substance requires that for the expansion-cock (Fig. 1) there should be substituted a cylinder and piston. If the air at the pressure of the condenser entered the cooler simply by means of an expansion-cock the temperature would not fall, and hence no refrigeration could be effected. In order to lower the temperature the air must be made to perform work against a piston while its pressure falls from that in the condenser to that of the cooler. Hence an expanding as well as a compressing cylinder must be provided. The work done by the air in the expanding cylinder is available to assist in compressing the air, but the losses by friction due to the presence of the extra cylinder considerably reduces the economy. If the air is drawn from and exhausted into the atmosphere at each stroke of the compressor, then in order to secure 5° F. as the minimum temperature a condenser pressure of 22 lb. per square inch absolute would be necessary with perfect action. The fuel for a given refrigerating effect would be about twice that required for ammonia, and the volume of the compressing-cylinder would have to be about sixty times that needed for ammonia. To secure smaller dimensions a condenser-pressure of about 60 lb. per square inch is used, which makes the volume of the compressing-cylinder only about twenty times that needed for the same refrigerating capacity with ammonia; but as the theoretical temperature in the cooler is then nearly 100° F. below zero, the consumption of fuel for a given refrigerating effect is about six times that for ammonia. If instead of drawing air from and discharging it into the atmosphere a closed system is used, so that the lowest air-pressure is about 40 lb., the volume of compressing-cylinder necessary is only about six times that required for ammonia, but the economy is about the same as in the atmospheric system. Air-machines are in extensive use in ships, because the use of air incurs no such risk of destruction of provisions preserved by the artificial cold as exists from danger from leakage when such chemicals as sulphur dioxide or ammonia are used. Many ships are now successfully refrigerated by ammonia compression, brine systems, however.

The table on the next page, abstracted from *Ledoux on Ice-making Machines*, shows the best results of tests of performance of current types of refrigerating-machines. The relative economy is shown by the figures in column seventeen, and the capacity by those in column fourteen. Both the economy and capacity may be observed to vary considerably with the suction-pressure, which is the controlling thermo-dynamical element. See *Transactions of the American Society of Mechanical Engineers*, vol. xii., p. 362.

The absorption principle described above can be applied with water or brine as the refrigerating substance, and sulphuric acid as the absorbent. The water or brine is fed into a chamber or cooler in which a vacuum of about ·16 inch of mercury, or less, is maintained by an air-pump. A portion of the liquid evaporates by free expansion, and temperatures as low as 32° are produced with water, or as low as 14° with brine. The unevaporated liquid is frozen to ice if it is water, or circulated through the spaces to be refrigerated if it is brine. The vapor is drawn into a vessel or acid-chamber, adjoining the cooler, containing anhydrous sulphuric acid, which absorbs it. The resulting mixture, or dilute acid, is pumped into the still or generator, which frees it of water, and it is then returned to the acid-chamber to reabsorb the vapor. Experiments with the apparatus on a small scale indicate that the economy of the process for general refrigerating purposes may be superior to that in which ammonia is used, and that it may afford a means of making ice with considerably less expense and space for plant than by the use of any other of the refrigerating substances. This method is employed in one of the oldest forms of refrigerating-machines, where, by means of a hand-pump, a vacuum is produced in a glass bottle or caraffe filled with water, and ice is formed inside the bottle for table use. One-fourth of the water is vaporized and absorbed by sulphuric acid or other substances having a strong affinity for water, and the remaining three-fourths is converted into ice. D. S. Jacobus.

ACTUAL PERFORMANCE OF ICE-MAKING MACHINES.

CLASS OF MACHINE.	Authority.	Dimensions of compressing-cylinder, in inches.		Absolute pressure, in lb. per square inch.		Temperature corresponding to pressure, in degrees Fahr. * Temperature of air at entrance and exit of expansion-cylinder.

Refrigeration of the Earth: the gradual cooling of the earth in the course of ages. According to the Nebular Hypothesis (*q. v.*) the earth was originally a mass of fiery liquid, and known geological facts have established that its surface was at one period much hotter than it is now. The fact that the temperature increases from the surface inward implies that there is a continual loss of heat from the interior by gradual conduction through the outer crust and atmosphere to external space. (See Energy, Dissipation of.) This loss is very small, in proportion, compared with that of the sun—owing, doubtless, to the existence of the crust. It has been suggested, however, that the internal heat might be kept up by chemical action—that is, by the transformation of chemical energy of combination into heat, or by the passage of the earth through a hotter region of space, a hypothesis due to Poisson. Lord Kelvin regards these views as improbable, and making use only of Fourier's mathematical theory of heat has arrived at some important results. He assumes that at a certain critical epoch a superficial layer of rocks became solidified, at a temperature of about 7,000° F., and shows that it is probable that the amount of heat of the crust went on diminishing by a quantity proportional to the square root of the time from the epoch. Further, his analysis would lead to the inference that during the last 96,000,000 years the rate of increase of the temperature from the surface inward has diminished from about $\frac{1}{10}$th to about $\frac{1}{50}$th of a degree F. per foot, and that the thickness of the crust through which any degree of stated cooling has been experienced has increased up to its present thickness from a fifth of that thickness. Lord Kelvin believes also that the earth is not, as is commonly supposed, a mass of fiery liquid covered with a crust of from 30 to 100 miles thick, but on the whole more rigid than a solid globe of glass, or even of steel of the same dimensions, and he observes that a decided negative should be given to the suggestion that internal heat exerted any sensible effect on climate. See Earth (*Internal Temperatures*). R. A. Roberts.

Refuge, Cities of: See Cities of Refuge.

Regal'di, Giuseppe: poet; b. at Novara, Italy, in Nov., 1809; began the study of jurisprudence in the University of Turin, but failing in his first examinations, and having heard the improvisatore Giustiniani, he resolved to rival him. From 1833 to 1856 his course was a continual triumph; he improvised in all the principal cities of Italy, in France, in Switzerland, in Germany; visited Greece, Asia Minor, Mt. Lebanon, and Egypt, and there gathered fresh inspirations. In 1860 he was appointed Professor of History in the Lyceum of Parma; then (1862) in the University of Cagliari; and finally, in 1866, in the University of Bologna. D. at Bologna, Feb., 1883. Among his volumes of verse are *La guerra* (1832); *Poesie estemporanee e pensate* (1839); *Canti* (1840); *Canti nazionali* (2 vols., 1841); *La Bibbia* (1852); *Canti e prose* (1861–65); *Poesie scelte* (1874); *L'acqua* (1878). We have also a volume of travels, *Dora* (2d ed. 1867), and a collection of essays, *Storia e letteratura* (1879). See F. Orlando, *Giuseppe Regaldi* (1880). Many illustrious French and Italian poets have written verses in his honor, among others Lamartine. Revised by A. R. Marsh.

Regelation [Lat. *re-*, again + *gela'tio*, a freezing, deriv. of *gela're*, freeze]: the freezing together, without the application of outward cold, of contiguous surfaces (of ice or of certain other solids at the melting-point) when subjected to pressure and then released.

This phenomenon, which was discovered by Faraday in 1850, is common to all substances which increase in volume upon freezing. It has been studied chiefly in the case of ice, a material in which the process is of particular interest on account of the part which it plays in the motion of glaciers.

Regelation depends upon a principle stated by James Thompson, viz., that any substance the volume of which is greater in the solid state at the melting-point than when liquefied at the same temperature will have its melting temperature lowered by pressure. The effect, even in the case of water, is very small, amounting to a reduction of 0·0075° per atmosphere. By means of it, however, Mouton in 1858 was able to prevent that liquid from freezing even at −18° C. The pressure necessary to the purpose was 13,000 atmospheres. This minute change in the melting-point is sufficient to enable regelation to take place.

The explanation of the phenomenon is as follows:

When two ice blocks in contact are subjected to pressure, a slight lowering of the melting-point occurs and a certain amount of ice is liquefied. To convert ice into the liquid form, even without rise of temperature, requires, however, a large amount of heat (heat of fusion = 79·9 calories per gramme). This is obtained at the expense of the temperature of the liquid and of the surrounding ice masses, which are thus brought below the normal melting-point. As soon as the pressure is removed, freezing takes place and the adjacent surfaces of the two blocks are united.

Under the conditions of an ordinary laboratory experiment the range of temperature changes is very minute, but when we come to consider glacial action, where immeasurably great pressures are brought to bear, we find in regelation an agency which, taken in connection with ordinary plasticity, is quite sufficient to account for the extraordinary motions of the ice. E. L. Nichols.

Regeneration [from Lat. *re-*, again + *genera're*, beget]: a theological term used to express the initial stage of the change experienced by one who enters upon the Christian life. It is derived from the New Testament, where the "new-birth" (1 Pet. i. 3, 23; Titus iii. 5; John iii. 3 f.) is the beginning of that "renewal" which produces the "new creature." In the history of theology the term has been used with varying latitude of meaning. Among the Jews it was employed in an external sense to express the change of relation which took place when a heathen became a Jew; from them it was adopted in this sense by many of the Fathers, and is still so used by many advocates of "baptismal regeneration." It is used in the Latin Church to express the whole real change which corresponds to this external change of relation. The Reformers separated justification by itself as something wrought on, not in, the sinner, and employed regeneration to express the whole process of inner renovation in all its stages. In the development of Protestant theology the term has been still further narrowed: first, to express the opening stage of this subjective work as distinguished from its continuance in sanctification; and then, since the seventeenth century, to express the initial divine act in this opening stage itself, as distinguished from the broader term conversion, which includes, along with the act of God, revivifying man, also the act of man in turning to God.

The nature of regeneration is of course variously conceived by different schools, according to their various views of the nature of the soul and its relation to God, of original or habitual sin, and of divine grace.

1. *Pelagians*, in accordance with their view of freedom and of sin, necessarily regard regeneration as a self-determined change in the general moral course of man's life, an act of the man himself, without any gracious assistance other than that involved in instruction and favorable providential conditions. This was the teaching of Pelagius in the early part of the fifth century; and although not adopted by an historical Church, it has been reproduced in various combinations by Rationalists and Socinians.

2. The *Semi-Pelagian* doctrine taught by John Cassian (d. 440) admits that divine grace (*assistentia*) is necessary to enable a sinner to return unto God and live, yet holds that, from the nature of the human will, man may first spontaneously, of himself, desire and attempt to choose and obey God. They deny the necessity of *prevenient* but admit the necessity of *co-operative* grace and conceive regeneration as the product of this co-operative grace.

3. The *Mediæval and Papal* doctrine, which is practically that of Thomas Aquinas, and is hence often called "Thomism," admits original sin and the necessity of prevenient grace, but places the efficacy of grace in the non-resistance of the subject. (See the *Council of Trent*, sess. 6, can. 4, chs. v. and vi., and sess. 7, cans. 6 and 8.) But this grace is supposed to be exercised only through the instrumentality of baptism, which acts as an *opus operatum*, *ex vi actionis ipsius*, effecting regeneration and the entire removal of sin, and consequently of guilt, from every infant, and from every adult who does not willfully resist (*non ponentibus obicem*). *Council of Trent*, sess. 7, can. 6; Bellarmin, *De Sacramentis*, 2, 1.

4. The *Arminian* view of regeneration admits total depravity and consequent moral impotency, yet holds that man is not really responsible until there is redemptively bestowed upon him for Christ's sake *sufficient* grace to reendow him with ability (gracious, substituted for natural) to do right, which grace becomes *efficient* when the sinner co-operates with it, and thus effects the end intended.

5. The *Synergistic* view was held by a party among the Lutherans, under the leadership of Melanchthon. At the Leipzig Conference (1548) Melanchthon said: "There concur three causes of a good action—the word of God, the Holy Spirit, and the human will assenting, not resisting the word of God." *Loc. Com.*, p. 90.

6. The *Lutheran* standard, the *Formula Concordiæ*, teaches that: (1) Human nature is spiritually dead; and (2) the Holy Ghost is the sole efficient agent who quickens the dead soul to life, without the least co-operation of the will of the subject; but the non-regeneration of the unbeliever is referred not to the absence nor to any deficiency of grace, but to the positive resistance of the man himself. *Formula Concordiæ*, pp. 662, 666, 582, 677.

7. The *Reformed* doctrine teaches as follows: (1) As to the *nature* of regeneration: (*a*) There are in the soul, besides its several faculties, habits or dispositions, innate or acquired, which lay the foundation for the soul's exercising its faculties in a particular way. (*b*) These dispositions (moral) are anterior to moral action, and determine its character as good or evil. (*c*) In creation God made the dispositions of Adam's heart holy. (*d*) In regeneration God recreates the governing dispositions of the regenerated man's heart holy. Regeneration is therefore essentially the communication of a new spiritual life, and is properly called a "new birth." (2) As to its *efficient cause*: It is effected by divine power acting supernaturally and immediately upon the soul, quickening it to spiritual life, and implanting gracious principles of action. (3) As to man's action: Conversion (*conversio actualis*) instantly follows, as the change of action consequent upon the change of character, and consists in repentance, faith, holy obedience, etc. *Thirty-nine Articles*, art. 10; *Can. of Synod of Dort*, ch. iii., art. 3; *Westminster Confession*, ch. x.

What is called *baptismal regeneration* is held by members of the Church of England and others in various senses. (1) Some hold that the Holy Spirit through the instrumentality of baptism implants a germ of spiritual life in the soul, which may long remain latent, and may be subsequently developed (in conversion) or blasted. (2) Others hold that there are two regenerations—one a change of *state* or *relation*, and the other a change of *nature*; the first is baptismal and the second moral, though both are spiritual, since both are wrought by the Holy Ghost.

Revised by B. B. Warfield.

Regensburg: See Ratisbon.

Regent-bird: a name given to one of the bower-birds (*Sericulus melinus*), in honor of the prince regent, afterward George IV., because the black and golden yellow plumage of the male represented his family colors. It is an inhabitant of New South Wales. F. A. L.

Reggio di Calabria, red'jō-dee-kăă-laab'rĕĕ-ăă (anc. *Rhegium*, *Regium*): city of Italy; in the province of Reggio; on the Strait of Messina (see map of Italy, ref. 9–G). The ancient name, signifying rending, probably refers to some grand natural convulsion, and possibly to that which separated Sicily from the mainland in prehistoric times. Reggio was first colonized by Chalcidians, whom fugitive Messenians joined about 723 B. C. Toward the end of the

fifth century B. C. it lost its republican organization; after an obstinate resistance it was captured by Dionysius the Elder, tyrant of Syracuse (387 B. C.). Under the Romans it became again wealthy and magnificent. The Castor and Pollux with St. Paul on board entered the harbor (63), and, according to tradition, St. Paul landed and founded a church. The ecclesiastical history of Reggio is interesting and somewhat important. The city shared all the vicissitudes of Southern Italy during the Middle Ages. It was burned by Alaric (410), captured by Totila, King of the Goths (549), by the Saracens (918), by the Pisans (1005), by Robert Guiscard (1060), and by the Ottomans (1552 and 1597). Nevertheless, it was flourishing and opulent when in 1783 it was utterly overthrown by earthquake. Though suffering from earthquakes often since, it has been partially rebuilt and presents a modern appearance with handsome and spacious streets. The city now rises in amphitheatrical form upon a gently sloping hill; its suburbs are attractive and it enjoys splendid sunset views over the strait, with Etna and Sicily in the foreground. It has a few manufactories and an inconsiderable maritime trade. Pop., with the suburban villages (1893), 43,000. E. A. GROSVENOR.

Reggio nell' Emilia, red'jō-nel-lā-mee'leĕ-ăă (anc. *Rhegium Lepidi*): city of Italy, in the province of the same name; on the railway between Parma and Modena (see map of Italy, ref. 3–C). It is a walled town, with broad streets, many of which are lined with arcades. Some of the churches are imposing and contain precious objects of art. Over the altar of St. Prospero once stood the *Nativity* of Correggio, known as *La Notte*, now in the Dresden Gallery. Reggio contains a fine cathedral, partly of the twelfth century, a spacious theater, a library with 56,000 volumes, an academy of fine arts, and a museum with the natural historical collection of Spallanzani, born here in 1729. The small house in which Ariosto was born (1474) is still seen. The Asylum for the Insane, outside the town, is one of the best-managed philanthropic establishments in Italy. The origin of the town is uncertain, but it is often mentioned by Latin writers. It was captured by the Goths in 409, was oppressed by the Exarchs of Ravenna, and was rebuilt by Charlemagne in the ninth century. It suffered severely during the Guelph and Ghibelline wars. An independent commonwealth in the twelfth century, during the thirteenth it was prominent in mediæval learning. For several hundred years it was generally ruled by the Este and Austro-Este family, and joined the modern kingdom of Italy in 1859. Now it is the commercial center of a fertile province, carries on a large trade in country products, and has some industries of its own, as manufactures of carriages, brooms, and sailcloth. Pop. 18,634. E. A. GROSVENOR.

Regiment [from O. Fr. *regiment*, government, later a regiment of soldiers < Lat. *regimen'tum*, government, rule, deriv. of *re'gere*, rule]: a military organization made up of one or more battalions of infantry, squadrons of cavalry, or batteries of artillery. The organization being permanent, its history, records, and traditions become matters of regimental pride and a potent factor in preserving its *esprit de corps*. Regiments are generally designated by numbers; but they frequently have special names, derived from the locality of their enlistment or from some marked service rendered by them.

In the U. S. the infantry regiment is made up of ten companies and varies in strength from about 500 men on a peace footing to about 1,000 men on a war footing. In the more modern organization of the European armies it consists of three, or sometimes four, battalions, of about 1,000 men each on a war footing, reduced to about 600 on a peace footing. The cavalry regiment of the U. S. contains 12 troops, or 6 squadrons, and the artillery regiment 12 batteries. In European armies these numbers vary somewhat widely.

The regiment is commanded by a colonel, or in his absence by its lieutenant-colonel. Each battalion is commanded by a major, and each company by a captain. The regimental staff usually consists of an adjutant, quartermaster, commissary, and surgeon. Some regiments have also a chaplain.

The regiment is the *administrative unit* of the army, the battalion the *tactical unit*, and the company the *unit of combat*. See ARMY. JAMES MERCUR.

Regi'na [Lat., Queen]: town of Assiniboia, Canada, and capital of the Northwest Territories; station on the Canadian Pacific Railway, 357 miles W. of Winnipeg (see map of Canada, ref. 9–G). It contains fine public buildings, and is the headquarters of the Northwest mounted police. It is well provided with churches and schools, and has the nucleus of a parliamentary library. Pop. (1895) 1,583.

Regiomonta'nus, JOHANN MÜLLER: astronomer and mathematician; b. at Königsberg in Franconia, June 6, 1436; studied mathematics under Purbach at Vienna, and astronomy at Padua; lived for some time at the court of Matthias Corvinus of Hungary, afterward at Nuremberg, and was invited to Rome in 1474 by Pope Sixtus IV. in order to reform the calendar. D. in Rome, July 6, 1476—some say by the plague, others by assassination at the hands of the sons of George of Trebizond, in whose writings he had pointed out some glaring errors. His *Ephemerides ab Anno 1475–1506* (continued by Bernhard Walther) made him very famous among astronomers. Among his numerous other works are *De Reformatione Calendarii* (1489) and *De Triangulis Omnimodis* (1533). See Alexander Ziegler, *Regiomontanus* (Langensalza, 1874).

Registration of Titles: See the Appendix.

Regnard, rān-yaar', JEAN FRANÇOIS: dramatist; b. in Paris, France, Feb., 1655. Of a wealthy family, he was well educated, and traveled extensively in Italy, Algiers, whither he was taken as captive by pirates in 1678, Scandinavia, Lapland, Germany, Poland, and Hungary. He settled in Paris in 1684, and began first to write for the Théâtre Italien, but after 1696 wrote entirely for the Théâtre Français. He followed Molière, but at a long distance, naturalness and delineation of character being sacrificed to the comic effect, for which his talent was great. *Le Joueur* (1696), *Les Ménechmes* (1705), imitated from Plautus, and *Le Légataire universel* (1708) are his best-known comedies. D. Sept. 4, 1709. He also wrote an account of his *Voyages* and a partly autobiographical story, *La Provençale*. Editions of his works have been given by Michiels (2 vols., Paris, 1854–55) and Moland (Paris, 1875). A. G. CANFIELD.

Regnault, re-nō', ALEXANDRE GEORGES HENRI: historical, genre, and portrait painter; b. in Paris, France, Oct. 30, 1843. Pupil of Montfort, Lamothe, and Cabanel; grand prix de Rome 1866; painted in Italy and Spain 1866–69, and in Africa in 1870. He returned to France and enlisted in the Sixty-ninth Battalion of the National Guard at the outbreak of the war with Germany, and was killed in a skirmish at Buzenval, Jan. 19, 1871. His works are very fine in color and possess qualities of the highest order. Though only twenty-eight years of age at the time of his death, he had already painted a number of important compositions, one of the most famous of which is his equestrian *Portrait of General Prim*, now in the Louvre. In the Louvre also is his *Execution without Judgment—Granada*. In the Museum of Fine Arts, Boston, is a picture entitled *Automedon with the Horses of Achilles*, which, though not one of his most successful works, gives a fair idea of his power as a draughtsman and his ability to handle a large canvas with unity of effect. WILLIAM A. COFFIN.

Regnault, HENRI VICTOR: physicist and chemist; b. at Aix-la-Chapelle, Germany, July 21, 1810; studied at the École Polytechnique of Paris; was appointed Professor of Chemistry at that school in 1840, in Physics at the Collège de France in 1841; chief engineer of mines in 1847, and director of the porcelain-works of Sèvres in 1854. The first work of his which attracted attention was his *Action du Chlore sur l'Éther chlorhydrique* (1840), but his physical researches, especially concerning heat, gained for him his great reputation. In 1848 he received the Rumford medal from the Royal Society of London for his *Experiments to determine the Laws and the Numerical Data which enter into the Calculation of Steam-engines*. His investigations in verification of the law of Mariotte and Boyle were communicated in vols. xxi. and xxvi. of the *Mémoires de l'Académie des Sciences*. His *Premiers Éléments de Chimie* (1850), an abridgment of his *Cours Élémentaire de Chimie* (1847–49), has been translated into several languages. His work on the practical treatment of steam-engines forms vol. xxi. of the *Mémoires de l'Académie des Sciences*. D. Jan. 19, 1878.

Regnault, JEAN BAPTISTE, Baron: painter; b. in Paris, France, Oct. 19, 1754; led for some time a roving life as a sailor, and visited Africa and America; entered in 1771 the studio of the painter Bardin, whom he accompanied to Rome; gained in 1774 the great medal for his *Alexander and Diogenes*; became a member of the Academy in 1782, subsequently professor in the School of Art, and stood by the side of David at the head of the French school of paint-

ing till his death Oct. 29, 1829. Among his most celebrated pictures are *Perseus and Andromeda* (1782); the *Education of Achilles* (1783); and *Cupid and Psyche* (1829).

Regnier, rān'yā', MATHURIN: satirist; b. at Chartres, France, Dec. 21, 1573. He was educated for the Church; accompanied Cardinal de Joyeuse to Rome in 1593, and returned in 1604 with the Duc de Béthune, French ambassador; was appointed canon of the Cathedral of Chartres in 1609. D. at Rouen, Oct. 22, 1613. In spite of his ecclesiastical position he led a dissipated life. His *Satires*, sixteen in number, are coarse, but full of shrewd observation of men, humorous, witty, and striking, and free from all malignity. He was refractory to the refining reforms of Malherbe, and followed rather the tradition of the direct and familiar speech of Villon and Marot. He wrote also some epistles and elegies. Good editions of his works are by Viollet-le-Duc (Paris, 1853), Barthélemy (Paris, 1862), L. Lacour (Paris, 1867), and Courbet (Paris, 1875).

Revised by A. G. CANFIELD.

Regular Clergy [*regular* is from *regula*, a monastic rule]: in the Roman Catholic Church, ordained clergy who live under a monastic rule, as distinguished from the secular clergy or ordinary parish priests, and other clergy free from monastic rules. The regular clergy may, however, be appointed to act as parish priests, and frequently assist the seculars.

Reg'ulus, MARCUS ATILIUS: a soldier belonging to an old plebeian family in Rome; was consul the first time in 267 B. C., and again in 256. In this year, the ninth of the first Punic war, Regulus and his colleague Manlius transferred the war from Sicily to Africa, and even after the return of Manlius with his part of the army Regulus achieved great successes against the Carthaginians. Fortune turned, however, when Xanthippus, a Lacedæmonian general, was put at the head of the Carthaginian army. Regulus was defeated, his army was routed and nearly destroyed, and he himself was taken prisoner. Concerning his death we have no well-authenticated information. The celebrated story, so eloquently told by Horace (*Odes*, iii., 5), of his mission to Rome with Carthaginian envoys to arrange an advantageous peace, of his advice to the senate to reject their propositions, and of his voluntary return to captivity and to a death of ingenious cruelty, is generally believed to be an invention of national and family pride.

Revised by G. L. HENDRICKSON.

Rehan, ADA: actress; b. in Limerick, Ireland, Apr. 22, 1859. She was taken to the U. S. when very young and was educated in the Brooklyn public schools. At the age of fifteen she made a public appearance on the stage, but subsequently resumed her studies for a year. She began a regular professional career in Mrs. Drew's theater, Philadelphia, where she played for two seasons, when she was engaged by Augustin Daly and became leading lady at his theater in New York, and there achieved much success in comedy parts, especially in those of Shakspeare and other old dramatists. She attained an equal reputation in comic *rôles* of a less exacting character. In 1888 Mr. Daly took his company to London, where Miss Rehan's performances were favorably criticised. Subsequent visits in 1889, 1890, 1891, and 1892 confirmed the verdict of approval by the English press. Among the characters which she has personated most successfully are Katherine in *The Taming of the Shrew*, Maid Marian in Lord Tennyson's *Foresters*, and the principal woman *rôles* in *The Railroad of Love*, *A Night Off*, *Needles and Pins*, and *The Squire*.

B. B. VALLENTINE.

Rehobo'am [from Heb. *Rᵉchabᵉ'ām*, liter., he who enlarges the people]: son and successor of Solomon. His mother was Naamah, an Ammonite princess (1 Kgs. xiv. 21, 31). His accession, about 975 B. C. (Usher) or 990 B. C. (Hales), was the signal for the revolt of the ten tribes and the dismemberment of the kingdom (1 Kgs. xii.). He died at the age of fifty-eight, after a reign of seventeen years (1 Kgs. xiv. 21).

Reho'both [from Heb. *Rᵉchōbhōth*, liter., streets, wide spaces]: the name of three biblical sites: (1) In Gen. x. 11, one of the four Assyrian cities founded by Asshur, or, as Schrader understands the passage, one of the four parts of the "great city" Nineveh. (2) In Gen. xxvi. 22, a well dug by Isaac, recently identified with an ancient well, now filled up, 12 feet in diameter, in the Wadi er-Ruhaibeh, about 20 miles S. of Beersheba. Robinson and Smith found the wadi in 1838, but did not see the well. (3) In Gen. xxxvi. 37, the city of an early Edomite king named Saul, described as being "by the river"—i. e. the Euphrates. It has been identified with Rachaba, on the east side of the Euphrates, and 4 miles from it.

Reichenbach, rīch'en-bāȧkh, KARL, Baron: chemist; b. at Stuttgart, Germany, Feb. 12, 1788; educated at the University of Tübingen; after a short political imprisonment at the instigation of the French authorities, devoted himself to the study of natural science, and achieved considerable practical results by his iron-works and beetroot-sugar factory at Blansko, Moravia, and also some scientific triumphs by his discovery of different useful compounds, such as creosote and paraffin, but became most widely known by his half-mystical works on a new natural force which he called *Od*. Among his works are *Physikalisch-physiologische Untersuchungen über die Dynamide des Magnetismus* (3 vols., 1849) and *Odisch-magnetische Briefe* (1852), both translated into English. D. at Leipzig, Jan. 19, 1869. See ODIC FORCE.

Reichenberg, -bārch: town of Bohemia; on the Neisse, 86 miles by rail N. E. of Prague (see map of Austria-Hungary, ref. 2–E). It is one of the most important manufacturing places of the Austrian empire, linen, woolen, and cotton stuffs of various kinds being made extensively, besides leather, shoes, hats, firearms, gold and silver ware, and musical instruments. Pop. (1890) 30,890.

Reichert, EDWARD TYSON, M. D.: physiologist; b. in Philadelphia, Pa., Feb. 5, 1855; studied medicine at the Universities of Pennsylvania, Leipzig, and Geneva, graduating M. D. from the former in 1879; in 1886 was elected Professor of Physiology in the University of Pennsylvania. He is the author of a number of papers on the physiological action of drugs, on comparative physiology, and on experimental and human physiology. His principal work is *A Text-book of Physiology* (Philadelphia, 1894).

S. T. A.

Reichstadt, DUKE OF: See NAPOLEON II.

Reid, ALEXANDER P.: See the Appendix.

Reid, JOHN MORRISON, D. D., LL. D.: b. May 30, 1820, in New York; graduated at the University of the City of New York in 1839, and at Union Theological Seminary; was admitted to the New York conference of the Methodist Episcopal Church in 1844, and preached in Western Connecticut, on Long Island, and in New York; president of Genesee College, New York, 1858–64; editor of *The Western Christian Advocate* 1864–68; editor of *The Northwestern Christian Advocate* 1868–72; corresponding secretary of the Methodist Episcopal Missionary Society 1872–88, and its honorary secretary from that time until his death May 16, 1896. He was author of *Missions and Missionary Society of the Methodist Episcopal Church* (2 vols., 1879); *Doomed Religions* (1884), etc.

Reid, MAYNE: writer of boys' stories; b. in the north of Ireland in 1818; went to the U. S. 1838; ascended the Red and Missouri rivers in quest of adventure; traveled through most of the States; settled in Philadelphia, where he devoted himself to literature; was a volunteer, U. S. service, in the Mexican war, and distinguished at Chapultepec, where he was wounded; about 1849 settled in London; became a voluminous and popular writer, chiefly of romances of American adventure. Among his books are *The Rifle Rangers* (1849); *The Scalp-hunters* (1850); *The White Chief* (1855); *The Quadroon* (1856); *Osceola* (1858); *The Maroon* (1862); *The Castaways: a Story of Adventure in the Wilds of Borneo*; *The Yellow Chief: a Romance of the Rocky Mountains* (1870). A collective edition of his works appeared in New York (15 vols., 1868); other editions in London (1875, 1878). D. near London, England, Oct. 22, 1883.

Reid, SAMUEL CHESTER: naval officer; b. at Norwich, Conn., Aug. 25, 1783; entered the U. S. navy as midshipman at an early age; commanded the privateer brig Gen. Armstrong in a two days' engagement with the boats of three British men-of-war in the port of Fayal, Sept. 26 and 27, 1814, resulting to the British in a loss of 250 killed and wounded, while the privateer was scuttled by Reid with a loss of only 2 killed and 9 wounded. The violation of neutral waters by the British led to a prolonged diplomatic controversy, finally decided by Louis Napoleon, as arbitrator, adversely to the American complaint. Soon after his return to the U. S. Capt. Reid was appointed sailing-master in the navy; became warden of the port of New York, where he regulated the pilot-boat service and erected signal telegraphs at the Battery and the Narrows. He was also the designer of the present U. S. flag. D. in New York, Jan. 28, 1861.

Reid, Thomas: philosopher; b. at Strachan, Kincardineshire, Scotland, Apr. 26, 1710. His father was a minister. He received his first instruction at home and in the parish school of Kincardine. In 1722 he was sent to Marischal College in Aberdeen, where he graduated in 1726, and occupied a position as college librarian and in studying mathematics and philosophy until 1737, when he was appointed minister at New Machar in Aberdeenshire. His parishioners are said to have opposed his appointment very strenuously, and he had so little confidence in his own powers that he never himself composed the sermons which he preached, but used such as were published by English divines, especially Tillotson and Evans. Nevertheless, his life as a minister at New Machar turned out to the satisfaction of all. In 1740 he married, and in 1748 he published his first philosophical essay, *On Quantity*, in the *Transactions* of the Royal Society of London. It was a criticism of the manner in which the mathematical terminology was used at that time in metaphysics and morals, especially by Hutcheson. In 1752 he accepted the position of Professor of Philosophy at King's College, Aberdeen, where he had to teach mathematics, natural philosophy, and moral philosophy; but in 1763 he moved to Glasgow as the successor of Adam Smith in the chair of Moral Philosophy. Here he published his *Inquiry into the Human Mind on the Principle of Common Sense*, in 1764, and read at the meetings of a philosophical society several papers, such as *Examination of Dr. Priestley's Opinion concerning Matter and Mind* and *Physiological Reflections on Muscular Motion*. In 1781, however, he resigned his office in order to devote himself exclusively to philosophical studies, and published *Essays on the Intellectual Powers of Man*, in 1785, and *Essays on the Active Powers of Man*, in 1788. D. Oct. 7, 1796. Originally, he was a disciple of Berkeley, but David Hume's *Treatise upon Human Nature*, published in 1740, showed him at once to what consequences idealism might lead, and roused him to independent speculation. In opposition to Hume's skepticism he tried in his *Inquiry into the Human Mind on the Principle of Common Sense* to establish a series of fundamental truths independent of experience and indisputable as primitive facts of the consciousness. On the Scottish school of philosophy, and more especially on the study of psychology, he exercised a powerful influence. This influence has extended to France (Royer-Collard and Victor Cousin); and to America and the British colonies, nearly all professors of philosophy in colleges for thirty years (1830 to 1860) being followers of Reid in all important respects. See English Literature (*Philosophy*). Revised by W. T. Harris.

Reid, Whitelaw: journalist; b. near Xenia, O., Oct. 27, 1837; graduated at Miami University in 1856; after acting for a year or more as superintendent of the graded schools at South Charleston, O., bought and edited the Xenia *News*; joined the Republican party at its birth and made political speeches in support of Fremont in 1856; advocated in the *News* the nomination of Abraham Lincoln in 1860; became city editor of the Cincinnati *Gazette*; during the civil war served on the staff of Gen. Morris in West Virginia and later on that of Gen. Rosecrans, and was war correspondent of the *Gazette*, writing over the signature of "Agate"; in 1863 was appointed librarian to the House of Representatives; in 1865 accompanied Chief Justice Salmon P. Chase on a tour of the South, undertaken by the latter at the request of President Johnson for the secret purpose of studying the condition and interests of the white and black races, and published *After the War, a Southern Tour* (Cincinnati, 1866); during the next two years engaged in cotton-planting in Louisiana and Alabama, and published *Ohio in the War* (2 vols., Cincinnati, 1868); in 1868 became one of the editors of the Cincinnati *Gazette*; at the invitation of Horace Greeley joined the editorial staff of *The New York Tribune* in 1868, and in 1869 became managing editor. Upon the nomination of Greeley for the presidency in 1872 Mr. Reid became editor-in-chief, and when the former died in the fall of that year he became chief proprietor as well as editor of the *Tribune*. In 1878 President Hayes offered him the U. S. mission to Berlin, which he declined. The offer was renewed under the administration of President Garfield, and again declined. In 1878 he was elected by the New York Legislature regent of the State University, to succeed Gov. Dix. In Mar., 1889, Mr. Reid accepted from President Harrison the appointment of minister to France, and resigned the editorship of the *Tribune*. After securing the repeal of the French decree prohibiting the importation of U. S. meats, and negotiating extradition and reciprocity treaties, he resigned office and returned to the U. S. in Apr., 1892. In June, 1892, he was nominated for the vice-presidency of the U. S. by the Republican national convention, but failed of election. His time since then has been divided between foreign travel and the direction of the *Tribune*. He was a member of the peace commission in 1898. Among his addresses published in book form are *Schools of Journalism* (New York, 1871); *The Scholar in Politics* (1873); *Some Newspaper Tendencies* (1879); *Town-hall Suggestions* (1881).

Reid, William, D. D.: minister and editor; b. in the parish of Kildrummy, Aberdeenshire, Scotland, Dec. 10, 1816; was educated at the University of Aberdeen; went to Canada as missionary of the Established Church of Scotland; was pastor at Graton and Colborne, Upper Canada, 1840–43; was one of the founders of the Presbyterian Church of Canada 1843; was pastor at Picton 1849–53; editor of *The Ecclesiastical and Missionary Record* 1853–75; since 1853 has been clerk of synod and treasurer of the schemes of the Church. Dr. Reid was moderator of the Synod in 1850 and 1873, and of the General Assembly in 1879.

C. K. Hoyt.

Reid, William James, D. D.: clergyman; b. at South Argyle, N. Y., Aug. 17, 1834; was educated at Union College and Allegheny Seminary; corresponding secretary of the United Presbyterian board of home missions 1868–72; principal clerk of the United Presbyterian General Assembly since 1875; and since 1889 pastor of the First United Presbyterian church, Pittsburg, Pa., and editor of *The United Presbyterian*. Dr. Reid has published numerous sermons and pamphlets: *Lectures on the Revelation* (Pittsburg, 1878); and *United Presbyterianism* (1881; 2d ed. 1883).

C. K. Hoyt.

Reidsville: town (founded in 1865); Rockingham co., N. C.; on the Southern Railway; 24 miles N. of Greensboro, and 24 miles S. W. of Danville, Va. (for location, see map of North Carolina, ref. 2–F). It is in the heart of the "bright" tobacco belt, and is a large leaf-tobacco market, selling about 8,000,000 lb. per year. There are 4 large warehouses for the sale of the leaf, tobacco, cigar, and cotton factories, flour and lumber mills, 8 churches, high school for boys, graded public schools, a female seminary, a State bank with capital of $50,000, an incorporated bank with capital of $50,000, and 3 weekly newspapers. Pop. (1880) 1,316; (1890) 2,969; (1900) 3,262.

Editor of "Review."

Reigate: town; in the county of Surrey, England; 21 miles S. of London (see map of England, ref. 13–J). The parish church of St. Mary (mixed Transition Norman and Perpendicular) dates from the reign of Henry VII. It contains a library with MSS. and rare books. Reigate carries on a considerable trade in fuller's earth and sand used in the manufacture of glass. Pop. (1891) 22,646.

Reign of Terror: the name given to that period of the French Revolution which lasted from Jan. 21, 1793, the day of the execution of Louis XVI., till July 27 (9 Thermidor), 1794, when Robespierre was guillotined and the committee of safety broken up. See France, History of.

Reims: a city of France. See Rheims.

Rein, rīn, Johannes Justus: scholar and compiler; b. at Rauenheim, Hesse-Darmstadt, 1835; studied at the University of Giessen, and taught for several years. In 1873 he undertook a mission to Japan on behalf of the Prussian Government for the purpose of studying Japanese industries and commerce, and spent two years in that country. On his return he was appointed Professor of Geography at Marburg, and in 1883 was transferred to a similar post at Bonn, where he succeeded Baron von Richthofen. In 1893 Dr. Rein served as a judge of art industry at the Columbian Exposition in Chicago. The results of his Japanese researches were embodied in his valuable *Japan nach Reisen und Studien dargestellt* (2 vols., Leipzig, 1881, 1886), of which an English translation has appeared under the titles *Japan, Travels and Researches* (London, 1884) and *The Industries of Japan* (London, 1889). A later work treats of Columbus and Spanish subjects—*Geographische und naturwissenschaftliche Abhandlungen* (Leipzig, 1892). J. M. Dixon.

Rein, Wilhelm, Ph. D.: professor of pedagogy; b. at Eisenach, Germany, Aug. 10, 1847; studied at Gymnasium, Eisenach, 1857–66, Jena University 1866–68, Heidelberg 1868–69, Leipzig 1870–71; teacher in Realschule, Barmen,

1871–72; professor in Normal School, Weimar, 1872–76; director of Normal School, Eisenach, 1876–86; professor in Jena University and director of training-school since the autumn of 1886. Rein (a pupil both of Stoy and of Ziller) unites in theory both schools of Herbartianism in Germany, but follows in practice Ziller rather than Stoy. His theories find practical application in the training-school of some forty elementary pupils in three classes, which is supported by the state. His direct influence is confined mainly to the lower schools of Thuringia, but among his hearers are many foreigners, chiefly from the Balkan states. His principal works are *Theorie und Praxis des Volksschul-Unterrichts*, with Pickel and Scheller (8vo, 1878); *Das Leben Dr. Luthers* (1883 Eng. transl.)]; *Pädagogik im Grundriss* (1893, Eng. transl.); *Am Ende der Schulreform?* (1893); *Encyklopädisches Handbuch der Pädagogik* (1894). He has edited several pedagogical works, and is a frequent contributor to educational journals, especially to *Pädagogische Studien*, which he founded, and to *Zeitschrift für Philosophie und Pädagogik*, of which he is coeditor. The annual *Aus dem Pädagogischen Universitäts-Seminar* represents the training-school since 1887.

Reindeer, [from Icel. *hreinn*, reindeer, from Lapp *reino*, pasturage, herding, especially of the reindeer. By popular etymology *reindeer* is now felt as through from *rein* + *deer*; cf. Germ. *rennthier*, apparently running animal]: a large species of deer (*Tarandus rangifer*) occurring in the northern portions of both the Old and New World, and known in North America as the caribou. The animal stands 3½ to 4 feet high at the shoulders, and is more heavily built than the other species of deer. The muzzle is wide, nostrils large, and nose hairy instead of bare and moist. The antlers are large, spreading, somewhat irregular in shape, and the basal snag on one side is widely palmated; small antlers are present in the female. The side hoofs are well developed, and the

The reindeer.

feet are wide-spreading, and well adapted for progress over hard snow. The general color in winter is light gray, lighter on the neck, white beneath: in summer the color is somewhat redder. There is considerable difference in the size of the reindeer, as well as in the size and shape of the antlers, according to locality. Reindeer feed on the shoots and twigs of trees, especially of the birch and willow, and on various lichens and moss. The animal has long been domesticated in Scandinavia and Siberia, where it is kept in herds and used as a beast of burden, besides furnishing food and clothing; but it has never been tamed by the natives of North America. In view of the rapid decrease in the number of wild animals in Alaska the U. S. Government in 1891 began the introduction into that Territory of the Siberian reindeer. See Report U. S. commissioner of education 1890–91, p. 945.

F. A. Lucas.

Reindeer-moss: the *Cladonia rangiferina*, a lichen most abundant in Arctic regions, where it forms the principal winter food of the reindeer. It is of a silvery-white color, even in summer. It is also used as an article of human food after having been boiled in reindeer's milk. It contains the nutritious lichenine, a form of starch. In the U. S. it abounds in damp woods under evergreens in all the Atlantic States down to Florida.

Reinecke, rī′ne-ke, Karl: composer; b. at Altona, Germany, June 23, 1824; studied under his father; in 1834 made a successful concert tour as a pianist. After much wandering he was in 1860 appointed kapellmeister of the Gewandhaus, Leipzig, and a professor in the conservatory there. He has had many famous pupils. His compositions include several operas, some cantatas, two masses, much orchestral music, solo and concerted, chamber music, concertos for piano, violin, and other instruments, much piano music, and many songs and choruses.

D. E. Hervey.

Reinick, Robert: poet; b. at Dantzic, Prussia, Feb. 22, 1805; was educated at the gymnasium of his native city; studied painting under Begas in Berlin and under Schadow at Düsseldorf; went to Italy in 1838; and finally settled in Dresden, where he died Feb. 7, 1852. The influence which the plastic artist in Reinick exerted upon the poet is evident in all of his lyric productions, which rank among the best in modern German literature. Few poets equal him in child-like humor, simplicity of tone, and artistic perfection of form. He published *Liederbuch für deutsche Künstler* (1833); *Liederbuch eines Malers* (1837–44); *Lieder und Fabeln für die Jugend* (1844); *Hebels allemannische Gedichte ins Hochdeutsche übertragen* (1851); *Gesammelte Lieder* (1852); *Märchen-, Lieder- und Geschichtenbuch* (1873).

Julius Goebel.

Reinkens, Joseph Hubert: bishop; b. at Burtscheid, near Aix-la-Chapelle, Germany, Mar. 1, 1821; studied theology at Bonn; took holy orders; was appointed extraordinary professor at Breslau in 1853, and ordinary professor in 1857; but was suspended Nov. 20, 1870, by the Bishop of Breslau because he had made a protest against the infallibility dogma. He became one of the leaders of the Old Catholic movement; was consecrated bishop in 1873 by the Jansenist Bishop of Deventer, and acknowledged by the German Government as bishop of the Old Catholic Church. His official residence was at Bonn, and he died there Jan. 4, 1896. He wrote *Hilarius von Poitiers* (Schaffhausen, 1864); *Martin von Tours* (1866); *Papst und Papstthum*; *Ueber päpstliche Unfehlbarkeit* (Münster, 1870); *Die päpstlichen Dekrete vom 18. Juli, 1870* (1871); *Revolution und Kirche* (Bonn, 1876); *Ueber Einheit der Katholischen Kirche* (Würzburg, 1877); *Melchior von Diepenbrock* (Leipzig, 1881); *Lessing über Toleranz* (1883).

Revised by S. M. Jackson.

Reinmar der Alte: minnesinger; b. about 1160 in Alsace, probably at the town of Hagenau; d. about 1207. He lived principally at the court of Vienna, and probably participated with Duke Leopold VI. in the crusade of 1190. He is the greatest representative of the artistic minnesong as it developed in Germany under the influence of French and Provençal models, his songs evincing great perfection of form, but also the narrow and almost sickly one-sidedness of this mediæval love-poetry. That he was greatly admired by his contemporaries may be judged not only from the praise bestowed on him by Gottfried von Strassburg (Tristan, 4,777), but also from the fact that the greatest lyrist of the Middle Ages, Walther von der Vogelweide, closely imitated him during the first period of his career, and, at the occasion of Reinmar's death, paid his art a glowing tribute in two beautiful poems (Lachmann, 84, 24). See the collection *Des Minnesangs Frühling*, in which Reinmar's songs are published as far as they are extant; Erich Schmidt, *Reinmar von Hagenau und Heinrich von Rugge* (1874); Konrad Burdach, *Reinmar der Alte und Walther v. d. Vogelweide*. See also Minnesingers.

Julius Goebel.

Reis Effendi [Turk., presiding effendi]: originally, chief secretary of the Divān of the Sublime Porte. He was directly under the grand vizier, and was the medium of communication between the Government and the representatives of foreign powers. He was the guardian of the privy seal, and dealt also with the rajahs of subjected nations. The office was abolished by Sultan Mahmūd II. (1808–39), and its place taken by a Minister of Foreign Affairs (Chārijiyyah Nasīrī). According to the constitution of Dec. 11–23, 1876, this minister is to be appointed by an irade of the sultan.

Richard Gottheil.

Reisig, rī′zich, Christian Karl: classical scholar; b. in Weissensee, Thuringia, Nov. 17, 1792. He was the most

highly gifted of the pupils of Gottfried Hermann, and an inspiring teacher of great learning and critical talent. He died, after occupying the chair of Classical Languages at Halle for a few years, at Veniee, Jan. 17, 1829. His principal works, which have not yet lost their value, are *Vorlesungen über Lateinische Sprachwissenschaft* (3d revised and enlarged ed. in 3 vols., 1888); *Coniectanea in Aristophanem*; critieal and exegetical edition of Sophocles's *Œdipus Coloneus* (2 vols., 1823). Cf. Fr. Ritschl, *Opusc.* (v., pp. 95 ff.); O. Ribbeck, *F. W. Ritschl* (i., pp. 34 ff.).

ALFRED GUDEMAN.

Reiske, rīs'ke, JOHANN JACOB: Greek scholar; b. in Zörbig, Saxony, Dec. 25, 1716; matriculated in 1733 at the University of Leipzig, where he devoted himself especially to the study of Arabic. In 1738 he went to Leyden to study the Arabic MSS. in the university library, and eked out a spare living by correcting proof-sheets and by giving private lessons. Amid such hardships he still found time for the study of medicine, graduating in 1746. Soon afterward he returned to Leipzig, and here also he lived in abject poverty for twelve years, when he secured the rectorate of the famous Nicolai Gymnasium. This position he retained till his death Aug. 14, 1774. Reiske is one of the greatest Greek seholars that Germany has produced, and his genius, though depreciated in his lifetime, is now becoming ever more generally recognized. His productivity is astounding; his most celebrated works are editions, commentaries, and translations of Plutarch (12 vols., 1782); Dionysius of Halicarnassus (6 vols., 1777); Oratores Græci (12 vols., 1770–75); Dion Chrysostomos (2 vols.); Libanius (4 vols.); Theocritus (2 vols.); Maximus Tyrius (2 vols.); and many other minor editions. To these must be added a collection of *Animadversiones in Græcos auctores* (5 vols., 1757–66). Many of his works were published posthumously by his wife, ERNESTINE CHRISTINE (1735–98; married 1764). See his *Autobiography*, pp. 818 (1783); M. Haupt, *Opuscula* (iii., pp. 137 ff.); Bursian, *Gesch. der classischen Philologie in Deutschland* (pp. 407–416). ALFRED GUDEMAN.

Reisner-work: See BUHL-WORK.

Reiss, WILHELM: traveler, ethnologist, and naturalist; b. at Mannheim, Germany, in 1838. He graduated at Heidelberg 1864; visited Greece 1866; and from 1868 to 1876 traveled in South America, generally in company with A. Stübel. Their most extended explorations were in Colombia, Ecuador, and Peru, where they ascended and measured many peaks of the Andes, and made valuable archæological and geological studies. Their most important joint publication was *Das Totenfeld von Ancon in Peru* (3 vols. folio, 1880–87), a magnifieently illustrated work on the Indian burial-grounds of Ancon, near Lima. They also published, jointly or separately, many papers in Spanish at Quito; and Reiss is the author of several works in German on South American geology and topography. H. H. SMITH.

Relapsing Fever, also known as **Famine Fever**, and, teehnically, as **Febris Recurrens** [*relapsing* is from Lat. *rela'bi*, *relap'sus*, fall baek, relapse; *re-*, baek, again + *la'bi*, slide, fall]: a specific infeetious and contagious disease due to the action of a micro-organism, the *Spirochæta obermeieri*, which flourishes in the blood. It occurs only at intervals of some years, and generally during seasons of privation and insalubrity, attaeking chiefly the lower classes, ill fed and housed. The idea was formerly held that relapsing fever is a dietetic disease pure and simple. This is not the case, though famine makes large masses of people susceptible to the speeific germ. Its formativc or incubating stage is from four to ten days. Its onset is sudden; the patient, having been perfectly well at the time, is able to fix the exaet time of the attack. It begins with an abrupt and severe rigor, or chill with nervous tremor, and immediate sense of extreme weakness. There is sharp frontal headache, pain in the back and limbs; then follow flushed face, thirst, dry tongue, high pulse, and a steady ascent of body heat. The facial expression and temperature are characteristic. The mind is unaffected, and the face, with the sunken but clear and full eyes, wears a pitiable, helpless, appealing look. The complexion has a bronzed hue, and may be slightly jaundiced. The temperature rapidly ascends and during four or five days remains 105°, 106°, 107°, 108° F.—an unusual fever heat unaccompanied by brain symptoms or danger of death. Physical examination may detect enlargement of the liver and spleen; the urine may contain not only albumin and urea in excess, but blood and casts indicative of acute congestion of the kidneys. The fever and extreme depression last from five to seven days, when, with some critical evacuation, as profuse perspiration, diarrhœa, or urination, a sudden abatement and rapid convalescence set in. Appetite and strength are slowly returning, and the invalid is about, when, on the fourteenth day from the first attack, he is seized by a second or relapse resembling the first. Very rarely, a third, fourth, and even a fifth relapse, occurs. The mortality is not as high as in typhus fever, nor as great as the severe symptoms would indicate. The treatment during the active period is essentially antiphlogistic and expectant—cooling drinks, gentle saline laxatives, sponging, light diet; during eonvalescence, free use of coneentrated liquid diet, tonics, especially liberal use of quinine and brandy. Revised by W. PEPPER.

Relativity: the principle in psychology according to whieh all mental states are influeneed by preceding and accompanying eonditions of conseiousness. The principle was formerly a theoretical doctrine of philosophy, and was discussed in all early English philosophy under the phrase "relativity of knowledge." Aceording to this theory, no knowledge was of an object as it really existed outside of the mind, but was only of an "idea" of this object in consciousness, subject to all the modifying influenees, both of the nervous system and of the come and go of other impressions and ideas. The historieal development of the doctrine is due mainly to Stuart Mill and Sir William Hamilton. The Kantian theory of knowledge, which made the mind's object a construction in certain forms native to the mind, was a further and important development of the doctrine of relativity toward subjeetive idealism. In current thought the law of relativity has become an established psychological doctrine. It gets its first application in the theory of SENSATION (*q. v.*). It is found that none of the attributes of sensation is eonstant, but that they all vary with the condition in which conseiousness already is when the sensation comes to it. Partieular applications are found in the theory of "color-contrast," in the modifying influence of attention on all sensations, in the working of Weber's law (see PSYCHO-PHYSICS) upon the intensities of sensation-states, and in the influence of muscular states and strains at the time that the sensation in question makes its advent in the mind. See the *Psychologies* of James, Höffding, Baldwin, under the heading *Relativity*; Hamilton, *Lectures on Metaphysics*; Mill, *Examination of the Philosophy of Hamilton*; and Lotze, *Metaphysic*.

J. MARK BALDWIN.

Release: in law, the extinguishment of a pre-existing right. It may eonsist in an agreement upon a legal eonsideration, or in a sealed contraet, or it may result from the aets of the parties or from the operation of law. While there is much authority for the statement that an obligation under seal can be released only by a contract under seal, the better modern view is that a release upon a legal consideration is equally effeetive in extinguishing an obligation with the common-law release under seal. The voluntary destruction of an obligation, or its surrender by the obligee to the obligor, with the intention of discharging the latter, will operate as a release. The law often works the discharge of an obligor in cases where the parties intended no such result. A contract for personal services is terminated by the death of either party. At common law the death of a joint eontractor extinguished the obligation so far as he or his estate was concerned. Likewise the release of one joint obligor worked the legal release of his co-obligors, and the release by one joint obligee was binding on his co-obligees. The language of a release is to be dealt with aecording to the general rules of INTERPRETATION (*q. v.*).

The right which is extinguished by a release may be a title to real property; hence a release may be a form of conveyance. Here it is classed as secondary or derivative because it presupposes a preceding conveyance. It passes the releaser's right in land to one who has a former estate in possession therein. It is said to inure by way of enlarging an estate, or by way of passing an estate, or by way of passing a right, or by way of extinguishment, or by way of entry and feoffment. (2 Blackstone's *Commentaries*, 324–325; *Miller* vs. *Emans*, 19 N. Y. 384.) See BARGAIN AND SALE, DOWER, JOINT OWNERSHIP, JOINTURE, and LANDLORD AND TENANT. For Roman law rules, see OBLIGATION.

FRANCIS M. BURDICK.

Relief: in sculpture and some decorative arts, the projection of figures from a background; also a work of sculpture in which the figures stand out from a background, instead of

being free and finished on all sides, as in a statue or statuette. The figures are generally of the same block or mass as the background; that is to say, the wood or the marble is cut into and dug out, so as to leave the figures *in relief*. The background may then be brought to one uniform plane, or it may be sunk deeper in one place than in others, or the subject may even provide its own background in places, as where drapery is spread broadly, or where the representation of a building or a hill serves to relieve some of the figures. But the figures, drapery, etc., of the relief may also be executed in a different piece of material and fastened on to the background. Thus in the frieze of the Erechtheion the background is of dark marble, and the figures of white marble were attached. In many Japanese decorative objects, reliefs in gold, silver, shakudo, shibu-ichi, and other alloys and colored metals are raised upon a background of polished bronze or smooth iron or silver, or even lacquer or polished wood. Carved wooden panels of cabinets and other decorative pieces of furniture are often made by gluing a thin piece of choice wood upon a pine board and carving deeply, so that the more valuable wood is cut away to an openwork pattern, rounded and modeled within itself, but having the pine showing between its parts; the pine being then removed, the sculptured openwork piece is glued firmly to a panel of the same wood as itself, which has previously been highly polished.

Relief may also be produced in other ways than by carving, as by modeling in clay or in softened paper, or by stamping boiled leather or thin plates of metal, or by the *repoussé* process. (See METAL-WORK.) Relief produced in these ways, and generally where thin plates or sheets are pressed or punched, is more often called *embossing*. Relief may also be got by casting, as metal, sulphur, or plaster; but in this instance the relief must exist first, and is only reproduced by the casting, although after the cast is made it may be modified by the chasing-tool or graver.

Relief is of several kinds. *Basso-rilievo*, or bas-relief, is that in which the projection of the figures from the background is not great—certainly less than half of the rounded form, as of the human figure, and generally much less than that. *Alto-rilievo*, or high-relief, is that of which the figures have more projection. In this it often happens that the heads, arms, etc., of some of the figures are wholly detached from the background, and that other parts are much *undercut*—that is, left in apparent separation from the background, but really supported by unseen connecting pieces of the material. As it is impossible to define exactly the limits of low-relief and high-relief, the term *mezzo-rilievo* is sometimes used to denote moderate relief. *Cavo-rilievo* is relief with no sunken background; the solid substance around the figures is left in its original state, the figures being immediately surrounded and outlined merely by a groove. This kind of relief is common in Egyptian sculptures, both on the walls of large buildings and on the sides and top of sarcophagi in very hard stones, like basalt; it is also seen in Japanese carvings in ivory and wood. The very low relief of coins and medals and of some sculptures in marble, especially of the Italian Renaissance, is sometimes called *schiacciato-rilievo* or *stiacciato-rilievo*—that is, crushed or flattened relief.

It is to be observed that the artist in modeling a relief is not limited to the actual curves of the natural surface which he is representing, nor even to a uniform reduction of these curves to a proportionate greater flatness. Very often the curve where the figure quits the background is abrupt, becoming very much more gradual and subtile on the front surface; thus a head will be modeled in almost imperceptible modifications of the surface, convex curves so delicate as to be hardly distinguishable from plane surfaces, but brought out from the flat background by a sudden sharp rising, or even by an undercutting introduced in order to furnish a sharp line of shadow to mark out the profile.

Sculpture in relief is that which is most used for architectural decoration, especially in Assyrian, Egyptian, Greck, Roman, and modern classic architecture. It is much used also in the mediæval styles. RUSSELL STURGIS.

Relief Presbytery, or **Relief Church**: the name of the body of Presbyterians in Scotland which joined with the United Secession Church to form the United Presbyterian Church. See PRESBYTERIAN CHURCH.

Religion, Comparative: the term commonly used either for the comparative study of religions or for the science of religion in general. Here it is taken in the first-named sense, including the comparative study of myths, dogmas, religious ethics, forms of worship, in short, of all the phenomena of religion. Considered as such, it is one of the two principal departments of the science of religion and the indispensable basis of the other—viz., the philosophy of religion.

Rise of the Comparative Study of Religions.—When the sacred writings of the principal civilized nations of the East—the Chinese Classics, the Veda, the Avesta, and a great many of more recent origin, but scarcely less interesting—could be studied in the original; when the key to the Egyptian hieroglyphics and the Babylonian and Assyrian cuneiform writing had been found and afforded a means of regaining a knowledge of the two most ancient civilizations; when the epigraphical studies were pursued after a strictly philological method, and the already known and newly discovered inscriptions of the Aramæans, Phœnicians, and kindred nations could be better understood, a comparative study of religions was not only to be aimed at, but became indispensable for the solution of all the problems due to the new discoveries. The base of comparative religion is the special study of the history of religions as living organisms, of their rise and growth, their spread and decline, till they are superseded by other forms of worship, either the results of internal reforms or of the preaching of a new doctrine by foreign missionaries. Attention must be paid to their relation to philosophy, science, and arts, to the state, to society, and to ethics; and their mutual historical relation and their place in the universal history of religion must be inquired into. To this historical inquiry must be added a comparative study of the constituent elements of religion, myths, dogmas, and sentiments, none of which must be separately regarded as religion itself, since they are rather its necessary manifestations, never wanting where there is a living religion. As a result of those comparative studies of religions and of their elements, there have been several attempts at a twofold classification of religions, one called the genealogical, in which they are grouped after their proved or probable descent and affinity, the other called the morphological, in which they are grouped after the degree of development they have reached, even though they are neither historically related nor contemporary.

The Genealogical Classification.—From the fact that by nearly all the Indo-European or Aryan nations the supreme God of heaven was called by the same name (Dyaus, Zeus, Ju (piter), Zio (Ty); that with nearly all of them also the same general name for "god" was used; that many names of divinities, common to several Aryan nations, though varying in form, are derived from the same root, by which the original unity of their conception is proved—from these and several other facts the conclusion was drawn that all Aryan religions have sprung from one primitive old Aryan religion, and that therefore, however much they may differ as to their standpoint of development, they belong genealogically to the same class, their relationship being like that of cousins, though twice or three times removed. With the religions of the so-called Semitic peoples, the same conclusion was arrived at from the absolutely general use of the name Ilu, El, Ilâh for "god," and the all but general use of other divine titles, as Ba'al, Bêl, Adōn, Malik, etc. It was not so easy to find arguments of the same kind for the common origin of the Polynesian, of the Ural-Altaic, the Mongolic and their relation to the Chinese religions, and it was quite impossible to prove the primitive unity of, let us say, the Nigritian, the American, and other religions of uncivilized and barbarous nations.

Still the philological argumentation was thought positively to hold good for the two most important families of religions, the Aryan and the Semitic, from which have sprung the two universalistic religions Buddhism and Christianity and the widely spread, semi-universalistic Islâm. Some scholars, however, have raised grave objections against the value of this reasoning and of the generally admitted comparative method, on the ground that the use of the same names for the divinity does not prove the common origin of the religions to which it belongs. But, even if we admit that the results of etymological and glottological research have not that great value for the comparative study of myths and religions which has been attributed to them, the science of language can not be dispensed with as an auxiliary for the science of religion, and affords at least one of the standards by which the relationship of myths, dogmas, religious systems, and forms of worship must be determined.

Classification after the Tendency of Development.—We

shall now endeavor to classify the religions of the world first after the line or tendency, then after the degree of their development. To determine the line or tendency of development which a family of religions has followed in the course of history, the principal charaeteristics of such a family must be found out. That which really characterizes a religion or a group of religions is the notion they have formed of the relation between God and the world, God and man, and of the manner in which the Deity chooses to be worshiped. By applying this method to the religions with which we are best acquainted, some distinct families ean be marked out with certainty even now, and by applying it to those which are not so well known, the documents and information from whieh they must be studied being less abundant, less elear, or less accessible, some probable hypotheses about their mutual relationship may be drawn.

Just as there are an Aryan and a Semitic family of speech, there are two corresponding great families of religions, which provisorily and only for convenience' sake may be called the Aryan and the Semitic religions. Studying these two groups we find that each of them develops, with marked and growing onesidedness, one of the fundamental ideas of religion without totally denying the other—viz., the Aryans the kinship between God and man, the Semites the eminence of God above man; the former regarding the Deity as the father of gods and men, the divine protector of the human race and of the same nature with it, though higher and mightier; the latter venerating their gods as lords, masters, and kings, whose obedient servants, nay, whose slaves, they are; the former laying the greatest stress on that which is dogmatically called the immanenee, the latter on that which is dogmatically called the transcendency of the Godhead. The former or Aryan religions may be called theanthropic; the latter or Semitic may be called theocratic.

Theanthropic Religions.—The principal theanthropic religions are—(1) the Vaidie religion in India and its offshoots; (2) the religion of the ancient Iranians, Medes, Persians, and Baetrians, of whieh the Zarathustric Mazdeism was a reform, protected by the Achaemenids and re-established under the latter Arsacids and the Sassanids, though perhaps partly altered under foreign influences. These two are branches of the same stem, as is proved by the many divinities, religious ideas and rites, espeeially the Soma-Haoma worship, which they have in common, but they have developed quite independently, and have really evolved into decided antagonists, the one led by uneontrolled theosophic speculation to the utmost limits of monistic pantheism, and even atheism, the other founding on a rather superficial dualism a practieal system of religious observances and sober morality. Originally not less closely related are the religions of (3) the ancient Greeks and of (4) the Romans; but the Greek or Hellenic religion, under the high pressure of various Eastern creeds and cults, grew into that most attractive, but from a moral standpoint dangerous, humane polytheism, the worship of beauty and genius, while the Roman religion was organized to a cold and formalistic ritualism, till it was totally reformed by a gradual infiltration of Hellenic gods, ideas, and rites. Next come (5) the nearly allied Germanic religions, including the Seandinavian and the Teutonic, which, if the moral dualism of the *Edda* ean be considered as old and original, show a great resemblanee to the Iranian religious system; (6) the rather primitive but vaguely poetical Windic or Slavonic, and (7) the Keltic religions, which are still imperfeetly known, but as far as they are known seem to represent the most ancient form of theanthropic religion, dissimulating its barbarous myths and bloody rites under a veil of magical mysticism.

Theocratic Religions.—The theocratic religions of Western Asia are mueh more closely related than are the theanthropic religions, the former covering a limited area, while the latter are spread from the Ganges to Iceland. The more primitive forms of worship belonging to this family must be sought among the Arabians and among other nomadic tribes of the desert. A marked theocratic charaeter is shown by the Babylonian religious system, of whieh the Assyrian is an offshoot, only slightly differing from it in detail, though grafted on the really heterogeneous religion of the older inhabitants of the eountry, the so-called Sumerians (Accadians), and having borrowed from it not a few gods and rites. The same may be said of the religions of the Aramæans, the Canaanites and Phœnicians, and the Hebrews. In the religion of Israel the same fundamental idea, combined with the conception of God's holiness—by which originally is meant that the heavenly Sovereign is inaccessible—has been developed by the Mosaic reform and the preaching of the prophets into that ethical monotheism which stands unequaled among the religions of antiquity. Even Islâm, the religion founded by Mohammed under the influence of imperfectly understood Judaism and Christianity, though semi-universalistic, must be regarded not only as a theocratic religion but as the one in which the conception of the Deity as an absolute sovereign has been worked out to its utmost consequences. In Christianity, on the contrary, the two currents meet; it is constantly struggling to maintain a kind of balance between the two principles, or even to combine them in a higher unity. It is only fair to say that the younger Judaism, which preceded it, had already prepared the way, as it had weakened the old, onesided theocratic doctrine by its moral dualism and its belief in personal immortality.

The Egyptian Religion.—It might be expected, as the Egyptian language contains so many Semitic elements, that the religion would likewise be theocratic; but, though decidedly theocratic, it is theanthropic as well, and so represents a stage of development at which the two principles were still equally acknowledged. Perhaps the pre-Babylonian religions of Western Asia were more or less closely related to the Egyptian religion; certain it is that some of the oldest Egyptian gods and myths show a great resemblanee to gods and myths probably borrowed by the Babylonians and other Western Asia nations from their predecessors. All this, however, is hypothetieal.

Some other Families of Religions.—It would be impossible to give a complete classification of all religions with the present data. However, mention may be made of the *patriarchal* religions, in which the divine beings, worshiped as "elders, old ones, grandparents," are mutually related in the same way as the heads of different tribes or families, of whom one is superior to the other inasmueh as he is mightier, but eaeh of whom exercises authority independently and in his own sphere. To these belong the religions of the Ural-Altaic peoples (Finns, Lapps, Esthonians, and their relatives, though the first named have borrowed much from the Germans), and perhaps also some religions of North American nations. The Chinese religions that are known are of another kind. They might be called *anthropocentric*, as the human spirits (*shin*) constitute the middle class between the two other classes, viz., the heavenly and the earthly, strictly distinguished from both of them, but just as well venerated by the living. Probably also these have formed a group or family with the religions of some kindred peoples, but of the latter little is known.

As to the remaining religions only the classifieation whieh corresponds to the ethnological and the glottological one can be given.

Classification after the Degree of Development.—To classify the religions aecording to the degree of their development, whieh is usually, but not quite correctly, called the morphological classification, one must observe them at the highest standpoint they have reaehed—not in their growth nor in their decline. It is true that of some religions we must assume that, having had their development checked by adverse causes, they have remained stationary on a lower level than was possible for them to attain, and that of other religions we may suppose that they have fallen into decay through isolation, oppression, general degeneration of a people; but as it is no longer possible to gather information eoneerning their better state otherwise than by guessing from some vague traces, we are compelled to classify them only by what we know of them with certainty. Aeeording to this standard of comparison religions are divided into the two great eategories of nature-religions and ethieal religions.

Nature-religions.—By nature-religions we mean those whose highest divinities, be they spirits, fetishes, or manlike beings, are mighty powers of nature, connected in some way with a definite natural object or phenomenon. From these religions the ethieal element is by no means excluded. On the eontrary, from the remotest times moral qualities have been attributed to the gods or have been deified themselves, and this has been done more and more according as the deities have become more anthropomorphized. The ethieal element, however, remains subjected to the nature-gods, and the latter are by no means bound by it.

Different Degrees of Nature-worship.—Among the nature-religions there is a great difference as to development, though all of them, even the highest, are still dominated by the same principle. On the lowest plane stands what has

been called naturism, a worshiping of natural phenomena, and powers of nature as beings endowed with magical powers, represented for the most part as animals, monsters, portentous mythical beings, such as we still observe in later mythologies. This stage of development may be better named the *Polyzoic.* We are not able to point out any religion that is still standing on this low degree. Polyzoism is known only from survivals in more recent formations, but it is a not improbable hypothesis.

Polydemonistic Magic Religions under the Control of Animism.—As soon as man has become conscious of the superiority of the spirit to the body and of his relative independence, ANIMISM (*q. v.*) arises, a kind of original philosophy, dominating his whole life and also religion. It is a belief in spirits or souls, freely moving in heaven and on earth, and, either of their own free will or under compulsion, embodied, permanently or temporarily, in all sorts of objects, which are living or at least seem to be living (Spiritism and Fetichism). So far as man considers himself dependent on them and stands in awe before them, they become the objects of his religious worship. To these belong, in the first place, the souls of the dead, which continue to live after having left the body and which he tries to appease, and the highest spirits, to whose agency he especially attributes the natural phenomena on which depend his existence and his well-being. In this stage arise the *polydemonistic magic* religions, with their yet unsettled, continually varying mythology, their belief in a magic power, not bound by any laws, which belongs not only to the worshiped spirits, but also to privileged human beings, sorcerers, and fetich priests, and, in accordance with this belief, their magic rites, in which fear constitutes the most powerful motive. All the religions of the so-called savage or uncivilized nations belong to this category, though they no longer offer a complete picture of what religion must have been when animism flourished.

Therianthropic-polytheistic Religions. — The religions which, as to their degree of development, come next to the polydemonistic magic religions, standing under the influence of animism, are the *therianthropic-polytheistic.* From the multitude of demons a number of select ones have detached themselves, superior to the others not only in rank, but also as regards kind: these are called gods. Lower spirits and fetiches are no longer worshiped independently, but only as connected with these gods, as their servants or their embodiments. The gods themselves are mostly represented therianthropically, in shapes partly human and partly animal, though the old tree and stone fetiches are still worshiped (as, indeed, they are even in a more advanced stage of the religion), but as being animated by the gods, as a kind of mystic symbols. Few new myths arise; the old ones are sorted, purified, and part of them are already considered as ancient history. It would be interesting to inquire in what manner the rise of the therianthropic religions is connected with the origin of the apologue and with the so-called totemism.

These religions may still be divided into those of a lower, unorganized sort, as the Anaryan (Dravidian) of Southern India, those of the Finns and Esthonians, the oldest Greek (so-called Pelasgic) and the oldest Italic cults and others, and those of a higher, organized kind, to which belong the religions of the half-civilized peoples of America (Maya, Natchez, Aztecs, Muyscas and Incas), the Egyptian, most probably the oldest Babylonian, and perhaps also the old Chinese religions.

Semi-ethical Anthropomorphic-polytheistic Religions.—Highest among the nature-religions stand the *anthropomorphic-polytheistic.* Man has become conscious of his superiority to the animal. The gods, though superhuman beings, can lay claim only to a human shape. The myths concerning their temporary metamorphoses are but a survival from former periods, and serve only as proofs of their still active magic power and as subject-matter for wanton poets. The animals, formerly their embodiments, have now become their companions and messengers, or, together with the trees and stones, their attributes and symbols. Some therianthropic beings still remain, but only as beings of a lower order or as enemies of the gods. The latter have all the human qualities together with the human shape ascribed to them, and thus the way is paved to the ethical element. Hence we may call these religions *semi-ethical*, but only *semi-ethical*, for the purely ethical standpoint they have not yet reached. The gods, although really vested with all kinds of moral qualities, and although mythology has already been worked up into a great world-drama, are still moved by passions and commit actions which, when viewed as descriptions of the conflict among the powers of nature, can not give offense, but yet are not in keeping with their superhuman though man-like nature. In accordance with their origin, all of them, even the highest, remain nature beings. When the ethical element gets the upper hand, the whole semi-ethical pantheon, together with the religion of which it constituted the basis, is doomed to annihilation.

The religions that belong to this category do not all stand at the same degree of development. Lowest, so far as we know them, are the Celtic and Old-German (with the exception of the Old-Norse, at least so far as can be ascertained by the picture the *Edda* gives of it); superior to these are the Vaidic religion and the religions of Asia Minor (Aramæans, Canaanites, Phœnicians, Sabeans); the highest standpoint was reached, along different ways, by the Babylonians and the Hellenes, in whose wake followed the Assyrians and the Romans.

Ethical Religions.—By *ethical religions* are meant those called by others individualistic or supranaturalistic—those, that is to say, in which the ethical element dominates the naturalistic, although not all the naturistic ideas and customs have been abandoned. The old nature-gods have been preserved as messengers (ἄγγελοι), servants, beings worthy of being worshiped (*yazatas*), and sometimes also as saints. If not all ethical religions are purely monotheistic or even pantheistic, yet they are much more so than the nature-religions, which are mostly polytheistic and can at best get to monolatry. The principal characteristic of the ethical religions is that they are not based on a national tradition, but on a doctrine of salvation, preached either by one prophet, reformer, messenger from God, or by a community of reformers. The ethnic and national elements are not wholly wanting, but they are subordinate. Most of those whose religious community is based on the preaching of such a doctrine ascribe to this doctrine a divine authority, which all have to consider as binding under penalty of being ejected. From the original preaching the divine authority is transferred to the oldest records in which it is contained; all ethical religions have a Holy Writ (which, considered as such, is wanting in nature-religions), however different may be the conceptions formed about it.

The Two Principal Categories of Ethical Religions.—The ethical religions have to be distinguished into at least two principal categories: (1) Those which may be called *nomistical* (nomothetical) or Law-religions (*Rechtsreligionen*), and whose sacred writings, at least part of them, are framed like laws, as the Chinese Confucianism, the religions of the Brahmanical and Jaina-sects, primitive Buddhism, Mazdeism, Mosaism, and Judaism; (2) those which are based upon more or less broadly conceived, universally human principles, and which might be called missionary religions, viz., Islamism, the younger Buddhism, and Christianity. The first-named are, as a rule, confined to a definite nationality, for even if they try to spread among other nations, as the Zarathustric Mazdeism and Judaism have done, the alien proselytes are never regarded as the equals of the native adherents. One can not belong to such a religion without at the same time adapting one's self to the civilization and the customs of the nation with which it has originated. The last named have more or less completely relinquished the principle of nationality, and consider all believers as equals, whatever may be their language or their nationality. Hence the two categories might also be called *particularistic* and *universalistic* ethical religions. The term world-religions, applied to the latter, has been objected to, and, strictly speaking, there can be only one world-religion, though the word may continue to be used for practical purposes, referring to those religions which at least strive after conquering the whole world. Another objection, to the effect that the distinction made here is not a fundamental one, is unreasonable. There is a fundamental difference between law and principle; and moreover, the religions of the first-named category are, as to their development, at a lower standpoint than those of the other. C. P. TIELE.

LITERATURE.—As materials for the study of comparative religion see *The Sacred Books of the East*, a series of translations edited by F. Max Müller (London, 1879, *seq.*, 1st series, 24 vols., 1879–85; 2d series, 24 vols., 1886, *seq.*); also *The Records of the Past*, being English translations of the Assyrian and Egyptian monuments (1st series edited by Samuel Birch, 12 vols., London, 1874–81; 2d series edited by A. H. Sayce, 6 vols., 1889–93). For detailed treatment of several religions, see the following Hibbert Lectures: *The Re-*

ligions of India (F. Max Müller, 1878); *The Religion of Ancient Egypt* (Renouf, 1879); *Indian Buddhism* (Rhys Davids, 1881); *The Native Religions of Mexico and Peru* (Reville, 1884); *Celtic Heathendom* (J. Rhys, 1886); *The Religion of Ancient Assyria and Babylonia* (Sayce, 1887); *The Religion of the Parsis* (Darmesteter, 1890); *The Religion of the Ancient Hebrews* (1892). General works in this department are: C. Hardwick, *Christ and other Masters* (3d ed., London, 1874); A. Kuenen, *National Religions and Universal Religions* (London, 1882); Tiele, *Outlines of the History of Religion* (London, 1884; 2d ed. 1888); A. Reville, *Prolegomena to the History of Religion* (Eng. trans., London, 1885); Chantepie de la Saussaye, *Lehrbuch der Religionsgeschichte* (Freiburg im Breisgau, 2 vols., 1887–89, trans. of vol. i. *Manual of the Science of Religion*, London, 1891). Readable are J. F. Clarke, *The Ten Great Religions* (2 vols., Boston, 1870–83; n. e. 1886); G. T. Bettany, *The World's Religions* (London, 1890); F. F. Ellinwood, *Oriental Religions and Christianity* (New York, 1892); *Religious Systems of the World*, by various authors (London, 1889; 3d ed. 1893).

Remainder [from O. Fr. *remaindre*, deriv. of *remaindre*, remain < Lat. *remane're*; *re*, back + *mane're*, stay, remain]: in law, a future estate in land to take effect immediately upon the termination of a prior, limited estate upon which it depends, and with which it was created. As is explained in the articles ESTATE and PROPERTY, the estate in fee simple is conceived of at common law as being susceptible of infinite subdivision. When a tenant in fee simple grants a present, limited estate, as an estate for years, for life, or in tail, the residual interest not thus disposed of is itself an estate capable of being separately dealt with. If by the same conveyance the grantor parts with this residual estate or any part of it to a third person, it is called a *remainder*; if he does not part with it, it "reverts" to him, and is known as a *reversion*. (See LANDLORD AND TENANT.) The present or "particular" estate, as it is called, may be followed by any number of future estates in remainder until the whole fee simple has been taken up. Thus if a tenant in fee simple gives lands, by deed or will, to A for ten years or for life, then to B for life, then to C in fee tail, then to D and his heirs, A is the particular tenant, and B, C, and D are remaindermen. If the last limitation (to D and his heirs) had been omitted the remaining estate in fee simple would have, after the termination of the last remainder (to C), reverted to the grantor and his heirs.

It was a peculiarity of the remainder at common law, which was inflexibly maintained by the courts, that it could be created only as a true remnant of a fee simple to follow a prior estate which was less than the whole estate of the grantor. In other words, a remainder could not take effect in derogation of or in substitution for a preceding estate. Thus if a tenant in fee simple should make a conveyance of his land to A in fee, but with the proviso that if A should die without surviving issue then the estate should go to B in fee, the limitation to B would be void and the estate belong absolutely to A. The whole estate of the grantor had become vested in A, and it could not be divested and transferred to any one else by the creation of a remainder. The result aimed at could, it is true, be secured by the creation of a shifting use (see USES), or by executory devise (see WILL), but it could not be accomplished by any form of limitation known to the common law. By legislation in many of the U. S. remainders have lost this artificial character. In the State of New York, for example, it is expressly provided by statute that any future estate which is dependent on a precedent estate may be called a remainder, and that a remainder may be limited upon a contingency which will operate to abridge or determine the precedent estate. 1 R. S. 723 (sec. 11), 725 (27).

In the remainder proper, as above described, the interest of the remainderman was said to be "vested"—that is, the remainder, although its enjoyment was postponed to a future time, and although it was described as a future estate, was really regarded as a present interest in the lands affected by it, and was accordingly real property, capable of alienation, or, if a remainder in fee, of transmission by will or descent. Like reversions, remainders were regarded as incorporeal interests, and were, like easements and other "incorporeal" rights in land, alienable only by grant. See HEREDITAMENTS (*Incorporeal*).

Originally this "vested" remainder was the only form of future or "expectant" estate which could be created at common law, but in the course of time a gift to take effect in the future in favor of a person not now existing, or not yet ascertained, or upon an event which might or might not happen, acquired recognition under the description of a "contingent" remainder. Such a remainder was not, properly speaking, an estate, inasmuch as it could not be alienated or devised, and would not descend to the heir of the contingent remainderman. It was, moreover, an interest of a most precarious character, as it was liable to destruction by any one of a variety of accidental or intentional circumstances. If the event upon which the contingent estate was limited to depend had not happened at the time when the preceding estate came to an end, the contingent remainder was destroyed. So also a release of the reversion to the particular tenant or the surrender of the estate of the latter to the reversioner, whereby the reversion and the particular estate were merged (see LANDLORD AND TENANT), had the effect of destroying the intervening contingent remainder. This process may be illustrated by supposing A to have a life-estate, with remainder to the (unborn) son of B for his life, with remainder to C in fee. If B's son has not come into being when A's life-estate comes to an end, the contingent remainder of the former is destroyed forever, and the estate vests at once in C. So if, before the birth of B's son, A should convey his life-estate to C, or C his vested remainder to A, the estate would be lost to the contingent remainderman forever. If, however, B's son should be born before any of the events above suggested have happened, his interest would at once become vested, and would from that time on be wholly unaffected by such contingencies. By legislation, whereby contingent remainders are preserved from destruction by the events above enumerated, and whereby they may be alienated or may descend to the heir of the contingent remainderman, these interests have been very generally assimilated to vested remainders both in England and in the U. S., and have thus in a greater or less degree acquired the character of true estates.

For further information, consult Digby, *History of the Law of Real Property*; Fearne on *Remainders*; Leake's *Law of Property in the Land*; the *Commentaries* of Blackstone and Kent, and the statutes of the several States.

Rembang': a Dutch residency of Java, East Indies, comprising 2,600 sq. miles, with (1888) 1,241,093 inhabitants, of whom about 18,000 are Chinese and 700 Europeans. The capital, Rembang, on the flat, hot, northern shore of Java (see map of East Indies, ref. 8–E), has 25,000 inhabitants and some ship-building. Revised by C. C. ADAMS.

Rembrandt (full name, *Rembrandt Harmenszoon Van Rijn*): painter and engraver; b. at Leyden, Holland, July 15, 1606. He first studied painting with Jacob von Swanenburch, and then under Peter Lastman, at Amsterdam. He returned to Leyden in 1623 and gave himself up to studying from nature and painting portraits. About 1629 he settled in Amsterdam, where he remained till his death. His fame was great, his studio crowded with scholars, and his works in great demand, yet in 1656 he became insolvent. It is supposed this may have been owing to the impoverished state of the republic, and to his reckless extravagance in collecting works of art. Sufficient data exist contradicting the oft-repeated tales of his miserly habits. Rembrandt was the greatest genius among Dutch painters, and his influence in the art of his country is paramount. He was married twice, and had in all four children. His son Titus by his first wife became a painter, but did not distinguish himself, and died in his father's lifetime. Among Rembrandt's best-known works are *The Presentation in the Temple*, at The Hague; a portrait of a young man in the royal collection at Windsor; the portrait of Coppenol at St. Petersburg; *The Anatomical Lecture* painted in 1632, at The Hague; *The Night Watch*, at Amsterdam, a prominent example of his maturer work, dated 1642; the portraits of the Syndics, also at Amsterdam, dated 1661, which shows his later manner. He is supposed to have been painting on *The Betrothed Jewess*, now in the Rijks Museum, Amsterdam, the year of his death, 1669. He was buried in the Wester Kirk, Oct. 8 of that year. Of his engravings the most famous are *Jesus Christ Healing the Sick*, six portraits of himself done between 1630 and 1654, *Burgomaster Six*, *Adam and Eve in the Garden of Eden*, *The Flight*

into Egypt, Jesus and the Woman of Samaria, Jesus Healing the Sick, the *Resurrection of Lazarus*, etc., in all 365, of which Bartsch, of Vienna, has made a catalogue. For further information consult Rev. C. H. Middleton, *Descriptive Catalogue of the Etched Work of Rembrandt*, and F. Seymour Haden, *Rembrandt's Etched Work* (1879).

W. J. Stillman.

Remensnyder, Junius B., D.D.: clergyman; b. near Staunton, Va., Feb. 24, 1842. Graduated at Pennsylvania College, and Theological Seminary, Gettysburg, Pa.; pastor, Lewistown, Pa., 1865–67; St. Luke's, Philadelphia, 1867–74; Savannah, Ga., 1874–80; St. James, New York, since 1881. Dr. Remensnyder, while a member of the General Synod South, offered the motion for the preparation of *Common Order of Service*, which has since been adopted by all English-speaking Lutherans. He has published *Heavenward* (Philadelphia, 1874); *Doom Eternal* (New York, 1880); *Six Days of Creation* (Philadelphia, 1886); and *The Lutheran Manual* (New York, 1893).

Rem'enyi, Edward: violinist; b. in 1830 in Hungary (at Herves or Miskole—accounts vary); studied at the Vienna Conservatory 1842–45 under Joseph Böhm, the teacher of Joachim. In 1848 he took part in the insurrection against Austrian rule, and was compelled to fly. He made a concert tour in the U. S. 1849–50, and in European capitals; returned to Hungary in 1860; played in Paris 1865 and again in 1875, in London 1877–78, and in the U. S. in 1878, 1887, and again in 1893. D. in San Francisco, Cal., May 15, 1898. His playing was characterized by great dash, fire, and emotional quality, combined with high technique. D. E. H.

Remig'ius: the name of three eminent French ecclesiastics: (1) St. Remi, the Bishop of Rheims, and the apostle of France, who in 496 baptized Clovis, the founder of the French monarchy. He was born at Laon in 437, became bishop in 459, and died Jan. 13, 533. His literary remains are in Migne, *Pat. Lat.*, lxv. (2) The Archbishop of Lyons, who sided with Gottschalk in the great anthropological controversy of the ninth century. He became archbishop in 853, and died after 875. His life and works are given in Migne, *Pat. Lat.*, cxxi. (3) A Benedictine monk of Auxerre, who was at the head of the bishop's school at Rheims in 882, and died about 908. He wrote commentaries on the Psalms, the last eleven of the Minor Prophets, and the Epistles of St. Paul, and an allegorical explanation of the mass. His works are reprinted in Migne, *Pat. Lat.*, cxxxi.

Remittent Fever [*remittent* is from Lat. *remit'tens*, pres. partic. of *remit'tere*, send back, slacken, relax; *re-*, back + *mit'tere*, send]: a form of malarial fever characterized by an abatement of the temperature occurring at certain intervals, but no return to the normal point while the fever lasts. In this it is unlike intermittent fever, in which there are periods of entire or almost entire apyrexia (absence of excessive heat). The cause of remittent fever is the same as that of any other malarial fever, and is believed to be a specific germ. Several such germs have been described, figured, cultivated, and successfully inoculated. The one which now has most general acceptance is that known as Laveran's. See Miasma.

Remittent fever is usually of a more mild type than active intermittent fever. Its symptoms are less pronounced; the chill is less severe; and in the course of the disease it may appear only once. The alterations of temperature are not unlike those of typhoid fever, and remittent is probably not infrequently taken to be mild typhoid fever. Bronchitis often occurs at the outset of remittent fever, and jaundice frequently follows it. This form of malarial fever is found in all parts of the world, in dry as well as in swampy regions. The diagnosis, made from the symptoms alone, may at times be quite difficult. To obviate this it has been suggested that in all cases the blood should be examined microscopically, and that those cases only should be regarded as malarial in which the specific germ of Laveran is found.

The treatment of remittent fever is that of any form of malarial fever—quinine, as a specific remedy, and tonics, with attention to the general health. See Intermittent Fever.

Remmius: See Palæmon.

Remonstrants [from Lat. *remon'strans*, *remonstran'tis*, pres. partic. of *remonstra're*, remonstrate; *re-*, again + *monstra're*, point out, show]: the name by which the adherents of Arminius were designated when in 1610 they addressed a remonstrance (*remonstrantia*) to the states of the province of Holland. Their adversaries, the adherents of Gomarus, answered with a counter-remonstrance, and were called Contra-Remonstrants, but both designations fell subsequently out of use.

Remsen, Ira, M. D., Ph. D., LL. D.: chemist; b. in New York, Feb. 10, 1846; graduated A. B. from the College of the City of New York in 1865, M. D. from the College of Physicians and Surgeons, New York, in 1867, and Ph. D. from the University of Göttingen, Germany, in 1870; was assistant in chemistry in the Universities of Tübingen, Munich, and Göttingen, Germany, from 1870 to 1872; Professor of Chemistry and Physics in Williams College from 1872 to 1876; Professor of Chemistry in Johns Hopkins University, 1876–1901; President Johns Hopkins, 1901. He received LL. D. from Columbia College in 1893. His more important publications are *Theoretical Chemistry* (1st edition, Philadelphia, 1876; 4th edition, 1892, translated into German and Italian); *Organic Chemistry* (Philadelphia, 1886, translated into German, Italian, and Russian); *Introduction to the Study of Chemistry* (New York, 1885, translated into German and Japanese); *A Text-book of Inorganic Chemistry* (Philadelphia, 1889). He is an associate editor of *The Universal Cyclopædia*.

S. T. Armstrong.

Remus: See Romulus.

Rémusat, rā'mü'zaa', Jean Pierre Abel: Orientalist; b. in Paris, Sept. 5, 1788; studied medicine, took his degree, but devoted himself principally to the study of the Asiatic languages, especially Chinese, and was appointed Professor of Chinese at the Collège de France in 1814, a chair which was established specially for him. D. in Paris, June 5, 1832. His principal works are *Recherches sur les Langues tatares* (1820); *Éléments de la Grammaire chinoise* (1822); *Mélanges asiatiques* (2 vols., 1825); *Nouvelles Mélanges asiatiques* (2 vols., 1828); numerous translations from the Chinese and Tibetan languages, besides minor essays in scientific periodicals.

Revised by Benj. Ide Wheeler.

Renaissance, Fr. pron. re-nā'sāăns' [=Fr. *renaissance*, a being born again, deriv. of *renaître* < Lat. *renas'ci*, *rena'tus*, be born again; *re-*, again + *nas'ci*, be born]: a great advance in learning or in the study and pursuit of literature, fine art, etc.; a name applied especially to the revival of learning in the fifteenth century, beginning in Italy, and to the change in most departments of thought which accompanied and followed it. The Renaissance in learning and in literature has been described under Humanism. The term is also used as an adjective, as Renaissance designing, Renaissance sculpture.

Painting and Sculpture.

The Beginning.—The fine art of painting had nearly disappeared from Western Europe during the early Middle Ages, but had been partly restored during the twelfth and subsequent centuries in the north, in vigorous if unskillful wall-pictures and in decorative windows (see Glass); in Italy, in panels painted under Byzantine Greek influence, and in wall-pictures more skillful and better arranged than those of the north; also in the decoration of manuscripts and in the very beautiful miniatures which they contained. (See Illuminated Manuscripts and Miniature.) The fine art of sculpture had been developed in connection with Gothic architecture to great excellence in the thirteenth century; the decorative value of the best works of the time, as part of a building, has never been equaled before or since, and its expressional and purely sculptural value was high. But in Italy in the thirteenth century there began a much closer study of those remains of ancient Roman work which had never been wholly neglected, and also some renewed influence from Constantinople is to be presumed. In 1280 Nicolo Pisano had been dead two years, and had left the remarkable *Descent from the Cross* at Lucca, the *Arca di San Domenico* at Bologna, and the pulpits of Pisa and Siena. His son Giovanni was thirty years old at least, and he and Rossi of Perugia had finished the Perugia fountain. Arnolfo di Cambio had completed the Braye tomb in S. Domenico of Orvieto. A classical feeling was visible in all this sculpture, and a strong effort to treat the figure subjects by and for themselves, apart from the architectural framework. In 1310 Giovanni Pisano had finished the Pistoja pulpit and the monument to Pope Benedict XI. at Perugia; and perhaps the angels and the lunette of the *Porta della Canonica* at Florence, which are of that time even if not by that

sculptor. In the same year Giotto was thirty-four years old, and had painted the Arena chapel at Padua and the chapel of the Florence Bargello, in which works are still to be seen the plain evidences of a combined realism and skill —a desire to think for himself, and a power to express thoughts in painting—which are at the bottom of later progress in painting. These early dates show that the Renaissance in fine art was well under way before any influence from the humanists or the restorers of classical learning had reached the painters and the sculptors. Those artists were thinking out for themselves the great question why the antique sarcophagi and the Græco-Roman engraved gems showed an art so much more learned and complete than theirs. Before Petrarch died, leaving the literary and philosophic Renaissance alive and in progress, if not yet assured, Andrea Pisano had completed the present south doors of the baptistery at Florence, Balduccio had put up his three or four important tombs at Milan, and Orcagna had adorned the Or San Michele at Florence with his marvelous work, ahead of its time and reaching on toward another century, the shrine of the Madonna. Then indeed there seemed to come a pause, and it is hard to understand why so little important art was produced between 1360 and the year 1420 or thereabouts, when Giacomo della Quercia and Lorenzo Ghiberti had come to the front, and Donatello was a promising young sculptor—when, in painting, Fra Angelico and Gentile da Fabriano were gradually leaving missal books and bridal chests for wall-pictures, and the great innovator Masaccio was fairly at work. The year 1425 may be taken as a good date for the triumphant establishment of the new wisdom and power in fine art. Then Masaccio's frescoes in the Brancacci chapel at Florence were well advanced. Then Giacomo della Quercia, who had completed the lovely recumbent figure of Ilaria del Carretto a year or two before, began his sculptured work at San Petronio at Bologna—sculptures associated with a mediæval-seeming doorway, but as far as need be from mediæval in character; indeed modern in conception and in modeling. Then, too, Lorenzo Ghiberti, who had just completed the present north doors of the Florence baptistery, had begun the more elaborate east doors—not necessarily superior to the earlier ones in real merit, but immensely in advance of them and of other previous sculpture in power over material, and in boldness and grasp of subject. And at that time Donatello, whose work is often less easy to date, had certainly completed the noble statues of the exterior of Or San Michele at Florence, the St. Peter and St. Mark, and the admirable St. George. Little had the Renaissance artists learned from the classical scholars up to this time, and yet modern sculpture and modern painting were begun, their possibilities shown, and their future course well indicated.

The Fully developed Renaissance.—The year 1475 is the central point in the century of greatest artistic achievement of the Italian Renaissance, excluding the Venetian painters. The one noticeable effect of the revival of letters upon fine art, the suggestion of subjects from classical antiquity, was then as noticeable as it was to become. This is not of great importance, for the great artists of that time, as of all times, cared little what stories their work was to tell to non-artistic beholders, and painted an allegory of the *Garden of Cupid* as cheerfully as a martyrdom. The important thing is the extraordinary variety of artistic power possessed by the men who were then at the head of the fine-art movement. In Florence Fra Filippo Lippi had been dead seven years, leaving behind him a large number of somewhat prosaic but vigorous and animated pictures. Berozzo Gozzoli was about fifty years old, and had painted his remarkable frescoes in the Pisan Campo Santo. Sandro Botticelli was twenty-eight years old; he had painted those wonderful round Madonna pictures which are now seen in the Louvre and the Uffizi; and either had painted or was on the point of undertaking that *Triumph of Spring* or *Flora*, the famous allegorical picture of the Florence Academy of Arts. The great Ghirlandajo was of about the same age, and had not quite reached his mature power. The two brothers Pollajuolo were at the height of their joint career. Luca della Robbia had done all his best work, both in marble and in glazed terra-cotta, and was an old man. Mino da Fiesole had finished the tomb and the altar of Fiesole cathedral and the noble compositions of the Florence Badia. Verocchio, painter and sculptor, forty years old, was at work upon the *David* of the Florence National Museum. His great pupil, Leonardo da Vinci, was twenty-three years old and at work, but destined to so long a career that he belongs rather to a later epoch than this. In the north, where Leonardo was to labor the most, Mantegna was forty-five years old, and had finished his work at the Eremitani at Padua and the castle at Mantua, besides a host of separate pictures and his principal engravings. Of the Venetian painters even, later to reach greatness and destined to hold it longer, the founder of the school, Giovanni Bellini, was fifty years old. He had painted the splendid altarpiece of the Church of SS. Giovanni e Paolo, Venice, which was burned in 1867, and the gigantic altarpiece at Pesaro, which still remains, and had perhaps reached his greatest strength, though he was to retain it long. These pictures are worthy to rank with those of Central Italy; it is not because the unmatched achievements of the later Venetians surpassed them that they should be depreciated. The Renaissance of fine art in its purest and loveliest form is in the best pictures of Giovanni Bellini. Still more powerful work was to come than any of these mid-Renaissance paintings and sculptures could offer—more powerful, but with not a greater charm.

The Late Renaissance.—Italian writers are extremely careful to mark the close as well as the beginning of their *Rinascimento* or *Risorgimento*. Most of them end this epoch with the early years of the sixteenth century, the *Cinque Cento*, and call the art of that century the *Classicismo*, because it is all, but especially architecture, strongly influenced by the study of ancient Roman remains, or the art of the *Decadenza*, as having lost the charm of spontaneity and unaffected grace, or simply the art of the *Cinque Cento*. The pre-Raphaelites had somewhat the same feeling when they took Raphael's work in Rome (1508 and following years) as the turning-point, with growth before, and decay after. Michelangelo's long career begins with our central year 1475, lasts through the splendid years of highest and purest achievement in Central Italy, and outlasts everything that was precious and hopeful in Italian art anywhere out of Venice.

By 1525 the artists who were great in 1475 were all dead, but this half century was filled with the labors and with the fame of most of the men named under the earlier date, and, besides them, of the following: Filippino Lippi, who died in 1505, Fra Bartolomeo, who died in 1517, and Lorenzo di Credi—all three men of the Florentine Renaissance proper; Andrea del Sarto, modestly keeping up the older traditions except when the overwhelming force of some one of his contemporaries swayed him, capable of anything, but original only in that he gave to his canvases an unwonted glow of color. Among the Umbrians and so-called Roman school, there were Perugino, who had died in 1524, and Francia (Raibolini), who had died in 1517—great workmen, whose art is somewhat lost in the splendor of Raphael's glory; Raphael, who had died in 1520, having made the deepest mark upon the artistic thought of his time, and gained a celebrity and a recognition far beyond what other artists had reached; and Luca Signorelli, of Venice and Central Italy, most powerful and accomplished of all the men who missed supreme greatness; finally (still excepting the great Venetians), Michelangelo in 1525 had painted the Sistine vault and had sculptured the *Moses*, the Florence *Pietà*, the bronze *Pope Julius*, and the *Christ* of Sta. Maria sopra Minerva.

After 1525 decay was rapid. Pontormo and Ridolfo Ghirlandajo, with such mechanicians as Vasari and Venusti, were in the field, and in the north Bernardo Luini was still alive and painting. Andrea Sansovino, best known by the splendid tombs in Sta. Maria del Popolo at Rome, was still alive in 1525, but near his end. Jacopo Sansovino, rather architect than sculptor, had still the divine gift of form in sculpture. Michelangelo was still to complete the Medici tombs at San Lorenzo. Benedetto da Rovezzano had taken his splendid talent to England; and both there and in Florence has left beautiful work behind him.

The Venetian Painters.—In 1525 Giorgione was dead. Titian was nearly fifty years old and in the fullness of his strength. Of the other giants Tintoretto was a boy, and Paolo Veronese unborn; but in Venice the conditions which obtained elsewhere were of no force. Venice was hardly an Italian city, but a little world by itself, poised between the East and the West. Decay did not set in there till much later than in the center. See the notices of the painters named above; also BELLINI and TIEPOLO.

In other Countries.—The descriptive term Renaissance hardly applies to the work of the painters and sculptors elsewhere than in Italy. The art work in France, Spain, Belgium, Germany, Holland, and England is rather a con-

tinuation of the mediæval schools of those countries until long after the Renaissance had run its course in Italy. Some exceptions to this rule exist, in France especially (see below), but in general it is true that the great Spaniards or Dutch or Flemings belong to the seventeenth century, or a later date, and to the history of modern painting and sculpture.

Architecture.

Under this heading it is proposed to consider architecture from the revival of learning to the beginning of the present era. Gothic architecture in Italy had been more or less a foreign style, used by the Cistercian and Franciscan monks in the thirteenth century, and followed, but not closely, by the Venetians, the Florentines, and generally throughout Italy in the fourteenth. Its system of construction, upon which it depends, indeed, and from which it arose, had never been adopted by the Italians with complete unreserve; it is indeed rather as a form given to openings and porches, and a certain freedom allowed to columns and other details than as a complete style that the Italian Gothic appears in the history of architecture. Round arches were never given up altogether, nor low-pitched roofs at all, nor broad, unbroken surfaces of wall, nor the use of surface decoration in large masses, nor marble sheathing and delicately worked sculpture in marble. Therefore when Brunelleschi, a sculptor and—like other sculptors of his time—a planner and designer of buildings, came back from Rome about 1407, and it appeared that he had been studying there the ancient monuments, then much less defaced than they now are, and that he meant to build in the spirit of ancient work, he had a less completely new doctrine to preach than would have been the case in the north. Round arches springing from simple and massive piers had been used with splendid effect by Orcagna and others, as, for instance, in the Loggia dei Lanzi, begun and its character determined probably about 1360. The smooth, large, easy-flowing lines of this noble structure, which yet preserves in its details much of the character of Florentine mediæval work, must have pointed to a gradual transition from Gothic, as the Italians understood it to be a kind of design which should be classical in feeling and made up of classical details, but not without a certain mediæval freedom. The Cathedral of Florence stood with its roof unfinished and the great octagon open to the sky. This great space, larger than that covered by any dome of masonry in Europe except the Pantheon, whose dome is low and hidden in the walls, Brunelleschi, about 1425, covered with the splendid cupola which still crowns Florence; light and high, culminating in a temple-like finial which alone is over 80 feet in vertical dimension, it is a thing as unlike anything Roman as it could well be, and yet a great step toward the Roman largeness of parts and simplicity of construction. So his first church, San Lorenzo, in Florence, begun about 1440, has the un-Roman device of arches springing from isolated columns. There are, indeed, suggestions of a classical entablature crowning each capital, but so reduced in comparative size as to seem a mere doubling of the abacus. The fine interior of Santo Spirito, a later design, preserves the same peculiarities. It is back to the fifth or to the tenth century, to the latest monuments of the dying empire, or else to the Christian basilicas, that Brunelleschi looked, not to the buildings of Augustus or of Hadrian. In like manner the Pitti Palace, begun about 1435, shows not one feature which any Roman building could ever have possessed. If it is so with Brunelleschi, the master, the originator so far as we can judge of the movement toward a classical revival, it is equally so with his great rivals. Michelozzo Michelozzi began the Medicean Palace, which is now called Riccardi, about 1430, and this is as un-Roman as the Pitti. Even Alberti built the exquisite but half mediæval front of Sta. Maria Novella, beginning it probably as late as 1460. In Venice the lovely Church of the Madonna dei Miracoli was built about 1480 by Pietro Lombardo; and the palace called the Casa Dario, on the Grand Canal, and one called Trevisan, or the house of Bianca Capello, behind the Ducal Palace, and the long stretch of the Procuratie Vecchie on the north side of the great square of St. Mark, were all built or begun before 1490; there is nothing Roman in these except a distant reference to antiquity in their details.

There was also, however, a deliberate and conscious attempt to design as the ancients designed, and because they did so. Alberti aided powerfully in this direction, for he was a scholar first of all and an antiquarian by nature. Brunelleschi was content to use classical details, a general classical character and spirit of design, but Alberti deliberately took a Roman triumphal arch as a model for the distribution of a church front. This he did as early as 1446, when the façade of the church at Rimini was begun, and this he repeated as late as 1470 or 1471, when work was begun upon S. Andrea at Mantua. This latter building, indeed, is wholly Roman in the combination of its parts. True, no structure could have been known to Alberti in which pilasters were used throughout as the main feature of the decoration, but it was easy to deduce this use of them from the Colosseum or the baths of Diocletian. True, no Roman building could have given him an example of large windows forming a vital part of the design, but it was his business to provide the large windows which were necessary, and still to keep a Roman look. So it seems that S. Andrea is conceived as an answer to this problem: How would a Roman architect of the second century have designed a building made up of long and narrow halls one story high, with windows, and without the large free columns which the Romans used freely, but which there were neither mechanical nor pecuniary means to provide at Mantua? It may be thought that nothing could have been more unfortunate for the future of art than the eager interest in this problem, taken by Italy at first and then by the rest of Europe; but it is sure that from this time on the study of Roman architecture, not merely for its suggestions but as a whole to be imitated, went on side by side with the fresh and original growth of the Renaissance architecture. Such graceful, simple, unimitative designs as the front of San Zaccharia at Venice, by Antonio di Marco, about 1456, of the Church of the Madonna dei Miracoli at Venice, about 1481, by Pietro Lombardo, and of the Palazzo del Consiglio at Verona, probably by Fra Giocondo (1430 or 1435–1529), and built during the closing years of the century, are the real glory of the Renaissance. Unluckily Fra Giocondo, one of the masters of graceful and original treatment of all kinds of unusual problems, was instrumental in the Roman decadence. He is said to have discovered at Paris a manuscript of Vitruvius more complete than had been known before; at all events, he had to do with editions of that author's work, *De Architectura*, supposed to be more complete and more critical than previous ones, and in this way did what he could to enchain architectural practice by half-understood rules arbitrarily laid down by a single writer of the Augustan age. The *Classicismo*, or classical revival, came in with the new century, or with the second decade of it. At all events, the Italian Renaissance in architecture passed away with all its charm and variety, and may almost be said to have died with the beginning of the new Church of St. Peter on the Vatican Hill.

Meantime in France the late Gothic, a style developed naturally out of the Gothic proper of the thirteenth century, was doing wonders—it is Gothic with Gothic sculpture. Not to mention earlier buildings, the magnificent Church of S. Wulfran of Abbeville was not begun until 1488, a half century after Brunelleschi's beginnings in Florence. The Church of St. Riquier, near Abbeville, is later still; the Hôtel de Cluny, in Paris, was not begun until 1490; the central and finest part of the Palais de Justice, at Rouen, was not begun until the last year of the century; the Church of Brou, at Bourg-en-Bresse, was not begun until 1505. In England fan-vaulting, the finest thing ever done in architecture in the British Isles, was in its glory at this time; the roofs of St. George's chapel at Windsor, Henry VII.'s chapel at Westminster, and, chief of all, King's College chapel at Cambridge, were all under construction in that same year, 1505. But it is also true that when Louis XII. came to the throne of France in 1498 there was already a spirit of longing after the classic splendors of Italy, half seen and half understood by the lords who had followed Charles VIII. in his expedition to Naples. In that year or the next work began upon the new Château of Amboise, and the designs for the lost Château of Gaillon, of which fragments decorate the court of the École des Beaux-Arts in Paris, must have been under consideration as early as 1500. There are sixty years between the beginnings of the architectural Renaissance in Italy and in France. There are perhaps eighty years between the firm establishment of the new style in the two countries, because in France the new style found an old one firmly intrenched, while no such thing is true of Italy, in spite of the charm of some Italian Gothic monuments of late date. The time of the early Renaissance in France, and of its final dawn in Germany and England, is a time of fatigued and self-conscious decay in

Italy, partly because of war and political decline, but partly also because of the substitution of a style of architecture made up of rules and fixed measurements for the fresh inspiration of the earlier time. Thus in the year 1535 the full classical style is embodied in perhaps its loveliest creation, the Library of St. Mark in Venice, and the Renaissance makes its farewell in the front of the Scuola di San Rocco. In that same year Francis I. was surrounded by his Italian and French artists and artisans, and they were still feeling their way with hesitating steps. The Château of Chambord was well advanced but far from completion, and so with Francis's own wing of the Château of Blois, but the new Louvre had not been begun. In Germany and in England the introduction of classical details had hardly begun, and not the least impression had been made upon the general character of the over-picturesque, gabled, and turreted character of the continental art, or of the prosaic Tudor style of England.

The full charm of the Renaissance continued in France through the reigns of Francis I. and Henry II., 1515–59. Then with the religious wars of succeeding reigns comparatively little was done. The style of Henry IV. succeeds, and the French writers are careful not to include that epoch in the Renaissance. If, however, we take the years 1600–10 as the reign, which it is, for our purpose, we find still the most marked difference in the character of the buildings in Italy and in the north. The very "orders," as understood by Henry's architects in Paris, are plastic, modified almost at will; and in Germany, where Ionic or Corinthian columns are seen at all, they are generally small colonnettes, decorating the bold bay windows and stepped gables of a style as picturesque and diversified as that of the Middle Ages. Meantime, in Italy, St. Peter's was being pushed toward completion; in fact, the great colonnade of the front was nearly complete in 1610. Palladio, chief of all classicists, had died in 1580, and all his designs which remain to us had been completed as we have them before 1600. The reign of formality was complete in Italy for nearly a century before it had much hold upon the north.

Buildings in the true classical spirit were built under Louis XIII., such as the wing of Gaston of Orleans at the Château of Blois. It was not, however, until the middle of the seventeenth century that the grandiose and formal style of Louis XIV. finally replaced the French Renaissance. The colonnade of the Louvre was begun in 1664. Before that time the country châteaux and the buildings in provincial cities kept much of the movement and variety of the sixteenth century. The colonnade of the Louvre, the Church of the Invalides, with its noble dome, and the colossal Château of Versailles, in which everything, even the chapel, was of a grandiose, pseudo-Roman type, finished the struggle. From that time the Roman style prevailed, even in Eastern Germany and in England. St. Paul's in London was begun in its present form about 1675.

The architectural style of the seventeenth century toward its close certainly sins on the side of coldness and formality. A singular result of this was the Barocco style which was so soon to follow—perhaps a natural and inevitable reaction. Germany, whose princes had tried to follow Louis XIV. and to build small imitations of Versailles, found the chilly grandeur of that style insupportable, and eagerly took up the novel variety and play of fancy, however insubordinate. The Zwinger Palace at Dresden is one of the earlier instances of this new taste; but that seems to have been thought extravagant. So fantastic a style in cut stone and out-of-doors was too much even for that period of doubtful taste. A better type, and one of the best instances of the developed Barocco style, is the Schloss of Brühl, near Bonn on the Rhine, begun about 1725. Here the exterior is stately and grave, with a "colossal order" of pilasters—that is, an order occupying the whole height of the main wall and including several stories. The smaller details indeed may be rather riotous, and the roof intemperate in curvature, but the full fancy of the designers is kept for the interior, where scroll-work and *rocaille* flourish in their fullest development. The Schloss at Bruchsal, near Heidelberg, is another such building, built about 1741, while the Brühl building was still incomplete. To find in France instances so characteristic of the Barocco style, it seems necessary to examine, for interiors, the Hôtel de Soubise (now the Archives Nationales) and the Hôtel de Toulouse (now the Bank of France). Something of the original exterior remains also in these buildings, but perhaps the great barrack called still the Military School, fronting on the Champ de Mars, and the Château of Compiègne, N. E. of Paris, are the best exteriors of the time. These are both the work of an architect of exceptional ability and good taste, Jaques Ange Gabriel (1699–1782). It is to be noticed that in such an epoch of careful reference to authority and submission to generally admitted rules stately buildings will be erected in the spirit of a previous epoch in spite of a more corrupt taste prevailing in minor arts. Thus in England the Cambridge University senate house, built in 1730, and the Ratcliffe Library at Oxford a little later, each by James Gibbs (1674–1754), are wholly admirable as pieces of design in a style which admits of but little originality. They are worthy to be compared, as to their exterior, with the French buildings of Gabriel, above named. It is in the interior fittings that the style alternates between unrestrained license and cold monotony. In the minor buildings of the time the same bad influence is at work, the only architectural feature recognized as noble being the colonnade or the order of pilasters, with their high plain basement beneath. Buildings which could not have these costly decorations were left with flat walls and square openings evenly spaced. The often complained of monotony of Baker Street and Regent Street in London came, not from the Renaissance proper, but from its unhappy successor, the grandiose Roman revival, begun in Italy in the seventeenth century.

Some attempt at a reaction was made under Louis XVI. Jaques Germain Soufflot (1714 or 1709–80) built the Church of St. Geneviève, or Panthéon, all but the cupola. Pierre Rousseau (b. 1750) built in 1786, for a private residence, the Hôtel of the Legion of Honor on the Quai d'Orsay. In these and in other structures of the time an originality of conception is shown foreign to the previous epoch of a hundred years or more. As under Louis XVI. a new spirit of refined and delicate design is seen in furniture and ornament, so in the most important buildings of the time were the evidences of perhaps a new Renaissance, a return to reason and thought as a substitute for obedience to authority. The great French Revolution put an end to this.

Modern Architecture.—In all the previous sketch it has been possible to speak of the style prevalent at any given time as universally and in all cases the same. At no time does any one builder deviate from the style used by others except as he makes slight modifications, which, at once adopted by others, who in their turn add and alter a little at a time, end in the slow development of the style of the succeeding epoch. In the present era, beginning with the end of the Napoleonic wars in 1815, we face a wholly new condition of things, a condition which had never existed before in all history. From 1815 until 1894 architects have built classical buildings with huge rows of columns, as their fathers or grandfathers had done; Renaissance buildings with delicate details like those of the fifteenth or sixteenth century; Gothic buildings copied from those of the thirteenth or of the fifteenth century; Romanesque buildings studied after models of the eleventh or twelfth century; buildings supposed to be Greek, and copied from the Parthenon; and even Egyptian or Moorish attempts at novelty. It is important to understand how completely this chaos of styles, existing in the absence of any reigning style, differs from all previous experience. Probably no architectural progress can be made under these conditions. Larger and more elegant buildings may be built, and now and then a pleasing result may follow in the way of an archæological study of some ancient structure or group of structures, but that can not be the beginning of a fine art of architecture.

Bibliography.—There are few works on this subject in English. Fergusson's *History of Modern Architecture* is of very little value in this respect. Walter Pater's *The Renaissance* (3d ed. 1888, a series of essays) is very valuable for its truthful insight, and is a suggestive book. J. A. Symonds's *Renaissance in Italy* (vol. iii.) is devoted to the fine arts and gives much general information, but the point of view is that of a literary man having little sense of the true nature of the graphic and plastic arts. The work of Crowe and Cavalcaselle on painting in Italy (9 vols., under different titles), is wholly confined to the period of the Renaissance, although not so announced. This is true also of Charles Perkin's *Tuscan Sculptors* and *Italian Sculptors*, and his smaller and comprehensive work, *Historical Handbook of Italian Sculpture*; but these works do not give the results of late researches, and their statements as to minor matters of fact are not always trustworthy. The same author wrote a sketch of *Sepulchral Monuments in Italy* for a publication of the Arundel Society. Mark Pattison's *The*

Renaissance of Art in France may be consulted, and there are translations of some of the following works, viz.: In the Quantin *Bibliothèque de l'Enseignement des Beaux-Arts* the volumes on *Les Styles Français*, by Lechevallier-Chevignard, and on *L'Architecture de la Renaissance*, by Léon Palustre. By this last-named author, *La Renaissance en France* (3 vols., 1879–89, out of a proposed series of twenty or more). Eugène Müntz, *Les Précurseurs de la Renaissance en Italie*, and *Histoire de l'Art pendant la Renaissance* (vols. i. and ii.); Charles Yriarte, *Un Condottière au Quinzième Siècle: Rimini*; Émile Gebhart, *Origines de la Renaissance en Italie*; Le Comte de Laborde, *La Renaissance des Arts à la Cour de France*. There are also books of plates, such as Fritsch's *Deutsche Renaissance*, and works on the general history of architecture; also monographs of special towns and buildings. RUSSELL STURGIS.

Renal Diseases [*renal* is viâ O. Fr. from Lat. *renalis*, pertaining to the kidneys, from *renes*, kidneys]: diseases of the kidneys. The chief of these are CALCULUS, or stone in the kidney, DIABETES, and BRIGHT'S DISEASE, sometimes called nephritis or inflammation of the kidneys, of which many forms exist. See the separate titles.

Renan, re-năn', JOSEPH ERNEST: philologist and historian; b. at Tréguier, Brittany, Feb. 27, 1823. He was destined for the Church, and at the age of sixteen went to Paris to study. At the Seminary of Saint-Sulpice his taste and talent for languages showed themselves, and his opinions and beliefs were so changed that he felt compelled to renounce the priesthood, and devoted himself to private teaching and study. He became familiar with German, and was much influenced by the methods and results of German historical criticism. In 1848 he received the Volney prize for a monograph on the Semitic languages, and was again honored by the Institute soon after for his essay *Étude de la langue grecque au moyen âge*. In 1849 he was sent on a literary mission to Italy, and collected the materials for his doctor's thesis, *Averroès et l'averroïsme* (1852). In 1851 he was appointed to the MS. department of the Bibliothèque Nationale, and in 1856 succeeded Augustin Thierry in the Académie des Inscriptions. In 1860 he was sent on a scientific mission to Syria, and in 1862 was appointed to the chair of Hebrew of the Collège de France, but the demonstration made at his opening lecture was so violent that he did not continue his course, and was removed the following year, after the appearance of his most famous work, *La vie de Jésus*, which drew upon him the attacks of the orthodox churchmen. He was reappointed to his chair in 1870. In 1872 he revisited Italy. He was chosen to the Academy in 1878, and his speech at his reception caused such highly excited comment in Germany by its political allusions that he thought it worth while to explain his meaning in a *Lettre à un ami d'Allemagne*. In 1880 he delivered in London the Hibbert lectures upon *The Influence of Rome on Christianity*. His attempts to enter the political field in 1869 and 1876 were unsuccessful. In 1873 he was chosen administrator of the Collège de France, and continued to be re-elected till his death, in Paris, Oct. 2, 1892. His chief subjects of study were the Semitic languages and the antecedents and beginnings of Christianity, and in reaching his results the methods of severe historical criticism are supplemented by a vivid and sympathetic imagination. He touched also many other fields, and his influence upon the world of ideas of his time was immense, especially with the younger generation, partly in virtue of the subtle charm of his style. His works include *Histoire générale des langues sémitiques* (1856); the translations **Job* (1859), **Cantique des Cantiques* (1860), *Ecclésiaste* (1881); **L'Histoire des origines du Christianisme*, comprising the *Vie de Jésus* (1863), *Les Apôtres* (1866), *Saint-Paul* (1867), *L'Antechrist* (1873), *Les Évangiles* (1877), *L'Église chrétienne* (1879), *Marc-Aurèle* (1881); **L'Histoire du peuple d'Israël* (3 vols., 1887–89; vol. iv., posthumous, 1893); the collected essays **Études d'histoire religieuse* (1857), *Essais de morale et de critique* (1859), *Questions contemporaines* (1868), *Mélanges d'histoire et voyages* (1878), **Nouvelles études d'histoire religieuse* (1884), *Discours et conférences* (1887); the philosophical dramas, *Caliban*, *L'Eau de Jouvence*, *Le Prêtre de Némi*, *Dialogue des morts*, *L'Abbesse de Jouarre*, and *Le Jour de l'an 1886*; the personal recollections, **Souvenirs d'enfance et de jeunesse* (1883) and *Feuilles détachées* (1892). Consult G. Monod, *Les Maîtres de l'histoire* (Paris, 1894); P. Bourget, *Essais de psychologie contemporaine* (Paris, 1883). A. G. CANFIELD.

* These works have been translated into English.

Rendel, Sir ALEXANDER MEADOWS, K. C. I. E., M. I. C. E.: civil engineer; b. in England, 1829; educated at King's School, Canterbury, and Trinity College, Cambridge; studied engineering with his father, at whose death, in 1856, he took his place as engineer to the London Dock Company, the Leith Harbor and Dock Company, and the East Indian Railway Company; has built numerous docks, etc., in England, bridges, railways, etc., in India, and is consulting engineer to the Secretary of State for India, and for various Indian railways operating 9,000 miles of road. W. R. HUTTON.

Rendel, GEORGE WHITWICK: civil engineer; b. in England, 1832; educated at Harrow and in the office of his father, James M. Rendel; assistant on the construction of the Ganges and Jumna bridges in India; in 1858 joined the Armstrong firm, was manager of the ordnance department; designed and constructed hydraulic machinery for heavy guns; designed the Chilian cruiser Esmeralda; member of committee to decide the types of British ships of war, and others. From 1882 to 1885 he was a civil lord of the Admiralty. He has received both the Watt and the Telford medals from the Institution of Civil Engineers, of which he has been a member since 1863. W. R. HUTTON.

René, re-nā', (or **Renatus**) **I.**, Count of Provence, Duke of Anjou: titular King of Naples; b. at Angers, Jan. 16, 1409; the second son of Louis of Anjou and Yolande of Aragon. Having married Isabelle of Lorraine, he laid claim to this country after the death of her father, Duke Charles, in 1431, but was opposed by a nephew of Charles, the Count of Vaudemont; was captured and imprisoned for several years. In 1434 his elder brother, Louis III., who had been in actual possession of the throne of Naples, died and left to him Provence, Anjou, Naples, Sicily, and Jerusalem. In 1437 René succeeded in buying his liberty and the acknowledgment of his right to Lorraine for 400,000 pieces of gold, and he led an army to Naples, where his claims were disputed by the King of Aragon. He was unsuccessful, and in 1442 returned to Provence, gave up all his ambitious schemes, and confined himself to the improvement of his family estates. He encouraged agriculture, manufactures, literature, and art. His subjects gave him the surname *The Good*, poets and artists gathered at his court, and he was himself a successful cultivator of literature. There is an edition of his writings (*Œuvres du Roi René*) by Quatrebarbes (4 vols., Paris, 1845). The crown of Aragon was offered him, but he refused it for himself, and accepted it only for his son, who, however, died shortly after entering the country. At René's death (at Aix, July 10, 1480) most of his possessions fell to the French crown—Anjou, Bar, Maine, and Provence—his sons having all died before him. See de Lecoy de la Marche, *Le Roi René, sa Vie et ses Travaux* (Paris, 1875).

Renfrew: county of Scotland; bordering N. and W. on the Clyde. Area, 245 sq. miles; pop. (1901) 268,418. The western part is hilly and moorland; the eastern, level and very fertile. Coal and other useful minerals abound; manufactures are important. Renfrew (a royal burgh), 50 miles W. of Edinburgh, pop. (1891) 6,764, is the county-town. The chief towns are Paisley, Greenock, and Port Glasgow. The county sends two members to Parliament.

Reni, GUIDO: See GUIDO RENI.

Ren'nell, JAMES: geographer; b. near Chudleigh, Devonshire, England, Dec. 3, 1742; early entered the British navy, from which he passed to the service of the East India Company; was distinguished in the campaigns of Lord Clive: was for thirteen years employed in the surveys of Bengal, and the results of his work were included in the first approximately correct map of India; returned to England 1786, and devoted many years with his pen to laborious elucidation of geography, giving special attention to India, Africa, ocean currents, and ancient geography. The offshoot of the Gulf Stream turning N. in the Bay of Biscay bears his name. He published an atlas of Bengal (1781); a map of Hindustan with an elaborate *Memoir* (1783); *Elucidations of African Geography* (1793–98); *The Geographical System of Herodotus examined and explained* (1800); *Observations on the Topography of the Plain of Troy* (1814); *Illustrations of the Expedition of the Younger Cyrus* (1816); *Comparative Geography of Western Asia* (1831); and *Investigation of the Currents of the Atlantic Ocean* (1832). D. in London, Mar. 29, 1830. Revised by C. C. ADAMS.

Rennes, ren (the *Condate* of the *Redones*): formerly the capital of Brittany, now the capital of the department of

Ille-et-Vilaine, France; at the confluence of the Ille and Vilaine, 234 miles W. S. W. of Paris (see map of France, ref. 4–C). It consists of two parts—an upper or new town of an elegant and modern appearance, and a lower or old part, mostly built of wood, with narrow and winding streets; these are connected by four bridges. Among the public buildings are the cathedral (Italian), completed in 1844; Notre Dame, with a dome surmounted by an image of the Virgin; the university (1855), with a picture gallery; the hôtel de ville, with a public library; and the Palace of Justice (1618–54). It has manufactures of sailcloth, linen, lace, and embroideries, and an active trade in honey, wax, butter, and poultry. Pop. (1896) 69,937.

Rennet: See CHEESE (*Coagulating the Curd*).

Rennie, Sir JOHN, F. R. S.: engineer; b. in London, Aug. 30, 1794. His father, a distinguished civil engineer (1761–1821), early introduced him to that profession as assistant in the construction of Southwark and Waterloo bridges. In 1821 he succeeded his father as engineer to the admiralty. The new London bridge was completed by him, from designs of his father, in 1831, when he was knighted. The important works of Sheerness dockyard, Ramsgate harbor, and Plymouth breakwater, commenced by his father, were completed by him, as well as the great system of drainage and land reclamation in Lincolnshire. Of the more important works designed and executed by himself are the Whitehaven and the Cardiff docks. With his brother George (1791–1866) the machinery for the mints of Bombay, Calcutta, and Mexico was designed and erected; also the Royal Clarence victualing-yard at Plymouth. Sir John was considered the highest authority on all subjects connected with hydraulic engineering, harbors, canals, irrigation, storage of water, and the management of rivers. He was president of the Institution of Civil Engineers 1845–49; author of *The Theory, Formation, and Construction of British and Foreign Harbors*, and many valuable professional papers. D. Sept. 3, 1874.

Reno: city; capital of Washoe co., Nev.; on the Truckee river, and the Nev., Cal. and Or., the S. Pac., and the Virginia and Truckee railways; 11 miles E. of the base of the Sierra Nevada Mountains, and 51 miles N. W. of Virginia City (for location, see map of Nevada, ref. 5–E). It is in an agricultural and mining region, and has large trade interests. The city contains the State University of Nevada, the State prison, the Bishop Whitaker School for Girls (Protestant Episcopal, opened in 1876), a high school, 2 libraries (State University and Whitaker Hall), a national bank with capital of $200,000, a State bank with capital of $150,000, and 2 daily, a semi-monthly, and 2 weekly newspapers. Pop. (1880) 1,302; (1890) 3,563; (1900) 4,500.

Reno, JESSE LEE: soldier; b. at Wheeling, West Va., June 20, 1823; graduated from the U. S. Military Academy, and entered the army as brevet second lieutenant of ordnance July, 1846; captain 1860. In the war with Mexico he was engaged in the siege of Vera Cruz and in the battles of Cerro Gordo, Contreras, Churubusco, and Chapultepec, and breveted first lieutenant and captain for gallantry; subsequently served on duty with his corps, being in command of Mt. Vernon Arsenal, Alabama, at the time of its capture Jan., 1861; appointed brigadier-general of volunteers in Nov., 1861, he accompanied Burnside's expedition to North Carolina; was promoted to be major-general of volunteers July, 1862, and in August assigned to the command of the Ninth Army-corps, which he led in the second battle of Bull Run and at Chantilly, Aug. 29–Sept. 1. At the battle of South Mountain, while at the head of his command, he was killed Sept. 14, 1862. Revised by JAMES MERCUR.

Renouf, *re-noof'*, ÉMILE: genre, marine, and landscape painter; b. in Paris, June 23, 1845; pupil of Carolus Duran, of Boulanger, and of Lefebvre; second-class medal, Salon, 1880; first-class, Paris Exposition, 1889; first-class, Munich Exhibition, 1883; Legion of Honor 1889. He spent several years in the U. S., and had a studio in New York for the greater part of the time. A large picture by him of the East river bridge, taken from the Brooklyn side at sunset, was painted in New York in 1887–88, and attracted much attention when exhibited there. His *Helping Hand*, a representative work, is in the Corcoran Gallery, Washington. D. at Havre, May 6, 1894. W. A. C.

Renouf, PETER LE PAGE: Egyptologist and Orientalist; b. in the island of Guernsey in 1824; studied at Pembroke College, Oxford; became a member of the Roman Catholic Church in 1842, and in 1855 was appointed Professor of Ancient History and Oriental Languages in the Catholic University of Ireland at its first opening. While professor he was one of the editors of *Atlantis* and of *The Home and Foreign Review*. He was an inspector of schools 1864–85; Keeper of the Egyptian and Assyrian antiquities in the British Museum 1885–92. In 1887 he became president of the Society of Biblical Archæology. D. in London, Oct. 14, 1897. Besides some early works on questions concerning the Roman Church in England he wrote *The Condemnation of Pope Honorius* (1868), and *The Case of Pope Honorius Reconsidered with Reference to Recent Apologies* (1869). The former work met with strong ultramontane criticism, and was placed on the *Index*. His principal Egyptological works are as follows: *Notes on some Negative Particles of the Egyptian Language* (1862); *A Prayer from the Egyptian Ritual, Translated from the Hieroglyphic Text* (1862); *Sir G. C. Lewis on the Decipherment and Interpretation of Dead Languages* (1863), occasioned by an attack upon Champollion and others; *Miscellaneous Notes on Egyptian Philology* (1866); *Note on Egyptian Prepositions* (1874); *An Elementary Manual of the Egyptian Language* (1875); *Lectures on the Origin and Growth of Religion, as Illustrated by the Religion of Ancient Egypt* (Hibbert lectures, 1879); and *The Egyptian Book of the Dead: Translation and Commentary*, first printed in the *Proceedings* of the Society of Biblical Archæology (Mar., 1892, ff.), and afterward separately (London, 1893, ff.). He edited for the trustees of the British Museum *Ancient Egyptian Texts from the Coffin of Amamu* (1886), and *Facsimile of the Papyrus of Ani*, with an introduction to the contents of the Book of the Dead (1890). He also contributed to the *Chronicle*, *The North British Review*, *The Academy*, and the *Aegyptische Zeitschrift*. CHARLES R. GILLETT.

Reno'vo: borough (founded in 1862, incorporated in 1866); Clinton co., Pa.; on the west branch of the Susquehanna river, and on the Phila. and Erie division of the Penn. Railroad; 28 miles N. W. of Lock Haven, the county-seat (for location, see map of Pennsylvania, ref. 3–E). It was founded by the Philadelphia and Erie Railroad Company, which established here a large foundry and extensive boiler-works and car and repair shops. It is in an oval-shaped valley with mountain-sides over 1,000 feet high, and is the center of a great tract of pine forest. The principal industries are coal-mining and lumbering. The borough contains 7 churches, 14 public and 5 parochial schools, a railway Y. M. C. A., national bank with capital of $50,000, private bank, and a daily and 2 weekly newspapers, and is a popular summer and autumn resort for tourists and sportsmen. Pop. (1880) 3,708; (1890) 4,154; (1900) 4,082. EDITOR OF "EVENING NEWS."

Rensselaer, *ren'se-ler*: town; capital of Jasper co., Ind.; on the Iroquois river, and the Louis., New Albany and Chi. Railway; 72 miles S. E. of Chicago (for location, see map of Indiana, ref. 3–C). It is in an agricultural, dairying, and stock-raising region; contains a public high school, St. Joseph's Indian Normal School (Roman Catholic), a State bank, 3 private banks, and 3 weekly newspapers, and has manufactories of flour and cigars. Pop. (1880) 968; (1890) 1,455; (1900) 2,255.

Rensselaer Polytechnic Institute: See the Appendix.

Rent [from O. Fr. *rente*: Ital. *rendita*: Span. *renta* < Lat. **rendita*, re-formed on analogy of *vendita* (*vendere*) from *red'dita* (sc. *pecu'nia*), money paid, perf. partic. of *red'dere*, pay back]: a payment for the use of land. In feudal times this payment was made in labor. Toward the close of the Middle Ages labor rents were generally commuted, either for a share of the produce (see METAYER) or for a fixed sum of money per year. For some centuries these money rents were chiefly fixed by custom; in modern times they are usually fixed by competition. Rent, as ordinarily reckoned, involves compensation for the improvements as well as for the land. If we deduct interest on these improvements, we have the amount of rent in its economic sense. Thus if a man invests $10,000 in improving a piece of land, and then rents the property for $1,200 a year, part of this $1,200 is due not to the land, but to the capital invested; and we must deduct something like $500 in order to find the economic rent. Rent is partly due to productiveness, especially in the case of mines and water-power, but chiefly to advantages of location. Improved means of transportation, by lessening the effect of differences in location, tend to reduce rent—witness the fall in agricultural rents in Great Britain, due to the fact that the lower transportation rates enable the farmers of other countries to compete on more

and more even terms in supplying the British consumers with food. For an analysis of the causes which give rise to rent, see Political Economy. See also Single Tax.

A. T. Hadley.

Rent: in law, as defined by Blackstone, "a certain profit issuing yearly out of lands and tenements corporeal." In its original meaning in English law the term involved no notion of a money payment, but signified a right vested in the feudal lord to exact of his tenant certain military or other services as the price and condition of his tenure. These services were, in process of time, commuted into money values, and were discharged by the payment of stipulated sums of money, or of other property. In this sense of the term, rent, or the right to exact services, or the money value of services, from another, is itself a species of property. It is treated by the common law as belonging to the class of incorporeal interests in land akin to easements and profits. See Hereditaments (*Incorporeal hereditaments.*)

As such it may be created and granted in fee simple, in fee tail, for life or for years. When in fee it may be devised or transmitted by descent in the same manner as an estate of inheritance in the land itself. In England it is not uncommon for landed proprietors, by deed or will, to create such interests in their lands in favor of their minor children, the lands themselves, upon which the rents are charged, going to the eldest son; but in the U. S. rent, as a right of property vested in one not the owner of the soil, is almost unknown. In the U. S. the term is commonly used to denote the sum paid by a tenant for years, or at will, to his landlord as compensation for the possession and use of the leased premises. See Landlord and Tenant.

The older common law distinguished three classes of rent —rent-service, rent-charge, and rent-seck. *Rent-service* existed where the tenant, for the land held of his lord, owed the latter some corporeal service, at least that of fealty, as, for example, a holding by fealty and ten shillings annually, or a holding by plowing the lord's land and five shillings annually, the personal service, however slight, affecting the entire rent. The lord could always distrain for arrears "of common right," without reserving any special power of distress. Originally, where every conveyance of land might by subinfeudation create a relation of tenure between the vendor and vendee, any rent reserved by the former was a rent-service, and might be enforced by distress; but after the statute *Quia Emptores*, which abolished subinfeudation, no rent could have the character of a rent-service unless it was attendant upon the reversion of the lands out of which the rent issued. (See Landlord and Tenant.) At present the rent payable on an ordinary lease for years is a rent-service, the necessity for an actual personal service having long since been done away with. A *rent-charge* was one where the owner of the rent had no future interest or reversion in the land, but had the right to distrain for arrears expressly reserved or granted to him by the deed. A *rent-seek*, or barren rent, arose like a rent-charge, by grant or reservation in favor of one who had no future interest or reversion in the land; but in this case, the right to distrain not being expressly conferred, the owner of the rent had no means of enforcing his claim. These distinctions have lost most of their importance in England, in consequence of modern legislation giving the remedy of distress in all cases to enforce the payment of rent. In the U. S., on the other hand, distress has been very generally abolished by statute.

In Pennsylvania a variety of rent-charge is still preserved in constant use under the name of ground-rent—that is, when the grantor of land in fee reserves a perpetual pecuniary rent to himself and his heirs. It was an attempt to enforce rents of this sort which had been long deemed obsolete that brought about the "anti-rent" disturbance in Eastern New York 1839–47. In other States a ground-rent is simply the rent reserved by the lessor in a building lease, or one wherein the lessee covenants to erect a building upon the land, and which is therefore given in most instances for a considerable term of years.

Read also, on the general subject, Blackstone's *Commentaries* (book ii., chap. iii., 41–43); Taylor, *Landlord and Tenant*; Williams on *Real Property*. For the origin and early history of distress, see Maine's *Early History of Institutions*, chaps. ix. and x. George W. Kirchwey.

Repeating Circle: an astronomical instrument of observation. It involves the principle of repeating an angle several times continuously along its graduated limb, which consists of an entire circle. See Sextant.

Reph'aim [from Heb. *Rĕfrā'īm*]: a people whom biblical tradition supposes to have inhabited parts of Palestine prior to the invasion of the Hebrews (Gen. xv. 20; Josh. xvii. 15). They are represented as living around Bashan (Deut. iii. 11, 13) and in the country of the Ammonites (Deut. ii. 19, 20). A valley of the Rephaim is mentioned (Josh. xv. 8) which has been identified with the valley Bak'a, S. of Jerusalem (cf. Josephus, *Antiq.*, vii., 4, 1). In Deut. ii. 11 the Emīm are said to belong to Rephaim. The Rephaim are probably identical with the children of Rāphā (a supposititious ancestor), mentioned 2 Sam. xxi. and 1 Chron. xx., who with the children of Anak were regarded as giants by the popular fancy. Cf. Ed. Meyer, *Kritik der Berichte über die Eroberung Palästinas* in *Zeitschr. f. Alttest. Wissensch.*, 1881, p. 117; *Gesch. d. Alterthums*, i., § 179.

The same name is given to the shades of the nether world (Ps. lxxxviii. 11; Is. xxvi. 14), who dwell in Sheol (Prov. ix. 18; xxi. 16) and under the waters of the sea (Job xxvi. 5). At the last judgment the earth will give them forth again (Is. xxvi. 19). A similar belief seems to have prevailed among the Phœnicians, as we see from a mention of the Rephaim in the inscriptions of Tabnit and Eshmunazar. Cf. *Corpus. Inscript. Semit.*, vol. i., No. 2, 8; *Rev. Archéologique*, vol. x., p. 3. Richard Gottheil.

Reph'idim [from Heb. *Rephīdhīm*, liter., props, supports]: a locality in the Sinaitic peninsula, where the Israelites under Moses and Joshua gained a great victory over the Amalekites (Ex. xvii. 8, *seq.*). Its identification depends upon that of Sinai, in whose immediate neighborhood it was. If Serbal was the mountain of law, Rephidim must have been in the wady Feiran. If Sufsafeh was the mountain—which can hardly be questioned—Rephidim must have been in the wady es-Sheikh, at the pass called el-Watiyeh.

Replenisher: an instrument required in connection with the quadrant Electrometer (*q. v.*) in order to give a definite value to the potential. In the replenisher, as used in the case of Thomson's electrometer, there are two metal shields insulated with regard to each other by a piece of ebonite. One of these connects with the guard plate and the other with the case of the instrument, and so with the outer coating of the Leyden jar used. A vertical shaft which can be turned round by means of a milled head carries two metal flies at the extremities of a horizontal arm of vulcanite, and these flies, when about to pass out from under the shields, are touched by two platinum springs electrically connected and mounted on ebonite. Now suppose the flies to be in contact with the springs and one shield to be positively electrified, then by induction one fly will be electrified negatively and the other positively. Next let the vertical shaft be revolved; then the first fly carries off its negative charge and comes in contact with a spring connected with a shield, and yields up its charge by transfer to the outside of the shield. At the same time the other fly gives up its positive charge to the other shield. The result of a revolution of the shaft is therefore to increase the positive and negative charges on the shields respectively, or, in other words, increase the difference of potentials of the shields. Thus by giving a sufficient number of revolutions in the proper direction the potential can be raised or lowered. For further particulars, see the books mentioned in the article Electrometer.

Replevin [from O. Fr. *replevin*, deriv. of *replevir*, to warrant; pledge, give bail; *re-*, back + *plevir*, pledge, warrant]: an ancient common-law form of action brought to recover the possession of specific goods unlawfully taken by the defendant and belonging to the plaintiff, or to which the latter has present right of possession. Originally, as still in England (where the action is mostly used to recover goods unlawfully distrained for rent), replevin could be brought only to recover goods unlawfully taken and detained, Detinue (*q. v.*) being the proper action for unlawful detention of goods lawfully taken; but in most of the States of the U. S. the scope of the action has been enlarged so that it lies to recover all specific goods unlawfully detained, regardless of the manner of taking. In some States this action as such has been abolished, and a suit similar in its features, its objects, and its relief has been provided for by statute.

The plaintiff at the beginning of the suit, by furnishing to the proper officer (in England formerly the sheriff, now the registrar of the county; in the U. S. generally the sheriff) security that he will prosecute the suit and that he will restore the goods upon failure to recover judgment, has the right to procure the immediate seizure of the goods by the officer

and their delivery into his own possession. The plaintiff when successful, if the goods have remained in the defendant's custody, recovers their possession, or in default thereof their value (assessed by the jury), together with damages for the unlawful detention or taking. If he has taken them into his own custody his title is confirmed, and he recovers the damages alone, while a judgment in such case for the defendant restores the possession, or the value, and lays the foundation for a suit for damages by him against the plaintiff. The title to the goods is not tried unless it is necessary to the decision of the question as to who has the right of possession, nor can the title to the land be directly brought into question. Sir Henry Maine, in his *Early History of Institutions*, traces the origin of this remedy to the right of a tenant to recover goods unlawfully distrained by his landlord —a right that can be traced among the Saxons prior to the Conquest, and in some of the primitive Germanic codes. See Wells's *Law of Replevin as administered in the Courts of the United States and England*, and Sedgwick on the *Measure of Damages*. F. STURGES ALLEN.

Reports, Law: See LAW REPORTS.

Reposia'nus: a Latin poet, perhaps of the early fifth century, although commonly assigned to the reign of Diocletian. (See Eskuche, *Rheinisches Museum*, 45, 256.) His hexameter poem *De concubitu Martis et Veneris* may be found in Baehrens's *Poet. Lat. Minores*, vol. iv., p. 348. M. W.

Repoussé, re-pōō'sā' [Fr., liter., thrust back, perf. partic. of *repousser*; *re-*, back + *pousser*, push < Lat. *pulsare*]: a French term for the art of producing reliefs, and even rounded forms, in metal by beating thin plates from behind (Germ. *das treiben*; Eng. *embossing*). The metals employed are those that by their malleability lend themselves most easily to the work—gold and silver, brass, copper, tin, and lead. This is a very ancient art; the Egyptians, Cypriotes, and Etruscans practiced it, and specimens of their skill in the art are preserved. In the Middle Ages it was widely employed both in Europe and in the East, and it has continued in use down to our own times. Some splendid pieces of repoussé work were produced in Italy in the fifteenth century. These were chiefly for the decoration of altars and shrines and for use in the ceremonies of the Church. The art was in a flourishing state in Europe in the seventeenth and eighteenth centuries, but the design was artistically inferior to that of an earlier time. The art then fell into disuse for a time, but it has shared in the general revival of the arts, and is much in fashion. In Italy, France, Great Britain, and the U. S. much repoussé work is now produced, and, so far as mechanical excellence is concerned, American smiths are not behind the rest of the world. The results produced by this process are superficially similar to those attained by casting, but the effects are more artistic and free, and in the best work, whether of semi-barbarous or of civilized peoples, there is more individuality expressed than any casting could give. In the old repoussé work, the coarse as well as the fine, the relief is distinguished by softness of outline and the design has a look of spontaneity. The workman has used his tools as if they were the pencils of a painter or the dab-sticks of a modeler in clay. In the Castellani collection of antique jewelry exhibited at Philadelphia in 1876 were specimens of Etruscan repoussé work which, though small in size and minute in execution, had all the largeness of antique sculpture. These were extraordinary pieces, but much of the Japanese, Indian, Arabic, Persian, and Moorish work of modern times has the same quality, though more rudely manifested. The repoussé work of modern French, British, and American smiths is chiefly applied to gold and silver, and is distinguished by great sharpness and decision of line, so that the work is scarcely to be told from casting. See METAL-WORK.

Representation: in the political sense of the term, the method of transmitting the will of the people into law or action by means of a few persons chosen by the people.

In the ancient city democracies the people made their own laws. When different states took part in government, as in the Achæan League, any citizen had, as a general rule, the right to appear, and representatives in the modern sense were not chosen, though of course the persons present from any state had authority to bind their constituents.

There seem to have been, however, certain instances of real representation in ancient times, as in provincial councils summoned by Augustus and in city leagues in Asia Minor. From very early times the Church employed the principle, and probably this had influence in determining its use among western nations. It first came into general political use among the Germanic nations, and has had its fullest development in Great Britain and the U. S. Representative democracy, the system of government that relies solely upon representation, as Bluntschli says, developed in the North American colonies and the U. S., where the causes of its development are to be found especially in the character of the people and in the extent of the territory that necessitated representation if free government were to exist. The representative system, however, is found fully developed in nearly all civilized modern states, whether republics, as France and Switzerland, or monarchies, as Germany, Austria, Italy. In the monarchies usually some check is placed upon the representative body by an hereditary or appointed upper house, as in Great Britain and Germany, and sometimes the monarch even is able to exert much power in this direction. See LEGISLATURES and LAW-MAKING, METHODS OF.

Nature of Constituencies.—Generally speaking, in the U. S., in France, in the German empire, and in some other countries, the constituencies are divided territorially, each representative being voted for by all classes of voters resident in his district. A system of class constituencies is in vogue, however, in some countries; for the classification of electors in Prussia, see LEGISLATURES (*Composition*). In local representative bodies in Austria members are elected by the great landed estates, by the most highly taxed industries and trades, by the towns and markets, by the rural communes, by boards of commerce, or trade-guilds. Somewhat similar constituencies are found in rural local government in Prussia. Even in England constituencies have been so divided as to separate cities from the rural districts, and economic conditions have divided constituencies in practice even more accurately than that.

Relation of the Representative to his Constituency.—Of grave import, both theoretically and practically, is the question whether a representative is to act merely as the mouthpiece of his constituency, blindly preferring its interest as its members see that interest, or whether he is to act with independent judgment, preferring the interests of the whole country to that of his constituency in case of conflict. Most writers adopt the latter theory as the right one from the standpoint of political science. In practice, however, representatives as a rule wish a re-election; and in consequence the expressed or understood wishes of their constituencies are likely to determine their votes. Indeed, some representatives have openly confessed that they were voting contrary to their own opinion of what was best for the country in deference to the wishes of their constituencies. This is apt to be oftener the case when the member represents a certain economic or social class than when his constituency includes all voters within a certain geographical district. If in general, however, the constituency determines the vote, the special advantage of the representative system—action by trained men after careful debate and consideration—would be lost, and the system might as well be abolished and the compulsory referendum introduced instead. On the other hand, it may be argued that the people's interests will be best guarded if the people instruct the representatives how to vote, as each person cares most for his own interests. Nevertheless, the desire for re-election will usually give the representative sufficient interest in conforming to the wishes of his constituents. The superior educational effect upon the constituencies of carefully deliberating upon specific measures so as either to vote themselves or to instruct their representative, instead of simply making a choice between two or three candidates, can not be doubted, but is probably too small to outweigh the disadvantages mentioned.

Majority versus Minority or Proportional Representation.—In most countries members of representative bodies are elected each in a single territorial district, or when elected in larger districts, as earlier in France by the *scrutin de liste*, all members of each party are put on the same ticket, so that the majority of voters are likely to secure all the representatives and to leave the minority unrepresented. For example, in 1892, the Congressional vote of Iowa stood as follows: Republican, 219,215; Democratic, 201,923; Prohibition, 6,602; People's, 13,633. These votes elected ten Republicans and one Democrat, whereas a fair division, according to the relative strength of the parties, would have elected six Republicans and five Democrats. Likewise, in Kentucky, in 1894, 122,308 Republican votes, 179,359 Democratic, 1,559 Prohibition, and 23,735 People's elected one Republican and ten Democrats, instead of four Republicans and six Democrats, as would have been just. In Maine, 1894, with 65,637 Re-

publican and 55,778 Democratic votes cast, all four Congressmen were Republican, whereas in Maryland, with 91,762 Republican and 113,932 Democratic votes cast, all six Congressmen were Democrats. In both cases the votes were so nearly equal that the delegation should have been divided equally. Inasmuch as laws are passed by a majority vote of the representatives elected, it often happens that representatives of but little more than one-fourth the voters pass laws. In Switzerland, where bills passed may, on petition, be submitted to the people, it has happened more than once that a bill passed by a small majority in the Legislature has been rejected on the referendum by nearly a three-fourths vote, thus proving that the majority of the Legislature was not in harmony with the people.

To remedy these evils various plans for securing proportional representation to minorities have been proposed, of which only four will be mentioned: 1. The "limited vote." Under the English Reform Act of 1867 this plan was adopted as follows: "At a contested election for a county or borough represented by three members, no person shall vote for more than two candidates." So in New York in selecting members at large for the Constitutional convention of 1867 no voter was allowed more than sixteen votes, there being thirty-two members to be chosen. A similar plan has worked well in Pennsylvania in choosing judges for the Supreme Court, county commissioners, county auditors, and inspectors of elections—all to be elected in groups of three. 2. The "free vote" is applied in Illinois in the election of members of the lower house of the Legislature, in accordance with the Constitution of 1870. The part of the section regarding this is as follows: "Three representatives shall be elected in each senatorial district at the general election in 1872, and every two years thereafter. In all elections of representatives aforesaid each qualified voter may cast as many votes for one candidate as there are representatives to be elected, or may distribute the same, or equal parts thereof, among the candidates, as he shall see fit, and the candidates highest in vote shall be declared elected." Under this provision, by concentrating their votes upon one candidate, a large minority may secure representation. 3. The "Hare system," sometimes called the Andrae system because it was introduced by Andrae into Denmark before Hare proposed it in England. Under this system the quotient obtained by dividing the total number of votes cast by the number of places to be filled gives the quota needed to elect a candidate. Each voter casts a ballot containing the names of as many candidates as he pleases, the names numbered in the order of his preference. As the ballots are taken from the box each is credited to the name indicated as first choice. If the electoral quota has already been secured for this first name, the ballot is credited to the second choice, and so on till all the full quotas have been ascertained. The largest fractions of quotas then elect. Under this system few votes are wasted. The chief objections to it are its relative complexity, and the element of chance that enters in counting the second choice. Many voters may have the same first choice, but differ on second choice. In that case the election might be determined by the order in which the ballots were counted on first choice. This system, too, seems to favor voting for individuals regardless of parties more than does any other system, hence is not favored by politicians. It is apt to be the favorite system among advocates of minority representation. 4. The "free-list" system is in use in four cantons of Switzerland—Ticino, Neuchâtel, Geneva, Zug—and seems to give excellent satisfaction. Under it any body of voters large enough to be entitled to nominate candidates may nominate as many as it sees fit up to the whole number of places to be filled. In the election each voter may cast as many votes as there are members to be elected, distributing them as he will among the candidates, but casting no more than one vote for any candidate. The quota of representation is found by dividing the total vote cast by the number of places to be filled. The total vote cast by each party divided by this quota gives the number of representatives to which each party is entitled. Should there not be enough full quotas to elect the whole number, the required number shall be filled from those parties having the largest fractional quotas. Candidates in each party shall be taken in order of their standing on their respective tickets. This system gives representation to parties in fair proportion, and has stood the test of experience.

Representers: a Scottish controversial designation used about 1722. See PRESBYTERIAN CHURCH (*Some of the Existing Presbyterian Churches*).

Reprisals: See INTERNATIONAL LAW.

Reproduction: in biology, that phenomenon in which a portion of any animal or any plant separates from the rest and eventually develops into a form essentially similar to that which gave it origin. It must be observed that there is no interruption in the continuity of life; no new life is created; the process is rather, as it has aptly been termed, discontinuous growth. Reproduction is of two kinds, sexual and asexual. In the higher forms of animals, as in those of plants, the distinction between these two is strongly marked, but in the simpler types the line is not sharply drawn.

Sexual reproduction in its simplest expression merely calls for the union of two separate cells as a prerequisite for the formation of new individuals, and these uniting cells may be, so far as microscopic analysis shows, exactly similar; and, further, they may compose the entire parent organisms. We here have a case of sexuality without any differentiation of the sexes. In the animal kingdom examples may be instanced in the Infusoria. In all other forms, however, there is a differentiation of the sexes and of the reproductive cells. In animals the male reproductive element is called the spermatozoön, the female the egg, and the union of these two (impregnation) results in the formation of a germ capable of development. In exceptional cases, however (see PARTHENOGENESIS), the egg develops without union with the male cell. For an outline of the processes of development following impregnation the reader is referred to the article EMBRYOLOGY. In general the fertilized egg divides up into several or many cells; in the lower forms (Protozoa) each of these becomes by simple growth an adult, while in the other groups the whole of the resulting cells are required to make a single form like that with which the cycle had its origin.

Asexual reproduction is accomplished without such union of sexual cells. Most of the various modifications of the process may be arranged in two categories—fission and budding. In fission the organism directly divides into two or more distinct individuals. Sometimes the division is incomplete, the new individuals remaining connected to a greater or less extent, and thus "colonies," as among the corals, may result. In budding, found in animals only in the lower forms, a small portion of the organism is differentiated, and this, whether detached or remaining connected with the parent, subsequently becomes developed into the original form.

For the sexual reproduction of animals the most valuable text-books are Balfour's *Comparative Embryology* (1880–81); Haddon's *Embryology* (1889); Korschelt and Heider, *Lehrbuch der vergleichenden Entwicklungsgeschichte der wirbellosen Thiere* (1890–93); Marshall, *Vertebrate Embryology* (1893); Hertwig, *Text-book of Embryology* (translated by Mark, 1892); Minot, *Human Embryology* (1892, containing much on all groups of vertebrates). J. S. KINGSLEY.

Reproduction (in plants): the processes by which plants perpetuate their kind. In single-celled plants every cell is capable of producing new plants. The same is true of some few-celled plants. Reproduction is here one of the functions of every cell. With the increase in complexity of the plant-body this function is more and more restricted to certain cells and aggregations of cells. We can thus speak of reproductive cells as distinct from vegetative cells, and finally of the reproductive organs in contrast with the vegetative organs of the plant.

Broadly speaking, there are two general ways by which plants are reproduced. In the first, a cell or a mass of cells may become detached and grow into a new plant, as in the common cases of the production and development of zoöspores in many aquatic plants, of conidia among fungi, and of brood-cells and brood-masses (*gemmæ*) among liverworts and mosses. The case is essentially the same where true buds and even branches separate from the parent plant, as

in the bulblets in the axils of the leaves of some lilies, and in the inflorescences of some onions, the runners of strawberries, the trailing runner-like stems of buffalo-grass, the tubers of many plants, as the potato, and perhaps the spontaneously deciduous twigs of cottonwoods and some willows. In all these cases the essential feature is the separation from the parent plant of one or more living cells, which continue to grow, eventually producing a plant like the parent. We go but a step further when we purposely cut off portions of plants, which are then grown as cuttings by being placed in moist earth. Even the familiar operations of grafting and budding are essentially those of asexual reproduction (Figs. 1 and 2).

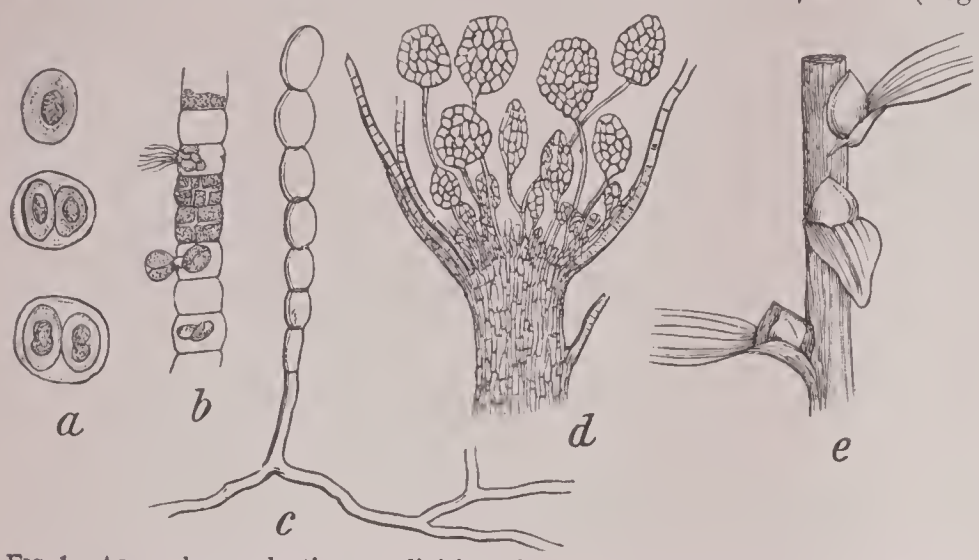

FIG. 1.—Asexual reproduction: *a*, division of *Glœocapsa*; *b*, formation of zoöspores of *Ulothrix*; *c*, conidia of *Podosphœra*; *d*, brood-masses of a moss; *e*, bulblets of lily.

In marked contrast to the foregoing are the various modifications of the sexual reproductive process, in which the essential feature is the union of two cells in the formation of the first cell of the new plant. In the simplest cases two apparently similar cells fuse into one (Fig. 3), but as we pass to higher plants there is an increasing differenee between the cells concerned; moreover, while in the simpler cases the fusion appears to involve the whole of each cell, in the higher plants it is confined to the nuclei.

Upon a close examination of sexual reproduction it is found that in the classes *Chlorophyceæ* and *Phæophyceæ* the two uniting cells may be alike in size and other obvious characters (isogamous), or they may be unlike in size and otherwise quite different also (oögamous). Thus all except the highest *Protococcoideæ*, all of the *Conjugatæ*, all but the higher *Siphoneæ* and *Confervoideæ* of the first-mentioned class, and nearly all of the second class, are isogamous. In the family *Volvocaceæ* (of the order *Protococcoideæ*) some genera are isogamous, while others are oögamous. The families *Vaucheriaceæ*, *Saprolegniaceæ*, and *Peronosporaceæ* (of the order *Siphoneæ*), and *Sphæropleaceæ*, *Cylindrocapsaceæ*, and *Œdogoneaceæ* (of the order *Confervoideæ*), are oögamous. Among the *Phæophyceæ* the *Fucoideæ* alone are oögamous. In all classes above the *Chlorophyceæ* and *Phæophyceæ* oögamy is the invariable rule.

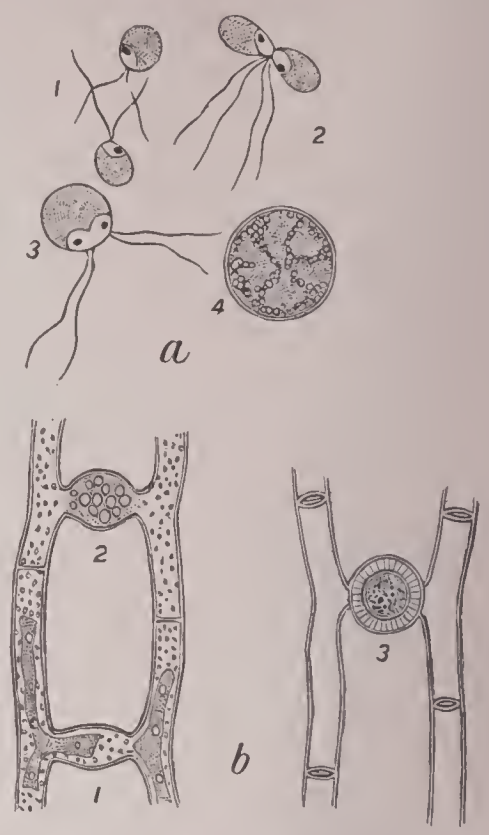

FIG. 3.—Sexual reproduction (isogamous): *a*, fusion of zoöspores of *Pandorina*; *b*, fusion of cells of *Mesocarpus* (highly magnified).

As we pass from the lower plants to the higher there is an increasing complexity in the results of the cell-union. In the *Chlorophyceæ* and *Phæophyceæ* the result is a single egg-like cell (oöspore), which sooner or later develops into one or more new plants (Figs. 3 and 4). The plants of these two classes are hence sometimes very properly called egg-spore plants. In passing to the *Coleochætaceæ* and *Florideæ* we find that in the former the single spore soon becomes invested with a cellular layer of protective tissue, and the spore itself upon germination becomes several-celled, thus forming a simple kind of spore fruit. In the *Florideæ* the fertilized cell not only divides early, but each segment emits a branch whose end segment becomes detached as a spore, and in the meantime the whole has become invested by a layer of protective tissue. In the *Charophyceæ* the growth of the protective tissue precedes fertilization, so that from a protective device which only *follows* fertilization we have now the same device developing much earlier and serving as a protection to the unfertilized

cell (Fig. 5). In the bryophytes and pteridophytes we recognize in the archegone (Fig. 6) the homologue of the struc-

by any absolute characters. The results of fertilization, however, are of a greater degree of complexity in the bryo-

phytes and pteridophytes than in the *Charophyceæ*. While in the latter the result is a single spore, in bryophytes it is a cylindrical many-celled axis, the upper portion of which develops spores by the division of internal cells, and in the pteridophytes it is an axis terminating in roots below and bearing leaves above. There is a noticeable immersion of

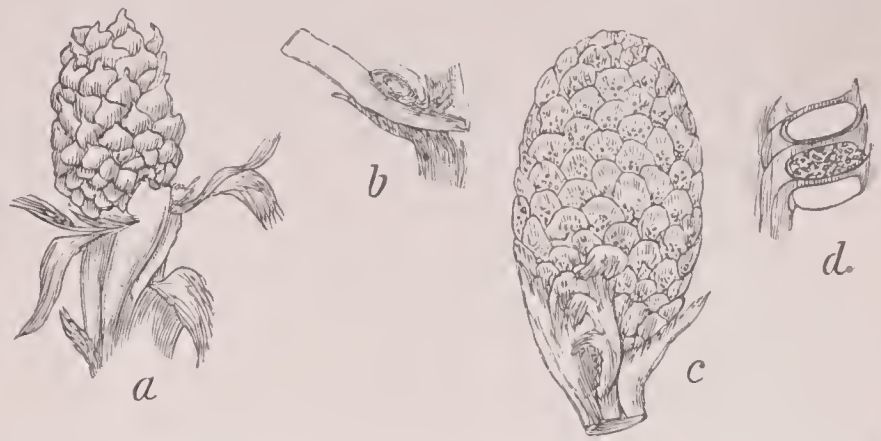

Fig. 7.—Reproduction in the pine: *a*, an ovuliferous cone; *b*, an ovule on its scale; *c*, a polleniferous cone; *d*, three stamens (magnified).

the archegone in the tissues of the parent plant in the pteridophytes, and in the gymnosperms there is a complete submergence. At the same time in the gymnosperms, with the retention of the macrospore within the sporangium (*nucellus*), and the development of one or two nucellar integuments, there is a still greater increase in the protective tissue surrounding the oösphere. This is carried a step further in the angiosperms, where the leaf (carpel) folds over and incloses the coated nucellus (ovule). The results of fertilization in gymnosperms and angiosperms (effected here by the pollen-tube) are little if any higher than in the pteridophytes, consisting in the development of an embryo plant with its root, stem, and leaves. The protective tissues surrounding the embryo, especially those of the seed-coats, are, however, notable additions, made necessary by the fact that the embryo is still to be separated from the parent plant.

When we take a comprehensive view of sexual reproduction, we note that as we pass from the lower plants to the higher there is, step by step, an increase in the aid given by the parent plant to the new organism. Additional protective devices appear and the period of parental care is prolonged in successively higher classes. See Botany and Embryology (in plants). Charles E. Bessey.

Reptil'ia [viâ Fr. from Lat. *rep'tilis*, creeping, crawling, deriv. of *re'pere*, creep. Cf. *serpent*, from Lat. *ser'pere*, crawl]: a class of vertebrates formerly associated with the *Batrachia*, but now known to be most nearly related to the birds and placed with them in a division called Sauropsida (*q. v.*). In form as well as in skeletal and other characters they vary greatly, but they may be briefly defined as having a three-chambered heart (incompletely four-chambered in crocodiles), an incomplete circulation, arterial and venous blood being mixed in the ventricles, respiration by lungs, functional gills never being developed, and cold blood. The body is covered by horny scales or bony plates. In the skeleton may be noted the suspension of the lower jaw by the quadrate bone, the presence of a single occipital condyle, a well-developed coracoid bone, and separate carpal and tarsal elements. Most of the species lay eggs, and the embryos, which develop without metamorphosis, have the fœtal structures amnion and allantois. See Embryology.

In most forms (the rhynchocephalian hatteria, lizards, snakes) the scales are horny and imbricated, passing on the ventral surface in the snakes into broader plates or scutes. In alligators and crocodiles these scales are strengthened by bony growths beneath, while in the turtles the scales have as a deeper support the peculiarly expanded and united ribs and vertebræ.

In the skeleton, besides the points noted above, may be mentioned the nearly complete ossification of the elements, cartilage being very scanty. The vertebræ may be concave either in front (*procœlous*), or behind (*opisthocœlous*), or on both surfaces (*amphicœlous*). When appendages are present four or five regions may be recognized in the vertebral column, but when limbs are lacking (snakes) no such distinctions are possible. These regions, which are given the same names as in mammalian anatomy, are exceedingly variable in the number of vertebræ they contain. The skull,

which varies considerably in form, usually has the bones distinct. Among the peculiarities separating these from other groups are the union of maxillary and premaxillary bones with the skull, the ossification and more or less complete union of palatine and quadrate with the cranial bones, the presence of a single occipital condyle on the basioccipital, and the distinctness of the bones (dentary, angulare, articulare, etc.) of the lower jaw. The quadrate bone, by means of which the lower jaw is connected with the cranium, is movable in some forms, firmly fixed in others.

The appendicular skeleton varies with the development of the limbs. A shoulder-girdle is present in all except the footless forms, while the pelvic girdle occurs even in some of these. The limbs vary greatly in character. Usually present and fitted for running or walking, they are modified into paddles in the ichthyosaurs and most *Sauropterygii*, while in the *Pterosauria* the anterior limbs are modified into organs of flight. In some lizards and all snakes the limbs are not developed, while in other lizards one (either) or both pairs are present. It is to be noted that in pythons and boas rudiments of the hind limbs exist. See Herpetology and Vertebrates, Fossil.

Trans.* (1867). J. S. Kingsley.

Republic [from Lat. *respub'lica*, commonwealth; *res*, affair + fem. of *publicus*, of the people, public, deriv. of *po'pulus*, people]: a political community in which the sovereign power is lodged in the whole body of the people or in a portion of them, and exercised through representatives or agents directly or indirectly elected by them for that purpose. It is called an *aristocratic* republic when the exercise of the sovereign power is confined to a privileged class of whatever description, to the exclusion of all others; a *democratic* republic when all classes of the people participate in the exercise of that power alike. The purest form of the democratic republic exists where all the people periodically assemble in general meeting to make their own laws and to appoint their agents for the execution and enforcement of those laws—a system which has been found practicable only in small or at least very compact communities, while in larger states the sovereignty of the people can act only through the instrumentality of representation, at present generally adopted.

Of the republics of ancient Greece, Sparta had a strictly aristocratic government, while Athens might have been called a democratic republic but for the circumstance that a majority of its population were slaves, and as such excluded from all political rights, at the time of its greatest prosperity the number of its free citizens being only 135,000, while that of the slaves rose to 365,000. The republic of Rome was, during the first centuries of its existence, aristocratic in its political organization, but in the course of time the patrician aristocracy found itself compelled to yield to the lower orders of the people, the *plebs*, access to the high offices of the government, which thereby acquired a more democratic character; all the while, however, as in all republics of antiquity, a large part of the population remained slaves and without political rights. The Italian republics which became the most flourishing and powerful commercial communities of the Middle Ages—notably Venice and Genoa—were strictly aristocratic; a number of patrician families, who chose from among themselves the head of the government, called the doge, enjoyed a monopoly of political power. The first important republic of the modern era, the United Netherlands—formed, after their separation from Spain, out of seven confederate provinces (1580), and recognized by Spain as an independent republic (1609)—was of a more democratic tendency, as was also the republic or "Commonwealth" sprung from the English revolution, which, however, after an existence of only eleven years (1649–60), was overthrown by the restoration of the Stuart dynasty. Of a similar character were most of the free cities and Hanse towns of Germany, only three of which—Hamburg, Bremen, and Lubeck—have to this time preserved their republican institutions as members of the German empire. Two miniature republics in the south of Europe have survived to our day—San Marino, in Italy, and Andorra, in the Pyrenees—remarkable mainly for their insignificance as independent states. Spain had, immediately after the abdication of King Amadeus (1873), a short period of democratic republican government, which, however, appeared only as a mere episode in a series of revolutions and reactions. At present there are only two republics of importance in Europe—Switzerland and France. (For the history of the Swiss republic, see Switzerland, History of.) The third French republic was proclaimed Sept. 4, 1870, when Napoleon III. had fallen into the hands of the German forces after the battle of Sedan. The National Assembly, organized in 1871, ultimately framed a constitution which went into effect in 1876, and has been in successful operation ever since. It is not unlike the English constitution, with the substitution of an elective president for the hereditary sovereign and an elective senate for the House of Lords. See France, History of.

In America all states except the colonial possessions of European powers have republican governments with democratic institutions. The largest and most powerful of them, the republic of the U. S., presents the realization of the democratic republican idea on the greatest scale.

The distinction between aristocratic and democratic republics has now scarcely more than historical importance, inasmuch as there is at present not a single state with a republican form of government in existence in which a nobility or a privileged class of any description enjoys a monopoly of power; and since the abolition of slavery and the enfranchisement of the colored race in the U. S. there is none in which any considerable class of people is excluded from the exercise of political rights. But while all republics, with a uniform tendency, have drifted toward democracy, as far as the equality of political rights among citizens is concerned, we find an essential difference between them as to the character of their political institutions in another respect. (1) The constitution of a republic may be such as to make the general government in its legislative and executive capacity the depository of the whole sovereignty of the people, so as to give it control not only of national affairs, but also of local administration; or (2) the general government of a republic may be one of strictly limited powers, being confined in its constitutional sphere of action to a certain class of things which concern the nation as a whole, while the administration of affairs of a local nature is left to the "self-government" of the people in their local organizations respectively, with entire independence of the central authority; or (3) these two systems may be so mixed as to leave to the local self-government of the people only a limited range, subject to supervision and interference by the central government. A government of the first description would be called a *centralized*, of the second a *decentralized* government, and of the third either one or the other as it more nearly approaches the first or the second standard. The French republic presents an illustration of the centralized system in a but slightly modified sense, while the so-called *federal* republics—and among them most conspicuously and on the greatest scale the republic of the U. S.—exemplify that which combines the independent administration of local interests by the people in their local organizations with a central government controlling affairs of national concern. For the system of centralization the advantage is claimed that it imparts to the government great power, energy, and rapidity of action by enabling it to employ the whole machinery of general and local administration for its purposes. It is therefore by many thought preferable in a country whose surroundings and international relations are such as to render the possibility of an instantaneous employment of all its resources desirable, or whose internal peace is threatened by a lawless and turbulent spirit, so as to require prompt and vigorous measures for the maintenance of order and security. But while the centralized system thus creates, in the common acceptation of the term, a "strong government" which may be used for good ends, it produces at the same time an accumulation of power which may become, and sometimes has shown itself, very dangerous to popular liberty and to the permanency of republican institutions. The centralized system holds out a tempting prize to popular insurrection at the seat of government, as well as to the *coup d'état* on the part of those in power; and what appears as an element of strength and energy in the government becomes thereby in reality an element of instability. This tendency is the more dangerous as the centralized system fosters among the people the habit of looking for all that is to be done for their interests not to themselves, but to the superior wisdom

of those directing the machinery of power. It is essential to the success of democratic republican government that the political intelligence of the masses of the people be well developed, and this the centralized system fails to bring about. People who are not permitted to learn how to manage their local concerns by independent action can not be depended upon to act with steady judgment and wisdom in exercising a directing and decisive influence upon the government of a great republic.

In the so-called *federal* republics the *decentralized system* of government has been a thing of natural growth. They were formed by uniting in common political organizations a number of already existing communities (cantons, colonies, states), and these pre-existing communities, after their union still preserving their identity, and also a degree of independence necessary to that end, remained, as to their local concerns, self-governing bodies, while within them the smaller units of local organization (municipalities, townships, counties) continued to stand in a similar relation, subject to certain necessary restrictions, to the respective cantons, states, etc. The UNITED STATES (*q. v*) affords an example of this complex system. (See also CONSTITUTION OF THE UNITED STATES.) In spite of the many constitutional limitations on the power of the central authorities in the U. S., the history of a century has demonstrated that the national Government possesses vigor enough to accomplish all the objects for which it was instituted, and that it has been able successfully to carry on foreign wars of considerable magnitude, and also to overcome an insurrection supported by nearly one-third of the people, organized upon a tremendous scale, and commanding great resources. It has even now and then, when under the control of an ambitious party spirit or under the pressure of great emergencies, shown a tendency, for special ends, to break through its constitutional restrictions or permanently to enlarge the scope of its powers. Commercial developments, in railroads and other forms of centralized business extending over an area too wide for the authority of individual States, have done much to widen the jurisdiction of the Federal Government. There is also an increasing tendency to seek national control over all matters affecting the election of federal officers instead of leaving them to local authorities. It might also be apprehended that under such a system in some of the several States powerful interests may obtain control, wield an oppressive rule over a part of the people, and intrench themselves behind the right of the States to govern their local concerns. This was the case in the States in which slavery existed, and remained so until slavery was abolished in consequence of the rebellion. Since then that particular form of local oppression within State limits has been guarded against by constitutional provision. Attempts by political factions or party organization to exercise an oppressive rule may be expected to find their remedy in the resources of popular government. There have been now and then conflicts of authority between the national Government and individual States, but, with the exception of that which gave rise to the rebellion of the slave States, they have all been settled peaceably.

A republican government so organized is unquestionably less subject to certain dangers to which centralized republics are apt to succumb. A *coup d'état* or an insurrection at the seat of the national Government, set on foot for the purpose of effecting a general revolution by one stroke of force, would in a country like the U. S. be a mere blow in the air. Neither will a political party in possession of the national Government be able to maintain itself or to oppress opposition by an arbitrary stretch of power, for the rights of the citizen are sheltered by the protection of local self-government. If there is any real danger threatening the political institutions of the U. S., it is certainly not that of their overthrow by force, but it is their deterioration by the influence of corrupt practices and habits. In this respect nothing can be more deplorable than the usage which has developed itself in the U. S. since 1830—to treat the offices of the Government as the mere "spoils" of party victory. See CIVIL SERVICE AND CIVIL SERVICE REFORM.

On the whole, it will be admitted, even by those not partial to the republican theory, that, in spite of temporary abuses and occasional jarrings, the decentralized system of republican government with its "checks and balances" of power has not only proved itself entirely practicable, and very successful even in holding together in one national organization a very numerous population spread over a vast extent of territory, but that the people living under it, in Switzerland as well as in the U. S., have attained a social condition remarkably prosperous, progressive, and happy. This has undoubtedly been owing in a very great measure to the stimulus which active self-government imparts to popular education, enabling men to manage their own affairs, private and common, upon their own well-understood responsibility, giving them an opportunity to reap the benefit of their own wisdom, and to learn from their own errors and blunders, thus signally advancing the standard of general intelligence and practical sense among the masses.

See, further, *Congressional Government* (Boston, 1885); Woodrow Wilson, *The State* (Boston, 1889); Burgess, *Political Science* (New York, 1891); Bryce, *The American Commonwealth* (London, 1888; new ed. 1895). CARL SCHURZ.
Revised by A. T. HADLEY.

Republican Party: one of the two great political parties in the U. S. Its distinctive aims and achievements will best appear from a sketch of its development and an exposition of its views on important national issues. Historically it is the successor of the Federalist and Whig parties, while the Anti-federalists, afterward called Republicans, may be regarded as the former representatives of the modern Democratic party. Although the names have varied, the two great groups which have respectively borne them have continued essentially the same.

The Anti-slavery Movement.—The Federalists were the men who revolted against the imbecility of the Confederation and led in forming the Constitution. They then organized the Government and established the great lines of national policy. They were resisted by the Anti-federalists, who held to the colonial traditions of separatism and later to the doctrine of a strict construction of the Constitution. After the country emerged from the period of foreign complications which culminated in the war of 1812 there ensued what was termed the "era of good feeling." In this description there was more irony than truth, but it was really a period during which the governmental organization and general policies of the Federalists passed into general acceptance, and while personal politics reigned in public life and the old lines of battle faded away, the same party groups were forming again to take up fresh issues. These new questions were of a domestic character and involved the policies to be pursued in the development of the resources of the country by internal improvements and of industrial independence by a system of tariff protection. The Whigs supported and the Democrats in a greater or less degree opposed both policies. But while current politics were absorbed with national banks, national improvements and protective tariffs, another and far different question—one destined to overshadow everything else—was slowly rising up and taking definite shape. This was the question of slavery, moral in its nature, but affecting the whole social and economic system of half the republic.

The anti-slavery movement began with the Abolitionists, who roused the attention and awakened the conscience of the North, but who were unable to form an effective political force. The feeling which they created, however, although they themselves could neither control nor direct it, swelled and widened until it finally cut for itself a new channel. The anti-slavery sentiment could find no support among the Democrats, as a party, for that party, without going into details, could not by its very nature have become the ally or the exponent of an attack upon an existing institution. The mass of the Whigs, on the other hand, inclined naturally to the opposition to slavery, but the Whig party, as an organization formed on economic issues, had a strong minority in the slave States. This minority could not throw the party upon the side of slavery, but it could and did prevent the Whig organization, naturally unwilling to lose a large body of supporters, from becoming an avowed anti-slavery party. The situation therefore was this: One of the two great political organizations was devoted to slavery, the other was unable to move against it, and the declared opponents, the Abolitionists, were impractical, divided among themselves, tainted with separatism, and incapable of commanding general popular confidence. The time again had come for forming parties along new lines in order to reach some practical result. What was needed was a party which was opposed on principle to slavery, and which at the same time aimed to make its resistance within the limits of the Constitution and to embody its principles in practical legislation. The new movement, when it began to take shape, went to no extremes. It did not propose any infringement of the

rights of the States as to their domestic institutions, but proceeded along the line of least resistance. It did not set out to abolish slavery, but merely to prevent its further extension. The first expressions of this anti-slavery movement, in a national way, were in the Free-soil and Liberty parties, both outside the two great parties and polling only a small vote. They had the effect that a balance of power vote sometimes attains in closely divided States, of defeating one of the great parties with the other, but they achieved little of their direct purpose beyond showing that the Democratic party would stand firm for slavery, and that the Whig party as an organization was useless against it. The anti-slavery vote defeated Clay in 1844, and gave New York to the Whigs in 1848. Even after this the Whigs, accepting the compromise of 1850, still refused to take up opposition to slavery, and the elections of 1852 were disastrous to them. The canvass of the Free-soilers, small as their vote was, joined with the general discontent of the Northern Whigs, together with the helplessness of their party against the slave power, wrecked that great organization in nearly every Northern State. Thus the ground was cleared for the development of a party which should take the place and assume the traditions of the Whigs unencumbered by their obligations to slavery.

The Formation of the Republican Party.—As always happens in such periods of political change, the dissolution of the Whig organization gave rise to various side movements, of which the most conspicuous was the Knownothing or Native American party. This outbreak had a brief and in some places an overwhelming success, but its career was short, for it had no firm resting-place of principle, and did not recognize the great question which was the one then really in the public mind. It served, however, as the recent elections had, to clear the field for the new party organization which the times demanded, and it was in this situation of politics that the Republican party came into existence. It is generally admitted now that the first formal adoption of the name Republican was made by the Michigan State convention early in June, 1854, and that it was due to a suggestion in a letter from Horace Greeley. Certain it is that the name spread rapidly and was adopted by State conventions in Maine, Ohio, Indiana, Illinois, Wisconsin, and Iowa. The new party principle prevailed in the Northern States, and wherever the Republicans ran a straight ticket they carried everything before them. It had looked in 1852, after the Democrats had swept the country without effective resistance from the perishing Whigs, as if resistance to the Democratic party was hopeless, and as if the compromises of 1850 were really built on the rocks and not upon the sands. Yet only two years later this new party, because it gave the first opportunity for an expression of a deep popular feeling and because in the midst of negations it meant something real, carried the Northern States. In spite of its lack of national organization, it elected enough members of Congress to control the House and to choose Nathaniel Banks Speaker after a long and bitter contest. Such sudden success showed how greatly a new means of expression for popular feeling was needed.

Stimulated alike by their victories at the polls and by the Kansas-Nebraska Bill and other measures, which proved that to the South compromises were merely stepping-stones to further aggression, the new party went quickly forward to a national organization. The first convention met at Pittsburg on Feb. 22, 1856. A national organization was there formed, and a call issued for another convention to nominate candidates for President and Vice-President. This second convention met in Philadelphia on June 17.

The serious character and the importance of the new movement were strikingly shown by the quality of the delegates who assembled in this convention. There were to be seen not only those who had been leaders of the Free-soil movement in the days when it was a forlorn hope, but many men who had been conspicuous in the Whig party, while delegations of Democrats were also present. Edwin D. Morgan, afterward Governor of New York, called the convention to order, Robert Emmett was made its temporary chairman, and Henry S. Lane, of Indiana, its permanent president. The platform was reported by David Wilmot, the author of the famous proviso, and was practically confined to the single issue which had called the new party into existence. It declared against the establishment of slavery in the Territories, and the third resolution, which has become in political literature a familiar quotation, ran as follows: "Resolved, That the Constitution confers upon Congress sovereign power over the Territories of the United States for their government; and that in the exercise of this power it is both the right and the imperative duty of Congress to prohibit in the Territories those twin relics of barbarism, polygamy and slavery." The fourth resolution discussed at length the condition of Kansas and denounced the Democratic administration for their policy in that Territory. The fifth resolution demanded the admission of Kansas; the sixth assailed the doctrines of the Ostend circular. The seventh and eighth comprised the only portion of the platform which went outside the slavery issue. These two resolutions declared in favor of national aid for a railway to the Pacific coast, and also for liberal appropriations for rivers and harbors. Like all new organizations which are engaged in mustering their forces from different elements of the community, the Republican convention of 1856 had a great deal to say about the issue on which all were agreed and which was the vital question of the day, and very little about other questions of longer standing and upon which there had been earlier party divisions. Nevertheless, these two comparatively unimportant resolutions about railways and rivers and harbors marked at the start the political ancestry of the Republicans, for they commit the party to the doctrine of internal improvement, which was one of the doctrines growing out of the liberal construction of the Constitution, and which had formed the fundamental principle of Federalists and Whigs alike in opposition to the strict construction of the Democrats.

Upon this platform the Republican convention placed as its candidates John C. Fremont, of California, and William L. Dayton, of New Jersey. There was no serious contest over either nomination, but it is interesting to notice that the leading candidate against Dayton for the vice-presidency was Abraham Lincoln, of Illinois. Fremont had no political record, but had been for some little time a popular hero, owing to his exploring expeditions and his brilliant services in California. The event proved that he was a well-chosen candidate for the purpose of getting votes, and the Republican campaign was full of enthusiasm and energy. The Democratic candidate was James Buchanan, who was elected, but the Republicans carried every Northern State except Pennsylvania, New Jersey, Indiana, Illinois, and California, and gave their ticket 114 electoral votes. Of the popular vote the Republicans polled 1,341,264. When it is considered that only four years before all effective opposition to the compromise measures and to the Democratic party had appeared to be extinct, the results achieved by the Republicans in the elections of 1856 were most impressive.

During the next four years events steadily strengthened the Republican cause. The subserviency of Buchanan to the South, the publication of the Dred Scott decision, the continuance of the atrocious Democratic policy toward Kansas, and finally John Brown's raid intensified the hostility of the North to slavery, and day by day added votes to the Republican party.

The Election of 1860.—The War.—When the national Republican convention assembled in Chicago on May 16, 1860, they faced a situation very different from that which had confronted them in 1856, and they now saw success well within their grasp. The Democratic party had met in convention on Apr. 23 at Charleston, S. C., and had there split hopelessly on the slavery question. They had adjourned without action and the warring factions had called two conventions, one of which nominated John C. Breckinridge and Joseph Lane on an extreme pro-slavery platform, while the other, adopting the squatter-sovereignty theory, nominated Stephen A. Douglas and Herschel V. Johnson. With their enemies thus divided and with so sure a promise of victory the contest for the Republican nomination was both sharp and determined. The first choice of a majority of Republicans was William H. Seward, of New York, to whom the Eastern States were especially devoted. It was very natural that this should be the case, for Seward had been for years one of the boldest and most effective opponents of slavery, both as Governor of New York and in the Senate of the U. S. He had, however, many active enemies, which a career like his was sure to produce. These men, led by Horace Greeley, united with the Western candidate and thus defeated Seward and secured the nomination of Lincoln. It was the most fortunate choice ever made by a political convention. The often repeated statement that Lincoln was an unknown man, selected merely on account of his availability, is a mistake. He had long been distinguished in the public life of the West. He had been voted for as a candidate for Vice-

President in the convention of 1856, and his debate with Douglas in 1858 had given him a national reputation and had shown to all who looked below the surface of current events that the opponent of Douglas was a man of uncommon abilities. The choice as it stood in May, 1860, was both reasonable and intelligent; but, although the convention did not take a leap in the dark and pick up an unknown man, it was not then possible to realize that the party had chosen for its candidate the greatest statesman and popular leader of the nineteenth century.

The West having received the presidency, the convention went to the extreme East for its candidate for the second place and nominated Hannibal Hamlin, of Maine, for Vice-President—a wise selection of an able man. The platform of 1860 bears witness to the development of the party, and to the strong feeling it now had that it existed for more than a single issue, great as that issue was. The resolutions recognized the rights of States in regard to their domestic institutions, but denounced the threats of secession which then filled the air and declared the Republican party to be the party of the Union. It took the old ground with renewed strength in regard to Kansas and the extension of slavery to the Territories, demanded the admission of Kansas as a State, and declared the reopening of the slave-trade to be a crime. The resolutions also called attention to the frauds and corruptions of the Democratic national administration, and urged the necessity of a return to economy and accountability. The thirteenth clause declared against the alienation of the public lands to any but actual settlers and in favor of the Homestead Act, which had already passed the House of Representatives. The resolutions also reiterated the declaration of 1856 as to internal improvements, but they now took a much longer step in the direction of Whig and Federalist policies. The twelfth clause was as follows: "That, while providing revenue for the support of the general government by duties upon imports, sound policy requires such an adjustment of these imposts as to encourage the development of the industrial interests of the whole country; and we commend that policy of national exchanges which secures to the workingmen liberal wages, to agriculture remunerating prices, to mechanics and manufacturers an adequate reward for their skill, labor, and enterprise, and to the nation commercial prosperity and independence." Thus in its early development the Republican party came squarely on to the ground first marked out by Hamilton and adopted as their general doctrines the liberal construction of the Constitution and the policy of protection to home industry. Even if this had not been the sentiment of the great mass of those who composed the Republican party this line of development would none the less have been pursued by mere force of circumstances. The interests of slavery were closely linked with free trade. Where slavery ruled there was only one great staple grown, and there was no diversification of industry. It was therefore to the advantage of slavery, unable to build up an industrial system where a blight rested on free labor, to have the markets of the world to buy in at the cheapest possible prices. The resistance to slavery in the North depended for its material strength on the industrial growth of the Northern States. This industrial growth had been checked by the low tariffs imposed by the South, and the panic of 1857, which those tariffs caused, had aroused a strong feeling against the Southern economic policy. Protection therefore was the first weapon ready to the hands of the Republicans in their warfare against the slave power. They grasped it boldly, and the wisdom of their action, both on material and political grounds, was shown by the fact that they were thus enabled to swing the great industrial State of Pennsylvania into the Republican column and to wrest it finally from the grip of the Democratic party.

The election of 1860 was hotly contested. In the North the chief struggle was between the Douglas Democrats and the Republicans, except in the East, where the principal opponents of the Republicans were the few remaining Whigs. In the South the Breckinridge Democrats were almost unopposed, except in the border States, where the Whig or "Union" party was successful. The result was a decisive victory for the Republicans. Lincoln had a large majority in the electoral college and a large plurality of the popular vote. The figures stood as follows: Lincoln, 1,857,610; Douglas, 1,291,574; Breckinridge, 850,082; Bell, 646,124. The electoral vote was divided as follows: Lincoln, 180; Breckinridge, 72; Bell, 39; and Douglas, 12.

The victory of the Republican party was the signal for the beginning of the secession movement in the South to destroy the Union and break up the nation. The South entered upon secession because it lost an election. Without even waiting for the Republican party to come into power, before any overt act by any possibility could have been committed, the South, because it had been defeated at the polls, began its movement to destroy the Government. No greater blow to free government resting on the will of the people was ever struck, no more wanton political crime was ever attempted. South Carolina seceded in December; other States followed during the winter, and in February a rebel Confederate Government was formed at Montgomery.

Lincoln was inaugurated Mar. 4, 1861, and his inaugural speech was temperate and moderate, but firm on the great point of maintaining the Union. A terrible situation confronted the new party and its great leader. They found the treasury bankrupt, treason in the War, Navy, and State Departments, and civil war close at hand. In April the storm broke and fighting began.

It would be impossible to trace here even in the barest outline the history of the Republican party during the next four years, for this history through that period is the history of the war for the Union. The Republicans were charged with the heavy work of administration and with the preservation of the Government and the nation. They had to build navies, raise armies, provide money, and fight battles. They were bent on the prosecution of the war to a final, absolute, and victorious decision. The Democrats who had withered away in the first days of the war when the people rallied for the defense of the national life took heart as the struggle was protracted and defeats were sustained. Their activity took various forms. Sometimes it was embodied in treasonable movements like that of Vallandigham in Ohio and of the Knights of the Golden Circle in Indiana. Sometimes it took shape in rioting, as in the city of New York, but everywhere and always the Democratic party as a political organization was opposed to the administration and to the conduct of the war. Popular discontent with military defeats and popular disappointment at the length and stubbornness of the conflict nearly threw the House into Democratic hands in the elections of 1862, but after that time the victories of the national armies and the rising fortunes of the Union cause, steadily strengthened the Republicans.

On Jan. 1, 1863, the proclamation of emancipation went into effect, while the capture of Vicksburg and the victory of Gettysburg six months later marked the decisive turning-point in the great conflict. In the elections of that year the Republicans regained all the States they had lost in the elections of 1862. The following year came the presidential election. Some extreme Republicans, dissatisfied with the administration, met at Cleveland and nominated Fremont for President and John Cochrane for Vice-President. This performance looks merely absurd in the pages of history, and even at the time it had but little effect; both the candidates ultimately withdrew and left the Republican party to face the election with an unbroken front.

The Republican convention met at Baltimore on June 7, 1864, and Robert J. Breckinridge, of Kentucky, was made its temporary chairman, and William Dennison, of Ohio, its permanent president. Lincoln was renominated by acclamation, but there was an active contest for the vice-presidency, to which Andrew Johnson, of Tennessee, was finally nominated. The platform declared for the prosecution of the war and against any compromise with the rebels. The second resolution sustained in the strongest terms the proclamation of emancipation, and pledged the support of the party to Lincoln. They also pledged themselves to the redemption of the national debt, and denounced the attempt of France to establish itself upon the Western continent. The only resolutions not relating to the war were those favoring foreign immigration and supporting the policy of giving government aid to the construction of the Pacific railroads.

The Democratic convention was held in Chicago. It attacked the administration with the utmost bitterness, and in its platform declared the war to be a failure. The Democrats nominated, in strict accordance with the platform, George B. McClellan, under whom, as general of the Army of the Potomac, the war had certainly been a failure, and placed with him as Vice-President George H. Pendleton, of Ohio. The issue was plain and was also the gravest that ever had come to the American people for decision at the ballot-box. Nothing less than the existence of the nation was staked on the verdict of the voters. The Re-

publicans swept the country. Lincoln had the electoral vote of every State not in the rebellion, except Kentucky, Delaware, and New Jersey. He received 212 electoral votes against 21 for McClellan. His popular vote was 2,213,665 against 1,802,237. This sweeping victory at the polls confirmed the victories of the armies in the field. Early in the following spring Richmond fell and Lee surrendered at Appomattox. In the midst of the popular rejoicing at the end of the great struggle, which resulted in the preservation of the nation, Lincoln was assassinated by Wilkes Booth on Apr. 21, 1865.

Reconstruction.—The death of Lincoln was not only a terrible calamity to the nation, but a great misfortune to the Republican party, for the work of reconstruction which confronted the victorious North demanded both from President and Congress the exercise of the highest wisdom as well as great firmness and moderation. These qualities possessed in an unequaled degree by Lincoln were almost wholly lacking in Andrew Johnson, who succeeded him in the presidency. Johnson was a hot-headed man of unbalanced judgment. He began by taking an extreme position against the South, uniting with the most radical wing of the Republican party, whence opposition to Lincoln had always proceeded. He then suddenly changed his attitude and swung to the opposite extreme, entering upon a policy of ardent opposition to the Republican measures of reconstruction. The effect of this course was to place the party in antagonism to the President, and by alienating all moderate men from the administration, to throw the guidance of the party into the hands of its more extreme members. Such a situation was most unfortunate for the country, and could not fail to damage the work of reorganization. Nevertheless, the party succeeded in passing its reconstruction laws, which gave a vote to all men in the South, black and white, except those who had participated in the rebellion. The Republicans also passed the Fourteenth Amendment to the Constitution, which established the freedom of the Negro and provided that no debts contracted in aid of the rebellion should be paid by the U. S. or any State. All these great measures were forced through over the President's veto, and the bitterness between the President and the Republican party reached such a point that in Feb., 1868, the House of Representatives impeached him, resting their charges on his illegal removal of Stanton, his attacks upon Congress, and his stopping the execution of some of the acts of Congress. The President was acquitted, the vote standing guilty 35, not guilty 19—not a two-thirds majority, as required by the Constitution.

In that same year a new presidential election came on. President Johnson's efforts to build up a personal party failed as completely as those of Tyler under like circumstances. No one followed him and neither of the great parties would have anything to do with him. The Republican party met in Chicago on May 20 and nominated Gen. Grant for the presidency by acclamation. Schuyler Colfax, of Indiana, was nominated for Vice-President on the fifth ballot. The Democratic national convention met in New York on July 4, and nominated Horatio Seymour for President and Francis P. Blair, of Missouri, for Vice-President. The Republican platform sustained the Constitutional amendment, which recognized the results of the war, and the freedom of the slave, and which guaranteed protection to the Negro in his rights. They also sustained the reconstruction acts of Congress, pledged themselves to maintain the national credit and to provide for the soldiers, and denounced all forms of repudiation which had been much advocated by the Democratic leaders.

The Democrats took ground against this platform, and showed by their attitude and their nominations alike their hostility to the Republican policy. The people, however, wearied by four years of war and by the angry struggles with Johnson, were anxious above all things for a final settlement of these war issues. Gen. Grant tersely summed up the situation in his famous phrase: "Let us have peace." This became the watchword of the contest, and the Democratic campaign really broke down before the polls were reached. Gen. Grant was elected by a popular vote of 3,012,833 against 2,703,249, receiving in the electoral college 214 votes against 80 for Seymour. This election was decisive in favor of the acceptance of the results of the war, and drove the Democrats from any further attempt to take ground against them. It also sustained the Republican policy of equal suffrage and the rights of citizenship to all citizens without regard to color, and this policy was finally secured by the Fifteenth Amendment to the Constitution, which soon after passed Congress, and, after ratification by the States, was proclaimed on Mar. 20, 1870.

Under the administration of Gen. Grant the leading question was the condition of the Southern States under the Reconstruction acts. The State governments which were then set up, resting on the black vote, were generally feeble and gave rise to many scandals. On the other hand, the murderous outrages committed by the Southern whites against all Republican voters angered the North and kept all the States lately in rebellion in a condition of disorder which invited the constant interference of the national authority. From every point of view the situation in the Southern States was depressing, and the dissatisfaction which it caused was directed very naturally against the party in power. This period also was one of general demoralization, the inevitable outcome of four years of fierce civil war, and the demoralization extended not only to politics but to business and society. It gave birth to wild stock speculations and to many scandals and corruptions, and the burden of these also fell, as it was sure to fall, on the party in power.

The Liberal Republican Movement.—The discontent thus engendered took shape in an independent movement in the Republican party headed by a number of Republican leaders who had broken with the administration on account of the San Domingo policy of Gen. Grant, and who were also desirious of attacking the abuses and corruptions to which the war period had given rise. These dissatisfied or Liberal Republicans, as they called themselves, held a national convention in Cincinnati in May, 1872. The plan was to nominate Charles Francis Adams for the presidency, a selection which would have made the movement a formidable one, but the convention broke away from the leaders and nominated Horace Greeley for President and B. Gratz Brown for Vice-President. They declared in their platform that sectional issues should be buried, that all the settlements of the war should be accepted, that civil-service reform should be begun, and that specie payments should be immediately restored. They left the tariff an open question and opposed all further grants of land to railroads. The regular Republicans met in Philadelphia in June and renominated Gen. Grant by acclamation, placing with him on the ticket Henry Wilson, of Massachusetts, for Vice-President. Their platform was more elaborate and touched upon more questions than that of the Liberals, but on those subjects in regard to which both platforms spoke the declarations were in principle the same. The regular Republicans reviewed the history of their party, demanded the acceptance of the results of the war and the protection of the colored voter, opposed grants to the railroads, and favored the reform of the civil service. They denounced the repudiation of the public debt and supported specie payments. The Liberals had left the tariff an open question, but had nominated a high protectionist as President. The regular Republicans declared squarely for protection, which had always been one of the cardinal principles of the party.

The Democrats met in July at Baltimore, ratified the nomination of the Liberal Republicans and adopted their platform. Thus they accepted as their candidate for the presidency a lifelong opponent, who had been an extreme abolitionist and was always a zealous protectionist, while they adopted as their platform a set of Republican principles in no one of which they believed. The result of such a performance it was not difficult to foresee. On the one hand it demoralized the Democratic party, while on the other the absurdity of the whole position prevented any serious break in the ranks of the Republicans. A straight-out Democratic ticket, nominated at Louisville in September, came to nothing and played no part in the election. Grant carried every State, except Georgia, Kentucky, Maryland, Missouri, Tennessee, and Texas. His popular vote was 3,597,070 against 2,834,079 for Greeley. In the electoral colleges Grant received 286 votes against 80 thrown for various candidates, Greeley having died between the election and the meeting of the colleges.

Although the Liberal movement broke down so completely in the presidential campaign, it made itself felt very strongly two years later, stimulated as it was by scandals which were connected with appointees and friends of the administration. During the preceding years, moreover, owing to the business disasters which followed the panic of 1872–73, a strong movement for "cheap money"—that is, for the unlimited issue of greenbacks—had grown up in certain States. Gen. Grant's veto of the inflation act of 1874, fol-

lowed by the specie resumption act of 1875, was the final expression of the Republican position. This cheap-money movement, however, added to the dissatisfaction of the Liberal Republicans, resulted in the defeat of the Republican party in many Northern States in the election of 1874. The House for the first time since the war had a Democratic majority, and it seemed as if the tide had turned finally against the Republicans. There were abundant predictions that the days of the Republicans were numbered, that their work was done, and that they would soon disband. The spectacle of the Democratic House, however, and the rise of the cheap-money movement with which the Democrats were prompt to ally themselves, soon altered the situation. The Republicans regained in 1875 many of the States which they had lost in the preceding year, and faced the approaching presidential election with much brighter prospects than any one in 1874 would have anticipated.

Election and Administration of Rutherford B. Hayes.—The Republican convention met at Cincinnati June 14, 1876. Blaine was the leading candidate. The other candidates were Senator Morton, of Indiana, Roscoe Conkling, of New York, Gov. Hartranft, of Pennsylvania, Gov. Hayes, of Ohio, and Benjamin H. Bristow, of Kentucky, who had a strong support from the Liberal Republican element and from all who were dissatisfied with the Grant administration. The convention was an exciting one, but finally a combination was made against Blaine by the friends of the other candidates, which resulted in the nomination of Hayes on the seventh ballot. William A. Wheeler, of New York, was then nominated for Vice-President. The platform declared for the maintenance of the public credit and the resumption of specie payments, for the enforcement of national laws in the South, for civil service reform, for protection, and for an immediate investigation of Chinese immigration. It declared against appropriations for sectarian schools, and against polygamy in the territories.

The Democratic convention met in St. Louis June 27. They demanded reform of every kind, were somewhat vague upon the money question, declared for a tariff for revenue only, and denounced the Republican party at great length. Upon this platform they nominated Samuel J. Tilden, of New York, and Thomas A. Hendricks, of Indiana. The election was hotly contested, and very close. The Democrats had now regained control of most of the Southern States, and by great frauds attempted to take them all. After the vote had been counted, the electoral votes of South Carolina, Florida, Louisiana, and Oregon were in controversy, and Tilden lacked only one vote of a majority. The dispute was carried into Congress and assumed a most threatening aspect. The good sense and patriotism, however, of the leaders on both sides prevailed, and the disputed votes were referred to an electoral commission to decide the points at issue. This commission, after full hearing, awarded all the contested votes to Hayes, thus giving him 185 electoral votes to 184 for Tilden. In this way the country escaped a very serious danger, and on Mar. 4 Hayes was peacefully inaugurated. President Hayes at the outset abandoned the policy of national interference to protect voters in the Southern States, and those which had been Republican up to 1876 now passed finally under Democratic control. In other respects the Hayes administration was a successful one. Its greatest triumph was the resumption of specie payments and the refunding of the public debt under the able management of John Sherman, the Secretary of the Treasury. There was also a great improvement in general administration, and many of the abuses which had grown up during and after the war were curtailed. In Congress these four years were marked by the rise of the agitation for the free coinage of silver. A bill for free coinage passed the House, but resulted in the final passage of a compromise measure known as the Bland-Allison act. This bill was vetoed by President Hayes, but passed over his veto, and went upon the statute books in 1878, where it remained for twelve years.

Administrations of Garfield and Arthur.—The Hayes administration as a whole strengthened the party, and the Republican convention met at Chicago in June, 1880, under favorable auspices. It was the most memorable convention held by any party since the Democratic convention at Charleston in 1860. The contest in the convention, beginning with the question of district representation, lasted a week. The leading candidates were Gen. Grant and Mr. Blaine. Gen. Grant had to contend with the intense popular prejudice against a third term, and also the extreme hostility of those elements which had been so dissatisfied with his previous administrations. Yet notwithstanding these obstacles, Grant's great military services and personal popularity, combined with the support of Senators Conkling, Logan, and Cameron, made his candidacy very formidable. Blaine also had a large vote in the convention, but little short of that given to Gen. Grant. The balance of power was held by the supporters of John Sherman and of Senator Edmunds, who had the support of Vermont and Massachusetts. Finally, after a most stubborn contest, the minority candidates combined against Gen. Grant and nominated Gen. Garfield, of Ohio, on the thirty-sixth ballot. Chester A. Arthur, of New York, was nominated for Vice-President, as representing the Grant forces in the convention. The platform reviewed the history of the two parties, asserted the national principle as opposed to States rights, and declared for protection and against Chinese immigration.

The Democratic convention met at Cincinnati on June 22. Mr. Tilden, who represented in his own person the issue upon which the Democrats had been insisting that they had been defrauded of the presidency four years before, wrote a letter declining the nomination. Rather unexpectedly, perhaps, the convention took him at his word and nominated Gen. Hancock for President and William H. English for Vice-President. The campaign at first was rather languid, the principal question being the old Southern issue; but when the Democrats in combination with the Greenbackers carried Maine in September, the Republicans, thoroughly alarmed, forced the tariff issue to the front, and, attacking the Democrats on their plank for a tariff for revenue only, carried Ohio and Indiana in October and the country in November. The victory would have been even more decisive but for a forged letter purporting to be written by Gen. Garfield in favor of the Chinese, which came out in the last hours of the campaign and which cost the Republican party California and Nevada. As it was, Garfield had 214 electoral votes against 155 for Hancock.

Gen. Garfield made up a strong cabinet with Blaine at its head as Secretary of State, but a bitter quarrel between the administration and the Senators from New York broke out almost at once. The New York appointments were made from those persons who had opposed Senator Conkling and supported Blaine for President. Particularly objectionable to the Senators was the selection of W. H. Robertson as collector of the port of New York, and upon this came an open break. Senators Conkling and Platt resigned and appealed to the New York Legislature to sustain them in their course by a re-election. This the Legislature after a bitter contest refused to do, and elected in their places Messrs. Lapham and Miller. This quarrel, and the attacks upon the Star Route contracts by the Government, filled the first months of the new administration with bitterness and strife. Indirectly it excited a disappointed office-seeker, Guiteau, of unbalanced mind and criminal propensities. Angered at not securing an office, he lay in wait at the railway station at Washington, D. C., and there shot the President on July 2, 1881. Gen. Garfield lingered for many weeks after the shooting, but finally died, on Sept. 19, at Elberon, N. J.

He was succeeded by Vice-President Arthur, who filled out the remainder of the term and gave the republic a most excellent and business-like, although uneventful, administration. The conflicts, however, within the party at the beginning of the Garfield administration bore fruit after the general grief over the assassination of the President had subsided. The elections of 1882 went heavily against the Republicans, especially in New York, where the interference of the administration with the nominations produced so much dissatisfaction that Grover Cleveland was elected governor over Secretary Folger, the Republican candidate, by a majority which reached nearly 200,000.

The Campaign of 1884.—In the convention of 1884 the old fight between those who had supported Gen. Grant and those who had opposed him, or between the "Stalwarts" and the "Half-Breeds," as they were called at the time, was fiercely renewed. Blaine was the leading candidate, and against him were arrayed the supporters of President Arthur combined with the elements which had united with Blaine in 1880 to defeat Gen. Grant. Nothing, however, could withstand Blaine's great personal popularity. He was nominated on the fourth ballot, and Gen. Logan, of Illinois, was put on the ticket with him as Vice-President. The platform, after reviewing the history of the Republican party, declared for international bimetallism, the regulation of interstate commerce, the reform of the civil service, and the resump-

tion of lapsed land grants. It favored also liberal pensions and the building up of the navy, and declared against Chinese immigration, and fraud and violence in the South. The leading resolution, however, concerned the tariff, which of late years had been coming more and more steadily to the front, and upon this the Republican party took, as it had always taken, bold and advanced ground in favor of protection to American industries. The Democrats met on July 8, at Chicago, and nominated Grover Cleveland for president and Thomas A. Hendricks for Vice-President. The platform declared in favor of reform in general after the manner of opposition platforms, but most particularly for tariff reform.

Platforms, however, played but little part in the exciting and bitter campaign which followed. There was a great deal of Republican opposition to Blaine, especially in the Eastern States, where it took the form of an open revolt of a most serious character against the Republican party. Although the Republicans tried to fight their battle on the tariff issue, this revolt made the campaign a purely personal one, and it had all the odious features of savage abuse of the candidates, which such contests are sure to engender. Issues were lost sight of, and the struggle finally turned solely on the question whether Blaine should or should not be President of the U. S. Despite the great schism, Blaine's personal popularity was so great that he attracted large bodies of Democratic voters and made up the Republican losses. New York, which decided the election, gave Cleveland, instead of the 192,000 plurality, which he had received in 1882, less than 1,200, and it was by many persons believed that even this narrow margin was obtained only by counting in New York city for Cleveland the vote cast there for Gen. Butler, who ran as an independent candidate for the presidency. In the electoral colleges Cleveland and Hendricks received 219 votes against 182 for Blaine and Logan. During the first two years of Cleveland's term the general talk in favor of reform went on, but very little was accomplished of a specific kind, and the fact that the Senate remained Republican prevented any violent legislation, if such had been desired. The elections of 1886 went against the Democrats, but they still retained control in the House by a narrow majority. The failure thus far to accomplish anything led, however, to a new departure. President Cleveland sent in to the Fiftieth Congress a message devoted to the single subject of the tariff and demanding instant and radical reductions. This message resulted in the introduction of the Mills Bill, which the House debated at great length for three or four months. It passed the House on July 13, 1888, and on the issue thus raised the two great parties appealed to the country.

The Administration of Harrison.—The Republicans met on June 19 at Chicago. Blaine withdrew his name, and on the eighth ballot Benjamin Harrison, of Indiana, was nominated for President, and this was followed by the nomination of Levi P. Morton, of New York, for Vice-President. The Republican platform favored bimetallism, the building up of the merchant marine, the admission of new States, and the reform of the civil service. It attacked the Democrats for their failure to settle the fishery question and for their feeble foreign policy, but, as in 1884, it made the tariff the leading issue, and declared more uncompromisingly than ever in favor of protection.

The Democrats met in July at St. Louis and nominated Grover Cleveland for President and Allen G. Thurman, of Ohio, for Vice-President. They too made the tariff the leading issue, and, although they did not declare for absolute free trade, they demanded such heavy reductions that the practical result would have been the same. The campaign turned on the issue of protection or free trade, and the Republicans were victorious throughout the Northern States, except in Connecticut and New Jersey. They also carried the House and kept their hold upon the Senate. They were therefore in control of every branch of the Government, and the Fifty-first Congress, which followed, was a remarkable and memorable one.

The first great contest was in the House of Representatives, where the Democratic minority undertook by the use of the rules to prevent the transaction of business. Thomas B. Reed, of Maine, was elected Speaker, and under his lead a reform of the rules was accomplished, which gave the majority power to act. Reed's policy and rulings were the subject of bitter attack, but every one of his principles has since been adopted by the Democrats themselves and sustained by the Supreme Court, thus completely vindicating his action. The Republicans were in this way enabled to pass a large amount of most important legislation. To this Congress is due the international copyright law, a long-delayed measure of justice and good sense. To it are also due the inspection laws which opened the markets of Europe to the meat products of the U. S., generous appropriations for building up the navy, and mail subsidies to develop steamship lines. Many other valuable measures of a non-political character were also carried through. The two great party measures were the bill to regulate national elections, which passed the House and failed in the Senate, and the new protective tariff, which became law on Oct. 1, 1890. In the elections which followed for the House of Representatives, the Republicans were very badly beaten. The amount of legislation which they had secured brought, as it always does, reaction and opposition, but the chief cause of their defeat was the outcry raised against the McKinley Act on the ground that it was too extreme and that it would raise prices. During the remaining years of President Harrison's administration the fact that the two Houses were controlled by different parties prevented action.

The Campaign of 1892.—In 1892 the Republican party met in convention at Minneapolis, and after a contest caused by the hostility to the administration among many party leaders, President Harrison was renominated and Whitelaw Reid, of New York, was put on the ticket with him as Vice-President. The Democrats renominated Grover Cleveland, who was bitterly but unavailingly opposed by the delegates from his own State, and nominated with him for Vice-President Adlai E. Stevenson, of Illinois.

This campaign, like the preceding one, turned upon the question of the tariff, the McKinley Act furnishing the text as the Mills Bill had done in 1888. The Republicans made a partial recovery from the disasters of 1890, but were nevertheless decisively beaten, several Northern States giving their votes to the Democrats for the first time. In the electoral colleges Cleveland and Stevenson received 277 votes to 145 votes for Harrison and Reid, and 22 votes for Weaver and Field, the Populist candidates. The Democrats also carried both the Senate and the House, and on Mar. 4, 1893, came for the first time in thirty-five years into full control of all branches of the Government. In April a business panic began, which reached in the following summer great intensity. The Democrats declared that this was due to the existence of the Sherman Act passed by a Republican Congress as a compromise measure, providing for the purchase, by the Treasury, of 4,500,000 oz. of silver bullion every month. President Cleveland called Congress in extra session on Aug. 7, and after an obstinate struggle of three months the purchasing clauses of the Sherman Act were finally repealed by a combination of Republican and Democratic votes, but the repeal, which was a wise measure, did not relieve or improve business. The business depression still continued while the Democrats were engaged in a revision of the tariff, which bore no resemblance to the promises of their platform, and the Republican party made large gains at all the by-elections. At last in August the Democrats passed their Tariff Bill just as it came from the Senate, where the House bill received over 600 amendments of a protective character. The President refused to sign the bill, and, after denouncing it in the severest terms in public letters to two members of the House, permitted it to become law without his signature. In the general elections of Nov., 1894, the Republicans appealed to the people against the Democratic failure in the matters of tariff and finance, the business disasters they had caused, and also against their feeble and blundering foreign policy. The Republicans carried the elections overwhelmingly, gaining over 100 seats in the House and seven seats in the Senate. H. C. Lodge.

Repudiation [from Lat. *repudia're*, divorce, reject, scorn, repudiate, deriv. of *repu'dium*, a casting off; *re-*, back + *pudet*, it shames]: an act by which an administration declines to be bound by debts contracted by the governments which have preceded it. In European history there are numerous instances of a government annihilating a portion of its debt by converting it into a lower denomination, and similar instances have occurred in Mississippi and Pennsylvania.

Requests, Courts of: See the Appendix.

Requisitions [from Lat. *requisi'tio*, a search for, requirement, deriv. of *requi'rere*, search for, require; *re-*, back, again + *quæ'rere*, *quæsi'tum*, seek, ask]: (1) formal demands by one government on another for the extradition of criminals (for treatment, see Extradition); (2) in the international laws of war, demands for necessaries by an invader on an

invaded country. These have not always been distinguished from CONTRIBUTIONS (*q. v.*). Calvo, after De Garden, draws this line between them: that a *contribution* is what the inhabitants of a country occupied by an invading army are forced to pay or give in order to secure themselves from pillage, while a *requisition* is the demand made by the military authorities that the inhabitants shall place things, and even persons, at their disposal. A contribution is especially a payment in money, whether for the purpose of carrying on civil government in the occupied district or for general military uses. Requisitions, specifically, are forced supplies of material necessary for the carrying on of war, such as food and drink, fodder, horses, rolling-stock for railways and highways, lodging, labor, and a variety of other things. They may be levied under the authority of the commander of any detached force, but can not be made without authority, for that would be pillage, which is illegal. To account for them, especially for contributions, as payments for exemptions from pillage, is absurd; for pillage is barbarous, and in modern warfare the principle is that war is not waged against a quiet private person, and that his property is in general safe. But the requirements of an army of occupation for food and shelter, as well as the immediate needs of war, and outrages by *tirailleurs* and by unorganized natives, who yet are sympathized with by the district, have made summary and harsh impositions in some cases seem just and necessary.

The following rules express what the regulations of war ought to be, except in circumstances of extreme necessity, or where severe punishment of towns or communes is called for by their conduct: (1) The private citizen, nowise engaged in the war, is not to be treated as an enemy, and his property is to be respected. (2) The civil government in occupied territory must go on, under control of the invading commander, at the expense of the inhabitants. For this end taxes must be raised as before. (3) Special services for the army, supplies of food, and other necessaries ought to be paid for sooner or later, and for this end receipts should be given. However, these do not necessarily involve payment by the requisitioning force, though this is sometimes given. At the end of the war their payment may be provided for either by the invading party as one of the terms of peace, or by the government of the citizen whose property is requisitioned. (4) It is an unjust rule to make war pay for war. Wrongs ought to be repaired at the making of a peace. The prevalent practice of feeding, clothing, and supplying an army through its own commissariat has lessened the necessity for requisitions, but they are still lawful. (5) For penalties on a town or district in the way of fines, or of bodily inflictions on leading citizens, or of burning, which has been threatened even in quite recent times, there is very seldom a sufficient justification. Nor do severe requisitions or wholesale punishments do any good. Napoleon in his *Memoirs* acknowledges that the excesses in the way of requisitions during the war with Spain contributed not a little to the French reverses in the Peninsula.

The following are some typical modern opinions on this important but, unhappily, somewhat indefinite subject: (1) In *The Instructions for the Armies of the United States in the Field* the rightfulness of seizing private property is limited to cases of necessity, and the spoliated owner is declared to be entitled to a receipt, that he may obtain indemnity. (See WAR.) (2) Massé concedes to an enemy the right of forcing merchants or others to supply his army with the necessary provisions, but on condition of purchasing them at a certain price determined in advance. (3) Heffter is more harsh. According to him (§ 131 of his *Völkerrecht*), the enemy can impose and exact contributions, demand products of the soil and personal services; in case of necessity or resistance can even take them by force, leaving all adjustments to the political arrangements of the future. A definite limit to the right of taking can not be laid down, for there is no measure of rights in war. (4) Bluntschli (§ 653), after speaking of what the population of an occupied province ought to be required to do for an army of occupation, adds: "All these services furnish ground, according to circumstances, for compensation. We must distinguish between services which can be demanded simply on the score of war, and obligation of the population to pay taxes—the extent of which is either defined by legislation or by practice, and in regard to which, in these particulars, much must be left to the discretion of the commander—and services which go beyond this measure, and therefore, by natural law, are to be called for only as giving a right to compensation. But," he adds, "this duty of compensation is hard to be reduced to rule, and harder still to be carried through in practice." (5) Calvo (§ 905) admits, with most authors, that an army occupying an enemy's territory may demand from the communes or from the inhabitants that which is necessary for its support and movements, but these requisitions ought to be limited to things absolutely indispensable. (6) Gen. Scott, in Mexico, refrained from requisitions, paid for provisions, and took nothing by force without indemnifying those who held the property, except on rare occasions, when it was impossible to act otherwise. (See *Calvo*, § 903.) (7) The project of an international declaration concerning the rules and usages of war, adopted at Brussels in 1874, which differs somewhat from the project submitted by Russia at the same congress, but probably not for the better in respect to requisitions, contains the following provisions: Art. 40. "As private property ought to be respected, the enemy shall not demand from communities, nor from their inhabitants, articles or services except such as relate to the necessities of war generally acknowledged, and are proportionate to the resources of the country, and which do not imply for the population the obligation to take part in the war against their country." Art. 41. "The enemy levying contributions, whether as an equivalent to imposts or to objects to be furnished in kind, or by way of fine, shall proceed therein, as far as possible, only according to the rules of assessment and the plan of imposts in use in the occupied territory. For every contribution a receipt shall be given to the person making the payment." Art. 42. "Requisitions shall be made only with the authorization of the commander of the locality occupied. For every requisition an indemnity shall be granted or a receipt delivered." A part of the Russian project which was not accepted is worthy of notice: § lii. "The enemy can demand from the local population all the imposts, services, and dues, in kind or in money, to which the armies of the legal government have a right." See Woolsey's *Introduction to International Law*, § 130.

Revised by T. S. WOOLSEY.

Resaca de la Palma, rā-saa'kăă-dā-lăă-paal'măă, sometimes called **Resaca de Guerrero**, -gwā-rā'rō: a ravine in Southern Texas, 4 miles N. of Matamoras, Mexico. After his victory at Palo Alto (May 8, 1846), Gen. Taylor, with 2,200 troops, pursued the Mexicans (4,000 to 5,000, commanded by Arista) to this place; on the 9th he attacked and completely defeated them, capturing all the artillery and trains.

Rescission [from Lat. *rescis'sio*, annulment, abrogation; deriv. of *rescin'dere*, *rescissus*, to cut up, to tear up, to annul; *re-*, back, again + *scin'dere*, cut]: in law, a vacating or making void; annulment; abrogation; in the law of contracts, the annulling or vacating of a contract so that it can no longer be enforced between the parties unless it is renewed by mutual consent. A contract may be expressly rescinded; or it may be treated as rescinded where one party to it fails to perform his part of the contract, or disables himself from performing it, and the other party has not been guilty of default on his part. Where, however, the failure in performance is partial, leaving a distinct part as a subsisting and executed consideration so that the other party may recover his damages for the part not performed in an action for that purpose, a contract can not generally be rescinded; nor can it generally be rescinded by one of the parties unless both can be restored to the condition they were in before the contract was made. See the general treatises on *Contracts* of Parsons, Story, and Bishop; Benjamin's *Law of Sale of Personal Property*, etc.

F. STURGES ALLEN.

Reservoir [from Fr. *reservoir* < Late Lat. *reservato'rium*, storehouse, deriv. of *reserva're*, keep, store up; *re-*, back, up + *serva're*, keep]: in engineering, a lake or basin for holding water fitted with appliances for regulating the outflow of water at different rates from the inflow, thus enabling either a more or less regular supply to be distributed at irregular intervals of time or an irregular supply to be distributed at a uniform rate. Of the first class are what are termed *storage reservoirs*, which are generally constructed on the course of a stream by the erection of a dam, enabling the constantly flowing water to be impounded when it is in excess of the quantity needed for regular use and to be drawn off when the natural flow of the stream is less than the average demand. Enormous reservoirs of this kind were constructed in India and in Egypt at periods antedating any historical records, and many of them are still used

for their original purpose of making agriculture possible in regions where the seasons of rainfall and of the growing crops are separated by a considerable interval of time, while of many others traces alone remain. It is claimed that in Egypt the building of such reservoirs may in all probability be traced back to the days of the patriarch Joseph. In India there remain traces of the Poonairy reservoir, which by the construction of 30 miles of dams flooded 40,000 acres of land, and the Veeranum reservoir, which flooded 22,000 acres. The great Mudduk Masoor reservoir in India, constructed in the fifteenth century, was 108 feet deep, flooded 26,000 acres, and held 280,000 million gal. In the island of Ceylon there is an ancient reservoir covering an area of 10,000 acres.

No reservoirs of such magnitude as these have been constructed for several hundred years, but there are many thousand smaller ones. In Madras alone there are 50,000. In the nineteenth century the largest have been built by the British in India for storing water for irrigation, and several of considerable size have been constructed in California and New Mexico for the same purpose. A number of large reservoirs have been built in Spain, also for irrigation. In the rest of Europe and in the eastern portion of the U. S. the principal purpose for which storage reservoirs have been constructed is the supply of water to cities, and a large number of such have been built.

The question of the capacity necessary to insure the most economical results in reservoirs fed by streams which are subject to great variations of flow and the water of which is to be used for supplying the demands of a population which is constantly increasing and which at the same time is irregular in its requirements, has received careful study from civil engineers. The determination of this question involves considerations of climatic peculiarities, the relation between different topographical and geological conditions and the amount of water which a watershed will annually yield to a stream, and the rate at which at different seasons of the year a given population will consume water. The general conclusions reached by hydraulic engineers with reference to the economical dimensions of storage reservoirs for city water-supply in the temperate zone are that such reservoirs should contain a quantity of water equivalent to one-half of the total annual consumption anticipated in the city, and that the greatest efficiency can be obtained from any reservoir when its capacity is about 100 million gal. for each square mile of territory from which its supply is derived.

Among the largest storage reservoirs for water-supply to cities are the Vyrnwy for Liverpool, containing 11,900 million gal.; the Vehar for Bombay, containing 10,800 million gal.; the San Mateo for San Francisco, holding 31,000 million gal.; the Yan Yean for Melbourne, Australia, 6,400 million gal.; on the Croton river, New York, the Boyd's Corners, 2,727 million gal.; the Middle Branch, 4,004 million gal.; the East Branch, 9,028 million gal.; the Titicus, 7,000 million gal.; the Carmel, 9,000 million gal.; and the new Croton, begun in 1894, to hold 32,000 million gal. There are numerous storage reservoirs for other cities in both Europe and America holding from 500 to 1,000 million gal. See the article Reservoir Dams.

For the immediate daily demands of cities *service reservoirs* are required, and their capacity need not be much in excess of a single day's supply, their function being merely to keep the supply constant during the varying draughts at different times of day and different seasons of the year. They are generally located as near the center of distribution as practicable, and the water furnished to them by gravity from storage reservoirs or by pumping from the source of supply. Wherever possible, they are constructed on a summit by excavating sufficient material to make an embankment around the pit, and thus give the greatest capacity at the highest elevation. The largest reservoir of this type is in Central Park, New York city, and covers 96 acres and contains 1,200 million gal. A good example of a service reservoir constructed entirely above the surface of the ground with masonry walls is the Murray Hill reservoir in New York city, which is 400 feet square and holds 24 million gal. In many cases of small supply in flat regions service reservoirs are iron tanks or stand pipes from 5 to 40 feet in diameter and 50 to 250 feet in height. A fine example of such a reservoir is at Princeton, N. J., where a tank 20 feet in diameter and 60 feet high is placed on an iron trestle 60 feet high. On top of the tank is a meteorological observatory.

J. James R. Croes.

Reservoir Dams: artificial structures built across valleys through which streams flow, for the purpose of obstructing the natural flow of the water, raising its level, and thereby forming lakes or reservoirs. The simplest dam is one formed by filling a narrow gorge between high banks with loose rock and stones and gravel and then permitting the interstices to become clogged by the sediment brought down by the stream in freshets or by earth thrown in above the dam for the purpose. This method has been adopted even in works of recent construction in the western parts of the U. S., but such dams have in several instances been destroyed by freshets.

Where this crude method seems impracticable or injudicious and yet small expenditure is essential, dams are built of a cribwork of timber filled in with stones and sometimes faced with plank with close joints and frequently backed up with earth. There is a dam of this type, 1,017 feet long and 28 to 32 feet high, across the Connecticut river at South Hadley Falls, Mass. In such dams as those above named the water of freshets in the stream may be allowed to flow over the top of the dam. In cases where the water of freshets can be carried off by an independent channel, the best form of construction of a dam not exceeding 40 to 50 feet in height is usually an earth embankment, the width at the bottom being from three to four times the height of the dam. It is essential to the safety of a dam of this kind that its foundations should be made secure against the percolation of water through the bank, that the bank should be built of selected material put on in thin layers and thoroughly moistened, rammed, and rolled, and that the face of the dam on the water side should be protected with a stone paving. Owing to the difficulty of making an earthen dam under heavy pressure absolutely tight, it is customary to build in the center of the embankment a wall either of puddled clay or of masonry. The neglect of proper precautions to prevent the percolation of water through high earthen dams, either with or without masonry heart walls, has resulted in severe disasters, such as the failure of the Dale dyke at Sheffield, England, in 1864, the Mill river dam in Connecticut in 1875, the Worcester dam in Massachusetts in 1876, the South Fork dam at Johnstown, Pa., on May 21, 1889, the Pottsville dam in 1892, and the Portland, Me., reservoir dam in 1893. There are in the U. S. ten earthen dams more than 60 feet high for waterworks, two of which—the dam at Pilarcitos, Cal., 95 feet high, and that at San Andreas, Cal., 93 feet high—have no central wall either of puddle or masonry. The highest is that at Druid Lake at Baltimore, which is 119 feet high and has a puddle heart wall.

A structure of water-tight stone masonry is the type of dam which is most susceptible of being built on scientific principles, so that the minimum amount of material may be used with the maximum beneficial effect. The earliest application of masonry to the construction of large dams is believed to have been made by Spanish engineers about the middle of the fifteenth century. The dam of Almanza, 69 feet high with a thickness of 10 feet at top and 34 feet at bottom, has stood for over 300 years, and sustains a greater pressure per square foot than any other reservoir dam or than is considered prudent in construction at present. The Alicante dam, 141 feet high, is still in use, creating a reservoir for irrigation which holds 975 million gal.

In France the earliest high masonry dam was built at Lampy about 1776. Several others were constructed during the first half of the nineteenth century. All the masonry dams over 50 feet in height built prior to 1850 are believed to be as follows:

NAMES.	Date.	Height.	THICKNESS.	
			Top.	Bottom.
Almanza, Spain	1560–65	69	10	34
Alicante, Spain	1579–94	141	66	111
Elche, Spain	1590	76	30	40
Huesca, Spain	1690	66	36	53
Lampy, France	1776–82	53	16	37
Puentes, Spain*	1785–91	165	36	146
Val de Infierno, Spain	1785–91	116	41	138
Grois Bois, France	1830–38	93	21	46
Chazilly, France	1840–45	74	13	53
Nijar, Spain	1843–48	101	24	68
Zola, France	1843–50	120	19	42
Lozoya, Spain	1850	105	22	128

* Failed.

It will be observed that there is a great difference in the proportions of these dams, displaying great diversity of opinion among the engineers who designed them. It was not

until the middle of the nineteenth century that an analytical investigation of the principles which should govern the proportioning of masonry walls to resist water was attempted. In 1852 Sazilly, a French engineer, published the results of such an investigation, and formulated a type of cross-section for masonry dams. He was followed by Delocre in 1858, by Molesworth in 1873, by Bouvier in 1875, and by Prof. Rankine in 1881. The principles established by these investigators are now generally accepted, and the efforts of scientists like Krantz, Harlacher, Wegmann, and Kreuter have been devoted chiefly to simplifying the very laborious calculations required to design a perfect form of dam.

The first dam constructed on Delocre's type was at Furens, in France, in 1860–65, and is noteworthy as being the first high masonry dam built on correct scientific principles, the highest dam then constructed, and as having been in every respect successful. Since then the masonry dams built by French and Spanish engineers in Europe and also in Algeria have been designed on the same general principles. The most important of these dams are as follows:

NAMES.	Date.	Height.	THICKNESS.	
			Top.	Bottom.
Furens, France	1860–65	184	11	162
Ternay, France	1865–68	130	16	82
Tlelat, Algiers	1865–69	69	13	40
Habra, Algiers	1865–73	110	14	88
Verdon, France	1866–70	59	14	49
Ban, France	1867–70	166	16	128
Villar, Spain	1870–78	170	15	155
Pas du Riot, France	1872–78	113	13	85
Djijionia, Algiers	1873–75	83	13	53
Hijar, Spain	1875–80	141	16	147
Bouzey, France	1880–82	75	13	46
Gran Cheurfas, Algiers	1882–84	130	13	134
Pont, France	1883	86	16	63
Cotatay, France	1884–87	113	13	85
Vingeanne, France	1884–88	114	11	80
Puentes, Spain (new)	1885	160	13	125
Hamiz, Algiers	1885	135	16	91
Tache, France	1887	161	13	160
Remilly, France	1886–90	116	15	94

Tansa, India	1887–92	118	12	100
Periyar, India	1890–95	173	12	139

The first high masonry dam in the U. S. was designed by Gen. George S. Greene in 1866 for a storage reservoir for the New York city water-supply at Boyd's Corners, N. Y. Except that for the upper 10 feet it was somewhat thinner, this dam approximated very closely to the type which the investigations of later years have agreed upon as the best. The design and construction of this dam were described in a paper read before the American Society of Civil Engineers in 1874. It is 78 feet high, 8·6 feet thick on top, and 53·6 feet at bottom. A masonry dam for Mt. Eden reservoir, Cincinnati, O., built 1868–74, was 118 feet high, 15 feet thick on top, and 48 feet at bottom. In 1885 it cracked from defective design.

In 1881 Benjamin S. Church, C. E., suggested the construction of a dam about 240 feet high on the Croton river for the New York water-supply. His suggestion, which was approved by other eminent civil engineers and the city authorities, aroused a discussion of the principles governing the construction of high masonry dams which extended over a period of ten years, and resulted in the adoption of plans and the beginning of the construction in 1893 of the largest masonry dam as yet designed, being 248 feet high, 16 feet thick on top, and 185 feet at bottom. The design as finally adopted by A. Fteley, the chief engineer, conforms closely to the French type. In the meantime three other dams for Croton storage reservoirs had been begun, and several dams had been built in the Western States, chiefly to create storage reservoirs for irrigation. Most of these differed materially from the standard type, and two of them, although of much less thickness than the standard type, are claimed by their designers to possess greater resisting power on account of their being curved in plan and thus acting as arches. It is still a disputed question among civil engineers whether a curved masonry dam does so act except where the gorge closed is very narrow and the radius of curvature short, as in the cases of the Zola, Geelong, and Bear Valley dams.

Reservoir Floods: See Floods.

Reshd, also **Resht**: town of Northern Persia; capital of the province of Gilan (see map of Persia and Arabia, ref. 1–G). It is well built and contains many bazaars and caravanserais. It is the chief entrepôt for the trade in silk, large quantities of which are sent from here to Russia and Turkey. Iron goods and metal ware are imported. Its port on the Caspian Sea is Enzelli, 16 miles distant, and the communication between this place and Reshd is by boat for 12 miles and by a road passing through forest and swamp for 4 miles, once noted for its almost impassable condition, but now fairly well maintained. Pop. about 25,000.

Revised by C. C. Adams.

Reshid Pasha (*Mustapha Mehemet*): statesman; b. in Constantinople, Feb. 18, 1802. He was educated by his brother-in-law, Ali Pasha, and early entered the Ottoman civil service. Rapidly promoted, he was ambassador in Paris at the death of Mahmud II. (1839). He was at once recalled and appointed Minister of Foreign Affairs. The quadruple alliance (Austria, Great Britain, Prussia, and Russia) nullified the victories of Mehemet Ali (*q. v.*), rescued the Ottoman empire from destruction, and greatly facilitated his task. The young Sultan Abd-ul Medjid was earnestly desirous of continuing his father's reforms, and found a supple and astute assistant in the new minister. Reshid Pasha had an important share in drawing up the Hatt-i-sherif of Gulhane —a sort of constitutional charter—wherein the sultan accorded many rights and privileges to his Christian subjects, who had hitherto occupied a position of civil inferiority. He was forced to resign in 1841, was grand vizier from 1846 to 1852, and was recalled to office on the outbreak of the Crimean war (1853). During that struggle he was hardly more than the tool of Lord Stratford de Redcliffe, the British ambassador, commonly called by the Ottomans Buyuk Eltchi, the Great Ambassador, and upon the close of the war was superseded. British influence caused his restoration, but his influence entirely waned before his death, which occurred on Jan. 7, 1858. A man of literary and scientific tastes, of large views and much diplomatic ability, enjoying exceptional opportunities, he was weak, timid, and often unreliable. The apparent reforms he instituted were the work of his master and not of himself, while the commercial treaties which he concluded with Great Britain and France were an injury to his country.

E. A. Grosvenor.

Resilience [from Lat. *resili're*, spring back; *re-*, back + *sali're*, leap]: the capacity of a material to resist shocks or repeated stresses, the measure of which is one-half the product of the force by the linear elongation or compression produced, provided the material is not strained beyond the elastic limit. Thus if two bars of metal stretch 0·03 and 0·06 inches under tensile stresses of 1,000 and 2,000 lb. respectively, their relative resiliences are as 0·03 by 1,000 to 0·06 by 2,000, or as 1 to 4. The modulus of resilience is the resilience for a bar 1 inch in length and 1 sq. inch in cross-section when the stress is equal to the elastic limit of the material. Approximate average values of the modulus of resilience for timber, cast iron, and wrought iron are 3, 1, and 12 inch pounds respectively. The total work done in rupture of a beam or bar is called its ultimate resilience. See Strength of Materials. Mansfield Merriman.

Resi'na: town of Italy; province of Naples; 5 miles S. E. of the city of Naples; at the foot of Vesuvius between Portici and Torre del Greco (see map of Italy, ref. 7–F). It is built on masses of lava which cover a large part of ancient Retina and Herculaneum. The sinking of a shaft here in 1709 led to the discovery of remains of the theater of Herculaneum 90 feet below. In the vicinity are many attractive villas, the most frequented being La Favorita, the principal hall of which is inlaid with marbles from the palace of Tiberius at Capri. Pop. 13,626. E. A. Grosvenor.

Resins [viâ O. Fr. from Lat. *resi'na*, from Gr. ῥητίνη, resin, pitch]: a class of bodies that occur very widely distributed in plants mostly together with volatile oils, dissolved in which they frequently flow from trees accidentally or intentionally cut. Crude resins are never crystallized, but have the form of drops, like gum. They are generally colored yellow. Most resins consist of several simple compounds which, however, as a rule, can not be separated from one another. The number of resins is very large. They are used for preparing Varnishes (*q. v.*), sealing-wax, soap, for stiffening hat-bodies, etc. The most important are Amber, Copal, Dammar, Dragon's Blood, Mastic, Lac, Rosin (or colophony), and Sandarach (*qq. v.*). See also Gum-resins.

Ira Remsen.

Resistance of a Ship: See the Appendix.

Resolution of Forces: the mathematical separation of forces into component parts; the converse of Composition of Forces (*q. v.*).

Resolution of Rotations: See Motion.

Resor'cin [*resin* + *orcin*], or **Resorcinol**: $C_6H_4(OH)_2$, a diatomic phenol prepared on the large scale by the action of caustic soda on benzene-disulphonic acid; soluble in water, alcohol, and ether, and used for preparing fluorescein, eosin, and other phthalic acid colors. See Phthalic Acid.

Respiration [from Lat. *respira'tio*, breathing, deriv. of *respira're*, breathe, inspire and expire; *re-*, again + *spira're*, breathe]: the special function of the lungs, the process which has for its ultimate object the supplying of red blood-globules with oxygen for transmission to the various parts of the body. To accomplish this result, atmospheric air must be introduced frequently and continuously, an extensive surface of contact for air and blood must exist, and the effete products of the chemico-vital interchange must be exhaled.

The physical act of respiration or breathing embraces two parts, inspiration and expiration, and there are two distinct methods of breathing, the abdominal and the thoracic. In abdominal breathing the muscles of the abdomen by contraction force the viscera upward against the diaphragm, which becomes arched into the thoracic cavity and forces the air out of the lungs. Then the diaphragm, contracting, pushes the abdominal viscera downward, and thereby makes room for entrance of inspiratory air. In the thoracic type of breathing various external muscles elevate the ribs and sternum, and thus materially increase the chest capacity, causing inspiration. This completed, the weight of the chest walls, with the assistance of certain muscles, causes descent of the sternum and ribs, and, in conjunction with the natural contractility of the lung substance, forces the air out. The abdominal type of breathing is predominant in men, the thoracic in women.

Respiratory action of the lungs is involuntary, although it may be voluntarily modified. The *besoin de respirer*, or involuntary incentive to breathe, is the result of impressions received by the medulla oblongata from the several regions of the body, which constantly demand oxygen, and transmitted to the respiratory muscles of the thorax and abdomen. From eighteen to twenty respiratory acts take place per minute, at each of which an average of about 26 cubic inches of air is inspired and expired. This definite volume of air which ebbs and flows is termed *tidal air*. In addition, fully 100 cubic inches of air, unaffected by respiratory movement, remains in the smaller bronchi and air-sacs, and is termed *residual air*. Tidal inspiratory air is fresh and pure; it enters as far as the fourth divisions of the bronchi, and becomes a part of the relatively impure residual air. Tidal expiratory air contains carbonic-acid gas, which is exhaled and removed from the body. Each inspiratory act, therefore, adds an increment of oxygen to the bulk of air in the lungs; this oxygen, by the law of diffusion of gases, permeates the residual air and reaches the air-sacs. The air-sacs are thin-walled; indeed, their walls are essentially a network of capillary vessels held together by a film of elastic tissue. In the aggregate, the walls of the innumerable air-sacs constitute a surface of many hundred square feet, upon which the *rete mirabile* or delicate network of capillary blood-vessels is spread. The pulmonary artery brings impure or venous blood to this extensive surface, carbonic-acid gas is exchanged for oxygen, and the purified, reddened, oxygenated blood is returned by the pulmonary vein to the left side of the heart, thence to be propelled through the entire circulation. The red blood-globules are the carriers of oxygen, and the full object of the preliminary respiratory efforts and the intermediate chemico-vital interchange is really attained as these red globules yield their quota of oxygen to the cells and tissues which constitute the body. For a description of the respiratory organs see Histology; for artificial respiration see Resuscitation; and for respiration in animals see Anatomy, Comparative, and Vivisection. See also Respiratory Sounds.

Revised by W. Pepper.

Respiration (in plants): See Physiology, Vegetable.

Respirators [from Lat. **respira'tor*, one who breathes, deriv. of *respira're*, breathe]: mouth-pieces of fine gauze and cloth, to be worn by persons with diseased or weak lungs to prevent the ingress of cold and damp air or foreign matter, as smoke, dust, or the grit of stone. They are little used in the U. S., but are much employed in Great Britain, especially by grinders and stone-carvers, and wherever the air is permeated by impalpable particles.

Respiratory Sounds [*respiratory* is from Lat. *respira're*, breathe]: the sounds produced by inspiration and expiration, as heard by the method termed auscultation, the application of the ear to the chest directly, or indirectly through the medium of the stethoscope. If the entire period of a respiratory act be represented by ten, inspiration will occupy five-tenths of this period; expiration immediately follows during the succeeding four-tenths; and finally a period of silence and rest from breathing during the supplementary period of one-tenth. During the entire period of the inspiratory act the ear applied to a healthy chest detects a clear, full, breezy, or blowing sound, gentle at its commencement, full and well defined at its middle, and graduated and faint as it is terminating. The inspiratory sound is soft and low-pitched in adults; in children is ruder and exaggerated, possessing tubular or friction quality. Expiratory sound is comparatively faint, occupying but a small part of the period of the expiratory act. It also is soft and low-pitched, but more feeble and distant than inspiratory sound, since the recedence of expired air from the chest-walls conducts the sound-waves away from the ear of the listener. Expiratory sound is loudest at its commencement, just as the transition from inspiration has taken place, and gently graduates until it ceases. Inspiratory sound is the result of air-friction with the system of bronchial tubes through which it passes. Hence inspiration is a compound sound, possessing an element of laryngeal origin, elements of sound developed in the trachea, the large and small bronchial tubes, and especially where the tubes bifurcate; and finally an important element developed by the entrance of air into the numberless air-sacs or pulmonary vesicles. This vesicular element of inspiratory sound is a test of the healthy lung. Departures from the normal respiratory sounds are evidences of bronchial, pleural, or pulmonary disease. The sounds are harsh in early bronchitis, replaced or accompanied by *râle* or musical sounds in advanced bronchitis; they are masked or completely obscured by pleurisy; their inspiratory and expiratory periods have changed relations and qualities in asthma and emphysema; and in

pneumonia, tuberculosis, and other consolidations of the lung respiratory sounds are brought to the ear with increased intensity and clearness, and much raised in pitch. For detailed description of respiratory sounds in health and disease see the works of A. Flint, Sr., on the *Respiratory Organs*.

Respiratory System (in animals): See ANATOMY, COMPARATIVE.

Responden'tia [Mod. Lat., liter., conformity, deriv. of Lat. *responde're*, answer, conform]: a maritime loan made upon the hypothecation of a ship's cargo or some part thereof. It is a written contract and frequently in the form of a bond. Unless a specific lien on the goods is stipulated for, the respondentia obligation is a personal one of the borrower. Where such a lien is created it gives no claim to the lender in case the goods are lost; for it is the essence of this form of loan that the principal and interest are hazarded upon the safe arrival of the cargo. From this principle it follows that nothing can be hypothecated which is not in danger of perishing by maritime risk during the time that the loan is running. (*Brett* vs. *Van Praag*, 157 Mass. 132.) Most of the rules applicable to this form of loan are identical with those relating to loans of BOTTOMRY (*q. v.*), and need not be repeated. The master of a ship may bind her cargo by respondentia in cases of necessity, but not without communication with the cargo's owner, if communication is practicable. *Kleinwort* vs. *The Cassa*, 2 Appeal Cases 156.

FRANCIS M. BURDICK.

Responsibility: See OBLIGATION, MORAL.

Rest-cure: the term by which medical writers designate a plan of treatment first systematized by S. Weir Mitchell. It is especially useful in the treatment of the various forms of neurasthenia and hysteria. The patient is kept at rest in bed, the diet is regulated, milk generally forming the principal element, and the muscles and circulation are kept in a healthy condition by massage. W. P.

Restigouche, res-ti-goosh': a small river of New Brunswick and Quebec which falls into Chaleur Bay; celebrated for its excellent canoeing and fishing. It has five large and nearly equal tributaries. Its course is but little impeded, its current strong, full, and unflagging, and its waters very clear. The Restigouche salmon is celebrated for its size and for its fighting qualities. (See *Scribner's Magazine*, May, 1888.) The Restigouche trout is hardly inferior to the salmon in attractive fishing qualities. The best fishing-grounds are in private hands. MARK W. HARRINGTON.

Restorationists [from Lat. *restaura'tio*, restoration, deriv. of *restaura're*, set up again]: those Christians, of whatever sect, who entertain the belief that the wicked who die in an impenitent state will, after suitable punishment and repentance, be restored to divine favor, and that all the human race will at last become for ever holy and blessed. The first who taught this doctrine was Origen, and it seems to have spread widely in the East. It was, nevertheless, condemned by the Council of Constantinople, 543, and in the West it found no adherents. In the Middle Ages it was held by the Brethren of the Free Spirit, in the Reformation by the Anabaptists, in the eighteenth century by the Rationalists, and always by the Universalists.

Restraint of Trade, Contracts in: See the Appendix.

Restre'po, JOSÉ MANUEL: statesman and historian; b. at Envigado, Antioquia, New Granada, about 1780. He studied law at Bogotá, and during the war for independence took a prominent part in politics; under Bolivar he was Secretary of State, and he was personally acquainted with many distinguished men of the period. His most important work was *Historia de la Revolución de la República de Colombia* (7 vols., with 3 appendatory of documents, 1827; 3d ed., 4 vols., 1858). It is one of the most important contributions to the history of the South American war for independence, and is remarkable for its moderation and fairness. D. at Bogotá about 1860. HERBERT H. SMITH.

Resurrection [from Lat. *resurrec'tio* (deriv. of *resur'gere*, rise again, rise from the dead; *re-*, again + *sur'gere*, go up, rise), trans. of Gr. ἔγερσις, awakening, raising up, deriv. of ἐγείρειν, excite, rouse up, awaken, raise from the dead]: the future general raising of the bodies of the dead by the power of God. It is a doctrine peculiarly of revelation. Hints of it appear in the Brahmanic and Stoical theories of "returning cycles," the "great year" of Plato, and the Egyptian mysteries. It was definitely taught by the Zoroastrians. It is implied, alluded to, or foretold in the Old Testament (Job xix. 26 (?); Ps. xvi. 10; xlix. 15; lxviii. 18; Isa. xxvi. 19; lxvi. 24; Ezek. xxxvii.; Hos. xiii. 14; Dan. xii. 2). It was believed by most of the later Jews, and appears in the Apocrypha (Wisd. iii. 7; 2 Macc. vii. 9, 14, 23, 29). It was a formal doctrine of the Pharisees, but was disputed by the Sadducees. It was clearly revealed in the New Testament by Christ and the apostles, has been accepted by all parts and ages of the Church, and is a prominent doctrine of Mohammedanism.

As held now, this doctrine rests on the incontrovertible historical fact of the resurrection of Christ. He rose on the third day after his death in the body, which, though changed as to its mode of being, was the identical body which was crucified. He was seen often in different places and circumstances by many witnesses. The proofs of Christ's resurrection rest on his predictions and references to it as a miraculous attestation of his truthfulness; on the testimony and assertions of the apostles, who had been intimate with him for three years, who were at first incredulous and so cool-headed, and showed their sincerity by dying for the truth of that which they asserted; on the testimony of disciples and friends, who were persons of the highest character and piety; of soldiers, and indirectly of Jews and enemies, who tried to hush up the facts, not to deny them. They rest also on the universal belief of the early Church, the gift of the Holy Spirit according to Christ's promise, the powers given to the apostles, the institution of the Lord's Day, and the Christian religion. It is impossible that in this matter there should have been invention, mistake, collusion, self-deception, or imposture. The fact is beyond doubt. It was the fulfillment of prophecies and promises, the vindication of the past, Christ's triumph over pain and evil, the divine seal, the consummation and confirmation of Christ's work on earth, part of his exaltation, the introduction to his heavenly work and mediatorial kingdom.

The New Testament teaches that all the dead are to rise at the last day to judgment—the good to bliss, the bad to punishment. It speaks of the resurrection of the dead, or from the dead, or of the *body* (σῶμα), not of the *flesh* (σάρξ, *caro*). The creeds and symbols of the Church have generally used the grosser form, the resurrection of the *flesh*. The Gnostics and Manichæans rejected the phrase, because, like the Oriental heathen and the Platonists, whom they resembled in a measure, they despised the body, they taught a merely spiritual resurrection. Most of the Fathers held the gross view, against which the early infidel attacks were directed. Origen first reaffirmed the distinction between the resurrection of the body and the flesh, between the essence and the phenomenal form. Augustine held at first to the spiritual view, afterward to the sensuous, though not in its grosser form. The Alexandrian and Eastern schools held the spiritualizing view—the Western schools, the literal. The Reformers mainly returned toward Origen's interpretation.

The doctrine is maintained by reference to Christ's rising —to the express words of Christ and his apostles (they were false if that was not a fact). It is confirmed by the fact that in a human person there is body as well as spirit. It has been illustrated by the analogies of the renewal of life in seeds and plants, the seasons, the morning, the waxing moon, the butterfly, etc.

Opponents of the doctrine have maintained that (1) Christ's body was stolen; (2) was resuscitated from a swoon; (3) the belief arose from subjective visions, or (4) grew up as a myth, or (5) from the determination of the disciples not to be disappointed in their projects or hopes, or (6) to meet the prejudices of the Jews; or (7) it was a conscious imposture, or (8) an allegory of the soul after death, or (9) of the regeneration of society, or (10) of the rising from sin, or (11) of the rising of souls from Hades to judgment.

The resurrection of Christ is treated as the fountain, type, and power of a new life—the corner stone of the Christian system, without which everything falls. It is related closely to every doctrine, and has always been a chief point of attack. The doctrine of the resurrection meets our desires and our intense belief in our indestructible personality. It is part of the antidote of the fall, from which, under the covenant of grace, the whole of human nature is to be redeemed and united to Christ. It gives dignity to the body which was created by God, redeemed by Christ, and is the "temple" and organ of the Holy Spirit. It gives hope and comfort—relief, in part, from the terror of death. It shows the power, love, and truth of God; fulfills the promises and prophecies; confirms the inspiration of the Scriptures; assures us of immortality; shows that the soul and body,

united in sin and redemption, will be united in judgment and glory or shame. It confirms the divinity of Christ and his atonement, and is intimately related to justification, faith, repentance, sanctification, and the whole Christian system. It is the foundation of the Christian week and year.

The resurrection implies the continued identity of the body —that the future body is in essence identical with the present body, one being the veiled germ, the other the glorious development. Concerning identity, it has been taught that (1) all the particles of matter that have ever been in the body are brought together again; (2) only the particles present at death; (3) certain more enduring parts are preserved, as an indestructible corporeal germ from which is made by divine power an organ of the soul adapted to its higher condition; (4) some of the particles remain, however few; (5) there is a "vital germ"; (6) a spiritual, "ethereal, luminous" body is evolved at the moment of death; (7) that the plastic formative principle of life (*anima, psyche*) is continually gathering and casting off the matter it needs for a body wherever it may be. The continuance of the vital principle constitutes identity, however the particles of matter may change, as in a flowing stream. In the case of Christ and those alive at his coming, the body then present supplies the material; in the case of the dead, the anima or psyche gathers in matter as it needs and makes the psychical body. The fundamental "form" or principle of bodily organism, which here appropriates earthly materials, shall in the resurrection appropriate higher materials: (8) That identity is in the spirit (*νοῦς*), the rational, immortal principle which shows itself in the body which it occupies and stamps with its own personality. Identity in an inorganic body—e. g. a stone—is in its substance and form; in an organic body, in the whole organism; in a person it rests in the consciousness.

The resurrection body is (1) spiritual (*soma pneumatikon*), as opposed to the "natural" (*soma psychikon*); (2) like Christ's body; (3) glorious, powerful, incorruptible, immortal.

The doctrine, held by some, of two resurrections at different times—one of the righteous, to which the New Testament specially refers, and the other of the wicked—rests on (1) the declaration, Rev. xx. 5, 6; (2) the use of the phrase "resurrection *from* the dead," used fifty times, and always referring to the good; the phrase "*of* the dead," referring to the bad; (3) on the New Testament distinctions concerning the resurrection of the just and unjust, the resurrection to life or condemnation; (4) the longing of the apostle to attain the first; and (5) on the order given, 1 Cor. xv. 23.

Revised by F. H. Foster.

Resurrection Plant: a popular name of several plants which, after drying, on the application of moisture expand again. One of these is the Rose of Jericho (see Jericho, Rose of) of the east Mediterranean region. Another common one is *Selaginella lepidophylla*, a Lycopod of the family *Selaginellaceæ*, a native of Mexico and Central America. It is a vivid green, rosulate, branching plant, covering a space on the ground from 5 to 8 inches in diameter. When dry it rolls up into a dull-grayish ball, but upon the return of moisture it expands again into a beautiful green rosette. These plants are imported into the U. S. in considerable numbers, and sold as curiosities. Charles E. Bessey.

Resuscitation, or **Artificial Respiration** [*resuscitation* is from Lat. *resuscita'tio*, deriv. of *resuscita're*, stir, rouse up again; *re-*, again + *subs*, from under, up + *cita're*, urge, excite, rouse]: motion of the ribs and exchange of air produced by external instead of internal and vital force. The natural exchange of air in respiration is effected by a mechanical process; and when the muscles which conduct it are deprived of their nervous stimulus by poisoning of the nerve-centers, that mechanical process can be kept going or be recommenced by mechanical means, and thus life be rekindled from apparent death. By compression of the ribs the chest-cavities are diminished, and a proportionate quantity of foul air is forced out by the mouth. On relinquishing that compression, the ribs by their own elasticity bound back to their former position, the chest-cavities are enlarged, and the air (if that be the surrounding medium) is sucked in to prevent a vacuum. Whatever the method, it is upon this principle alone, with the observance of proper alternation and rhythm, that such an exchange of air can be effected as to be a substitute for natural breathing. Its use is in suspended animation from suffocation, as in drowning and hanging, also from vapor of chloroform or other noxious gases, in which, death occurring from exclusion of air, a supply of air to the lungs is the one remedy.

The following is known as the "direct method" for artificial respiration:

Rule 1. To drain off Water from Chest and Stomach (in cases of Drowning).—Instantly strip the patient to the waist. Place him face downward, the pit of the stomach being raised above the level of the mouth by a large, hard roll of clothing placed transversely beneath the body. Throw your weight forcibly two or three times, for a moment or two, upon the patient's back, over the roll of clothing, so as to press all fluids in the stomach out of the mouth.

Rule 2. To perform Artificial Breathing.—Quickly turn the patient upon his back, the roll of clothing being so placed beneath as to make the breast-bone the highest point of the body. Kneel beside or astride patient's hips. Grasp front part of the chest on either side of the pit of the stomach, resting your fingers along the spaces between the short ribs. Brace your elbows against your sides, and, steadily grasping and pressing forward and upward, throw your whole weight upon the chest, gradually increasing the pressure while you can count *one—two—three.* Then suddenly let go with a final push, which springs you back to your first position. Rest erect upon your knee while you can count *one—two*; then make pressure again as before, repeating the entire motions at first about four or five times a minute, gradually increasing to about ten or twelve times. Use the same regularity as in blowing bellows and as is seen in natural breathing, which you are imitating. If another person be present, let him with one hand, by means of a dry piece of linen, hold the tip of the tongue out of one corner of the mouth, and with the other hand grasp both wrists and pin them to the ground above the patient's head.

Sylvester's method is the most generally applicable. The body being placed upon the back, with the head slightly elevated, the flexed arms, grasped just above the elbows, are carried outward and upward from the chest almost perpendicularly, and retained in their position for about two seconds. They are then lowered and brought closely to the sides of the chest, against which they are firmly pressed for the same length of time, in order to expel the air as during the act of expiration. These alternate movements of elevation and depression are repeated from twelve to fourteen times a minute, and are performed with all possible gentleness. *Fell's method* of direct artificial respiration is applicable especially to opium-poisoning or other forms of narcosis. A tube is inserted into the larynx and trachea and warmed air forced in by a bellows. By this method persons apparently dead have been resuscitated. Mouth-to-mouth insufflation, in children especially, is easily practicable and very useful.

The length of time persons have been under water, or have remained apparently dead after leaving the water, and yet been resuscitated, is uncertain. The reported time is so remarkably long in some cases as to justify efforts for resuscitation for at least an hour, the patient having breathed within half an hour or perhaps an hour. In experiments by a committee of the Royal Medico-Chirurgical Society of London in 1862, dogs after complete submersion a minute and a half never recovered. After respiratory acts had ceased, the heart continued to act never more than four minutes. In the human subject these periods doubtless may be much longer, governed largely by the continuousness of submersion, the rate of the circulation at the last moment of consciousness, the temperature of the water, the amount of it which enters the lungs, etc. Revised by W. Pepper.

Retaining Wall: a wall of stone built to sustain banks of earth in position. The lateral pressure of the earth depends upon its nature and upon the inclination of the wall. (See Earthwork.) The thickness of the wall at the top will be usually 2 feet or more, and its thickness at the base is to be so determined that ample security against sliding, rotating, and crushing will be secured. The last of these is liable to occur only in very high walls, and the first can be always avoided by inclining the joints backward. The use of formulas for computing the thickness is hence mainly confined to the case of rotation for ordinary walls, and these are deduced so that under the most unfavorable circumstances the line of direction of the resultant of the earth pressure and the weight of the wall shall cut the base within its middle third. The cross-section of the wall is usually trapezoidal, but walls with curved front surfaces are occasionally built. If the back of a trapezoidal wall be vert-

ical, and P be the horizontal pressure of the earth behind it, for a length of a foot, a be the top thickness in feet, and v the weight of a cubic foot of the masonry, then the formula

$$b = -\frac{a}{2} + \sqrt{\frac{2P}{v} + \frac{5a^2}{4}}$$

gives the proper base thickness for security against rotation. Retaining walls should be furnished with holes to permit drainage, and the top of the back should be arranged so that the frost may not exert a heavy lateral thrust. See Howe's *Retaining Walls for Earth* (1886), and Merriman's *Retaining Walls and Masonry Dams* (1892).

MANSFIELD MERRIMAN.

Retaliation: See INTERNATIONAL LAW (*International Relations as Affected by War*).

Rete Mirabile: See CIRCULATION OF THE BLOOD.

Ret'ene [from Gr. *ῥητίνη*, pine resin]: a hydrocarbon (formula $C_{18}H_{18}$) polymeric with benzene (C_6H_6), discovered in 1837 by Fikentscher and Trommsdorff. It occurs in fossil pine-stems, in peat and lignite, and associated with fichtelite. It is found among the products of the destructive distillation of very resinous pine and fir wood, and is produced with other bodies when acetylene or the product of the distillation of rosin (colophony) is passed through a red-hot tube. It is extracted from fossil wood or lignite by means of alcohol, and is purified by solution in bisulphide of carbon, then in benzene, and in combination with picric acid. The picrate is recrystallized, decomposed with ammonia, and the retene recrystallized from alcohol. It may also be obtained from the semisolid products of the latter part of the distillation of pine-tar. Retene appears in soft, shining, nacreous laminæ, inodorous and tasteless. It melts at 98° to 99° C. It evaporates at ordinary temperatures, and when melted gives off white fumes which condense to a woolly sublimate. It boils at about the boiling-point of mercury, and distills almost unchanged. It is insoluble in water, slowly soluble in cold, readily in boiling alcohol, easily in warm ether, in fixed and volatile oils, in benzene, and in bisulphide of carbon.

Revised by IRA REMSEN.

Retention of Urine [*retention* is from Lat. *reten'tio*, deriv. of *retine're*, *reten'tum*, hold back; *re-*, back + *tene're*, hold]: a condition in which the urine can not be evacuated from the bladder at all, or only with great difficulty, the former being known as complete, the latter as incomplete, retention. It should not be confounded with *suppression*, in which the urine has not been excreted by the kidneys, and consequently the bladder is empty. The symptoms consist of a great and urgent desire to pass water, and partial or complete inability to do so; this is accompanied by repeated straining efforts and violent pain, and extreme distress and restlessness; the countenance assumes an anxious expression, the pulse is quick, and the skin dry. The bladder is more or less distended according to the protraction of the trouble, and its position may be ascertained by percussion above the pubes. If this condition is not speedly relieved, it results in rupture of some portion of the urinary tract and extravasation of the contents of the bladder into the surrounding parts. Here the urine acts as a foreign body, and, by virtue of the bacteria which it contains, causes an inflammation which soon terminates fatally.

The causes may be classified as those due to (1) mechanical obstruction; (2) paralysis of the bladder, partial or complete; (3) hysteria; (4) miasm. The agents mechanically obstructing the flow of urine are numerous. Organic stricture of the urethra is a very common one, but it causes complete retention only when, after exposure of some kind or over-indulgence in spirituous liquors or sexual excitement, there is congestion or spasm added to it, and the urethral canal thus made impervious. The attempt should here be made to use a small catheter, but if this can not be done, the warm bath, local abstraction of blood, and the administration of ether or chloroform should be superadded. Should these means fail, the only resource left is to "tap" the bladder, either through the rectum or above the pubes. This is done by means of the aspirator. The relief, however, is only temporary; the stricture still remains, and some operation must be resorted to for its relief. Spasmodic contraction of the muscle surrounding the neck of the bladder or the muscular coat of the urethra sometimes exists as a cause of retention: when such is the case, the warm bath, purgatives, opium, and chloroform are the remedial agents. Inflammation along the urethral canal (gonorrhœa) often has retention of urine as a complication. Here it is caused by an intensely congested and swollen mucous membrane, and the same treatment as for muscular spasm may be adopted. Among the other mechanical causes the most important are (*a*) a small calculus impacted in the urethra; (*b*) small tumor in the urethra; (*c*) clotted blood in the urethra or bladder; (*d*) foreign bodies, as pieces of bougies, catheters, etc., in the urethra; (*e*) tumors of any kind, external to the urethra, which press upon it; (*f*) the results of falls upon the perineum or blows in that location, by which the urethra is ruptured. These causes operate quite frequently, and embrace all cases of retention due to chronic enlargement of the prostate, inflammation or acute congestion of the prostate, abscesses in the perineum, pressure of a loaded rectum, a displaced uterus, the head of the child during labor, or a pelvic tumor of any kind upon the neck of the bladder. The treatment should always be directed to the removal of the cause, and where this requires any great amount of time, the catheter and aspirator are palliative means. Paralysis of the bladder, causing retention, may be due to voluntary retention repeated and long kept up, apoplexy, injury to the spine, acute overdistention of the organ, shocks to the system from capital operations, and in certain high fevers, as typhoid, typhus, etc. The treatment in all these cases should be by the catheter. Hysterical retention is a disease of the mind, and depends wholly upon the volition of the patient. (See HYSTERIA.) Gross mentions a form of retention which is periodical in its nature, and which he ascribes to malarial influences, and accordingly adopts the treatment of miasmatic diseases, as quinine, etc.

Rethel, rā'tel, ALFRED: painter; b. at Aix-la-Chapelle, Germany, May 15, 1816; studied at Düsseldorf under Schadow, and at Frankfort under Veitt; visited Italy in 1844–45; painted after his return four great frescoes representing incidents in the history of Charlemagne in the city hall of his native city, and produced several grand and very interesting designs—*Hannibal crossing the Alps*, *Dance of Death*, etc.—but became insane in 1852. D. at Düsseldorf, Dec. 1, 1859.

Reticula'ria [Mod. Lat., dimin. derived from Lat. *rete*, a net]: a name used for the FORAMINIFERA (*q. v.*), in allusion to the network formed by the protoplasmic processes (*pseudopodia*) sent out by the body.

Retina: See EYE and HISTOLOGY (*Organs of Special Sense*).

Retrogradation [from Lat. *retrograda'tio*, a going backward, deriv. of *retrograda're*, go backward, retrograde, deriv. of *retrogra'dus*, going backward, deriv. of *retrogradi*; *retro-*, back + *gra'di*, step, go]: in astronomy, an apparent or real motion of a celestial object from E. to W., or contrary to the order of the signs in the heavens. Motion from W. to E. is called direct. The motion of all the primary planets of the solar system is direct, but that of some of the comets is retrograde. The planets, however, seem at times to have a retrograde motion, which is because their velocities in their orbits differ from that of the earth. The inferior planets move more rapidly than the earth, and the superior less rapidly. It happens, therefore, that the inferior planets have a motion apparently retrograde near the times of their inferior conjunctions. The apparent motion of the superior planets is retrograde for some time before and some time after their oppositions. Between the periods of direct and retrograde motion there are times when to the naked eye these bodies are apparently stationary. The mean periods of retrogradation are—for Mercury, 22 days; for Venus, 42; for Mars, 73; for Jupiter, 120; for Saturn, 140; for Uranus, 152; for Neptune, 158½.

Retz, GILLES DE LAVAL, de, generally called **Marshal Retz**: b. at Machecoul, department of Loire-Inférieure, France, in 1404; distinguished himself in the wars of Charles VII.; fought at the side of the Maid of Orleans; was made a marshal of France, but retired subsequently from public life to his castle of Retz. Implicated in a process with the Duke of Bretagne, the proceedings disclosed the most hideous crimes committed by him. During fourteen years he had enticed over one hundred children into his castle and sacrificed them to his lust and superstition, being a worshiper of Satan and addicted to magic. He was strangled and burned Oct. 25, 1440. See BLUEBEARD.

Retz, Jean François Paul de Gondi, Cardinal de: b. at Montmirail-en-Brie, France, Oct., 1614. His family held high ecclesiastical dignities, and forced him against his will into the Church. He led, nevertheless, an irregular life, and devoted himself to the service of a restless political ambition. He was active in intrigues against Richelieu, after whose death he was, in 1643, appointed by the queen-regent coadjutor to his uncle, the Archbishop of Paris. The power he acquired as a pulpit orator he turned to political ends and tried to supplant Mazarin, taking advantage of the troubles of the Fronde. He acquired a cardinal's hat in 1651 by his intrigues, but was outgeneraled by Mazarin, arrested in 1652, and imprisoned, first at Vincennes, then at Nantes. While in prison he became Archbishop of Paris. He escaped, fled to Spain, and remained a fugitive there and in Italy and Holland till after Mazarin's death, when, in 1662, he made his peace with Louis XIV., exchanged his archbishopric for the abbacy of St. Denis, in Paris, and spent the rest of his life in dignified and sumptuous quiet, employed in some delicate diplomatic missions to Rome, in writing his *Mémoires*, and in paying his debts. D. in Paris, Aug. 24, 1679. His *Mémoires* cover the years 1643–55, are very frank, not always truthful, but brilliantly written. They were first published in 1717; the best recent edition is that in the series of *Grands Écrivains de la France* (first 9 vols., Paris, 1872–87). A. G. Canfield.

Retzius, Magnus Gustaf: histologist; b. in Stockholm, Sweden, Oct. 27, 1842; widely known and quoted as an authority in anthropology. His work *Finska Kranier* (Finnish Skulls), published in 1878, is standard. In 1884 he compiled his German work *Das Gehörorgan der Wirbelthiere*. Since 1872 he has edited the volumes of *Ur vår tids Forskning*, and in 1881–82 he edited *Biologische Untersuchungen*, mainly written by himself. R. B. A.

Reuchlin, roich-leen' (Hellenized Capnio), Johann: classical and Hebrew scholar and humanist; b. at Pforzheim, Baden, Germany, Feb. 22, 1455. He was educated in the chapel of the Margrave of Baden, and followed in 1473 the young margrave to the University of Paris, where he began his studies in Greek. During two years' residence at Basel he wrote his Latin dictionary, *Vocabularius breviloquus sive Dictionarium, singulas Voces Latinas breviter explicans*; and during a second visit to France in 1478 he studied law at Orleans. In 1481 he lectured on jurisprudence and belles-lettres at the University of Tübingen, received the title of imperial counsellor from the emperor, and lived subsequently for several years at the court of the elector palatine, Philip, at Heidelberg (1492–96). To this period belong his first studies of the Hebrew language and his comedy, *Sergius, sive Capitis Caput*, whose satire against the clergy was heartily enjoyed. In 1498 he went to Rome, his patron, the elector palatine, having fallen under the papal ban, and he succeeded in procuring his absolution. After his return he was appointed president of the Suabian confederate tribunal, but he found time to continue his studies of Hebrew, the results of which were his *Rudimenta Hebraica* (1506), *De Arte Cabbalistica Libri III.*, and *De Accentibus et Orthographia Hebræorum Libri III.* (1518). By these works he inaugurated the study of the Hebrew language in Western Europe. He exercised a similar stimulating influence by his handbooks, editions (e. g. Xenophon's *Agesilaus, Hiero*, and the two speeches of Æschines and Demosthenes on *The Crown*), and personal exertions in the study in Germany of Latin and Greek. The pronunciation of the Greek language known as Iotacism originated with him. He was too liberal to escape clashing against the prejudices of his age. A converted Jew, Johann Pfefferkorn, proposed in 1510 that all Hebrew books, with the exception of the Bible, should be burned. The Dominicans were in raptures over the proposition; the Inquisition immediately recognized it as a new weapon of persecution; the emperor acquiesced. Meanwhile Reuchlin remonstrated, the emperor withdrew his consent, and the Inquisition and the monks flew into a fury. Reuchlin published his *Speculum Oculare* (*Augenspiegel*) (1512) and *Defensio contra Calumniatores* (1513), while Ulrich von Hutten and Franz von Sickingen kept guard over his personal safety. In 1515 appeared the first part of the *Epistolæ Obscurorum Virorum*, most of which were written by a friend of Reuchlin, Crotus Rubianus, others by Ulrich von Hutten. The success of this famous satire was instantaneous, and did not a little in paving the way for the Reformation. With Luther himself Reuchlin felt a deep sympathy, but he declined an invitation to come to Wittenberg, sending in his stead his nephew Melanchthon, and maintained his connection with the Roman Catholic Church to the last. In 1520 he was appointed professor at Ingolstadt, but when the plague broke out in that city he determined to retire to Tübingen, but died at Liebenzell, June 30, 1522. His *Life* was written by Gehres (1815), Meyerhoff (1830), Geiger (1871), and Horawitz (1877). Geiger also edited his *Letters* (1876). Revised by A. Gudeman.

Réunion, rā'ü'ni-ōn', called **Bourbon** prior to 1848; also **Île Bonaparte**: an island and French colony in the Indian Ocean; belonging to the Mascarene group; about 100 miles S. W. of Mauritius; lat. 20° 51′ 43″ S., lon. 55° 30′ 16″ E. It is 38 miles long, 28 miles wide; area, 965 sq. miles. It is volcanic, and is traversed by a mountain-chain the direction of which is N. and S. This mountain-range, of which one peak rises 10,000 feet above the sea, divides the island into two portions, differing in climate and productions. The Piton de la Fournaise, 7,200 feet high, is an active volcano, the eruptions of which occur on an average at least twice a year. The soil in some parts is very fertile, and the scenery is generally extremely beautiful. The climate was formerly healthful, but Europeans now suffer much from typhoid fever and dysentery. The mean annual temperature is about 77° F. The island is often visited by terrific hurricanes, which demolish houses and tear up trees by the roots. The chief articles of export are sugar, coffee, and dyewoods. Maize, rice, and tobacco are also cultivated. Réunion has no good harbors, and the coast is consequently dangerous. Capital, St. Denis. The chief port is Pointe-de-Galets, from which extends a railway 78 miles long. This island was discovered in 1545 by the Portuguese, and was occupied by the French in 1649. Pop. (1893) 171,713, of whom 23,161 are Hindus. Revised by M. W. Harrington.

Reuss, rois: the name of two small principalities of Germany belonging to an elder and younger line of the family of Reuss, and consisting of several separate territories situated between Prussia, Saxony, and Bavaria. The dominion of the elder line, Reuss-Greiz, has an area of 122 sq. miles. Pop. (1900) 68,287. Capital, Greiz. That of the younger line, Reuss-Schleiz Gera, has an area of 319 sq. miles. Pop. (1900) 138,993. Capital, Schleiz. The surface of both principalities is hilly, reaching over 2,000 feet high in the Thüringer Wald. More than a third is covered with forests, and there are extensive meadows on which cattle are fattened. Woolen, cotton, and silk goods are woven.

Reuss: a river of Switzerland. It rises in the canton of Uri, near St. Gothard, descends in its upper course 4,500 feet in a series of wild cataracts and magnificent cascades, enters the southern end of Lake Lucerne, issues from the northern end as a clear, deep-green, navigable stream, and joins the Aar in the canton of Aargau at Windisch after a course of about 100 miles.

Reuss, Édouard Guillaume Eugène, D. D.: theologian; b. at Strassburg (then a part of France), July 18, 1804; educated at the seminary of his native city; studied theology at Göttingen under Eichhorn, Oriental philology at Halle under Gesenius, and pursued the latter branch at Paris under Silvestre de Sacy; taught biblical criticism and Oriental languages in the theological school of Strassburg 1829–34; became extraordinary professor there 1834, and ordinary (regular) professor 1836; retired on a pension 1888; declined a call to the University of Jena; published (in German) a *History of the Books of the New Testament* (Halle, 1842; 6th ed. Brunswick, 1887; Eng. trans. from 5th ed. 1874, by E. L. Houghton, 2 vols., Boston, 1884), and *Geschichte der heiligen Schriften Alten Testaments* (1881; 2d ed. 1890); *Histoire de la Théologie chrétienne au siècle apostolique* (2 vols., Strassburg, 1852; 3d ed. 1864; Eng. trans. Edinburgh, 1872); *Histoire du Canon des Saintes Écritures dans l'Église chrétienne* (1863; Eng. trans. Edinburgh, 1884); and prepared an annotated French translation of the entire Bible (19 vols., Paris, 1874–81), and the same in German (Brunswick, 1892, *seq.*). He edited for many years a German review which appears at Jena (*Beiträge*, etc.), contributed largely to Colani's *Revue de Théologie*, and was one of the most learned and liberal theologians of the French Protestant Church. With Baum and Cunitz, and after their death alone, he edited the monumental edition of Calvin's *Opera*, not yet finished (vol. l., 1894). D. in Strassburg, Apr. 15, 1891. Revised by S. M. Jackson.

Reuter, roi'ter, Paul Julius, Baron: promoter of the telegraphic system on the continent of Europe; b. at Cassel,

Germany, July 21, 1821; became identified with the telegraph system at its first establishment; organized the first news agency in Aix-la-Chapelle 1849; transferred his office to London 1851, and instituted and completed the system until it finally included all parts of the world. He obtained a concession for the submarine telegraph line between England and Germany 1865; obtained a concession from the French Government for the construction of a cable between France and the U. S., which was completed in 1869; was granted in 1872 the exclusive privilege of constructing railways, working mines and forests, and making use of all the natural resources of Persia. This concession was annulled in 1889, and in lieu of it Baron Reuter received the concession of the Imperial Bank of Persia. C. H. THURBER.

Reutlingen, roit'ling-*en*: town of Würtemberg, Germany; on the Echatz, a tributary of the Neckar; 20 miles S. of Stuttgart (see map of German Empire, ref. 7–E). It is old, but well built and picturesque. The Gothic church of St. Mary (1247–1343) has a tower 243 feet high. The town lies in a fertile district rich in corn, wine, and fruit, and carries on a lively trade and extensive manufactures of woolen and linen fabrics, hosiery, leather, and cutlery. Pop. (1895) 19,822.

Rev'al, or **Revel**: capital of the government of Esthonia, European Russia; on the southern side of the Gulf of Finland; 232 miles by rail W. S. W. of St. Petersburg (see map of Russia, ref. 5–C). The upper or old town contains the cathedral, the castle, and the houses of the German nobility. The lower or new town extends outside the walls. Reval is an important port, exporting grain, spirits, flax, etc., to the value of about $13,000,000 annually; imports of cotton, coal, etc., about $32,000,000. Reval was founded by Waldemar II. of Denmark in 1219; became a flourishing Hanse town; was held by the Livonian knights from 1346 to 1561; then belonged to Sweden, and was finally annexed to Russia in 1710. Pop. (1897) 64,578.

Revelation [from Lat. *revela'tio*, an unveiling, revealing, deriv. of *revela're*, unveil; *re-*, back + *vela're*, to veil, deriv. of *ve'lum*, a veil]: in its active meaning, the act of God by which he communicates to man the truth concerning himself —his nature, works, will, or purposes; in the passive meaning, the knowledge resultant upon such activity of God. The term is commonly employed in two senses: a wider—general revelation; and a narrower—special revelation. In its wider sense it includes all modes in which God makes himself known to men; or, passively, all knowledge concerning God however attained, inasmuch as it is conceived that all such knowledge is, in one way or another, wrought by him. In its narrower sense it is confined to the communication of knowledge in a supernatural as distinguished from a natural mode; or, passively, to the knowledge of God which has been supernaturally made known to men. The reality of general revelation is disputed by none but the anti-theist and agnostic, of whom one denies the existence of a God to make himself known, and the other doubts the capacity of the human intellect, if there be a God, to read the vestiges he has left of himself in his handiwork. Most types of modern theology explicitly allow that all knowledge of God rests on revelation; that God can be known only because and so far as he reveals himself. In this the extremest "liberals," such as Biedermann, Lipsius, and Pfleiderer, agree with the extremest "conservatives." Revelation is everywhere represented as the implication of theism, and as necessary to the very being of religion: "The man who does not believe that God can speak to him will not speak to God" (*A. M. Fairbairn*). It is only with reference to the reality of special revelation that debate concerning revelation continues; and it is this that Christian apologetics needs to validate. Here, too, the controversy is ultimately with antitheistic presuppositions, with the postulates of an extreme deism or of an essential pantheism; but it is proximately with all those types of thought which seek to mediate between deistic or pantheizing conceptions and those of a truly Christian theism.

In the eighteenth century the debate was chiefly with deism in its one-sided emphasis upon the divine transcendence, and with the several compromising schemes which grew up in the course of the conflict, such as pure rationalism and dogmatistic rationalism. The deist denied the reality of all special revelation, on the grounds that it was not necessary for man and was either metaphysically impossible or morally unworthy of God. Convinced of the reality of special revelation, the rationalist still denied its necessity, while the dogmatist, admitting also its necessity, denied that it constituted the authoritative ground of the acceptance of truth. Kant's criticism struck a twofold blow at rationalism. On the negative side his treatment of the theistic proofs discredited the basis of natural (general) revelation, in which the rationalist placed his whole confidence. Thus the way was prepared for philosophical agnosticism and for that Christian agnosticism which is exemplified in the school of Ritschl. On the positive side he prepared the way for the idealistic philosophy, whose fundamentally pantheistic presuppositions introduced a radical change in the form of the controversy concerning the reality of a special revelation without in any way altering its essence. Instead of denying the supernatural with the deists, this new mode of thought formally denied the natural. All thought was conceived as the immanent work of God. This change of position antiquated the forms of statement and argument which had been wrought out against the deists; but the question at issue still remained the same—whether there is any special revelation of God possible, actual, extant, whether man has received any other knowledge of God than what is excogitable by the normal action of his own unaided faculties. Men's ontology of the human faculties and activities was changed; it was now affirmed that all that they excogitated was of God, and the natural was accordingly labeled supernatural. But a special supernatural interposition for a new gift of knowledge continued to be denied as strenuously as before. Thus it has come about that, in the nineteenth century, the controversy as to special revelation is no longer chiefly with the one-sided emphasis upon the transcendence of God of the deist, but with the equally one-sided emphasis upon the immanence of God of the pantheist, and with the various compromising schemes which have grown up in the course of the conflict, through efforts to mediate between pantheism and a truly Christian theism. It is no longer necessary to prove that God may and does speak in the souls of men; it is admitted on all hands that he reveals himself unceasingly through all the activities of creaturely minds. The task has come to be to distinguish between God's general and God's special revelations, to prove the possibility and actuality of the latter alongside of the former, and to vindicate for it a supernaturalness of a more immediate order than that which is freely attributed to all the thought of man concerning divine things.

In order to defend the idea of distinctively supernatural revelation against this insidious undermining, it has become necessary, in defining it in its highest and strictest sense, to emphasize the supernatural in the mode of knowledge and not merely in its source. When stress is laid upon the source only without taking into account the mode of knowledge, the way lies open to those who postulate immanent deity in all human thought to confound the categories of reason and revelation, and so practically to do away with the latter altogether. Even when the data on which our faculties work belong to a distinctively supernatural order, yet so long as the mode of acquisition of knowledge from them is conceived as purely human, the resultant knowledge remains natural knowledge; and, since intuition is a purely human mode of knowledge, so-called intuitions of divine truth would form no exception to this classification. Only such knowledge as is immediately communicated by God is, in the highest and strictest sense, supernaturally revealed. The differentia of revelation in its narrowest and strictest sense, therefore, is not merely that the knowledge so designated has God for its source, nor merely that it becomes the property of men by a supernatural agency, but further that it does not emerge into human consciousness as an acquisition of the human faculties, pure and simple.

Such a conception may give us a narrower category than that usually called special revelation. In contending for its reality it is by no means denied that there are other revelations of God which may deserve the name of special or supernatural in a distinctive sense. It is only affirmed that among the other modes in which God has revealed himself there exists also this mode of revelation, viz., a direct and immediate communication of truth, not only from God but by God, to minds which occupy relatively to the attainment of this truth a passive or receptive attitude, so that the mode of its acquisition is as supernatural as its source. In the knowledge of God which is acquired by man in the normal use of his own faculties—naturally, therefore, as to mode—some deserves the name of special and supernatural above the rest, because the data upon which the human faculties work in acquiring it belong to a supernatural order. Such knowledge forms an intermediate class between that obtained by the facul-

ties working upon natural data and that obtained in a supernatural mode as well as from a supernatural source. Again, in the knowledge of God, communicated by the objective activities of his Spirit upon the minds of special organs of revelation—supernaturally, thus, as to immediate origin as well as to ultimate source—some may emerge into consciousness along the lines of the ordinary action of the human faculties. Such knowledge would form a still higher intermediate class—between that obtained by the natural faculties working according to their native powers on supernatural data and that obtained in a purely supernatural mode, as well as from a supernatural source and by a supernatural agency. These modes of revelation are not to be overlooked. But neither is it to be overlooked that among the ways in which God has revealed himself is also this way —that he has spoken to man as Spirit to spirit, mouth to mouth, and has made himself and his gracious purposes known to him in an immediate and direct word of God, which is simply received and not in any sense attained by man. In these revelations we reach the culminating category of special revelation, in which its peculiar character is most clearly seen. And it is these direct revelations which modern thought finds most difficult to allow to be real, and which Christian apologists must especially vindicate.

Theories of Revelation.—In the state of the case which has just been pointed out, it is a matter of course that recent theories of revelation should very frequently leave no or but little place for the highest form of revelation, that by the direct word of God. The lowest class of theories represent revelation as taking place only through the purely natural activities of the human mind, and deny the reality of any special action of the Divine Spirit directly on the mind in the communication of revealed truth. Those who share this general position may differ very greatly in their presuppositions. They may, from a fundamentally deistic standpoint, jealously guard the processes of human thought from all intrusion on the part of God; or they may, from a fundamentally pantheistic standpoint, look upon all human thought as only the unfolding of the divine thought. They may differ also very greatly as to the nature and source of the objective data on which the mind is supposed to work in obtaining its knowledge of God. But they are at one in conceiving that which from the divine side is spoken of as revelation, as on the human side, simply the natural development of the moral and religious consciousness. The extreme deistic theory allows the possibility of no knowledge of God except what is obtained by the human mind working upon the data supplied by creation to the exclusion of providential government. Modern speculative theists correct the deistic conception by postulating an immanent divine activity, both in external providence and in mental action. The data on which the mind works are supplied, according to them, not only by creation, but also by God's moral government; and the theory grades upward in proportion as something like a special providence is admitted in the peculiar function ascribed to Israel in developing the idea of God, and the significance of Jesus Christ as the embodiment of the perfect relation between God and man is recognized. (Biedermann, *Christl. Dogmatik*, i., 264; Lipsius, *Dogmatik*, 41; Pfleiderer, *Religionsphilosophie*, iv., 46.) The school of Ritschl, though they speak of a "positive revelation" in Jesus Christ, make no real advance upon this. Denying not only all mystical connection of the soul with God, but also all rational knowledge of divine things, they confine the data of revelation to the historical manifestation of Christ, which makes an impression on the minds of men such as justifies us in speaking of him as revealing God to us. (Herrmann, *Der Begriff der Offenbarung*, and *Der Verkehr des Christen mit Gott*; Kaftan, *Das Wesen*, etc.)

We are on higher ground, however, although still moving in essentially the same circle of conceptions as to the nature of revelation, when we rise to the theory which identifies revelation strictly with the series of redemptive acts (Koehler, *Stud. und Kritiken*, 1852, p. 875). From this point of view, as truly as from that of the deist or speculative theist, revelation is confined to the purely external manifestation of God in a series of acts. It is differentiated from the conceptions of the deist and speculative theist only in the nature of the works of God, which are supposed to supply the data which are observed and worked into knowledge by the unaided activities of the human mind. In emphasizing here those acts of a special providence which constitute the redemptive activity of God, this theory for the first time lays the foundation for a distinction between general and special revelation; and it grades upward in proportion as the truly miraculous character of God's redemptive work is recognized, and acts of a truly miraculous nature are included in it. And it rises above itself in proportion as, along with the supernatural character of the series of objective acts with which it formally identifies revelation, it recognizes an immediate action of God's Spirit on the mind of man, preparing, fitting, and enabling him to apprehend and interpret aright the revelation made objectively in the redemptive acts. J. Chr. K. Hofmann in his earlier work, *Prophecy and Fulfillment*, announces this theory in a lower form, but corrects it in his later *Schriftbeweis*. Richard Rothe (*Zur Dogmatik*, p. 54) is an outstanding example of one of its higher forms. To him revelation consists fundamentally in the "manifestation" of God in the series of redemptive acts, by which God enters into natural history by means of an unambiguously supernatural and peculiarly divine history, and which man is enabled to understand and rightly to interpret by virtue of an inward work of the Divine Spirit that Rothe calls "inspiration." But this internal action of the Spirit does not communicate new truth; it only enables the subject to combine the elements of knowledge naturally received into a new combination, from which springs an essentially new thought which he is clearly conscious that he did not produce. The theory propounded by Prof. A. B. Bruce in his well-known lectures on *The Chief End of Revelation* stands possibly one stage higher than Rothe's, to which it bears a very express relation. Dr. Bruce speaks with great circumspection. He represents revelation as consisting in the "self-manifestation of God in human history as the God of a gracious purpose—the manifestation being made not merely or chiefly by words, but very specially by deeds" (p. 155); while he looks upon "inspiration" as "not enabling the prophets to originate a new idea of God," but "rather as assisting them to read aright the divine name and nature." Dr. Bruce transcends the position of the class of theorists here under consideration in proportion as he magnifies the office of inner "inspiration," and, above all, in proportion to the extent of meaning which he attaches to the saving clause that revelation is *not merely* by word, but *also* by deed. The theory commended by the great name of Bishop B. F. Westcott (*The Gospel of Life*) is quite similar to Dr. Bruce's.

By these transitional theories we are already carried well into a second class of theories, which recognize that revelation is fundamentally the work of the Spirit of God in direct communication with the human mind. At its lowest level this conception need not rise above the pantheistic postulate of the unfolding of the life and thought of God within the world. The Divine Spirit stirs men's hearts, and feelings and ideas spring up, which are no less revelations of God than movements of the human soul. A higher level is attained when the action of God is conceived as working in the heart of man an inward certainty of divine life—as, for example, by Schultz (*Old Testament Theology*); revelation being confined as much as possible to the inner life of man apparently to avoid the recognition of objective miracle. A still higher level is reached where the action of the Spirit is thought of—after the fashion of Rothe, for example—as a necessary aid granted to certain men to enable them to apprehend and interpret aright the objective manifestation of God. The theory rises in character in proportion as the necessity of this action of the Spirit, its relative importance, and the nature of the effect produced by it are magnified. So long, however, as it conceives of this work of the Spirit as secondary, and ordinarily if not invariably successive to the series of redemptive acts of God, which are thought to constitute the real core of the revelation, it falls short of the biblical idea. According to the biblical representations, the fundamental element in revelation is not the objective process of redemptive acts, but the revealing operations of the Spirit of God, which run through the whole series of modes of communication proper to Spirit, culminating in communications by the objective word. The characteristic element in the Bible idea of revelation in its highest sense is that the organs of revelation are not creatively concerned in the revelations made through them, but occupy a receptive attitude. The contents of their messages are not something thought out, inferred, hoped, or feared by them, but something conveyed to them, often forced upon them by the irresistible might of the revealing Spirit. No conception can do justice to the Bible idea of revelation which neglects these facts. Nor is justice done even to the rational idea of revelation when they are neg-

lected. Here, too, we must interpret by the highest category in our reach. "Can man commune with man," it has been eloquently asked, "through the high gift of language, and is the Infinite mind not to express itself, or is it to do so but faintly or uncertainly, through dumb material symbols, never by blessed speech?" (W. Morrison, *Footprints of the Revealer*, p. 52).

The Doctrine of Revelation.—The doctrine of revelation which has been wrought out by Christian thinkers in their effort to do justice to all the biblical facts, includes the following features. God has never left himself without a witness. In the act of creation he has impressed himself on the work of his hands. In his work of providence he manifests himself as the righteous ruler of the world. Through this natural revelation men in the normal use of reason rise to a knowledge of God—a *notitia Dei acquisita*, based on the *notitia Dei insita*—which is trustworthy and valuable, but is insufficient for their necessities as sinners, and by its very insufficiency awakens a longing for a fuller knowledge of God and his purposes. To this purely natural revelation God has added a revelation of himself as the God of grace, in a connected series of redemptive acts, which constitute as a whole the mighty process of the new creation. To even the natural mind contemplating this series of supernatural acts which culminate in the coming of Christ, a higher knowledge of God should be conveyed than what is attainable from mere nature, though it would be limited to the capacity of the natural mind to apprehend divine things. In the process of the new creation God, however, works also inwardly by his regenerating grace, creating new hearts in men and illuminating their minds for apprehending divine things: thus, over against the new manifestation of himself in the series of redemptive acts, he creates a new subject to apprehend and profit by them. But neither by the presentation of supernatural facts to the mind nor by the breaking of the power of sin within, by which the eyes of the mind were holden that they should not see, is the human mind enabled to rise above itself, that it may know as God knows, unravel the manifestation of his gracious purposes from the incompleted pattern which he is weaving into the fabric of history, or even interpret aright an unexplained series of marvelous facts involving mysteries which "angels desire to look into." It may be doubted whether even the supreme revelation of God in Jesus Christ could have been known as such in the absence of preparatory, accompanying and succeeding explanatory revelations in words: "the kingdom of God cometh not with observation." God has therefore, in his infinite mercy, added a revelation of himself, strictly so called, communicating by his Spirit directly to men knowledge concerning himself, his works, will, and purposes. The modes of communication may be various—by dreams or visions, in ecstasy or theophany, by inward guidance, or by the simple objective word; but in all cases the object and result are the direct supernatural communication of special knowledge.

Of this special revelation it is to be said: (1) It was not given all at once, but *progressively*, "by divers portions and in divers manners," in the form of a regular historical development. (2) Its progressive unfolding stands in *a very express relation to the progress of God's redemptive work.* If it is not to be conceived, on the one hand, however, as an isolated act, wholly out of relation to God's redemptive work, neither is it to be simply identified with the series of his redemptive acts. The phrase, "revelation is for redemption and not for instruction," presents a false antithesis. Revelation as such is certainly just "to make wise," though it is to make wise only "unto salvation." It is not an alternative name for the redemptive process, but a specific part of the redemptive process. Nor does it merely grow out of the redemptive acts as their accompanying or following explanation; it is rather itself one of the redemptive acts, and takes its place along with the other redemptive acts, co-operative with them to the one great end. (3) *Its relation to miracles* has often been very unnecessarily confused by one-sided statements. Miracles are not merely credentials of revelation, but vehicles of revelation as well; but they are primarily credentials; and some of them are so barely "signs" as to serve no other purpose. As works of God, however, they are inevitably revelatory of God. Because the nature of the acts performed necessarily reveals the character of the actor is no proof, nevertheless, that their primary purpose was self-revelation; but this fact gives them a place in revelation itself; and as revelation as a whole is a substantial part of the redemptive work of God, also in the redemptive work of God. (4) *Its relation to predictive prophecy* is in some respects different. As a rule, at all events, predictive prophecy is primarily a part of revelation, and becomes a credential of it only secondarily, on account of the nature of the particular revelation which it conveys. When a revelation is, in its very contents, such as could come only from God, it obviously becomes a credential of itself as a revelation, and carries with it an evidence of the divine character of the whole body of revelation with which it stands in organic connection. (5) *Its relation to the Scriptures* is already apparent from what has been said. As revelation does not exist solely for the increase of knowledge, but by increasing knowledge to build up the kingdom of God, so neither did it come into being for no other purpose than the production of the Scriptures. The Scriptures also are a means to the one end, and exist only as a part of God's redemptive work. But if, thus, the Scriptures can not be exalted as the sole end of revelation, neither can they be degraded into the mere human record of revelation. They are themselves a substantial part of God's revelation; one form which his revealing activity chose for itself; and that its final and complete form, adopted as such for the very purpose of making God's revealed will the permanent and universal possession of man. Among the manifold methods of God's revelation, revelation through "inspiration" thus takes its natural place; and the Scriptures, as the product of this "inspiration," become thus a work of God; not only a substantial part of revelation, but, along with the rest of revelation, a substantial part of his redemptive work. Along with the other acts of God which make up the connected series of his redemptive acts, the giving of the Scriptures ranks as an element of the building up of the kingdom of God. That within the limits of Scripture there appears the record of revelations in a narrower and stricter sense of the term, in nowise voids its claim to be itself revelation. Scripture records the sequence of God's great redeeming acts. But it is much more than merely "the record, the interpretation, and the literary reflection of God's grace in history." Scripture records the direct revelations which God gave to men in days past, so far as those revelations were intended for permanent and universal use. But it is much more than a record of past revelations. It is itself the final revelation of God, completing the whole disclosure of his unfathomable love to lost sinners, the whole proclamation of his purposes of grace, and the whole exhibition of his gracious provisions for their salvation.

BENJAMIN B. WARFIELD.

Revelation, Book of [*Revelation* is from Lat. *Revela'tio* (see REVELATION), used as transl. of Gr. Ἀποκάλυψις, Revelation, liter., an uncovering, revealing; ἀπό, off + καλύπτειν, cover]: the concluding book of the New Testament as now arranged; sometimes called the APOCALYPSE. There are in a voyage three points to observe: (1) the moment of departure; (2) the way: and (3) the arrival. Such is also the general division of the book of Revelation. (I.) After indicating the subject by these words, "I am Alpha and Omega, the beginning and the ending, saith the Lord, which is, and which was, and which is to come" (i. 8), John fixes the point of departure in the first three chapters; it is the state of the Church at the moment in which he writes. The state is depicted in the letters which he addresses from the Lord to the seven chosen churches of Asia Minor. (II.) From ch. iv. to xix. 10 he describes the coming itself—that is, the chastisements of the Judge, who calls the world to repent before the final judgment, and the graces of the Bridegroom, who elevates his Church to perfection for the wedding-day. (III.) Finally, from xix. 11 he describes the arrival with all its consequences, both for the world and for the Church, and he finishes with a proper conclusion, intended to make the reader feel the importance of the book.

This book of mysteries has received various explanations. The traditional interpretation seeks in the vision for a detailed picture of all the events of the history of the Church from the first century to the return of Christ. Faber, Bengel, Elliot, Gaussen, de Rougemont, and many others have in this way produced wonders of exegetical ability and historical learning. But the method carries along with it a signal of warning in its character of arbitrariness. The same vision—that of the locusts, for instance, in ch. ix.—designates, according to one, the great invasion by the Arabs in the seventh century; according to another, the invasions by the Persians under Chosroes; according to a third, the introduction of the Talmud among the Jews; according to

a fourth, the introduction of monachism, etc. Such a diversity rises simply from the imagination having been set free and working without any fixed rule. It is, moreover, inadmissible that it should be necessary to possess the whole treasury of learning belonging to a professor of history in order to understand a book which God has given to his people for the purpose of edification. The modern rationalists have broken with this method of interpretation for many reasons, good and bad; first, no doubt, because it presupposes divine inspiration, but also because their whole system leads them to seek the key to the interpretation of a book in the circumstances under which it was written. Hence the interpretation of the beast as the Roman empire, and of the head wounded to death, but reappearing as Antichrist, as the Emperor Nero. Insurmountable difficulties are, however, involved in this method of explanation; and it seems very singular that a book so holily conceived and so severely planned should be a mere tissue of fancies and hallucinations.

There remains the method which recognizes in the Revelation a picture of the general progress of the Church, to whose understanding no other premises are necessary than such as may be drawn from the Scriptures themselves. There is still room for individual views. Thus Bossuet sees in the destruction of the beast the fall of the Roman empire; Hengstenberg considers the reign of a thousand years as the predominance of Christianity from Charlemagne to our days; John Nelson Darby, the principal founder of the Plymouth Brethren, holds that the whole history of the Church from the apostolic age up to that preceding the return of Christ is omitted in the picture, and must be placed in the interval between the third and fourth chapters, so that the whole vision (iv.–xix.) relates exclusively to the future, to that which precedes immediately the coming of the Lord. It is impossible to enter here into a discussion of these individual points of view, but it is hoped that the reader, following the outline which has been given, will find in the Revelation points sufficiently precise to indicate the course of the religious progress of humanity, and at the same time sufficiently elevated to enlighten and fortify his heart under all the various events of his life. There is the same power in this vision as in that through which God revealed to Moses in six successive pictures the origin of the world. At every moment of a person's life he finds himself in contact with the religious bearing of this vision in Genesis. At every moment, too, but especially when he is under the cross, his soul gathers new life from the spirit of the apocalyptic expectations. It is solely for this purpose of edification, and not in order to satisfy our curiosity, that God has permitted us to see, on the one hand, through the eyes of Moses, the stream of the times issuing forth from eternity, and on the other, through the eyes of John, the times returning to the sea of eternity. Christ is coming (the Old Testament); Christ has come (the gospel); Christ shall come again (the Revelation)—such is the sum of the history of mankind.

One of the chief problems of the book relates to Antichrist. There are two leading opinions respecting his person. Some consider him merely as a poetical personification of a principle, of the spirit of rebellion against God and Christ, which shall go on increasing till the final triumph of the gospel. Others recognize in him a real man, who shall concentrate in his own person to the utmost extent the spirit of apostasy. The second chapter of the Second Epistle to the Thessalonians, in which his apparition is described, speaks decidedly in favor of the second explanation. Antichrist is here designated as the man of sin, who shall place himself as a god in the temple of God; he is called the wicked man whom the Lord shall destroy by the breath of his mouth. His theological system may be summed up in the three following theses: (1) There is no personal God without and above the universe; (2) man is himself his own god—he is the god of this world; (3) "I am the true representative of humanity; by worshiping me mankind worships itself." Even from this general point of view there still remain certain differences of opinion. According to some this person has already appeared on the stage; he is the pope. It is evident, however, that the pope has never actually substituted himself for God or Christ; on the contrary, he rests his authority on that of Christ and God. The pope may be said to be on the way which ends with the arrival of Antichrist, but he is not yet Antichrist himself. Others hold that the Antichrist announced in the Revelation is only an empty supposition, which has never been revealed. The author of the prophecy, they say, thought of the Emperor Nero, that matchless monster, the first persecutor of the Church, whose death the world could not believe in, and whom the terrified Church feared to see return suddenly and assume the part of the man of sin and the universal suppressor. The number 666, which, according to xiii. 18, is the number of the beast, was explained in accordance with this view. The letters of the two words KAISAR NERON, when taken as ciphers and counted in Hebrew, give indeed the sum of 666. This fear was never realized, however, and thus the Revelation became an unfulfilled prophecy on this capital point. It is difficult to understand how under such circumstances the book can have survived in spite of the discredit which fell on it immediately after its appearance, and how the author, if he was a serious man, could suffer it to circulate without retraction. It must also be noticed that in order to obtain the sum of 666 from this name it must be written *Kesar*, and not *Kaisar*, which is against custom and orthographical rules. Finally, it would be somewhat strange if the name which was to be figured out of the number had been put down in Hebrew, while all the rest of the work is in Greek. In speaking of the man of sin, St. Paul, far from identifying this person with the Roman emperor, hints that, on the contrary, it was the imperial power which prevented Antichrist from appearing. "Ye know," he says (2 Thess. ii. 6), "what withholdeth that he might be revealed in his time." The apostle considers Antichrist as the realization of the false Messiah, the terrestrial king, the new Solomon, whom the carnal Israel expects. What was it that prevented the Jews of that time from putting forth this false Messiah, the object of their hearts' longings? It was the Roman legions, which on the mere nod of the emperor would have invaded the Holy Land and put down any attempt at insurrection. It is the powers instituted by and inherited from the Roman empire which up to this very day have prevented Antichrist, the false Messiah of the Jews, from appearing; but he will not fail to come forth as soon as these powers fall; the Jewish people will then have acquired that preponderance in all civilized states which is necessary before it can give its insatiable ambition the reins. With respect to the number 666 numerous solutions of this enigma have been given, but none which is thoroughly satisfactory. A peculiar fact has lately attracted attention. The Greeks do not designate numbers by particular signs called ciphers, but by the letters of the alphabet, to which a numerical value is assigned. Thus 600 is expressed by the letter χ (*ch*), 60 by ξ (*x*), and 6 by ϛ (*s*). The name of Christ (*Christos*) is represented by the first and last letters, χϛ, and these two letters represent the two numbers 600 and 6. If between these two letters the letter ξ, which signifies 60, is introduced, the sum of 666 is obtained; and the three letters, χξϛ, represent the abridged form of the name of Christ, but in such a manner that the first and third letters are separated by the ξ, the emblem of the serpent. Thus in Greek 666 is the emblem of the Messiah, of Satan, or of Antichrist. It may also be noticed that, according to the symbolism of numbers employed in the Revelation, the number 7 always expresses the divine plenitude, and that God, as the Father, the Son, and the Holy Spirit, must consequently be represented in ciphers by 777. Thus the number 666 would signify the creature's highest though still impotent effort at attaining divine glory and power, and the representation would comprise the three persons which form the diabolical trinity—namely, Satan, or the dragon, the beast, or Antichrist, and the second beast, or the false prophet. Satan can not become God, nor can Antichrist attain the dignity of the Son-Messiah, nor the false prophet equal the Holy Ghost. Nevertheless it is no doubt wise to apply to our age that which in the second century the pious Irenæus said to his: "If the author of the propheey would have made the name known to this time, he would have designated it more plainly." Irenæus mentions several explanations propounded in his time, of which the least improbable is the word *Lateinos*—that is, Latin, Roman, the Roman emperor. The Greek letters of which this word is composed give, indeed, when added together as ciphers, the exact sum 666.

FRÉDÉRIC GODET.

The author calls himself "John" in i. 1, 4, 9, xxii. 8, and traditionally the Revelation has been assigned to the apostle John. Bishop Boyd Carpenter, in Elliott's *Commentary on Revelation*, thus sums up the case on the orthodox side: 'The author represents himself as John in a way and at a

time that would naturally suggest that he was either John the apostle and evangelist or wished to pass as such. The general consensus of early opinion believed that the apostle was the writer. The doubts grew out of doctrinal prejudice. There is no reasonable ground for disputing the residence of the apostle in Asia Minor. There are not wanting traces of personal reminiscences such as the beloved disciple would have cherished. The portrait of Jesus Christ is in complete harmony with apostolic teaching; and the difficulties which beset the theory that there were two Johns —one who wrote the Gospel, and the other the Apocalypse —are greater than those which surround the theory of a common authorship." As the above summary suggests, the so-called "critical" position disputes each of the statements. The most recent theories are (1) that the book is composed of literary strata of different periods, and in it may be discovered traces of the glacial action of early heresies (*Völter*); (2) that the book is a Jewish apocalypse with Christian interpretations (*Vischer*). Both theories have failed of general acceptance.

The question of date is apart from that of authorship, and those who accept the apostolic authorship do not agree. The choice lies between A. D. 68 or 69 and A. D. 96—i. e. prior or subsequent to the destruction of Jerusalem. The preponderance of scholarly opinion inclines to the earlier date, but the arguments are evenly balanced.

LITERATURE.—The reader will be best served by using commentaries and treatises upon the book of recognized sober and scholarly character. Such are the commentary by Moses Stuart (n. e. 2 vols., Andover, 1864); E. B. Elliott's *Horæ Apocalypticæ* (4 vols., 5th ed. London, 1862); and especially the masterly works on the Revelation by W. Milligan, *The Revelation of St. John* (Baird lectures, London, 1886); *Lectures on the Apocalypse* (1892); *Discussions on the Apocalypse* (1893); the commentary in Schaff's *Popular Commentary*, and the volume in the *Expositor's Bible* (1889). Milligan's theory of the interpretation of the Revelation deserves separate mention. Briefly it is this, using his own language: "The book is not prophetic in the ordinary sense of the word. It is not intended to set before us any *series of events* which were to occur during the long period known to us, though not to the early Christians, or to precede the Lord's second coming. We shall be wrong, therefore, if we treat the book as predictive, and if we seek in particular events either of the Church's or the world's history for the fulfillment of its supposed predictions. The book is mainly occupied with the enunciation of the great principles which guide the action of the Church's Lord until the time of his return. It shows us in symbolical presentation the principles upon which God founds and propagates his Church in the world. The action of the book covers the whole Christian era from its beginning to its end. Everything contained in the Apocalypse is to be understood symbolically and spiritually." *Book by Book*, pp. 556, *seq.*

SAMUEL MACAULEY JACKSON.

Revenue [from O. Fr. *revenue*, liter., that which comes back, deriv. of *revenir*, come back, return]: (1) income or annual proceeds from land or other property. (2) The income of a state or nation derived from duties, taxes, and other sources for public use. See FINANCE and TAXATION.

Revere, PAUL: patriot; b. in Boston, Mass., Jan. 1, 1735; served in the campaign on Lake George as lieutenant of artillery 1756; became a goldsmith, and afterward a copperplate engraver; produced prints illustrative of the repeal of the Stamp Act, of the "Boston Massacre," and the landing of the British troops at Boston; was a member of the "tea-party," and at the instance of Gen. Warren rendered an important service to his country by secretly leaving Boston at ten o'clock on the night of Apr. 18, 1775, and riding through Charlestown to Concord to announce the British expedition of the following day, which was resisted at Lexington and Concord. (See Longfellow's poem, *The Midnight Ride of Paul Revere.*) In the same year he engraved the plates and printed the bills of the paper-money of Massachusetts; afterward set up a powder-mill; became lieutenant-colonel of State artillery and participated in the Penobscot expedition of 1779; after the war established a foundry for casting cannon and church-bells, and built extensive copper-rolling mills at Canton, Mass. As grand master of the Masonic order he assisted in laying the corner-stone of the Boston State-house 1795. D. in Boston, May 10, 1818. In his honor the town of North Chelsea, Mass., took the name of Revere, Mar. 24, 1871.

Reversion: See EVOLUTION (*Heredity*).

Reversion (in law): See LANDLORD AND TENANT and REMAINDER.

Réville, rā′veel′, ALBERT, D. D.: clergyman and author; b. at Dieppe, France, Nov. 4, 1826; became a leading minister of the French Protestant church at Nîmes and Luneray; pastor of the Walloon church at Rotterdam, Holland, 1851; retired to Dieppe 1872; went to Paris as Professor of History of Religions in the College of France in 1880. He has published many translations of religious works from the English and the German; is author of *De la Rédemption* (1859); *Essais de Critique religieuse* (1860); *Études critiques sur l'Évangile selon S. Matthieu* (1862); *La Vie de Jésus de M. Renan devant les Orthodoxes et devant la Critique* (1863); *Manuel d'instruction religiense* (1863; 2d ed. 1866; Eng. trans. *Manual of Religious Instruction*, London, 1864); *Notre Christianisme et notre Bon Droit* (1864); *Histoire du Dogme de la Divinité de Jésus-Christ* (1869; Eng. trans. *History of the Doctrine of the Deity of Jesus Christ*, 1870); *Prolégomènes de l'histoire des religions* (1880; 4th ed. 1886; Eng. trans. *Prolegomena to the History of Religion*, 1884, 1885); *Histoire des religions* (4 vols., 1883–88); Eng. trans of vol. ii., *The Native Religions of Mexico and Peru.*

Revision of the Bible: See BIBLE REVISION.

Revival of Learning: See RENAISSANCE and HUMANISM.

Revolution: in politics, the overthrow of an established political system; a radical change in the government effected by extra-legal means. For a discussion of the right of revolution, see the article POLITICAL SCIENCE, and for an account of particular revolutionary movements, see the articles on the various countries, especially ENGLAND, HISTORY OF, for the Revolution of 1688, FRANCE, HISTORY OF, for the Revolution of 1789, UNITED STATES for the Revolution of the North American colonies, and MEXICO and the different states of South and Central America for the numerous revolutions that have marked the history of these countries.

Revolver: a magazine small arm resembling a pistol. It has a chamber which carries a number of cartridges, usually five or six, and which revolves, thus bringing the cartridges in succession in front of the barrel. Revolvers were known to have been used in the early part of the seventeenth century. Colt perfected the revolver by causing the cocking of the hammer to revolve the chamber. A later form of revolver is a hammerless self-cocker; by simply pulling the trigger the chamber is revolved and the piece is fired.

Re'wah: a state of India, under the protection of the British Government. Area, 10,300 sq. miles. Pop. (1891) 1,508,943. It extends from lat. 22° 39′ to 25° 12′ N., and from lon. 80° 46′ to 82° 51′ E. The northern and smaller part is a fertile plateau, yielding abundant crops. The southern part is rich in timber and coal, but not in agriculture. The capital, Rewah, has (1891) 23,626 inhabitants.

Revised by C. C. ADAMS.

Reward [from O. Fr. *reward*, earlier form of *regard*, deriv. of *rewarder*, *regarder*, regard, mark, notice again; *re-*, again + *warder*, *garder*, mark, heed, from O. H. Germ. *wartên*, watch over > Germ. *warten*, wait]: in law, compensation offered indefinitely to any one for a particular act, such as the restoration of stolen property, or the apprehension of a criminal. The offer may be withdrawn, in the manner in which it was made, at any time before acceptance. Accordingly where a reward for the arrest of a criminal is offered by public proclamation, and withdrawn in the same manner, a person who procures the arrest of the criminal after the withdrawal, although ignorant that the offer had been revoked, can not recover the reward. (*Shuey* vs. *U. S.*, 92 U. S. 73.) Acceptance of the offer consists in the performance of the particular act, with knowledge of the offer (*Fitch* vs. *Snedeker*, 38 N. Y. 248), although there are decisions to the effect that knowledge of the offer is not essential to acceptance. (*Russell* vs. *Stewart*, 44 Vt. 170.) From considerations of public policy a peace officer can not claim a reward for services which are a part of his official duties. Nor can one recover a reward which was made necessary by his own misconduct. (*Harsan* vs. *Doe*, 38 Me. 45.)

FRANCIS M. BURDICK.

Reybaud, rā′bō′, MARIE ROCH LOUIS: author; b. at Marseilles, France, Aug. 15, 1799; educated for commercial business; traveled much in India and other Eastern countries;

settled in 1829 in Paris, and devoted himself to literature, writing for many liberal journals; edited *Histoire scientifique et militaire de l'Expédition française en Égypte* (10 vols., 1830–36); published from 1836 to 1840, in the *Revue des Deux Mondes*, his *Études sur les Réformateurs, ou Socialistes modernes*, which in 1841 received the Montyon prize from the Academy and has since passed through several editions; published in 1843 *Jérôme Paturot à la Recherche d'une Position sociale*, his most popular work, which was followed in 1848 by *Jérôme Paturot à la Recherche de la meilleure des républiques* (1848). He became a member of the Academy in 1850, and continued to write romances, economical essays, political pamphlets, and literary and social criticisms. He was several times elected to the legislature, and after the *coup d'état* of 1851 was a member of the consultative commission. D. in Paris, Oct. 28, 1879.
Revised by F. M. Colby.

Reyer, rā'i-ā', Louis Étienne Ernest (real name **Rey**): composer; b. at Marseilles, France, Dec. 1, 1823; began to study music there; when sixteen years of age went to Algiers, in the service of the Government. In 1848 he returned to France and continued to study in Paris. His first important composition was *Le Sélam*, an Oriental symphony with choruses, produced Apr. 5, 1850. Since then he has composed several operas with more or less success, prominent among which are *Sacountala* (1858); *La Statue* (1861); *Érostrate* (Baden, 1862; Paris, 1871); and *Sigurd* (Brussels, 1884). His latest work is *Salammbô* (1893). He is also an accomplished feuilletonist. He was decorated with the Legion of Honor in 1862 and raised to the rank of commander in 1891. He is a member of the Academy of Fine Arts.
D. E. Hervey.

Reykjavik, rīk'yaa-vik: the capital of Iceland, on the southwestern coast of the island, in lat. 64° 8′ N., lon. 21° 5′ W., at the head of Faxafjord. It is the seat of the government, has a college with a library of 10,000 volumes, medical and divinity schools, an observatory and a museum, an important annual fair, and regular communication by steamships with Leith and Copenhagen. It was founded in 874. Pop. 1,400. Revised by P. Groth.

Reynard the Fox: a popular epic of European origin. Despite the efforts of Jacob Grimm (*Reinhart Fuchs*, 1834) to establish the existence of a native and purely popular Germanic beast-epos, of which *Reynard the Fox* formed the most conspicuous example, scholars now agree in regarding this beast-epos in general, and *Reynard* in particular, as an outgrowth of the old fables which were worked into this or that shape for prevailingly satirical purposes. To be sure, we must admit a certain admixture of native material, and not ascribe every shred of these fables to the Orient. Yet in any case, whatever the material, monks, not popular fancy, were responsible for the development of the fables into later forms; they used the stories which came mainly from the East and drifted, by way of Greece and Italy, over Western Europe. A fable of Æsop got footing in German literature as early as the seventh century; another, the story of the sick lion and the fox, soon followed, and was treated as independent or purely local tradition. In the tenth century this fable was used as a convenient allegory for the fortunes of a monk; and a few years later, probably in Flanders, names were given to the principal beasts: Isengrim (iron-masked) to the wolf; Noble to the lion; and Reynard (originally the Germanic word meaning good or firm in counsel; the Low German form is Reineke or Reinke, while French Renard, as a generic name, has actually supplanted the Old French *goulpil*, from Latin *vulpes*) to the fox. Bruin for bear is almost as common in English. The earlier literature had been in Latin and was didactic or satirical; but now, like the mediæval legend, this popular material found voice in the vernacular. It grew into a sort of epos; and indeed the Latin *Isengrimus* (about 1150) had already assumed epic proportions. The first German epos of Reynard was composed about 1180. French jongleurs worked the material into a sort of romance, the *Roman de Renart*, with many so-called branches. About the middle of the thirteenth century one of these French versions was used by a Fleming named Willem as basis for the admirable *Roman van den Vos Reinaerde*. This, again, was worked over and furnished with sundry additions by an unknown Fleming in the fourteenth century, under the name of *Reinært's Historie*; this, in turn, toward the close of the fifteenth century, was enlarged by explanations in prose; and finally it was translated into Low German as the famous *Reinke de Vos*, or *Reineke Vos*, appearing about 1500. Enormously popular, these versions made their way into the various tongues of Europe. Caxton translated one of them and printed it, June, 1481, as *The History of Reynard the Fox*. (See Arber's reprint in the *English Scholar's Library*.) In modern times Goethe has told us this familiar story, the *Unheilige Weltbibel*, as he called it—in hexameters which hold a nice balance between epic and satire—*Reineke Fuchs*; an English translation was made by T. J. Arnold, and was published with Kaulbach's and Wolfe's illustrations.

It was Willem who gave Reynard his commanding place as hero of the little epic and representative of desperate craftiness. Willem, however, takes sides against his hero; while later versions make the fox a thoroughly triumphant rascal. The ethical problem involved is discussed half humorously, half seriously, by Froude in his *Short Studies on Great Subjects*. The student must be referred for details of bibliography to E. Martin, *Le Roman de Renart* (Strassburg, 1882 ff.), and *Reinaert* (Paderborn, 1874); also to the preface of Arber's reprint of Caxton, and the introduction by W. J. Thoms to *The History of Reynard the Fox* (Percy Society, 1844). Francis B. Gummere.

Reynolds, Henry Robert, D. D.: clergyman and author; b. at Romsey, Hampshire, England, Feb. 26, 1825; educated at University College, London; became minister of a Congregational church at Halstead, Essex, England, in 1846; of East Parade Congregational church, Leeds, in 1849; president of Countess of Huntingdon's College, at Cheshunt, in 1860, and also Professor of Theology and Exegesis; was one of the editors of *The British Quarterly Review* 1866–74; author of *Beginnings of the Divine Life* (1858); *John the Baptist, a Contribution to Christian Evidences* (1874); *The Philosophy of Prayer, and other Essays* (1881); commentaries on Hosea and Amos, on the Gospel of John, *Athanasius, his Life and Work* (1889), and of important contributions to theological cyclopædias and reviews. D. at Broxbourn, Herts, Sept. 10, 1896. Revised by G. P. Fisher.

Reynolds, Ignatius Aloysius, D. D.: bishop; b. near Bardstown, Ky., Aug. 22, 1798; educated at St. Mary's College, Baltimore, Md.; ordained a Roman Catholic priest 1823; was successively vicar-general of Kentucky, rector of St. Joseph's College, and president of the Nazareth Female Institute of Kentucky, and was consecrated Bishop of Charleston, Mar. 19, 1844. D. at Charleston, Mar. 9, 1855.

Reynolds, or **Rainolds**, John, D. D.: clergyman and author; b. at Pinhoe, Devonshire, England, in 1549; studied at Merton College, Oxford, 1562; became fellow of Corpus Christi 1566; lectured on Aristotle; was appointed reader of the theological lecture founded by Sir Francis Walsingham 1586; was dean of Lincoln 1593; refused a bishopric in order to accept the presidency of Corpus Christi College 1598; was eminently distinguished as a Hebraist, regarded as the leader of the Puritan party, and was said by Hallam to have been "the most eminently learned man of Queen Elizabeth's reign"; took a prominent part in the Hampton Court conferences of 1603, where he maintained the necessity of a new version of the Bible; executed a small portion of King James's version, and revised much more in the weekly meetings of the translators held at his chambers. D. at Oxford, May 21, 1607. His works consist chiefly of separate sermons, controversial treatises against the Church of Rome, academical discourses, and some writings upon biblical criticism, the most elaborate being one successfully directed against the admission of the Apocrypha as part of the Old Testament canon—*Censura Librorum Apocryphorum Veteris Testamenti*, posthumously printed (Oppenheim, 2 vols., 1611). —His brother, William Reynolds, b. at Pinhoe about 1540, was educated at Oxford; became a Roman Catholic; was Professor of Divinity and Hebrew at Douay and Rheims; took an important part in the translation of the Rheims Testament; translated from English into Latin all the works of Thomas Harding; wrote several theological and controversial treatises, and became chaplain to the Beguin nunnery at Antwerp, where he died Aug. 24, 1594.

Reynolds, John Fulton: soldier; b. at Lancaster, Pa., Sept. 20, 1820; graduated at the U. S. Military Academy, and appointed brevet second lieutenant of artillery, July, 1841; captain 1855; served in the war with Mexico, winning the brevets of captain and major; in Sept., 1860, was selected as commandant of cadets at West Point; in May, 1861, was transferred to the infantry with rank of lieutenant-colonel (colonel, June, 1863), and in August appointed brigadier-general of volunteers, and assigned to command of

a brigade of the Pennsylvania Reserve Corps, which he commanded in the Virginia peninsular campaign of 1862 at Mechanicsville, Gaines's Mill, and Glendale, where he was taken prisoner. Exchanged in August, he commanded a division in the second battle of Bull Run, and in the Maryland campaign of Sept., 1862, was selected to command the Pennsylvania militia for the defense of the State. In Nov., 1862, he was promoted to be major-general of volunteers, and placed in command of the First Corps of the Army of the Potomac, which was engaged on the left in the battle of Fredericksburg, Dec. 13, 1862. At Chancellorsville his corps was held in reserve, along with the Fifth, and not allowed to engage the enemy. At the battle of Gettysburg, on the opening day (July 1, 1863), after having made the disposition of his troops in person, he was killed by a rifle ball.

Revised by JAMES MERCUR.

Reynolds, JOSEPH JONES: soldier; b. at Flemingsburg, Ky., Jan. 4, 1822; graduated at the U. S. Military Academy, and entered the army as brevet second lieutenant of artillery July 1, 1843. After serving in garrison and in Texas, he was in 1846 selected as Assistant Professor of Geography, History, and Ethics at West Point; in 1847 became Assistant Professor of Natural and Experimental Philosophy, and from 1849 to 1855 was principal assistant professor. In 1857 he accepted the chair of Mechanics and Engineering in Washington University, St. Louis, Mo., which he held until 1860. In 1861 he was appointed colonel and brigadier-general of Indiana volunteers, and May, 1861, was commissioned brigadier-general of U. S. volunteers, serving in West Virginia. He again resigned in Jan., 1862, but was reappointed Sept. 17, 1862, and on Nov. 29, 1862, was promoted to be major-general of volunteers, serving with the Army of the Cumberland. At the battle of Chattanooga he was chief of staff of that army. Subsequently he held various important commands in the Southwest. On July 28, 1866, he was appointed colonel of the Twenty-sixth U. S. Infantry; transferred to Twenty-fifth Infantry Jan., 1870, and to Third Cavalry Dec. 15, 1870; brevet brigadier and major-general for gallantry. Retired June, 1877.

Reynolds, Sir JOSHUA: painter; b. at Plympton-Earle, Devonshire, England, July 16, 1723. He showed much natural bent toward drawing, and at the age of eighteen was sent to London to the studio of Thomas Hudson, a portrait-painter. Two years later he began to paint portraits professionally, sometimes at Plymouth Dock, now Devonport, and sometimes in London; but in 1749 he accepted the invitation of Capt. Augustus Keppel, afterward admiral and viscount, to go with him to the Mediterranean. This gave Reynolds the opportunity to study Italian painting, and he remained over two years at Rome and other cities in Italy. In 1752 he returned to London, and was almost immediately successful as a portrait-painter. Although already very deaf, in consequence of a chill and resulting illness while in Italy, he was a model of graceful courtesy and won everybody's good word. In 1760 he took the house in Leicester Square, London, in which he lived and painted until his death. In 1768 the Royal Academy was founded, and Reynolds was elected its president. He was knighted soon after by George III. The presidency he retained until 1790, his long term setting an example which in the academy has been generally followed since. He took up the custom of delivering each year at the distribution of awards a carefully prepared address on some topic immediately connected with fine art, usually painting, and these are the well-known *Discourses of Sir Joshua Reynolds.*

He remained a bachelor, and was the central figure in several clubs or societies of literary, artistic, and political men. Among his especial friends were Edmund Burke, Dr. Johnson, Garrick, and Oliver Goldsmith. It was in connection with one of these gatherings that Goldsmith wrote his poem *Retaliation*, in which occurs a celebrated passage about Reynolds. An enormous number of pictures were painted by Reynolds, and he accumulated a fortune large for the time and almost unprecedented as the result of an artist's work for the public. D. in London, Feb. 23, 1792.

As a painter Reynolds is remarkable for the beauty of color which he seems to have gained from the study of the Venetian painters, except in so far as it was an inborn gift. His painting was in a high degree experimental; even in his maturity he painted in a tentative way, trying different ways of producing his effect, and the result has been that many of his pictures have faded very badly. He avows, in his *Discourses*, an opinion that very few colors should be used by the painter, and bases this untenable theory upon the alleged practice of some of the ancient Greeks. His teaching and his practice, however, often differ; thus he is never weary of advocating the grand style and of lauding Michelangelo as the first of painters, but his life's work was portrait-painting, with scarcely any interruption or change, even his so-called "ideal" pictures being mere groups of portraits, and his way of work is based upon that of Titian much more than upon that of Michelangelo. Moreover, although his especial merit is as a colorist, his work was always begun in monochrome or what was almost wholly monochrome, and the coloration is only in the surface-painting.

At the Royal Academy in London are a number of important pictures, among them *Portrait of Lord Heathfield*; *Portrait of Admiral Keppel*, Reynolds's early friend; *Portrait of the Prince of Wales*, afterward George IV.; his own portrait in his early manhood and another of a later date; portrait group of *Members of the Society of Dilettanti* and a second and similar group; *The Age of Innocence*; *The Graces Decorating the Altar of Hymen*; *Heads of Angels*, being several different studies on the same canvas of the head of a daughter of Lord William Gordon; *Robinetta*, a fancy portrait of Mrs. Tollemache. A large number of portraits are in the National Portrait Gallery; among them one of Edmund Burke and one of Sir William Chambers, the architect. In the Royal Academy permanent exhibition are an admirable portrait of himself, one of George III., and a second one of Sir William Chambers. In the South Kensington Museum, the Soane Museum, Grosvenor House (the Duke of Westminster's private gallery), Devonshire House, and several other private houses open to the public are perhaps thirty important works, so that Reynolds can be perfectly well studied without leaving London. At the Dulwich Gallery, the Edinburgh National Gallery, the Oxford University Gallery, and at the Hermitage, St. Petersburg, are many other pictures.

Many of his paintings have been engraved, about twenty-five of them by Francis Bartolozzi in stipple, but many more in mezzotint by John Dixon, Edward Fisher, Valentine Green, John Jones, James McArdell, and J. Raphael Smith, besides many engravers who made two or three plates each. These mezzotints are among the finest ever made, and constitute by themselves an important department of art.

RUSSELL STURGIS.

Reynolds, WILLIAM MORTON, D. D.: clergyman and educator; b. in Fayette co., Pa., Mar. 4, 1812; graduated at Jefferson College 1832; became a clergyman of the Lutheran Church; was professor in Pennsylvania College 1833–50; president of Capital University, Ohio, 1850–57, and of Illinois State University 1857–60; was ordained in the Protestant Episcopal Church 1864. Author of *Discourse on the Swedish Churches*, of several occasional essays, addresses, and pamphlets; edited the *Captivi* of Plautus (1846); founded and conducted *The Evangelical Magazine* (1840), *The Literary Record* (1845), and *The Evangelical Review* (1849–62). Dr. Reynolds translated from the Swedish with introduction and notes *A History of New Sweden, or the Settlements on the River Delaware, by Israel Acrelius, Provost of the Swedish Churches in America, and Rector of the Old Swedes' Church, Wilmington, Delaware*, published by the Pennsylvania Historical Society. D. at Oak Park, Ill., Sept. 5, 1876.

Re'zin [from Heb. *Retsīn*, liter., prince]: the eighth and last of a line of kings of Damascus, beginning with Hadad, contemporary with David. He began to reign about 745 B. C. (2 Kings xv.). He fought against Judah in conjunction with Pekah of Samaria (2 Kings xv. 37; xvi. 5, *seq.*). Against them King Ahaz hired Tiglath-pileser, who came and took Damascus and put Rezin to death (B. C. 732). The Assyrian inscriptions show that Rezin, or *Rasun*, was paid tribute in 738, and that when Damascus was taken many of the inhabitants were carried into captivity.

Revised by S. M. JACKSON.

Rezonville, Battle of: another name for the Battle of Gravelotte. See GRAVELOTTE.

Rhachiglos'sa [Gr. *ῥάχις*, spine + *γλῶσσα*, tongue]: a group of carnivorous marine gasteropod molluscs, embracing the volutes, olive-shells, harp-shells, miter-shells, whelks, etc.

Rhachitis: the technical name of RICKETS (*q. v.*).

Rhadaman'thus (in Gr. *Ῥαδάμανθος*): son of Zeus by Europa, and a brother of Minos, King of Crete. He was driven

out of Crete by Minos and fled to Bœotia, where, after the death of Amphitryon, he married Alcmene. As a special favor Zeus translated him to the Elysian Fields, where later on he became a judge. J. R. S. S.

Rhæ'tia: an ancient province of the Roman empire; bounded N. by Vindelicia, E. by Noricum, S. by Gallia Cisalpina, and W. by Helvetia. It corresponded to the modern Tyrol and the Swiss canton of Grisons. Its inhabitants, the Rhæti, who lived as shepherds, were said by Livy and Pliny to be of Etruscan descent, and were subdued by the Romans 15 B. C. During the last days of the Roman empire, when the barbarian hordes swarmed around its frontiers and devastated its provinces, Rhætia became nearly depopulated.

Rhæto-Romance, or **Rhæto-Romanic Dialects**: a group of Romance dialects on the border between German and Italian speech. The region in which they are spoken embraces most of the canton Graubünden (Grisons), including the Engadine, in Switzerland, two or three strips of territory in Tyrol, and the whole of Friuli in the corner of Italy N. E. of Venice and extending as far as the Isonzo. The Swiss part of the territory has a population of about 40,000, the Tyrolese about 11,000, and the Friulan about 464,000, making a total of about 515,000, according to Gartner in his grammar of these dialects (1883). The name Rhæto-Romance is given from the Roman province Rhætia (or Rætia); other names, not generally applied to all the dialects, are Romansch, Romaunsch, Rumonsch, etc. (from a Latin adverbial form *Romanice*), and Ladin (i. e. Latin). These dialects vary considerably in vocabulary, phonology, and inflections, and they have not many distinctive features common even to most of them, which at the same time distinguish them from the adjoining Lombard and Venetian dialects of Italy, nor is it possible to draw a sharp line of division from these latter. Some generally convenient tests are, for example, the words for head, brother, sister, son, daughter, sun, which in these dialects usually are descended from Latin (or Low Latin), *caput*, *frater*, *soror*, *filius*, *filia*, *soliculus* (a diminutive of *sol*), while the Italian dialects here concerned have forms corresponding to the literary Italian *testa*, *fratello*, *sorella*, *figliuolo*, *figliuola*, *sole*. The treatment of Latin vowels after the accent is not dissimilar to that in French or Provençal; Latin initial *bl*, *pl*, *fl*, *cl*, *gl* are generally retained and not changed as in Italian; the treatment of original *ca* and *ga* shows a resemblance to that seen in French; Latin final *s* is retained in certain inflectional endings; the imperfect subjunctive is much used as a conditional also, and perhaps this use was formerly regular in regions where now another conditional form is found. There are interesting features of certain dialects, and not all those which may serve to distinguish Rhæto-Romance from Italian are here mentioned. In the phonology occur vowels like those written *u* and *eu* in French, also a vowel resembling the French so-called "mute *e*." Latin *au* is in some regions retained without change. Some dialects have also peculiar inflectional formations in verbs, for instance, the conditional. The future indicative in the western region is formed by using an auxiliary from Latin *venire*; in Tyrol and Friuli the common Romance formation is found. The descendant of the Latin perfect indicative is nearly or quite lost in the spoken dialects. Both German and Italian have exerted a considerable influence on these dialects.

In literary production only Graubünden and Friuli need be considered, and in Friuli, though documents are preserved from the fourteenth century on, yet the strong Venetian influence has prevented the development of an independent literature, and the productions are comparatively unimportant, serving for temporary amusement only—as comedies, or otherwise having little value, as newspapers. (See the *Archivio glottologico italiano*, iv., 185 ff.) In Graubünden, however, in the dialects along the Rhine (Oberländisch, including Obwaldisch, or Surselvisch, and Niedwaldisch) and in the Engadine (Upper and Lower are here to be distinguished) a stronger literary movement has produced more ambitious works, the main cause being the religious feeling due to the Reformation. Noteworthy especially are Bifrun's translation of the New Testament (1560) in the Upper Engadine, Chiampel's translation of the Psalms (1562) in the Lower Engadine, Bonifaci's *Catechismus* (a translation from German, 1601) in an Oberland dialect, L. Gabriel, *Ilg Nief Testament* (The New Testament, 1648), also some epic or historical verse, as *Tobia* (probably of the sixteenth century; see *Romanische Studien*, i., 336 ff.), Travers's *Chanzun dalla guerra dalg Chiasté d'Müsch* (sometimes referred to as the *Müsserkrieg*, sixteenth century), and Giocrin Wietzel's poem, commonly referred to as the *Veltlinerkrieg* (seventeenth century). There are some dramatic works belonging to the sixteenth and seventeenth centuries; those of the sixteenth at least are nearly if not quite all translations. To the sixteenth century belong a *Susanna*, *Joseph*, and some others (see *Zeitschrift für romanische Philologie*, ii., 515 ff., v., 461 ff., and *Romanische Studien*, vi., 239 ff.). To the seventeenth century belong some by Fadri Wietzel and others (see *Zeitschrift für romanische Philologie*, iv., 1 ff., *Le Sacrifice d'Abraham* in *Romania*, viii., 374 ff., *Susanna* in *Archivio glottologico italiano*, viii., 263 ff., *Revue des langues romanes*, xxvii., 121 ff., 162 ff.). Some early Oberland texts of interest under the general title *Quattro testi soprasilvani*, among them a *Barlaam and Josaphat* (*Vita de Soing Giosaphat*, etc.), were published by Decurtins in *Archivio glottologico italiano*, vii., 149 ff. The later literary production comprises (besides religious compositions) lyric poems, tales, translations, schoolbooks, etc. A fairly adequate view of the literature can be obtained from J. Ulrich's *Rhätoromanische Chrestomathie* (2 vols., with glossaries, 1882–83), supplemented by reference to texts and articles in the periodicals mentioned above, particularly the bibliographical lists of Böhmer entitled *Verzeichniss Rätoromanischer Litteratur* in *Romanische Studien*, vi., 109–238. The *Catalogue of the Rhæto-Romanic Collection* presented to the Cornell University Library by Willard Fiske (1894) contains some other titles; see also the bibliographies in the *Zeitschr. für roman. Philol.* For the grammatical and historical study of the dialects, see especially Ascoli, *Saggi ladini* in *Archivio glottologico italiano*, i.; Gartner, *Rætoromanische Grammatik* (1883); *id.*, in Gröber's *Grundriss der romanischen Philologie*, i., 461 ff. (1888), etc. See also ROMANCE LANGUAGES. E. S. SHELDON.

Rhamnus: See BUCKTHORN.

Rhamphas'tidæ [Mod. Lat., named from *Rhamphas'tus*, the typical genus, from Gr. *ῥάμφος*, a crooked beak of birds]: a family of carinate birds, including the toucans. They are distinguished by their bills, which are long, high, and compressed, decurved at the tip, and with the lateral margins serrated; the nostrils are inconspicuous, superior, and at the base of the upper mandible; no bristles are developed; the wings are rather short and rounded; the tail is moderate and more or less convex; the tarsi are rather robust and covered with broad scales; the toes in pairs, two being directed forward and two backward; the inner toes anteriorly and posteriorly, shorter than the outer; the claws strong and curved. They are somewhat related to the cuckoos. The species are peculiar to America, especially the tropical regions; a few, however, extend northward into Mexico, but none is found within the limits of the U. S. They are generally combined under two genera—*Rhamphastus*, in which the nostrils are concealed, including seventeen species; and *Pteroglossus*, with the nostrils exposed, comprising forty-five species. They frequent lofty trees, feeding upon various fruits, especially the banana, but also live partly upon insects, and even reptiles, as well as young birds and eggs. The female makes her nest in holes in the trunks of trees, and generally deposits therein two eggs. See ARACARI.

The ariel toucan.

Revised by F. A. LUCAS.

Rhaph'ides, or **Raphides** [Mod. Lat., from Gr. *ῥαφίς*, plur. *ῥαφίδες*, needle]: the crystals, often needle-shaped, of salts found within certain plant-cells. The oxalates, carbonates, and sulphates, and other salts of lime are those most commonly found. See HISTOLOGY, VEGETABLE.

Rhapsodists [from Gr. *ῥαψῳδός*, a rhapsodist; *ῥάπτειν*, *ῥάψαι*, sew, stitch, patch together + *ᾠδή*, song]: a class of wandering minstrels in ancient Greece whose occupation was the recital of the Homeric and other poetry. After these poems were reduced to writing these rhapsodists ceased to be the honored singers of the early days of Greece.

Rhatany [from Span. *rataña* = Peruv.]: a drug, being the root of the *Krameria triandra* and *Krameria ixina*, small woody shrubs of a genus generally referred to the family *Polygalaceæ*, growing in the Bolivian and Peruvian Cordilleras. Rhatany-root is sold in pieces of various sizes, composed of a dark, reddish-brown bark and a central lighter-colored, woody portion. It has no smell, but a bitter, somewhat sweetish, and very astringent taste. The medicinal principle is a form of tannin, called rhatani-tannic acid. This is found only in the cortical part of the root, where it exists in the proportion of about 20 per cent. The physiological effects of rhatany are simply those of the tannin it contains, and preparations of the root are used in medicine almost exclusively as astringents in diarrhœal affections.

Rhea, in ornithology: See Rheidæ.

Rhea, in Greek mythology: See Cybele.

Rhea Silvia: See Romulus.

Rhegium: See Reggio di Calabria.

Rhe'idæ [Mod. Lat., named from *Rhe'a*, the genus, from Lat. *Rhe'a* = Gr. Ῥέα, name of a goddess]: a family of birds of the order or sub-order *Ratitæ*, containing the South American ostriches, and differing externally from the African ostriches simply by the three-toed feet, the more slender bill, and the want of caudal plumes. The bill is comparatively short, depressed gradually, and narrowed toward the tip; the nostrils large, oval, and nearly in the middle of the bill; the wings are furnished with long, soft feathers; the tail is not apparent; the tarsi are long and covered in front with broad transverse scales; toes three, the lateral shorter than the middle; the claws compressed and curved. They are distinguished anatomically by a number of characters. The species of this group are confined to South America, where they inhabit the open plains and exhibit habits analogous to those of the ostriches of Africa. They are generally seen alone; they run with considerable fleetness, and generally against the wind, expanding their wings in starting to assist in making headway. They feed chiefly upon grass and roots. The females lay their eggs in combination, sometimes depositing together as many as eighty eggs. These are collected together by the male bird, who hatches them and attends for a short time to the young. Three species are known: (1) The *Rhea americana*, extending from Southern Brazil on the N. to the Straits of Magellan on the S.; (2) *R. darwinii*, from the Straits of Magellan to the Rio Negro, or the boundary between Patagonia and Buenos Ayres; and (3) *R. macrorhyncha*, whose habitat is uncertain.

Revised by F. A. Lucas.

Rheims, or **Reims**, reemz, Fr. pron. răñs [anc. *Durocortorum*; also called *Remi*, the name of the people]: a large old city of France, department of Marne, on the Vesle (see map of France, ref. 3–G). It is generally well built, has fine streets, squares, and public buildings, and is surrounded with walls and ramparts planted with trees and affording beautiful promenades. The cathedral, 466 feet long, 99 feet broad, and 144 feet high, built in the first part of the thirteenth century, is one of the finest Gothic edifices of Europe; its western front is especially magnificent. In this church all of the monarchs of France from Philippe Auguste (1180) to Charles X. (1824) were consecrated, excepting Henry IV., Napoleon I., and Louis XVIII. During the Revolution the people stormed the cathedral and broke the *sainte ampoule* containing the sacred oil, which was believed to be of miraculous origin. St. Remigius, the apostle of the Franks, is buried in one of the suburbs. Rheims has extensive manufactures of woolen fabrics, and a large trade in champagne wines. Pop. (1881) 93,823; (1896) 107,963.

Rheinberger, rīn'bār-ger, Joseph: composer; b. at Vaduz, principality of Liechtenstein, Mar. 17, 1839; learned to play the piano at the age of five, and at the age of seven was organist of the church in his native place. When twelve years of age he was sent to the Munich Conservatory, and remained there until he was nineteen. Subsequently he became Professor of Counterpoint and Organ in the conservatory. His compositions are numerous and mostly in the large forms, including several symphonies, two operas, several cantatas, much orchestral and chamber music, two Stabat Maters, a mass in eight parts, another mass, many organ pieces, much church music, and many works for chorus and for male voices. He is a Hofkapellmeister and professor, and a member of the Academy of Arts, Berlin.

D. E. Hervey.

Rhena'nus, Beatus (*Bilde von Rheinau*): classical scholar; b. at Schlettstadt, Alsace, in 1485; educated at the University of Paris; lived in Basel from 1511 to 1527. He spent the rest of life in scholarly leisure in his native town. Among the fruits of his labors were editions of Seneca's *Apocolocyntosis*, Quintus Curtius, Tertullian, Tacitus, and Livy. He was the first to question the authenticity of the *Dialogus* of Tacitus, and he issued the *editio princeps* of Velleius Paterculus, having discovered the single extant MS. of this historian in 1515, in an Alsatian monastery. Rhenanus's learning and critical talent were of a high order. D. May 18, 1547. See A. Horawitz, *Vienna Acad. Proceed. Philos. histor. Class.*, vol. lxx., pp. 189 ff.; lxxi., pp. 643 ff.; lxxii., pp. 323 ff.; lxxviii., pp. 313 ff. Alfred Gudeman.

Rhenish [from Lat. *Rhe'nus*, Rhine] **Confederation**: a confederation of German principalities under the protectorate of Napoleon. By the Peace of Presburg (Dec. 26, 1805) Bavaria and Würtemberg were erected into kingdoms, and their princes received sovereignty independent of the German emperor. Thus the dissolution of the German empire was prepared, and on Aug. 1, 1806, sixteen princes of Southern and Western Germany threw off their allegiance to the emperor and formed a confederacy, the Rheinbund, or Rhenish Confederation, under the protectorate of Napoleon. On Aug. 6 the emperor, Francis II., abdicated the imperial dignity and crown of Germany, and assumed the title of Emperor of Austria, and after the war between France and Prussia most of the princes of Central and Northern Germany entered the confederacy, which continued till the war of liberation in 1813.

Rhenish Wines, or **Rhine Wines**: wine produced on and near the banks of the Rhine. See Wine and Wine-making.

Rhetoric [via O. Fr. from Lat. *rheto'rica* = Gr. ῥητορική (sc. τέχνη, art), the art of speaking or oratory, liter., fem. of ῥητορικός, pertaining to an orator, deriv. of ῥήτωρ, orator]: according to Aristotle, the art of persuasion; according to Whately, the art of conviction; according to Campbell, the art of discourse. Campbell's definition is to be preferred, as more comprehensive than either of the others, although Aristotle justly emphasizes the highest end of all rhetorical study. All writers on the subject agree in regarding rhetoric as an art (that is, a body of practical precepts), rather than a science; but precepts imply underlying principles, and there has been much question with reference to the science or sciences on which rhetoric is founded. Some—notably, Whately—have said logic; others—of whom Blair may be taken as an example—would seem to say æsthetics; still others—following Theremin—would say ethics. If rhetoric is founded upon any single science, it is unquestionably logic; but in so far as rhetoric is founded upon logic it is only mediately, through grammar. Grammar receives the material of thought elaborated into concepts, judgments, and reasonings, expresses them with *correctness* (that is, with due regard to purity, propriety, concord, and precision), and turns them over to rhetoric to be woven into discourse with clearness, energy, and elegance, and in adaptation to the special ends that the writer or speaker has in view. Grammar has to do with the sentence, rhetoric with the discourse. Grammar regards correct expression as an end in itself; rhetoric regards expression as merely a means to an end. Instead of regarding rhetoric as founded on a single underlying science, it is perhaps preferable to recognize three departments of rhetoric, corresponding to the three nomological sciences recognized by Sir William Hamilton: 1. *Inventive rhetoric*, founded on logic, having to do with the matter of discourse, and helping us to attain to the true; 2. *Æsthetic rhetoric*, founded on æsthetics, having to do with the form of discourse, and helping us to attain to the pleasurable; 3. *Ethical rhetoric*, founded on ethics, having to do with the purpose of discourse, and helping us to attain to that which we esteem good. In this classification it will be seen that a department of rhetoric is recognized corresponding to each of the three divisions which are ordinarily made of the human faculties—the intellect, the sensibilities, and the will—while yet, as these faculties are but so many manifestations of the unit of consciousness, we have a sufficient basis of unity.

Rhetoric, taken as a whole, may be viewed either as constructive or critical. Critical rhetoric embraces the study of rhetorical precepts and the study of literary models. Constructive rhetoric consists in the practical application of rhetorical precepts and the imitation of literary models. Objections have been made to the study of either branch of the art, but they are trivial in themselves, and inconsistent

with the practice of the best writers and speakers. The precepts of rhetoric are not the arbitrary enactment of any man or any body of men, but simply deductions from the generalized experience and observation of generations of writers and speakers, with which all who propose to write or speak will do well to familiarize themselves.

Rhetoric recognizes three forms of discourse:

1. *Representative discourse*, in which the matter is presented for its own sake, without especial purpose or especial regard to form. Under this head are treated (1) things —description; (2) facts—narration; (3) truths—exposition. Clearness, accuracy, and completeness are the prime essentials of representative discourse.

2. *Poetry*, in which the matter and the purpose are subordinate to the form. Under poetry the following classification may be recognized: (1) The poetry of thought, or didactic poetry; (2) the poetry of feeling, or lyric poetry; (3) the poetry of action, or epic poetry, and dramatic poetry. The prime essentials to poetry are, first, a poetic thought; second, poetic diction—to characterize either of which would fall under the province of a special discussion.

3. *Oratory*, which proposes an end to be attained, to which the matter and form of discourse are merely ancillary. The ancients recognized three kinds of oratory—demonstrative, judicial, and deliberative. Blair proposes to recognize, instead, the eloquence of popular assemblies, the eloquence of the bar, and the eloquence of the pulpit. If a classification of oratory be attempted at all, it is better to make the basis of classification the purpose, rather than the occasion, of its exercise. Oratory is commonly regarded by rhetoricians as the normal type of discourse, embodying the fullest and loftiest ideal of the art. The orator generally seeks to bring something to pass; hence he appeals not to the intellect or to the feelings alone, but to the will. He must sway the whole man, or he must fail in the object he has in view. It is especially necessary for him to study adaptation, and his discourse, while not deficient in clearness and not offensive to the taste of his hearers, must excel in energy.

Inventive rhetoric has to do with the choice of themes, the accumulation of material, and the disposition of material. It was much more fully treated by the ancient rhetoricians than by those of the present day, many of whom ignore it altogether, regarding it as a mere department of ethical rhetoric, which does, in fact, greatly limit it.

Ethical rhetoric has especially reference to the purpose contemplated in discourse. This purpose may be either (1) *enlightenment*—i. e. to develop in the mind a new cognition; (2) *conviction*—i. e. to lead the mind to adopt a given opinion; (3) *excitation*—i. e. to move the feelings; or (4) *persuasion*—i. e. to determine the will to action. Excitation is not regarded as a distinct end of discourse by many rhetoricians, since, ordinarily, we seek to excite emotion only that through emotion we may influence the will. But the distinct recognition of excitation is essential to a complete analysis of ethical rhetoric; the methods of excitation may be separately studied; and excitation is sometimes (as in demonstrative oratory and in certain kinds of poetry and fiction) an end in itself. In all discourse—but especially in oratory—some one of the purposes mentioned above dominates. It is the function of rhetoric to show how discourse may, in matter and manner, be made subservient to that purpose.

Æsthetic rhetoric has reference to style, or the art of expressing clearly, energetically, and elegantly, the products of inventive rhetoric in adaptation to the ends of ethical rhetoric. Under the head of style the things of prime importance are (1) naturalness; (2) adaptation; (3) clearness; (4) energy; (5) elegance. These characteristics of style are discussed, with greater or less fullness, in all rhetorical treatises. Clearness, the most important attribute of a good style, is admirably treated in *How to Write Clearly*, by Prof. E. A. Abbott, of the City of London School.

Figurative language (or language which deviates from the plain and ordinary method of describing an object or stating a fact) may be included under the head of style, since it tends to promote clearness by associating the object or fact under discussion with more familiar objects or events; energy, by associating the object or fact under discussion with more exciting objects or facts; elegance, by associating the object or fact under discussion with more pleasing objects or facts. Figurative language embraces *figures of speech*, which consist in a mere modification of the form of expression, and *figures of thought*, which involve an essential modification of the conception. These figures depend on three principles—(1) the principle of similarity; (2) the principle of dissimilarity; (3) the principle of association. Under the head of figures of speech come (1) alliteration, or the repetition of similar sounds at the beginning of successive words; e. g.

Apt alliteration's artful aid.—*Churchill.*

(2) Paronomasia, or the use of words in the same connection which are similar in sound, but dissimilar in sense; e. g.

Not on thy *sole;* but on thy *soul*, harsh Jew.—*Shakspeare.*

(3) Meiosis or litotes, in which an affirmative is represented by the negative of its contrary; e. g. "A citizen of *no mean* city" (*Paul*). (4) Pleonasm, which consists in the use of more words to express one's meaning than are strictly necessary, and which should be sharply discriminated from tautology, or the meaningless reiteration of thought. (5) Hyperbole, which consists in representing an object as larger than it really is, or stating a fact more strongly than is consistent with literal truth; e. g. "The English gain two hours a day by clipping their words" (*Voltaire*). (6) Climax, which consists in gradually rising, by more and more emphatic statements, to the fullest and most expressive utterance of thought; e. g. "Jesus of Nazareth pours forth a doctrine beautiful as light, sublime as heaven, and true as God" (*Theodore Parker*). Figures of speech comprise also ellipsis, asyndeton, polysyndeton, aposiopesis, epizeuxis, epanalepsis, and interrogation, for the careful discrimination of which references must be made to special treatises.

Under the head of figures of thought that are *founded on the principle of similarity* there are—(1) The simile, which is an expressed comparison; e. g. "*Like as* a father pitieth his children, *so* the Lord pitieth them that fear him." (2) The metaphor, which is an implied comparison; e. g. "I am the Good Shepherd, and know my sheep." Similes are more conducive to clearness, metaphors to energy. Either may be made conducive to elegance. The metaphor may be tested by reducing it to an equation of ratios: e. g. "The ship plows the sea" equals "The ship is to the sea as the plow is to the land." Any metaphor which will not submit to this test is radically defective, introducing more than four terms or suggesting an unreal similarity. Under this head are recognized also (3) the allegory, which is an extended metaphor. Bunyan's *Pilgrim's Progress* is the best example. (4) The fable, which is essentially similar to the allegory, although briefer, more obviously didactic, and characterized by the free endowment of the brute (and even the inanimate) creation with the attributes of reason and speech. The fables of Æsop will at once suggest themselves. (5) The parable, which is a religious allegory. (6) Personification, which regards things inanimate as if they were animate; e. g. "The pyramids, doting with age, have forgotten the names of their founders" (*Fuller*). Under this head, too, are included prosopopœia, vision, and apostrophe.

Under the head of figures of thought that are *founded upon the principle of dissimilarity* there are contrast, antithesis, irony, which hardly require to be characterized or exemplified.

Founded on the principle of association is metonymy, or a transference of names (Gr. μετά and ὄνομα), involving the substitution of—(1) The cause for the effect and *vice versâ*; e. g. "The Lord is *my song*. He is become my salvation." (2) The container for the thing contained; e. g. "He is a slave to the *bottle*." (3) The sign for the thing signified; e. g. "*The scepter* shall not depart from Judah." (4) The instrument for the agent: e. g. "*The pen* is mightier than the sword" (*Bulwer*). (5) The author for his works; e. g. "They have *Moses and the prophets*." (6) The place of manufacture for the thing made; e. g. "I prefer *Axminster* to *Brussels*."

Synecdoche must be classed under the head of similarity and dissimilarity combined; it is concerned with objects that are similar in kind, but dissimilar in extent or degree. By synecdoche one puts a part for the whole, as a sail for a ship, or a blade for a sword, etc. More specifically, synecdoche consists in the substitution of—(1) the concrete for the abstract; (2) the species for the genus; (3) the individual for the species; (4) the member for the individual; (5) the material for the thing made. Its employment is highly conducive to energy.

It falls within the province of rhetoric accurately to discriminate between the figures of speech which have been mentioned, and to give rules which shall facilitate their effective use.

The great masters of rhetoric among the Greeks were Aristotle and Longinus. Aristotle indeed may fairly be regarded as the father of the art. The second book of his *Art of Rhetoric*—in which he embodies a subtle analysis of the mental and moral characteristics to which the orator must adapt his discourse—is still of capital significance. The best modern commentator on Aristotle is Cope. Among the Romans the most eminent names are those of Cicero, Quintilian, and Horace. Of all the ancient rhetoricians, Quintilian is the most useful, and Horace the most attractive. Horace's *Epistle to the Pisos* (the material of which is largely borrowed from Aristotle) has been imitated by Vida in his *Poetics*, by Boileau in *L'Art Poétique*, and by Pope in his *Essay on Criticism*, and has thus exerted a widespread influence on modern style. Volckmar's *Die Rhetorik der Griechen und Römer* is a valuable compend of the results attained by the ancient rhetoricians.

Of English authors, mention should be made of Whately (best on conviction and persuasion), Blair (best on style), Kames (best on figurative language), and Campbell (best on the grammatical properties of style). De Quincey (*Historical Essays*, vol. ii.) has valuable essays on rhetoric and style; and Herbert Spencer's essays on style must not be overlooked. W. G. T. Shedd's *Literary Essays* and the same author's translation of *Theremin* contain valuable material. Of recent treatises on critical rhetoric, J. F. Genung's *Practical Rhetoric* is certainly the most popular and perhaps the best. More attention is now given, however, to constructive rhetoric, and Barrett Wendell's *English Composition* (a book of wider scope than its title indicates) is very helpful in this direction. J. H. Gilmore.

Rhett, Robert Barnwell: politician; b. at Beaufort, S. C., Dec. 24, 1800; was originally named Smith; adopted in 1837, with the other members of his family, the name of Rhett, in memory of an ancestor; was liberally educated; studied law; was elected to the State Legislature 1826; became attorney-general of South Carolina 1832; was one of the most pronounced advocates of State rights, nullification, and secession; was a member of Congress 1837–49, and U. S. Senator 1851–52; expressed himself openly in favor of a dissolution of the Union both in Congress and in the columns of the Charleston *Mercury*, the organ of the so-called fire-eaters, which he owned and conducted; was a leader in the State convention of South Carolina which passed an ordinance of secession Dec. 20, 1860; was chairman of the committee which reported the constitution of the Confederate States to the Montgomery convention Feb., 1861, and subsequently a member of the Confederate Congress. D. in St. James parish, La., Sept. 14, 1876.

Rhe'um: a genus of herbs of the Buckwheat Family (*q. v.*), natives of Siberia, the Himalayas, and Western Asia. See also Rhubarb.

Rheumatism [from Lat. *rheumatis'mus* = Gr. *ῥευματισμός*, rheum, deriv. of *ῥευματίζεσθαι*, have the rheum, deriv. of *ῥεῦμα*, flow, flux, rheum, deriv. of *ῥεῖν*, flow]: an acute or chronic disease affecting the joints and other structures, and characterized by signs of inflammation and by great pain. Some modern authorities would include it among the infectious diseases, but no specific microbe has been discovered, and for the present it must be regarded as a disease resulting from disturbed metabolism—that is, disturbed chemical action in the tissues and the blood. There are three principal kinds of rheumatism: acute and chronic articular rheumatism, and abarticular rheumatism, the last named including all forms affecting parts other than the joints.

Acute articular rheumatism generally begins at early adult age, and is apt to recur through life. Exposure is a strong determining cause, and its occurrence in certain families proclaims the hereditary tendency. After a short period of indefinite disturbance of health the joints swell and become red and extremely painful; there are fever, a tendency to excessive perspiration, especially at night, and general symptoms indicative of fever. The joints affected are usually the larger ones, like the ankle and knee, and as a rule several are diseased at once. The inflammation may subside very quickly in one joint and appear in another, and thus before the termination of the disease all of the large joints may be involved. On examination they are seen to be greatly swollen and inflamed, and are boggy from liquid exudation in the capsule. Rarely, however, does suppuration ensue. Under suitable care and nursing the disease generally subsides in six or eight weeks, but with treatment the duration is shorter. Few diseases, however, are so treacherous and so liable to relapse. Complications are numerous. By far the most important is acute endocarditis, which goes on to chronic organic disease of the valves of the heart. In other instances the pericardium, the membranes of the brain, or the pleuræ may be inflamed, and serious symptoms result.

Chronic articular rheumatism is a disease of old age. It may result from repetition of acute attacks or may come on as a chronic disease from the first. The joints are enlarged and frequently deformed and stiffened by fibrous adhesions of the bones composing them. Persons suffering with this malady may be comfortable at most times, but with every change of weather present symptoms similar to those seen in acute rheumatism, although less severe. The joints are swollen slightly, are a little red, and are painful. There is little or no fever or disturbance of the general health. Chronic rheumatic subjects are very liable to chronic bronchitis, to throat troubles, such as chronic tonsilitis or pharyngitis, and to eczema and other skin diseases.

Among the forms of rheumatism not affecting the joints the most important is muscular rheumatism. This disease is probably in reality an affection of the connective tissues binding the muscles together. It receives various names, according to the location of the disease; thus it is called *lumbago* when the muscles of the back are affected; *torticollis* or *wryneck* when the disease is located in the neck; *pleurodynia* when the intercostal muscles are implicated. Other forms of abarticular rheumatism, so called, are more of the nature of complications, but all of these doubtless occur in rheumatic persons entirely unassociated with joint symptoms. Thus there are rheumatic skin affections, inflammatory disease of the heart and blood-vessels, and rheumatic inflammations of the eye and very frequently of the tonsils.

The treatment of rheumatism has undergone many changes. Formerly reliance was placed mainly upon alkalies, which are given to restore the normal alkalinity of the blood and fluids of the body. More recently salicylic acid and its various combinations have been found to possess remarkable power to control the pain of rheumatism, and possibly they shorten the duration. Rest in bed and warmth are essential. Local treatment of the joints is useful in relieving the distress of the patient. Bland, unirritating diet, especially milk, is required. In chronic rheumatism iodide of potash, arsenic, and tonics are valuable, but the disease is difficult to cure. William Pepper.

Rhianus of Crete: Greek poet; flourished in the latter half of the third century B. C., and composed, among other epic poems, *The Story of Messene* (Μεσσηνιακά), the great source of Pausanias (*q. v.*) in his fourth book. B. L. G.

Rhinas'ter: See Rhinocerotidæ.

Rhine (Germ. *Rhein*; Lat. *Rhenus*): an important river of Europe. It is formed at Reichenau, in the canton of Grisons, in the Swiss Alps, at an elevation of 1,922 feet, by the union of two small streams, the Vorder and Hinter Rhein, the former of which, rising on the northeastern side of the mountain group of St. Gothard, at an elevation of 7,600 feet, is generally considered as the principal source. Immediately after its formation the Rhine is navigable for rafts and small craft, but during its whole upper course, from Reichenau to Basel, through Switzerland, the Lake of Constance, and along the frontier between Switzerland, Bavaria, and Baden, its navigation is difficult, and in many places entirely interrupted by rapids and cataracts, of which that of Schaffhausen, where the water suddenly leaps from a rock 70 feet high, is the most remarkable. During its middle course, from Basel to Cologne, it winds its way through a broad and fertile valley between the Vosges and the Schwartzwald —the Rheinthal, often called the "garden of Germany"— thence it flows, by a narrow gorge, through the plateau of the lower Rhine. In this latter part the Rhine is not only an important route of traffic, but it also presents some of the most beautiful scenery in the world, flowing along between vineclad hills, which now and then hem it in between steep, towering rocks crowned with old castles, and then again open into long, beautiful valleys. Its course from Cologne to the North Sea leads through low and level ground, and is uninteresting; it branches off into the Waal, Yssel, Leck, and Vecht, and reaches the ocean as a small stream, almost disappearing among the sandbanks of the shore. The entire length of the Rhine is 960 miles; its breadth at Basel is 750 feet; at Mentz, 1,500 feet; at its entrance into the Netherlands, 2,150 feet; its depth varies

from 5 to 28 feet; its elevation is 814 feet at Basel, 121 feet at Cologne. Its principal affluents are the Aar in Switzerland, the Neckar and Main in the Rheinthal, and the Lahn and Moselle in the highlands of the lower Rhine.

Revised by M. W. Harrington.

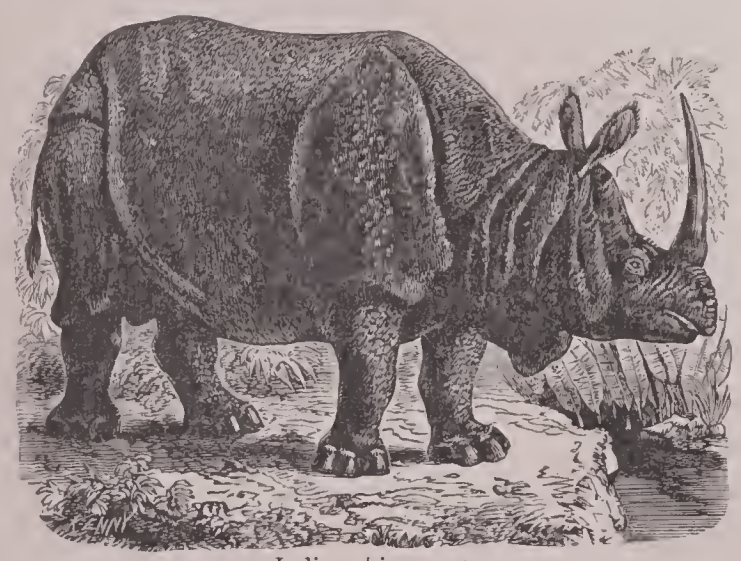
Rhinebeck: village; Rhinebeek town, Dntchess co., N. Y.; on the N. Y. Cent. and Hudson River (station name, Rhinecliff) and the Phila., Reading and New Eng. railways; 2 miles E. of the Hudson river, opposite Kingston, 15 miles N. of Poughkeepsie (for location, see map of New York, ref. 7–J). It is in an agricultural and stock-raising region, and is the chief shipping-point for the surrounding country. There are five churches, union free school with academic department, Starr Institute (founded in 1860), a national bank with capital of $125,000, a savings-bank, and a weekly newspaper. A part of the town was laid out for settlers from the Rhine palatinate in 1714, a precinct was organized in 1737, a hamlet named Rhinebeck Flats was laid out in 1792, and the hamlet was incorporated as a village in 1834. Pop. (1880) 1,569; (1890) 1,649; (1900) 1,494.

Editor of "Gazette."

Rhinelander: village; capital of Oneida co., Wis.; on the Wisconsin river, and the Chicago and N. W. and the Minn., St. P. and Sault Ste. Marie railways; 65 miles N. of Wausau, 255 miles N. by W. of Milwaukee (for location, see map of Wisconsin, ref. 3–D). It is in a lumbering region, has considerable milling and manufacturing interests, and contains a national bank with capital of $50,000, a State bank with capital of $50,000, and three weekly newspapers. Pop. (1890) 2,658; (1900) 4,998.

Rhinoceros: See Rhinocerotidæ.

Rhinocerot'idæ [Mod. Lat., named from *Rhino'ceros*, the typical genus, from Gr. *ῥινόκερως*, *ῥινοκέρωτος*, rhinoceros; *ῥίς*, *ῥινός*, nose + *κέρας*, horn]: a family of ungulate mammals embracing the various species combined under the popular name rhinoceros. They are distinguished by their massive form; short neck; long head: the presence in all the living forms of one or two horns on the middle of the nasal region, and the broad elavate feet, each of which has three toes. The teeth are M. $\frac{3}{3}$, P. M. $\frac{4}{4}$, C. $\frac{0}{0}$, I. variable—i. e. entirely wanting, $\frac{1}{2}$, or, in extinct forms, $\frac{2}{3}$; the upper molars have a continuous outer wall, are without complete transverse crests; the lower molars (P. M. 2, M. 3) have two curved transverse crests. The family embraces few recent species, which have been variously grouped, but appear to represent only two genera—(1) *Rhinoceros*, including the Asiatic species, which are distinguished by the elongate and free intermaxillary bones, the long upper incisor teeth, the produced nasal bones, and the skin corrugated by well-marked folds. To this genus belongs the Indian rhinoceros



Indian rhinoceros.

(*R. unicornis*), the largest of the group, having a single horn and the folds of skin unusually well developed. It is now restricted to a part of Nepal, Bhutan, and Assam, in Northeastern India. The genus also includes the smallest species, the Sumatran rhinoceros (*R. sumatrensis*), which has two horns. It ranges from Northeastern India to the Malay Peninsula, Sumatra, and Borneo. (2) *Rhinaster*, embracing the African species, in which the intermaxillary bones are very small and free, the upper incisor teeth wanting, the nasal bones broad and rounded, and the skin smooth and not corrugated. There are but two species, each having two horns. One of these, *R. simus*, improperly known as the white rhinoceros, is almost extinct, and the other, *R. bicornis*, is rapidly disappearing. In geological epochs other forms flourished, and one of these (*Cœlodonta*) survived long after the appearance of man on the globe; this form was distinguished by the union of the nasal and intermaxillary bones into one mass, and the ossification of the nasal septum. The existing species of the family are peculiar to Asia and Africa, but formerly the range of the family extended far northward into Europe and Siberia, and at a still earlier period the group was represented in North America.

Revised by F. A. Lucas.

Rhinthon of Tarentum: Greek poet; originator of the so-called *Hilarotragœdia* (*ἱλαροτραγῳδία*), a serio-comic treatment of tragic themes, drawn from Greek mythology. See Völker, *Rhinthonis fragmenta* (1887).

B. L. G.

Rhipæ'an Mountains (in Gr. *τὰ Ῥιπαῖα ὄρη*): in Grecian mythology, mountains lying in the extreme north (or west). Servius derived the word from *ῥίπτειν*, because the north wind came from these mountains. Ancient geographers identified them now with the Alps and now with the western outliers of the Ural range. See Hyperboreans, Hesperides, and Græ.

J. R. S. S.

Rhipidoglos'sa [Mod. Lat., from Gr. *ῥιπίς*, fan + *γλῶσσα*, tongue]: a term sometimes employed for the abalones, keyhole limpets, and allied molluscs, usually called *Zygobranchia*. See Gasteropoda.

Rhizocarps: See Plants, Fossil.

Rhizocephʹala: See Cirripedia.

Rhizome: See Morphology, Vegetable.

Rhizop'oda [Gr. *ῥίζα*, a root + *πούς*, *ποδός*, foot]: a class of Protozoa (*g. v.*) characterized by the ability of the individuals to extend temporary protoplasmic processes of the body by means of which locomotion is effected and food obtained (*pseudopodia*). There is no cell-wall, but the animals may secrete internal or external calcareous or siliceous skeletons, or they may form protective cases of horny matter or by cementing together solid particles found in the water in which they dwell. The Rhizopods (which live in the ocean, in fresh water, and in moist earth) are usually divided into the *Lobosa*, *Reticularia* (*Foraminifera*), *Heliozoa*, and *Radiolaria*; while the *Monera* of Haeckel differ from the *Lobosa* only in the fact that in them a nucleus has not yet been discovered. Here, too, may possibly belong those forms classed sometimes as *Mycetozoa* in the animal kingdom, sometimes as *Myxomycetes* or slime moulds in the vegetable kingdom. Reference should be made to the different divisions for descriptions of the forms included.

J. S. Kingsley.

Rhode Island: one of the U. S. of North America (North Atlantic group); the last of the thirteen original States that ratified the Federal Constitution; the smallest State in the Union, and the thirty-fourth in population in 1900.

Location and Area.—It lies between lat. 41° 18′ and 42° 3′ N., and lon. 71° 8′ and 71° 53′ W.; is bounded on the N. and E. by Massachusetts, on the S. by the Atlantic Ocean, and on the W. by Connecticut; extreme length from N. to S., 48 miles; extreme width from E. to W. about 37 miles; area, 1,250 sq. miles (800,000 acres), of which 165 sq. miles is water surface.

Rhode Island seal.

Physical Features. — Narragansett Bay, extending inland about 30 miles, divides Rhode Island into two unequal parts. The surface of the State is for the most part hilly, though the hills never rise to any great height, Durfee Hill, the highest point of land, rising only 805 feet above the sea-level. Extensive salt-marshes border the ocean. In Narragansett Bay are many islands. Of these the most widely known is Rhode

island, from which the State derives its name, and upon which Newport is situated. This island was named Roodt Eylandt (the Red island) by Adrian Block, when early in the seventeenth century he cast anchor in the bay, because of the red clay along its shores. Its Indian name was Aquidneck. Other islands in the bay are Canonicut, Prudence, Patience, Hope, Perry, Dyer's, Dutch, and Starve Goat. Block island, so named from Adrian Block, is 10 miles from the mainland. The principal rivers are the Pawcatuck, the Pawtuxet, and the Pawtucket, which is navigable as far as Pawtucket, and above Pawtucket Falls becomes the Blackstone. The Pawcatuck forms part of the boundary between Rhode Island and Connecticut.

Geology.—The western half of the State and a small tract along the east shore of Narragansett Bay are Eozoic, belonging to the same formation as that of Eastern Connecticut and Central and part of Southeastern Massachusetts; but a tract covering all the islands of Narragansett Bay and part of its west shore, and extending N. E. into Bristol co., Mass., belongs to the Carboniferous era, and forms the extreme eastern bed of anthracite in the U. S. Block island belongs to the Tertiary era.

Soil and Productions.—Little attention is paid to agriculture. The soil is stony, and, as a rule, unfruitful. Farm production is steadily declining as manufactures increase. Some market-gardening is carried on profitably on a large scale, especially in Cranston. The gardeners depend upon irrigation to secure their crops.

The following summary of the census reports of 1880 and 1890 shows the extent of farm operations in the State:

FARMS, ETC.	1880.	1890.	Per cent.*
Total number of farms	6,216	5,500	11·5
Total acreage of farms	514,813	469,281	8·8
Total value of farms, including buildings and fences	$25,882,079	$21,873,479	15·3

* Decrease.

The following table shows the acreage, yield, and value of the principal crops in the calendar year 1900:

CROPS.	Acreage.	Yield.	Value.
Corn	8,197	262,304 bush.	$175,744
Oats	3,705	114,484 "	43,504
Barley	312	8,736 "	6,727
Potatoes	7,428	698,232 "	488,762
Hay	72,278	66,496 tons	1,243,475
Totals	91,920	.....	$1,958,212

The farm animals on Jan. 1, 1900, comprised 10,384 horses, value $896,906; 25,256 milch cows, value $1,008,977; 10,149 oxen and other cattle, value $302,788; 10,608 sheep, value $40,974; and about 10,000 swine, value $140,000—total head, 66,397; total value, $2,389,645.

The anthracite coal of this region is not regarded as equal in quality to that of the Pennsylvania field, and the coal lies so near the bottom of the bay that it can not be mined safely in most places. The deposit became known in 1809, and is estimated to contain 38,000,000 tons. For smelting iron and copper it is the best known. Until 1880, about 15,000 tons were mined annually. Since then the production has ceased. Graphitic coal, sold under the name of graphite, is mined in Cranston for blast furnaces. Iron Rock Hill, in Cumberland, is an immense mass of magnetic iron. More than 6,000,000 cubic feet of it is above natural drainage. In the town of Lincoln the business of lime-burning has been steadily carried on for more than 200 years. The lime burned at Lime Rock is the best in quality in the U. S. There are in the State about twenty granite quarries, the most noted of which are in Westerly, where the granite is specially valuable for monumental work.

Climate.—The climate, as a whole, is variable, yet not so much so as that of the other portions of New England, or indeed of the eastern parts of Massachusetts. The cold east winds that afflict Boston are here almost unknown. The presence of such a large body of salt water as Narragansett Bay has undoubtedly much to do with this. At Newport, and in the southern parts of the State generally, by reason of the proximity of the Gulf Stream the climate is warm and moist. The rainfall in the eastern part (average for forty-three years 40 inches) is less than that of the western part, which frequently reaches 44 inches. The average fall at Providence for forty-three years was 44·81 inches.

Divisions.—For administrative purposes the State is divided into five counties and has thirty-two towns, four cities, and one district. Providence is the capital. Until 1899 there were two capitals, Providence and Newport.

COUNTIES AND COUNTY-TOWNS, WITH POPULATION.

COUNTIES.	*Ref.	Pop. 1890.	Pop. 1900.	COUNTY-TOWNS.	Pop. 1900.

Totals	.....	345,506	428,556		

* Reference for location of counties, see map of Rhode Island.

Principal Cities and Towns, with Population for 1900.—Providence, 175,597; Pawtucket, 39,231; Woonsocket, 28,204; Newport, 22,034; Warwick, 21,316; Central Falls, 18,167; Cranston, 13,343; East Providence, 12,138; Lincoln, 8,937; Cumberland, 8,925; Westerly, 7,541; Bristol, 6,901; Burrillville, 6,317; Coventry, 5,279; Johnston, 4,305.

Population and Races.—In 1880, 276,531; 1890, 345,506 (native, 239,201; foreign, 106,305; males, 168,025; females, 177,481; white, 337,859; colored, 7,647, of whom 7,393 were persons of African descent, 69 Chinese, 5 Japanese, and 180 civilized Indians). In 1895 the population was 384,758.

Industries and Business Interests.—The census returns of 1890 showed that 3,377 manufacturing establishments reported. These had a combined capital of $126,483,401, employed 85,976 persons, paid $37,927,921 for wages and $76,253,023 for materials, and had products valued at $142,500,625. In the assessed valuation of property *per capita* the State ranks second in the Union. Its valuation is $931.28. In the manufacture of cotton goods it is surpassed only by Massachusetts, having 94 establishments with a capital of $38,798,161. These mills contained 1,924,486 spindles and 43,106 looms, a greater number than in all the Southern States with their 239 establishments, or in the Middle States, also with 239 establishments. One firm in Providence manufactures more cotton than any other in the world; it operates more than 400,000 spindles. The business of cotton-manufacturing in the U. S. began in Rhode Island in 1790, when Samuel Slater set up his machines for spinning by water-power at Pawtucket. In dyeing and finishing textiles the State is third in the Union (Massachusetts and Pennsylvania surpassing it), with 22 establishments, and a capital of $6,318,480. In combined textiles there were 182 establishments with a capital of $64,959,778, the State ranking fourth. The State ranked also fourth in the wool industry, having 91 establishments with a capital of $28,886,337. There were also six idle mills. The manufacture of woolens began at Peacedale in 1804. The iron and steel business has almost ceased to exist; but in foundry and machine-shop products there were 57 establishments in Providence with a capital of $7,519,742. In the manufacture of jewelry Providence ranked first in the U. S., having 167 establishments with a capital of $7,104,161. Four silverware manufactories with a capital of $3,055,770 were also located there. Pawtucket, with its diversified industries, had an aggregate capital of $14,208,632 invested in manufacturing. Bristol is famous for the yachts constructed there.

Finance.—The official report on State finances for 1900 showed a balance on Jan. 1, 1900, of $52,557.28; receipts, $1,481,479.75; expenditures, $1,355,447.95; balance on Jan. 1, 1901, $178,589.08. On the latter date the total bonded debt was $2,300,000.

Banking.—On Sept. 5, 1900, there were 45 national banks, with a combined capital of $14,680,250; surplus and profits of $5,006,716.12, and deposits of $17,405,131.03; on June 30, 4 State banks, with capital of $495,000, surplus and profits of $147,923, and deposits of $720,580; 6 loan and trust companies, with capital of $2,940,741, surplus and profits of $2,834,792, and deposits of $40,582,389; and 29 mutual savings-banks with a surplus fund of $3,311,420, and $73,489,533 in savings-deposits from 142,096 depositors.

Post-offices and Periodicals.—In Jan., 1901, there were 146 post-offices, of which 20 were presidential (3 first-class, 4 second-class, 13 third-class) and 126 fourth-class, with 109 money-order offices, and 23 money-order stations. There were 58 periodicals—12 daily, 1 tri-weekly, 2 semi-weekly, 30 weekly, 1 bi-weekly, 11 monthly, and 1 quarterly.

Means of Communication.—According to the report of the railway commissioner in Jan., 1901, the capital stock of the steam roads owned and operated in the State is $105,582,475; total indebtedness, $71,855,919.04; total receipts, $43,858,-

651.32; net earnings, $6,614,602.44; miles of road in this State, 209 +; miles single track, 435. The capital stock of the electric roads is $16,582,000; total indebtedness, $4,410,-054.70; total receipts, $2,609,572.26; expenditures, $1,644,-029.26; net earnings, $965,543; miles of road in this State, 208 +; miles single track, 248. Various steamship lines connect Providence with the other towns upon the bay, and with New York, Philadelphia, Norfolk, and Baltimore.

Churches.—The census of 1890 gave the following statistics of the religious bodies having a membership of 500 and upward each in the State:

DENOMINATIONS.	Organizations.	Churches and halls.	Members.	Value of church property.
Roman Catholic	51	52	96,755	$2,295,700
Baptist, Regular	68	75	12,055	1,151,960
Protestant Episcopal	50	63	9,458	1,189,700
Congregational	34	42	7,192	905,800
Methodist Episcopal	39	40	6,064	495,000
Baptist, Free-will	26	28	3,252	226,757
Unitarian	6	7	1,595	393,500
Baptist, Seventh-day	7	7	1,271	55,700
Universalist	10	10	998	301,500
Christian	8	8	972	48,800
Advent Christian	12	12	950	27,450
Jews	5	5	910	45,000
Friends, Orthodox	11	11	617	58,800
Presb. in the U. S. of America	4	4	608	61,000
African Methodist Episcopal	4	4	595	95,000

Schools.—The principal educational institution of the State is BROWN UNIVERSITY (*q. v.*). Other superior institutions are the Rhode Island College of Agriculture and Mechanic Arts, with large agricultural experiment farm, in Kingston; the Rhode Island School of Design and the State Normal School, in Providence. In 1899 there were 64,537 children enrolled in the public schools, with an average attendance of 46,087. There were 534 schools, and 1,913 teachers, receiving an average monthly salary of $77.37. The value of school property was $5,175,045; expenditure for schools $1,570,895.

Libraries.—According to a U. S. Government report on public libraries of 1,000 volumes and upward each in 1891, Rhode Island had 73 libraries, which contained 481,729 bound volumes and 85,141 pamphlets. The libraries were classified as follows: General, 54; school, 5; college, 1; law, 1; medical, 1; public institution, 3; Y. M. C. A., 2; historical, 2; garrison, 2; society, 1; and unreported, 1. In the year ending June 30, 1900, 50 public libraries received aid from the State board of education.

Charitable, Reformatory, and Penal Institutions.—The charitable institutions comprise the Butler Asylum for the Insane, opened 1847; the Rhode Island Hospital, 1868; the State Home and School for Children, 1885; the Rhode Island Institute for the Deaf, 1893—all in Providence; and the State Soldiers' Home, 1891, in Bristol. The reformatory and penal institutions are located on the State farm of about 538 acres, in Cranston, and comprise the State Workhouse and House of Correction, the State Asylum for the Incurable Insane, the State Almshouse, the State Prison and Providence County Jail, the Sockanosset School for Boys, and the Oaklawn School for Girls, the two last being departments of the State Reform School.

Political Organization.—The Governor, general State officers, and members of the Legislature are elected annually. The Governor has no veto power. He exercises the pardoning power only "by and with the advice and consent of the Senate." The Lieutenant-Governor is a member-at-large of the State Senate, which numbers, besides thirty-six members, one from each of the thirty-two towns and four cities. The representation in the lower house is unequal. Its membership is limited to seventy-two. Each town and city must have one representative, but no town or city may have more than one-sixth of the whole number. Thus the city of Providence, with its population of almost 150,000 in 1894, had but twelve representatives. This principle of representation accounts for the peculiar existence of the district of Narragansett. In 1888 this district was taken from South Kingstown, and given all the powers of a town except representation in the General Assembly. Every male citizen of the age of twenty-one years, who has been a resident of the State two years and of the town or city six months, is entitled to vote in town and ward meetings and in the election of all civil officers, if registered on the last day of the preceding December. No person may vote in the election of city councils, or on any proposition involving the expenditure of money, unless he has paid a tax in the year preceding on property valued at least at $134. Every male citizen of the age of twenty-one, who has been a resident of the State one year and of the town or city six months, may vote on all questions and in all elections if he possesses in his own right real estate valued at $134. Until 1894 a majority of votes was necessary to an election by the people, but in that year a plurality amendment was adopted.

History.—The founder of the colony was ROGER WILLIAMS (*q. v.*). In the winter of 1635–36 he was ordered to leave the colony of Massachusetts Bay within six weeks, under penalty of being sent back to England. He fled to the Narragansett country, and in 1636 settled near the mouth of the "Moosh-ausick" river and gave his place of abode the name Providence, "because of God's merciful providence to him in his distress." The first written compact that has come down to us from the settlers of Providence sets forth the ideas which ever after governed the colony. In it the subscribers promise to subject themselves "in active or passive obedience to all such orders or agreements as shall be made for the public good . . . only in civil things." The utmost liberty was allowed in matters of religion. It was by request of the colonists that the patent obtained by Williams limited the authority to be exercised under it to civil matters. The colony originally consisted of four towns—Providence (1636), Portsmouth (1638), Newport (1639), and Warwick (1642). The executive heads of Portsmouth and Newport were called judges until 1640, when on the union of the towns the executive was called governor. Providence and Warwick had no executive head until 1647, when the four towns were united under a patent granted by Parliament in 1643. This was too feeble an instrument to answer the purposes of a charter. It produced a confederacy, not a union, and allowed the magistrates of the various towns to usurp dictatorial powers. In 1651 the two island towns separated from those on the mainland, and in 1654 they were reunited. In 1663 a charter was obtained from Charles II. This instrument was remarkably liberal. In its provision that no person should be "in anywise molested, punished, disquieted, or called in question for any differences in opinion that do not actually disturb the civil peace," it used almost the exact words of Charles's famous Declaration from Breda, which in 1660 had done so much to secure to him the throne of England. Under this charter the colony and State of Rhode Island and Providence Plantations were governed for 179 years. Rhode Island opposed the policy of the other colonies which led to King Philip's war, and yet suffered most severely from that war. King Philip was killed in what is now the town of Bristol. In the Narragansett country, in 1675, was fought the "great swamp fight," when more than a thousand Indians lost their lives. In 1686–87 Sir Edmund Andros suspended the charter, though he was not able to get possession of the document. On his deposition in 1690 the government was reorganized under it. Early in the nineteenth century it was seen that the charter had become too antiquated for the needs of the State, and repeated efforts were made to replace it with a constitution; but the General Assembly was supreme. It was dominated by the county-towns, which did not propose to surrender their power to the large seaport settlements. In 1841 a people's convention, not ordered by the General Assembly, met and framed a constitution. This illegal action precipitated a crisis. (See DORR REBELLION.) A new convention was soon called. The present constitution was prepared in Nov., 1842, ratified by the people, and put in operation 1843. The defect of the charter was its provision for a limited suffrage. In 1840, out of a population of 108,830, about 9,500 men composed the electorate. Not until 1888 were the present suffrage laws adopted.

With its privateers Rhode Island took a conspicuous part in all the wars waged upon the ocean in which Great Britain was engaged. When the news of the declaration of the war with Spain reached the colony in 1740 six vessels of war were at once placed in commission. In 1756 there were upon the ocean fifty Rhode Island privateers manned by 1,500 sailors. Privateering was ever a favorite pursuit, and in the Revolutionary war great wealth came into the colony from this source. In the war of 1812 the privateer Yankee of Bristol took more prizes than any other privateer hailing from the U. S., and sent into Bristol more than $1,000,000 as the profit from her six cruises. Commodore Oliver Hazard Perry, of Rhode Island, and his sailors made the naval renown of the State immortal in the battle of Lake Erie.

The colony first suggested to Congress the establishment of a navy. This was natural, as naval hostilities began in Rhode Island. In June, 1772, his Majesty's armed schooner

Gaspee was burned in Narragansett Bay by an expedition led by Abraham Whipple. Her commander was wounded in the fight. This was the first British blood shed in consequence of open organized rebellion before the Revolution began. The Gaspee had made herself particularly obnoxious by needless severity in enforcing the revenue laws. Of the thirteen frigates voted by Congress at the beginning of the war two were ordered to be built in Rhode Island. The colony contributed largely of men and money to the Revolutionary armies. Its most eminent soldier was Gen. Nathanael Greene (*q. v.*). It suffered greatly during the war, and but for this conflict Newport might have continued to be a great commercial center. In 1776–79 the city was held by British troops, and frequent expeditions were sent out from it against the other towns upon the bay. In one Bristol was bombarded, and in another burnt. In 1780 the French allies made Newport their headquarters.

Rhode Island was the last of the thirteen colonies to enter the Union. Its commerce was then very great. A greater number of vessels belonged to Providence than to New York, and many vessels were owned in Newport and Bristol. From early days trade was carried on not only with the West Indies and Europe, but also with the East Indies. For the first seventy-five years of its existence the colony had been engaged with its neighbors in a struggle for its life. For more than a century and a half it had enjoyed a degree of civil and religious freedom unknown in the other colonies. Now it stood forth as the champion of State's rights. As a whole, it saw danger to its commerce if it entered the Union, even though the seaports greatly desired it. The influence of the country towns was sufficient to postpone the adoption of the Constitution until 1790.

GOVERNORS OF RHODE ISLAND.

COLONIAL.

Presidents under the Patent.

John Coggeshall	1647–48
William Coddington	1648–49
John Smith	1649–50
Nicholas Easton	1650–51

The Division (1651–54).

(*a*) *Providence and Warwick.*

Pres. Samuel Gorton	1651–52
Pres. John Smith	1652–53
Pres. Gregory Dexter	1653–54

(*b*) *Portsmouth and Newport (1651–54).*

Pres. John Sanford, Sen.	1653–54

Reunion of Towns (1654–63). Presidents.

* Died in office. † Charter suspended till 1689. ‡ Deposed.

Authorities.—*Rhode Island Colonial Records*, 10 vols.; Arnold's *History of Rhode Island* (2 vols., New York, 1860).

Wilfred H. Munro.

Rhodes [from Lat. *Rho'dus* = Gr. Ῥόδος, Rhodes]: a mountainous island between the Grecian Archipelago and Mediterranean; the largest and most S. E. of the Sporades; 9 miles S. of the nearest point in Asia Minor (see map of Greece, ref. 18–O). Area, 420 sq. miles. The climate is healthful and delightful, the soil fertile, producing figs, oranges, olives, and grapes. Sponges of the finest quality are found all along the coast, and constitute an important industry. Pop. of island 36,000, mainly Greeks, with a few Jews and Ottomans. Famous in mythology, Rhodes was during the classic period by turns a great independent maritime power and the ally or victim of the Persians, Lacedemonians, and Athenians. It was famous for its artists, poets, and philosophers, and for its Colossus, one of the Seven Wonders of the world, thrown down by earthquake 224 B. C. Overrun by Moaviah, general of Omar, in the seventh century, it subsequently belonged to the Byzantine empire, and repelled invasions of the Arabs, Genoese, and Seldjuk Turks. In 1309 Foulques de Villaret, grand-master of the Knights of St. John of Jerusalem, made it the headquarters of his order. During 214 years it was the southern bulwark of Christendom against the Mussulmans. The capital, Rhodes, endured a forty-four days' siege by the Egyptians in 1444, and repulsed Mohammed II. after a siege of three months in 1480. In 1522 the grand-master, Villiers de l'Isle-Adam, with 4,500 soldiers and 600 knights, withstood during five months the Ottoman fleet of 300 ships and 100,000 soldiers commanded by Suleïman I. himself. This resistance is one of the most glorious exploits of martial Christianity. When unable to hold out longer the knights were granted an honorable capitulation. On Jan. 1, 1523, accompanied by 400 of the inhabitants, they abandoned the island, which since that time has belonged to the Ottomans. The capital, situated on a splendid harbor at the northern extremity of the island, presents an imposing appearance with its lines of maritime fortifications. The streets are for the most part narrow and winding. Armorial remains and historic monuments of all sorts, together with its natural features, render the city one of the most interesting in the Archipelago. It is the seat of a Greek archbishopric. Pop. of city (1889) 14,000.

E. A. Grosvenor.

Rhodes, Cecil, D. C. L.: statesman: b. in Hertfordshire, England, July 5, 1853; went to South Africa and became interested in the Kimberley mines, amassing a great fortune. Entering into Cape politics, he represented West Barkly for a short time, and afterward held a position in the ministry of Sir T. Scanlon. In 1890 he became prime minister, but resigned Jan. 6, 1895, on account of his supposed connection with Jameson's raid into the Transvaal. To his energy was due the acquisition of mining rights over Mashonaland. As chairman of the British South Africa Company, he was prominent in the difficulty with Lobengula. His policy aimed at the removal of race prejudices, and the establishment, under the British flag, of a federal dominion composed of Cape Colony, Natal, the South African Republic, and other countries of South Africa. He received the degree of doctor of civil law from Oxford University in 1899.

Rhodes, Inner and **Outer**: See Appenzell.

Rhodesia: See the Appendix.

Rho'dium [Mod. Lat., from Gr. ῥόδον, rose. So called from the color of some of its compounds]: a metal found in 1804 by Wollaston associated in small quantity with native platinum. The process of obtaining it from the platinum residues is complex, and will be found described in the chemical text-books. Rhodium is whitish gray and very hard; highest density when fused, 12·1; atomic weight, about 104. It is one of the most infusible metals, but may be fused in the oxyhydrogen quicklime furnace of Deville. When pure, it is not acted on by the most powerful acids, but in alloy with some of the other metals it may be dissolved in aqua regia. Fusion with saltpeter oxidizes it easily, and even fusion with sulphate of potash converts it into a soluble double salt. Chlorine combines with it at a red heat, forming a soluble chloride. It forms four oxides (RdO, Rd_2O_3, RdO_2, and RdO_3). The first two are insoluble in the strongest acids, and the third almost so.

Revised by Ira Remsen.

Rhodium, Oil of: a balsamic volatile oil obtained from Canary island rosewood, the woody root of two convolvulaceous plants, *Rhodoriza scoparia* and *R. florida*. The oil is employed as a perfume, and to attract fishes and game to traps of various kinds. Horses are very fond of the odor.

Rhododen'dron [Mod. Lat., from Gr. *ῥοδόδενδρον*, oleander; *ῥόδον*, rose + *δένδρον*, tree]: a large genus of plants of the heath family (*Ericaceæ*), comprising trees, shrubs, and rootlet-climbing epiphytes, with entire, alternate evergreen, or rarely deciduous leaves, and showy flowers in terminal clusters; these with funnel-form five-lobed corollas and usually ten declining stamens. Passing S. of the equator only into Java and the neighboring islands, the rhododendron is found throughout the mountainous districts of the northern hemisphere. The greatest number of species occurs in the high mountain regions extending from Java and Borneo on the S. to Yun-nan and the Sikkim Himalaya in the N. Several are found in China and Japan, two reach Kamtchatka, and one Alaska. The arctic *R. lapponicum* of Lapland and Greenland occurs in the alpine region of the White Mountains of New Hampshire. The only two other European species are *R. ferrugineum* and *R. hirsutum*, the *Alpenrosen* of the Swiss Alps. The species peculiar to North America are, on the Atlantic side, *R. maximum*, which occurs sparingly as far N. as Canada, and abundantly throughout the whole length of the Alleghany Mountains; *R. catawbiense*, a lower and earlier-flowered species on the higher mountains from Virginia southward; and *R. punctatum*, a graceful but less showy species of the middle country of the Southern States E. of the mountains. In the higher Northern Rocky Mountains there is a peculiar deciduous-leaved species, *R. albiflorum*; in Oregon, *R. macrophyllum*, apparently near *R. maximum*; in California, *R. californicum*, nearer *R. catawbiense*, but taller, and with more showy blossoms. The contrast in the size attained by the different species of this genus is as remarkable as its geographical range is extensive. The arctic *R. lapponicum* is but a few inches high, while *R. rollissonii* of Ceylon attains a height of 30 feet, with a stem over a foot in diameter. The useful properties of this genus are few and unimportant; the Siberian *R. chrysanthum*, however, supplies a narcotic sometimes used medicinally. Horticulturally, rhododendrons play a more important part. Several of the South Asiatic species are conspicuous inhabitants of conservatories, the best suited for such cultivation being *R. arboreum*, *R. dalhousiæ*, *R. argentium*, *R. hodgsoni*, *R. javanicum*, and *R. jasminiflorum*. Of hardy species, the most so in the northern parts of the U. S. is the Siberian *R. dauricum*, with small deciduous leaves and rose-colored flowers, appearing very early in the spring; but to the patient skill of the hybridizer we owe a race of hardy rhododendrons with showy flowers and foliage, and of greater horticultural value than any of the original types. These hybrids, the result of crossing the Alleghany *R. catawbiense* with the Eastern *R. ponticum* or with the Indian *R. arboreum*, are deservedly more generally planted than any other rhododendrons. Loving moisture and unable to withstand the severe summer droughts so common in many parts of the U. S., and not thriving in soils strongly impregnated with lime, the rhododendron as a garden-plant can be successfully cultivated only in the Atlantic States from Massachusetts to Virginia. To develop its greatest beauty the rhododendron should be planted in well-drained peat or in soil largely composed of decaying leaf-mould, and situations should be selected for it somewhat protected from the winter sun, the greatest enemy, with the summer droughts, to all evergreens in the U. S.

C. S. Sargent.

Rhodope, rod'ō-pē̆ (in Gr. *Ῥοδόπη*): a lofty mountain range in Thrace, noted in poetry as the scene of the revels of the Bacchantes, or female followers of Dionysus.

Rhône, rōn: a department of France, bordering E. on the Saône and Rhône, and comprising an area of 1,077 sq. miles. It is mountainous, covered with offshoots of the Cévennes, but with the exception of some fertile valleys the soil is mediocre. Copper, iron, and lead are found; excellent wine is produced, and the manufactures of silk and muslin are of great importance. Pop. (1896) 839,329.

Rhône (anc. *Rho'danus*): a river of France which rises in Switzerland, in the Alps, on the western side of the St. Gothard, flows through the Lake of Geneva, crosses the Jura Mountains, turns at Lyons, where it receives the Saône, to the S., and falls, 644 miles distant, into the Mediterranean, through two branches which form the island of Camargue. Its lower course is through swampy and unhealthful districts, but its whole middle course leads through beautiful and fertile regions producing some of the finest wines of France. It is everywhere very rapid, and the difficulty of navigation caused by the rapidity of the current is increased by the suddenly shifting sandbanks and other obstructions, especially near the mouth. An extensive system of canals connects the river with the Mediterranean, and with the Seine, Loire, Garonne, and (by the Saône) the Rhine.

Rhopaloc'era [from Gr. *ῥόπαλον*, club + *κέρας*, horn]: the group of butterflies, the name being given in allusion to the club-shaped antennæ. See Lepidoptera.

Rhotacism: the change of an *s* (*z*) to *r*; a technical term in historical grammar. The voiced form of *s*, i. e. *z*, shows a tendency in many different languages to become *r*. The sound of *r* as it appears, for instance, in English differs from *z* only in a slight retraction and elevation of the tip of the tongue. Rhotacism appears, e. g., in the Teutonic languages (except Gothic) where a medial *s* is preserved, but a medial *z* becomes *r*; thus Eng. *was* : *were*; *lose* : *forlorn* (Germ. *verloren*); also in Lat. between vowels; thus *generis* for **genesis*, cf. *genus*; *dirimo* for **dis-imo*, cf. *dissilio*; in certain Greek dialects as Laconian and Elean; cf. Laconian, *σιός* = *θεός*, Elean, *τίρ* = *τίς*.

Benj. Ide Wheeler.

Rhubarb [viâ O. Fr. from Late Lat. *rheubar'barum*, from Gr. *ῥῆον βάρβαρον*; *ῥῆον*, rhubarb, liter., the plant from the Rha or Volga (Gr. *Ῥᾶ*) + neut. of *βάρβαρος*, foreign]: a plant of the genus *Rheum*, or its root employed in pharmacy. The botanical source of the drug is not definitely known, the *United States Pharmacopœia* defining it as the root of *Rheum officinale* and other undetermined species of *Rheum*, the *British* as the sliced and dried root of *Rheum palmatum*, *R. officinale*, and probably other species collected and preserved in China and Tibet. A specimen of *Rheum* was obtained through French missionaries in 1867 and sent to France, where it flowered at Montmorenci in 1871. It seemed to correspond in all respects with the descriptions of the true rhubarb-plant, such as they are, and the root was apparently identical with the Asiatic rhubarb of commerce. This species has been described by Baillon under the name of *R. officinale*. Rhubarb has been known as a drug from a remote period. It was first brought to Europe by land from China to the Levant ports, whence the name Turkey rhubarb, or was shipped directly from China or by way of India, whence the variety called China, Canton, or East India rhubarb. Later, a direct trade between Russia and China was established, and under supervision of the Russian Government rhubarb was transported overland through Central Asia to Russia. For a long time, owing to the rigid inspection of Russian officials, this Russian or Turkey rhubarb was of unvarying good quality. Chinese rhubarb is now shipped direct from China. Chinese rhubarb is a rusty brown in color, and the texture is finely veined and marbled. Rhubarb has a peculiar smell, a disagreeable, bitter, and astringent taste, and a complex composition. A bit of the root if chewed feels gritty, from the presence of crystals of calcium oxalate. In small dose rhubarb behaves as a stomachic bitter, but in larger quantities is an active purge, producing liquid mucous evacuations. By reason of the tannin it contains it is also secondarily astringent. It is used in medicine as a stomachic and a laxative or purge, and is especially useful in summer diarrhœas from relaxation of the bowels or improper diet. The pharmacentical preparations are very numerous. Among the most commonly used is the spiced or aromatic sirup, which is a tincture of rhubarb, cloves, cinnamon, and nutmeg diluted with six times its measure of sirup. The proportion of rhubarb is small, the preparation being intended as an aromatic astringent stomachic in the bowel complaints of children. *R. rhaponticum*, *R. undulatum*, and *R. palmatum*, or hybrids between them, are cultivated for their leaf-stalks, and to some extent for their roots.

Revised by H. A. Hare.

Rhumb [from O. Fr. *rumb*, from Span. *rumbo*, appar. from Gr. *ῥόμβος*, magic wheel, whirling motion, deriv. of *ῥέμβειν*, turn]: in navigation, the track of a ship sailing on a certain course. A rhumb-line cuts all the meridians at the same angle, and when this angle is acute the rhumb is a species of spherical spiral, continually approaching the pole, but reaching it only after an infinite number of turns. The angle under which a rhumb-line cuts any meridian is called the angle of the rhumb, and the angle that it makes with the prime vertical at any point is called the complement of the rhumb. The projection of a rhumb on the plane of the equator is a logarithmic spiral.

Rhus [Mod. Lat., from Lat. *rhus* = Gr. *ῥοῦς*, sumach]: a genus of shrubs or trees of the *Anacardiaceæ* or cashew

family, including about 120 species, mostly natives of warm or hot climates. The flowers have from four to ten stamens and from four to six imbricated petals, and are small, in axillary or terminal panicles; the leaves are usually primate, with from three to five leaflets, though sometimes simple, as in the smoke-tree (*Rhus cotinus*); the fruit is a compressed drupe. The poison oak or ivy (*Rhus toxicodendron*), found from Canada to Georgia, mostly creeping or climbing along rocks, fences, etc., though sometimes erect, has alternate leaves with three leaflets, flowers in loose slender panicles, and a smooth pale-brown fruit. The whole plant, especially the root and leaves, contains a poisonous caustic milky juice which on contact with the human skin in most cases produces redness, itching, swelling, and vesication. An inhalation from the leaves will produce in some an erysipelatoid affection. The poison-sumach or poisonous dogwood (*R. venenata*) of swamps, with from seven to thirteen leaflets, is even more poisonous. See SUMACH FAMILY.

Rhyme, or (less commonly) **Rime** [*rhyme* (with spelling adapted to *rhythm*, etc.) is < M. Eng. *ryme* < O. Eng. *rīm*, number, and from O. Fr. *rime*, rhyme (from O. H. Germ. *rīm*, number)]: formerly the systematic alliteration of Anglo-Saxon poetry; now usually the similarity between the endings of verses and sometimes of cola. The degree of resemblance between the endings varies with different poets, but strict rhyme requires that the last stress-vowel and what follows it should be exactly alike in the rhyming lines, while what precedes the vowel must be in some respect different. Hence "rain" and "reign" do not rhyme, but "rain," "train," and "strain" rhyme with each other. Sometimes, however, words identical in sound but different in sense, such as "rain" and "reign," are allowed to rhyme. Mere spelling has nothing to do with rhyme. Thus "again" rhymes with "men," but not with "complain." As the rhyme begins with the stress-syllable, lines ending in a trochee (´˘) or a dactyl (´˘˘) require the similarity to cover respectively two and three syllables, as "revealing," "unfeeling," "charity," "rarity." Sometimes, however, the secondary word-accent is used as stress, so that "charity," for instance, may be read ´˘´, and then only the last syllable is covered by the rhyme. When the stress is on the last syllable the rhyme is masculine, and when the stress is followed by one or more syllables the rhyme is feminine. The gradation from the perfect rhyme to mere assonance (similarity of vowels only) or other remote resemblance is by such small steps that no definite line can be drawn for legitimate practice; but no case should be admitted where the consonants following the stress-syllable are totally different.

Sometimes poets of the first rank indulge in bad rhymes, as in Milton's

> Untwisting all the chains that tie
> The hidden soul of harmony.

This treatment of secondary stress on final *y* is not rare, but is not as correct as that seen in

> My country, 'tis of thee,
> Sweet land of liberty, . . .

Rhyme is chiefly at the ends of lines, sometimes at the ends of cola (Leonine rhyme), rarely between almost consecutive words. This last is rather jingle than rhyme, as in Southey's *Cataract of Lodore*. Comic or humorous poetry allows many liberties, and even oddities, in both the distribution and the character of rhymes.

Rhyming lines may have almost any conceivable combination, as the couplet *a a*; the triplet *a a a*, the double distich with the first and third, and second and fourth, rhyming *a b a b*; the same with only the second and fourth, rhyming *a b c b*; the quatrain *a b b a*, and so on. The following schemes are taken from existing poems: *a b a b a b a b*, *a a b a*, *a b a*, *a b c d a b c d*, *a a b c c c b*, *a a b c c b*, *a a b b a*, *a b a a b b*, *a b a a b*, *a a a b c c a b*, *a a b a b*, *a b a b c c d d e d e* (the Chant Royal), *a b a a a b a b* (the triolets), *a b a a a a a b c c c*, *a b b a a b b a + c d d c d c*, and the sonnet-schemes, *a b b a a b b a c d e c d e*, *a b b a a b b a c d c d c d*, *a b b a a b b a c d e d c e*. Many more schemes might be cited. For a good elementary treatment, see Parson's *English Versification*.

Though several important contributions to the subject have appeared, the history of rhyme is yet to be written. In ancient Greek, rhyme seems to have been occasionally employed, but its use was never systematic, and it bore about the same relation to modern rhyme that our occasional alliteration bears to the systematic alliteration of Anglo-Saxon. The ancient Roman usage was about the same as the Greek; but systematic rhyme seems to have begun in the times of Augustine (A. D. 400), and with it begins the use of accent as ictus and the neglect of the classical quantity of syllables. Sometimes, however, rhyming poetry still preserved the ancient quantity. The Arabians employed systematic rhyme, and some believe that the Romans derived it from that source; but it seems more probable that it developed in Latin and Greek from the early occasional and accidental rhymes. Even the Leonine rhyme frequently occurs in ancient hexameters, as Hom. *Il.*, v., 544,

> ἀφνειὸς βιότοιο, γένος δ' ἦν ἐκ ποταμοῖο,

and still more frequently in pentameters, as Prop. II., i., 82,

> Et breve in exiguo marmore nomen ero.

Rhyme is not at all indispensable to English poetry, the greatest works of our age and perhaps of all ages being composed in blank or rhymeless verse.

MILTON W. HUMPHREYS.

Rhymer, or **Rymour**, THOMAS, THE: the name by which an early poet of Scotland is usually mentioned. There is reason to believe that his real name was Thomas Learmount of Ereildoune (modern Earlston), Berwickshire, who flourished under the reign of Alexander III. (*circa* 1283), whose death he is said to have foretold. He was popularly believed to be possessed of prophetic powers derived from the queen of the fairies, who had carried him away and kept him in fairy-land three years, after which he was permitted to come back to earth. The prophecies of Thomas the Rhymer were long preserved by memory, the earliest edition bearing date 1603. He is mentioned by Bower, Mair, Harry the Minstrel, Barbour, Robert of Bourne, and other ancient chroniclers, Scottish and English. The ballad relating his adventures and prophecies is found in MSS. of about the year 1400. It has been printed by Scott, Jamieson, and other ballad-collectors, and Scott attributed to Thomas Rhymer the metrical romance of Sir Tristram. See his edition of *Sir Tristram* (1806) and *Minstrelsy of the Scottish Border* (1806); also *The Romance and Prophecies of Thomas of Erceldoune*, by J. A. H. Murray, publications of the Early English Text Society (London, 1875).

Revised by H. A. BEERS.

Rhynchocepha'lia [Mod. Lat.; Gr. ῥύγχος, snout, beak + κεφαλή, head]: an order of reptiles of the genus HATTERIA (*q. v.*).

Rhynchoph'ora [Mod. Lat., from Gr. ῥύγχος, snout, beak + root of φέρειν, to bear]: a group or sub-order of beetles (see COLEOPTERA), embracing the weevils, in which the anterior part of the head is drawn out into a beak which bears the antennæ and mouth-parts. Of these latter the labrum of normal insects is usually absent and the palpi are short and rigid. Of the weevils some ten families and 10,000 species are recognized, all of which are injurious to human interests, since they bore into and feed upon wood, nuts, grain, etc. See Leconte and Horn, *Rhynchophora of North America*, in the *Proceedings* of the American Philosophical Society (1876).

J. S. KINGSLEY.

Rhynchota: See HEMIPTERA.

Rhyolite [Gr. ῥεῖν, to flow + λίθος, stone]: a mineral generally consisting of a groundmass and porphyritical crystals (phenocrysts) in variable proportions. At one extreme the phenocrysts exceed the groundmass in amount; at the other they are few and scattered, or are entirely absent. According to their prominence they give character or habit to the rock. While their chemical composition corresponds to that of more acid granites (see GRANITE), their mineral components do not necessarily correspond to those of chemically similar granites, partly because not all of the molten magma may have crystallized in rhyolites, and partly because the minerals in each case may have formed under different physical conditions. Quartz is usually prominent in rhyolite, but may not have crystallized in some cases; the same is true for potash-feldspar, which is generally the variety sanidine. Biotite may be present in small amounts. Muscovite never occurs as a pyrogenetic mineral in rhyolite, and potash-microcline is almost unknown in these rocks. On the other hand, pyroxene is oftener present in small amounts. The presence of alkali-feldspars rich in soda (soda microcline, anorthoclase) constitutes a variety of rhyolite called *quartz-pantellerite*. The presence of considerable lime-soda-feldspar (oligoclase, andesine) constitutes the greater part of what are called *dacite*, chemically equiva-

lent to the less acid granites. The groundmass may be lithoidal or porcelain-like, earthy, porous, or cavernous; or it may be dense glass or pumiecous glass. Its color varies from white and shades of gray to black. The lithoidal forms generally exhibit lighter colors, the glassy ones the darker colors, except in the case of pumice. The colors are white, blue-gray, greenish and purplish gray, pink to red, yellow, orange, brown, and black. The color may be uniform through the mass, or variegated in patches and streaks (*eutaxitic*), or in bands and layers (*flow-structure*). The rock may be massive and compact, or split into layers or laminæ parallel to planes of flow. It may be cracked into prisms or columns like those often seen in basalt. It may carry spheroidal stony bodies (*spherulites*) of various sizes, and hollow ones called *lithophysæ*. These spheroidal bodies are special forms of crystallization of the magma.

Varieties of rhyolites based on textural features are nevadite, having relatively many phenocrysts; liparite, relatively few; lithoidal rhyolite; hyaline rhyolite, when glassy. The most glassy forms are perlite, pitchstone, obsidian, and pumice. When the groundmass is more crystalline, it grades into porphyry. With increasing calcium, magnesium, and iron, it grades through dacite into andesite. With increasing alkalies and decreasing silica, it grades into quartz-trachyte and trachyte.

The name *rhyolite* was introduced by von Richthofen in 1860. Liparite (Lipari islands) was introduced by J. Roth in 1861 for essentially the same rocks, and is in quite general use in Germany for the whole rock-group. Rhyolite forms lava-sheets of great size and extent throughout the western part of the U. S., where it was erupted during Tertiary times. Its most notable occurrence is in the Yellowstone National Park. It is well known in Wyoming, Idaho, Nevada, Utah, Colorado, New Mexico, and Arizona. It also occurs in Mexico, Iceland, Hungary, Lipari, and elsewhere. As a building-stone its delicate color adds greatly to its value.

J. P. Iddings.

Rhys, rees, John: Celtic philologist; b. at Abercaero, Cardiganshire, Wales, June 21, 1840; educated at Jesus College, Oxford; studied at the Sorbonne and at Heidelberg and Leipzig 1868–71. Professor of Celtic in Oxford since 1877. He is the author of *Lectures on Welsh Philology* (1877; 2d. ed. 1879); *Celtic Britain* (1882; 2d ed. 1884); *Hibbert Lectures on Celtic Heathendom* (1888); *Studies in the Arthurian Legends* (1891); *Rhind Lectures on the Early Ethnology of the British Isles* (1890–91); joint editor of various Welsh texts.

B. I. W.

Rhythm [via O. Fr. from Lat. *ryth'mus* = Gr. *ῥυθμός*, flow, measured motion, rhythm, deriv. of *ῥεῖν* (fut. *ῥυήσομαι*), flow]: the division of time into small approximately equal units by corresponding units of sound, or less sensibly by muscular movement or visible motion. Rhythm bears the same relation to time that symmetry bears to space. The arts of space and rest, or completion—statuary, architecture, and painting—are based on symmetry, while the arts of time and motion, or execution—dance, music, and poetry—are based on rhythm. Symmetry and rhythm are often confounded, as when it is stated that the windings of a valley form an instance of rhythm. One of the most common perversions of the term is its application to accentual as distinguished from quantitative verse. In English the accent, which is chiefly stress, marks the rhythmical unit, while in Latin and Greek, where the accent was chiefly pitch, the unit was marked, not by the accent, but by stress, usually that of long syllables as compared with short; but in both kinds of verse, if there is rhythm, the units, whether marked by accent or by stress, must be virtually equal. The fact that the quantity of syllables is more unsettled in English than in the ancient classics does not prevent us from making the feet equivalent.

Rhythm may be felt in movements of the body, as in marching or dancing (for even the deaf enjoy the dance), but it will be sufficient to treat of the rhythm whose substance (*ἐκμαγεῖον* or *ῥυθμιζόμενον*) is sound.

Just as a vast expanse of uniform color, however pleasant to the eye, does not show symmetry, so one continuous uniform sound, however agreeable to the ear, does not present rhythm. Any kind of sound may be made rhythmical, but here only music and speech need be recognized. Again, poor music and bad poetry may have faultless rhythm, so that rhythm may be treated independently of the other characteristics of music and poetry.

The quantitative relation of syllables to each other is much more delicately perceived in singing than in reciting. Rhythm of the former kind is indicated by musical notes, of the latter by metrical marks. Recited poetry may be rendered more exact by the accompaniment of some time-measuring device, such as the metronome or *κλεψίαμβος*; but even that often regulates the feet rather than the individual syllables.

The ancient musical notes did not indicate quantity, but when the latter had to be marked, as in instrumental music, it was done by writing metrical marks (the same that we use) over the notes. Even the modern system of notation is faulty, being based on the fiction of the "whole note." The whole note has no fixed length, and is not the unit of rhythm (though it may happen to be). The true unit is the bar or measure; hence in $\frac{3}{4}$-time, for instance, the so-called $\frac{1}{4}$-note is really one-third of the unit. The tempo or time-rate of performance is, in any case, fixed by the composer, and approximately indicated by the words andante, allegro, etc., or more exactly by indicating how the metronome is to be set.

Each unit of rhythm contains a loud or strong part and a weak part. In beating time the hand or bâton descends and remains down during the strong part, then rises and remains up during the weak part (except when the bar calls for more than two movements). The foot, in marching, performs analogous functions. Hence the strong part is called thesis (*θέσις*, putting down; also *βάσις*, step, and *ὁ κάτω χρόνος*, the down time), and the weak part arsis (*ἄρσις*, lifting up; also *ὁ ἄνω χρόνος*, the up time); but in meter many follow the Roman grammarians and interchange the terms arsis and thesis. Each movement of the hand was called ictus (beat) by the Romans, but we apply this term only to the down beat or the accompanying stress.

Bars or measures are to music what feet or measures are to verse; but bars always begin with the stress or musical accent, whereas feet may begin with the weak part. The anapæstic dimeter (tetrapody), for instance, has the metrical form ⏑ ⏑ – | ⏑ ⏑ – | ⏑ ⏑ – | ⏑ ⏑ – ‖; but if sung in $\frac{2}{4}$-time it becomes  the first and last bars being supplementary. In verse of this kind the weak part or arsis of the first foot is sometimes called anacrusis (*ἀνάκρουσις*, up beat—a modern use of the word), and the scheme written ⏑ ⏑ ; – ⏑ ⏑ | – ⏑ ⏑ |, etc.

The ancient rhythmists recognized a great variety of compound bars, some of them containing several simple bars or feet, so that a rhythmical bar (*ποὺς ῥυθμικός*) was often really a colon or musical sentence. In modern music the bars or measures most used are: $\frac{2}{2}$  , $\frac{2}{4}$  , $\frac{4}{4}$  , $\frac{3}{2}$  , $\frac{3}{4}$  , $\frac{3}{8}$  , $\frac{6}{4}$  , $\frac{6}{8}$  , and analogously $\frac{9}{4}$, $\frac{9}{8}$, and $\frac{12}{8}$. In $\frac{4}{4}$-time the third note receives secondary stress, and in all the bars consisting of multiples of three the first note of each triplet receives stress. It really makes no difference what note is taken as the unit of the measure, so that $\frac{6}{4}$-time and $\frac{6}{8}$-time, for instance, are practically the same. There are other bars (for instance, the very rare $\frac{5}{8}$), but a full discussion of this subject belongs to technical works on music. For the application of rhythm to speech and for the metrical feet of poetry, see Metres, Prosody, and Quantity.

The equalization of seemingly different bars or feet in ancient poetry is the subject of endless controversy, some denying that they were in any way modified from their apparent form, others maintaining that an approximation to equality was made, while still others assert that absolute equality was established. It is certain that in trochaic and iambic meter the seeming spondee, by a partial shortening of one syllable so that it became irrational (*ἄλογος*) with respect to the other, the foot was made to approximate a pure foot, and there is no proof that it was not by change of tempo made virtually equal to such foot—that is, the trochaic measure – ⏑ – – is really – ⏑ – >, in which > is irrational and – > is equivalent to – ⏑. So the light dactyl, – ⏑ ⏑, analogous to  , and the cyclic anapæst were probably made respectively equivalent to the trochee and iambus. (See Prosody.) It must be granted, however, that there were changes of the rhythm in the same composition; but that a change could take place in the same colon seems incredible.

Milton W. Humphreys.

Rhythm, in music: such an arrangement or grouping of notes and measures as gives to the ear a sense of relative proportion and conduces to the development of sentiment and beauty. Musical notes when thus grouped into form and measure may possess a certain degree of meaning and connection; but neither melody nor harmony can give adequate expression to musical sentiment and feeling without a further grouping into portions equal to each other and marked by accent. This constitutes a higher kind of rhythm, to which the name of compound rhythm is sometimes given. Almost any succession of musical sounds will win attention and interest when the ear recognizes at certain intervals the pulsations of accent and the indications of a regular rhythmical division. A series of sounds without these periodical divisions, with their necessary cadences, would be as difficult to comprehend as a series of words without clauses, sentences, periods, and grammatical connection. In all regular compositions, therefore, we find an orderly succession of periods, formed of groups of two, four, eight, or more measures, as the case may be, with subdivisions into phrases, strains, or clauses. Of these periods, those consisting of four or eight bars are the most simple and natural to the ear. Periods of three, six, or nine bars are also in use, but those consisting of five or seven are irregular and less satisfactory, unless it may happen that the composer's purpose is to create a disturbing effect for dramatic or emotional reasons whereby the exception may be justified. In the use of terms to designate these divisions there is great diversity among musical theorists, and much obscurity in their definitions. In the present article the term period is used as denoting one of those larger symmetrical divisions which contains within itself the full expression of some musical sentiment. Such periods may terminate with cadences of various kinds, but the closing period must always end with the perfect final cadence. A period, as already said, is susceptible of division into several parts or members. Thus a period of eight bars is readily divisible into two phrases or strains, and each of these phrases also admits of division into two clauses. A period of six bars may be similarly divided either into two or three portions, and each of these portions may be regarded as a phrase or a clause. The chief difference between a phrase and a period lies in the cadence. This should be less conclusive in the phrase than in the period, even though formed of the same chords. The term section is applied to those still larger divisions which comprehend several periods. In many cases it is not easy to define the boundaries of these several divisions of section, period, and phrase. Sometimes a shortened or lengthened period occurs which breaks in upon the uniformity of the movement; sometimes also periods overlap each other, as when a new one commences before the former one has terminated; and in numerous cases periods and phrases are broken up into irregular forms for the production of special effects, thereby suspending for a time all regard to rhythmical symmetry. Notwithstanding these irregularities, which occur even in the highest works of art, the study of rhythm is of essential importance as the foundation of all regularity and excellence in musical composition.

Revised by DUDLEY BUCK.

Riazan', or **Ryazan**: government of European Russia, bounded N. W. by the government of Moscow. Area, 16,255 sq. miles. N. of the Oka the country is low and flat, and the soil generally sandy and little productive; the southern part is higher, more diversified and fertile. Wheat, rye, hops, hemp, and fruits are produced. Cattle and a fine breed of horses are reared. Iron ore abounds, but agriculture is the only industry carried on with energy. Pop. (1897) 1,827,537.

Riazan, or **Ryazan**: town of European Russia, capital of the government of Riazan; on the Trubesh, an affluent of the Oka (see map of Russia, ref. 8–E). It is the see of an archbishop, has many educational institutions, and carries on an important trade in grain. The city received its present name in 1777 from Catherine II. In its vicinity is the village of Grishina, with a large factory in which knives, scissors, surgical instruments, and mechanics' tools are produced. Pop. (1897) 33,110.

Ribal'ta, FRANCISCO: painter; b. at Castellon de la Plana, Spain, in 1551. At a very early age he went to Valencia, where he studied painting with a master with whose daughter he fell in love. On being refused as a son-in-law Ribalta went to Rome, where he studied the works of Raphael, the Caracci, and especially of Sebastiano del Piombo. Four years later he returned to his master's house, where he found a sketch on the easel, and, the artist being absent, set to work to finish it. When the painter saw the masterpiece he said to his daughter, "I would allow you to marry such an artist, but not the miserable Ribalta." The daughter replied that it was his work, and so the marriage was happily concluded. The first work Ribalta executed for his native country was a *Cena* for the College of Corpus Christi. His fame became so great that most of the churches of Valencia possessed some of his paintings, as also those of Castellon, Toledo, Segovia, S. Ildefonso, Madrid, and other cities. Ribalta was a severe draughtsman, knew anatomy thoroughly, and had studied the nude. His coloring is rather harsh. He died at Madrid, Jan. 12, 1628. W. J. STILLMAN.

Ribault, or **Ribaut**, rē̆'bō', JEAN: soldier and colonist; b. at Dieppe, France, about 1520. He was a Protestant, and was employed by Coligny to establish a French Protestant colony in North America. Leaving Dieppe Feb. 18, 1562, he explored the St. Johns river, Florida, thence sailed northward, and established twenty-six colonists in a blockhouse called Fort Charles on Port Royal harbor. Ribault then returned to France. Owing to the distracted state of affairs no aid was sent to the colonists, and after enduring great sufferings they abandoned the fort. In 1564 Ribault was commissioned governor of a contemplated colony in Florida. He sent René de Laudonnière, who built Fort Caroline on the St. Johns river. In May, 1565, Ribault sailed for this colony with seven vessels and 300 men. In September of that year the French were attacked by Spaniards under Menendez de Avilés; the fort was taken and its garrison massacred; Ribault's ships were wrecked in a hurricane, and he and his companions after wandering for some time on the coast capitulated to Menendez. Though promise of quarter had been given, they were immediately butchered, "not as Frenchmen, but as heretics." H. H. S.

Ribbeck, JOHANN KARL OTTO: classical scholar; b. at Erfurt, Germany, July 23, 1827; studied under Ritschl at Bonn, and was called successively to Berne, Basel, Kiel, Heidelberg, and finally to Leipzig as the successor of his teacher. Ribbeck's work, confined chiefly to Latin poetry, is characterized by profound learning, subtle ingenuity, and a brilliant style. His most noted works are *Tragicorum Latinorum reliquiæ* (1862), *Comicorum Latinorum reliquiæ* (1855), the standard editions on the subject; *Vergilii Opera*, with exhaustive prolegomena and complete critical notes (5 vols., 1859–69); *Der echte und unechte Juvenal* (1865, a highly ingenious but hypercritical attempt to prove the spuriousness of a number of Juvenal's *Satires*); Horace's *Epistles* (1869), an edition containing valuable exegetical material, but marred by a radical disregard of MS. tradition leading to a wanton readjustment of the poems; *Die römische Tragödie im Zeitalter der Republik* (1875); *Zur Lehre von den latein. Partikeln* (1869); an edition of Plautus's *Miles Gloriosus* (1881); biography of *Friedrich Ritschl* (2 vols., 1879–81, one of the best biographies in any language). Finally, omitting numerous short treatises (such as the *Alazon* and the *Kolax*) partly published in the *Rheinische Museum*, of which Ribbeck is one of the editors, there is the *Geschichte der römischen Dichtkunst*, in 3 vols., unquestionably the ablest exposition of the subject that has appeared. ALFRED GUDEMAN.

Ribbon [from O. Fr. *riban* > Fr. *ruban*, probably from Germ. *ringband*]: a narrow band of woven silk, used chiefly as an ornament of female attire. Though used in many nations from remote antiquity, the manufacture of ribbons as an important article of commerce dates only from the seventeenth century, and has flourished chiefly in France, the cities of Tours, Lyons, and Avignon being largely engaged therein. The chief seats of ribbon manufacture are St.-Étienne, France, Basel, Switzerland, Crefeld in Rhenish Prussia, and Coventry in England. The French ribbons have an admitted superiority, owing to the employment of hand-looms instead of power-looms. See WEAVING.

Ribbon-fish: a name given to various fishes, chiefly belonging to the family *Trachypteridæ*. They are so called on account of their much compressed, elongated, and band-like bodies. See TRACHYPTERIDÆ.

Ribbon-worms: a name sometimes given to worms of the group NEMERTINES and the order *Turbellaria*: so called from their ribbon-shaped form and great length.

Ribeiro, rē̆e-bā'ē̆e-rō, BERNARDIM: poet; b. at Torrão, in the province of Alemtejo, Portugal, about 1486 (?). There is

little precise information about him, and the difficulty in this regard has increased by the appearance at the same period of several persons of the same name. At the age of twenty-one he had to leave his home for the court, because of a plague that was devastating his native province. He became the friend of the best poets in Lisbon, Falcão, Sâ de Miranda, and Montemayor. He had also a tragic love-adventure, the object of his passion being possibly a certain Donha Joana de Vilhena, cousin of the king, Dom Manuel, and wife after 1516 of Dom Francisco de Portugal, Count of Vimioso. After the failure of his suit he seems to have gone to Spain, and probably to Italy. D. about 1550. He is a noteworthy figure in Portuguese literature, as having been one of the introducers of the Italian pastoral style that has ever since held such sway in Portugal. There are extant five idyls, or *eglogas*, in which experiences of his own and of his poet friends are idealized; and also a pastoral romance in prose, interspersed with verse, in which the main theme is his own love, under the name Bimnarder, for a lady disguised as "Aonia." This romance is commonly called *Menina e Moça*, but the author probably knew it as *Tristezas*, or *Saudades*. Two parts of it have come down to us, but it is uncertain what share, if any, Ribeiro had in the second. The work's chief defect is that so many matters besides the main theme are interwoven as to make the whole extremely confused; yet it had a very great influence in both Portugal and Spain, and to some extent outside the Peninsula. Besides the above Ribeiro wrote a number of lyrics in the style of the older Portuguese poets, some of which are printed in the so-called *Cancioneiro de Resende*. The first edition of the *Menina e Moça* was published at Ferrara in 1554; the second, better known, at Evora in 1557. In 1559 it was again printed with the addition of the lyrics. The *Obras de Bernardim Ribeiro* appeared in 1645, 1785, 1852. An excellent edition of the *Menina e Moça* is that of D. José Pessanha (with *Prefacio*, 1891).

A. R. Marsh.

Ribera, rĕe-bā'răă, José, called *Lo Spagnoletto* (the little Spaniard): painter; b. at Játiva, near Valencia, Jan. 12, 1588. He studied art with Ribalta, and then went to Italy, where in extreme poverty he worked at painting, depending on the charity of his fellow students in Rome. Later he went to Naples, where he married the daughter of a rich picture-dealer, and was employed by the Spanish viceroy, the Count de Monterey, for Philip IV. of Spain. In 1630 the Academy of St. Luke at Rome elected him as one of its members. The pope decorated him with the insignia of the Abito di Cristo in 1644. Some biographers assert that he died in Naples, rich and honored, in 1656, while Dominici, the Italian historian, says that Lo Spagnoletto disappeared in 1648, and was no more heard of. Luca Giordano and Salvator Rosa were his most eminent pupils.

W. J. Stillman.

Ribot, rĕe'bō', Alexander Félix Joseph: statesman; b. at St.-Omer, France, Feb. 7, 1842; was educated for the bar; received an official appointment in 1870, but afterward returned to the practice of his profession in Paris, and in 1878 was elected to the Chamber of Deputies as a representative of the moderate republican party. In 1890 he became Minister of Foreign Affairs, and was Prime Minister from Dec., 1892, to Mar., 1893. In Jan., 1895, he again became Prime Minister after the election of Faure as president, but resigned with his cabinet Oct. 28 of the same year, having been defeated on a railway question. He is the author of several works.

Ribot, Augustin Théodule: genre and portrait painter; b. at Breteuil, Eure, France, Aug. 8, 1823; pupil of Glaize; medals, Salons, 1864 and 1865; third-class medal, Paris Exposition, 1878; Legion of Honor 1878. His work is robust in style and notable for strong modeling. His charcoal drawings are exceedingly good. *St. Sebastian* (1865), *Christ and the Doctors* (1866), and *The Good Samaritan* (1870) are in the Luxembourg Gallery, Paris. D. at Colombes, Seine, Sept. 12, 1891. W. A. C.

Ribot, Théodule Armand: psychologist; b. at Guingamp, France, Dec. 18, 1839; educated at the Lycée de St.-Brieuc and at the École Normale in Paris; was professor in different lycées 1869–71; engaged in laboratories and clinics in Paris until 1876; founder and editor of *La Revue Philosophique* 1876–94; lecturer at the Sorbonne 1885–88; professor in the Collège de France since 1888. His principal works are *La Psychologie anglaise contemporaine* (1870); *L'Hérédité psychologique* (1873; 4th ed. 1892); *La Psychologie allemande contemporaine* (1879; Eng. trans. 1886); *Les Maladies de la Mémoire* (1881; 9th ed. 1894); *Les Maladies de la Volonté* (1883; 10th ed. 1894); *Les Maladies de la Personnalité* (1885); and *La Psychologie de l'Attention* (1889).

J. Mark Baldwin.

Ribs [O. Eng. *rib*: O. H. Ger. *rippa* (> Mod. Ger. *rippe*): Icel. *rif* < Indo-Europ. *rebhyo-*; cf. O. Bulg. *rebro*, rib]: the curved bones which form the lateral framework of the thorax or chest. They serve as substantial points of attachment for the thoracic muscles, which perform the respiratory motions, and by their resistance and elasticity protect the lungs, heart, and great vessels from external violence and injury. The ribs, in man, are usually twenty-four in number, twelve on each side, but may be one or two more or less in exceptional cases. They are articulated to the spine behind, but in front only the upper seven are connected with the sternum or breast-bone by intervening costal cartilages. Of the remaining five, three connect with the cartilage of the seventh, while the lower two are unattached and termed free or floating ribs. The ribs are elastic, and being articulated in front and behind move freely upward and outward in inspiration, and reversely downward and inward in expiration. The ribs, like other bones, may be inflamed and thickened from contusion or from blood-disease; they are often distorted by collapse of a part or whole of a lung and external atmospheric pressure. The chief injuries to the ribs are separation from their attachments to the spine or sternum, and fracture. The fractured rib is detected by local crepitation of the fragments in respiratory movement, and by the severe local stitch or pain it gives the patient. The treatment consists in application of a firm bandage or broad adhesive band around the body to suspend thoracic movement until the rib is united; respiration meanwhile is conducted chiefly by motion of the diaphragm. Revised by W. Pepper.

Ricar'do, David: political economist; b. in London, Apr. 19, 1772. His father, who was a Jew and a native of Holland, settled in London, and as a member of the Stock Exchange gained a fortune. David Ricardo was a partner with his father till in 1793 he embraced the Christian faith and formed a marriage connection contrary to his father's wishes, which caused the partnership to be dissolved. Through the aid of other members of the Stock Exchange the younger Ricardo started in business by himself, and succeeded in a few years in securing a fortune. He then gave his time to the study of mathematics, chemistry, mineralogy, and geology, and was active in securing the organization of the London Geological Society. In 1809 he published a tract entitled *The High Price of Bullion, a Proof of the Depreciation of Bank-notes*; in 1817 published his most important work on *The Principles of Political Economy and Taxation*. Its leading feature was a theory of rent, which, though embodying ideas before announced by others, was received by the public as a new and important theory, especially in connection with the theory of Malthus on population, then much discussed. He subsequently became a member of Parliament, where he took a prominent part in the discussion of economic questions. D. at Gatscomb Park, Gloucestershire, Sept. 11, 1823. Ricardo stands next to Adam Smith in the British free-trade school of political economists, and his writings have exerted a powerful influence upon subsequent students of the science. A collection of his works, edited by J. R. McCulloch, was published in 1846, and his *Letters to Malthus* appeared in 1887.

Revised by F. M. Colby.

Ricasoli, rĕe-kaa'sō-lĕe, Bettino, Baron: statesman; b. in Florence, Mar. 9, 1809, of an old noble Florentine family. In 1848 he was a prominent advocate of the unity of Italy; was elected to the Tuscan parliament, and was offered a place in the ministry, which he declined, as the grand duke had turned against the democratic movement. After the defeat of Novara, hoping to prevent the entrance of the Austrians into Tuscany, he took the initiative in recalling the grand duke, but retired from the court when the latter withdrew the constitution. In 1859 he again put himself at the head of the Tusean liberal movement, and aided in the expulsion of the grand duke, and, as provisional dictator, in the union of Tuscany with Piedmont. This being accomplished, he was appointed governor-general of Tuscany, an office which he held till Mar., 1861. The city of Florence elected him deputy to the Italian parliament, and after the death of Cavour he became president of the council in the new ministry which was afterward overthrown by the opposition of Rattazzi. In June, 1866, Baron Ricasoli returned to power and resumed the direction of public affairs, but

was again obliged to retire in Apr., 1867. After this he took no active part in politics. D. in Rome Oct. 23, 1880. Ricasoli wrote several works on the cultivation of the olive, the vine, and the mulberry. His *Letters and Papers* were published at Florence (1886–89).

Riccio, David: See Rizzio.

Rice [from O. Fr. *ris* < Lat. *ory'za* (Later *ory'sum*) = Gr. ὄρυζα, from O. Pers. Cf. Pushtu (Afghan) *wrijzey*, *wrijey*, and Sanskr. *vrīha*, rice]: the *Oryza sativa*, a cereal of the grass family. The tribe *Oryzeæ* is characterized by a one-flowered spikelet with small glumes, less than one-fourth the length of the palets, which completely envelop the grain when mature; six stamens; stigmas with branching hairs; oblong, free, smooth grain; flowers in a somewhat erect panicle, which droops as the grain matures; it is an annual, 2 to 5 feet high at maturity.

Rice is indigenous in some parts of India and in tropical Australia. There is no trace of it as a native plant in Egypt, Persia, Greece, or Rome. In India it has been cultivated from the earliest times, and was introduced into China about 2822 B. C. It was cultivated in the Euphrates valley at least 400 years before Christ. The Arabs carried it into Spain under the name *Aruz*. It was first cultivated near Pisa in Italy, in the year 1468. At what period it was introduced into the U. S. is not well settled, but one account states that it was grown in Virginia by Sir William Berkley as early as 1647. Another account claims a later date, and traces it to some seeds from the island of Madagascar, sown in a garden in Charleston, S. C., near the close of the seventeenth century. It is extensively cultivated in India, Siam, China, Japan, and portions of South Africa, in which countries it constitutes the principal article of food for their dense population. In many of the marshy districts of those countries it is almost the only object of agricultural labor. There is also a variety grown successfully upon the high lands, yielding upon an average about one-fourth less per acre than the low land rice. It is also extensively cultivated in Southern Europe, and in the tropical and semi-tropical portions of North and South America.

In Oriental countries, where rice is the most important cereal, the several processes of cultivation and harvesting are still carried on in a primitive way. In Japan, the plow is rarely used. The soil is dug up and worked over with a mattock; then an implement similar to a harrow is occasionally used to pulverize it. This may be drawn by a horse or ox, but most of the work is manual. The rice is sown in beds, which are watered and carefully tended till the plants are 6 to 10 inches high, when they are taken up and set in rows, the field having been previously prepared and flooded with about 2 inches of water. The rice is cut with an implement similar to a sickle, bound in small bundles, and hung upon poles to dry; the threshing and the winnowing are mainly done by hand. The average product per acre is 40 bush. on marsh-land and 30 bush. on high land. Four or five acres of marsh-land form quite a respectable holding for a farmer in Japan. The average value of such land is $200 per acre, and the annual tax upon it for government and local purposes is $6, or 3 per cent. The wages of an able-bodied farm-hand are about $35 per year, with board, and $50 per year without board; and women can be hired for much less. In the shops, rice is sold at 2 or 3 cents per pound. Importers in the U. S. prefer Japan rice, because the quality is uniform, and, on account of the short, plump berry, it is less liable to be broken in milling, though the flavor is inferior to that of the U. S.

In the U. S. the Carolina methods of rice-culture have mainly prevailed. Alluvial lands are selected along the rivers, above salt water, and low enough to be subject to overflow by the tide. The tract selected is thoroughly ditched, so as to be easily drained, and is protected by a strong levee next the river. Occasionally a ditch is made broad enough to float a small flat-boat, used in transporting the grain. The fields are from 4 to 20 acres in size, and are usually intersected by small parallel drains, about 200 feet apart. Late in the fall or early in the winter the fields are plowed and afterward flooded with water, admitted through the levee. The object of flooding is to prevent the growth of grass, and to loosen and fertilize the soil. In the latter part of February the water is drawn off, and in a few weeks the land becomes dry enough for cultivation, when the clods are pulverized by a harrow and the soil brought into the requisite tilth. When ready for planting, at any time in April or the fore part of May, trenches are made with a hoe, or a small cultivator, 12 to 15 inches apart and 3 or 4 inches deep, at right angles with the drains. The seed is then sown at the rate of 2 to 3 bush. per acre, and covered lightly with soil. On large plantations, where the soil has been well prepared, a horse-drill can be used. As soon as a field is planted, which should be done in one day, sufficient water is let in to saturate the soil thoroughly, and this condition of perfect saturation is continued for four or six days, till the grain begins to sprout. Water is again applied when the sprout is 2 or 3 inches above the ground. This second water is removed after about six days, and the earth is stirred with the hoe once or twice, till the plant is about six weeks old, when the field is again irrigated for two weeks. If the field is free from water-weeds the water may remain on permanently; if not, it should be drawn off, and as soon as the soil is dry it should be hoed, then flooded till the grain begins to ripen. When mature the rice is cut with a sickle, bound in small bundles, and shocked in the field like wheat, or upon some dry place. As soon as dry it is put into stacks, about 6 feet in diameter, till cured, and afterward transferred to large stacks. If put into large stacks from the shock, there is some danger of discoloring the grain by stack-burning.

Along the Mississippi bottoms in Louisiana the conditions of rice-culture are quite similar to the Carolina method. Behind the great levees, necessary to restrain the waters of the Mississippi, the broad alluvial lands are ditched at right angles to the embankment, to give good drainage. The land is plowed in February, March, and April just prior to planting. When ready for the seed the fields are divided into plats of a few acres by back-furrowing (or this may be delayed till after the planting). One object of this is to maintain an even depth of water on each plat; the even ripening of the grain depends upon it. This could not be secured without the small cross-levees, as the surface of the land gradually falls from the river. About 2 bush. of seed per acre is used, and may be sown broadcast and harrowed in or drilled. Formerly irrigation was secured by flumes through the levee, but this is prohibited by law, and the pump is used as a substitute, or in high water a siphon. The crop is cut and harvested as in the Carolinas. The average product per acre is from 10 to 12 barrels of 162 lb. each.

In the prairies of Southwestern Louisiana an entirely different method of management prevails. The rice-lands lie along small creeks and streams, where flooding is secured by pumping or by damming the stream. The levees are constructed mainly by a plow with the land-side and mould-board greatly lengthened by wood attachments, so as to push the furrow 4 or 5 feet on to an embankment. The fields are plowed with gang-plows and thoroughly harrowed; then the seed is sown broadcast, and the land again harrowed, or the seed may be put in with horse-drills. Many farmers fertilize with bone phosphate at a cost of $1 per acre. This quickens and strengthens the young plants, and increases the yield of grain from one to two barrels per acre. The firm subsoil of these prairies allows the use of the binder and header in cutting the grain. The shocks of grain are allowed to stand in the field till dry enough to be transferred to large stacks. Steam-threshers are in universal use. The product per acre is from 8 to 18 barrels. The cost of production is from $1 to $1.50 per barrel, according to management and yield per acre. The labor is almost entirely performed by white men. The prairie rice-marshes are not considered unhealthful for the laborers or for near residents.

The most favorable conditions for rice-growing are much vegetable matter in the soil, and such a depth of water as to irrigate without cooling or heating the roots too much. When the water is very shallow it sometimes becomes too warm for the plant, and by turning on a large body of river-water, just after a heavy rain, the water may become too cool. It requires an atmospheric temperature of from 70° to 80° to ripen the grain properly, and for this reason rice should be grown near large bodies of water. In the interior great changes of temperature are sudden and frequent, to which the rice-plant is very sensitive. A temperature higher than 85° during the hardening of the grain tends to shrink the kernel and renders it too brittle for profitable milling; a lower temperature than 60° prevents perfect development.

Rice as it comes from the thresher is known as rough rice, or paddy. For handling and storing it is better to leave it in this condition, as the hull is a great protection to the

grain. The primitive method of removing the hull was by hand, using a pestle and mortar. The mortar was a large block of wood set on end; the pestle was about 2½ inches in diameter, and 2 feet long. By light pounding and then winnowing the hull and the cuticle were removed and the grain was fitted for use.

In a modern rice-mill the rice is emptied from a sack into a hopper at the storehouse; it passes from the hopper into a large fanning-mill or separator, where it is freed from all foreign substances; it is then transferred to the mill by a belt-conveyor; the hull is removed by passing the grain between heavy millstones (about 5 feet in diameter) which revolve rapidly, but are not close enough together to break the kernel; it then goes to the mortar and is pounded for two hours, or in some mills the Engleburg huller is used in place of the pounding process; by these processes the hull and cuticle are removed and the grain is scoured. The hulls are disposed of as worthless refuse; the cuticle and undercoating scoured off are the rice-bran. The rice then passes through an inclined cylindrical wire revolving screen, with the meshes becoming coarser toward the lower end, thus assorting the rice into three or four grades; the finest is the brewers' rice, the second—a middling rice—includes the larger broken rice, and the third is the whole rice or head rice; the head rice passes from the screen into the polisher, where it is brushed and finished. Rice-bran and rice-polish are excellent food for cattle and hogs, rating higher than wheat-bran and wheat-middlings; brewers' rice is used for the production of light beer, and usually brings about one-half the price of head rice; middling rice sells for nearly one cent per pound less than head rice.

Rice as a food (see Food) is deficient in the flesh-forming principles, but its almost perfect digestibility increases its food-value 20 or 25 per cent., and makes it exceedingly valuable for the sick or people inclined to dyspepsia. Physicians quite generally prescribe a rice diet in some form where there is any inflammation of the mucous membrane, whether of the lungs, stomach, or bowels. Two precautions should be observed: the rice should be more than three months old, and should be thoroughly cooked. With beef, fish, milk, cheese, or beans it makes a well-balanced nutritive ration. In warm countries rice is extensively used in meat soups and as a substitute for the potato. No meal is considered complete without it in some form. It is made into bread, puddings, biscuits, griddle-cakes, and other food. It makes an effective paste, and in Oriental countries it is used in the production of a spirituous liquor known as arraek.

Rice-straw is more palatable to animals than oat-straw, and preferred as a coarse fodder; it is largely used for wintering stock. It makes an excellent quality of paper.

Rice production in the U. S. attained considerable proportion in the colonial times. In 1707 seventeen ships left South Carolina with cargoes of rice. In 1730 the product was 21,153,054 lb.; in 1755 it reached 50,747,090 lb.; and in 1770, 75,264,500 lb. This was raised with slave-labor, and mostly exported to Europe and the West Indies. For the next seventy years there was practically no increase. The product of 1840 was 84,145,800 lb. In 1860 it was 117,885,000 lb. During the civil war little rice was raised, and in 1865 the total amount was only 4,740,580 lb. In 1880 it had increased to 85,596,800 lb.; in 1890 to 131,722,000 lb.; and in 1899 to 136,990,720 lb., of which amount Louisiana produced 107,792,000 lb., North Carolina 2,560,000 lb., South Carolina 23,054,720 lb., and Georgia 3,584,000 lb. In 1893 Louisiana produced 182,400,000 lb., and the U. S. 237,546,900 lb. Drought in Louisiana and floods in other States reduced the crop to less than one-half the following year.

S. A. Knapp.

Rice, Allen Thorndike: See the Appendix.

Rice, Edwin Wilbur: See the Appendix.

Rice, James: novelist; b. in Northampton, England, in 1844; was educated at Queen's College, Cambridge; called to the bar in 1871; edited *Once a Week* 1868–72; and for eight years was London correspondent of the Toronto *Globe*. D. in London, Apr. 25, 1882. He was joint author with Walter Besant of many novels. See Besant, Walter.

Rice-bird, or **Rice-bunting**: the Bobolink (*q. v.*); the Java Sparrow (*q. v.*) is also called rice-bird.

Rice, Indian, Water-rice, or **Water-oats**: an annual aquatic grass (*Zizania aquatica*) belonging to the true rice tribe, though of inferior value, from 5 to 10 feet high, which abounds in marshy regions of the U. S., especially in Minnesota. Its grain was formerly much used by the Dakota and Chippewa Indians, and forms an important portion of the food of the game-birds of the Northwest. Its stem is employed as a paper-stock.

Rice Lake: city; Barron co., Wis.; on the Red Cedar river, Rice Lake, and the Chi., St. P., Minn., and Omaha Railway; 48 miles N. of Menomonie, 56 miles N. of Eau Claire (for location, see map of Wisconsin, ref. 3–B). It is in an agricultural and lumbering region, is engaged in manufacturing, and has a State bank with capital of $50,000, a private bank, and a weekly newspaper. Pop. (1880) 362; (1890) 2,130; (1900) 3,002.

Rice-paper: See Paper.

Rich, Edmund (*Saint Edmund*): Archbishop of Canterbury; b. at Abingdon, England, about 1170; educated at Oxford, where he "wedded the Virgin Mary," as he called his vow of special service, and at Paris; became an instructor at Oxford, where the university was then developing a revival of scholarship; was prebendary of Calne and treasurer of Salisbury Cathedral 1219–22; was a famous preacher; at the pope's command preached the crusade over a considerable part of England, probably in 1227; was appointed Archbishop of Canterbury 1233, and was consecrated Apr. 2, 1234; exhibited energy as a reformer in the face of opposition from the clergy and from the Roman hierarchy; went to Rome in 1238 and again in 1240 to settle various difficulties with his monks, but finding that the pope demanded more and more unreasonable concessions he resigned his see and retired to the monastery of Pontigny, in France, in the summer of 1240; thence a little later he went for his health to the priory of Soissy, where he died, Nov. 16, 1240. His remains were taken to Pontigny, and having been canonized by Innocent IV. in 1247, his shrine (known in France as that of St. Edme) became a place of pilgrimage. Cardinal (then Archbishop) Manning and Lord Edmund Howard, with 500 British pilgrims, went thither to invoke his intercession in behalf of the Roman Catholic Church Sept. 3, 1874. He wrote a volume of *Constitutions* in thirty-six canons (1236), *Speculum Ecclesiæ*, and left MS. treatises, now in the Bodleian Library. There is a MS. biography by his brother Robert in the Cottonian collection. Another, written by Bertrand, prior of Pontigny, was published in Martène's *Thesaurus Anecdotorum*. iii., 1774–1826; cf. Hook's *Lives of the Archbishops of Canterbury*, s. v.

Richard, Édouard: See the Appendix.

Richard I. (Plantagenet), surnamed Cœur de Lion (lion-hearted): King of England; third son of Henry II. and Eleanor of Aquitaine; b. at Oxford, Sept. 13, 1157; was noted from youth for rash valor and a turbulent disposition; received the duchy of Aquitaine by the treaty of Montmirail (Jan. 6, 1169), under the feudal supremacy of King Louis VII. of France, to whose youngest daughter, Adelaide, he was at the same time betrothed; joined his mother and his two brothers in rebellion against his father 1173; was reconciled to him Sept., 1174; became involved in wars with his brothers, but was reconciled to them in London in 1184. He also made war upon the Count of Toulouse, aided his father against Philip Augustus, and later, in alliance with Philip Augustus, waged successful war on his father. Succeeding to the throne in July, 1189, he spent a few months in arranging the affairs of the kingdom, and then set out on the third crusade, July, 1190, with the King of France. On his way to the Holy Land he captured Messina and conquered the island of Cyprus. Arriving before Acre June 8, he took part in the capture of the city, but soon quarreled with the French king, who returned to France. Richard advanced immediately toward Jerusalem; defeated the Saracens at Arsuf in September; took and fortified Jaffa; advanced on Askalon, which he took Jan., 1192; set out twice for Jerusalem, but was called back each time by hostilities in his rear; lost and regained Jaffa; performed many brilliant exploits of personal valor, but, being obliged by the state of affairs in England to return, made a truce with Sultan Saladin, and sailed from Acre in October. On his way home he was shipwrecked at the head of the Adriatic; endeavored to make his way by land through Austria; was seized and imprisoned by Leopold, Duke of Austria, with whom he had quarreled in the Holy Land; was handed over to the Emperor of Germany, by whom he was detained more than a year; was liberated on pledge of a heavy ransom in Feb., 1194; found his brother John assuming the functions of king, but soon forgave him; engaged in a war with Philip Augustus of France, whom he defeated and forced to sign a disadvantageous truce, and renewed the war three years

later with a similar result, but was mortally wounded Mar. 26 by an arrow shot from the petty castle of Chalus-Chabrol, which he was besieging, and died Apr. 6, 1199, leaving no legitimate children. His fame as a soldier was magnified by tradition, by poetry, and by romance, which attributed to him incredible feats of valor, and he was reputed to be highly accomplished as a troubadour. On the other hand, he was cruel and unscrupulous, and as a ruler regarded his kingdom as a mere source of supplies for carrying on his costly and fruitless wars. He was a representative Provençal prince of the age of chivalry, having, beyond the accidents of birth and inheritance, little connection with England. The chief characteristic of his reign in England was the exorbitant taxation rendered necessary by his foreign wars. To meet these demands the king's officers improved the financial system in order that the greatest possible revenue might be secured with the least pressure upon the people, and this side of the administration was brought to a high degree of efficiency. Revised by F. M. Colby.

Richard II.: King of England; son of Edward the Black Prince and Joanna of Kent; b. at Bordeaux, France, Apr. 13, 1366; succeeded to the throne on the death of his grandfather, Edward III., June 21, 1377; was under the tutelage of a council of twelve nobles, but was really controlled by his uncle, John of Gaunt, Duke of Lancaster; maintained a feeble warfare with France; encountered a vigorous opposition from Parliament and from the common people in the imposition and collection of a poll-tax, which gave rise to the insurrection of Wat Tyler, June, 1381; married Anne of Bohemia, daughter of the Emperor Charles IV., in Jan., 1382; invaded Scotland with slight result beyond the burning of Edinburgh, Aug., 1385; attempted to emancipate himself from the council of regency, which was reorganized under the Duke of Gloucester in Nov., 1386, but without success, his leading supporters being defeated and put to death with the sanction of Parliament 1387–88; succeeded by a sudden display of vigor in assuming the government in May, 1389. From this time he was really king, and for the next few years ruled constitutionally, but in 1397, calling a new Parliament, he took vengeance on Gloucester and his adherents. The former was carried to Calais, where he died under suspicious circumstances. Quarreling with his cousin, Henry of Bolingbroke, Duke of Hereford, Richard banished him for ten years, 1398, and in the following year seized the Lancaster estates, John of Gaunt having died. Bolingbroke prepared to recover his estates, and when Richard returned from a short visit to Ireland he found his rival already in possession of the kingdom. Richard was taken prisoner and deposed by Parliament in favor of Bolingbroke, who ascended the throne under the title of Henry IV., to the exclusion of the legitimate heir, Roger Mortimer, Earl of March. The dethroned king was kept a prisoner at Pontefract Castle, but soon disappeared, having been murdered, as was believed, by his keeper about 1400. The reign of Richard is a remarkable period in the constitutional history of England, and still more so in religion and literature, from the eminent names of Wycliffe, Chaucer, and Gower, who were patronized by him.
Revised by F. M. Colby.

Richard III.: last King of England of the Plantagenet line; b. at Fotheringay Castle, Oct. 2, 1452; third son of Richard, Duke of York, and Cicely Neville. On his father's defeat and death in 1460 he was sent for safety to Holland, but was recalled in the following year by his brother, Edward IV., who created him Duke of Gloucester and lord high admiral. He was faithful to his brother throughout the reign, sharing in his flight in 1470 and commanding the van of the Yorkist army at the battles of Barnet and Tewksbury in 1471. In recognition of his services he was placed in possession of numerous forfeited estates, especially those which had belonged to Warwick, the king-maker, whose daughter, Anne Neville (his own cousin, previously betrothed to Prince Edward), he married in 1474. He was made lieutenant-general of the kingdom upon the breaking out of war with Scotland 1480; took possession of Berwick; penetrated to Edinburgh, and dictated terms of peace 1482. Hearing of the death of Edward IV. while still in Scotland in 1483, he took the oath of allegiance to his nephew, Edward V., and required his generals to do the same; but soon afterward he forcibly assumed the guardianship of the young king, imprisoning Lord Rivers, Lord Grey, and other nobles of the queen's party. Appointed protector and defender of the realm early in May, he ordered the seizure and instant execution of Lord Chamberlain Hastings on a charge of conspiracy June 13; asserted his own title to the throne on the ground of illegitimacy of his nephews June 22–24; obtained from Parliament a favorable decision, and was crowned king July 6. He was soon suspected of having caused the princes to be murdered in the Tower. (See Edward V.) Having repressed a conspiracy in behalf of the Earl of Richmond as head of the Lancastrian party, and put to death the Duke of Buckingham (his own former partisan) he convoked a parliament which declared him lawful king Jan., 1484. On the death of his only son, Edward, Prince of Wales, Apr. 9, he named as his heir Edward, Earl of Warwick, but soon substituted for him John de la Pole, Earl of Lincoln. The queen died in 1485. Richard sought to strengthen his throne by treaties with Scotland and Brittany, but was unable to prevent the invasion of the Earl of Richmond, who landed at Milford Haven Aug. 7, 1485, and was defeated and killed at Bosworth Aug. 22, 1485, the victor becoming king under the title of Henry VII. See H. Walpole, *Historic Doubts on Richard III.* (1768), and Gairdner, *Life and Reign of Richard III.* (1878). Revised by F. M. Colby.

Richard Plantagenet: Earl of Cornwall and titular Emperor of Germany; b. at Winchester, England, Jan. 5, 1209; was a younger son of King John; commanded an expedition to Guienne 1225; went on a crusade 1240; returned to England Jan., 1242; accompanied his brother, Henry III., in his French campaign of that year, but soon lost the province of Guienne and escaped to England; married a princess of Provence 1243; was chosen Emperor of Germany by a faction 1256, and crowned King of the Romans at Aix-la-Chapelle May 17, 1257, but was unable to obtain general recognition, and was driven to take refuge in England; was taken prisoner by Simon de Montfort at the battle of Lewes, May 13, 1264; held a diet at Worms 1269; returned to England 1269. D. at Kirkham, England, 1272.

Richards, Henry Charles: See the Appendix.

Richards, Matthias Henry, D. D.: educator; b. at Germantown, Pa., June 17, 1841. His father, Rev. Dr. J. W. Richards, was grandson of Rev. Henry Melchior Muhlenberg. He graduated at Pennsylvania College and Theological Seminary, Gettysburg; was pastor at Phillipsburg, N. J., 1865–68, and Indianapolis, Ind., 1874–77; Professor of English Language and Literature in Muhlenberg College 1868–74; and from 1877 to the present; in 1877 became editor of *Church Lesson Leaves* and *The Helper*; since 1883 has also been on the editorial staff of *The Lutheran*, Philadelphia.

Richards, Theodore W.: See the Appendix.

Richards, Thomas Addison: landscape-painter; b. in London, England, Dec. 3, 1820; was taken to the U. S. when a child by his parents, who settled in Georgia; removed to New York in 1845; studied at the National Academy, New York; National Academician 1851; Professor of Art in the University of the City of New York; first director of the Cooper Union School of Design for Women; corresponding secretary National Academy 1852–92. W. A. C.

Richards, William Trost: landscape and marine painter; b. in Philadelphia, Pa., Nov. 14, 1833. Pupil of Paul Weber in Philadelphia; traveled and painted in Europe in 1855, 1866–67, and in 1878–80; honorary member Pennsylvania Academy of Fine Arts; medal Centennial Exhibition, Philadelphia, 1876. *On the Coast of New Jersey* (1883) is in the Corcoran Gallery, Washington. W. A. C.

Richardson, Sir Benjamin Ward, F. R. S.: hygienist; b. at Somerby, Leicestershire, England, Oct. 31, 1828; educated at Anderson's University and at St. Andrews Hospital, both in Glasgow; graduated in medicine 1854, M. A. hon. in 1859, and LL. D. in 1877; practiced in Saffron Walden and at Narborough; settled in London 1849; physician to the Royal Hospital for Diseases of the Chest 1854 to 1867, to the Royal Literary Fund from 1871, and to the Newspaper Press Fund from 1874 to the present time; was chosen a member of the Royal College of Physicians and Surgeons 1856, and fellow in 1861; founded and edited *The Journal of Health and Sanitary Review* (1855, *seq.*); gained the Astley Cooper prize of £300 by his treatise *On the Cause of the Coagulation of the Blood* (1856), and the Fothergillian gold medal by a disquisition *On the Diseases of the Fœtus* (1856); originated the use of ether spray for the local relief of pain in surgical operations (1866); introduced methylene bichloride as a general anæsthetic (1867); was president of the Medical Society of London; and gained a high position by original experiment. He was knighted in 1893. D. in London, Nov. 21, 1896. From 1854 Sir Benjamin was an earnest

advocate of advance in national sanitation, and was a zealous partisan of the temperance movement. For some years (1884–92) he edited and published a quarterly journal, *The Asclepiad*. Among his works are *The Health of Nations* (London, 1887); *National Health* (London, 1890).

Revised by S. T. Armstrong.

Richardson, Charles: philologist; b. in England in July, 1775; studied but never practiced law: devoted himself to literature in London; published *Illustrations of English Philology* (1815); undertook the lexicographical articles in *The Encyclopædia Metropolitana*, for which he also prepared his great work, a *New Dictionary of the English Language*, which (the first part appearing in 1818) was suspended soon afterward by the failure of the proprietors, and completed (as a separate work) in 1837. The complete work appeared in new editions in 1837, 1838, and 1839. Richardson also published a *Supplement* to his dictionary (1855), a work *On the Study of Language* (1854), and an *Historical Essay on English Grammar and English Grammarians*, several philological papers in the *Gentleman's Magazine*, and some comments on Shakspeare; was a contributor to *Notes and Queries*; received a pension from 1852 until his death at Feltham, Middlesex, Oct. 6, 1865.

Richardson, Charles Francis: scholar; b. at Hallowell, Me., May 29, 1851. He graduated at Dartmouth College 1871, was connected with the New York *Independent* 1872–78, and in 1882 was appointed Professor of English at Dartmouth. He has published *A Primer of American Literature* (1876); *The Cross*, poems (1879); *The Choice of Books* (1881); and *American Literature* (2 vols., 1887–89).

Richardson, Ernest Cushing: See the Appendix.

Richardson, Hugh: See the Appendix.

Richardson, Samuel: novelist; b. in Derbyshire, England, about 1689; learned the printing-trade; became a publisher in London, printer of the journals of the House of Commons, master of the Stationer's Company, and purchased in 1760 a half-interest in the office of king's printer. D. in London, July 4, 1761. His novels *Pamela* (1740, with a continuation in 1741), *Clarissa Harlowe* (1748), *Sir Charles Grandison* (1754) enjoyed an unbounded success, and had numerous imitators not only in England, but in Germany and France, where they profoundly influenced the whole development of prose fiction. Richardson is the first English novelist. His novels are all in the form of letters, and are long and sentimental. They show little acquaintance with men on the part of their author, but an intense and sympathetic absorption in the feelings of the female heart, and they had their strongest popularity among women. See English Literature.

Richardson, William Adams, LL. D.: jurist and financier; b. at Tyngsborough, Mass., Nov. 2, 1821; graduated at Harvard 1843; admitted to the bar at Boston 1846; practiced law at Lowell; was one of the revisers of the *General Statutes of Massachusetts* (1860), and of the *Supplement* to the same (1863–64); became judge of probate 1856, Assistant Secretary of the Treasury 1869–73, and was secretary 1873–74; judge of U. S. court of claims 1874, and chief justice of same 1885–96. D. Oct. 19, 1896. Author of *The Banking Laws of Massachusetts* (1855); *Practical Information concerning the Public Debt of the United States*, with the *National Banking Laws* (1872); *History of the Court of Claims* (1882–85), etc.

Richardt, Christian Ernst: poet; b. in Copenhagen, Denmark, May 25, 1831. After studying theology he accepted a call to a country church, and continued to be a parish priest until his death. During the last years of his life he was chaplain of Vemmetofte Cloister in Zealand. His first work was a comedy, *Deklarationen* (1851), which was later produced at the Royal theater. In 1861 appeared *Smaadigte*, consisting of a number of delicate lyrics; in 1874 *Billeder og Sange* (Pictures and Songs); in 1878 *Halvhundrede Digte* (Fifty Poems); in 1884 *Vaar og Höst* (Spring and Autumn); and in 1891 *Blandede Digte* (Miscellaneous Poems). His tragic music-drama *Drot og Marsk* (King and Constable, 1878), with music by P. Heise, is one of the most popular pieces in the repertory of the Royal theater. In his religious depth, his patriotic enthusiasm, and his sincere love of nature, he stands first in later Danish lyrical poetry. D. 1893. His collected poems were published in Copenhagen in 1894. D. K. Dodge.

Richelieu, rĕĕ-she-loo′, also called **Sorel**, or **Chambly**: an historic and beautiful river of Quebec, Canada; right-hand affluent of the St. Lawrence, discharging Lake Champlain; length, 80 miles. Its course is northerly and very straight; the width, at first 1 or 2 miles, becomes gradually contracted to 1,000 or 1,200 feet. It is navigable, except for rapids between St. John and Chambly, and this gap is supplied by a canal. Navigation closes between Nov. 16 and Dec. 13, and opens between Mar. 20 and May 1. The valley is fertile and attractive, and in it were made some of the earliest settlements in the province. It also served as a battle-ground for over two centuries, beginning with Champlain's Iroquois campaign in 1609. M. W. H.

Richelieu (Fr. pron. rĕĕsh′li-ö′), Armand Jean Duplessis, de, Duke and Cardinal: statesman; b. in Paris, France, Sept. 5, 1585; was educated for the military profession in the Collège de Navarre, but, having a prospect of succeeding to the bishopric of Luçon, did not enter the army, but studied theology, and was consecrated bishop Apr. 16, 1607. Elected a deputy of the clergy to the States-General in 1614, he allied himself with the queen-mother and regent, Marie de Médicis; was appointed her almoner, and became a member of the council of state. When, shortly after, dissensions broke out between the king (Louis XIII.) and his mother, Richelieu accompanied the latter to Blois, and retired subsequently to his diocese, but succeeded, nevertheless, in bringing about a reconciliation between mother and son; was rewarded with the cardinal's hat in 1622; re-entered the council of state, and was soon after made prime minister, which office he filled uninterruptedly to his death, exercising a most decisive influence on the history of France, externally and internally. His foreign policy centered in the idea of humiliating Austria. For this purpose he encouraged the rising of the Protestant princes in Germany, the revolution of the provinces in the Netherlands, and even the revolt in Catalonia. He subsidized Gustavus Adolphus, and after the death of the latter he took the Duke of Saxe-Weimar and his army into the French service, and carried on the war against the emperor with great vigor. He also declared war against Spain, and although his plans in the Netherlands failed, he succeeded in separating Portugal from Spain in 1640, and conquered Perpignan in 1642. The final results of these wars he did not live to see, but by the Peace of Westphalia (1648) the progress of the house of Austria was effectually checked and its dream of establishing a world-empire was destroyed. By his internal policy he finished what Louis XI. had begun—the overthrow of the feudal power of the nobility. His government was marked by an almost uninterrupted series of conspiracies among the feudal nobility of the realm, headed by the queen-mother (whose favor had turned into a deadly hatred), by the queen herself, Anne of Austria, by Gaston of Orleans, the brother of the king, and by the royal princes. A master in intrigue and the very genius of detective police superintendence, he was always well informed and fully prepared, and punished the conspirators with merciless severity. The king felt a deep antipathy against him, and on this circumstance the first conspirators based their hope of overthrowing him. With the king, however, this almost physical aversion was wholly overawed by a mixture of admiration and fear of the towering spirit of his minister, and on Nov. 11, 1630 (*la journée des dupes*), when the king had consented to his dismissal and the whole court exulted, Richelieu forced himself into the presence of Louis, turned him around in a moment, and reappeared with great dramatic effect among his enemies, stronger than ever. Afterward the conspirators sought and found support in foreign countries, especially in Spain, and Richelieu needed armies to maintain himself, but he proved unconquerable. Marie de Médicis fled from place to place in foreign countries; Gaston of Orleans was made utterly contemptible by his cowardly submission: Montmorency, Marillac, Cinq-Mars, and many others were beheaded. The scaffold, the dungeon, and exile were the end of all resistance to him who wielded the royal power. Besides the feudal nobility, there was another political power in France at the time when Richelieu took the reins—namely, the Huguenots—and to crush this young but steadily increasing influence was one of the three great objects of his policy. He laid siege to their principal stronghold, La Rochelle, and this siege is one of the most memorable events in the history of France. On Oct. 28, 1628, the city surrendered, four-fifths of its inhabitants having perished by the sword and by famine. By the fall of La Rochelle the political power of the Huguenots was wholly broken, but Richelieu's further measures concerning them were moderate and even magnanimous. The cardinal

built the Palais Cardinal, afterward the Palais Royal, which entirely outshone the royal residence. He showed great interest in literature and art. He founded the Jardin des Plantes, enlarged the Sorbonne and the royal library, and gave substantial encouragement to many scholars, poets, and artists. His interest in literature, however, was not only a merit, but also a foible with him. He wrote *Mirame* and *La Grande Pastorale*. His *Lettres, Instructions diplomatiques, etc.*, were edited by Avenel (6 vols., Paris, 1853–68). Of the *Mémoires du Cardinal de Richelieu*, *Testament politique du Cardinal de Richelieu*, and *Journal du Cardinal de Richelieu*, the last is spurious, and the first two of doubtful authenticity. D. in his palace in Paris, Dec. 4, 1642. The best authorities are Caillet, *L'Administration en France sous le Ministère du Cardinal de Richetieu* (2 vols.), and Bazin, *Histoire de France sous Louis XIII.* (4 vols.)

Revised by C. K. Adams.

Richepin, rēesh'păn', Jean: poet, dramatist, and novelist; b. at Médéah, Algiers, Feb. 4, 1849. After studying in Paris at the Lycée Napoléon and the Lycée Charlemagne, he began to study medicine, and in 1868 entered the École Normale. After some newspaper work in 1870–71, he produced a novel, *Jules Valtès* (1872), and, in company with André Gill, a play, *L'Étoile*. He first attracted attention by the volume of poems, *La Chanson des Gueux* (1876), for which he was condemned to a fine of 500 francs and imprisonment for a month. In prison he wrote *Les Morts Bizarres* (1887). He went next to sea, but soon returned to Paris, and has since been a prolific author of poetry, novels, and plays. A partial list is *Les Caresses* (1877), *Les Btasphèmes* (1884), *La Mer* (1886), *Mes Paradis* (1893), in verse; *Madame André* (1874), *La Glu* (1881), *Braves Gens* (1888), novels; *Nana Sahib* (1882), *Monsieur Scapin* (1886), *Le Flibustier* (1888), *Par le Glaive* (1892), plays. A. G. Canfield.

Richer, rēe'shā', Edmund: a learned champion of Gallican Church rights against the papacy; b., of humble parentage, at Chaource, France, Sept. 30, 1560; was made doctor of the Sorbonne 1590; director of the college of Cardinal Lemoine 1594; later a syndic of the Sorbonne. In 1595 he played a prominent part in the expulsion of the Jesuits. His famous *De Ecctesiastica et Politica Potestate* was written in 1611, and in it he gave vigorous expression to his Gallicanism. The Jesuits had their revenge when the Sorbonne deposed him as syndic 1613, and the daggers of Richelieu compelled him to recant 1629. D. Nov. 28, 1631. See his *Life*, by A. Baillet (Liège, 1714; n. e. Amsterdam, 1715) and by G. L. Calabre-Perau (Paris, 1748).

Revised by S. M. Jackson.

Richer, Paul, M. D.: neurologist; b. at Chartres, department of Eure-et-Loir, France, Jan. 17, 1849; received his scholastic education at the Institution des Pères Maristes in Montençon, and his medical education at the Paris School of Medicine, graduating M. D. in 1879; in 1882 was made chief of the laboratory of the clinic of diseases of the nervous system at the Salpêtrière. Besides numerous monographs on neurological topics, he is the author of *Étude descriptive de la grande attaque hystérique ou attaque hystéro-épileptique et de ses principales variétés* (Paris, 1879); *Études cliniques sur l'hystéro-épilepsie ou grande hystérie* (Paris, 1881); *Anatomie artistique* (Paris, 1890); *Paralysies et contractures hystériques* (Paris, 1892); *Canon des proportions du corps humain* (Paris, 1893); *Physiotogie artistique de l'homme en mouvement* (Paris, 1894). S. T. A.

Richet, rēe'shā', Alfred Louis, M. D.: surgeon; b. at Dijon, France, Mar. 16, 1816; began the study of medicine in Paris in 1835; became assistant in anatomy in 1841 and prosector in 1843; graduated M. D. in 1844, his thesis being a valuable monograph, *Études d'anatomie, de physiotogie et de pathologie pour servir à l'histoire des tumeurs blanches*; in 1847 passed the *concours* for associate professor in the faculty of Paris; was successively surgeon to the Lourcine, St.-Antoine, Pitié, and Hôtel-Dieu hospitals; was president of the Société de Chirurgie in 1864, and of the Academy of Medicine in 1879; was appointed professor of clinical surgery in 1864; became a member of the Institute in 1883; in 1848 was made a chevalier, in 1873 a commander of the Legion of Honor. He was the author of a number of important papers on surgical topics. His most important work was *Traité pratique d'anatomie médico-chirurgicate* (Paris, 1857). D. at Hyères, Dec. 3, 1891. S. T. Armstrong.

Richet, Charles: physiologist; b. in Paris, France, Aug. 26, 1850; educated in Paris; has been Professor of Physiology in the Faculty of Medicine at Paris since 1887; editor of the *Revue Scientifique* since 1878. His principal works are *L'homme et l'intettigence* (2d ed. 1891); *Psychologie générate* (2d ed. 1891); *Physiotogie générate des muscles et des nerfs* (1883); *Travaux du Laboratoire de physiologie* (3 vols., 1890–94); and *La chaleur animate* (1889). J. M. B.

Richey, Matthew Henry: See the Appendix.

Richfield: city; capital of Sevier co., Utah; on the Sevier river; 42 miles S. W. of Manti (for location, see map of Utah, ref. 5–M). It is in an agricultural region, and has a weekly newspaper and a private bank. Pop. (1900) 1,969.

Richfield Springs: village; Otsego co., N. Y.; at the head of Canadarago (formerly Schuyler) Lake, and on the Del., Lack. and W. Railroad; 16 miles N. of Cooperstown, the county-seat, 35 miles S. E. of Utica (for location, see map of New York, ref. 5–H). In and near the village are seventeen mineral springs, one of which, of sulphur, is widely known for its curative properties in cases of rheumatism and cutaneous disorders. There are eleven summer hotels, fine drives to Cooperstown, Otsego Lake, and other interesting points, and many attractions for the summer tourist and boarder. The village has several manufactories, including a Scotch-cap factory, knitting-mill, and glove-factory, a national bank with capital of $100,000, and a weekly newspaper. Pop. (1880) 1,307; (1890) 1,623; (1900) 1,537. Editor of "Mercury."

Richford: village; Franklin co., Vt.; on the Missisquoi river; and the Cent. Vt. and the Canadian Pac. railways; 28 miles E. N. E. of St. Albans (for location, see map of Vermont, ref. 2–B). It is a noted lumber-manufacturing center, has a number of mills run by steam and water power, and contains a savings-bank and trust company with capital of $50,000, and two weekly newspapers. Pop. (1880) 789; (1890) 1,162; (1900) 1,513.

Rich Hill: city; Bates co., Mo.; on the Osage river, and the Kan. City, Fort Scott and Memphis and the Mo. Pac. railways; 20 miles N. E. of Fort Scott, 85 miles S. by E. of Kansas City (for location, see map of Missouri, ref. 5–E). It has an elevation of 800 feet above sea-level, and is the center of the largest coal-area in the State. There are 12 churches, 3 large public-school buildings, water, gas, electric-light and electric street-railway plants, 2 ten-acre public parks, 2 State banks with combined capital of $100.000, and 5 newspapers. Besides the coal-mines in operation, there are vitrified brick-works, zinc-smelters, flour-mills, distillery, foundry, machine-shops, and factories for cigars and for canning. Pop. (1880) 36; (1890) 4,008; (1900) 4,053.

Editor of "Daily Review."

Richibucto, rish-i-bŭk'tō, formerly Liverpool: a port of entry and capital of Kent co., New Brunswick; eastern terminus of the Kent Northern Railway, connecting with the Intercolonial at Kent Junction; at the mouth of Richibucto river, which is navigable for 15 miles; latitude of entrance, 46° 43′ N., lon. 64° 50′ W. (see map of Quebec, etc., ref. 4–I). Lumber and fish are largely exported, and shipbuilding is a leading pursuit. Pop. (1891) 3,986.

Richland Centre: city; capital of Richland co., Wis.; on the Pine river, and the Chi., Mil. and St. Paul Railway; 12 miles N. of the Wisconsin river, 59 miles W. by N. of Madison (for location, see map of Wisconsin, ref. 7–C). It is in an agricultural, dairying, stock-raising, and lumbering region, has a large trade in cheese, flour, railway-ties, and stoves, and contains a high school and three weekly newspapers. Pop. (1880) 1,227; (1890) 1,819; (1900) 2,321.

Richmond (anc. *Syenes* and *Sheen*): town; in the county of Surrey, England; on the summit and slope of Richmond Hill and on the level right bank of the Thames, 10 miles S. W. of St. Paul's, London (see map of England, ref. 12–J). Only a gateway remains of the royal palace of Sheen, rebuilt by Edward III., who died there. In 1499 the palace was burned down, but was rebuilt by Henry VII., who changed the name to Richmond. Elizabeth was imprisoned here for a short time by Mary; she afterward often resided here, and died here in 1603. Under the Commonwealth the palace was partially destroyed, and in the eighteenth century was pulled down. In the neighborhood is Richmond Park, formed by Charles I. in 1634; it covers 2,253 acres, and is surrounded by a brick wall nearly 8 miles in length. From Richmond Hill and Richmond bridge (1774–77) striking views of the surrounding beautiful scenery can be obtained. Market-gardening and nursery-gardening is the principal industry. Pop. (1891) 22,684.

Richmond: city of Victoria, Australia; 2 miles E. of Melbourne (see map of Australia, ref. 8–H). Pop. (1889) 37,550. It has a distinct municipality and the rank of a city, but is really only a suburb of Melbourne.

Richmond: *chef-lieu* of the counties of Richmond and Wolfe, Canada; on the St. Francis, a tributary of the St. Lawrence; 76 miles E. of Montreal (see map of Quebec, ref. 5–C). It is an important center of the Grand Trunk Railway, the Portland section extending from it 221 miles, the Montreal section 76 miles, and the Quebec branch 96 miles. The river is spanned by a passenger-bridge connecting the picturesque village of Melbourne with Richmond. St. Francis College, an institution affiliated to McGill University, is situated on a commanding site at the upper end of the town. Two newspapers are published in the place. The chief industry is connected with the railway-works and machine-shops. Pop. (1890) 2,056. J. M. Harper.

Richmond: city; capital of Wayne co., Ind.; on the Whitewater river, and the Grand Rapids and Ind. and the Pitts., Cin., Chi. and St. L. railways; 68 miles E. of Indianapolis, 92 miles S. by E. of Fort Wayne (for location, see map of Indiana, ref. 6–G). It is in an agricultural region, has an elevation of 700 feet above tide-water, and is engaged in manufacturing and in general trade. The city has gas and electric-light plants, an abundant supply of natural gas for fuel, excellent water and drainage systems, and electric street-railways. There are 21 churches, 9 public-school buildings, a high school, public-school property valued at about $300,000, Earlham College (Orthodox Friends, opened in 1847), 5 libraries (Earlham College 3, Morrison Public, and County Law) containing over 27,000 volumes, 3 national banks with combined capital of $450,000, 4 building and loan associations, and a semi-monthly, a quarterly, 4 daily, 7 weekly, and 3 monthly periodicals. In 1890 there were 293 manufacturing establishments, which had a combined capital of $4,000,000, employed about 3,000 persons, and had products valued at about $6,000,000. The public buildings include a new county court-house, a new State asylum for the insane, two orphans' homes, a Home for Friendless Women, and a city hospital. Pop. (1880) 12,742; (1890) 16,608; (1900) 18,226.

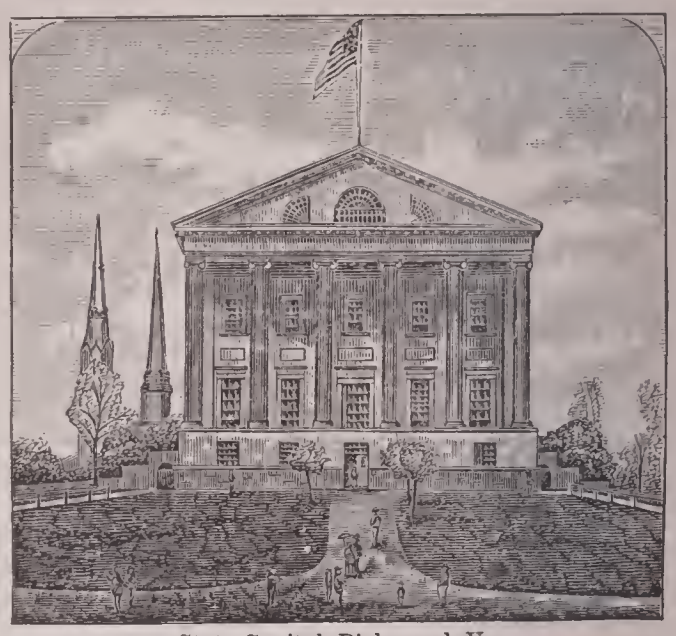
Richmond: town; capital of Madison co., Ky.; on the Louis. and Nash. and the Rich., Nicholasville, Irvine and Beattyville railways; 25 miles S. S. E. of Lexington, 54 miles S. E. of Frankfort, the State capital (for location, see map of Kentucky, ref. 3–I). It is in an agricultural region; is noted for breeding horses, mules, and cattle; and contains the Central University (Southern Presbyterian, chartered in 1873), 4 national banks with capital of $750,000, and 2 weekly periodicals. Pop. (1890) 5,073; (1900) 4,653.

Richmond: town; Sagadahoc co., Me.; on the Kennebec river, and the Maine Central Railroad; 17 miles S. of Augusta, and 44 miles N. E. of Portland (for location, see map of Maine, ref. 10–C). It is principally engaged in the manufacture of boots and shoes, has sawmills and planing-mills, and contains a public high school, public library (founded in 1868), two national banks with combined capital of $170,000, and a weekly and a monthly periodical. Pop. (1880) 2,658; (1890) 3,082; (1900) 2,049.

Richmond: city; capital of Ray co., Mo.; on the Atch., Top. and S. Fé Railroad; 40 miles E. of Kansas City, 68 miles S. E. of St. Louis (for location, see map of Missouri, ref. 3–E). It is in an agricultural and coal-mining region, and contains several flour-mills, foundry, public high school, Woodson Institute, new water-works plant, electric lights, 3 State banks with combined capital of $200,000, and a daily and 3 weekly newspapers. Pop. (1890) 2,895; (1900) 3,478.

Richmond, Borough of: See the Appendix.

Richmond: city (named after Richmond, Surrey, England): port of entry; capital of Virginia and of Henrico County; on the north branch of the James river, and the Ches. and Ohio, the Richmond and Petersburg, the Rich., Fredericksburg and Potomac, and the Southern railways; 116 miles S. by W. of Washington, D. C., 127 miles N. W. of the Atlantic Ocean (for location, see map of Virginia, ref. 6–H). It has an area within incorporated limits of 4·85 sq. miles, and with suburbs of about 16 sq. miles; is built on a series of hills, and ranges in altitude above sea-level from 172 to 249 feet. The river is here crossed by five bridges, connecting the city with Manchester, Spring Hill, and other suburban places. There are 106 miles of streets, generally wide, of which 36 miles are sewered and 23 miles paved; sidewalks are chiefly of brick. Main Street is the principal business thoroughfare; Broad Street is the widest; West Franklin and Grace contain the most fashionable residences. The streets are lighted by gas and electricity. The supply of water for domestic and fire purposes is obtained from two points on the river above the city, where it is pumped into two large reservoirs for distribution. Both the gas and water-works plants are owned by the city.



State Capitol, Richmond, Va.

Parks and Public Buildings.—The most noted of the parks and squares, which comprise 357 acres in all, is Capitol Square, a tract of 12 acres on the summit of Shockoe Hill. It contains the State Capitol, a Græco-composite building with a portico of Ionic columns, erected in 1796 after the plans of the Maison Carrée of Nîmes, France, built according to the suggestions of Thomas Jefferson. The building contains Houdon's marble statue of Washington, and many portraits of governors, military officers, and other distinguished Virginians; and the two legislative halls. The State Library building, in which are preserved the parole signed by Lord Cornwallis at Yorktown, the original Virginia bill of rights, and the Virginia ordinance of secession, is located in the same square. The park surrounding the Capitol has three fountains; Crawford's equestrian statue of Washington surrounded by bronze statues of Patrick Henry, John Marshall, Andrew Lewis, George Mason, Thomas Jefferson, and Thomas Nelson, by Crawford and Rogers; Foley's bronze statue of "Stonewall" Jackson; and Hart's marble statue of Henry Clay. Other public buildings on the square are the Governor's mansion, the new Public Library, and the old bell-house. The largest park, of 300 acres, contains the new reservoir, a beautiful lake, and a fine boulevard, and is a favorite resort. Libby Park, on Libby Hill, is terraced from the summit to Main Street, and on its highest point has a Confederate Soldiers' and Sailors' Monument. Monroe Park contains a statue of Gen. W. C. Wickham. Chimborazo Hill Park has an area of 36 acres, and an elevation of 200 feet. Howitzer Place has a monument in memory of the Richmond Howitzer battalion. Gamble's Hill Park is on the James river and Kanawha Canal, and Jefferson Park is between Marshall and Pleasant Streets. Lee Circle, in the west of the city, contains a bronze equestrian statue of Gen. Robert E. Lee. In Hollywood Cemetery, where 12,000 Confederate soldiers lie, is a memorial of rough blocks of granite, forming a pyramid 90 feet high, erected by the women of Richmond. Other notable buildings are St. John's Protestant Episcopal church, on Church Hill, in which Patrick Henry made his famous declaration for liberty or death; the Colonial Stone House on Main Street, believed to have been occupied by Washington; the "White House of the Confederacy," the home of Jefferson Davis during the civil war, and now a museum for Confederate relics; the Masonic Temple, the first erected in the U. S. (corner-stone laid 1785); Monumental church (Protestant Episcopal), erected on the site of the theater burned in 1811, when sixty lives were lost; two armories; St. Luke's Hospital; Retreat for the Sick; Lee Camp Soldiers' Home; the Male and Female Orphan asylums; the Virginia Medical College; the Colored Baptist church, in which the constitutional convention of 1850–51 was held; and the penitentiary, to which a farm is now attached.

Churches and Schools.—Richmond has 128 religious organizations and 88 church edifices, 63 for white people and 25 for colored. The Baptists have 14 churches for white members; Episcopalians, 12; Methodists, 10; Presbyterians, 8; Roman Catholics, 4; Lutherans, 4; Jews, 4; Christians, 2; and Friends, 1. The public-school system has been developed since the civil war. In 1894 there were 17 public-school buildings, including high and normal schools for whites and colored, and public-school property valued at $500,000. For evening instruction there are the Virginia Mechanics' Institute and 6 other night-schools. There are 10 private and numerous parochial schools. The institutions for advanced instruction include the Virginia Medical College (founded in 1837); University College of Medicine (established in 1893); Richmond Female Institute (Baptist, founded in 1854); Monte Marie Institute (Roman Catholic, established in 1860); St. Mary's Benedictine Institute; Richmond Female Seminary (Protestant Episcopal); Hartshorne Memorial College for the Education of Colored Girls (Baptist, opened in 1883); Richmond Theological Seminary (Baptist, opened in 1867); and Richmond College (Baptist, opened in 1832). There are 5 public libraries, with an aggregate of 50,000 volumes, and in Jan., 1894, there were 6 daily, 21 weekly, 14 monthly, and 2 quarterly periodicals.

Business Interests.—In the 1890 census 966 manufacturing establishments (representing 103 industries) reported. These had a combined capital of $16,785,242, employed 18,512 persons, paid $7,192,646 for wages and $14,014,214 for materials, and had products valued at $27,792,672. The principal industry is the manufacture of tobacco. In 1893 there were 120 establishments engaged in this industry, having a capital of $5,058,000, employing 8,820 persons, and yielding products valued at $12,538,000. The establishments comprised 64 cigarette and cheroot factories, 31 smoking and chewing tobacco factories, and 25 stemmeries and other works. The internal revenue collections average $1,500,000 per annum. Iron manufactures rank next to tobacco, and, including carriages and agricultural implements, average in value $7,095,000 per annum. Flour and grist mill products have an annual value of $2,735,000; fertilizers, $1,075,000; and lumber, $770,000. In 1893 Richmond had 20 banking institutions, of which 4 were national and 10 had State charters. There were 7 savings-banks, 5 private banks, and several loan and deposit companies. The incorporated banks had an aggregate capital of $6,040,056; deposits, $11,150,000; loans and discounts, $12,520,000; and total resources, $17,900,000. In the fiscal year ending June 30, 1894, the transactions at the custom-house showed imports of foreign merchandise, $43,989; exports of domestic products and merchandise, $3,971,837. The assessed valuations of the city in 1893 were, personal, $18,958,368; real, $40,255,919—total, $59,214,288; the bonded debt was $6,609,237; the annual receipts were $2,256,000; and the municipal assets included the city-hall, gas and water plants, parks, railway stock, and other items, aggregating $6,000,000.

History.—As early as 1609 a settlement was made by the English on what is now the lower portion of the city. Col. William Byrd built a mill near the falls in 1679, and afterward a warehouse. The place was known as Byrd's Warehouse till May, 1742, when it was incorporated as a town, and laid off into squares with wide streets. In 1779 the seat of government of the commonwealth was removed from Williamsburg to Richmond. In 1781 the city was taken and burned by the traitor Arnold. In June, 1861, it was made the capital of the Confederate States, and there the Confederate Congress met on July 20 following. During the civil war the city was the objective point of the principal operations of the Union army in Virginia, and it was evacuated in Apr., 1865; the main business portion of the city was then burned. On Apr. 27, 1870, over sixty persons were killed or mortally wounded by the yielding of the floor of the court-room of the court of appeals beneath the weight of the multitude gathered to hear the decision in the contested election for mayor; and the great flood in James river in Sept., 1870, inundated a large portion of the city. Pop. (1880) 63,600; (1890) 81,388. MALCOLM A. COLES.

Richmond, LEGH: religious writer; b. in Liverpool, England, Jan. 29, 1772; graduated at Cambridge, 1794; took orders in the Church of England 1797; became curate of Brading and Yaverland in the Isle of Wight 1798, chaplain to the Lock Hospital, London, 1805, and was presented in the same year to the rectory of Turvey, Bedfordshire, which he held until his death May 8, 1827. He was the author of several popular tracts, which have been circulated by millions in many languages; especially *The Dairyman's Daughter*, *The Negro Servant*, and *The Young Cottager*. He also edited *The Fathers of the English Church, or a Selection from the Writings of the Reformers and Early Protestant Divines of the Church of England* (8 vols., 1807–11). See his *Life*, by T. S. Grimshawe (London, 1826; ed. G. T. Bedell, Philadelphia, 1846).

Richmond, MARGARET BEAUFORT, Countess of: daughter of Edmund Beaufort, Duke of Somerset; b. at Bletsoe, Bedfordshire, England, about 1441; married Edmund Tudor, Earl of Richmond, to whom she bore a son, Henry Tudor (afterward King Henry VII.); after the death of her first husband she married Sir Henry Stafford 1459, and left a second time a widow in 1481, married Thomas, Lord Stanley, in the following year. She was known as Countess of Derby during the reign of her son, her husband having been created Earl of Derby as a reward for his defection from Richard III. on Bosworth Field. She was noted for her charity and devotion, and also for her patronage of letters and her own literary taste; translated *The Mirroure of Gold for the Sinfull Soule*, from a French version of the *Speculum Aureum Peccatorum* (printed by Pynson), and the fourth book of the *Imitation of Christ* (1504); endowed Christ's College 1505, and St. John's College, Cambridge, by bequest 1511, founding the Lady Margaret professorship of divinity, still maintained. D. in 1509. The principal title of the Tudor, Stuart, and Brunswick dynasties to the English throne was derived through this lady's descent from Edward III. through John of Gaunt. Revised by F. M. COLBY.

Richmond College: an institution at Richmond, Va. It began in 1830 as a Baptist seminary for the education of ministerial candidates. In 1840 it was chartered as a college. The civil war shut its doors and destroyed its endowment. In 1866 it was reorganized on the system of independent schools, of which there are eight, and elective studies. Each professor is responsible for the efficient control of his own school, and admits to graduation therein only upon rigid written examination. The chief executive officer was chairman of the faculty, chosen annually, but in 1894 Prof. F. W. Boatwright was elected president for an indefinite period. The degree of B. A. is conferred upon such students as have graduated in a prescribed course, about equal to six schools; the degree of M. A., upon such as have graduated in all the eight schools. Attendance on religious exercises is voluntary. Two free courses of subsidiary lectures are given every session. There are large dormitories, ample lecture-rooms, spacious halls for library and museum, and a campus of 13 acres. There were 16 professors and 225 students in 1900. Revised by W. H. WHITSITT.

Richter, *rich'ter*, GUSTAV KARL LUDWIG: historical and portrait painter; b. in Berlin, Germany, Aug. 31, 1823; studied at the Berlin Academy and under Léon Cogniet in Paris; professor in Berlin Academy; member of Munich and Vienna Academies; medals at the exhibitions in Brussels and Vienna 1873, Philadelphia 1876, and Munich 1883; second-class medals, Paris Salons, 1857 and 1859, and Paris Exposition 1855. D. in Berlin, Apr. 3, 1884. One of his most celebrated works is *Portrait of Queen Louise* (1879) in the Cologne Museum. He was the most famous portrait-painter in Germany in his time. Works by him are in the National Gallery, Berlin; Maximilianeum, Munich; and the museum at Dantzic. WILLIAM A. COFFIN.

Richter, JEAN PAUL FRIEDRICH, generally called **Jean Paul**: author; b. at Wunsiedel, Bavaria, Mar. 21, 1763. His father was a poor country minister, and when he died, in 1779, he left to his family nothing but debt. The son, nevertheless, went to Leipzig in 1781 to study at the university, and he contrived to stay there four years, though he lived in the most pinching poverty. In 1784 he fled from Leipzig in order to escape imprisonment for debt, and for three years lived with his mother at Hof. From 1787 to 1789 he was private tutor in a family at Leipzig, and from 1790 to 1794 a schoolmaster at Schwarzenbach. Compared with his life in Leipzig and at Hof, these positions offered him affluence, and in the meantime he had become a celebrated author. He had originally gone to Leipzig to study theology, and had read much of this science, as of everything else; but having been poorly taught in his youth, he was incapable of systematic and exhaustive study. There was something roving and diffuse in his intellect, as in his talent. Thus by his studies at Leipzig he had only prepared himself for a miscellaneous literary activity, and his first at-

tempts were not successful. His *Grönländische Processe* (Lawsuits in Greenland, 2 vols., 1784) and *Auswahl aus des Teufels Papieren* (Selections from the Papers of the Devil, 1789) were not read; their satire is narrow, their humor forced, their form unripe. In 1793 his romance, *Die Unsichtbare Loge* (The Invisible Lodge, 2 vols.), turned the scales of fortune, and now followed in rapid succession, and with decided success, *Hesperus* (4 vols., 1795), *Biographische Belustigungen unter der Gehirnschale einer Riesin* (Biographical Recreations under the Cranium of a Giantess, 1796), *Leben des Quintus Fixlein* (1796), *Blumen-, Frucht- und Dornenstücke, oder Ehestand, Tod und Hochzeit des Armenadvocaten Siebenkäs* (Flower, Fruit, and Thorn Pieces, or Marriage, Death, and Wedding of Lawyer Siebenkäs, 4 vols., 1797), *Der Jubelsenior* (1797), *Das Kampaner Thal* (1797). These writings made Richter the literary favorite of Germany. In 1794 he gave up his position as a schoolmaster, and began a life of visits to the different literary centers—Leipzig, Weimar, Dresden, and Berlin. He was everywhere well received, and made many intimate friends, among whom, however, Goethe and Schiller were not. It was especially the fair sex which was enthusiastic about him. In 1801 he married in Berlin the beautiful and spirited Caroline Mayer, and removed first to Meiningen, then to Bayreuth. From the prince-primate Dalberg he received an annual pension of 1,000 florins, which was continued afterward by the King of Bavaria, and the University of Heidelberg made him a doctor. In 1803 he published his *Titan*, and in 1804 *Die Flegeljahre* (Wild Oats, 4 vols.), which two romances, together with his first philosophical attempt, *Vorschule der Æsthetik* (Introduction to Æsthetics, 3 vols., 1805), may be considered as indicating the culmination of his talent. In 1807 he wrote another philosophical book on education, *Levana oder Erziehungslehre*, and in the following years he published a great number of political and satirical pamphlets, sermons, humorous sketches, etc. D. at Bayreuth, Nov. 14, 1825. Richter is without doubt the greatest humorist of modern German literature, but his utter disregard for literary form, the lack of artistic composition, and his barbarous style make it a laborious task to read and enjoy him. Having, however, penetrated the hard shell of the imperfect form of his writings, one finds him a poet of divine inspirations, lofty sentiments, and irresistible humor. In order to do him justice it is necessary not only to consider him in his literary relations to the earlier English and German humorists, like Swift, Sterne, Hippel, Lichtenberg, and others, but also to keep in mind the miserable political and social conditions of Germany in his time and the strong current of sentimentality which had not been checked by the classic productions of Goethe and Schiller. While these latter poets and their followers had created in their works an ideal poetic world unconcerned about the miserable conditions around them in which they really lived, Richter makes the very contrast between the German idealism and the prosaic reality of his time the subject-matter of his humorous representations. With a loving spirit he embraces the lowest and most humble in this prosaic reality, and thus he produces idyls like *Quintus Fixlein*, *Leben Fibels*, etc., in which his contemporaries found a picture of their own life, and which we could call classic but for their poor literary form. He is especially great in his descriptions of nature, while in the delineation of human characters he is frequently less successful. As defective as his style was, it found a great many imitators. The tendency which prompts authors like Börne, Heine, and their literary offspring to parade their vain subjectivity is due to the example of Richter, to whom Heine especially owes more than he might have been willing to acknowledge.

See R. O. Spazier, *Jean Paul Fr. Richter, ein biographischer Commentar zu dessen Werken* (1833); E. Förster, *Denkwürdigkeiten aus dem Leben J. P. F. Richters* (1863); Fr. Th. Vischer, *Kritische Gänge*; G. Nerrlich, *Jean Paul und seine Zeitgenossen* (1889); Carlyle, *Essays*.

Revised by JULIUS GOEBEL.

Richthofen, richt'hō-fen, Baron FERDINAND, von, Ph. D.: geologist and geographer; member of a distinguished Silesian family; b. at Carlsruhe, Germany, May 5, 1833; studied at Breslau and Berlin 1850–56. During 1856–60 he was in Austria studying the geology of the Tyrol, Siebenbürgen, and Northeastern Hungary. He then accompanied, as geologist, Count Eulenberg on the Prussian expedition to the far East, and remained twelve years in China, Indo-China, Java, Celebes, the Philippine islands, Formosa, Japan, California and Nevada, returning to Europe in 1872. The last four years of his sojourn abroad were spent in traveling all over Northern and Central China in the interests of the Shanghai Chamber of Commerce. Was Professor of Geography at Bonn 1879, Leipzig 1883, and Berlin 1886. D. May 8, 1888. His publications, which were numerous, include *The Comstock* [Nev.] *Lode* (1865); *Principles of the Natural System of Volcanic Rocks* (1867); *Letters to the Shanghai Chamber of Commerce* (1869–72). The most noteworthy of his works is *China, Ergebnisse eigner Reisen und darauf gegründeter Studien* (vol. i., 1877; vol. ii., 1882; vol. iv., 1883). MARK W. HARRINGTON.

Richwood: village; Union co., O.; on the Erie Railroad; 15 miles S. W. of Marion (for location, see map of Ohio, ref. 4–E). It is in an agricultural region, and has 2 large flour-mills, 2 steam tile-mills, several large grain elevators, a planing-mill, 2 private banks, and 2 weekly newspapers. Pop. (1890) 1,415; (1900) 1,640. PUBLISHER OF "GAZETTE."

Ric'inus: See CASTOR-OIL PLANT.

Rickets: a disease characterized by deformities of the bones and various visceral disturbances. It occurs as a rule in infants from twelve to eighteen months of age. The predisposing causes are the influence of bad hygienic surroundings, and improper food and clothing. The symptoms develop gradually and almost imperceptibly. The little patient seems to lose spirit, and indigestion sets in, accompanied by swelling of the abdomen and colic. There is early a tendency to sweating about the head and restlessness during sleep. The muscles become soft and flabby, the face sallow, and the skin dry, and there is scanty and turbid urine and thin fetid evacuations. The fontanelles and sutures remain open until a late period. The teeth are very late in making their appearance, and decay rapidly after doing so. As the disease advances the bones grow softer, and become distorted by the superincumbent weight and muscular contraction. Various deformities of the head, limbs, chest, and pelvis are brought about. (See ORTHOPÆDIC SURGERY.) As a disease of the bones, rickets is never dangerous. It is from the deformities resulting, and their interference with the action of the lungs and other viscera, that the danger arises. The treatment can be summed up in a few words—fresh air, sunlight, good food, bathing, and cod-liver oil. It is remarkable that rachitic children frequently develop and become unusually strong, though deformed, in adult years. Many, too, are brilliant mentally, as the records of great names in literature and science show.

Revised by W. PEPPER.

Ricketts, JAMES BREWERTON: soldier; b. in New York, June 21, 1817; graduated at U. S. Military Academy, and entered the artillery July, 1839; served in the Mexican war and on frontier duty up to 1861, when as captain he commanded a battery in the capture of Alexandria May 24, as in the battle of Bull Run July 21, 1861, where he was severely wounded, and from which date he was breveted lieutenant colonel and made brigadier-general of volunteers. He was engaged in the battle of Cedar Mountain, at the second battle of Bull Run, and at Chantilly commanded a division, as at South Mountain and Antietam; major First U. S. Artillery June, 1863; participated in the final Richmond campaign in command of a division from the battles of the Wilderness to the investment of Petersburg; recalled to Washington July, 1864, to aid in the defense against Early's threatened attack, and engaged in the subsequent pursuit of Early's army, participating in the battles of Monocacy, Opequan, Fisher's Hill, and Cedar Creek, where he was severely wounded; breveted major-general for gallantry; in Jan., 1867, was retired on the full rank of major-general. D. at Washington, D. C., Sept. 22, 1887. JAMES MERCUR.

Ricketts, PALMER CHAMBERLAINE, C. E.: civil engineer and educator; b. at Elkton, Md., Jan. 17, 1856; educated at the Rensselaer Polytechnic Institute, Troy, N. Y., where he graduated in 1875. During 1875–84 he was Assistant Professor of Mathematics; since 1884 has been Professor of Mechanics, and since 1892 director of the Rensselaer Polytechnic Institute. He has been consulting bridge-engineer for two railways, and since 1891 engineer of the public improvement commission of Troy, N. Y. In 1891 he was appointed brigadier-general and chief of engineers of the State of New York. He is the author of reports and technical discussions in engineering periodicals.

Rico, ree'ko: town; capital of Dolores co., Col.; on the Dolores river, and the Rio Grande Southern Railroad; 66

miles S. W. of Ridgway, 95 miles N. by W. of Durango (for location, see map of Colorado, ref. 5–B). The completion of the railway between Ridgway and Durango in 1892 added much to the importance of the town and quickened the development of gold, silver, copper, iron, and coal in its immediate vicinity. Rico has a national bank with capital of $50,000, a State bank with capital of $50,000, and two weekly newspapers. Pop. (1880) 894; (1890) 1,134; (1900) 811.

Rico, Martin: landscape-painter; b. in Madrid, Spain; pupil in Madrid of Federico de Madrazo and afterward studied in Paris and Rome; third-class medal, Paris Exposition, 1878; second-class medal, Paris Exposition, 1889; Legion of Honor 1878. His subjects are chiefly architectural, and for the most part consist of views in Venice. His pictures are painted with great cleverness, and are remarkable for delicacy of color and brilliancy of effect. Two works, *Grand Canal, Venice* and *Italian Garden*, are in the Metropolitan Museum, New York. W. A. C.

Ricord, rē̆e′kōr′, Philippe, M. D.: surgeon; b. in Baltimore, Md., of French parentage, Dec. 10, 1800; went to Paris 1820; received his medical degree 1826; practiced in the provinces for two years; returned to Paris, passed the Concours examination, and was attached to the Pitié Hospital as surgeon; in 1831 was surgeon-in-chief of the Hôpital du Midi at Paris; acquired a wide reputation by his treatment of venereal diseases; obtained the Monthyon prize 1842, and was appointed consulting surgeon to the Emperor Napoleon III. Oct., 1869. In 1860 he was made commander, and in 1871 (for his services in the ambulance-corps during the siege of Paris) grand officer of the Legion of Honor. He received more than 200 decorations from foreign governments throughout the world, and was president of the French Academy of Medicine, and author of numerous surgical works in his special department. D. Oct. 22, 1889.

Revised by S. T. Armstrong.

Ricot'ti, Ercole: author; b. at Voghera, Oct. 12, 1816; graduated at the University of Turin, and at the age of twenty-one presented to the Academy of Sciences of that city his *chef-d'œuvre, Storia delle Compagnie di Ventura*. For this he was honored with a prize, although the work only appeared completed in 1843–44, when it was published in Turin in four volumes. This was followed by other works —*Corso di Lezioni sopra la Storia d'Italia dal Basso Impero ai Comuni* (Turin, 1848); *Breve Storia d'Europa e specialmente d'Italia* (2 vols., Turin, 1850–51); *Storia della Monarchia Piemontese* (6 vols., 1861–69); *Della Vita e degli Scritti di Cesare Balbo* (1856); *Storia della Costituzione Inglese* (Turin). At first a civil engineer, then a lieutenant in the army, he was in 1846 appointed Professor of Modern History in the University of Turin; was a deputy of the Subalpine Parliament 1848–53; rector of the University of Turin 1862–65, and senator of Italy 1862, *seq.* D. at Turin, Feb. 24, 1883. See Manni, *Ricordi di E. Ricotti* (Turin, 1886); Ferrero, *Della vita e degli scritti di E. Ricotti* (Florence, 1888). Revised by A. R. Marsh.

Ridderstad, Karl Fredrik: novelist and poet; b. in Södermannland, Sweden, 1807; was a member of the Riksdag, where his eloquence and patriotism gained him a prominent position. He was the author of several historical romances from the time of Gustavus, the best of which are *Drabanten* (The Halberdier) and *Fürsten* (The Prince), and a number of novels of contemporary life in imitation of Eugene Sue, including *Stockholms Mysterier*, and *Den svarta handen* (The Black Hand, etc.), which show less force and originality. His dramas, among them *Drottning Kristina i Italien* (Queen Christina in Italy), are rhetorical and lack power of characterization. As a lyrical poet of the Tegnér school he was more successful. D. 1886. D. K. Dodge.

Riddle: See Enigma.

Riddle, Albert Gallatin: lawyer and author; b. at Monson, Mass., May 28, 1816; was taken in infancy to Northern Ohio; educated at Painesville Academy and at Western Reserve College; studied law; was prosecuting attorney for his county 1840–46, and again 1854–56; served in the Ohio Legislature 1848–50, and in Congress 1861–63; was for some time consul at Matanzas, and afterward settled as a lawyer at Washington, D. C. Author of *Students and Lawyers* (1873); *Bart. Ridgley* (1873); *The Portrait* (1874); *Alice Brand* (1875); *The House of Ross* (1887); *The Tory's Daughter* (1888), and other works. Revised by H. A. Beers.

Riddle, Joseph Esmond: classical scholar; b. in England about 1804; was educated at St. Edmund Hall, Oxford; took orders in the Church of England 1832; was for some years curate of Harrow; was Bampton lecturer 1852. D. at Cheltenham, Aug. 27, 1859. He was the author of a valuable *Latin-English Dictionary* (1836); an *English-Latin Dictionary* (1838); a *Manual of Christian Antiquities* (1839); *Natural History of Infidelity* (Bampton lectures, 1852); and many other works, theological and educational.

Revised by Benj. Ide Wheeler.

Riddle, Matthew Brown, D. D.: educator and author; b. at Pittsburg, Pa., Oct. 17, 1836; educated at Jefferson College, Pennsylvania, Western and New Brunswick Theological Seminaries, and Heidelberg; was Adjunct Professor of Greek in Jefferson College 1857–58; chaplain in the army 1861; pastor of the Reformed Dutch church, Hoboken, N. J., 1861–65; of the Second Reformed church, Newark, N. J., 1865–69; engaged in literary work in Europe 1869–71; was Professor of New Testament Literature and Exegesis in Hartford Seminary 1871–87; since 1887 has held the same chair in Western Theological Seminary. He was one of the revisers of the New Testament, and a member of the committee for revising the Confession of Faith. Of Lange's *Commentaries* he translated and edited Ephesians and Colossians, and edited the latter half of Romans and Galatians; prepared for the *International Commentary* Ephesians and Colossians, and Matthew, Mark, Luke, and Romans with Dr. Schaff; for the *International Revision Commentary*, Mark, Luke, and Romans; edited for the American edition of Meyer's *Commentary* Mark and Luke; revised and edited Robinson's *Greek Harmony of the Gospels* (1885) and his *English Harmony* (1886); edited for the *Library of the Ante-Nicene Fathers* in vol. vii. *The Teachings of the Twelve Apostles, The Second Epistle of Clement, The Apostolic Constitutions*, and in vol. viii. *The Clementine Recognitions and Homilies* and *The Apocrypha of the New Testament*; for the *Nicene and Post-Nicene Library* Chrysostom's *Homilies on Matthew* (first series, vol. x.) and Augustine's *Harmony* (vol. vi.); with Dr. J. E. Todd, prepared *Notes on the Sunday-school Lessons* (1878–81); and for the *American Supplement of the Encyclopædia Britannica* a number of articles covering most of the New Testament. C. K. Hoyt.

Rideau, rē̆e′dō′: lake, river, and canal of Ontario, Canada. The canal connects Ottawa on the Ottawa river with Kingston on the St. Lawrence, passing from Lake Rideau along Rideau river to the N., and through Mud Lake and along the Cataraqui to the S.; length, 126 miles. Projected in 1812, it formed an important means of internal communication, now rendered relatively unimportant by railways.

Rideing, William Henry: See the Appendix.

Ridgaway, Henry Bascom, D. D., LL. D.: clergyman and educator; b. in Talbot co., Maryland, Sept. 7, 1830; graduated at Dickinson College, Carlisle, Pa., in 1849; entered the ministry of the Methodist Episcopal Church; served as pastor in the Baltimore, Maine, New York, and Cincinnati conferences from 1851 to 1882. From 1882 he was professor in and president of Garrett Biblical Institute, Evanston, Ill. D. Mar. 30, 1895. He published *Life of Alfred Cookman* (1871); *The Lord's Land, a Narrative of Travels in Sinai, Arabia Petræa, and Palestine* (1876); and *Life of Edmund S. Janes, Senior Bishop of the Methodist Episcopal Church* (1882). A. Osborn.

Ridgefield: town; Fairfield co., Conn.; on the N. Y., N. H. and Hartford Railroad; 10 miles S. by W. of Danbury, 17 miles N. by W. of Norwalk (for location, see map of Connecticut, ref. 11–D). It is in an agricultural region, is a popular summer resort, and contains a public library, a savings-bank, a weekly newspaper, several manufactories, and many country residences of New York business men. Pop. (1880) 2,028; (1890) 2,235; (1900) 2,626.

Ridgetown: town of County Kent, Ontario, Canada; half way between the Thames river and the north shore of Lake Erie; a station on the Michigan Central Railroad (see map of Ontario, ref. 6–B). Pop. (1891) 2,254.

Ridgeville: town; Randolph co., Ind.; on the Mississinewa river, and the Grand Rapids and Ind., and the Pitts., Cin., Chi. and St. L. railways; 10 miles N. of Winchester, the county-seat, 59 miles S. of Fort Wayne (for location, see map of Indiana, ref. 5–G). It is in an agricultural region, has a private bank and a weekly newspaper, and is the seat of Ridgeville College (Congregational, organized as Free-will Baptist in 1867), which in 1894–95 had 7 instructors, 100 students, and $40,000 invested in grounds, buildings, and productive securities. Pop. (1890) 922; (1900) 1,098.

Ridgway: borough; capital of Elk co., Pa.; on the Clarion river and the Penn. and the Buffalo, Rochester and Pitts. railways; 118 miles S. E. of Erie, and 156 miles N. E. of Pittsburg (for location, see map of Pennsylvania, ref. 3–D). It is in a lumbering region, and contains tanneries, foundry, machine-shop, a private bank, and two weekly newspapers. Pop. (1880) 1,100; (1890) 1,903; (1900) 3,515.

Ridgway, Robert: ornithologist; b. at Mt. Carmel, Ill., July 2, 1850; educated in the common schools of that place. He was appointed zoölogist to the U. S. geological exploration of the 40th parallel, under Clarence King (1867–69), and is curator of the department of birds of the U. S. National Museum. He assisted Prof. Baird in the preparation of the technical portion of the *History of North American Birds* (1871–74). The three volumes were upon land-birds, and in 1884 two more volumes, upon water-birds, were issued. Although published as the works of Baird, Brewer, and Ridgway, the technical parts were entirely written by Ridgway. He is also author of *Report on Ornithology of the 40th Parallel*, an elaborate treatise on 262 species, and a work of 367 Government quarto pages; *A Nomenclature of Colors for Naturalists* (Boston, 1886); and *A Manual of North American Birds* (Philadelphia, 1887). Besides this, he is author of about 200 separate papers, some of considerable extent. Revised by F. A. Lucas.

Ridley, Nicholas, D. D.: bishop and martyr; b. at Unthank, Northumberland, England, about 1500; educated in the grammar school at Newcastle-upon-Tyne; graduated at Cambridge, 1522; obtained a fellowship at Pembroke College and was ordained priest 1524; studied theology at the Sorbonne, Paris, and at the University of Louvain 1527–29; became on his return to Cambridge under-treasurer to the university, and soon afterward senior proctor (1533) and public orator, in which capacities he protested against the usurpations of ecclesiastical jurisdiction by the papacy, procuring a decree of the university to the same effect; was appointed domestic chaplain to Archbishop Cranmer 1537, vicar of Herne, Kent, 1538, master of Pembroke College and chaplain to the king 1540; was accused of heresy, at the instigation of Bishop Gardiner, on account of having preached against the Six Articles, but acquitted by Cranmer 1541; became prebendary of Westminster 1545, Bishop of Rochester Aug. 14, 1547; bore an important part in all the ecclesiastical measures of the reign of Edward VI.; assisted Cranmer in compiling the Liturgy (1548) and framing the forty-one Articles of Religion; induced the king to change Greyfriars and St. Bartholomew's priories into charitable institutions; converted his own house at Bridewell into a workhouse; was instrumental in founding Christ's, St. Thomas's, and Bethlehem Hospitals in London; was a member of the commission which deposed Bonner, and was his successor as Bishop of London Apr., 1550; aided in the deposition of Gardiner, Bishop of Winchester; visited the Princess Mary at Hunsdon, desiring to gain her acquiescence in his views of Church reform, but was unsuccessful, 1552; concurred in the proclamation of Lady Jane Grey as queen, and was induced by the Duke of Northumberland to preach a sermon at Paul's Cross in defense of her title July 16, 1553; was committed to the Tower on the accession of Mary a few days later; was taken to Oxford Apr., 1554, to participate in a discussion with the court theologians on the Real Presence; was formally tried for heresy with Cranmer and Latimer by a commission named by Cardinal Pole, and condemned to death as an obstinate heretic Oct. 1, 1555, and, having refused to recant, was burned at the stake with Latimer in front of Baliol College, Oxford, Oct. 16, 1555. His *Life* was published by his descendant, Dr. Gloucester Ridley (1763), and his *Works*, chiefly tracts in favor of the Reformation, were edited, with a *Life*, by Rev. Henry Christmas for the Parker Society (London, 1841). Revised by S. M. Jackson.

Ridolfo, Zeno: See Schadow, Rudolph.

Ridpath, John Clark, A. M., LL. D.: historian and educator; b. in Putnam co., Ind., Apr. 26, 1840; educated at Indiana Asbury (now De Pauw) University; served as principal of Thorntown Academy, superintendent of Lawrenceburg schools, Professor of English Literature, Professor of Belles-lettres and History, and vice-president of De Pauw University. He published *Academic History of the United States* (1875); *Grammar School History of the United States* (1876); *Popular History of the United States* (1877); *Inductive Grammar of the English Language* (1879); *Life and Work of Garfield*, in English and German (1881); *History of the World* (3 vols., 1885; rev. ed. 4 vols., 1889); *Life of Washington Charles De Pauw* (1887); *Christopher Columbus: the Epoch, the Man, and the Work* (1890); *Columbia: a Quadricentennial Story* (1891); *Great Races of Mankind* (3 vols., 1892); *Epic of Life*, a poem (1894); and many monographs. D. July 31, 1900.

Rie'desel, Friedrich Adolph, Baron von: soldier; b. at Lauterbach, Hesse, June 3, 1738; studied at the College of Marburg; was an officer of a Hessian regiment in the British service during the Seven Years' war, distinguishing himself at the battle of Minden. In 1776 he was sent to America in command of the division of 4,000 Brunswickers hired by Great Britain. Arriving at Quebec, he spent a year in Canada exercising his troops in the Indian methods of warfare; joined Burgoyne in his campaign against Albany 1777; surrendered with Burgoyne Oct. 17, and was held a prisoner for over two years. After his exchange he was placed by Sir Henry Clinton in command of Long Island; was transferred to Canada, and returned to Germany, Aug., 1783. D. at Brunswick, Jan. 6, 1800. His *Memoirs, Letters, and Journals*, edited by Max von Eelking, were translated by William L. Stone (2 vols., Albany, 1868).—His wife, Friedrike Charlotte Luise (1746–1808), wrote an interesting series of letters descriptive of life in Canada, of the incidents of Burgoyne's campaign, and of her residence as a prisoner at Cambridge and elsewhere. They were translated by William L. Stone, and published under the title of *Letters and Journals relating to the War of the American Revolution* (Albany, 1867).

Riehl, Alois: philosopher; b. at Bozen, Tyrol, Apr. 27, 1844; educated in Vienna, Munich, and Gratz universities; became Professor of Philosophy at Gratz 1873, and at Freiburg in 1883. He has published *Der philosophische Kriticismus und seine Bedeutung für die positive Wissenschaft* (Leipzig and Tübingen, 1876–87: *Ueber wissenschaftliche und nicht wissenschaftliche Philosophie* (Freiburg im Breisgau, 1883); *Beiträge zur Logik* (Leipzig, 1892). J. M. B.

Riehl, Wilhelm Heinrich: historian and novelist; b. at Biberich on the Rhine, May 6, 1823; studied theology at Marburg, Göttingen, and Giessen; was for a number of years editor of various newspapers, and was finally appointed Professor of Kulturgeschichte at the University of Munich. He is the author of a number of excellent historical and ethnological works, the most prominent of which are *Naturgeschichte des Volks als Grundlage einer deutschen Nationalpolitik* (1851–69); *Die Pfälzer* (1857); *Culturstudien aus drei Jahrhunderten* (1859). He also published a series of well-written stories and novels, based on his historical and ethnological studies. D. in Munich, Nov. 16, 1897. J. G.

Rienzi, or **Rienze**, Cola, di: political reformer; b. in Rome about 1313; the son of a tavern-keeper; was an enthusiastic student of the old Latin poets and historians, and early conceived the purpose of restoring the ancient greatness of Rome. The city was in a condition of anarchy, distracted by the feuds among the lords and violence and cruelties against the people. One of the nobles assassinated Rienzi's brother, and the impossibility of bringing the murderer to punishment gave his visions at once a practical bearing; from a dreamer he became a reformer. After a vain attempt to induce the pope at Avignon to return to Rome and protect the people against the oppression of the nobles, Rienzi began the work of reform himself, well knowing that he could not carry it through without a revolution. On May 19, 1347, he proposed the establishment of a better form of government, recalling to the minds of his hearers the greatness of the ancient republic. Proclaimed tribune of the "holy Roman republic," he straightway forced the nobles to render him allegiance, and restored order in the city. So successful were his reforms that not only other Italian cities, but foreign monarchs, sent deputations and embassies to congratulate the tribune; but not content with restoring order and peace to Rome, he now seemed to aim at universal empire. The foreign princes were disgusted and offended at his arrogance. The Roman populace grew tired of his magnificent processions and of his taxes. The papal legates declared him a traitor and a heretic, and the nobles, taking advantage of the general discontent, attacked him in Dec., 1347, and drove him from the city seven months after his accession to power. After two years of retirement among the Franciscan monks in Southern Italy, he again appeared in the *rôle* of a political reformer at the court of the Emperor Charles IV., who sent him as a prisoner to the pope at Avignon. Innocent VI., however, the successor of Clement VI., thought that Rienzi could be used to restore

peace and order in Rome, where, during the rule of the nobles, things were worse than ever. Releasing him from prison, he sent him with Cardinal Albornoz to Rome in the quality of a senator, and in Aug., 1354, Rienzi made a sort of triumphal entry into the city. He was received with enthusiasm, but very soon it became apparent that the man's character had changed sorely under his misfortunes. His fantastic arrogance was the same, but now it was accompanied by caprice, suspicion, and cruelty. The nobles never acknowledged his government, and he had to besiege them in their castles; and the populace became so infuriated by his arbitrary measures that a crowd surrounded him on the stairs of the Capitol and killed him Oct. 8, 1354.

Revised by F. M. Colby.

Riesengebirge, ree'zen-ge-beer'ge [Germ., Giant Mountains]: a mountain range which, for a distance of about 50 miles, forms the boundary between Bohemia and Prussian Silesia. It is continued on the W. by the Erzgebirge, and on the E. by the Sudeten. The highest peak is Schneekoppe, 5,253 feet.

Rieti, rĕe-ā'tĕe (anc. *Reate*): town; in the province of Perugia, Italy; on the Velino; 40 miles N. E. of Rome (see map of Italy, ref. 5–E). The walls which still surround the town, now divided into the old and the new city, were reconstructed on earlier foundations in 1250. There is a fine cathedral, with a monument by Thorwaldsen. The first Bishop of Rieti is said to have been Prosdocimus, a disciple of St. Peter. The fruits and other agricultural products of the neighborhood are of a superior quality. Pop. 9,618.

Revised by M. W. Harrington.

Rif: a region of high mountains of plutonic origin fronting on the Mediterranean, between Tetuan and Melilla, Northwest Morocco. The mountains are well wooded with wild olive and cork trees. Troglodyte caves have been found. Small game abounds. Grain is grown in the rich valleys, and the natives, partly Berber and partly Arab tribes, are well-to-do and fine people physically, but so extremely fanatical that their country has not been satisfactorily explored, though lying near Europe. They are frequently in trouble with the government, as they often refuse to pay taxes. C. C. A.

Rifle [from *rifle*, to groove, from Dan. *rifle*, to chamfer, rifle, groove; cf. Ger. *riefeln*, rifle, deriv. of *riefe*, groove]: a firearm (large or small) having the barrel grooved to give a rotary movement to the projectile. See Small-arms and Rifling of Ordnance.

Rifle-bird: a name applied by the early Australian settlers to the birds of paradise of the genus *Ptilorhis*, on account of the fancied resemblance of their plumage to the colors of the rifle brigade. The plumage of the male is black with beautiful steely-blue and green reflections. These are particularly brilliant on the lower part of the throat. The general color of the female is brown. *P. paradisea* is found in New South Wales, and other species occur in other parts of Australia and in New Guinea. F. A. L.

Rifling of Ordnance: the system of grooves in the bore of a firearm designed to give rotary motion to the projectile. The adoption of oblong projectiles necessitated some device to keep them point first in the air, and this can be done only by giving to the projectile a motion of rotation about its longer axis sufficient to counteract the tendency to rotation about its shorter axis. The rifling consists of a number of spiral grooves separated by lands; into them fits the rotating device on the projectile (see Projectiles), which compels it to rotate while the motion of translation is is being imparted to it. The studded system of projectiles requires deeper grooves than the other systems, and the number of grooves must be the same as the number of rows of studs. The expansive and compressive systems do not require any special number or depth of grooves. By the twist of the rifling is meant the angle made by the tangent to the rifle-curve with the axis of the bore. The twist may be uniform or increasing. *Uniform twist* was the kind first employed. It has the advantage of simplicity, and the projectile leaves the muzzle of the gun with a steady flight. The disadvantage of the uniform twist is that the pressure on the rotating device is not uniform at all points in the bore. It requires a very large pressure at first to cause the projectile to start, and this pressure rapidly decreases. This high initial resistance will delay the starting of the projectile, and may cause the powder-gas to reach a sufficiently high pressure to strain the gun.

The *increasing twist* has, on account of these objections, been adopted in the guns of larger caliber. With the increasing twist there is a gradual change from little or no twist at the beginning of the rifling to the maximum twist at or near the muzzle. When the grooves start almost parallel to the axis of the bore, the initial resistance to the starting of the projectile is reduced to a minimum. This is as it should be, since it is in this vicinity of the bore that the maximum powder pressure occurs. The object is to select such a rifle-curve that its twist will increase as the powder pressure falls off, and thus keep constant the pressure on the rotating device.

The British have adopted the parabola, whose equation is

$$x^2 = py,$$

for all guns except the 80-ton muzzle-loading rifle, which has for its twist a semi-cubic parabola, whose equation is

$$x^3 = py^2.$$

The latter is the form of the rifling in the U. S. service for the larger caliber guns. The twist of the army guns begins with 1 turn in 50 calibers at the breech, and increases to 1 turn in 25 calibers at a point about 2 calibers from the muzzle, where the twist becomes uniform for the rest of the distance in order to steady the projectile. In the naval guns the twist varies from 1 turn in 180 calibers at the breech to 1 turn in 30 calibers at the muzzle. The angular velocity with which a projectile leaves the muzzle, for the same muzzle velocity, depends only on the twist of the rifling at the muzzle. To cut the rifling in a gun it is mounted on a rifling-machine. A strip of steel is then bent into the developed form of the curve of the rifling and fixed to the bed of the machine to serve as a guide for the rifling-bar, which has a motion of rotation and translation, and carries at its end a cylindrical head with cutters.

J. C. W. Brooks.

RIFLING OF THE GUNS IN THE U. S. SERVICE.

KIND OF GUN. BREECH-LOADING, STEEL.	Kind of twist.	Twist in number of calibers.	Number of grooves.	Width of grooves, inches.	Depth of grooves, inches.	Width of lands, inches.

Ri'ga: capital of the government of Livonia, Russia; on the right bank of the Dwina, 7 miles from its mouth in the Gulf of Riga; 350 miles by rail S. W. of St. Petersburg (see map of Russia, ref. 6–B). The fortifications of the city have been razed and the walls converted into promenades which surround the old city, separating it from its suburbs. The former has narrow streets and mediæval houses, while the

latter are laid out in broad streets with modern buildings. Among the public buildings the most notable are St. Peter's church, built in 1406, with a tower 460 feet high; the governor's residence, formerly the palace of the grand-master of the order of the Knights of the Sword, built 1494–1515; the city-hall, and the new exchange. There are manufactories of cotton, woolen, linen, and iron goods, cigars, corks, spirits, oil, glass, paper, jute, etc., and the ship-building industry is very flourishing. Riga derives its greatest importance, however, from its commerce. An average of 2,400 vessels, of over 1,000,000 tons, enter its harbor annually. The value of its annual imports—comprising coal, salt, iron, steel, dyewoods, fish and wine, etc.—averages about 22,000,000 rubles, and that of its exports—comprising flax, hemp, timber, grain, hides, oilcake, camel and horse hair, and mineral oil—averages about 55,000,000 rubles. The city was founded in the beginning of the thirteenth century by Albert von Apeldern, Bishop of Livonia. He established the order of the Knights of the Sword, which within a few years was united to the order of the Teutonic Knights. The prosperity of Riga began when it became a member of the Hanseatic League under the protectorate of Poland. It was taken by Gustavus Adolphus in 1621, and incorporated with Russia in 1710. Nearly half the inhabitants are Germans and German-speaking Jews, the remainder being about equally divided between Russians and Letts. Pop., with suburbs (1897) 282,943.

Riga, Gulf of: an inlet of the Baltic, 100 miles long, 80 miles broad, bounded by the Russian governments of Kurland, Livonia, and Esthonia. It receives the Dwina. Oesel is a large island at its entrance.

Rigdon, Sidney: Mormon elder; b. in St. Clair township, Allegheny co., Pa., Feb. 19, 1793; received a fair English education, and was working as a printer at Pittsburg when about 1812 a manuscript was offered for publication by an eccentric preacher named Solomon Spaulding. It was entitled *The Manuscript Found, or The Book of Mormon*, and pleased Rigdon so much that he made a copy before it was returned to Spaulding, who died soon after. In 1819 Rigdon became a Baptist preacher; about 1821 a Disciple minister; and though at first professing orthodoxy, soon began to propagate singular doctrines connected with the manuscript in question. In 1829 he became acquainted with Joseph Smith, and with him devised the publication of *The Book of Mormon* as the basis of a new sect. He accompanied Smith to Kirtland, O., to Missouri, and to Nauvoo, where he was one of the presidents of the Church; was one of the originators of the "new revelation" permitting polygamy; was twice tarred and feathered, several times imprisoned, and was a candidate for the succession to the leadership on the death of Smith. On the election of Brigham Young (1844) Rigdon refused to acknowledge his authority, was excommunicated, returned to Pittsburg, Pa., and lived in obscurity; later removed to Friendship, N. Y., where he died July 14, 1876.

Rigg, James Harrison, D. D.: minister and educator; b. at Newcastle-on-Tyne, England, Jan. 16, 1821; educated at the Old Kingswood School; entered the Wesleyan Methodist ministry in 1845; appointed principal of Westminster Training College for Schoolmasters 1868; president of the Wesleyan Methodist Conference 1878–79, and for the second time in 1892–93; member of royal commission of national education in England 1886–88; on the staff of *The Quarterly Review* from the first (1853); one of the editors for many years, and sole editor since 1885. He has published *Principles of Wesleyan Methodism* (London, 1850); *Congregationalism and Connexionalism Contrasted* (1852); *Modern Anglican Theology* (1857; 3d ed. enlarged, with *Memoir* of Kingsley, 1879); *Essays for the Times on Social and Ecclesiastical Subjects* (1866); *The Sabbath and the Sabbath Law before and after Christ* (1869); *The Living Wesley* (1875; new ed., enlarged as *Centenary Life of Wesley*, 1891); *Churchmanship of John Wesley* (1878); *The Connexional Economy of Wesleyan Methodism* (1879); and important pamphlets on ecclesiastical and educational topics.

A. Osborn.

Riggs, Elias, D. D., LL. D: missionary and linguist; b. at New Providence, N. J., Nov. 10, 1810; graduated at Amherst College 1829 and at Andover Theological Seminary 1832. He was in Athens, Greece, 1832–34, in Argos 1834–38, in Smyrna 1838–53, and from 1853 in Constantinople, except in 1857–58, when he taught Hebrew and the cognate languages in Union Theological Seminary, New York. He translated the Bible into Bulgarian, Armenian, and Turkish, and published *A Manual of the Chaldee Language* (1832; 2d ed. 1858); *Grammar of the Modern Armenian Language* (1847); *Vocabulary of Words used in Modern Armenian, but not found in the Ancient Armenian Lexicons* (1847); *Notes on the Grammar of the Bulgarian Language* (1847); *Outline of a Grammar of the Turkish Language as written in the Armenian Character* (1856); *Suggested Emendations of the Authorized English Version* (1873); *Notes on Difficult Passages of the New Testament* (1889), and other writings. Revised by Benj. I. Wheeler.

Riggs, James Stevenson, D. D.: minister and New Testament scholar; b. in New York, July 16, 1853; graduated at the College of New Jersey in 1874; spent two years at Leipzig and Tübingen; graduated at Auburn Theological Seminary in 1880. After a pastorate of four years in Fulton, N. Y., he was Professor of Biblical Greek in Auburn Theological Seminary 1884–92; since 1892 Professor of Biblical Criticism and the New Testament. He is the author of many articles and pamphlets, and of *The Bible in Art* (1895).

Riggs, Kate Douglas (*Wiggin*): See the Appendix.

Right Ascension: in astronomy, the angular distance between the first point of Aries (*q. v.*) and the point in which the circle, passing through a heavenly body and the poles of the heavens, intersects the celestial equator. It is always measured from W. to E., and corresponds to longitude on the earth, as Declination (*q. v.*) corresponds to latitude. The right ascension of a heavenly body is ascertained by a transit instrument and a clock. These determine the meridian passage and the time at which it takes place, respectively. Right ascension is usually expressed in time, one hour corresponding to 15° on the celestial sphere.

R. A. Roberts.

Rights: See Jurisprudence, Political Science, and Justice.

Rights, Bill of: See Bill of Rights.

Rigi, or **Righi**, ree'gĕe: a mountain of Switzerland, in the canton of Schwytz. It is isolated between the lakes of Zug and Lucerne, and rises 5,902 feet above the sea, 4,500 feet above the lake. Several carriage-roads and two railways lead from the base of the mountain to the top, which offers a very extensive view.

Rigor Mor'tis [Lat., rigor or stiffness of death; cf. *rige're*, be stiff]: the condition of muscular rigidity developing shortly after the death of the body. It is due to suspended nutrition of the tissues, and begins when their response to artificial irritation and electricity ceases. Rigor mortis develops at a variable period after death, and when established lasts a variable time. In persons who die suddenly, as by accident or by heart disease, and in whom the muscles are well developed and nourished, rigor mortis may be postponed for many hours—twelve or twenty-four—and may then persist for two or three days. Reversely, when death is the result of exhaustive disease, the blood is impoverished and the muscles are wasted and flabby, rigor mortis develops speedily—within an hour, or even a few minutes—and is incomplete and of brief duration. As soon as rigor mortis passes off, the relaxed body begins to decompose. Rigor mortis was formerly explained as a state of contraction, the death-act of the muscular fiber. It is now believed to be due to the separation and coagulation of the albuminoid substance in the fluid of the muscle, following the cessation of nutrition. Revised by W. Pepper.

Rigveda: See Sanskrit Literature.

Riley, Charles Valentine, M. A., Ph. D.: entomologist; b. in London, England, Sept. 18, 1843; studied at college, Dieppe, France, 1854–57, and Bonn, Prussia, 1857–59; removed to U. S. 1860; studied practical agriculture 1860–63; connected with *The Evening Journal* and *Prairie Farmer* at Chicago 1863–68; appointed State entomologist of Missouri 1868, in which year he began, with Benjamin D. Walsh, State entomologist of Illinois, the publication of *The American Entomologist*; president of the Academy of Science of St. Louis 1876–77; appointed chief of the U. S. entomological commission (with Dr. Alpheus S. Packard, Jr., and Prof. Cyrus Thomas) under the Interior Department 1877; U. S. entomologist under the Department of Agriculture 1878; curator of insects U. S. National Museum 1881; general secretary American Association for the Advancement of Science 1881. D. in Washington, D. C., Sept. 14, 1895. He published nine annual reports on the insects of Missouri (1868–77) and three annual reports as U. S. entomologist. He was also the author of *The Locust Plague in the United*

States and of *Potato Pests*, and of many other works on insects injurious to vegetation. The French Government presented him in 1873 with a grand gold medal for services rendered to French grape-culture, and he received the only first gold medal awarded to an American at the international forestry exhibition, Edinburgh, 1884. He presented to the National Museum, Washington, D. C., his collection of over 20,000 species of North American insects.

Riley, James Whitcomb: poet; b. at Greenfield, Ind., in 1853. He became a sign-painter, then a strolling player, and afterward an editorial writer on the Indianapolis *Journal*. His dialect poems became very popular, and he took to giving public recitations of them in many cities. Among his books are *The Old Swimmin' Hole* (1883); *The Boss Girl* (1886); *Afterwhiles* (1888); *Pipes o' Pan* (1889); *Rhymes of Childhood* (1890); *Green Fields and Running Brooks* (1892); *Armazindy* (1894); *A Child-World* (1896).

Rime: a more correct spelling of the word Rhyme (*q. v.*).

Rimini, ree'mĕe-nĕe (anc. *Ariminum*): town; province of Forlì, Italy; on the Marecchia, near the Adriatic; 44° 4′ N. lat., 12° 34′ E. lon. (see map of Italy, ref. 4–E). It is walled and well built, with fine streets and squares, but has an air of decay. The main street is the Corso, the two principal squares, Piazza Cavour and Piazza Giulio Cesare, opening upon it. The latter derives its name from the tradition that on a stone pedestal, still seen, Cæsar harangued his troops after crossing the Rubicon. The city possesses two remarkable antiquities—the bridge of Augustus, of pure white marble with five arches, begun by that emperor and finished by Tiberius, still in good preservation, and the Porta Romana, a triumphal arch, erected 27 B. C. in honor of Augustus. There are also ruins of an amphitheater. The Cathedral of San Francesco, built in the fourteenth century and splendidly restored in the fifteenth by Sigismondo Malatesta, is a masterpiece of the Gotho-Italic. Several other churches and the Palazzo del Comune contain admirable pictures. The house of Francesca di Rimini, whose story suggested the most pathetic passage in Dante's *Inferno*, is still pointed out. So, too, is St. Anthony's chapel, and another chapel on the canal indicating the scene of his famous sermon to the fishes. In the Gambelunga Library, founded 1617, are 23,000 volumes. Rimini occupies the site of an ancient Umbro-Etruscan city, subsequently a Roman stronghold, enlarged and embellished by Julius Cæsar and later Roman emperors. It became the seat of an archbishop in 260; a great council of 400 Western bishops was convened here in 359. Under the exarchate of Ravenna it was the chief city of the maritime Pentapolis, the other four towns being Pesaro, Fano, Sinigaglia, and Ancona. From 1200 until 1503 it was, save for a brief period, governed by the great Ghibelline family of the Malatestas. Their tombs are seen in the cathedral, and their quaint castle is now a prison. After 1528 it was definitely included as papal territory in the so-called legation of Ravenna, until in 1860 it was united to the kingdom of Italy. The fisheries furnish its principal industry. The harbor is nearly filled up by sand, but vessels of 100 tons may enter the Porto Canale. Rimini is a popular resort for sea-bathing. Pop. 10,838. E. A. Grosvenor.

Rimouski, ree̊-moos-kee': popular summer resort and port; on the right bank of the lower St. Lawrence, County Rimouski, Quebec, Canada; station on the Intercolonial Railway, 184 miles N. E. of Quebec (see map of Quebec, ref. 2–F). It is the see of a Roman Catholic bishop, and has a fine cathedral and a college. In the Rimouski river and lakes near by the trout and salmon fishing is good. The chief industries are fishing and lumber. Pop. (1891) 1,417.

Rimsky-Korsakow, Nicolaus A.: See the Appendix.

Rin'derpest, Cattle-plague, or **Steppe Murrain** [*rinderpest* = Germ.; *rinder*, cattle, plur. of *rind*, ox, cow + *pest*, plague]: a contagious eruptive fever among cattle, endemic or nearly so in Russia, and occasionally sweeping as a most destructive epizoötic throughout Europe. It considerably resembles smallpox in its symptoms and progress. It is not confined to neat cattle, but attacks nearly all other ruminant mammals, and even some others. Man, the horse, swine, and fowls are quite exempt from it, so far as is known. The best treatment is the prompt destruction of all diseased animals. The only other treatment advised is the use of strong disinfectants and occasional stimulation; but it is found very difficult by any system of isolation and treatment to prevent the spread of the disease. From 30 to 90 per cent. of the diseased animals die under any treatment.

Rindfleisch, rint'flish, Georg Eduard, M. D.: pathologist; b. at Cöthen, duchy of Anhalt, Dec. 15, 1836; studied medicine in the University of Berlin, graduating M. D. in 1860; in 1861 began to practice in Breslau; in 1862 became Extraordinary Professor of Pathology at the University of Zurich; accepted the same chair at Bonn in 1874, subsequently filling the chair at the University of Würzburg. He is one of the foremost living pathologists. His master work, *Lehrbuch der pathologischen Gewebelehre* (1867; 6th ed. 1886), has been translated into the principal European languages. S. T. Armstrong.

Rinehart, William Henry: sculptor; b. in Carroll co., Md., Sept. 13, 1825; at the age of eighteen became assistant to a stonecutter; at the age of twenty-one went to Baltimore, where he apprenticed himself to a marble-worker. In 1855 he sailed for Italy, and remained there two years. In Baltimore he modeled several busts, a fountain figure for the U. S. General Post-office, and two supporting figures (*Indian* and *Backwoodsman*) for the clock in the new House of Representatives, Washington. In 1858 he settled in Rome. At the instance of Crawford's widow he completed the modeling of the bronze doors of the U. S. Capitol, which Crawford had left unfinished at his death; produced the life-size *Angel of the Resurrection* and *Jesus*, also a group of two *Sleeping Children*. One of his highest works was of this period—*Love Reconciled with Death*—bronze, life-size, for the tomb of Mrs. Walters. His portrait-busts became widely recognized. The State of Maryland commissioned him to make an heroic statue in bronze of Chief Justice Taney for the State-house grounds, Annapolis. His statue of *Clytie Forsaken by Apollo* was bought by a gentleman of Baltimore, who gave it to the Peabody Institute of that city. Besides the works already named, Rinehart in his later years produced the group of *Latona and her Children*, *Antigone*, *Atalanta*, and *Endymion*. D. in Rome, Oct. 28, 1874.
Revised by Russell Sturgis.

Ring [O. Eng. *hring*: O. H. Germ. *hring*, *ring* (> Mod. Germ. *ring*): Icel. *hringr* < Teuton. *hringos*: O. Bulg. *kragŭ*, circle]: an ornament worn on the finger, frequently invested with symbolical meaning. From the remotest antiquity the finger-ring (usually connected with a seal) was an emblem of an authority which could be delegated by the simple process of delivering it to an agent. The cases of Pharaoh and Ahasuerus are instances in point. Precious stones of great value were employed in rings by the Hebrews and Persians, and later by the Greeks and Romans. They have long been in almost universal use in Christendom as tokens of marriage or betrothal, and are often engraved with mottoes. The "fisherman's ring" is an indispensable article of the papal chancery, and the custom has been imitated by the bishops of some Christian churches. Magical virtues have often been ascribed to rings both by pagan and Christian nations, and traditions of poison concealed in rings have played a large part in the criminal annals of the Middle Ages.

Ring, Bernard Jacques Joseph Maximilien, de: archæologist; b. at Bonn, Rhenish Prussia, May 27, 1799, of Alsatian parents; received a completely French education; devoted himself from his sixteenth year to the study of archæology; resided from 1815 to 1848 in various places of Germany, investigating German antiquities, and wrote *Vues pittoresques des Vieux Châteaux du Grand-duché de Bade* (folio, 1829): *Description du Château de Tubingue* (1835); *Établissements celtiques dans le Sud-ouest de l'Allemagne* (1842); *Histoire des Germains depuis les temps les plus reculés jusqu'à Charlemagne* (1850); *Établissements romains du Rhin et du Danube* (2 vols., 1852–53, crowned by the Academy); *Essais sur la Rigsmaal-Saga et sur les trois Classes de la Société germanique* (1854); and *Histoire des Peuples opiques, de leur Législation, de leur Mœurs, de leur Langue, etc.* (1859). D. at Bischheim, Alsace, in 1875.

Ringbone: an exostosis or bony tumor on the coronet of the horse, most common on overworked horses, but sometimes seen on colts, or even newly dropped foals. Ringbone may stiffen and spoil a horse for the road, although not unfrequently there is no practical trouble from it; but it injures a horse's market-value, and is practically incurable.

Ringworm: a parasitic cutaneous disease occurring most frequently among children and upon the face and neck. It is properly called *tinea circinata*, being analogous to *tinea sycosis*, or barber's itch. These diseases are due to a parasitic growth, consisting of innumerable sporules which

find a nidus in the hair-follicles and excite secondary inflammation of the skin. Ringworm is contagious, not only from person to person by close contact, but in the uncleanly is transplanted from spot to spot on the head and hands or wrists. The treatment is by parasiticides, or remedies destructive to parasitic life; local application of tincture of iodine, iodine and ammonia, sulphurous acid, sulphur dry or in ointment, carbolic acid, creosote, oil of cade, mercurial ointment, oleate of mercury, solution of corrosive sublimate, and cantharidal collodion. Revised by W. Pepper.

Rink, Henrich Johann: naturalist; b. at Copenhagen, Denmark, Aug. 26, 1819. He took part in the Galatea expedition around the world 1845–47, and as a result published *Die nikobarischen Inseln* (1847). He held many positions in connection with Greenland, and made extensive researches in that country. In 1852 he published *Den geografiske Beskaffenhed af de danske Handelsdistrikter i Nordgrönland*; in 1866–71 he published his *Eskimoiske Eventyr og Sagn*; in 1875 *Om Grönlands Indland og Muligheden af at bereise samme.* In 1877 he published in London *Danish Greenland*, and in 1887, in Copenhagen, *The Eskimo Tribes*, with a comparative vocabulary. D. Christiania in 1894. Revised by Rasmus B. Anderson.

Riobamba, rēĕ-ō-baam′băă: a town of Ecuador; 103 miles S. S. W. of Quito; on a plain between the Chimborazo and Altar Mountains, 9,100 feet above the sea (see map of South America, ref. 3–B). It was an ancient Indian town, and important during the conquest. On Feb. 4, 1797, it was completely destroyed by an earthquake in which over 20,000 persons are said to have perished. The new town is badly built and has little importance except as a station on the road from Quito to Guayaquil. Pop. 12,000. H. H. S.

Rio Branco: See Rio Negro.

Rio Bravo: the Rio Grande (*q. v.*).

Rio Cuarto, ree′ō-kwaar′tō (formerly *Concepcion*): a town of the province of Córdoba, Argentine Republic; on the Rio Cuarto, 112 miles S. of Córdoba (see map of South America, ref. 8–D). Until 1874 it was a frontier post, exposed to Indian attacks; it is growing rapidly, and is the second town of the province in population, an important railway center, and the emporium of a rich grazing district. Pop. (1892) 14,000. H. H. S.

Rio de Janeiro, Portug. pron. ree′ō-dā-zhăă-nāi′-rō [Portug., river of January, a name given to the bay, then supposed to be a river's mouth, because it was discovered on Jan. 1]: a maritime state of Brazil, bordering on São Paulo, Minas Geraes, and Espirito Santo, and inclosing the Municipio Neutro or federal district. Area (excluding the Municipio Neutro), 26,634 sq. miles. It includes the mountainous districts of the Coast Range and part of the valley of the Parahyba river, with lowlands near the mouth of the latter containing the Lagoa Feia (see Feia); there are also lowlands and lagoons along the coast. Rio de Janeiro is one of the great coffee-producing states, and sugar-cane and rice are raised on the lowlands. Most of the trade is through the port of Rio de Janeiro. The manufactures are considerable. Up to 1894 the capital was Nictheroy; it is now Petropolis. Pop. (1894) estimated, 1,390,398. H. H. S.

Rio de Janeiro: capital and most important port of Brazil, and the largest city of South America; on the west side of the bay of Rio de Janeiro; lat. (of the observatory) 22° 54′ 24″ S., lon. 43° 10′ 21″ W. (see map of South America, ref. 7–G). The bay is perhaps the most magnificent harbor in the world. The entrance, between high rocks, is about a mile wide and perfectly clear; within, it expands into a broad sheet with many bays, stretching inland for 17 miles, the whole surrounded by strangely formed mountains and hills, with the needle-like pinnacles of the Serra dos Orgãos at the northern end. Most ships can be loaded directly at the fine docks. The city occupies flat land and hills partly surrounding a group of wooded mountains. The older streets are narrow and often crooked, with few pretentious buildings; the newer ones, farther back from the bay, are wide and lined with substantial houses. The business center, from which street-cars run to the outskirts, is the narrow Rua do Ouvidor; it is lined with retail shops, *cafés*, etc., and is a favorite afternoon promenade; no carriages are allowed on it. The finest dwellings, surrounded by gardens, are in the outskirts and on the hills; the beauty of the scenery in these outskirts elicits the admiration of every tourist; Botofogo, for example, lies between the mountains and a placid arm of the bay, with the Sugar Loaf rock, 1,200 feet high, before it. There are several public parks, including the beautiful Passeo Publico, and the Botanical Garden in the suburbs. The handsomest church and the most richly decorated building in South America is the Candelaria. The old monasteries are now used for public buildings, and have been supplemented by handsome modern structures, such as those of the Department of Agriculture, the national printing-office, and the mint. There are several hospitals, and that called Mizericordia is said to be the largest and most richly endowed in the world. There is a well-appointed observatory; a national library, the largest and most valuable in South America, besides several other libraries; polytechnic school, national college, schools of medicine, fine arts, etc., and a naval school. The museum occupies the old imperial palace, an unpretentious building, but surrounded by a beautiful park; the collections in some branches are very valuable. The bay is defended by several forts, and there is an extensive navy-yard. The Corcovado Mountain, about 2,500 feet high, has precipitous sides looking down on the streets; a mountain-railway runs to a hotel on the summit. Other beautiful resorts are the high valley of Tijuca, and Nictheroy, on the other side of the bay.

Rio de Janeiro has a large foreign element, and much of the trade is in the hands of foreign merchants. The commerce is very important. Rio exports more than half of the total coffee product of the world, or some 400,000,000 lb. annually; the crop is brought in by railways. The largest exports, especially of coffee, are to the U. S.; most of the imports are from Europe. Regular steamers run to the U. S., Europe, the western coast of South America, New Zealand, etc. The climate is warm from May to October, temperate during the rest of the year, and always damp and somewhat changeable; lung diseases are consequently prevalent. Notwithstanding good drainage and modern sanitary improvements, yellow fever is generally prevalent during the warm months, and at intervals there are severe epidemics. A good but somewhat inadequate water-supply is obtained by fine aqueducts from the Corcovado and Tijuca. The bay was discovered (probably) by João Manoel and Amerigo Vespucci Jan. 1, 1502. French Protestants tried to form a settlement on it, but were driven out in 1567 by the Portuguese, who then founded São Sebastião, or Rio de Janeiro. It became the capital of Southern Brazil in 1762, and of the whole of Brazil in 1774. From 1808 to 1821 it was the residence of the Portuguese court, and hence the capital of Portugal. The revolution of 1889 broke out here; during the naval rebellion of 1893–94 the city was bombarded, but not seriously injured. Population of the city proper (1893) about 300,000. The Municipio Neutro, which includes the city, is a federal reservation, similar in character and government to the District of Columbia in the U. S.; area, 538 sq. miles; estimated population, with the city (1893), 471,775. See Valle Cabral, *Guia do Viajante no Rio de Janeiro* (1884); Agassiz, *A Journey in Brazil* (1868). Herbert H. Smith.

Rio de la Plata: See Plata, Rio de la.

Rio de Oro: a bay (mistaken by an early explorer for a river) lying between the African mainland and the Ed-Dajla peninsula, on the Atlantic coast, N. of the Tropic of Cancer. It is in Spanish territory, and the Spaniards have establishments there devoted chiefly to fishing. The Spanish possessions on this Saharan coast extend (since 1884) from Cape Bojador to Cape Blanco, and part of the region inland consists of the oases of Adrar, where grain is raised to some extent, and many sheep, goats, camels, horses, and cattle graze. The chief town of Adrar is Shingeti, and 30,000 people live there. C. C. Adams.

Rio Grande, or **Rio Grande del Norte**, ree′ō-graan′dā-dĕl-nōr′tā [Span., great river of the north]: a large river which rises in Southwestern Colorado, flows first E. and then S. through New Mexico, flows thence S. E., forming for several hundred miles the boundary between the U. S. and Mexico, and falls into the Gulf of Mexico after a course of about 1,800 miles. It is navigable for small boats only for about 450 miles, or to Kingsbury Rapids; is generally shallow, frequently interrupted by rocks and cataracts, and is subject to periodical inundations near its mouth. Its principal tributary is the Rio Pecos. Brownsville, Tex., and Matamoras, Mexico, are situated on opposite sides of the Rio Grande, 35 miles above its mouth.

Rio Grande do Belmonte: See Jequitinhonha.

Rio Grande do Norte: an eastern maritime state of Brazil, between Ceará and Parahyba, with a coast including

the angle formed by Cape St. Roque. Area, 22,195 sq. miles. The coast-lands are low, bordered by immense sand-dunes, and without good harbors; the interior is an irregular plateau continuous with that of Ceará, and like it in its long, dry seasons and occasional destructive droughts. This is one of the poorest and least populous of the Brazilian states; grazing and sugar and cotton planting are the only industries of importance; hides, sugar, and a little cotton and rice are exported. Pop. (1894) estimated, 347,818. The capital and principal town and port is Natal.

HERBERT H. SMITH.

Rio Grande do Sul [Portug., great river of the south]: the common name of São Pedro do Rio Grande do Sul, the southernmost and one of the most important states of Brazil, between Santa Catharina, the Atlantic, Uruguay, and the Argentine Republic. Area, 91,335 sq. miles. Near the coast are two large lakes, the LAGOA DOS PATOS (*q. v.*) and the Lagoa Mirí, the latter partly in Uruguay; they are separated from the ocean by low and swampy lands, and communicate with it by the navigable Rio Grande do Sul, which gives its name to the state. Inland from the lakes the surface is varied, but generally hilly, rising to low mountains in the center and N., and subsiding to plains westward, where the river Uruguay forms the boundary with the Argentine Republic. The river JACUHY (*q. v.*) and the lakes form interior waterways of great importance, and the upper Uruguay is also navigable for vessels of light draught. To the N. of the Jacuhy the land is wooded, fertile, and well suited for agriculture; large tracts are taken up by thriving agricultural colonies of Germans and Italians, their trade centering at Porto Alegre, the capital. An extensive region in the northwest is unsettled. S. of the Jacuhy the land is open, resembling Uruguay; it supports great herds of cattle, which are marketed at Pelotas; the lower classes in this district resemble the Uruguayan gauchos. The exports are hides, dried meat, maize, beans, etc. The manufactures (in the northern part only) are growing in importance. The state lies beyond the tropics; frosts occur during the winter (June–September), and light snows fall on the hills. The revolutionary spirit, which has frequently shown itself in this state, is nearly confined to the southern or pastoral districts. An attempt to secede and form a republic begun in 1835 was put down only after nearly ten years of civil war, and there was a formidable rebellion 1892–94. Pop. (1894) estimated, 774,406, including 150,000 German and Italian colonists. HERBERT H. SMITH.

Rio Grande do Sul: city; the most important port of the state of the same name; on the Rio Grande do Sul, a channel through which the Lagoa dos Patos discharges into the Atlantic (see map of South America, ref. 8–F). The mouth of this channel is obstructed by shifting sandbars, which at intervals have nearly closed the passage, and expensive engineering works have failed to keep it clear. Vessels drawing 12 feet pass at favorable times. The city, on flat land backed by swamps, is important only for its commerce. A railway connects it with Pelotas, and steamers ply regularly on the lakes. Pop. 20,000. H. H. S.

Rioja, rĕe-ō′*k*ha, FRANCISCO, de: poet; b. at Seville, Spain, about 1585. He was educated in the University of Seville, and obtained such knowledge of Greek, Latin, and Hebrew as to excite the admiration of his contemporaries. He entered the Church, and seems at first to have had a place at Seville. About 1614, however, he went for a time to Madrid, apparently attracted by the great Count-Duke Olivares, who seems to have known and liked him before he had himself risen to power. This first taste of life at court was probably not to Rioja's mind, for shortly after he was again in Seville, writing his excellent poetical *Epístola moral á Fabio*, full of sound advice as to the superiority of a quiet and unambitious life. But in 1321 the death of Philip III. gave Olivares entire direction of affairs, and the poet was unable to resist an invitation from him to come to Madrid as his friend and counselor. He was given the place of librarian of the royal library, and was for a time chronicler of Castile. He also made the acquaintance of the best wits of the court, and Lope de Vega, Cervantes, Montalván, and others spoke of him as one of the best poets and scholars of the time. It is probable that his residence at Madrid was broken by a period in Seville, and it is certain that he had the bitter experience of imprisonment by reason of a false charge made to Olivares about him. When the latter fell from power in 1643, however, Rioja was one of those who accompanied him from the court. In 1645 Olivares died and the poet retired to Seville. But once more, in 1654, this time apparently by royal command, Rioja removed to Madrid, being given a position as councilor in the supreme court of the Inquisition, which he held till his death, which occurred at Madrid, Aug. 8, 1659. The body of Rioja's poetical work is not great, but almost everything he wrote is distinguished by beauty of form, delicacy of style, and deep feeling for nature. Hence few poets of the Siglo de Oro are better known. His *Poesías* have been published, with extensive biography, by D. Cayetano Alberto de la Barrera (*Soc. de Bibliófilos Españ.*, Madrid, 1867). The same editor has also issued *Adiciones á las poesías de D. Francisco de Rioja* (Seville, 1872). A. R. MARSH.

Rioja, La: a northwestern province of the Argentine Republic, between Catamarca, Córdoba, San Luis, San Juan, and Chili. Area, 31,500 sq. miles. The Andes, with an average height of 13,000 feet, form the western frontier, and there are several parallel ranges covering more than half the province. The high valleys between these are the inhabited regions. The southeastern part is mainly an arid plain very thinly settled. The climate is very dry and little of the land can be cultivated without irrigation. This and the lack of communications make Rioja one of the poorest provinces. The principal industry is agriculture. Wine, wheat, maize, lucern, etc., are produced. There are rich deposits of copper, silver, and gold, as yet but little utilized. The province long resisted Rosas and the confederation, and until 1863 it was distracted by wars. Pop. about 70,000. La Rioja (pop. about 10,000), the capital and largest town, was founded in 1591. H. H. S.

Rion: See PHASIS.

Rio Negro [Span., black river]: a river in the region of the Argentine Republic known as Patagonia; rises in the Andes, flows N. E., E., and E. S. E., and enters the Atlantic near lat. 41° S. Length about 650 miles. Nearly the whole course is said to be navigable for vessels of light draught, and small steamers now ply on the lower portion, where there are several thriving settlements. H. H. S.

Rio Negro: one of the most important northern tributaries of the Amazon; rises in Southern Venezuela and (after entering Brazilian territory) keeps a general E. S. E. course to its mouth in lon. 59° 58′ W. Length about 1,350 miles. The lower course is broad and lake-like, and is navigable for about 600 miles. Above this about 20 miles are obstructed by rapids, but beyond them the river is navigable for a long distance. Above the rapids it is connected by the CASSIQUIARE (*q. v.*) with the Orinoco. The principal western branch is the Uaupés, rising in the Colombian Andes, probably over 700 miles long, and navigable. The Rio Branco rises on the confines of Venezuela, British Guiana, and Brazil, and flows S. over 400 miles to the Rio Negro. All these rivers run through generally forest-covered regions with but few civilized settlements. They are much frequented by rubber gatherers and traders. Manáos, the capital of the state of Amazonas, is at the mouth of the Negro. H. H. SMITH.

Rio Negro: a territory of the Argentine Republic; in the northern part of Patagonia, bordering on Neuquen, La Pampa, Buenos Ayres, the Atlantic, Chubut, and Chili. Area said to be 130,000 sq. miles, but the limits are not yet fixed. The Andes and their spurs cover the southwest. Most of the remaining surface is a plateau crossed by the valleys of the Colorado on the N. and the Rio Negro farther S. Large tracts are suitable for grazing. The territory, abandoned until about 1880, is being rapidly taken up for grazing purposes. In 1895 there were about 10,000 inhabitants, and the exports were valued at $1,560,000. The capital, Viedma, has about 3,000 inhabitants. H. H. S.

Rio São Gonçalo: See LAGOA DOS PATOS.

Riot [from O. Fr. *riote*, *riotte*, quarreling, brawling, reveling, feasting: Ital. *riotta*, quarrel, probably from dimin. of Lat. *reus*, defendant, the accused]; at common law, a disturbance of the peace by three or more persons acting in concert and in a manner calculated to inspire terror. Many text-writers declare that the riotous enterprise must be of a private nature, and that if it is of a public nature it amounts to treason; but there is judicial authority for the view, which seems the correct one, that a tumultuous disturbance of the peace is punishable as a riot, although engaged in for the purpose of showing an unlawful opposition to the government. *Pennsylvania* vs. *Morrison*, Addison (Pa.) 274; *People* vs. *Most*, 128 N. Y. 108.

It is not necessary that the persons plan in advance of

their assembling to do any unlawful act. For example, if having gathered in front of a theater without preconcerted design to commit a breach of the peace, they attempt to force their way into the building and attack the police who are guarding the doors and rescue those who are arrested, they are rioters. (*People* vs. *Judson*, 11 Daly 1.) Nor is it necessary that they intend to terrify others. They may intend to engage in a mere frolic, as in a charivari or "horning" of a householder, or in entering the stable of another and shaving his horse's tail; yet if this is done in a tumultuous and terrifying manner the enterprise is a riot. *State* vs. *Alexander*, 7 Richardson (S. C.), 5.

An *unlawful assembly* is the meeting of three or more persons with a riotous purpose. If they enter upon the execution of that purpose, yet fall short of an act amounting to a riot, their offense is a *rout*. Modern legislation has modified the common-law rules governing these three offenses.

FRANCIS M. BURDICK.

Riouw-Lingga, rĕe-ow'ling'gă: an archipelago of the China Sea, making an extension of the Malay Peninsula; belonging to the Dutch and forming part of the residency of Riouw. It is formed of two groups of islands, that of Riouw being the northern and adjacent to Singapore, and Lingga the southern. The Riouw group consists of about thirty islands, the largest of which is Bintang with an area of about 400 sq. miles. The Lingga group is separated from the preceding by the Strait of Dempo, 10 miles broad. It consists of two large islands—Lingga (area, 320 sq. miles) and Singkep (area, 204 sq. miles)—and many smaller ones. The area of the whole archipelago is estimated at 1,823 sq. miles. The islands are rocky, like the peninsula rather than the adjacent alluvial shores of Sumatra. The highest peak is that of Lingga, 3,711 feet high. The islands are covered with thick and valuable forests. Among the productions are sago, rice, pepper, and gambir, the last forming the principal export. Tin has long been mined. The aborigines are Indonesian and negrito, and have nearly disappeared. The inhabitants are now mainly Malays, Chinese, Klings, and Javanese, with a few Europeans. Pop. about 80,000.

MARK W. HARRINGTON.

Riparian Rights [*riparian* is from Lat. *riparius*, deriv. of *ripa*, the bank of a stream]: strictly speaking, such rights as appertain to the ownership of land upon the banks of rivers and other natural water-courses. Thus defined, the expression would include the rights enjoyed by riparian proprietors over the public streams by which their lands are bounded (such as the right of access, of wharfage, of ferriage, etc.), as well as those mutually exclusive rights of user in the private streams, whose beds are the property of the adjoining owners.

The expression is sometimes, however, more loosely and with less propriety used to describe all of the rights, whether of the public or of adjoining owners, which the law recognizes in any public or private waters. As thus employed it would comprehend the public right of navigation on the sea or on navigable streams, as well as the mutual rights of the abutting "littoral" proprietor and the public in the seashore.

For these several classes of rights, see LAKES, RIVERS, and SEASHORE. See also FILUM AQUÆ and WATERCOURSES, and consult the following authorities: Angell on *Tidewaters* and on *Watercourses*; Hall on *The Seashore*; Gould on *Waters*; and Pomeroy on *Riparian Rights*.

G. W. KIRCHWEY.

Ripley: village; Brown co., O.; on the Ohio river and the Chesapeake and Ohio Railway; 50 miles S. S. E. of Cincinnati (for location, see map of Ohio, ref. 8–D). It occupies a site between the river and a steep bluff, is in a noted "white burley" tobacco-growing region, has a large river commerce, and contains flour and saw mills, piano and shoe factories, leaf-tobacco packing-houses, 2 national banks with combined capital of $200,000, and 2 weekly newspapers. Pop. (1880) 2,546; (1890) 2,483; (1900) 2,248.

EDITOR OF "BEE."

Ripley, ELEAZER WHEELOCK: soldier; b. at Hanover, N. H., Apr. 15, 1782; a nephew of President John Wheelock and a son of Sylvanus Ripley, D. D., Professor of Divinity at Dartmouth (d. Feb. 5, 1787); graduated at Dartmouth College 1800; practiced law in Maine, residing chiefly at Portland; was a member of the Massachusetts Legislature 1810–11; Speaker and elected State Senator 1812; was appointed colonel of the Twenty-first Infantry 1813; was wounded in the attack upon York (now Toronto), Canada, Apr. 24, 1813; became brigadier-general Apr. 14, 1814; commanded the Second Brigade under Gen. Brown on the Niagara frontier; took part in the battles of Chippewa and Niagara, being severely wounded in the latter, in which he won the brevet rank of major-general; was conspicuous for gallantry in the defense of Fort Erie Aug. 15, and in the sortie of Sept. 17; received a gold medal from Congress; resigned from the army 1820; settled in Louisiana, where he practiced law; served in the State Senate, and was a member of Congress 1835–39. D. at West Feliciana, La., Mar. 2, 1839.

Ripley, GEORGE: critic and journalist; b. at Greenfield, Mass., Oct. 3, 1802; graduated at Harvard 1823, and at Cambridge Divinity School 1826; was pastor of a Unitarian church in Boston 1826–41; resided several years in Europe, where he made a careful study of French and German literature; wrote *Discourses on the Philosophy of Religion* (1839); *Letters to Andrews Norton on the Latest Form of Infidelity* (1840); and edited *Specimens of Foreign Standard Literature* (14 vols., Boston, 1838–42); was associated with Emerson and Margaret Fuller in conducting *The Dial* 1840–41; contributed to *The Christian Examiner* and other magazines; was the chief promoter of the celebrated socialistic experiment at Brook Farm, Roxbury, Mass., 1841–47; was one of the editors of *The Harbinger*, a Fourierite organ, 1844–48; removed to New York 1847; became literary editor of *The New York Tribune* 1849, and remained so until his death; published (with Bayard Taylor) *A Handbook of Literature and the Fine Arts* (1852), and edited (with Charles A. Dana) *The American Cyclopædia* (New York, 16 vols., 1858–63), which was revised (Dr. Ripley, editor-in-chief), and appeared 1873–76. D. in New York, July 4, 1880. See his *Life*, by O. B. Frothingham (Boston, 1882).

Revised by H. A. BEERS.

Ripon; town; in Yorkshire, England; on the Ure; 23 miles N. W. of York (see map of England, ref. 6–I). The cathedral was originally founded on the ruins of St. Wilfrid's Abbey about 680, but of this building the crypt only remains. The present structure was begun in the twelfth century, and was entirely restored by Sir Gilbert Scott (1862–76). Its chief interest is from its various styles of architecture. Ripon has been the seat of a bishopric since 1836. There are several tanneries and foundries. Pop. (1891) 7,512.

Ripon: city; Fond du Lac co., Wis.; on the inlet of Green Lake, and the Chi., Mil. and St. P. and the Chi. and N. W. railways; 20 miles W. by N. of Fond du Lac, 86 miles N. W. of Milwaukee (for location, see map of Wisconsin, ref. 6–E). It is in an agricultural, dairying, and stock-raising region; has good water-power and water and sewerage systems; and contains Ripon College, 9 churches, a public library, 2 national banks with combined capital of $110,000, a monthly and 2 weekly periodicals, 2 flour and feed mills, several creameries, knitting-factory, pickle-works, and box and crate factory. Pop. (1880) 3,117; (1890) 3,358; (1900) 3,818.

EDITOR OF "COMMONWEALTH."

Ripon, GEORGE FREDERICK SAMUEL ROBINSON, Marquis of: statesman; b. in London, England, Oct. 24, 1827; became *attaché* to the British legation at Brussels 1849; sat in Parliament from 1852 until he succeeded his father as Earl of Ripon and Viscount Goderich, Jan. 28, 1859; inherited the earldom of De Grey on the death of an uncle Nov. 14, 1859; became in the same year Under-Secretary for War, and in Feb., 1861, Under-Secretary for India; became Secretary for War, with a seat in the cabinet, Apr., 1863; was made Secretary of State for India Feb., 1866, and lord president of the council Dec., 1868; was chairman of the high joint commission which negotiated the Treaty of Washington 1871; was rewarded with the title of marquis on his return June 23; was installed grand-master of the Freemasons of England Apr. 23, 1870, but resigned that position Aug., 1874, and was received into the Roman Catholic Church at Brompton Sept. 4, 1874. On the return of Gladstone to power the Marquis of Ripon was appointed Viceroy of India, which office he held until 1884. His attempts to extend the rights of the natives and to curtail in some respects the privileges of the Europeans made him most unpopular with the latter. He was First Lord of the Admiralty in 1886, and was appointed Colonial Secretary in 1892.

Revised by F. M. COLBY.

Ripon College: an institution at Ripon, Wis., in a campus of 10 acres. It was organized in 1854, and is privately endowed for the purpose of furnishing to young men and women opportunities for obtaining an education of the high-

est college grade. It has four departments—college, preparatory, music, and art. Three college courses are offered—the classical, the scientific, and the literary. Though owing its establishment and prosperity chiefly to the Congregationalists, it sustains no organic denominational connection. Its ideals are Christian, but not sectarian. It has six buildings, a library of 10,000 volumes, mineralogical and botanical cabinets, and considerable apparatus for work in chemistry, biology, and physics. There are 14 instructors and about 150 students. RUFUS C. FLAGG, D. D., *President.*

Ripple-marks: a wavy surface produced on sands or other granular material by the passage of a current of air or water. They are seen in great perfection and beauty on dunes, where the crests of the wavelets are usually a few inches apart. They appear on a much larger scale, with crests several feet or even yards apart, on barren, wind-swept slopes of volcanic cinders. They appear on the beds of streams, not only under the continuous current but in embayments where the water sways to and fro. They are extensively developed on sandy coasts, in shoal water outside the line of breakers, and doubtless they occur on the ocean-bottom at all depths where currents are swift enough to move sand. They are less frequently seen on surfaces of fine mud. The surfaces of sandstone layers frequently exhibit ripples identical with those observed along shores, and these are accepted by the geologist as evidence that the sand composing the sandstone was deposited in a zone of active currents and presumptively in shallow water. Ripple-marks are also found, but less commonly, upon layers of limestone.
G. K. GILBERT.

Riprap: a deposit of loose angular stones of large size, used for constructing a breakwater, or as a protection to piles and piers. See BREAKWATER.

Ristić, JOHN: statesman and author; b. at Kragujevatz, Servia, 1831; studied in Germany and Paris; took an important part in the exciting political events of his country; Minister of Foreign Affairs 1867 and again in 1872, and during the war with Turkey in 1877; represented Servia at the Congress of Berlin 1878; was head of the regency during the minority of King Alexander from the abdication of King Milan in 1889 until the king's assumption of government, Apr. 13, 1893; published in German *Kurze Charakteristik des geistigen und sittlichen Zustandes von Serbien* (Heidelberg, 1851) and *Die Neuere Literatur der Serben* (Berlin, 1852). C. H. THURBER.

Risto'ri, ADELAIDE: actress; b. at Cividale, Friuli, Italy, Jan. 29, 1822; the daughter of humble comedians. When but four years of age she played childish parts, and at the age of twenty she had attained distinction at Parma, and later was successful at Leghorn. At this period her talent was in comedy; her favorite pieces were the plays of Goldoni. In 1847 she married Marquis Capranica del Grillo and withdrew from the profession for about two years. During the siege of Rome Ristori left the stage for the hospitals, and there labored as a sister of charity. In 1850 she reappeared, and for several years played in the Italian cities, as Myrrha, Francesca di Rimini, and Mary Stuart. In 1856 Ristori made her *début* in Paris, where she met with great success, and won the homage of such men as Jules Janin and Dumas. She subsequently appeared in Spain, Holland, St. Petersburg, Berlin, and Constantinople; in 1866 visited the U. S., going thence to South America, Brazil, the Argentine Republic, and Havana; in 1874 was again in America. The popular pieces in America were *Queen Elizabeth*, *Marie Antoinette*, and *Mary Stuart*. She played also Judith, Medea, Lucrezia Borgia, etc. In 1884 she made a farewell visit to the U. S., but she had lost her ability to hold an audience. She published an autobiography—*Ricordi e studi artistici* (Turin, 1887). Revised by B. B. VALLENTINE.

Ritchie, ANNE ISABELLA (*Thackeray*): author; b. in London in 1838; a daughter of William Makepeace Thackeray. She passed a part of her childhood in France, was married in 1877 to her cousin, Richmond Thackeray Ritchie, and has resided mostly at Kensington. Among her writings are *Old Kensington* (1873); *Toilers and Spinsters* (1873); *Bluebeard's Keys* (1874); *Miss Angel* (1875); *Madame de Sévigné* (1881); *Records of Tennyson, Ruskin, and Browning* (1892); *Lord Tennyson and his Friends* (1893); and, with R. Evans, *Lord Amherst and the British Advance Eastward to Burma* (1894). H. A. BEERS.

Ritchie, Sir WILLIAM JOHNSTON: jurist; b. at Annapolis, Nova Scotia, Oct. 28, 1813; educated at Pictou, and was called to the bar in 1838. He was a member of the executive council of New Brunswick from 1854 till appointed a puisne judge of the Supreme Court of New Brunswick, Aug. 17, 1855, which position he retained until appointed chief justice of New Brunswick, Dec. 6, 1865. He became puisne judge of the Supreme Court of Canada Oct. 8, 1875, and was appointed chief justice Jan. 11, 1879. He was knighted in 1881, and was deputy governor of Canada from July, 1881, to Jan., 1882, and again from Sept. to Dec., 1882. He was appointed deputy of the governor-general Mar. 5, 1884. D. Sept. 25, 1892. NEIL MACDONALD.

Rite [Lat. *ritus*, a usage]: a term which designates not merely a religious ceremony, but the aggregate of such ceremonies or the ritual system of any Church. Thus there is the Latin and the EASTERN RITE (*q. v.*), and the Latin rite has some minor rites. The Ambrosian rite in Northern Italy had more than 1,000,000 followers as late as the latter half of the nineteenth century; the Mozarabic rite in Spain had a limited use, etc. See RITUALIST.
Revised by W. S. PERRY.

Rites, Congregation of: a department of the administration of the Roman Catholic Church: first organized by Pope Sixtus V., and consisting originally of six cardinals and a corresponding number of secretaries and consultors. Everything belonging to the liturgy, the rites of the administration of the sacraments, the ceremonies of the Church, the beatification and canonization of saints, etc., falls under its jurisdiction. It consists of cardinals, consultors, and secretaries. See Bangen, *Die römische Curie.*
Revised by J. J. KEANE.

Ritschl, ALBRECHT, D. D.: theologian; b. in Berlin, Germany, Mar. 25, 1822; studied at Bonn and Halle; instructor and professor at Bonn 1846 to 1864, and then at Göttingen till his death there Mar. 20, 1889. He became the head of a school of theology bearing his name. In his earlier years he was an adherent of the Tübingen school, but broke away from it in 1857, when he published the second edition of his *Entstehung der altkatholischen Kirche* (1st ed. Bonn, 1850). His other principal works are *Die christliche Lehre von der Rechtfertigung und Versöhnung* (3 vols., 1870–74; 2d ed. 1882; 3d ed. 1888; also translated into English *A Critical History of the Christian Doctrine of Justification and Reconciliation*, Edinburgh, 1872); *Die Geschichte des Pietismus* (1880); *Theologie und Metaphysik* (1881; 2d ed. 1887); *Unterricht in der christlichen Religion* (1875; 2d ed. 1881; 3d 1886); *Schleiermacher's Reden über die Religion* (1874); besides a number of essays in periodicals. Ritschl's theological system is found in a compendious form in his *Unterricht.* The work on *Rechtfertigung*, etc., presents it in a much fuller though less systematic form.

Ritschl adopts as a fundamental principle the Neo-Kantian (more particularly, Lotze's) doctrine of cognition, emphasizing the view that we know things not as they are in themselves, but as they are for us; or, as he expresses it, that all religious judgments are judgments of value. He lays stress accordingly on the subjective element—on personal experience—as being the ultimate fact in religion. Hence he condemns the introduction of merely speculative discussions into theology. He rejects the doctrines of original sin, of the Trinity, and of the Incarnation, as being metaphysical rather than religious. He does not believe in the personal pre-existence or miraculous birth of Christ. He regards Christ, however, as having been specially called to reveal God to men, which revelation he accomplished through a faultless life of devotion to his work of establishing the kingdom of God—i. e. a community of men led by the principle of mutual love. As being the first to exemplify a perfect devotion to God's will, Christ became a mediator, or priest, to bring men to God. He made God known as being essentially love, the love being manifested especially in the free forgiveness of men's sins, no propitiation being needed as a condition. All pardonable sins are to be reckoned as sins of ignorance.

Ritschl rejects natural theology, and makes little account of external evidences for Christianity. The occurrence of miracles he admits in name rather than in fact; but he emphasizes the historical character of Christianity, and insists that men are pardoned and saved only as they are members of the Christian community. He accordingly strongly condemns mysticism and pietism, holding that the notion of direct individual relations between men and God or Christ is essentially fanatical and mischievous. While he regards the Scriptures as containing the most authentic statement

of what the original Christianity was, he adopts no strict doctrine of inspiration; and he and his school entertain very free views as to the prerogatives of biblical criticism, holding that the essential thing is faith in the person of Christ rather than in his deeds or words or in dogmatic statements about him.

The theology of Ritschl is original only in the sense of being a peculiar composite. Like Schleiermacher, he holds that the religious sense is something immediate and ultimate, and that theology is independent of all secular science. With ordinary orthodox Christians he holds that Christianity came by a divine revelation. With the rationalists he is inclined to reject the mysterious and the supernatural, and to hold loose views of the inspiration and authenticity of the Scriptures; and in spite of Ritschl's denunciation of mysticism, the difficulty of combining this latter feature with perfect assurance of faith leads him (and more especially some of his followers, as Herrmann and Kaftan) to a sort of mysticism in the exposition of the relation of the Christian to Christ.

Notwithstanding some marked divergences of doctrinal views among Ritschl's adherents (some of them, e. g., disagreeing with him respecting the pre-existence of Christ), there is among them a strong *esprit de corps*, and they work together zealously in propagating their views and in securing the appointment of men of their school for the vacant places in the theological faculties. Among the more prominent representatives of the Ritschl school are W. Herrmann, of Marburg, Th. Häring, of Göttingen, Julius Kaftan, of Berlin, and H. Wendt, of Jena (dogmaticians); A. Harnack, of Berlin, and F. Loofs, of Halle (historians); E. Schürer, of Kiel. and H. Schultz, of Göttingen (exegetes).

C. M. Mead.

Ritschl, Friedrich Wilhelm: classical scholar; b. at Grossvargula, Thuringia, Apr. 6, 1806; studied under Reisig at Halle; privat docent there 1829; professor 1832; at Breslau 1833; at Bonn from 1839–65, when he resigned in consequence of petty intrigues, accepting a call to Leipzig, where he died Nov. 8, 1876. Ritschl's magnetic influence as a teacher can only be compared to that of Gottfried Hermann; he may be said to have been the founder of a philological school, and many of his pupils have been called to occupy chairs in German universities. His lasting fame as a scholar rests upon his work on *Plautus*, and the epigraphical and linguistic studies of early Latin to which it gave rise. The complete edition of the comic poet was begun in 1871 with the *Trinummus*, to which are added exhaustive and justly celebrated Prolegomena, and was completed in 1894 by some of his pupils. Of his other contributions, many of which are of an epoch-making character, only a few can be here cited: *Parerga Plautina et Terentiana* (1845) contain, among other valuable treatises, the famous dissertation on the *Fabulæ Varronianæ*; in the *Priscæ Latinitatis Monumenta Epigraphica* the author collected in 100 large folio plates artistic facsimiles of Latin inscriptions of the republican period, to which he added an exhaustive commentary. His minor writings, among which the various articles on the *Alexandrian Library* and on the *Literary Activity of Varro* are perhaps the most noteworthy, have been republished in five volumes of *Opuscula*. See L. Müller, *Friedrich W. Ritschl* (1877); Bursian, *Gesch. der class. Philol. in Deutschland*, pp. 812–840; and especially O. Ribbeck, *F. W. Ritschl, Ein Beitrag zur Gesch. der Philologie*, 2 vols., pp. 348, 591 (1879–81).

Alfred Gudeman.

Ritson, Joseph: scholar; b. at Stockton-on-Tees, England, Oct. 2, 1752; studied law; became a conveyancer in London and deputy high bailiff of the duchy of Lancaster; devoted most of his time for many years to antiquarian researches; edited a vast number of reprints of old and rare books. D. at Hoxton, Sept. 3, 1803. Among his works were *Observations on Warton's History of English Poetry* (1782); *Ancient Songs from the Time of King Henry III. to the Revolution* (1790); *A Collection of Scottish Songs* (1794); *Robin Hood Ballads* (1795); *Bibliographia Poetica* (1802); and *Ancient English Metrical Romances, with Dissertation and Glossary* (3 vols., 1802). See his *Letters*, edited with a memoir, by Sir N. Harris Nicolas (2 vols., 1833).

Revised by H. A. Beers.

Rittenhouse, Benjamin: instrument and clock maker; b. in Norriton township, (now) Montgomery co., Pa., 1740 or 1741; brother and assistant to David Rittenhouse. From Feb. 26, 1776, to Dec., 1778, the State of Pennsylvania maintained a gun-factory, of which he was superintendent. He was representative in the Ninth, Tenth, and Twelfth General Assemblies of Pennsylvania (1784–88); commissioner to survey the Schuylkill river Oct. 20, 1789; associate judge of the court of common pleas of Montgomery co., Pa., Mar. 28, 1792, for ten or fifteen years, when he moved to Philadelphia. In 1796–97 he made a surveyor's chain, by order of Congress, which has been the standard of the U. S. Land-office ever since. He was elected a member of the American Philosophical Society Jan. 16, 1789. D. in Philadelphia, Aug. 31, 1825.

Anita N. McGee.

Rittenhouse, David, F. R. S., LL. D.: astronomer and mathematician; b. Apr. 8, 1732, at Paper-mill Run, Roxborough township, near Germantown, Pa., where about 1690 his great-grandfather, William Rittinghuysen, a Hollander, established the first paper-mill in America. In boyhood he worked on his father's farm at Norriton, during which time he came into possession of some mathematical books: made himself master of Newton's *Principia*: discovered for himself the method of fluxions when in his nineteenth year; made a clock at a still earlier age, and undertook clock-making as a profession in 1751. He afterward made an orrery, which was purchased by Princeton College 1770, and later a larger one for the University of Pennsylvania. In connection with Mason and Dixon he was employed in 1763, to determine the initial point of their survey, which he did with instruments of his own construction; fixed the northern, southern, and western boundaries of Pennsylvania, and performed similar tasks for other States; was appointed by the American Philosophical Society to observe the transit of Venus June 3, 1769, which he did successfully in his private observatory at Norriton; calculated the elements of the (future) transit of Dec. 8, 1874; and observed the transits of Mercury of 1769 and 1782. In 1770 he settled at Philadelphia, where he continued the manufacture of clocks and mathematical instruments. He was elected to the provincial Legislature in 1776; was a member of the convention which formed the State constitution of Pennsylvania 1776; held various official positions during the Revolution; was State treasurer 1777–89; director of the U. S. mint 1792–95. In the latter year, after the death of Franklin, he became president of the American Philosophical Society, and was chosen a fellow of the Royal Society. D. in Philadelphia, June 26, 1796. His papers on astronomical, physical, and mathematical subjects are found in the first four volumes of the *Transactions* of the American Philosophical Society. A *Eulogium* upon him was delivered by Dr. Benjamin Rush 1796; his *Life* was written by his nephew, William Barton (1813), and by Prof. James Renwick in Sparks's *American Biography*, 1st series, vol. vii. (1834).

Revised by Anita N. McGee.

Ritter, Carl: geographer; b. at Quedlinburg, Prussian Saxony, Aug. 7, 1779; studied at Halle; traveled much, and was appointed Professor of Geography at the University of Berlin in 1820. By his lectures, as well as by his works, he exercised a decisive influence on the study of geography, remodeling the whole science and attracting general attention to its problems and results. D. in Berlin, Sept. 29, 1859. His principal works are *Die Erdkunde im Verhältniss zur Natur und zur Geschichte des Menschen* (1st ed. 2 vols., 1817–18; 2d ed. 19 vols., 1822–59, comprising only Africa (i.) and Asia (ii.–xix.)); *Europa, ein geographisch-historisch-statistisches Gemälde* (2 vols., 1807); *Die Stupas* (1838); *Einleitung zur allgemeinen vergleichenden Geographie und Abhandlungen zu einer mehr wissenschaftlichen Behandlung der Erdkunde* (1852). After his death were published *Geschichte der Erdkunde* (1861); *Allgemeine Erdkunde* (1862); and *Europa* (1863). Parts of his works have been translated into English by W. L. Gage: *Comparative Geography* (1865) and *The Comparative Geography of Palestine and the Sinaitic Peninsula* (4 vols., 1866). His *Life* was written by W. L. Gage (Edinburgh, 1867).

Ritter, Frederic Louis: See the Appendix.

Ritter, Heinrich: philosopher; b. at Zerbst, Germany, Nov. 21, 1791; studied theology and philosophy at Halle, Göttingen, and Berlin, and was appointed Professor of Philosophy at Berlin in 1824, at Kiel in 1833, at Göttingen in 1837, where he died Feb. 3, 1869. His principal work is his *Geschichte der Philosophie* (Hamburg, 12 vols., 1829–55), ending with Kant; the most prominent of his works, all relating to the history of philosophy, are *Versuch zur Verständigung über die neuste deutsche Philosophie* (1853); *Die Halbkantianer und der Pantheismus* (1827); and *Ueber Unsterblichkeit* (several times reprinted).

Ritual: See Liturgics.

Ritualist [from Lat. *ri'tus*, form and manner of religious observances, a religious usage or ceremony]: strictly speaking, one who has made the rights and usages of the Church a matter of study; but the term is commonly used to designate a party in the Anglican Church which seeks to minimize the effect of the Reformation, which is regarded by them as a "deformation," and, in order to show sympathy with the ante-Reformation Church, and to make prominent doctrines which they regard as "Catholic," has revived rites and practices which have their origin in the mediæval days. The Ritualists claim that in reviving these usages they follow in obedience to the letter of Church law; in other cases they conform to Catholic practice, and their acts are not forbidden. They style themselves simply Catholics. As a body, they have shown great zeal and self-denial, and in some respects resemble the early Methodists. Denounced as Romanizers and betrayers of their Church, the Church Association, powerful through the money it commands, was formed for their prosecution, culminating in the celebrated trial of the Bishop of Lincoln for alleged ritualistic practices, which terminated in a practical victory for the bishop and his sympathizers. The decision in this case of the Archbishop of Canterbury has been generally accepted and further prosecutions are unlikely.

From the Church of England, ritualism has extended to her daughter in the U. S., and has occupied the attention of more than one general convention. In 1871, at the Baltimore General Convention, the discussions on ritualism occupied the greater portion of the session. After most brilliant and prolonged debates a canon forbidding certain practices was adopted which has proved practically inoperative, and there has been throughout the American Church an increasing reverence and dignity marking the conduct of the Church's services which are certainly results of the ritual movement. There has not been found to any extent that development of ritual which tends to the inculcation of Roman Catholic doctrine. The ritual canon of 1871 still stands in the *Digest of Canons*, but it is doubtful if a prosecution for its infraction would be attempted on any section of the Church. See Liturgics. Revised by W. S. Perry.

Ritual Law: See the Appendix.

Ritual of the Dead, or **Book of the Dead** (Egypt. *Per-m-hru*, going forth by day, Fr. *rituel funéraire*, Germ. *Totenbuch*): the collection of sacred writings of the Egyptians which, in greater or less compass, were placed on the walls of tombs and pyramids, on sarcophagi, and on various articles of funereal furniture, or on papyri which were deposited with the mummies of the dead. In part it was of very ancient composition, but its chapters had no organic connection between themselves, and the whole did not have any definite and final form till very late in Egyptian history.

The general view made Thoth the author of this as of other sacred writings. The oldest chapters are said to have been composed in Heliopolis; the 130th and 64th chapters are reputed to have been found at Denderah in the time of Hesep-ti, the fifth king of the first dynasty, while the 178th chapter is inscribed on the sarcophagus of Mycerinos of the fourth dynasty. As time passed the number of chapters grew and their length increased, till a fairly complete copy filled a papyrus 15 inches wide and from 80 to 90 feet long. Theban copies of the eighteenth to the twentieth dynasties contained ninety chapters at most, while a text of the twenty-sixth dynasty, republished by Lepsius in his *Totenbuch*, contains 165 chapters. In a complete compilation the number would be considerably greater. According to Édouard Naville, who has made special investigations on the subject, there were four recensions of the text: (1) That of the Old and Middle Kingdoms down to the thirteenth dynasty, found only in the hieroglyphic writing; (2) the Theban, of the eighteenth to the twentieth dynasties, written generally in the hieroglyphic, though sometimes in the hieratic character; (3) a similar recension found after the twentieth dynasty, usually written in the hieratic, and with no fixed order of chapters; and (4) the Saitic and Ptolemaic, in both hieroglyphic and hieratic script, the text thoroughly revised, and the number and order of the chapters quite fixed and uniform. The first recension has come to us in selected extracts in the texts on the sarcophagi, tombs, and pyramids of the fifth and sixth dynasties, and on the sarcophagi and papyri of the eleventh and twelfth dynasties. The Theban copies of the eighteenth to the twentieth dynasties are found on sarcophagi, but particularly on papyri in hieroglyphic or hieratic characters, accompanied by vignettes, which contain sometimes as many as thirteen colors. The titles of the chapters are in red and the text in black ink. When written in hieroglyphs the lines are vertical; in hieratic script, horizontal. These papyrus rolls were sometimes placed in a niche in the wall near the head of the mummy, or, later, beside or beneath it, or even inside the encasing bands. Occasionally they were put in a little drawer in the pedestal of an Osirian figure which was deposited with the mummy. Extracts from the *Book of the Dead* have also been found written on the linen mummy-bands themselves. The chapters thus buried were the most important in the collection.

The book, as a whole, is entirely lacking in logical or chronological order, and in a systematic arrangement of its parts. It is also not properly or entirely a funeral ritual, since the acts prescribed are only in part to be done to or for the dead. The deceased is himself the principal active agent. Aside from certain ceremonial observances and directions, the book is concerned with the journey of the dead through Amenti, the western region of the departed; with the speeches and prayers which he is to address to the gods and other beings whom he will meet in the course of his migrations; with the magical formulas which are calculated to deliver him from the ills and dangers that threaten; with the formulas which were placed on amulets to insure the safety of his bodily members; with the hymns to be sung in honor of the great gods; and with the scenes of the judgment in the hall of Osiris when the heart of the deceased is weighed in the scales over against the symbol of truth and justice, and where the "negative confession" that the deceased has *not* committed certain reprehensible or heinous acts of irreligion or of immorality is repeated to the forty-two assessors.

The localities of the future existence of the soul were vague, and the most that can be said is that they were generally patterned after the conditions known in Egypt, especially those of the Delta region. There was a river divided into branches, islands, and fruitful fields, which produced sure harvests wrought by labor in which the "justified" had a share. But before reaching these beatific regions of Àaru (or Àalu) the dead was brought into the Hall of Double Justice (truth and righteousness), where Osiris was seated beneath a canopy. Before him were seated the forty-two assessors or judges, each from a different city of Egypt, and each set to judge of a particular form of sin. The four genii who had special charge of the vital organs of the deceased were also present. Anubis, the god of the dead, led in the deceased, who was received by Mat, the goddess of truth. The "negative confession" was repeated, and the truth of the protestations of innocence thus made was tested by weighing the heart of the dead, Horus being the principal actor, Mat the witness, and Thoth the recorder of the event. If declared righteous, the heart of the justified one was returned to him, along with his various bodily powers, and he became a whole man again. If the result was adverse the fate of the dead is not clear, but he seems to have died a second time, being devoured by the judge or by a female hippopotamus which guarded the entrance to the fields of Àaru. The beatific life was similar to the terrestrial, but from it the justified could return to the earth by means of magical formulas, and could even return again to the mummy itself. At will the dead could take on any desired form of bird or beast, and in the speeches set for repetition the dead set himself on terms of equality with the very gods. For the literature of the subject, see Egyptology. Renouf's translation mentioned in that article was published separately (London, 1893–94), and Pierret's translation was rendered in English by Charles H. S. Davis (New York, 1894).

Charles R. Gillett.

Rivas, or **Nicaragua**: a town of Nicaragua; capital of a department of the same name; 4 miles from the west shore of Lake Nicaragua, a little N. of the line of the proposed ship-canal (see map of Central America, ref. 7–H). It was the ancient Indian town of Nicarao, noted in the history of the conquest; most of the inhabitants are Indians. The place is very picturesque, its scattered houses being surrounded by fruit-trees, but it has little commercial importance. Here Walker was finally defeated in Nov.–Dec., 1856. Pop. about 10,000. H. H. S.

Rivas, Angel de Saavedra, Duke of: See Saavedra, Angel, de.

Rive-de-Gier, reev'de-zhi-ā' (Fr., bank of the Gier): town of the department of the Loire; 14 miles E. N. E. of St.-Étienne; on the Gier, an affluent of the Rhône, on the Givor

Canal, and on the railway from Lyons to St.-Étienne (see map of France, ref. 6-G). It is a center of iron manufacturing and has important coal mines in its neighborhood. It has also glass-factories, tanneries, and factories of articles in leather. Pop. (1896) 13,803. M. W. H.

Rivera, rē̆e-vā'rāă, José Fructuoso: soldier and politician; b. at Paysandú, Uruguay, about 1790. He was a partisan leader in the civil wars, and after Uruguay became independent was the first regularly elected president 1830–35. In 1836 he revolted against his successor, Oribe, heading the Colorados party, whose long struggle with the Blancos marks the subsequent history of Uruguay. Oribe was driven out, and Rivera was again president 1838–42. Then Rosas, dictator of Buenos Ayres, aided Oribe, who began the "nine years' siege." Rivera acted against him in the field, but on Mar. 28, 1845, was defeated at India Muerta by Urquiza, Oribe's ally. In 1853 Rivera aided in the deposition of Giro at Montevideo, and became a member of the executive triumvirate. D. at Montevideo, Jan. 13, 1854. H. H. S.

River-bullhead: See Miller's Thumb.

River Falls: city (settled in 1851, incorporated in 1885); Pierce and St. Croix cos., Wis.; on the Kinnickinnick river, and the Chi., St. P., Minn. and Omaha Railway; 12 miles S. E. of Hudson, 16 miles N. E. of Hastings, Minn. (for location, see map of Wisconsin, ref. 4–A). It is in an agricultural region; has abundant power for manufacturing from the river; and contains 6 churches, 2 public-school buildings, a high school, the Fourth Normal School of the State, gas and water-works, 2 State banks with combined capital of $64,000, and a weekly newspaper. The principal manufactures are flour and starch. Pop. (1880) 1,499; (1890) 1,783; (1900) 2,008. Editor of "Journal."

Riverhead: town; capital of Suffolk co., N. Y.; on the Peconic river, at the west end of Great Peconic Bay, and the Long Island Railroad; 4 miles S. of Long Island Sound, 75 miles E. by N. of Brooklyn (for location, see map of New York, ref. 8–F). It contains a national bank with capital of $50,000, a State bank with capital of $5,000, a savings-bank, a weekly newspaper, grist, woolen, paper, planing, and moulding mills, and carriage, chocolate, organ, and soap works. Pop. (1890) 4,010; (1900) 4,503.

River Hydraulics: that branch of hydraulics which deals with the flow of water in rivers. The principles are also applicable in a simplified form to canals and other artificial conduits. In the early part of the seventeenth century Castelli and Torricelli, pupils of Galileo, applied the principles of that master to hydraulics. The latter discovered the law governing the issue of fluid-veins from small orifices in the sides of a reservoir, and suggested this law as applicable to the flow of rivers. Near the close of the century Guglielmini elaborated this theory, which was generally adopted by the scientific world because no one attempted to verify its consequences by actual experiment. In 1732 Pitot, by observing sub-surface changes of velocity with the tube which bears his name, overturned this school of hydraulics. Attention being thus called to the importance of a practical treatment of the problem, experiment was multiplied; and finally, in 1786, Dubuat laid the foundation of the modern school by announcing his great principle that the flow is due to gravity acting through the slope of the surface, and that the true method of enunciating in mathematical language the law of motion is to equate expressions for the accelerating and retarding forces. During the nineteenth century many investigators have attacked the problem upon this general basis, and the general laws of distribution of velocities in a cross-section of a stream have become fairly known, while many formulas for mean velocity have been proposed.

The elaborate hydraulic survey of the Mississippi river, made from 1850 to 1860 by Humphreys and Abbot, resulted in a system of river hydraulics of which the following is a brief outline: The law of distribution of velocity in both vertical and horizontal planes was shown to be parabolic. The ratio between the mid depth and mean velocity is sensibly constant, being about 0·96, and it is independent of wind effect. This last discovery has been of particular value in reducing the labor of gauging streams. In algebraic language, the most important of these laws for sub-surface velocity are expressed as follows, with D, d_1, and d denoting, respectively, the total depth, the depth of the axis, and the depth of any particular point; and v, V, V_0, V_D, $V_{\frac{1}{2}D}$, V_{d_1}, V_m denoting, respectively, the mean velocity of the river, the velocity at any depth d, the surface velocity, the velocity at the bottom of the river (the depth being D), the velocity at half the depth, the maximum velocity, and the mean of the whole vertical curve:

$$b = \frac{1{\cdot}69}{\sqrt{D + 1{\cdot}5}}. \tag{1}$$

$$V = V_{d_1} - \sqrt{bv}\left(\frac{d - d_1}{D}\right)^2. \tag{2}$$

$$V_m = \tfrac{8}{3} V_{d_1} + \tfrac{1}{3} V_D + \frac{d_1}{D}(\tfrac{1}{3} V_0 - \tfrac{1}{3} V_D). \tag{3}$$

$$V_{\frac{1}{2}D} = V_m + \tfrac{1}{12}\sqrt{bv}. \tag{4}$$

The formula for the mean velocity deduced is the following, in English feet: v denotes the mean velocity per second; a, the area of cross-section; p, the wetted perimeter; W, the width; b, the value given in eq. (1); s, the sine of the slope corrected for bends—its numerical value is the quotient of the total fall in water-surface between the terminal stations, less the value of h in the bend formula, by the total distance between them measured on the middle line of the channel; N represents the number of angular changes each 30° of the latter line. The value of v in the bend formula is found by successive approximations.

$$v = \left(\sqrt{0{\cdot}0081b + \left(\frac{225a\sqrt{s}}{p + W}\right)^{\frac{1}{2}}} - 0{\cdot}09\sqrt{b}\right)^2. \tag{5}$$

$$h = \frac{Nv^2}{536} \quad \text{(bend formula)}. \tag{6}$$

Among other formulas for mean velocity that of Kutter (see Hydraulics) has received the widest acceptance, and as it contains a coefficient of roughness, it can be adapted to different classes of streams as well as to artificial channels.

Gauging of Rivers.—For practically gauging the discharge of a large river the following plan is recommended: Select a locality in a straight portion where the current is regular. Lay out a base-line 200 feet long parallel to the direction of the flow, and determine accurately the cross-section in front. Establish two theodolites, and, for numerous floats well distributed between the banks, note the angular distance from, and the time of transit past, each end of the base. These floats should be made double, the surface float being a tin ellipsoid or other light body bearing a little flag. The lower float may be a large open keg, ballasted with lead so as to hang vertically. The connecting cord should be as small as practicable. The rate of movement of the whole will thus be essentially that of the lower keg. The center of this keg should be placed at six-tenths of the depth below the surface, because in the absence of wind the velocity at that point very nearly represents the mean of the velocities in the vertical. The level of the water on a gauge should be read at regular intervals. To reduce the observations draw upon a sheet of section-paper the base-line and two perpendiculars to mark the lines across which the times of transit were noted. From the recorded angles and a table of natural tangents the paths of each float are plotted, and upon each is written the seconds of its transit past the base. The total width of the river is next divided into as many equal divisions as show sensibly unvarying velocity. The mean of all the seconds of transit in each division is then reduced to feet per second, and adopted as the velocity in that division. A mean of all these velocities, interpolations being made if any are missing, closely approximates to the mean velocity of the river.

Where the depth will permit, rods or tubes, loaded to float vertically, and extending from the surface nearly to the bottom, are often used, thus integrating mechanically the velocities in a vertical. For small streams various forms of meters are often employed, which consist essentially of a submerged wheel, with apparatus designed to record the number of its revolutions; and the accuracy of the result, of course, depends entirely upon the precision with which these revolutions can be translated into feet per second. Electricity has been skillfully applied to record the number of revolutions of the wheel, and thus the registering apparatus can be observed on land or in a boat.

Oscillations.—As the volume of water in the channel increases, the surface-level of the river rises. The amount of this rise varies greatly in different parts of the course, especially when the stream discharges into the sea or a large lake. In such cases the oscillation is insignificant near the

mouth, and the range between high and low water regularly increases for a certain distance until the influence of the sensibly unchanging level of the recipient of its waters disappears. Above this point the range becomes more uniform for the main river, but ultimately diminishes as the sources are approached. The mathematical laws governing this oscillation were first experimentally studied upon the Mississippi, and with the following results: (1) The local slope at any station is far from constant, since the measured discharge exhibits extraordinary but normal changes at different epochs for any given reading of the gauge, when the other conditions upon which the flow depends must be identical. Near the mouth of the Ohio these variations at high stages exceed 30 per cent., the discharge being much larger with a rising than with a falling river. (2) This variation is not the same in all rises, the difference being greater in high than in low stages, and larger in the upper river than near its mouth. (3) The local slope in any particular rise increases regularly as the river rises, and more rapidly in large than in small oscillations; it attains its maximum value when the surface still lacks a few inches of extreme height. In falling, the slope is always much less than at corresponding levels in rising. (4) During any given oscillation the rate of the increase of local slope in rising is usually the same as that of the loss in falling.

Mechanical Work.—A great river is constantly performing an immense amount of mechanical work in pulverizing and moving forward solid material. Its capacity for this work is proportional to the *vis viva* of its waters, but the amount actually performed depends in great measure upon the nature of its bed and upon the geological formations through which it flows. The Mississippi annually transports in suspension to the sea a mass of alluvion 1 sq. mile in area and 241 feet in height, weighing over 400,000,000 tons, while at the same time it is pushing over the bars at its mouth an additional amount equal to one-tenth of this enormous quantity.

The fact that, in general, under the moving waters lies a moving bed, presents in a forcible light the difficulties encountered by the hydraulic engineer in attempting to permanently improve the navigable channel of a great river. A bar removed at one point often reappears, perhaps in an aggravated form, below. The river is always at work, and to oppose it or modify its action usually exacts continuous labor. On many rivers the banks, especially in the bends, are abraded by the current; and this action, occurring in the sinuous course which is characteristic of large volumes of water in motion, often results in cutting off a bend, thus violently changing the regimen of the stream for long distances, and entailing difficulties not easily foreseen or prevented. The general effect of such cut-offs is the following: Immediately above the site the water-surface is lowered by the full amount of the bend resistance (eq. 6) and by one-half of the fall of the river in a straight portion of its course equal in length to the shortening effected by the cut-off. Immediately below the site the water-surface is raised by the latter quantity. In receding from the site, both above and below, these effects become less, and ultimately disappear. Where the banks are liable to erosion by the river a cut-off is always a misfortune. Any immediate benefit above is compensated by injury below, and the ultimate effects upon the channel are liable to be disastrous to both sections.

When a sediment-bearing river flows through a district below the level of its floods other peculiar phenomena are presented. The water escaping over the natural banks loses its velocity and deposits the matter held in suspension. The heavier particles drop first, and the result is to gradually raise the level of the banks near the river, and thus cause it apparently to traverse a low ridge sloping in both directions from the main channel. If the banks are sufficiently tenacious to resist erosion, this action, continued for a long period, may result in confining the stream between natural embankments. Such cases, however, are rare, but artificial works are often employed to assist nature when the fertility of the region to be thus reclaimed offers sufficient pecuniary inducements. Many of the chief rivers of Europe, and some of those of America, Asia, and Africa, are thus more or less perfectly confined to their channels throughout their alluvial regions. The Po is a well-known example of this kind, and is often cited as proving that the ultimate effect of levees is to raise the bed of the main river by preventing the escape of the sediment brought down by the floods. This is an error of fact, as has been fully demonstrated by Lombardini, the most eminent hydraulic authority of Italy. Indeed, no effect of this kind has ever been established as occurring upon any river. In the U. S. the Mississippi is the most conspicuous example of the application of levees to the prevention of inundations. A gigantic system has been inaugurated, extending from the mouth of the Ohio to the Gulf, and, although imperfect in its details and execution, it has added immensely to the wealth of the region. Similar artificial embankments upon a grand scale are in progress of construction upon the Irrawadi, in British Burma.

Reference is made to Humphreys and Abbot's *Physics and Hydraulics of the Mississippi River* for an exhaustive discussion of the laws of flow above briefly indicated. For the application of Kutter's formula, see Herring and Trautwine's *Flow of Water in Rivers and other Channels* (1889). See also the articles HARBORS, HYDRAULICS, LEVEES, MISSISSIPPI RIVER, etc.

HENRY L. ABBOT.
Revised by M. MERRIMAN.

Rivers [from O. Fr. *riviere*, Fr. *rivière* : Ital. *riviera* : Span. *ribera* < Lat. **riparia*, subst. of adjec. *riparius*, deriv. of *ripa*, bank]: streams of considerable size by which the water gathered from a certain catchment area or basin, bearing with it the waste of the land-surface, is led to lower ground, usually to the sea. All those streams which unite in a single trunk on their way to the sea constitute a river system. As the volume of a typical river is supplied only by the rainfall over its basin, those streams and rivers near the seacoast whose volume is dependent on the inflow of the tide should be called tidal rivers; those, like the lower Delaware or Hudson, whose volume depends on the submergence of their lower valleys beneath sea-level should be called estuaries or fiords (see FIORDS); while those strips of salt water included between the mainland and adjacent linear sand-bars, as Indian and Banana "rivers" on the Florida coast, are lagoons, and should not be called rivers at all.

Rivers may be treated in three ways: First, their general natural history, in which the development of rivers is traced from the beginnings to the latest phases of their history, from the simplest to the most complicated examples; second, their descriptive geography, in which the existing rivers of the world are described locally; third, their hydrography, in which their manner of flow, their floods, and their uses as water-powers and in irrigation and navigation are considered. This article is chiefly devoted to the first of these headings.

The Origin of Rivers.—A new-made or original river begins its life either on the surface of a newly raised land area, or on an old land whose surface has been so deformed by mountain growth as to extinguish all pre-existing rivers. The intermittent surface rivulets of wet weather, and the slow-creeping ground water beneath the surface, follow the new constructional slopes of the land, and gather in the trough lines between the slopes to form streams, the ground water emerging in springs not only at the head of the streams, but at innumerable points along the stream channels. The various streams that are led by the form of the new land to unite on the way to the sea form a single constructional river system, each stream occupying a constructional trough or valley, the total drainage area being inclosed by a watershed or divide that is determined by the shape in which the land has been uplifted or deformed, and hence called a main constructional divide; the branches of the system are separated by subordinate divides, which may be appropriately called subdivides. If the new-made land is smooth, like the coastal plain of Texas, the streams follow its gentle slope to the sea, their nearly parallel courses being determined only by the faint inequality of the surface. When the new-made land is uneven, the divides are better defined; in such regions the inequality of uplift generally forms basin-like depressions—hence constructional lakes are often found on an infantile river system; such imperfections of drainage discharge are very characteristic of the earliest stages of river life. Good examples of infantile, lacustrine river systems are found in the recently broken country of Southern Oregon, where the ridges still closely retain their constructional form, and where the depressions between them are frequently basin-shaped; but as the rainfall there is moderate or scanty, the rivers of the region are dwarfed from lack of water-supply; few of the basins overflow, and hence many of the rivers fail to reach the sea.

Young Rivers.—Thus established, the various members of the river system proceed to cut down their channels as close to sea-level as they can. The trenches cut below the

original constructional troughs of the country are called consequent valleys. All but the deepest of the constructional lakes are in this way drained, and the flow of the streams becomes more continuous. The river now enters well on its life-work of carrying along the waste of the land on its way to the sea, the waste being received partly from the cutting of the stream channels, partly from the creeping and washing of the soil from the steep sides of the young consequent valleys, and partly from the broad constructional slopes of the region. Whenever, during the process of channel cutting, the streams pass from a resistant to a weak rock structure, an increase of slope is developed at the point of contrast, forming rapids; where the contrast of resistance is well marked, the increase of slope may be abrupt, and thus many waterfalls may come to characterize youthful streams. See CATARACTS.

Adolescent Rivers.—A river of good size soon cuts down its valley close to sea-level, or base-level, as it is now generally called, and on thus assuming a gently sloping course it enters its adolescence; but its small side-streams may still retain youthful features. Adolescence of the trunk stream is therefore characterized not only by the disappearance of the initial constructional lakes, but also by the wearing away or recession of the youthful waterfalls, and the attainment of a slope on which the ability of the river to do work is just equal to the work that it has to do. The river course is then said to be graded. Large streams may attain a graded course on weak rocks during the youth of their system; small branches on resistant rocks will not grade their courses until after adolescence. The depth of an adolescent valley depends on several factors: First, the height of the land in which the valley is cut; the rivers of low-lying Florida are unable to cut deep valleys, because their drainage area is hardly above base-level; while the COLORADO RIVER (*q. v.*) is cutting down a vast cañon, because the plateaus across which its course is laid have been lifted so high; it still has rapids and falls, and is only entering adolescence. Second, the depth depends on how close the channel may approach base-level; this depends on the grade that the river may assume, and this in turn depends on the volume and load of the stream—for example, in a region of given height a large river will cut down a deeper consequent valley and assume a gentler grade than a small river; for the large one can carry its load on a faint slope, while the small one will need a steeper slope on which to gain velocity with which to do its work; for this reason a graded river descends more rapidly in its upper course, where the volume is small, than in its lower course, where its volume is greater. Again, in two river basins of similar area and structure, but one in a dry and the other in a wet climate, the river in the first can not in its adolescence cut down so deep a valley as the river in the second; for the volumes of the two rivers must differ. Still again, of two rivers of equal size, one trenching a region of hard rocks, the other at work in a region of similar form and height but of weak rocks, the former will cut a deeper adolescent valley than the latter, because the former will have but a moderate load of land-waste, while the latter will be surcharged with detritus from the easily weathered rocks of its basin, and will need a comparatively steep grade on which to do its work. It is for two of these reasons, the dryness of the climate and the weakness of the rocks, that the rivers of the U. S. which cross the elevated western plains from the Rocky Mountains eastward have not cut deeply intrenched valleys; they are characteristic adolescent rivers with well-graded courses, but the land-waste from the weak rocks of the plains is shed into them so rapidly, and their volume is so reduced by the small rainfall, that they have practically ceased deepening their valleys, while their slope is still comparatively steep and their channels are still high above base-level. Other illustrations of the control of grade by load are found in those rivers which run from the Alps out upon the plains of Lombardy. Some of them pass through lakes on the way, and are there filtered of their load from the mountains; then below the lakes they cut down the plain that they traverse, while others emerge from the mountains well charged with detritus and are unable to trench the plain; they may even build it up by depositing some of their load upon it.

Subsequent Rivers.—While the trunk river is grading its valley and the consequent lateral streams are advancing toward the graded condition as fast as they can, certain new branches, not represented in the original constructional river system, make their appearance. These are developed at various points, but especially wherever the walls of a consequent valley expose a weak stratum or rock-mass; for as the consequent valley widens by the wasting of its side-slopes, the widening will be fastest where the slopes consist of weak rocks; and thus in time numerous lateral ravines will be developed, lengthening headwards into valleys along the lead of the weak rocks by which they are guided. Such valleys and the streams that drain them are called subsequent. As the subsequent streams increase their drainage area, the original basins of the consequent branch streams are split up; thus the whole drainage area is more minutely subdivided and the rainfall is more promptly delivered to the water-courses. Commensurate with this change, the area of wasting slopes is increased, and thus the load washed down to the streams, and by them to the main river, is also increased. It may happen that the grade assumed by the main stream at the beginning of its adolescence is then found to be too faint, and hence some of the load is laid down, building a FLOOD-PLAIN (*q. v.*), and thus steepening the grade of the river and giving it a velocity that enables it to carry the remaining load. The deep alluvium with which the trench of the Missouri river is partially filled may have been accumulated in this manner, for the upper branches of this river are actively gnawing into the plains, and rapidly increasing the area of wasting slopes from which the load of the trunk river is chiefly derived.

Migration of Divides.—During the adolescent stage of river life it frequently happens that a stream may gnaw its way headward into the valley of another stream of the same river system or of an adjacent system, whose channel is at a higher level on account of greater distance to the sea, or of resistant rocks which have retarded its deepening somewhere farther down its course. Then the growing stream, working to advantage on the steeper slope or on the weaker rocks which guide its growth, may tap the other, thus abstracting its upper part and diverting it to the growing stream and leaving its diminished and beheaded lower part to follow its former valley. Subsequent streams are particularly active in making captures of this kind. Thus one river system may grow at the expense of another, as the divide between them is forced to migrate away from the steeper streams at the heads of the deeper valleys. Changes of this kind are going on in the Alps, where the Italian streams are frequently gaining at the expense of those discharging northward—as, for example, in the upper Engadine valley, where the Maira is capturing the headwaters of the Inn.

Deltas.—During all this time of river growth most of the land-waste that has been carried down to the river mouth accumulates there, forming a DELTA (*q. v.*), while the finest waste is carried out to deeper water. Rivers that enter the sea from steep mountain-slopes build stony deltas; but ordinarily the delta is composed of silt, reduced to fine texture during its long travel from its source down the valley to the sea. Under a fitting climate deltas are therefore fertile, and may support a large population, although exposed to the danger of sudden changes in the course of the river branches that traverse them and of FLOODS (*q. v.*) both from the rivers and the sea, the latter being caused by the high water of on-shore storm-winds. The outline taken by the growing delta varies according to the ratio of the power and load of the river to the activity of the shore-waves and currents. When the former are in excess, as at the mouth of the Mississippi, the delta grows rapidly forward with branching fingers wherever the distributary streams enter the sea; but where the waves and currents have the upper hand, the front of the delta is rounded, as in the case of the Rio Grande, where there is a smooth curve, convex seaward. The delta of the Po is of intermediate form. Acutely pointed deltas, like that of the Tiber, are probably caused by the combined action of river and shore currents.

Flood-plains.—As the delta grows forward there is necessarily a slight building up all along the flood-plain in order to maintain the needed grade of the river; and this entails an extension of the flood-plain up the valley, particularly at that stage of river life when the load is increasing. Hence with advancing adolescence this extremely valuable portion of the river valley increases its area, tempting occupation from its fertility, but, like the delta, subject to danger from floods. The Ohio valley offers an excellent illustration of this phase of river growth. The flood-plain and delta are somewhat higher along the river banks, where the silt is deposited at time of overflow; the plain slopes gently to either margin as well as down the valley. Consequently,

small lateral tributaries are frequently deflected down the faint depression between the valley-wall and the flood-plain; thus the Yazoo runs southward along the eastern side of the Mississippi flood-plain for many miles, and would continue to the Gulf as an independent stream if the main river did not swing over to the eastern bluffs and take it in at Vicksburg.

Meanders.—During the deepening of valleys of moderate slope the initial bends in the river course are frequently exaggerated until a distinctly sinuous channel is produced. This feature is still further increased when the river is free to swing from side to side on a flood-plain. Fully developed meanders are then developed, their radius of curvature increasing with the volume of the stream, and their arc of curvature lengthening with the faintness of grade. As the meanders appear, the river course is lengthened; hence the deepening of the valley is retarded, or else the valley previously deepened may have to be somewhat filled. A meandering river tends to cut its outer bank, particularly at time of high water, and the silt thus gathered at one bend is deposited on the inside of other bends farther down stream; thus the location of the meanders is continually changing. It often happens that a cut-off is formed across the neck of a long meander, thus diverting the river to a shorter course, and leaving the abandoned curve to form an ox-bow lake. All stages of these changes may be seen on the flood-plain of the Mississippi.

Maturity.—With the advancing development of these various features, a river system gradually enters its maturity, and during this stage its activities are in fullest play. The rainfall was at first only imperfectly delivered to the river, having long distances to creep on the broad slopes of the constructional surface, and often being delayed in lakes. It now everywhere finds some well-prepared slope, down which it is promptly led to one of the numerous streams of the system; the loss by evaporation is much reduced. The perfect dissection of the land-surface by many valleys promotes the shedding of waste from the slopes at the fastest possible rate; the nice arrangement of graded channels, steepest at head waters and thence decreasing to the mouth, enables the streams to work most effectively as transporting agents. Moreover, the development of subsequent branch streams, and the rearrangement of original lines of flow by tapping and diversion, have brought about a mature adjustment of streams to structures, possible only as a result of the patient search for the best lines of work by the denuding and transporting forces, of which the river is the more visible expression. The clear testimony that well-adjusted rivers give in favor of the uniformity of geological processes deserves more attention than it has generally received.

It is during maturity that the three parts of a river system, often referred to as if normally characterizing all rivers and all stages of development, are best represented. The head waters or torrent portion, where the volume is small, where the slope is steep, where falls may still exist, and where the waste of the land is chiefly derived; the middle portion, of larger volume and strong, steady flow on a moderate grade, with a narrow flood-plain in a well-inclosed valley; and the lower portion, where the valley is more widely opened, where there is a widespread flood-plain ending in a forward-growing delta, the river meandering freely on the plain, and branching out to several mouths at the delta front. It is during and after maturity that rivers are most useful as navigable waterways.

Old Age.—After maturity the powers of the river gradually decay. The surface of the river basin is reduced to a peneplain of slight relief, the rainfall is less promptly discharged, and more is lost by evaporation; even the upper branches lose their activity, and the waste of the land is carried away more and more slowly. As the load thus decreases, the flood-plains that were built up during maturity are gradually attacked and worn down to fainter and fainter grades. At the same time the river and its branches wander more and more freely to one side or the other, being little restrained by the fading valley-slopes; and thus the well-defined, mature adjustment of streams to structures is somewhat lost. This stage is rather ideal than actual, however, for few rivers enter so late a period without some disturbing interruptions in the course of their normal development, such as those considered below.

Effects of Depression.—When the region drained by a river is evenly depressed, the lower part of the valley is submerged and converted into an estuary, bay, or fiord (see Coast); at the same time all the branches which formerly entered the trunk river below the head of the estuary now enter the sea independently, and must thereafter be regarded as separate rivers. Thus the Taunton, Blackstone, and Pawtuxet rivers now enter Narragansett Bay separately, and are properly described as independent rivers; but they are only the dissevered branches of a trunk stream that once flowed down the valley which is now submerged. The Susquehanna, Potomac, James, and others are similarly the dissevered branches of a former Chesapeake river. In the same manner it is probable that all the streams which now enter the Baltic Sea independently once joined a trunk river, which followed the axial line of the sea-trough.

Effects of Elevation.—When the region drained by a river system is evenly uplifted changes of two kinds are introduced. First, a new strip of land is added outside of the former coast-line, and the old trunk river is extended across this strip to a new mouth. By such extension it often happens that several formerly separate rivers are ingrafted on a single new trunk. Many branches of the lower Mississippi have thus been joined to the main river by the elevation of the coastal plain and the recession of the waters of the Gulf of Mexico. Second, inasmuch as the slope of the new coastal borderland is nearly always steeper than the grade needed by the extended river, the uplift allows the river to cut its valley to a greater depth than before; thus its powers are revived. This is particularly apparent in the case of a well-graded mature or old river, whose valley has become open; in consequence of uplift a narrow young valley will be cut along the bottom of the older and wider valley, and thus a composite topography—a topography developed with relation to two base-levels—will be introduced, of which many examples may be found. Most of the rivers of Pennsylvania and Virginia follow valleys of this composite nature. The cañon of the Colorado river is sunk in the bottom of a more open upper valley. The gorge of the middle Rhine is cut down in the bottom of a more open valley that traverses the highlands of the Schiefergebirge. The Ohio and the Missouri are both believed to be thus revived from a former old age, their narrow adolescent valleys of the present cycle of denudation being eroded beneath uplifted peneplains of a former cycle of denudation. The Great Falls of the Missouri in Montana are a characteristic feature of the second youth of that river.

When a meandering old river is uplifted it cuts down a steep-sided meandering valley, and usually enlarges the radius of its curves in doing so, cutting steep valley walls on the outside of the curves and long slopes on the spurs of land that descend between the curves. The north branch of the Susquehanna in Pennsylvania, the Osage in Missouri, the Seine in Northwestern France, and the Moselle in Western Germany—all exhibit these incised meanders. The meanders are sometimes so strong that the necks of the spurs are cut through, and the roundabout river course is abandoned. Such deserted incised meanders are known on the upper Ohio near Pittsburg, on the Moselle, and on the Neckar.

One of the most marked consequences of uplift is a revival of the processes of capture of such streams as deepen their courses slowly, by others (chiefly subsequent streams) whose channels are cut down more rapidly. The adjustment of streams to structures thus proceeds even further than in the previous cycle, for at the beginning of the first cycle there were no subsequent streams along weak structures, but at the beginning of the second cycle the subsequents are well formed, and they soon far outstrip the remaining consequents in their conquest for drainage area. It is believed that by such changes as these the Schuylkill has been greatly curtailed by the Susquehanna on the W. and the Lehigh and Delaware on the E.; in England the Trent has beheaded the Witham, and the Severn has probably beheaded the Thames, which seems once to have risen in Wales; the upper Meuse has lost branches on the W. to the Seine and on the E. to the Moselle.

Effects of Deformation.—Interruptions in the normal progress of river development are frequently caused by some uneven movement of the region, rather than by a simple uplift or depression. The region may be tilted by a slight angle, increasing or decreasing the slope toward the sea. A large part of the Atlantic coastal slope of North America was thus affected at a time when its rivers had reached old age, and the surface of the land had been reduced to a peneplain of moderate relief: then the tilting gave an increased slope to the rivers and an emphatic revival of their waning powers, and they are now in adoles-

cence or maturity of the cycle thus introduced. For example, the slanting upland of New England is dissected by the Connecticut, whose valley deepens inland in consequence of the greater elevation that the old lowland has received in Northern Massachusetts than at the coast. The valleys of the Hudson, Delaware, Susquehanna, Potomac, and others are similarly accounted for.

Inequality of slope in adjacent river systems introduced by gentle warping is an effective means of promoting the migration of divides, the steepened streams gaining area at the expense of those whose slope is decreased. Thus it is believed that the present northwest course of the Tennessee, near Chattanooga, is a diversion from a former southwest course, in consequence of slight deformation of the region.

More decided deformation is detected along the northern margin of the Alps, where the mountain-making forces seem to be invading the Piedmont districts and crushing them into incipient folds. When a land-surface is thus more or less warped the graded courses of its rivers are deformed; thus lakes may be formed where the river trough is depressed, and more active valley cutting may be indueed where it is elevated, and in this way the marginal lakes of the Alps are explained, although glacial action has also undoubtedly contributed to their origin. The deformation of the Linmat, producing Lake Zurich, has been minutely studied.

Similar changes have progressed to a more advanced stage in the southern marginal ranges of the Himalaya; but while ephemeral lakes may have been formed on various outflowing rivers up-stream from the line of uplift, this stage is now past, and the rivers escape across the new ranges with unobstructed flow and essentially along their former courses; for the upturned strata of the foot-hills are the delta deposits of the earlier stage of river history. Rivers like these, of which the Sutlej may be taken as the type, maintained their flow in spite of uplifts across their course, and are called antecedent. The Green river of Wyoming, a chief headstream of the Colorado, is by some regarded as antecedent, being thought to have kept its course through the great uplift of the Uinta Mountains; but the argument to this conclusion does not seem to be decisive.

Volcanic Accidents.—The lava-flows poured forth by volcanic or fissure eruptions run to the lowest ground that they can reach, and gradually congeal. In this way the rivers of the lava-buried areas are displaced and take new courses alongside of or across the lava surface. Thus the Snake river, gathering mature head waters among the mountains of Western Wyoming, crosses the lava-plains of Idaho in a young cañon; its upper and lower parts are as dissimilar as the upper and lower parts of an extended river that comes from older inland uplands to a newer coastal plain. If the region possessing displaced rivers of this kind is elevated the revived streams cut down new valleys to one side of their buried valleys, such being the relation of several older and newer rivers on the western slope of the Sierra Nevada in California, where the old river-gravels buried under the lava-flows are much sought for as a source of gold, while the new rivers flow in deep cañons.

Climatic Accidents—Desiccation.—When the climate of a region turns from humid to arid the supply of a river system weakens, the head waters shorten, and the volume diminishes. In crossing lowlands the river is further lessened by evaporation, so that it may at last disappear, though its course to the sea remains open. Withered rivers of this kind may be found in the Argentine Republic, where they fail to reach the ocean, although the country slopes forward from their lower ends. Many withered rivers are found in the Great Basin of the U. S., where the side-streams, descending from the mountains, are unable to reach their former trunk stream, while the dwindling trunk stream fades away on the desert plains. During winter rains the withered system is somewhat invigorated; in summer droughts it is reduced to dissevered remnants. In the Sahara the withering of the rivers is often complete; the valleys or wadies remain, but they lead no water, unless beneath the sands of their trough.

Climatic Accidents—Glaciation.—The effects of glaciation (see GLACIERS) are among the most interesting accidents that can happen to rivers; and they are of great importance to civilized nations, inasmuch as they prevail over parts of Northeastern America and Northwestern Europe. During the occupation of a country by an ice-sheet there is a peculiar drainage system upon and under the ice, as is observed in Greenland and Alaska. Streams fed by rains and surface-melting in summer flow for a time on the surface, and then disappear by plunging down crevasses; they emerge from tunnels at the ice margin, sometimes bursting out with much energy, and bearing a heavy load of coarse and fine detritus, which they spread out in their further course, often building up stony flood-plains in their valleys or deltas in the sea.

During the retreat of an ice-sheet it sometimes evacuates a district that slopes toward its front. A marginal lake then accumulates in the depression and overflows at the lowest point in the rim, scouring down a valley trench of considerable size; but when a still further retreat of the ice allows a lower discharge of the lake, this trench is abandoned except by such local drainage as it may receive from either side. In this way explanation is given of certain small rivers in broad valleys in the northern part of the U. S.; the upper Minnesota, the Desplaines by Chicago, Little river between the heads of the Maumee and the Wabash in Ohio, the Mohawk by Rome, N. Y., all being examples of this curious kind (*Popular Science Monthly*, Nov., 1894).

The most striking glacial accidents in river history are found after the retreat of the ice from the glaciated country, when the surface streams again take unconstrained possession of it. Supposing that the region had had a matured drainage system before the ice invasion, then the ice rounds off the peaks and ridges, deepens and widens the valleys, often eroding basins in their troughs, or clogging them with the drift that is left irregularly distributed over the country. The preglacial stream lines are therefore more or less obstructed, and hence the post-glacial streams often lose their way, being here detained in an eroded basin or in a hollow behind a drift barrier, and there turning across an old divide or spur along a new line of flow. Streams thus affected are as a rule characterized by frequent lakes and long reaches alternating with rapids or gorges along their new courses. (See LAKES, CATARACTS, and GORGE.) The delicacy of adjustment to structural lines that prevailed in the preglacial drainage system is confused or lost. There are little streams in large valleys; large streams in little valleys; falls in the lower portion of the river courses; and lakes everywhere. The rivers of Canada, Maine, Scandinavia, and other glaciated regions exhibit all these features in profusion. They are rapidly establishing better graded channels; filling lakes, which appear as meadows; pushing back falls and cutting down gorges (see NIAGARA FALLS); terracing valleys that were clogged with drift. The economic value of the rapids and falls thus produced is very great; nearly all the manufacturing cities of New England are located at water-powers of this accidental origin; Ottawa, Rochester, and Minneapolis are similarly determined.

Complicated History of Large Rivers.—While the several phases in the life and development of rivers here outlined are easily apprehended when considered separately, such is not the case with the development of actual rivers of large size, such as the Mississippi, Amazon, Rhine, or Danube. The successive uplifts by which the present drainage area has been constructed; the various cycles or partial cycles of denudation through which one part or another of the river has advanced; the accidents that its different branches have suffered—all combine to accumulate a history so complex that geographical study in its present state does not suffice to apprehend it clearly. Yet the real significance of each part is so closely dependent on its plan of development, and the relations of the various parts of a river system follow so distinctly from the history that they have been through, that nothing less than an analysis of their origin suffices to bring them clearly before the understanding. A full account of the Mississippi system would require an extended monograph. Its oldest parts are probably to be found in the upper branches of the Tennessee and New rivers, which descend from the mountains of Carolina and Virginia. Similar ancient head waters in Pennsylvania have been turned by diversion or deformation into the Atlantic rivers. Along the northern watershed the deposits of glacial drift are at many points sufficient to alter the direction of preglacial drainage; the so-called head of the Mississippi is certainly one of its youngest parts. The great western branches, the Missouri, Arkansas, and others, are young compared to the Ohio. The lower course of the trunk stream is a recent addition to the upper branches.

Economic Relations of Rivers.—In the economies of nature rivers are the great avenues of transportation along which the waste of the land, gathered by the creep of the soil and the wash of the wet-weather streams, is carried to

the sea. In the economies of man rivers appear in the most varied relations. In regions where rivers are young, their valleys are not yet prepared for occupation, but are so steep-sided that they are left over as waste or forested land; settlements are then generally on the uplands away from the streams, as is repeatedly illustrated on the dissected coastal plain of the U. S. and on the dissected plains of the interior, as those of Central Missouri. As the river life advances, and the valley widens in adolescence and later on, settlements are made near the streams, and the more thoroughly dissected uplands are less populated. The early races of man must frequently have been dwellers in open valleys of mature rivers, judging by the repeated accounts of floods in traditional history. Villages from which modern cities have sprung have often been located by certain peculiar river features; at river mouths, as New York; at the head of bays formed by submerging rivers, as Providence; at the head of tide-water on submerged rivers, as Albany and Trenton; at the junction of river branches, as Pittsburg; at waterfalls, as Lowell. Rivers whose volume is large, by reason of the fortunate growth of their basins, serve as most important means of internal communication, as the Amazon; but the modern development of the railway seriously lessens the use of communication by river, as in the case of the Mississippi and its branches. The head waters of rivers are often used as furnishing water-supply for cities, while the trunk streams are employed in the disposal of sewage. Irrigation involves the diversion of streams in their upper courses into canals, which are led along the valley-sides at a gentle grade, thus even reaching the divides between adjacent streams, whence their water is easily distributed to the fields on the slopes. An opposite art is developed in the construction of dikes or levees near the river-banks, to prevent the overflow of the flood-plain, as on the Mississippi. Extensive operations of this description are undertaken to restrain a river from shifting its meanders, as on the Missouri; or to lead it into a more direct course than its natural channel, as has been done for the Rhine.

W. M. Davis.

Law of Rivers.—Under this title is comprehended not only riparian rights proper, or such as are peculiar to the ownership of land on the bank of a river, but also the rights of all persons, whether riparian proprietors or not, in public or private streams.

Flowing waters are by their nature, and so by law, incapable of private ownership. Whether the waters in question are those of a great river, flowing in a bed as wide and free as the sea, or whether they make their way in a tiny watercourse through the lands of private owners, no one, whether he owns the bed of the stream or not, can lay claim to the water as private property. He has, at the most, certain rights of use and enjoyment, exclusive or common, in the water of the stream. If he is a riparian proprietor he has certain peculiar and exclusive rights in the water, which arise out of and constitute a part of his property in the soil over which it flows. If he is not a proprietor he may nevertheless share in the general or common right of the public to use the stream for navigation or other proper purpose. In the case of a public or so-called navigable stream, the riparian or private rights are inconsiderable, and the law concerns itself almost wholly with the rights of the public in the stream; in the case of private or non-navigable waters, on the other hand, the public rights are insignificant in comparison with the private rights of the riparian proprietors. The subject therefore naturally divides itself into two distinct topics, viz., the law of public and that of private streams.

Public Streams.—A public stream is one the bed of which is vested in the state. At common law no rivers have this public character except such as are navigable by great ships, and only those rivers are deemed to be navigable in which (and only so far as) the tide ebbs and flows. Accordingly, the expression "navigable river" has come into general use to denote a public stream, though the common-law test of navigability—the presence or absence of tides—which in Great Britain is always consistent with the physical fact, is obviously inapplicable to the great internal waterways of the U. S., and has generally been abandoned. The principle is now well established in the U. S. that all streams which are navigable in fact for vessels customarily used in the operations of commerce are navigable in law. Used in its natural sense, however, the term navigable is a very elastic one and affords a very uncertain test of the public character of a stream, inasmuch as a watercourse which will not admit great ships may nevertheless support a considerable commerce carried on in small boats or barges. Accordingly, the question as to whether a certain stream is public or not is often a vexed question of fact, and streams which have no relation to the great waterways of commerce may nevertheless, by legislative or judicial determination, have the character of public waters impressed upon them.

As has been said above, the most important characteristic of a public river is that it is, like the seashore, subject to no private property rights. Riparian proprietors, as such, have in general no greater rights in the stream than are enjoyed by the public at large. The only exception to this rule at common law is the owner's right of access to his own land, and of mooring vessels in the river adjoining his land and keeping them there a reasonable time for the purpose of loading and unloading. His rights in these respects are precisely analogous to those of an owner of land upon a highway the fee of which is vested in the state. Indeed, it is as highways that public waters are chiefly regarded in law, and the most important of the public rights in them is that of navigation in vessels of all kinds for purposes of commerce or pleasure. Navigable rivers are, moreover, arms of the sea, and are, as such, subject to the common rights of fishing, of taking seaweed, and of cutting and taking ice, as well as to any other uses of profit or convenience which may be enjoyed in common by all persons having occasion to resort thereto. The only restrictions upon these public or common rights is that they shall be exercised reasonably and with due regard to their mutual enjoyment, and that the less important rights (as fishing, for example) shall be exercised in due subordination to those that are more important (as navigation). It may be added that there is at common law no right in the public to use the bank of a river—the same being private property—even for purposes connected with the navigation of the river, as towing, mooring vessels, etc. The civil law, on the other hand, recognized easements of this nature in favor of the public over riparian lands, and the principle has survived in the modern codes which are based on the Roman system.

The law of the seashore, which makes high-water mark the line of division between the property of the littoral proprietor and that of the state, applies equally to tidal rivers. In the case of public waters which are not subject to the ebb and flow of the tide, the limit of riparian ownership is the ordinary water-mark. Below that line—as below high-water mark on the seashore—lies the property of the crown, or state. This property right in the bed of a river (which the state may grant to a riparian proprietor or to any other individual or corporation, in fee simple or otherwise) is in the U. S. generally vested in the several States which have political jurisdiction over the waters in question, though the Federal Government, in the case of rivers flowing through or between several States, exercises a general jurisdiction in the interests of commerce.

Private Streams.—The law governing private streams concerns itself for the most part with the mutual rights and obligations of the riparian proprietors. An owner of land through which such a stream flows is deemed to be the owner of its bed. Opposite riparian owners are presumptively owners of the bed to the middle line of the stream respectively. (See Filum Aquæ.) As has been said above, however, this proprietorship of the bank and bed does not carry with it any exclusive property in the water of the stream. Every such proprietor has the right to use the running water so long as it is within his own territory, but he can not pollute or divert it, or appreciably diminish its volume, nor, in fact, make any use of it which is inconsistent with a similar use by every other riparian owner. He has the sole right of fishing, of cutting ice, of boating or skating in and upon such parts of the stream as flow over his land, and may grant any or all of these rights to others who are not riparian proprietors. But such a grant will not put the grantee in the position of a riparian owner so as to give him a right of action against other riparian proprietors for an excessive or improper use of the stream on their part. Exclusive rights to use the water, to divert it permanently into artificial channels, to discharge it upon the land below, or to overflow the land above, may be gained by express grant from the proprietors whose lands are affected by such user, or by prescription. The soil of one riparian proprietor may be gradually increased or diminished by the action of the current, or by imperceptible changes in the course of the stream. The law recognizes this process of enlargement of one man's boundaries at the expense of his neighbor under

the name of "accretion," as a valid means of acquiring title to land. The legal consequences of accretion are the same whether it goes on in public or private streams or on the seashore; but if the process of change be a sudden or violent one, it will have no legal consequences whatever. Thus if a watercourse should suddenly desert its ancient bed and form for itself a new channel, the original boundary-line between the opposite owners, running through the middle of the old bed, will be preserved unchanged.

The rights of the public, so extensive and important in the case of public waters, are greatly narrowed in the case of private streams. There is in general no common right of navigation or fishing or any other user in such waters. Nevertheless, a stream which is strictly private so far as the title to its shores and bed is concerned, may become subject to a public easement of navigation or of floating logs. The public right in such cases is presumably acquired from the riparian owners, a grant or dedication by the latter being presumed from the long and general use of the stream for such purpose by the public. It is, however, highly probable that considerations of public policy will, in the newer parts of the U. S. at least, lead to a general recognition of common rights of navigation in suitable private streams, even where there has been no general use of the stream from which to infer a dedication.

For the distinction between riparian rights proper and such as pertain to waters percolating through the soil or flowing in undefined channels, see the article on Watercourses. For other similar and related rights, see Lakes, Riparian Rights, Seashore, and authorities there cited.

George W. Kirchwey.

Rivers, Richard Henderson, D. D.: educator and minister of the Methodist Episcopal Church South; b. in Montgomery co., Tenn., Sept. 11, 1814; graduated at La Grange College, Alabama, in 1835; elected Assistant Professor of Languages, and in 1836 Professor of Languages, in that institution; was president of the conference school at Athens, Ala., in 1843; vice-president and Professor of Moral Science in Centenary College, Louisiana, in 1848, and president in 1849; was called to the presidency of La Grange College in 1854, and remained in that position after the removal of the institution to Florence, Ala., and the change of the name to Wesleyan University, until it was broken up by the civil war; was subsequently president of Somerville Female College, Tennessee, Centenary Institute, Summerfield, Ala., and Logan Female College, Kentucky; was president of Martin Female College, Pulaski, Tenn., 1874–78; was pastor in Auburn and Eufaula, Ala., 1878–83; took charge of Broadway church, Louisville, Ky., 1883–87; was a member of the Tennessee Conference; published *Mental Philosophy*, *Moral Philosophy*, *Our Young People* (1880); *The Life of Robert Paine* (1884); and *Arrows from Two Quivers* (1890). D. at Louisville, June 21, 1894. Revised by A. Osborn.

Riverside: city (founded in 1870); capital of Riverside co. (created from the southwest part of San Bernardino County in 1893), Cal.; on the Santa Ana river, and the Southern Cal. Railway; 118 miles N. W. of San Diego (for location, see map of California, ref. 12–G). It was founded by colonists from New England, who constructed two irrigating canals, one of which cost $50,000, and engaged extensively in the cultivation of oranges, lemons, figs, and grapes, the manufacture of pottery and cabinet furniture, and the production of raisins. There are several churches, public and private schools, high school, two libraries (Library Association, founded in 1879, and Public, founded in 1889), 2 national banks with combined capital of $200,000, 3 State banks, a savings-bank, and 2 daily and 3 weekly newspapers. Pop. (1890) 4,683; (1900) 7,973.

Rives, Amélie: See Chanler, Amélie.

Rives, William Cabell: Senator; b. in Nelson co., Va., May 4, 1793; educated at Hampden-Sidney and William and Mary Colleges; studied law under Jefferson; served as a volunteer in the war with England 1812–15; became prominent in Virginia politics; was a member of Congress 1823–27; minister to France 1829–32, and again 1849–53; Senator from 1832 to 1845, with a brief interruption; a member of the peace conference of 1861, and of the Confederate Congress at Montgomery. D. near Charlottesville, Va., Apr. 26, 1868. He was the author of *The Life and Times of James Madison* (Boston, 3 vols., 1859–69) and other works.

Riviera, rēē-vēē-ā'răă (i. e. the shore): name given to the coast of Liguria, Italy, from the French frontier to the Cape of Porto Venere, near Spezia (see map of Italy, ref. 4–B). It is celebrated for its natural beauty and the salubrity of its climate. Its winter climate is one of the most mild and genial known, and this, with its ready accessibility, attracts to it each winter a very large number of invalids. It is customary to divide it into the Eastern Riviera (Riviera di Levante) and the Western (Riviera di Ponente), the two meeting at Genoa. See Black, *The Riviera, or the Coast from Marseilles to Leghorn* (1890); Murray, *A Handbook for Travellers on the Riviera* (1890); Macmillan, *The Riviera* (1892). Mark W. Harrington.

Riviere, rēē'vi-ār', Briton: figure and animal painter; b. in London, Aug. 14, 1840; pupil of his father, William Riviere (1806–76); graduated at Oxford in 1867; Royal Academician 1881; medal, Centennial Exposition, Philadelphia, 1876; third-class medals, Paris Expositions, 1878 and 1889. Two of his most celebrated works are *Let Sleeping Dogs Lie* and *The Astrologer*. Studio in London. W. A. C.

Rivière du Loup (en Bas), -dü-loo': post-village (called also Fraserville); Temiscouata County, Quebec, Canada; on the southeastern shore of the river St. Lawrence, 125 miles below Quebec, and terminus of the Temiscouata Railway, at the mouth of the picturesque stream of the same name (see map of Quebec, ref. 3–E). It is the seat of Fraserville Institute, a convent, and an academy, and has a good trade. It is a place of summer resort. Pop. (1891) 4,175, nearly all French.

Rivière du Loup (en Haut), now **Louiseville**: post-village; capital of Maskinongé County, Quebec, Canada; on the north shore of Lake St. Peter, 66 miles below Montreal (see map of Quebec, ref. 4–B). It has a good trade and manufactures of leather. Pop. about 2,000.

Rix-dollar [from Swed. *riksdaler*: Germ. *reichsthaler*; *reich* (Swed. *rik*), kingdom, realm + *thaler* (Swed. *daler*), thaler, dollar]: a silver coin formerly used in the Scandinavian countries and Germany. Its value varied in the different countries from a little less than 40 cents to a little more than a dollar.

Rizzio, rit'sēē-ō, or **Riccio**, rit'chēē-ō, David: minister of Mary, Queen of Scots; b. at Turin, Italy, in 1540; the son of a dancing-master; was brought up in France; became an accomplished musician; obtained favor at the court of Savoy, where he was selected on account of his skill in languages to accompany an embassy sent to Scotland about 1563. Having attracted the attention of Mary, Queen of Scots, by his musical talent, she appointed him one of the pages of her chamber, and soon afterward (Dec., 1564) made him her secretary for foreign languages. He acquired great influence over her, and was accordingly hated by less fortunate courtiers; was an advocate of the marriage to Darnley, after which he was appointed keeper of the privy purse to the king and queen; was bitterly denounced by Knox and the Reformers on account of his Roman Catholicism; has even been regarded by some writers as a secret papal legate, and was regarded by many as the queen's paramour and father of Prince James. Several of the most powerful nobles, especially Morton, Ruthven, Lindsay, and Maitland, formed a conspiracy to assassinate him, and obtained the written concurrence of the weak Darnley by working upon his jealousy and by promising him the title of king. Introduced by Darnley into the queen's chamber, Ruthven and George Douglass struck down Rizzio in her presence, dragged him into the adjoining room, and killed him Mar. 9, 1566. It has been charged that Knox and other Reformers were privy to this murder. This is improbable, but Knox wrote of it in his *History of Scotland* as "a just act, and most worthy of all praise." F. M. Colby.

Roach [M. Eng. *roche*, connected with O. Eng. *reohha*, Germ. *roche*, roach. The Eng. *ray*, name of same fish < Fr. *raie* < Lat. *rāja*]: a kind of fish, the *Rutilus rutilus*, of the family *Cyprinidæ*. It is placed with its associates in a group distinguished by the pharyngeal teeth being in single series of five or six each, with crenate ridges and slightly hooked tips, the presence of twelve to fourteen anal rays, and the position of the dorsal fin opposite to the ventrals; the body is silvery, and the lower fins tinged with red, at least in the adult; the mouth is terminal. The roach generally attains a length of about 8 inches, and sometimes reaches as much as 10 or 12, and is under a pound in weight. It is distributed throughout Europe N. of the Alps, and, though insignificant as a game-fish, it is generally included in European works on angling. In the U. S.

the name is applied to several related species of cyprinoids, as the chub or fallfish (*Semotilus bullaris*), and in some

The European roach.

places to the sunfish (*Lepomis gibbosus*), and even to the sciænoid spot or lafayette (*Liostomus xanthurus*).

Revised by F. A. Lucas.

Roach: a kind of insect. See Cockroach.

Road, Law or **Rule of the**: primarily, the law governing the meeting or passing of travelers upon the highways; secondarily, the rules governing the steering, sailing, etc., of vessels meeting or passing upon navigable waters.

Law of the Road for Vehicles, etc.—This may be summed up as follows: (1) When two vehicles meet, each must bear to the right in the U. S., to the left in Great Britain. (2) In general, of vehicles following paths that cross, the one first to reach the point of meeting has the right of way. (3) In Great Britain, when one vehicle overtakes another, the foremost gives way to the left, and the other passes on at the right. These rules are not so peremptory that they must always be observed by drivers of vehicles, but their observance depends upon the general rule that all persons traversing a highway, whether walking, riding, or driving, must use reasonable care and diligence, under the circumstances, to avoid collision, even though it should be necessary to turn in the opposite direction from that prescribed by the customary law of the road. (See Angell on *Highways*). For pedestrians, the rule on both sides of the Atlantic is to keep to the right.

Law, or Rule, of the Road at Sea.—The rules governing the meeting, crossing, etc., of vessels at sea, and the precautions required to avoid collision, have now become a matter of international importance; and the tendency is toward the adoption of a uniform system by all maritime countries. On Oct. 16, 1889, a maritime conference met at Washington, D. C., at the invitation of the President of the U. S., issued in pursuance of specific provisions of Congress to all maritime nations in diplomatic relations with the U. S. The object of the conference was to discuss, revise, and amend the rules, regulations, and proceedings concerning vessels at sea, and navigation generally. The conference rose on Dec. 31, 1889, and a report of its proceedings was published in three volumes. The rule of the road as recommended by the conference in most respects corresponds closely with that which already existed, and was in general adopted by Austria, France, Germany, the Netherlands, Portugal, Sweden, Spain, and the U. S.; it was to go into effect on Mar. 1, 1895. British shipping-masters, pilots, etc., however, strenuously opposed its adoption, maintaining that in some important respects (as with respect to fog-signals and the screening of side lights) the rule was impracticable. In deference, therefore, to representations made by the British Government the date at which the rule should go into effect was postponed. They now acquiesce, and the date has been fixed as July 1, 1897. The following is a statement of the law which was enacted by the U. S. Congress to carry out the provisions of the recommendation of the conference, as proclaimed by the President Dec. 31, 1896.

Steering and Sailing Rules.—(1) When two sailing vessels are approaching one another, so as to involve risk of collision, (*a*) a vessel running free shall keep out of the way of a vessel which is close-hauled; (*b*) a vessel close-hauled on the port tack shall keep out of the way of a vessel close-hauled on the starboard tack; (*c*) when both are running free, with the wind on different sides, the vessel with the wind on the port shall keep out of the way of the other; (*d*) when both are running free, with the wind on the same side, the one to windward shall keep out of the way of the other; (*e*) a vessel with the wind aft shall keep out of the way of the other. (2) When two steam-vessels are meeting end on, or nearly so, each shall alter her course to starboard, so that each may pass on the port side of the other. (3) When two steam-vessels are crossing so as to involve risk of collision, the one which has the other on her starboard shall keep out of the way of the other. (4) When a steam-vessel and a sailing vessel are proceeding so as to involve risk of collision, the steam-vessel shall keep out of the way of the other. (5) Every vessel overtaking another shall keep out of the way of the overtaken vessel. (6) In narrow channels every steam-vessel shall, when it is safe and practicable, keep to that side of fair-way or mid-channel which lies on the starboard side of such vessel. (7) Where by any rule one vessel shall keep out of the way of the other, the latter shall keep her course and speed, and the former, if the circumstances of the case admit, shall avoid crossing ahead of the other.

In obeying and construing these rules due regard shall be had to all dangers of navigation and collision, and to any special circumstances which may render a departure from these rules necessary in order to avoid immediate danger.

Rules in regard to the Lights.—(1) The rules regarding lights shall be complied with in all weather from sunset to sunrise, and during such time no other lights which may be mistaken for the prescribed lights shall be exhibited. (2) A steam-vessel shall carry forward in front of the foremast, if there be one, and not less than 20 feet above the hull, a white light; on the starboard side a green light; on the port side a red light. The two side lights must be arranged with screens so that they can not be seen across the bow, nor more than two points abaft the beam. A steam-vessel when under way may carry an additional white light forward. (3) A steam-vessel towing another vessel shall in addition to her side lights carry two, if towing more than one vessel three, white lights. (4) A vessel not under command through accident shall carry two red lights in a vertical line not less than 6 feet apart aft of its white lights, or, in the day, two black shapes or balls 2 feet in diameter. (5) A sailing-vessel under way, and any vessel being towed, shall carry the same lights as are prescribed for a steam-vessel under way, with the exception of the white lights, which they shall never carry. (6) A vessel being overtaken by another shall show from her stern a white light or a flare-up light. (7) A vessel under 150 feet in length, when at anchor, shall carry forward, not more than 20 feet above the hull, a white light; a vessel 150 feet or more in length shall carry forward a white light, not less than 20 nor more than 40 feet above the hull, and aft another such light not less than 15 feet below the forward one.

Special rules are provided for steam-vessels of less than 40 tons, and vessels under oars or sails of less than 20 tons, which enable those vessels to carry a prescribed number and kinds of lights in a way more adapted to their size. Special rules are provided for pilot-boats, ferry-boats, etc.

Sound-signals in Fog, etc.—(1) All signals prescribed for vessels under way shall be given by steam-vessels on the whistle or siren; by sailing vessels and vessels towed, on the fog-horn. (2) A steam-vessel under way shall sound at intervals of not more than two minutes a prolonged blast. (3) A steam-vessel under way, but stopped and having no way upon her, shall sound at intervals of not more than two minutes two prolonged blasts with an interval of about one second between them. (4) A sailing vessel under way shall sound at intervals of not more than one minute when on the starboard tack one blast, when on the port tack two blasts in succession, and when with the wind abaft the beam three blasts in succession. (5) A vessel at anchor shall at intervals of not more than a minute ring the bell rapidly for about five seconds. (6) A vessel towing shall at intervals of not more than two minutes sound three blasts in succession, one long, followed by two short, and shall not give any other signal. (7) A steam-vessel wishing to indicate to another "The way is off my vessel, you may feel your way past me," may sound three blasts in succession, a short, long, and short.

Sound-signals for Vessels in sight of one another.—Steam-vessels must indicate their course by one short blast for "I am directing my course to starboard"; two short blasts, "I am directing my course to port"; three short blasts, "My engines are going full speed astern."

In all these rules every steam-vessel under sail and not under steam is considered a sailing vessel, and every vessel under steam, whether under sail or not, is considered a steam-vessel. "Steam-vessel" includes any vessel propelled by machinery. A vessel is "under way" when not at anchor or made fast to the shore or aground. F. Sturges Allen.

Road-runner: See Cuckoo.

Roads [O. Eng. *rād*, a riding, journey, road, deriv. of *rīdan*, ride]: highways in the country and the streets in vil-

lages and small towns, often called common roads to distinguish them from paved city streets and from railways. The number of roads in a civilized community involves a large outlay for construction, and a heavy annual expenditure for repairs, so that the question of economy in road-making and maintenance is an important one. Good roads promote traffic and industry, while poor ones are a constant bar to the development of the towns which they connect. The location, construction, and maintenance of roads form a branch of civil engineering, and it is only the engineer who can conduct these operations so as to secure the greatest public convenience with the least expenditure.

The Romans built many roads extending to all parts of the empire, and portions of some of these are found at the present day in fair condition. Twenty-nine military roads centered at Rome, which with their numerous branches had, according to Antoninus, a total length of 52,964 Roman miles. The most important of these had a paved width of 16 feet, with curbs and unpaved sidewalks, but the prevailing width was 8 feet. There were also roads for single carriages, and for horsemen, of lesser width. The military roads were essentially pavements of dressed stone blocks, laid with very close joints on a foundation of concrete which rested on a sub-foundation of large flat stones, the entire thickness being about 3 feet. The road surface was quite smooth, and level transversely. Grade was usually disregarded, and the course of the road laid out in a straight line over hills and valleys. Milestones marked the distances from all parts of the empire to a gilt column in the Forum at Rome. In respect to durability, these roads were probably superior to any since constructed, but they were very expensive and the steep grades often rendered portions ill adapted to traffic. Macadam has said that their construction "was a kind of desperate remedy to which ignorance has had recourse," and from the point of view of engineering economy and the proper adaptation of means to ends Roman roads can not be recommended.

A number of Roman roads were built in England in the second and third centuries, and later some of these were widened and made public highways. The roads in England and throughout Europe were, however, in a deplorable condition during the Middle Ages, and indeed until the beginning of the nineteenth century no systematic method of construction and repair was known. About 1350 certain roads in England were given to private companies to repair, and toll was allowed to be collected. In 1553 the parishes were made responsible for the maintenance of the roads, but the burden proved to be too heavy, and the results were unsatisfactory.

The early explorers of Mexico and Peru found excellent roads between the prineipal towns. One of the military roads of Peru is said to have been nearly 2,000 miles long, with tunnels through mountains and bridges or ferries over streams; this was 20 feet wide and paved with flagstones covered with bitumen. In India and Persia there were also a few good roads in early times. In the latter country royal roads for the use of the ruler were built by the side of the common roads and kept in better condition, from which originated the phrase "There is no royal road to learning."

The earliest roads in the U. S. were mere Indian trails along watercourses and through gaps in mountain ranges. In New England the towns had control of roads, and there are records of some "eight and ten rods wide" which were authorized to be laid out, but only about one or two rods were devoted to traffic, the remainder being left uncleared. The prevailing method of construction and repair, when any method at all was used, was to plow two parallel furrows about 20 feet apart and scrape the loosened earth upon the space between them to form the road-bed.

Turnpikes were maintained in the U. S. during the eighteenth century by private companies which were allowed to collect toll, and the surface of these was often of gravel or broken stone. In 1796 an act of Congress authorized a national road from Baltimore westward, which was built for 650 miles through Pennsylvania, Ohio, and Illinois; its width is 80 feet, of which 30 feet is of broken stone, sometimes on a foundation of large stones. Although not properly kept up since the introduction of railways, it is still known as a good road.

The roads of Europe are in a far better condition than those of the U. S. This is due partly to the fact that they are older, but mainly to better and more effective methods of construction and maintenance. Gravel or broken stone is employed for a road surface, proper drainage is provided, and systematic repairs are made at stated intervals. The dirt from the gutters is carted away instead of being spread on the road-bed, while this is kept in good condition by the frequent addition of broken stone properly compacted and rolled. Among the famous roads of Europe may be mentioned that from Geneva, over the Simplon Pass of the Alps, to Milan, which was built by Napoleon as a military route, and which cost the French Government about $3,250,000, or nearly $15,000 per mile; this is more than double the cost of construction of good roads under ordinary conditions.

About 1885 public opinion in the U. S. began to be aroused, mainly through the influence of bicycle riders and manufacturers, as to the deplorable condition of country roads and the great advantage of better methods of construction and repair. This movement has been productive of excellent results, yet very much remains to be done in order that these roads may be in a condition comparable to those of Europe. Methods of locating, building, and repairing roads are well known to civil engineers, and can be as easily carried out as those for the construction and maintenance of railways, but the public refuses or neglects to intrust the work to them. County commissioners, township supervisors, selectmen, and borough committees are the authorities who control the building and repair of roads, and these generally decide nearly all questions relating thereto, irrespective of the experience of other localities or of the rules of engineering. The method, so extensively prevailing, whereby farmers are allowed to work out their road-tax instead of paying it in money, is perhaps the greatest evil of the present system, and wherever it prevails good roads can never be secured. Under this method the mud of the gutters is annually loosened by the plow, transferred by the scraper to the middle of the street, and spread to a rounded surface without any attempt at compacting or rolling, so that the rains wash it quickly back again to the sides and the condition of the road during a large part of the year is very poor. It is safe to say that in the majority of cases the money spent in such repairs is entirely wasted.

The cost of road improvements in fifty counties of the State of New York during 1892 was $2,716,000, and this does not include that spent in cities, towns, and villages. This annual sum, if expended in accordance with engineering principles, is sufficient to produce in a few years roads comparable in every respect with those of Europe.

It is one of the gratifying features of the road agitation that State Legislatures are urged to make such laws as will insure that the construction and maintenance of common roads shall be placed in the hands of civil engineers. Every effort spent in securing the passage of such laws tends to the improvement of roads. The building of a common road is easy compared to that of a railway; the principles and methods are given in great detail in engineering literature, and it is by the scientific application of these that the roads of Europe have been brought to such a high degree of perfection.

Location.—A road should be so laid out that its length between the points to be connected is as short as possible, the grades at the same time being such as to allow easy traction for vehicles and also thorough drainage. A slight grade will provide for drainage if proper ditches are constructed. The maximum grade for earth roads should be about 10 per cent.—that is, 10 feet of vertical rise to 100 feet of horizontal distance, while gravel roads may be limited to 7 per cent., and macadam roads to about 4 or 5 per cent. On these grades a horse exerts twice as much force in pulling up the load as on a level.

The width of roads in the U. S. has usually been too great. Sixteen feet is sufficient for the easy passage of two vehicles, and it is better that this width should be kept in good condition than that 30 or 40 feet should be maintained in poor order at greater cost. In the neighborhood of cities widths of 24 or 30 feet are sometimes required. To these widths are to be added those necessary for gutters or ditches, and for sidewalks when such are necessary.

The best transverse form is that of two planes of slight inclination connected by a short curved surface near the middle. It is a common error to make the section too rounding and the inclination of the sides too steep. Many good roads show to the eye but little elevation in the middle, and the harder and smoother the road-covering the less is the elevation required.

Construction.—In order to render the road free from dust and mud and the traction easy to animals some kind of road covering other than the natural soil is usually neces-

sary. Gravel is often employed for this purpose, and when properly compacted or rolled on a good foundation it gives good satisfaction. This gravel should consist of angular grains in order that it may form a compact bed. The effect of frost on the road-bed is to be prevented by ditches which are deep enough to drain the subsoil, the longitudinal grade carrying away the water.

The system of road-making devised by Macadam in the early part of the nineteenth century has been much used in Great Britain. The road-bed is first excavated to a depth of 8 or 10 inches and compacted by rolling. Successive layers of broken stone are then laid and each layer thoroughly consolidated. The top layer is generally composed of splinters or smaller stones, and this is made thicker at the middle than at the sides so as to give the proper transverse form. The stone should be broken into fragments nearly cubical, and no stone should be used which will not pass through a ring $2\frac{1}{2}$ inches in diameter. Macadam's influence greatly improved the condition of roads in Scotland and England, and Parliament awarded him £2,000 in recognition of his services.

The system introduced by Telford is similar to that of Macadam, except that stone blocks are set in contact to serve as a foundation for the broken stone. The term "macadam road" is, however, popularly applied to both systems of constructions. Fig. 1 is a part of a cross-section of a road, showing a layer of stone blocks about 6 inches in depth, a layer of broken stone 4 inches deep, and a top layer of binding material 1 or 2 inches thick. The stone blocks are set in close contact, with the widest ends down, and rammed. The broken stone is applied in two or three thicknesses, each being thoroughly rolled while moistened. In Fig. 2 an arrangement of the stone blocks more suitable for soft soils is shown, the upper figure being a section across the road and the lower one a plan. In very soft soils concrete may be used as a foundation.

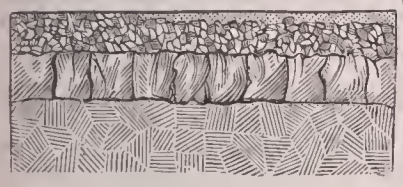

Fig. 1.

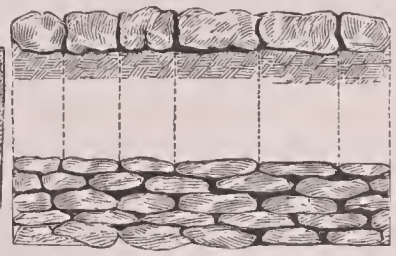

Fig. 2.

Road-coverings should be of tough and durable materials, trap and granitic rock being the best. Some limestones make good roads, while others are entirely unsuitable, as they grind into dust under the action of the traffic. It is important that the road-bed should be thoroughly rolled, and for this purpose a steam-roller is superior to one drawn by horses. A 10 or 12 ton roller appears in general to produce the best results. Each layer should be rolled about fifty times in order to secure a first-class roadway.

Maintenance.—In Europe there are two methods for keeping road-surfaces in proper order: one of constant repairs in which the dust and mud are daily swept up and removed, while new material is supplied to fill ruts and depressions; and the other of partial repairs by which at stated periods additions of fresh material are made to the road-bed, while the daily work is confined to sweeping and to filling ruts by leveling off the surface. The former method is applicable to roads of light traffic, and the latter to those of heavy traffic. The high price of labor in the U. S. precludes the system of constant daily repairs, except on city streets and park roads. In addition to renewal of the road-surface, the ditches and drains are to be kept open and the refuse carted away. The cost of maintenance of a broken-stone road is usually about the same as the interest on the cost of construction.

The cost of the construction of macadam road-surfaces ranges from 50 cents to $1.60 per square yard of surface, or from $3,000 to $9,000 per mile, depending upon width of road, depth of the stone, and character of the foundation. Such roads are well adapted to streets of light traffic in towns and cities. In the article Pavements are given statistics of fifty-one cities in 1892; these same cities reported in that year 1,446 miles of macadam and telford roads. The advantage and economy of these systems for common roads are so great that they are rapidly being built in the eastern part of the U. S. In order, however, that they may be kept in the best order, very heavy loads should not be allowed to pass over them, unless on wide tires.

In 1891 a committee of the citizens of Philadelphia offered prizes for the best papers on the making and care of common roads. The prize papers were published under the auspices of the University of Pennsylvania, under the title *A Move for Better Roads*, and the adjudicators also expressed the four following recommendations in relation to the subject: (1) That in the improvement of roads the macadam system, consisting of small angular fragments, in sizes not exceeding from 2 to $2\frac{1}{2}$ inches in their longest dimension, according to quality, should be used, wherever a stone surface is both practicable and justifiable; (2) that the minimum width of the metaled surface for a single track should be $8\frac{1}{4}$ feet, of such depth as the amount of traffic and character of the subsoil may require, to be determined by the engineer in charge; (3) that the bed to receive the stone must be so prepared that it can not be saturated with water, and to accomplish this great attention should be paid to the character and drainage of the subsoil; (4) that there should be legislative enactment regulating the width of the tires of wheels, and that the minimum width for all cart, dray-wagon, or other heavy draught vehicles should be 4 inches, to be increased, when the capacity of the vehicle exceeds half a net ton per wheel, at the rate of 1 inch for each 400 lb.

References.—The literature of the subject is very extensive, particularly that in periodicals. Macadam's essays on road-making were published in London from 1820 to 1825, and then collected in a book which passed through many editions. Gillespie's *Manual of Road-making*, one of the earliest American books, was first issued in 1845, and revised in 1871. See also Gillmore's *Roads, Streets, and Pavements* (1876); Herschel and North's *Road-making and Maintenance* (1880); and Byrne's *Highway Construction* (1892). Special reports from U. S. consuls concerning the roads of Europe will be found in a volume issued by the Department of State in 1891 under the title *Streets and Highways in Foreign Countries*. A monthly magazine of a popular character, called *Good Roads*, is published in New York. An organization called the National League for Good Roads has issued literature of a useful character, and in 1893 it exhibited several short pieces of road at the Columbian Exposition at Chicago, illustrating methods of construction. See also Pavements. Mansfield Merriman.

Roanne, rō′aan′: town; in the department of Loire, France; 52 miles by rail N. W. of Lyons; on the Loire, which here becomes navigable and is crossed by a stone bridge (see map of France, ref. 6–G). It is a handsome town; has some manufactures of cotton, muslins, jewelry, and paper, and has considerable importance as an intermediate station of the traffic between Southern and Northern France. Pop. (1896) 33,912.

Roanoke: city (formerly the town of Big Lick, incorporated as a city in 1884); Roanoke co., Va.; on the Roanoke river, and the Norfolk and Western Railroad; 7 miles E. of Salem, the county-seat, 90 miles W. S. W. of Richmond (for location, see map of Virginia, ref. 6–E). It is in an agricultural and iron-mining region, at an elevation of 950 feet above sea-level, and is surrounded on all sides by mountains. The city has improved systems of water-works and sewerage, gas and electric light plants, and a street-railway system connecting it with Vinton on the E. and Salem on the W. There are 14 churches, 4 public-school buildings, public-school property valued at over $30,000, 5 large and several small hotels, 3 national banks with combined capital of $300,000, a State bank with capital of $250,000, an incorporated bank with capital of $200,000, a trust and deposit company with capital of $50,000, 3 building and loan associations, and 3 daily and 5 weekly periodicals. The assessed valuations in 1893 aggregate $10,987,741, and the net debt in 1894 was $758,500. The industrial establishments include locomotive-works, railway-car shops, iron and steel works, bridge-works, foundries and machine-shops, hydraulic-engine works, ice, canning and preserving, and paper-box factories, brick-works, and elevator-factory. Pop. (1880) Big Lick town, 669; (1890) city, 16,159; (1900) 21,495.

Roanoke College: an institution at Salem, Va.; chartered by the Legislature in the year 1853. It is governed by a self-perpetuating board of trustees. It has enrolled about 3,000 students, and a majority of its graduates (among whom have been included several Choctaw Indians) become ministers and teachers. There were 175 students in attendance

from eighteen States and Territories and four foreign countries in 1900. The college offers a four years' course, with electives. The grounds embrace about 20 acres. There are four brick buildings for college purposes. One of these is set apart for the library, which contains 22,000 volumes. An annex to this building was erected in 1894 for a reference library and reading-room. The mineralogical and geological cabinets contain about 14,000 specimens, and there is also a valuable numismatic collection. Two literary societies and a Y. M. C. A. are maintained. JULIUS D. DREHER.

Roanoke River: a stream formed by the union of the Dan and Staunton rivers at Clarkesville, Va. It flows 250 miles in an E. S. E. course into Albemarle Sound near Plymouth, N. C. It is a tidal stream to Halifax Falls, N. C., 75 miles from its mouth, and is navigable 75 miles farther to Weldon by steamboats, and throughout its course by bateaux. Its valley is picturesque and fertile.

Roaring: the noise made by some horses while drawing in the breath, especially while traveling fast. It is caused by a kind of wasting disease of the muscles of the larynx, and is incurable. Nevertheless, some of the best horses, like the great Eclipse, have been confirmed roarers. In England tracheotomy and the continued use of the tracheotomy-tube have been successfully employed for its relief.

Roasting: See COOKERY; also METALLURGY.

Roatan: See RUATAN.

Robbery [from O. Fr. *roberie*, deriv. of *rober*, rob : Ital. *rubare*, from O. H. Germ. *roubōn* > Mod. Germ. *rauben*, plunder, rob]: larceny from the person of another by violence or putting him in fear. The force or fear must precede or accompany the larceny. Hence it is not robbery to snatch from the hand of another and carry away his purse, or stealthily to take it from his pocket and then frighten him from retaking it. On the other hand, if the article taken is so attached to the person that violence is necessary to detach it, as where a watch-cord is broken in taking a watch, or where an earring is torn from the ear, or if the owner surrenders the property because put in fear by the taker, robbery is committed. The fear need not be of injury to the body of the person robbed. Fear of injury to that which he has a right to defend by force, as his child or his property, will suffice. It has been held that a threat to injure another's character in order to induce him to surrender his property is a sufficient putting in fear. Other decisions hold that the threat of injury to character must consist in charging the victim with unnatural crime. *Britt* vs. *State*, 7 Humphrey (Tenn.) 45.

The courts have given to "the person" an extended meaning in the definition of robbery. Whenever the stolen property is so in the possession or under the control of an individual that violence or putting in fear is the means used by the thief to secure it, the taking is from the person. Accordingly, a thief commits robbery when he binds the owner in one room of his house and frightens him into telling where property is to be found in another part of the building. *State* vs. *Calhoun*, 72 Iowa 432.

Robbery was a capital felony at common law. It is punishable in Great Britain by penal servitude. In many of the U. S. it has been defined by statute and divided into degrees, punishable by imprisonment for periods of varying length. See LARCENY. FRANCIS M. BURDICK.

Rob'bia, LUCA, della: sculptor; b. in Florence, Italy, about 1399; at first a goldsmith, he soon devoted himself to larger work in bronze and marble. At the age of fifteen he went to Rimini, where he sculptured some fine bas-reliefs for the tomb of the wife of Sigismund Malatesta. Being recalled to Florence by an order to do work for Santa Maria del Fiore, he executed six compositions for the campanile. At the age of seventeen he was further commissioned to design the marble ornament of one of the organs of the cathedral, having Donatello in competition with him. Luca's design was considered the finer, although neither was executed; but the bronze door of the sacristy beneath this organ was intrusted to him, for which he modeled ten figures and many lovely heads and other ornaments. After these works he gave up bronze and modeled in clay, having discovered a glaze that protected his work from atmospheric injury. The first of his decorations in this medium are in Santa Maria del Fiore, in the arch over his own bronze door, as well as over the arch of the sacristy, as also a *Resurrection* of marvelous beauty, now in the Academy of Fine Arts in Florence. Luca afterward found out how to give color to his ware. His first experiment in the colored glaze was in Or San Michele, and this reminds one of maiolica in its brilliancy. The fame of this new decorative work soon spread through Italy and over Europe, and his orders were innumerable—both for large panels for the inner decoration of churches as well as for outer walls above doorways, etc. His works abound in Tuscany. His brothers Ottaviano and Agostino, who were his pupils, helped him in the production of these works, and continued them after his death (in 1482). ANDREA DELLA ROBBIA, nephew of the famous Luca and son of his brother Mark, was born in Florence about 1436. He showed great artistic capabilities from an early age. After having shown his skill in the marble decorations of the chapel of Santa Maria delle Grazie, outside Arezzo, he devoted himself to producing colored reliefs in terra-cotta for Santa Maria delle Grazie, for the Cathedral of Arezzo, and for the loggia of the Hospital of the Innocents in Florence, besides much other work. He died in 1525.—His sons, GIOVANNI, LUCA, and GIROLAMO, also worked in their father's manner. Although the elder Luca, as the founder of the art, enjoys a special prestige among the Robbias, Andrea undoubtedly was the most talented. W. J. STILLMAN.

Robbins, CHANDLER, D. D.: clergyman; b. at Lynn, Mass., Feb. 14, 1810; graduated at Harvard 1829, and became pastor of the Second church (Unitarian) at Boston 1833, which position he long retained. He was the author of many addresses, sermons, and occasional publications: of a *History of the Second Church* (1852); of *Memoirs* of Maria E. Clapp (1858) and William Appleton (1863); and one of the editors of the *Proceedings* of the Massachusetts Historical Society, of which he was an active member. D. at Weston, Mass., Sept. 11, 1882. For biographical sketch, see Rev. O. B. Frothingham's *Boston Unitarianism* (1890).

Revised by J. W. CHADWICK.

Robert I. (King of Scotland): See BRUCE, ROBERT.

Robert II.: King of Scotland; founder of the Stuart dynasty; b. in Scotland, Mar. 2, 1316; son of Lord Walter Stewart, by Marjory, daughter of Robert Bruce; fought at the battle of Halidon Hill (1333); became joint regent with the Earl of Murray 1334, and sole regent 1338–41, during the minority and absence in France of his uncle, King David II.; was again regent with the Earl of March from the capture of the king at the battle of Nevill's Cross Oct., 1346–57; opposed a successful resistance to the project of imposing Lionel, Duke of Clarence, upon Scotland as king, and renewed his oath of fealty to David II. 1363; was imprisoned 1363–69; declared king after the death of David Feb., 1371; was crowned at Scone Mar. 26, 1371; conducted two wars with Richard II. of England, in the second of which the successful forays of Richard II. and the Duke of Lancaster into Scotland took place. These were avenged in 1388 by a successful invasion of England by two armies, one of which, commanded by James, Earl of Douglas, fought and won the celebrated battle of Otterburn (or Chevy Chase) July 21, 1388, but lost its leader. The kingdom suffered much from the border wars and from the disorders of the turbulent barons. D. at Dundonald Castle, May 13, 1390.

Revised by F. M. COLBY.

Robert III.: King of Scotland; son of Robert II. by his first wife, Elizabeth Mure of Rowallan; b. in Scotland about 1340; was first known as John Stuart, Earl of Carrick; succeeded to the throne in 1390; renewed the war with England 1399; was an imbecile ruler and left the administration in the hands of his ambitious and unscrupulous brother, Robert Stuart, Earl of Menteith, by whom the heir to the throne, David, Duke of Rothesay, was imprisoned and starved to death in Falkland Castle 1402. In 1400 occurred the invasion of Scotland by Henry IV. of England and the retaliatory expedition of the Scots resulted in their terrible defeat at Homildon Hill 1402. Robert sent his surviving son, Prince James, to France for safety against the designs of Menteith, and became the victim of incurable melancholy on learning the imprisonment of his son by the English, May, 1405. D. at Rothesay, Bute, in 1406.

Robert II., surnamed THE DEVIL: Duke of Normandy; son of Richard the Good; succeeded his brother Richard in 1028. He humiliated his vassals and kept order in his realm; conquered districts from his neighbors and regulated his frontiers; supported Count Baldwin IV. of Flanders against his sons, King Henry I. of France against his mother, and his nephews, Alfred and Edward of England, against Canute of Denmark; made Normandy the most powerful state in

France; and was the very image of mediæval energy, audaeity, unscrupulousness, and cruelty. From the height of his success he suddenly fell into melaneholy. He repaired to Rome with a magnifieent retinue; thence he went next year to Constantinople with a more modest train; and from Constantinople he journeyed on foot to Jerusalem. At the Holy Sepulchre he found consolation, but on his return died suddenly at Nicæa, July 2, 1035. His only ehild, born to him by a mistress, was William the Conqueror, who succeeded him. The text of the famous opera by Meyerbeer, *Robert le Diable*, is based on a romance of 1496, and has very little to do with history.

Robert, rō′bãr′, Louis Léopold: painter; b. in the canton of Neuchâtel, Switzerland, May 13, 1794. He studied in Paris with Charles Girardet, a Swiss painter, and partly under J. C. David, and gained a prize for engraving when twenty years of age. In 1818 he was able, with the help of a friend, to visit Italy, where he worked and studied for years, and spent much of his life thereafter. His peculiar gift as an artist was graceful composition, grouping of romantie figures in a picturesque way, and he found among the peasantry of Central Italy and the brigands who had been captured by the authorities the material which he liked. He exhibited many pietures from 1827 to 1836, many of them made popular by engraving; and his reputation was very high in France under Louis Philippe. His work is not very important in the purely artistic sense, as his color is cold and his painting not skillful, but will always be popular. D. by his own hand, in consequence of disappointment in love, at Venice, Mar. 20, 1835. At the Louvre are his pictures *Return of the Pilgrimage to the Madonna de l'Arco*, *A Roman Peasant Woman*, and the well-known *Harvesters of the Pontine Marshes*. Of other pictures, the *Neapolitan Improvisator* was exhibited in 1824 and the *Fishers of the Adriatic* in 1836, these marking the beginning and the end of his brief and brilliant career.

Russell Sturgis.

Robert College: an institution of learning at Constantinople, Turkey, projected by James H. and William B. Dwight, sons of Rev. Harrison G. O. Dwight, a veteran missionary in Turkey, and opened in 1863, under the control of Christopher R. Robert, a wealthy philanthropist of New York, who made arrangements with his friend Rev. Cyrus Hamlin, D. D., of Constantinople, to take charge of the college as its first president. Mr. Robert supported the college until his decease in 1878, when he bequeathed to it one-fifth of his estate. His total benefactions to it were about $450,000. The institution was opened in a rented building. In 1864 it was incorporated in the State of New York as one of the colleges of the University of New York. Under permission of the sultan, granted in 1869, the two main buildings were erected in 1871 and 1893 respectively, on a fine site on the Bosphorus. After fourteen years of service Dr. Hamlin resigned in 1877, and was succeeded by Rev. George Washburn, D. D. The curriculum corresponds generally to that of a New England college, though special attention is paid to the languages, no fewer than thirteen being taught. The chief language of instruction is the English. There is a preparatory course of two years, and a collegiate baccalaureate course of five years, both including instruction in the vernaculars of the students. From 1863 to 1893, inclusive, the total number of students by years was 5,149; of different students, 1,715; of graduates, 274. The college has already attained a most honorable standing, and has become of national, if not of international, importance.

William B. Dwight.

Robert-Fleury, rō′bãr′flō′ree′, Joseph Nicolas: historical and genre painter; b. at Cologne, of French parents, Aug. 8, 1797; pupil of Girodet, Baron Gros, and Horace Vernet; second-class medal, Salon, 1824, first-class 1834, and first-class Paris Expositions, 1855 and 1867; commander Legion of Honor 1867; member of the Institute 1850; director of the French Academy in Rome 1866. In 1833 he exhibited in Paris his *Massacre of St. Bartholomew*, which at once gained him a high reputation. His *Conference at Poissy in 1561* (1840), *Jane Shore* (1850), and *Sack of a Jew's House* (1855) are in the Luxembourg Gallery, Paris. Various works are in the museums at Versailles, Nantes, Montpelier, and Antwerp. D. in Paris in 1890.

William A. Coffin.

Robert-Fleury, Tony: historical, genre, and portrait painter; b. in Paris, France, Sept. 16, 1838; son of Joseph Nicolas Robert-Fleury; pupil of Paul Delaroche and Léon Cogniet; medals, Salons, 1864 and 1867; medal of honor, Salon, 1870; first-class medals, Paris Expositions, 1878 and 1889; officer Legion of Honor 1884. His *Last Day of Corinth* (1870) is in the Luxembourg Gallery, Paris. Studio in Paris.

W. A. C.

Robert Guiscard: See Guiscard, Robert.

Robert of Gloucester: a chronicler of English annals, of whose life nothing is known except that he was living at the time of the battle of Evesham (1265). His metrieal chronicle of England from the time of the fabulous Brutus to his own times was chiefly based upon Geoffrey of Monmouth's work. It extends to 10,000 lines, and is valuable as one of the earliest specimens of the English language. It was printed by Thomas Hearne (1724), and reprinted 1810.

Roberts, Benjamin Titus, A. M.: general superintendent Free Methodist Church; b. at Leon, Cattaraugus co., N. Y., in 1823; graduated at Wesleyan University in 1848; was a member of Genesee Conference, Methodist Episcopal Church, 1848–58; general superintendent of Free Methodist Church 1860–93; founder (1865) and president (1869–93) of A. M. Chesbrough Seminary, North Chili, N. Y.; published *Fishers of Men* (1878); *Why Another Sect?* (1879); *First Lessons on Money* (1886); *Ordaining Women* (1891). Founder (1860) and editor (1860–93) of *The Earnest Christian*, and editor of *The Free Methodist* 1886–90. D. Feb. 27, 1893.

Roberts, Charles G. D.: See the Appendix.

Roberts, David, R. A.: painter; b. at Stockbridge, Scotland, Oct. 24, 1796. He was educated as a decorative painter, and became a theatrical scene-painter; but was much attracted by the picturesque in architecture, and, after studying English buildings of the Middle Ages, went to France in 1824. In 1826 he exhibited his *Rouen Cathedral*, which was the beginning of his career as a painter of romantic landscape. In 1831 he was engaged in the founding of the Society of British Artists, and became its first president. In 1832 he visited Spain, and made many drawings afterward published in lithography. About 1838 he went to Palestine, and thence to Egypt; his pictures painted at this time, either in the East or after his return, and from studies made in the East, are the best of his work. In 1841 he was elected a Royal Academician. In 1851 he visited Italy, and his pictures for several years thereafter were of Italian subjects. In his old age he took the London waterside as his field of study, and painted picturesque views of the town as seen from the Thames. His work never attained any special value as landscape in the artistic sense, and lost less by rendering in lithography than most drawing or painting from nature would lose. Spirited and popular treatment of ruined buildings, Gothic cathedrals, men in unfamiliar costume, and the like, were his favorite themes. D. in London, Nov. 25, 1864. He published *Picturesque Sketches in Spain* (1837); *The Holy Land and Syria* (finished in 1849, 4 large vols.); *Italy: Classical, Historical, and Picturesque* (1859). Of his pictures, those of his middle life and strongest period are *Church of the Holy Nativity at Bethlehem*, the *Statue of Memnon at Sunrise*, the *Ruins of Philæ*, the *Gateway of the Temple at Baalbeck*. In the National Gallery in London are his *Church of St. Paul, Antwerp*, and the *Cathedral of Burgos*. Russell Sturgis.

Roberts, Ellis Henry, LL. D.: journalist; b. at Utica, N. Y., Sept. 30, 1827; learned the printing-trade: graduated at Yale College 1850; became in 1851 editor and proprietor of the Utica *Morning Herald*, an influential newspaper of Whig and subsequently of Republican principles; was a member of the presidential conventions of 1864 and 1868, of the State Legislature 1867, and of Congress 1871–75; was assistant treasurer U. S. at New York 1889–93; became treasurer of the U. S. in 1897. He published *Government Revenue* (1884) and *The Planting and Growth of the Empire State*, American Commonwealth Series (1887).

Roberts, Howard: See the Appendix.

Roberts, Robert Richford, D. D.: bishop of the Methodist Episcopal Church; b. in Frederick co., Md., Aug. 2, 1776; emigrated with his father's family in 1785 to Ligonier Valley, Western Pennsylvania, then the frontier of that State, where he was found "in the woods" by the earliest Methodist itinerants, "a stalwart youth in hunting-shirt of tow linen, buckskin breeches, and moccasin shoes." They supplied him with Methodist books, licensed him to exhort in 1800, and to preach in 1802. In the latter year he joined the Baltimore Conference, which then stretched over the Alleghanies. After itinerating in West Virginia and Penn-

sylvania, he was appointed to important churches in Baltimore, Philadelphia, etc., and in 1816 was elected bishop. He immediately returned to Western Pennsylvania and thence removed to Indiana, then the far West. He did much for Western missions, and the Indians called him "the grandfather of all the missionaries." D. in Lawrence co., Ind., Mar. 26, 1843. Revised by A. OSBORN.

Roberts, Sir WILLIAM, M. D., F. R. S.: clinician; b. in Anglesea, Wales, Mar. 18, 1830; graduated M. D. London University 1854; was physician to the Manchester Royal Infirmary 1855 to 1886, and Professor of Clinical Medicine at the Victoria University from 1876 to 1886. He practiced his profession in Manchester from 1885 to 1889, removing to London in the latter year. His more important publications are *A Practical Treatise on Urinary and Renal Diseases* (London, 1865; 4th ed. 1885); *Lectures on Dietetics and Dyspepsia* (London, 1885; 2d ed. 1886); *On the Chemistry and Therapeutics of Uric Acid, Gravel, and Gout* (London, 1892). S. T. ARMSTRONG.

Roberts, WILLIAM CHARLES, D. D., LL. D.: minister, educator, and secretary; b. at Galltmai, Cardiganshire, South Wales, Sept. 23, 1832; educated at Princeton College and Theological Seminary; was pastor of the First Presbyterian church, Wilmington, Del., 1858–61; of the First Presbyterian church, Columbus, O., 1861–64; copastor in the Second church, Elizabeth, N. J., 1864–66; pastor of the Westminster church, organized from the Second church under his leadership, 1866–80; corresponding secretary of the board of home missions 1880–86; president of Lake Forest University 1886–92; and was reappointed corresponding secretary of the board of home missions in 1892. Dr. Roberts was chairman of the committee that established Wooster University, Ohio; member of the first Pan-Presbyterian council, Edinburgh, 1877, and of the third, Belfast, 1884, where he read a paper on American colleges; moderator of the General Assembly, New York, 1889, and a member of the committee for the revision of the Confession of Faith. He is the author of a series of letters on the great preachers of Wales, the translator of the *Shorter Catechism* into Welsh, and has published occasional sermons. C. K. HOYT.

Roberts, WILLIAM HENRY, D. D., LL. D.: minister and professor; b. at Holyhead, Wales, Jan. 3, 1844; was educated at the College of the City of New York and Princeton Theological Seminary; statistical clerk in the U. S. Treasury Department 1863–65; assistant librarian of Congress 1866–72; pastor at Cranford, N. J., 1873–77; librarian of Princeton Theological Seminary 1877–86; Professor of Practical Theology in Lane Seminary 1886–93; permanent clerk of the General Assembly 1880–84. He has published *History of the Presbyterian Church in the United States of America* (1888); *Ecclesiastical Status of Theological Seminaries* (1892).

Roberts of Kandahar, FREDERICK SLEIGH ROBERTS, Earl: British general; b. in Cawnpur, India, Sept. 30, 1832; educated at Eton, Sandhurst, and Addiscombe; entered the Bengal artillery 1851; promoted through various grades to that of lieutenant-general 1883; served with great distinction in the Indian mutiny campaign, the Abyssinian campaign, and the Afghan campaigns; commander-in-chief in India 1885–93. His most noted exploit was the relief of Kandahar in the summer of 1880. He was created a baronet in 1881, and Baron Roberts of Kandahar, Jan., 1892. The soldiers nicknamed him Bobs Bahadur, the latter word meaning hero or champion. He was made field-marshal May 25, 1895, and commanded the forces in Ireland from 1895 till 1899; he was commander-in-chief in South Africa, 1899–1900. In October he was made commander-in-chief of the British army to succeed Lord Wolseley. He turned over the South African command to Lord Kitchener Nov. 30, 1900, and returned to England, arriving early in 1901, and was received with great honors and created an earl.

Robertson, FREDERICK WILLIAM: clergyman; b. in London, England, Feb. 3, 1816; abandoned the plan he had formed of entering the army; entered Brasenose College, Oxford, 1837, and graduated 1840; was settled in Winchester 1840–42, in Cheltenham 1842–47, in Oxford 1847, going that year to Brighton, where he died Aug. 15, 1853. Of his works, there have been published *Sermons preached at Trinity Chapel, Brighton* (five series, London, 1855–64); *Lectures and Addresses on Literary and Social Topics* (1858); *Expository Lectures on St. Paul's Epistles to the Corinthians* (1859); and *Notes on Genesis* (1877). His fame was posthumous, but it is permanent. His writings and biography were reprinted in the U. S. and widely read. He was one of the greatest and most inspiring of modern preachers, and has exerted great influence in liberalizing religious thought. He was, however, more a preacher than a theologian, and he left little in systematic form. He is usually, although perhaps erroneously, classed with Maurice and Stanley as a founder of the modern Broad Church party in the Church of England. See his *Life and Letters*, edited by Stopford A. Brooke (2 vols., 1865).

Robertson, GEORGE CROOM: educator and metaphysician; b. at Aberdeen, Scotland, Mar. 10, 1842; educated at Aberdeen, Berlin, and Göttingen Universities; became Assistant Professor in Greek at Aberdeen in 1864; Professor of Philosophy in University College, London, 1866–92; was editor of *Mind* 1876–91. D. in London, Sept. 21, 1892. His principal writings are *Hobbes*, in Blackwood's *Philosophical Classics* (1886), and several articles in *Encyclopædia Britannica* (9th ed.) and in the *Dictionary of National Biography*. He aided Alexander Bain in editing Grote's posthumous work on *Aristotle* (1872). See *Philosophical Remains of George Croom Robertson*, edited by Alexander Bain.

Robertson, HENRY: See the Appendix.

Robertson, JAMES: royal governor of New York; b. in Fifeshire, Scotland, about 1710; served as deputy quartermaster-general in the campaigns against Louisburg and Ticonderoga 1758–59; was appointed lieutenant-colonel of the Fifty-fifth Regiment; exchanged into the Sixteenth; was stationed at New York as barrack-master 1763–75; became notorious for his extortions and peculations; was appointed colonel 1772; went to Boston July, 1775; was appointed major-general Jan. 1, 1776; commanded a brigade in the battle of Long Island; went to England 1777; was appointed royal governor of New York 1779; took the oath of office Mar. 23, 1780; exerted himself with Gen. Greene to procure the exchange of Maj. André; became lieutenant-general Nov. 20, 1782; d. in England Mar. 4, 1788.

Robertson, JAMES, D. D.: minister and professor; b. at Alyth, Perthshire, Scotland, Mar. 2, 1840; educated at the Universities of Aberdeen and St. Andrews; missionary in Hasskeni, Constantinople, 1862–64; in Beyrout, Syria, 1864–75; minister of Mayfield church, Edinburgh, 1876–77; since 1877 Professor of Oriental Languages in the University of Glasgow. Dr. Robertson has published many articles on Eastern topics in various magazines; translated and edited *Müller's Outline of Hebrew Syntax* (Glasgow, 1882; three subsequent editions); published *Introduction to the Pentateuch* in Virtue's *New Illustrated Bible*, republished in *Book by Book* (London, 1892); *The Early Religion of Israel*, Baird lectures, 1889 (Edinburgh, 1892; three later editions); *The Old Testament and its Contents*, in *Guild and Bible Class Text-books* (Edinburgh, 1893); and *The Psalms: their Place in the History and Religion of Israel*, Croall lectures, 1894 (Edinburgh, 1895). C. K. HOYT.

Robertson, JOHN ROSS: See the Appendix.

Robertson, THOMAS WILLIAM: actor and dramatist; b. in England, Jan. 9, 1829; became an actor in a traveling company of which his father was manager; produced a play, *A Night's Adventure*, in 1851; settled in London and devoted himself to literature 1860, and wrote several very successful dramas, including *David Garrick* (1864); *Society* (1865); *Ours* (1866); *Caste* and *Play* (1868); *School* (1869); *M. P.* (1870); and *Dreams* (1869). D. in London, Feb. 3, 1871. See his *Principal Dramatic Works* (London, 1889).

Robertson, WILLIAM, D. D.: historian; b. at Borthwick, near Edinburgh, Scotland, Sept. 19, 1721; graduated at the University of Edinburgh 1741; became a minister of the Scottish Church at Gladsmuir 1743; joint minister of Greyfriars church, Edinburgh, 1759; principal of the University of Edinburgh 1762, and was appointed historiographer of Scotland 1764. D. at Grange House, near Edinburgh, June 11, 1793. Author of a *History of Scotland during the Reigns of Mary and James VI.* (2 vols., 1758–59); *History of the Reign of the Emperor Charles V.* (3 vols., 1769); a *History of America* (2 vols., 1777); and an *Historical Disquisition concerning the Knowledge which the Ancients had of India* (1791). During his lifetime and long afterward his name was ranked with those of Gibbon and Hume, and his complete *Works* have been often reprinted, but are now little read. His *Life* was written by Dugald Stewart (1801) and by Lord Brougham, who was a family connection.

Robespierre, rō'bes-pi-ār', MAXIMILIEN MARIE ISIDORE: revolutionist; b. at Arras, France, May 6, 1758. Losing his

parents at an early age, he was brought up by his maternal grandfather. He showed unusual promise, and took high rank at Arras and at the Collège Louis le Grand in Paris, where he studied with Camille Desmoulins. Admitted to the bar in 1781, he was soon advanced to the rank of criminal judge, but resigned on account of his reluctance to pronounce sentence of death. He was a devoted student of Rousseau, whose sentimentality made a great impression upon him. He drew up the *cahier* for the guild of cobblers at Arras, and was sent as a delegate of the *tiers état* to the States-General in 1789. His earnestness soon commanded attention and enabled him to exert a powerful influence, not only in the Assembly but in the Jacobin Club. Early in 1791 he urged and carried a motion to prevent any member of the present Assembly from being eligible for the next, and to prevent any deputy from taking office for the next four years. Having thus reduced the Government to mediocrity, the very course dreaded by Mirabeau, his own talent had free play. He was appointed public accuser, but on the flight of the king to Varennes he was overcome with fear and took refuge in the house of a carpenter. The club took a theatrical oath to defend his life, and finally, at the end of the Constituent Assembly, Sept. 30, 1791, responded to his hysterical appeals by carrying him home in triumph. He was the embodiment of sentimentality, his feelings impelling him alternately to peace and war. When the Girondists in the Legislative Assembly advocated war, Robespierre offered the most strenuous opposition in the Jacobin Club. His orations were pedantic and inflated in form, but they exerted not a little influence. In Apr., 1792, he resigned his office as public prosecutor, and in August we find him petitioning the Legislative Assembly for a revolutionary tribunal and a new national convention. For his success he was elected the first deputy to the new Convention, which opened Sept. 21. The Jacobins were bitterly attacked by the Girondists, but Robespierre and Danton drew together and succeeded in gaining the ascendency. The execution of the king, Jan. 29, 1793, still further strengthened the Jacobins, whose triumph became complete June 2. The Committee of Public Safety then took absolute control of affairs. Robespierre was elected member of this committee July 27. His popularity with the mob in Paris, his personal respectability, and his fluent oratory gave him great influence. Standing in the committee midway between the extreme and unscrupulous radicals on the one hand and the conservative element on the other, he strengthened his own position by pitting them against one another, and thus contributing to the general destruction that followed. The desperate intrigues of Mar. and Apr., 1794, sent Hébert, Desmoulins, and Danton, as well as their followers, to the scaffold, and left Robespierre in absolute power. He placed his friends in all the prominent Government positions, assumed complete control of the revolutionary tribunal, and ordered that the jury need not listen to a defense if it was otherwise convinced. This infamous provision, sweeping away as it did all guarantees of justice, was perhaps the most characteristic act of the Reign of Terror. The executions from this time till the fall of Robespierre averaged about thirty a day. The number of his enemies increased with his power. He surrounded himself with a body-guard, the fantastic trappings of which excited ridicule, and he set all Paris laughing at him by his method of setting up a new religion. He was to have thirty-six annual festivals, and the first of these he celebrated by walking at the head of a procession, and after a windy harangue setting fire to paper figures of Vice, Atheism, Selfishness, Annihilation, and Crime. All Paris suddenly awakened to a consciousness that they were ruled by a mountebank, as ridiculous as he was cruel. Signs of insubordination showed themselves immediately. Robespierre fought off inevitable disaster with desperation. In the Assembly he was assailed with the most violent epithets, and his voice was drowned in the tumult. He broke away from the Convention to appeal to the mob, whereupon the Convention declared him an outlaw. In the *mêlée* that ensued his jaw was broken by the shot of a gendarme, and the following day, July 28, 1794, Robespierre, with Saint-Just and twenty others, was carted to the guillotine amid the jeers of the populace.

AUTHORITIES.—Aulard, *La Société des Jacobins* (4 vols., 1891); Hamel, *Vie de Robespierre* (3 vols., 1865–67); Hamel, *Thermidor*; Lamartine, *History of the Girondists*; and the histories of the French Revolution by Thiers, Michelet, Louis Blanc, von Sybel, Stephens, Carlyle, and Taine.

C. K. ADAMS.

Robin [(shortened from *Robin-redbreast*) from O. Fr. *Robin*, dimin. of *Robert*, Robert]: the name applied in Great Britain to several well-known singing-birds of the family *Erythacinæ*, and improperly given in the U. S. to a species of thrush, the *Turdus migratorius*. There are fifteen genera of robins in Europe, Western Asia, and Northern Africa, most of them widely spread, resembling each other in their chief characteristic—the short tapering bill, curved at the extremity and partly covered with bristles. They all feed on worms, insects, and fruits, generally live on cultivated grounds, and have but slight fear of man. The best-known species is *Erythacus rubecula*, the robin-redbreast whose song is familiar to every British country household.

Robin, rō′băn′, CHARLES PHILIPPE: biologist and pathologist; b. at Josseron, department of Ain, France, June 4, 1821; graduated M. D. in Paris in 1846; devoted himself to the study of normal and pathological anatomy; in 1847 was made Associate Professor of Natural Sciences in the medical faculty; in 1858 was elected to the Academy of Medicine, and in 1866 to the Academy of Sciences; in 1862 he was appointed to the newly established chair of Histology. In 1865 he edited Nysten's *Encyclopædic Dictionary of Medicine*, for which he wrote a number of monographs. In 1864 he established the *Journal de l'anatomie et de la physiologie normales*, which he edited until 1885. In 1875 he was elected senator from Ain, and was re-elected in 1884. The progress made in France in histology is entirely due to his teaching. Among his numerous works are *Traité du microscope* (Paris, 1871); *Anatomie et physiologie cellulaire* (Paris, 1873); *Nouveau dictionnaire abrégé de médecine* (Paris, 1886). D. Oct. 6, 1885. S. T. ARMSTRONG.

Robin Goodfellow: a famous personage in English folklore; reputed to be a son of Oberon, king of the fairies, by a mortal mother; noted for his roguish tricks, his fondness for disturbing the peace of families, and his power of assuming various shapes, the "shrewd and knavish sprite" whose characteristics are fully given by Shakspeare in a well-known passage of *A Midsummer Night's Dream*. Shakspeare identifies him with the Puck or Hobgoblin, a domestic sprite who answers to the Knecht Ruprecht of Germany and the brownie of Scotch superstition. He is the "lubber fiend" of Milton's *L'Allegro*, who pinches sluttish maids, but rewards the clean-swept floor and the "cream-bowl duly set" for him, by threshing corn, grinding meal, breaking flax, etc., and sometimes leaves a silver sixpence in the good housemaid's shoe. (See Keightley's *Fairy Mythology*.) A popular volume entitled *The Mad Pranks and Merry Jests of Robin Goodfellow* appeared in 1628, and was reprinted by the Percy Society 1841. Revised by H. A. BEERS.

Robin Hood: See HOOD, ROBIN.

Robins, BENJAMIN: mathematician; b. at Bath, England, in 1707; devoted himself to mathematics, which he taught in London; invented the ballistic pendulum; made experiments on the resisting force of the air to projectiles, and studied fortification in Flanders; became engineer-in-chief to the East India Company 1749; fortified Madras, where he died of fever July 29, 1751. He prepared for the press in the name of Rev. Richard Walter, chaplain of the Centurion, the narrative of Anson's *Voyage around the World* (1748), and was author of *New Principles of Gunnery* (1742), besides other scientific writings.

Robin Snipe: See KNOT.

Robinson: city; capital of Crawford co., Ill.; on the Cleve., Cin., Chi. and St. L., and the Ind. and Ill. S. railways; 25 miles N. N. W. of Vincennes, and 44 miles S. of Paris (for location, see map of Illinois, ref. 8–G). It is in a fruit, corn, and wheat growing region, and has large wool interests, a private bank and three weekly newspapers. Pop. (1880) 1,380; (1890) 1,387; (1900) 1,683.

Robinson, BEVERLEY: soldier; b. in Virginia in 1723; was a major under Wolfe at Quebec 1759; married a daughter of Frederick Phillipse, thereby coming into possession of immense tracts of land on the Hudson; was opposed to the measures of the British ministry, but was loyal to the Government; removed into New York at the outbreak of the Revolution; recruited and commanded the Loyal American Regiment, of which he was colonel; was concerned in the negotiations preliminary to the treason of Arnold (who at that time occupied Robinson's country-seat); lost his property by confiscation; at the conclusion of the war went to New Brunswick, and then to England, and died at Thornbury in 1792.

Robinson, Charles Seymour, D. D., LL. D.: clergyman and hymnologist; b. in Bennington, Vt., Mar. 31, 1829; educated at Williams College and Union and Princeton Seminaries; pastor of Presbyterian churches—Park, in Troy, N. Y., 1855–60; First, in Brooklyn, 1860–68; American chapel in Paris 1868–70; Madison Avenue church, New York, 1870–87; Thirteenth Street 1890–92; New York Presbyterian church 1892–97. He published *Songs of the Church* (1862); *Songs of the Sanctuary* (1865); *Songs for Christian Worship* (1866); *Short Studies for Sunday-school Teachers* (1868); *Chapel Songs* (1872); *Bethel and Penuel* (1873); *Church Work* (1873); *Calvary Songs for Sunday-schools* (1875); *Psalms and Hymns* (1875); *Spiritual Songs* (1878); *Studies in the New Testament* (1880); *Spiritual Songs for Social Worship* (1881); *Spiritual Songs for Sunday-schools* (1881); *Studies of Neglected Texts* (1883); *Laudes Domini* (1884); *Sermons in Songs* (1885); *Sabbath Evening Sermons* (1886); *Simon Peter: Early Life and Times* (1887); *The Pharaohs of the Bondage and Exodus* (1887); *Studies in Mark's Gospel* (1888); *Laudes Domini for the Sunday-school* (1888); *Laudes Domini for the Prayer Meeting* (1889); *From Samuel to Solomon* (1889); *Studies in Luke's Gospel* (1889); *New Laudes Domini* (1892); *Annotations upon Popular Hymns* (1893); *Simon Peter: Later Life and Labors* (1894). D. Feb. 1, 1899.

Robinson, Christopher: See the Appendix.

Robinson, Edward, D. D., LL. D.: biblical scholar; b. at Southington, Conn., Apr. 10, 1794; graduated at Hamilton College 1816; was tutor there 1817–18; remained in Clinton, engaged in classical studies, till the autumn of 1821, when he went to Andover, Mass., to publish an edition of eleven books of the *Iliad* (the first nine, the 18th, and the 22d); was instructor in Hebrew in Andover Seminary 1823–26, under Prof. Stuart, whom he assisted in preparing the second edition (1823) of his *Hebrew Grammar*, publishing meanwhile (1825) his translation of Wahl's *Clavis Philologica Novi Testamenti*; studied in Europe, mostly at Halle and Berlin, 1826–30; in 1828 married, as his second wife, Therese Albertine Luise von Jakob, daughter of a distinguished professor at Halle (see Robinson, Therese); returned to the U. S., and was professor extraordinary at Andover 1830–33; broke down in health, and resided in Boston 1833–37; was professor in Union Theological Seminary, New York, from 1837 till his death Jan. 27, 1863. In 1838, and again in 1852, he traveled in Palestine with Rev. Eli Smith, the learned missionary. Besides the works already mentioned, he published Taylor's *Calmet* (1832); *A Dictionary of the Bible for the use of Schools and Young Persons* (1833); Buttman's *Greek Grammar* (1833; 2d ed. 1839; 3d ed. 1851); Gesenius's *Hebrew Lexicon* (1836: 5th ed. 1854); *Greek and English Lexicon of the New Testament* (1836; 2d ed. 1847); *Greek Harmony of the Gospels* (1845; 2d ed. 1851); *English Harmony of the Gospels* (1846); *Memoir of the Rev. William Robinson* (1859). In 1831 he founded *The Biblical Repository*, which he edited for four years, and in 1843 the *Bibliotheca Sacra*, for which he continued to write till 1855. His greatest work was *Biblical Researches* (1841, 3 vols.; compressed into two, and a third added 1856), for which, in 1842, he received the gold medal of the Royal Geographical Society. He also received the degree of D. D., previously (1831) conferred by Dartmouth College, from the University of Halle in 1842, and that of LL. D. from Yale College in 1844. His *Physical Geography of the Holy Land* was edited by Mrs. Robinson in 1864, and published in 1865. See *The Life, Writings, and Character of Edward Robinson*, by R. D. Hitchcock (New York, 1863).

Robinson, Sir Frederick Phillipse: soldier; son of Col. Beverley Robinson; b. on the Phillipse Manor, New York, in Sept., 1763; became an ensign in his father's Loyal American Regiment Feb., 1777; was wounded and taken prisoner at Stony Point; served in the West Indies, and with great distinction under Wellington in the Peninsular war, rising to be general; was commander-in-chief of the British forces in Canada 1812; participated in the campaign on Lake Champlain Sept., 1814; was knighted 1815; was governor of Upper Canada 1815–16; removed to the West Indies, where he commanded the forces; became full general 1841. D. at Brighton, England, Jan. 1, 1852.

Robinson, Henry Crabb: lawyer and man of letters; b. at Bury St. Edmunds, England, May 13, 1775; was articled to a lawyer at Colchester, and afterward in London; studied several years (1800–05) at Jena and other German universities, where he acquired a very thorough knowledge of modern German literature and philosophy; enjoyed the intimate friendship of Goethe, Wieland, Schiller, the Schlegels, and other eminent people; furnished data to Madame de Staël for her work on Germany; was correspondent of *The Times* in Spain at the beginning of the Peninsular war 1808–09; was engaged on his return to London as a regular writer for that journal; was called to the bar at the Middle Temple 1813; became a highly successful and prosperous lawyer on the Norfolk circuit, from which he retired with a fortune in 1828, and for the remainder of his life devoted himself to society and literary leisure, being prominently known as the intimate friend of Wordsworth, Blake, Clarkson, Flaxman, Lamb, Coleridge, Southey, and their compeers. He was one of the first members of the Athenæum Club, one of the founders of University College, London, and of the Flaxman Gallery, to which latter institution he left liberal bequests. D. in London, Feb. 5, 1867. He published little, but left a copious *Diary and Correspondence*, from which interesting selections were published in 1869. Revised by H. A. Beers.

Robinson, John: clergyman; b. in England, probably in Lincolnshire, 1575; entered Cambridge University 1592; pursued his studies in Corpus Christi College, and there became attached to Puritan doctrines; took preliminary orders in the Church of England; obtained a benefice near Great Yarmouth, Norfolk; was suspended by the bishop for nonconformity in ecclesiastical ceremonies 1602; gathered an Independent congregation at Norwich; formally separated from the Church of England 1604; resigned his fellowship at Cambridge; became assistant, and soon after sole, pastor of a Dissenting congregation (1604) gathered at Scrooby, Nottinghamshire (near the borders of Yorkshire and Lincolnshire), where the Brewsters, Bradfords, and Mortons were among his flock; suffered a persecution which led many of his congregation to emigrate with him to Amsterdam, Holland, 1608; removed to Leyden 1609; gathered there a numerous church, constantly re-enforced by arrivals from England; attended lectures at the university, of which he afterward became a member; held a public discussion with the Dutch professor Episcopius, the successor of Arminius, upon the Calvinistic doctrine of predestination, 1613; entered into the plans for colonization in New England about 1617; was active in promoting the negotiations, through Cushman, Carver, and Brewster, with the Plymouth Company of capitalists; dismissed a portion of his congregation with a memorable sermon on their embarkation for America July 22, 1620, intending to follow them the next year; but before the negotiations were completed he died at Leyden about Mar. 1, 1625. He was buried in St. Peter's church, the members of the university and the ministers of the city attending his funeral. Among his numerous controversial publications were *A Justification of Separation* (1610); *Of Religious Communion* (1614); *Apologia Justa et Necessaria* (1619); *A Defense of the Doctrine propounded by the Synod of Dort* (1624); *Essays or Observations, Divine or Moral* (1628); *A Treatise of the Lawfulness of Hearing of the Ministers in the Church of England* (1634); and *An Apology for Certain Christians no less contumeliously than commonly called Brownists or Barrowists*. His complete *Works*, with a memoir, appeared in London and Boston in 3 vols., 1851. In 1891 a bronze tablet to his memory, placed on an outer wall of St. Peter's, was dedicated by representatives of the National Council of the Congregational Churches of the U. S. Revised by G. P. Fisher.

Robinson, John Cleveland: soldier; b. at Binghamton, N. Y., Apr. 10, 1817; entered the U. S. Military Academy 1835, but without graduating began the study of law in 1838. In 1839, however, he accepted a second lieutenancy in the Fifth Infantry, and served in the war with Mexico and in Florida against the Indians. In Sept., 1861, he was appointed colonel of the First Michigan Volunteers, and in Apr., 1862, brigadier-general of volunteers, serving in command of a brigade with the Army of the Potomac in the Virginia peninsular campaign of 1862, at the second battle of Bull Run, Chantilly, and Fredericksburg. At Gettysburg and in the Richmond campaign of 1864 he commanded a division with great bravery, losing a leg on the fourth day of fighting in the latter campaign, near Spottsylvania Courthouse, while leading the advance of the army; was appointed brevet brigadier-general and major-general for gallantry. In 1866 he attained the colonelcy of the Forty-third Infantry, and in 1869 was retired from active service on the full rank of major-general. In 1872 he was elected Lieutenant-Governor of the State of New York, and in 1894

received from the Secretary of War a medal of honor for distinguished gallantry in action near Spottsylvania Courthouse. D. in Binghamton, N. Y., Feb. 18, 1897.

Robinson, Lucius, LL.D.: Governor of New York; b. at Windham, Greene co., N. Y., Nov. 4, 1810; educated at the academy at Delhi; studied law, and was admitted to the bar in 1832; appointed master in chancery in 1843, and reappointed in 1845; joined the Republican party on its formation; elected to Legislature in 1859, and appointed comptroller of the State in 1861, and again in 1863; nominated by the Democrats in 1865 to the same office, but was defeated; was a member of constitutional commission 1871–72; elected comptroller of the State on the Democratic ticket in 1875, and Governor in 1876; nominated for Governor of New York by the Democrats in 1879, but was not elected. D. at Elmira, N. Y., Mar. 23, 1891.

Robinson, Robert: preacher; b. at Swaffham, Norfolk, England, Oct., 1735; studied in the grammar school at Scarning; was apprenticed in his fifteenth year to a London hair-dresser; began preaching as a Calvinistic Methodist 1755; soon became a Baptist and formed a congregation at Cambridge, eking out his small stipend by selling grain and coals; applied himself to the study of languages; acquired a deservedly high reputation for eloquence, wit, goodness, and liberality (being the Sydney Smith of the time); made a translation of Saurin's *Sermons* (5 vols., 1775–84); published *A Plea for the Divinity of our Lord Jesus Christ* (1776), popular hymns and tracts, and left a learned *History of Baptism* (1790), posthumously published. D. in Birmingham, June 8, 1790. He was said to have become a Socinian (i. e. Unitarian) in his later years. His *Life*, by George Dyer (1796), is a valuable work.

Revised by W. H. Whitsitt.

Robinson, Therese Albertine Luise (*von Jakob*); author; daughter of Prof. Ludwig H. von Jakob; b. at Halle, Prussia, Jan. 26, 1797; translated Scott's *Old Mortality* and *Black Dwarf* into German (1822); published *Psyche*, *Original Tales* (1824), under the *nom de plume* of *Talvj* (the initials of her name), and *Servian Songs* (2 vols., 1825–26); married Prof. Edward Robinson 1828 (see Robinson, Edward); contributed largely to *The Biblical Repository*, edited by her husband; published in Germany *Characteristics of the Popular Songs of the German Nations* (1840) and a treatise *On the Authenticity of the Poems of Ossian* (1840). In 1850 appeared her chief work (in English), *An Historical View of the Languages and Literature of the Slavic Nations* (New York and London). D. in Hamburg, Apr. 13, 1869. A posthumous work appeared under the title *Fifteen Years, a Picture from the Last Century* (New York, 1870).

Robinson Crusoe: See English Literature (*Defoe*).

Robitaille, rō′bi-taal′, Theodore: senator; b. at Varennes, P. Q., Canada, Jan. 29, 1834; graduated M. D. at McGill College in 1858. He represented Bonaventure in the Canadian Assembly 1861–67; the same constituency in the Parliament of the Dominion 1867–78; and was receiver-general from Jan. 30, 1873, until Nov. 5, same year, when he resigned with the other members of the cabinet, on the Pacific Railway matter. He was Lieutenant-Governor of Quebec 1877–84, and was called to the Senate Jan. 29, 1885. N. M.

Rob Roy: the popular name of a Scotch outlaw (*Roy* or *ruidh* meaning "red" in Gaelic), whose true name was Robert MacGregor; b. in Scotland about 1660; changed his name to Campbell on the outlawry of the clan MacGregor 1693; became a partisan of the Pretender in 1715, and for many years thereafter continued to make depredations, chiefly upon the retainers of the Duke of Montrose. D. near Aberfoyle, Dec. 28, 1734. His exploits, long traditional in Scotland, formed the basis of a novel by Sir Walter Scott. See the *Lives* by Macleay (1818; new ed. 1881) and Miller (1883).

Robson, Stuart: actor; b. at Annapolis, Md., Mar. 4, 1836. He made his first appearance in Baltimore Jan. 5, 1852, in *Uncle Tom's Cabin as It Is*. In June, 1855, he played small parts at the Washington Varieties. He was afterward engaged as second low comedian at the Troy Museum. On Sept. 15, 1862, he made his first appearance in New York at Laura Keene's theater as Bob in *Old Heads and Young Hearts*. He became popular and added to his repute by his engagements at the Arch Street theater in Philadelphia. From 1868 to 1870 he played in Boston; in the season of 1873–74 he made his most pronounced metropolitan hit as Hector in *Led Astray* at the Union Square theater, New York. He did not, however, repeat his success in London, where he went with Dion Boucicault at the end of 1874. In 1877 he entered into partnership with W. H. Crane and successfully produced *Our Boarding House* at the Park theater, New York, Jan. 29, 1877. *Our Bachelors* and *Sharps and Flats* also proved successful. Robson and Crane's conspicuous success in *The Henrietta* ended after two years, Robson playing alone in the piece and making it the principal one in his repertory. B. B. Vallentine.

Robusti, rō-boos′tĕĕ, Jacopo, called **Tintoretto**: painter; b. at Venice in 1512 or 1518. He was the son of a dyer (*tintore*, hence *il tintoretto*, the young or little dyer). He is said to have been a pupil of Titian for a very short time only, and no other teacher is named, except that he had Andrea Schiavone as a fellow worker, who, however, was younger than he. He lived poor and unknown for several years, exercising his surprising natural gift for painting, studying also the art of modeling in wax and clay and arranging groups and compositions of figures so made. Among his earlier pictures are two, now in the Academy of Fine Arts at Venice, but painted for the ancient Scuola (charitable society) della Trinità; these are the *Fall of Man* and *The Death of Abel*, noble pictures. The *Abel* in particular is a beautiful piece of warm color, and in character quite different from the work of Titian or of any other Venetian. Cole, who made on the spot a wonderful wood-engraving from this picture, speaks of it as "a Venetian Rembrandt" in its depth and softness. In this and in the *Fall of Man* appears a tendency toward the unusual in composition; the main lines are strongly diagonal in one and twisted or involved in loops in the other. The one is the scene of violent action, the other of repose, but in each the unusual power of drawing the human body in movement is very visible. A very remarkable love of landscape is also evident in these pictures. All these gifts and peculiarities are marked throughout the artist's career. The *Bacchus and Ariadne* of his later life is very similar in composition to the *Fall of Man*, and something of the same thought is in the *Three Graces with Mercury*. About 1546 he seems to have undertaken the two very large pictures in Santa Maria dell' Orto, the *Last Judgment* and *Moses on Mt. Sinai*, or the *Golden Calf* as it is sometimes called, and from that time he was always busy, and generally upon large and important pictures. Strange stories are told of his eagerness to work on the largest scale, indoors or on house-fronts, at the lowest prices or for nothing. He is said to have painted a large picture during the few days allowed for making sketches in competition for the Scuola di San Rocco, and in this way to have secured the employment he desired, though at a very low rate of payment, at least at first. The largest picture in Europe is Tintoretto's *Last Judgment*, in the hall of the Greater Council in the ducal palace, given as 75 feet long." It is only at very favorable times that any clear view of this picture can be had; it is faded and smoked, and has been repainted in many places, and opinions of competent persons differ widely as to the value of what is left. Another very large painting is *The Crucifixion*, in the Scuola di San Rocco, which must be 45 feet long, as it fills all the upper wall of the Sala del Albergo. This picture is famous; it has been engraved on a large scale by Agostino Caracci, and it is called Tintoretto's masterpiece. In color and in the highest artistic qualities it is not his best work, but it shows, as well as any, some of his excellences as a designer and as an executant. Thus the event of the Crucifixion is taken before it is complete, and it is evident that the whole series of acts making up the public execution of three persons by the cross has been seen with the eye of imagination. In full harmony with this power of perception and interpretation is the artist's power of drawing the human form in vigorous action. All in the picture is movement and stir, and every figure in the enormous panoramic scene is busied in some special way, but nowhere does the skill and knowledge of the draughtsman fail him for a moment. It is evident that this is not at all the way in which the events of the New Testament history were generally represented by the great Italians; this is the modern way of proceeding, the story is told as the event might actually have taken place. Now it is probable that the very highest artistic qualities, as beauty of composition in line and mass and beauty of color, are incompatible with such vigorous narrative; but if Tintoretto's large paintings had not suffered so cruelly from fading and from candle-smoke and from repainting

we should know more than we do of what graphic art is capable. The best and best-preserved specimen of his historical or descriptive work is the *Miracle of St. Mark*, in the Academy at Venice, which is splendid and deeply satisfying in color, while full of strenuous action; and if its composition in line and mass is not altogether of the highest order, it only misses this excellence by a little. Still, for many art lovers, such smaller and more simple pictures, as the *Death of Abel*, mentioned above, or the *Bacchus and Ariadne*, or the *Pallas defending Peace and Abundance*, in the Antieollegio of the ducal palace, or even the not uncommon portraits of robed senators, are more precious than the large pictures of action.

Little is known of the details of this artist's life, for it was filled with hard work in Venice, which city he seldom left. The work in the Scuola di San Rocco was begun in 1560, and soon after this time his first paintings in the ducal palace were undertaken. After the fire which destroyed half the palace in 1577 he undertook other works there, and the San Rocco work was also continued during all those years. The great *Paradise* was painted about 1586. D. at Venice, May 31, 1594.

Of his numerous pictures the following may be mentioned: In the Scuola di San Roeco, eight large pictures on the walls of the lower hall, thirteen on the walls of the upper hall, and thirteen on the ceiling of the same, all of biblical subject except two or three, which deal with the legend of St. Roch (S. Rocco); also, in the Albergo, *The Crucifixion* and another large picture. In the ducal palaee, ten historical pictnres, besides the great *Paradise*, on the wall of the Greater Council, and, in the smaller halls of the upper story, fifteen large pictures, mostly of Venetian historical and emblematic subject with several mythological subject and two of the Bible history, besides many portraits. In the Academy of Fine Arts, besides the three already named, there are a *Crucifixion with the Three Marys*, a *Descent from the Cross*, a *Virgin and Child*, each of these having portraits of Venetian nobles introduced, an *Assumption of the Virgin and Mary*, and portraits of extraordinary value. In the Church of Madonna del Salute is *The Marriage of Cana*, a noble work. In the Madonna dell' Orto are the pictures described above and three others, of which the *Last Judgment* has been much described and commented on. In the Carmini, or Church of the Carmelite friars, is a *Presentation in the Temple*. In S. Giorgio Maggiore are the *Last Supper*, *The Israelites gathering the Manna*, and several other important pictures. Perhaps a dozen other churches in Venice have works which should be studied. Pictures of his hang in the galleries of the Uffizi and the Pitti Palace at Florence, in the British Museum, in the Old Pinakothek at Munich, in the Louvre, and in the National Gallery of London.

Little has been published about Robusti except the notices in biographical dictionaries and guide-books, probably because the interest of his career lies in his art alone. A biography by W. R. Osler in the Great Artist Series was published in 1879. See Janitschek, *Kunst und Künstler*.

RUSSELL STURGIS.

Roby, HENRY JOHN: educator; b. at Tamworth, England, Aug. 12, 1830; graduated at Cambridge 1853; became fellow of St. John's College 1854; was assistant tutor 1855–56, and reappointed 1860; was university examiner in law, classics, and moral sciences 1859–61; member of, and secretary to, the local examination syndicate 1858–59; took a prominent part in urging university reform: was assistant master of Dulwich College 1861–65; Professor of Jurisprudence at University College, London, 1866–68; was appointed by the crown secretary to the schools inquiry commission Dec., 1864, to the endowed schools commission Aug., 1869, and was a member of that body 1872–75. He was elected member of Parliament for Eccles Oct., 1890. He edited the *Report* of the school commissioners and the numerous volumes of documents thereto appended (Mar., 1868); author of an *Elementary Latin Grammar* (1862; 2d ed. 1882); and a valuable *Grammar of the Latin Language, from Plautus to Suetonius* (2 vols., 1871–74; 5th ed. 1887); *Introduction to Study of Justinian's Digest* (1884).

Revised by BENJ. IDE WHEELER.

Roca, JULIO A.: general and statesman; b. at Tucuman, Argentine Republic, July, 1843. He studied in the military school at Paraná, joined the army, and became general in 1874. He was Minister of War under President Avellaneda 1878–80, and in this capacity headed the expedition by which the Indians of Patagonia were finally reduced to subjection. He was president Oct. 12, 1880, to Oct. 12, 1886, and was again chosen in 1898. Specie payments were suspended in 1885, marking the beginning of the great Argentine crisis which soon after convulsed the financial world. H. H. S.

Rocafuerte, rō-kaă-fwār'tā, VICENTE: statesman; b. at Guayaquil, Ecuador, May 3, 1783. He was educated in France and England, where he derived republican ideas from Miranda, Bolivar, and their associates. In 1812 he was elected deputy for Guayaquil to the Spanish Cortes. After his country became a part of Colombia he held diplomatic positions in North America and Europe, and he resided several years in Mexico, where he was a prominent journalist. Returning to Guayaquil in 1833 he was elected to congress, but his liberal opinions caused him to be exiled. The same year the liberals revolted at Guayaquil and proclaimed him supreme chief, but he was defeated and captured by Flores. The latter magnanimously offered to co-operate with him in the reorganization of the republic, and under this arrangement Rocafuerte was president from 1835 to 1839. This period was the most prosperous in the history of Ecuador, and the president won universal respect. Subsequently he held various civil and diplomatic positions. He published many works on political subjects. Rocafuerte was unquestionably the greatest statesman of Ecuador. D. at Lima, Peru, May 16, 1847. HERBERT H. SMITH.

Roc'ambole [= Fr., from Germ. *rockenbolle*, rocambole, liter., rye-bulb; so called because it grows among rye]: the *Allium scorodoprasum*, a plant of the garlic family, much resembling garlic, but larger and milder. It is cultivated in European kitchen-gardens, and is a native of northern regions.

Rochambeau, rō'shăń'bō', JEAN BAPTISTE DONATIEN DE VIMEUR, Count de: marshal of France; b. at Vendôme, France, July 1, 1725; entered the army 1742; was distinguished in the campaigns of the Seven Years' war; was made lieutenant-general Mar. 1, 1780; commanded the French forces in the U. S. during the war of independence 1780–82; took a prominent part in the campaign of Yorktown 1781; became governor of Picardy 1783; was made marshal 1791; commanded the Army of the North from Mar. to June, 1792; was imprisoned during the Reign of Terror, and escaped the guillotine only through the death of Robespierre; was appointed by Napoleon, when First Consul, grand officer of the Legion of Honor (1804). D. at Thoré, May 10, 1807. His *Mémoires* were published in 1809, and translated into English in 1838.

Rocha Pitta, SEBASTIÃO, da: author; b. at Bahia, Brazil, May 3, 1660; educated at Bahia and at Coimbra, in Portugal, he married early and settled on his property, living a life of studious leisure. He wrote there some mediocre verse and a now forgotten romance. Late in life he determined to write a history of Brazil, and undertook the most extensive preparations for the task. He even went to Lisbon in search of documents. In 1728 he completed the work, calling it *Historia da America portugueza desde o seu descobrimento até o anno 1724* (Lisbon, 1730). His success was great, and brought him many honors. His last years were spent in retirement on his estates near Cachoeira, Brazil. D. Nov. 3, 1738. His book was the first real history of Brazil, and though he was often over-credulous in his use of documents, he gathered a vast mass of material for his successors. A. R. MARSH.

Rochdale: town; in Lancashire, England; on both sides of the Roch; 11 miles N. by E. of Manchester (see map of England, ref. 7–G). St. Chad's parish church (twelfth century, restored 1885) is a Perpendicular building, approached by a flight of 122 steps. The town-hall (1866–71) is a fine example of the Gothic style. Rochdale has large manufactures of woolen goods, such as baize, flannels, blankets, and kerseys, cotton goods, especially calicoes, and iron and steel ware. It is distinguished as having made the first successful attempt at CO-OPERATION (*q. v.*). It returns one member to parliament. Pop. of parliamentary borough (1891) 76,161; (1901) 83,112.

Rochefort, rōsh'fōr', or **Rochefort-sur-Mer**, -sür-mār' (anc. *Rupifortium*): town; in the department of Charente-Inférieure, France; on the right bank of the Charente, 9 miles from its mouth. It has a port and a naval arsenal, is surrounded by walls and ramparts planted with trees, and is defended by forts at the entrance into the river (see map of France, ref. 6–D). Outside is a roadstead protected by the

islands of Ré, Oleron, and Aix. Its two harbors are spacious and safe, able to accommodate the largest ships of war, and lined with wharves, docks, arsenals, ropewalks, cannon-foundries, etc. It has a large naval hospital and schools of navigation. It was founded as a naval station by Colbert in 1665, and fortified by Vauban. Pop. (1896) 34,392.

Rochefort, Victor Henri, Marquis de Rochefort-Luçay: journalist; b. in Paris, France, Jan. 30, 1830; educated at the college of St. Louis; became one of the editors of *Figaro*, and was removed from that position because of his satires on the imperial Government. In June, 1868, he founded *La Lanterne*, in which he so bitterly attacked the empire that in August of the same year the journal was suppressed and its editor condemned to one year's imprisonment and a fine of 10,000 francs. He fled to Belgium, and there resumed the publication of *La Lanterne*, which was circulated surreptitiously in France. In 1869 he was elected a member of the Corps Législatif. Later in the same year he founded a radical journal, *La Marseillaise*, and in Jan., 1870, was sentenced to six months' imprisonment and fined 3,000 francs for violent language. He remained in prison until the fall of the empire at Sedan, Sept. 4, 1870. In that month he became a member of the government of national defense and member of the committee on barricades. In 1871 he founded another journal, *Le Mot d'Ordre*, and was chosen a member of the National Assembly, from which he resigned after voting against the proposed basis of peace. He declined to be a member of the Commune, but violently opposed the Government. On the entrance of the national troops into Paris he fled toward Belgium, but was arrested, tried for complicity in the acts of the Commune, sentenced to imprisonment for life in a fortress, and sent to the penal settlement of New Caledonia, whence he and several of his associates escaped in the spring of 1874, and returned to Europe by way of the U. S. He resided at Geneva until the amnesty of July 11, 1880, allowed him to return to Paris, where he founded a new radical paper, *L'Intransigeant*. He was elected to the Chamber in 1885, but resigned a few months later, and devoted himself to his paper, which became notorious for the virulence of its language in attacks on the leading politicians of the time. He was an ardent champion of Boulangism in 1888, and was condemned by the high court of justice in the following year, but he escaped imprisonment by fleeing to London. Profiting by an amnesty in 1895 he returned to Paris. In his long and turbulent career he has been involved in many lawsuits and duels. He is the author of a number of farces, vaudevilles, comic romances, etc. Revised by F. M. Colby.

Rochefoucauld: See La Rochefoucauld.

Rochefoucauld-Liancourt, Duc de la: See La Rochefoucauld-Liancourt.

Rochejacquelein: See La Rochejacquelein.

Rochelle: city; Ogle co., Ill.; on the Burl. Route and the Chi. and N. W. railways; 27 miles S. of Rockford, 75 miles W. of Chicago (for location, see map of Illinois, ref. 2–E). It is the geographical and trade center of a large agricultural and stock-raising region, and contains a national bank with a capital of $50,000, a private bank, and two weekly newspapers. Pop. (1890) 1,789; (1900) 2,073.

Rochelle Salt (named from La Rochelle in France, where it was first prepared in 1672): the double tartrate of sodium and potassium, an efficient cathartic, considered more palatable than most preparations of the kind. It is chiefly used in preparing seidlitz powders.

Rochester: city; in Kent, England; on the Medway; 29 miles E. S. E. of London (see map of England, ref. 12–K). It is continuous with Chatham, and connected with Strood by an iron swing-bridge. Near the bridge is a castle founded in 1126; the wall overlooking the river is a fine specimen of Norman architecture of an earlier date. The bishopric was founded in 604, and the foundations of the cathedral then built have been brought to light. Another cathedral was built about 1100. This has been rebuilt and restored several times. Features of interest are the Early English choir and the Norman nave. Rochester has some trade in coal and hops. Pop. (1891) 26,170.

Rochester: town; capital of Fulton co., Ind.; on the outlet of Lake Manitou, and the Erie and the Lake Erie and West. railways; 24 miles N. by E. of Logansport, 90 miles N. of Indianapolis (for location, see map of Indiana, ref. 3–E). It has large water-power from the lake, and contains several flour and grist mills and other manufactories, a State bank with capital of $50,000, 2 private banks, a high school, and a daily and 3 weekly newspapers. It ships large quantities of flour, grain, and produce. Pop. (1890) 2,467; (1900) 3,421. Editor of "Republican."

Rochester: city; capital of Olmsted co., Minn.; on the Zumbro river, and the Chicago and N. W. Railway; 40 miles S. of Red Wing, 90 miles S. by E. of St. Paul (for location, see map of Minnesota, ref. 11–G). It is the center of a great grain-growing region, and has large dairying and horse-breeding interests. Excellent water-power is derived from the river and utilized in manufacturing. There are several flour and grist mills, elevators, foundries, and machine-shops, a high school, the Second Minnesota Hospital for the Insane, 4 libraries (the Public, High School, Insane Hospital, and German) containing over 7,000 volumes, the Notre Dame de Lourdes Academy (Roman Catholic, opened 1877), 3 national banks with combined capital of $200,000, and a monthly, 3 daily, and 5 weekly periodicals. Pop. (1880) 5,103; (1890) 5,321; (1900) 6,843.

Rochester: city (settled in 1728, incorporated as a township in 1737, chartered as a city in 1891); Strafford co., N. H.; on Salmon Falls, the Cocheco river, and the Boston and Maine Railway; 10 miles N. N. W. of Dover, and 30 miles E. by N. of Concord (for location, see map of New Hampshire, ref. 8–G). It has exceptional water-power, manufactories of shoes and woolen goods, 6 churches, a national bank with capital of $100,000, 2 savings-banks, a library (founded in 1792), and 3 weekly newspapers. Pop. (1890) 7,396; (1900) 8,466. Editor of "Courier."

Rochester: city, port of entry, and capital of Monroe co., N. Y.; 229 miles W. of Albany; lat. 43° 9′ 22″ N., lon. 77° 36′ 51″ W. (for location, see map of New York, ref. 4–D). The site is upon a level plain on both banks of the Genesee river, 7 miles from, 263 feet above, Lake Ontario, and 510 feet above sea-level. Within the city limits there are three falls of 96 feet, 26 feet, and 83 feet respectively, below the last of which the stream becomes navigable for lake vessels. From the upper fall, near the center of the city, N. nearly to the lake, the river banks are of precipitous rock, varying in height from 100 to 210 feet. The fine bridges spanning this gorge afford a view that is especially attractive to visitors. On the banks of the river, both to the N. and S., beautiful parks, embracing 615 acres, have been laid out, and the lake shore, where there are numerous and attractive summer resorts, is accessible by spacious boulevards and by both steam and electric cars on either side of the river. The main line of the New York Central and Hudson River Railroad crosses the city at the upper fall upon elevated tracks, and there are three branches of the road entering here—one to Syracuse viâ Auburn, one to Niagara Falls, and one to the mouth of the Genesee. Other railways having termini here are the Rochester Division of the Erie, the Northern Central, running to Baltimore, the Buffalo, Rochester and Pittsburg, the Western N. Y. and Penn., the Lehigh Valley, the Rome, Watertown and Ogdensburg, the West Shore, and a belt line connecting all the other lines with one another and with the port of Genesee. The Erie Canal crosses the river by a fine stone aqueduct, 848 feet long, on seven arches. The city has an average length of 5 miles, by about the same breadth. It is laid out in broad streets, generally well paved and lighted, and abounding in fine shade trees. The dwellings are, to a much greater degree than is usual in cities of its size, detached and surrounded by lawns and shrubbery. The business portion contains an unusually large number of fine buildings.

Public Buildings.—The court-house, city-hall, and adjacent buildings form a striking architectural group in the center of the city. Other notable edifices are the Government building and the State arsenal, with the Soldiers' Monument in front of it. The Lyceum theater, the Genesee Valley Club-house and the Eureka Club-house compare favorably with similar structures in other cities. The Y. M. C. A. has a fine building, and there are 118 churches, of which several have new and very attractive houses of worship. The Presbyterians report 7,940 communicants; the Lutherans, 7,990; the Baptists, 4,945; the Episcopalians, 3,667; the Methodists, 4,150. Rochester is a cathedral city and the Catholics are numerically very strong.

Schools and Colleges.—In the matter of education Rochester has for many years been prominent. The university (see Rochester, University of) has taken high rank among the colleges of the U. S. There is also a flourishing Baptist Theological Seminary that maintains a German as well as

an English department; Wagner College, supported by the Lutherans; and St. Bernard's Seminary, designed to educate candidates for the Catholic priesthood. The Western New York Institute for Deaf Mutes has achieved a world-wide reputation by its improved methods of instruction; and the Mechanics' Institute, with a fine new building, is placing technical instruction and familiarity with the homelier arts of life within reach of the masses. There is a young but vigorous Historical Society, and an Academy of Science. There are 38 public schools, 5 schools connected with orphan asylums but supported and supervised by the city, and a High School, in all of which 24,765 pupils are instructed by 698 teachers, at an expense of $26.77 per annum for each pupil. It is estimated that 8,000 pupils attend the parochial and other private schools. In the High School building there is a public library of 35,000 volumes; in the court-house there is a valuable law library of 25,000 volumes; the Reynolds Free Library contains 45,000 volumes, and is especially complete in books of reference; the library of the university contains 37,000 volumes, and that of the Theological Seminary 30,000 volumes.

Public Institutions.—There are four hospitals (City, St. Mary's, Homœopathic, and Hahnemannian) with spacious buildings, capable of providing for 700 patients. The State Industrial School is situated in the northern part of the city, and occupies an inclosure of 42 acres, on which there are nine large buildings. Juvenile offenders are received from all parts of the State except New York and Kings County, and the school numbers about 650 boys and 150 girls. The Monroe County penitentiary, almshouse, and asylum for the insane are situated just S. of the city. Mt. Hope Cemetery, one of the oldest of its kind in the U. S., was established 1838, has a naturally beautiful site, and has been laid out with much care and taste. The Catholic Cemetery of the Holy Sepulchre, established 1872, is located on a fine site of 140 acres upon the river bank N. of the city; and near this is the new and beautiful Riverside Cemetery. A gas and electric company, with a capital of $4,300,000 and 200 miles of mains, supplies the city with light. The Rochester Street-railway Company, with a capital of $5,000,000, maintains 12 lines of electric cars, with a trackage of 86 miles. A magnificent system of water-works was constructed in 1874, with two sources of supply—one from the river, the water being forced through 10 miles of mains in the business center by the Holly patent, and used for suppressing fires and running light machinery; the other from Hemlock Lake, 29 miles S. and 400 feet above the city. The water from this source is distributed through 273 miles of mains, which can furnish 23,000,000 gal. daily. The total cost of the system was $7,000,000.

Business Interests.—There are in Rochester 7 banks of discount, with a capital and surplus of $2,830,000 and deposits of over $13,000,000; 4 savings-banks and 4 trust companies, with deposits of over $50,000,000 and a surplus of over $5,500,000. Owing to the surpassing fertility of the Genesee valley and its fine water-power, flour was formerly the chief product of Rochester. There are still 16 flouring-mills in operation, with an aggregate capacity of 5,000 barrels a day. The nursery business has, however, become of far more importance, and in this line Rochester outranks every other city. In the manufacture of clothing Rochester ranks third among the cities of the U. S., with an annual output of $10,000,000. In the manufacture of shoes it ranks fourth. Several large breweries send out 538,000 barrels of beer per annum. A single tobacco-factory employs 450 hands, and the value of the city's output in that line of business is $4,500,000. The largest carriage-factory in the U. S., employing 800 hands, is situated here; also, the largest button-factory, and the largest manufactory of optical instruments. The kodak camera business originated here, and there is $5,000,000 invested in it. Several large establishments are engaged in the manufacture of perfumery. Rochester locks, microscopes, and vacuum oil-products have a worldwide celebrity, and contribute much to the prosperity of the city. According to the U. S. census of 1890 Rochester had 1,892 manufactories, employing 37,720 persons, and yielding products valued at $65,091,156. From its proximity to the coalfields of Pennsylvania, it has become a great distributing center for coal, which is loaded from railways on the banks of the river into vessels that convey it to all points on the lakes. In 1900 Rochester ranked sixth in exports and fourth in imports of the lake ports of the U. S.

History, etc.—The first house was erected in 1812, and the place was incorporated as the village of Rochesterville in 1817 and as a city in 1834. From the first there has been a steady growth in wealth and population, which lately, through the influence of an energetic chamber of commerce, have increased with phenomenal rapidity. The assessed valuation is $127,935,545. From the "Rochester rappings" (1848–49) the city may be regarded as the birthplace of modern Spiritualism; it was also the center of the anti-Masonic excitement (1827–29). Pop. (1820) 1,500; (1880) 89,366; (1890) 133,896; (1900) 162,608. J. H. Gilmore.

Rochester: borough; Beaver co., Pa.; at the confluence of the Ohio and Beaver rivers, and on the Pitts., Ft. Wayne and Chi. and the Cleve. and Pitts. railways; 26 miles N. W. of Pittsburg (for location, see map of Pennsylvania, ref. 4–A). It is in a fire-clay, coal, oil, and building-stone region, and is connected by electric street-railway with New Brighton, Beaver, and Beaver Falls, and by a bridge across the Beaver river with Bridgewater. There are 11 churches, 2 graded public schools, 2 hotels, 22 societies and lodges, Masonic temple, a national bank with capital of $50,000, a private bank, and a weekly newspaper. The manufactures include tumblers, bottles, stoves, brick, flour, and lumber. Pop. (1800) 2,552; (1890) 3,649; (1900) 4,688.

Rochester, John Wilmot, Earl of: b. at Ditchley, Oxfordshire, England, Apr. 10, 1648; succeeded to the title 1659. He became a favorite at the court of Charles II.; wrote poems in accordance with the prevailing taste; was famous for his wit and infamous for his vices. He had Dryden beaten by a gang of hired bullies in 1679 in revenge for a passage lampooning Rochester in Dryden's alleged *Essay on Satire*. His death-bed repentance was described by Bishop Burnet in a pamphlet which had an extraordinary sale. D. July 26, 1680. His *Poems* and *Familiar Letters* were posthumously published. See his *Life*, by Dr. Johnson. Revised by H. A. Beers.

Rochester, University of: a college established at Rochester, N. Y., in 1850. At that time the whole of Western New York was without any important institution of this kind. The founders were principally Baptists, although the charter contains no denominational restriction. The university has had three presidents, Martin B. Anderson, who served from 1853 to 1888; David J. Hill, elected in 1888; and Rush Rhees, 1900. Among the local benefactors have been Hiram Sibley, who gave $100,000 for the erection of Sibley Hall, a fire-proof building containing the library and museum; Mortimer F. Reynolds, who built a chemical laboratory; and Don Alonzo Watson, who established a professorship in history and political science with an endowment of $50,000. The original campus, afterward enlarged to 24 acres, was the gift of the Hon. Azariah Boody. The assets of the university in 1899 were $1,193,812, of which $724,301 was invested in productive funds yielding an annual income of $33,368, and the remainder, $469,511, in buildings, books, and appliances. In 1900 the faculty was composed of 18 professors and instructors, and the students numbered 230. There are four courses of study leading to a degree, embracing 100 courses of instruction. The library contains nearly 36,000 bound volumes, and several thousand pamphlets. The reputation of the institution has rested chiefly upon the character of its work as a classical college, but within recent years the natural sciences have occupied a larger place in the curriculum. Since Sept. 8, 1900, women have been admitted to all courses on the same terms as men. The geological museum is one of the finest in the U. S., being the original Ward collection amplified.

Rochet, rō'shā', Louis: sculptor; b. in Paris, Aug. 24, 1813; studied under Pierre Jean David, called David d'Angers, and began to exhibit in 1835, his first statue being a *Boy Extracting a Thorn from his Foot*. Among his most prominent works are the *Statue of Marshal Drouet*, at the Versailles Museum; *William the Conqueror*, a statue at Falaise in Normandy; a life-size statue of *Napoleon*, and another, *Napoleon as a Scholar at Brienne* (1853); *Madame de Sévigné*, at Grignan (1857); a colossal equestrian statue of Pedro I., at Rio de Janeiro (1861); and a similar statue of Charlemagne (1867). D. in Paris, Jan 21, 1878.

Rockall Islet: See the Appendix.

Rock-butter: See Butter.

Rock-crystal: See Quartz.

Rocker: an instrument used in mezzotint engraving. See Engraving (*Mezzotint*).

Rocket: See Dyers' Weed.

Rocket [from O. Ital. *rochetta*, rocket, dimin. of *rocca*, distaff]: a projectile known from remote antiquity in China and India, but first introduced into Europe about A. D. 900. Its distinguishing characteristic is that it is set in motion by a force within itself, and therefore combines the functions of gun and projectile. Rockets were employed at first chiefly in fireworks for popular amusement; were subsequently utilized in war for igniting an enemy's citadel; and were also used for signals. About the beginning of the nineteenth century Sir William Congreve gave them greater precision, and prepared them for extended military employment as weapons of offense. Their chief use, however, remains that of pyrotechnic display.

Rock Falls: city; Whiteside co., Ill.; on the Rock river, and the Chi., Burl. and Quincy Railroad; 20 miles W. by N. of Amboy, 77 miles W. of Aurora (for location, see map of Illinois, ref. 2–D). It has good water-power, contains a public high school, a private bank, and a weekly newspaper, and is principally engaged in the manufacture of agricultural implements, barbed wire, wagons, furniture, flour, and paper. Pop. (1880) 894; (1890) 1,900; (1900) 2,176.

Rockfish, or **Rock**: a name under which the *Roccus lineatus* (striped bass) is known along the Atlantic seaboard of the U. S. from Southern New Jersey southward to Virginia. See Bass and Fisheries.

Rockford: city (settled in 1836, incorporated as a city in 1852, enlarged by annexations in 1890); capital of Winnebago co., Ill.; on both sides of the Rock river, and the Burlington Route, the Chi. and N. W., the Chi., Mil. and St. P., and the Ill. Cent. railways; 28 miles E. of Freeport, and 92 miles W. of Chicago (for location, see map of Illinois, ref. 1–E). A dam across the river creates excellent water-power for manufacturing, and 3 railway and 3 highway bridges facilitate communication. Water for domestic and fire-extinguishing purposes is provided by a system which utilizes five artesian wells, and has a reserve main from the river. The city contains 28 churches, 14 public-school buildings, high school, Rockford Seminary (non-sectarian, chartered in 1847), business college, public library containing over 20,000 volumes, city hospital, 6 national banks with combined capital of $725,000, a State bank with capital of $125,000, and 4 daily, 9 weekly, and 2 monthly periodicals. The census of 1890 showed 246 manufacturing establishments with a combined capital of $7,715,069, employing 5,223 persons, paying $2,474,703 for wages and $4,248,001 for materials, with products valued at $8,888,904. The principal industry is the manufacture of agricultural implements, 10 establishments with a combined capital of $1,456,798, and products valued at $776,862. In 1893 the city had an assessed valuation of $6,531,265, and in 1894 a bonded debt of $309,600. Pop. (1880) 13,129; (1890) 23,584; after annexations, estimated, 27,000; (1900) 31,051.

Rockhampton: town of County Livingstone, Queensland, Australia; second in size in the colony; 320 miles N. W. of Brisbane; on the right bank of the Fitzroy river and at the head of navigation, 45 miles from its mouth; terminus of a railway passing W. to the interior plains (see map of Australia, ref. 4–I). It is separated by mountains from the sea and has a hot climate. It is bare and unattractive in appearance, but it is the chief center for the wool industry in the colony. Large vessels discharge and load at Port Alma, at the mouth of the Fitzroy, but small craft ascend to the town. Important gold mines are worked in the vicinity, and that of Mt. Morgan, 25 miles S. S. E., is considered the richest in Australia. Pop. (1891) 11,629. M. W. H.

Rock Hill: town; York co., S. C.; on the Charleston, Cin. and Chi. and the Southern railways; 19 miles N. N. E. of Chester, 26 miles S. S. W. of Charlotte, N. C. (for location, see map of South Carolina, ref. 4–D). It is in an agricultural and cotton-growing region, and has a national bank with capital of $75,000, a State bank with capital of $50,000, and a semi-weekly newspaper. Pop. (1880) 809; (1890) 2,744; (1900) 5,485.

Rockingham, Charles Watson Wentworth, Marquis of: statesman; b. in England, May 13, 1730; was educated at Eton; became Earl of Malton in the peerage of Ireland 1750, and succeeded to the marquisate in December of the same year; became Premier in 1765, acquiring popularity in the American colonies on account of the repeal of the Stamp Act Mar., 1776; retired from office July 12, 1766, and again became Premier on the resignation of Lord North Mar. 22, 1782. D. at Wimbledon, Surrey, July 1, 1782.

Rock Island: city; capital of Rock Island co., Ill.; on the Mississippi river, and the Burlington Route, the Chi., Mil. and St. P., the Chi., Rock Is. and Pac., and the Rock Is. and Peoria railways; 91 miles N. W. of Peoria, 182 miles W. by S. of Chicago (for location, see map of Illinois, ref. 3–C). The city derives its name from an island in the river, about 3 miles long, based on limestone, belonging to the U. S. Government, and the site of its central arsenal and armory. The river on the west side of the island is navigable and on the east side was dammed by the U. S. Government, giving the city, the island, Milan, and Moline great water-power for manufacturing. A combined railway and highway bridge, built by the U. S. Government and the Chi., Rock Is. and Pac. Railway Company at a cost of over $1,000,000, connects the island with the city of Rock Island and with Davenport, Ia., and another bridge connects the island with Moline. The city is lighted by electricity; is supplied with water for domestic and fire purposes from the river by the Holly system, completed in 1871 and rebuilt in 1881; and has electric street-railways, 15 churches, 8 public-school buildings, public library containing over 10,500 volumes, 2 national banks with combined capital of $200,000, a State bank with capital of $100,000, a private bank, and 2 daily, a semi-weekly, 5 weekly, and 3 monthly periodicals. The railway and river shipping facilities give the city large commercial importance, and the excellent water-power has greatly promoted manufacturing. The industrial establishments include flour and lumber mills, sash, door, and blind factories, glass, stove, and agricultural-implement works, carriage and wagon factories, etc. Rock Island contains Augustana College and Theological Seminary (*q. v.*). The island was the site of a series of block-houses, known as Fort Armstrong, prior to and during the Black Hawk war of 1832, and was the place of confinement of many Confederate prisoners in the civil war. Pop. of city (1880) 11,659; (1890) 13,634; (1900) 19,493.

Rockland: city (incorporated in 1848, chartered as a city in 1854); capital of Knox co., Me.; on the west shore of Penobscot Bay, 10 miles from the ocean, and on the Maine Cent. Railroad; 40 miles E. S. E. of Augusta, 49 miles E. N. E. of Bath (see map of Maine, ref. 9–D). It has a water front of nearly 5 miles and an excellent harbor protected by a granite breakwater; is a stopping-point of the Bangor and Boston steamboats, and has a large trade in granite and lime. The city contains gas, electric-light, water, and sewerage plants, a U. S. Government building which cost $175,000, a county court-house (cost $80,000), a public library, 10 churches, 12 public-school buildings, 3 national banks with combined capital of $355,000, a savings-bank with capital of $100,000, a loan and trust company, and 3 weekly papers. The principal industries are granite-quarrying, lime-burning, ship-building, and the manufacture of clothing. The post-offices in New York and Cincinnati and the U. S. custom-house in St. Louis were built of granite from the county quarries. Pop. (1880) 7,599; (1890) 8,174; (1900) 8,150. Editor of "Courier-Gazette."

Rockland: town; Plymouth co., Mass.; on the N. Y., N. H. and Hart. Railroad; 19 miles S. of Boston (for location, see map of Massachusetts, ref. 4–J). It is noted for its extensive boot and shoe and tack factories, and has a national bank with capital of $50,000, a savings-bank, a public library, and two weekly newspapers. Pop. (1880) 4,553; (1890) 5,213; (1900) 5,327.

Rockport: city; capital of Spencer co., Ind.; on the Ohio river, and the Louisv., Evansv. and St. Louis Consolidated Railroad; 17 miles S. of Lincoln, 106 miles S. W. of Louisville, Ky. (for location, see map of Indiana, ref. 12–C). It is built on a hill 100 feet above high water, is in a tobacco, grain, fruit, and hard-wood region, and is a popular summer resort. There are water-works, electric lights, 2 State banks with combined capital of $70,000, the Ohio Township Library (founded in 1855), 2 weekly newspapers, geometrical block factory, foundry, machine-shops, flour, grist, and planing mills, tobacco-stemmeries, brick-yards, creamery, wagon and carriage shops, and chain, furniture, vinegar, stirrup, hoop, and basket factories. Pop. (1880) 2,382; (1890) 2,314; (1900) 2,882.

R. W. May, editor of "Democrat."

Rockport: town; Essex co., Mass.; on the Atlantic Ocean, and the Boston and Maine Railroad; 32 miles N. E. of Boston (for location, see map of Massachusetts, ref. 1–I). It is in an agricultural region, has extensive quarries of granite, and its northeast part, at the extremity of Cape

Ann, known as Pigeon Cove, is a popular summer resort. The town has a public high school, public library, national bank (capital $100,000), a savings-bank, a weekly newspaper, and manufactories of cotton goods, isinglass, shoes, and organs. The Boston post-office was built of Rockport granite. Pop. (1880) 3,912; (1890) 4,087; (1900) 4,592.

Rockport: town; capital of Aransas co., Tex.: on Live Oak Point peninsula in Aransas Bay, Gulf of Mexico, and on the San Ant. and Aran. Pass Railway; 10 miles N. E. of Aransas Pass (for location, see map of Texas, ref. 7–I). It is in an agricultural, fruit-growing, and stock-raising region; has considerable oyster, fish, and turtle interests, exports large quantities of cattle and hides, and is a popular summer and winter health resort. There are several large hotels, a national bank with capital of $60,000, and two weekly newspapers. The vicinity abounds in wild game of many varieties. Pop. (1880) not separately returned; (1890) 1,069; (1900) 1,153.

Rock Rapids: town (founded in 1872); capital of Lyon co., Ia.; on the Rock river, and the Chi., St. P., Minn. and Omaha, the Burl., Cedar Rap. and N., and the Ill. Cent. railways; 22 miles W. of Sibley, 60 miles N. of Sioux City (for location, see map of Iowa, ref. 2–C). It is in an agricultural and stock-raising region, has good water-power for manufacturing, and contains 5 churches, several graded public schools, a national bank with capital of $50,000, a private bank, and 2 weekly newspapers. Pop. (1890) 1,394; (1900) 1,766. EDITOR OF "REVIEW."

Rock-roses: See CISTUS.

Rocks [M. Eng. *rokke*, prob. blending O. Fr. *roke* (> Fr. *roche*, rock) and O. Eng. **rocc* in *stōn-rocc*, stone-rock]: natural masses of solid mineral matter. The term is used in various ways. Popularly and in general literature a rock is characterized as hard and unyielding, and is placed in antithesis to sand, clay, or mud, and in almost all instances where it is used in a figurative sense this is the prominent idea. Modern geological usage extends the term so as to embrace any natural mass of solid mineral matter, whether compact or incoherent. Thus granite, limestone, sandstone, chalk, and deposits of sand, clay, and soil are all considered under the general head of rocks. A third usage arises from the closer discriminations of petrography, which has in effect defined a rock as any natural mass of solid mineral matter that possesses nearly uniform structure, texture, and composition. Thus masses which may have like composition but different structure and texture are called different rocks, viz., granite, gneiss, porphyry, rhyolite, etc.; and rocks with similar textures but with different compositions are different rocks, as granite, diorite, gabbro. A fourth usage springs from the petrological idea of the individuality of a rock-mass as a geological body which has been brought into place by one act, as a continuous lava-stream, or which is the result of the continued action of any set of forces upon a given kind of material, as a continuous bed of sand and gravel. One rock-body may consist of several kinds of rocks, as a stratum whose basal portion is conglomerate and upper portion sandstone; a lava-stream which is partly rhyolite, obsidian, and pumice. The language has not yet discriminated between these ideas, hence the uses of the term rocks are confusing.

Formation of Rocks.—Conclusions regarding the formation of rocks are partly a matter of observation, partly a matter of inference. 1. Lavas flow out from craters and crevices in the earth in a highly liquid condition and, upon cooling, solidify into rocks. Similar material is thrown into the air in dust-like particles and larger fragments, and accumulates upon the surface in more or less compacted masses, as tuffs, breccias, etc.; or the lavas may remain within fissures and openings in the earth's crust where their solidification can not be observed. Similarity in composition and analogies in texture and in mineralogical characteristics between surface lavas and intratellural rock-bodies, as well as their disposition toward surrounding rocks, permit logical inferences to be drawn regarding the original nature of intratellural bodies as molten lavas or magmas. All such rocks are classed as *igneous* or *eruptive*. 2. Sand, silt, and soil are washed down slopes by water and carried along by streams, or as sand and dust are blown about by winds to be deposited when the force of the current lessens. They accumulate in layers or beds, horizontal or inclined, and by drying or cementation may become more or less coherent masses. Mineral springs deposit layers of calcium-carbonate, silica, etc., sometimes acquiring great thickness. These observed processes result in the formation of rocks similar in composition, texture, and structure to others whose formation may be inferred to have been occasioned by similar agencies. All such deposits are known as *sedimentary* rocks. 3. Alterations in rocks of the two first categories may affect their composition, texture, or structure. Changes that cause the rock to disintegrate are classed as weathering or decomposition. Changes that convert it into a mass still possessing great durability are classed as metamorphism. Such metamorphism may be occasioned by heat, by solutions, or by dynamic forces, and the results may be recrystallization, the production of new minerals, fracturing, and rearrangement of the fragments. All rocks resulting from the metamorphism of igneous or sedimentary rocks, and those resembling them whose original nature may not be determinable, are called *metamorphic* rocks. See METAMORPHISM.

IGNEOUS or eruptive rocks which solidified on or near the surface of the earth are called *volcanic*, if considerably below the surface *plutonic* or *abyssal*. If lavas reached the surface they are *extrusive* or *surface lavas*, if not they are *intrusive*. The latter often metamorphose adjacent rocks by heating or by impregnation with hot solutions and vapors, and in turn often exhibit modifications in structure, texture, and composition resulting from cooling produced by surrounding rocks. Intrusive igneous rocks form dikes, sheets, laccolites, batholites, stocks, or necks. Extrusive rocks form lava streams and sheets, domes, breccias, agglomerates, and tuffs. The last may be stratified and bedded, and if deposited in water are not distinct from sedimentary rocks.

Chemical and Physical Characters.—All igneous rocks consist of oxygen, silicon, aluminium, with sodium and potassium, or calcium, magnesium, and iron in variable proportions. Usually all eight are present. Besides these elements are small amounts of titanium, phosphorus, hydrogen, and often traces of manganese, nickel, cobalt, lithium, barium, strontium, chlorine, sulphur. These are usually expressed in analyses as oxides, but are mostly combined in silicate minerals, together with some that are oxides. The molten magmas must be considered as solutions of compounds of these elements at high temperatures, their exact molecular character being unknown. Those with more than 65 per cent. silica are called acid magmas; those between 65 and 55 per cent. silica, intermediate; and those with less than 55 per cent. silica, basic. The extreme limits are about 80 and 35 per cent. silica. Molten magmas are often very liquid at the time of eruption, especially those with less than 60 per cent. silica. The more siliceous ones are more viscous at like temperatures. As the temperature falls the magmas become more viscous, and crystallization usually sets in. If cooling is very sudden, the magma forms an amorphous mass (glass) without crystals. With slower cooling crystals form more or less perfectly, their shape and chemical composition depending upon the physical as well as the chemical condition of the magma, molecular shifting and arrangement being more easily accomplished in more liquid magmas, which, however, must be below the fusion-point of the minerals crystallizing. Slowest cooling permits most perfect molecular adjustment, resulting in fewer but larger crystals. Other agencies affecting crystallization are absorbed vapors, and possibly pressure. The size and arrangement of the crystals control the texture of the rock, which may be glassy or *vitreous*, stony or *lithoidal*, and *crystalline*. When the grains are visible to the naked eye the texture is *phanerocrystalline*; if not, then *aphanitic*. Rocks are *porphyritic* when they consist of a groundmass of any texture bearing larger, prominent crystals (*phenocrysts*). Particular textures have special names, as *granitic*, *poikilitic*, *ophitic*, *trachytic*, *rhyolitic*, etc. Structures due to the physical continuity of the mass are *compact*, *porous*, *vesicular*, *pumiceous*, *jointed*, *columnar*, *laminated*, etc. The commonest minerals that crystallize from molten magmas (pyrogenetic) are quartz, potash-feldspar or orthoclase, lime-soda-feldspars, the feldspathic minerals (nephelite or eleolite, leucite, and sodalite), and certain ferromagnesian minerals (amphiboles, pyroxenes, micas, and olivine); among others are titanite, magnetite, ilmenite, apatite, zircon, and less often garnet, tourmaline, allanite, and spinels. Minerals prominent in the most acid rocks (granites) are quartz, alkali (potash, soda) feldspars; less abundant lime-soda-feldspars, with muscovite, biotite, and hornblende. As we pass to less acid rocks quartz diminishes; feldspars increase to a certain point, and then diminish and disappear in the most basic rocks (peridotites). Alkali-feldspars increase

to a maximum in syenite and in eleolite-syenite, and are accompanied by nephelite and sodalite. Lime-soda-feldspars become richer in lime from acid to basic rocks, and predominate in diorites, as oligoclase and andesine, and in gabbros, as labradorite and anorthite. The range of the ferromagnesian minerals is from biotite through hornblende, augite, hypersthene, to olivine, the first being most prominent in acid rocks, the last in most basic rocks. One rock-body may vary in chemical and mineral composition in different parts, and may exhibit variable structures and textures.

Genetic relationships exist between igneous rocks of one district or about one center of eruption. They appear in chemical and mineral characteristics common to such a group of rocks, which distinguish them from rocks of some other region. Regions so distinguished are called *petrographical provinces*. These characteristics, together with geological ones, prove that varieties of igneous rocks in one region originated from a parent molten magma by chemicophysical differentiation, lime-iron-magnesia-silicates tending to separate from alumina-alkali-silicates and free silica. Magmas may be erupted at any stage of differentiation, hence igneous rocks have no fixed chemical composition, and the distinctions attached to the definitions of various kinds of rocks must be arbitrarily chosen, there being no natural lines of demarkation between them. The consanguinity, so to speak, of igneous rocks about one eruptive center is one of their most essential characteristics.

Classification of igneous rocks may be accomplished in different ways owing to the number of their variable features. Each method proposed has developed inherent weaknesses. The one here adopted classes together all rocks with similar chemical composition and then subdivides them on a basis of texture, and further on one of mineral composition, choosing certain coarse-grained granular rocks as the standards for the chemical groups. These are granite, diorite, gabbro, peridotite, syenite, and eleolite-syenite, whose special characters may be learned under their separate headings. Under each of these groups are chemically similar rocks having fine-grained and usually porphyritic texture, commonly called porphyry, besides lithoidal to glassy forms. They have been variously named, and only a general sketch of them can be given.

To the *granite* class belong granite, granite-porphyry, quartz-porphyry, quartz-keratophyre, rhyolite, rhyolitic obsidian, perlite and pumice, quartz-pantellerite, dacite and its glassy forms. Granites are subdivided on a basis of the predominant ferromagnesian minerals—muscovite, biotite, hornblende, augite, etc. The fine-grained and aphanitic, porphyritic varieties are subdivided on a mineralogical basis in part, when the feldspars are included as of chief importance, potash-feldspars predominating in quartz-porphyries and rhyolites, soda-feldspars in quartz-keratophyre and quartz-pantellerite, and lime-soda-feldspar (oligoclase, andesine) in dacite. Other subdivisions are based on the character of the groundmass and the relative abundance of phenocrysts.

To the *diorite* class belong diorite, diorite-porphyry, andesite-porphyry (porphyrite), andesite and andesitic glasses. These rocks are subdivided on a mineralogical basis, the minerals involved being quartz, mica, hornblende, hypersthene, and augite. These names are placed as prefixes to the rock-names to designate varieties.

To the *gabbro* class belong gabbro, gabbro-(augite-) porphyry, dolerite, diabase, basalt, tachylyte (basaltic glass). These are subdivided mineralogically.

To the *peridotite* class belong peridotite, pikrite-(peridotite-) porphyry, limburgite. The class is distinguished by the absence of feldspar, or its presence in very small amounts, and is subdivided mineralogically according to predominant ferromagnesian silicates.

To the *syenite* class belong syenite, syenite-(orthoclase-) porphyry, keratophyre, trachyte, pantellerite, and trachytic glasses. They are subdivided according to the presence of quartz, nephelite, leucite, sodalite, and the ferromagnesian silicates.

To the *eleolite-syenite* class belong eleolite-syenite and its porphyries and phonolite; mineralogical subdivisions according to the presence of nephelite, leucite, and certain ferromagnesian minerals.

Other classes of rocks not represented by coarse-grained forms include the porphyries (minettes and kersantites), the lavas (leucite-basalt and nephelite-basalt), and the highly alkaline rocks (leucitite and nephelinite). These are basic rocks, more or less rich in alkalies.

Sedimentary rocks, as already said, may be composed of particles of other rocks when they are *fragmental* or *clastic*, or they may consist of fragments of organic remains, both animal and vegetable. They may be precipitations from aqueous solutions—*crystalline*. The composition and character of clastic rocks depend on the mineral character of the rocks from which they were derived, and on the transporting currents which deposited them. The mechanical effect of the stream is to assort the material according to its gravity and surface resistance, the heaviest fragments settling soonest. The process is one of separation, tending to differentiate the particles according to their mineral character, the ultimate extremes having the simplest composition, and the more soluble portions going into solution. Such rocks may approximate closely to the composition of igneous ones, or they may differ so widely from them as to consist of but one of their constituent minerals, as quartz. The texture of fragmental rocks may be due to the aggregation of the minutest particles, or of grains varying in size up to that of gravel and bowlders. The fragments are usually rounded, and the resulting mass, if sandy, is fine sand, gravel, or shingle; and when indurated or cemented by interstitial material, is sandstone or conglomerate. These rocks are largely quartz. If other minerals, as feldspar, and various rock-fragments accompany quartz, the rock is graywacke. When the fragments are angular it is breccia. Rocks consisting of extremely minute particles have been derived largely from the more easily decomposable minerals, feldspars, micas, etc. These are largely aluminous, and are more or less impure clays, indurated to different degrees—clays, clay-slate, and shale. Fragmental material derived directly from volcanic explosions, and deposited by currents of air or water has already been alluded to. The finest-grained aggregates are tuffs.

Fragmental rocks of organic origin are chiefly *calcareous*, as calcareous ooze (foraminiferal), chalk, shell-sand and marl, coral-rock and limestones; *siliceous*, as diatomaceous earth, and siliceous ooze (radiolarian); *phosphatic*, as guano, phosphatic limestone and marls, and deposits of bone phosphates; *carbonaceous*, including coals and their natural distillation products. It is questionable whether this last group does not properly belong to the series of metamorphic rocks.

Sedimentary rocks formed by precipitation or crystallization from solutions may be from large bodies of water, as many limestones and dolomites; or from smaller bodies, as certain iron ores, salt, etc.; or from springs, as travertine (calcareous) and calcareous onyx, oölite, sinter (siliceous), or geyserite; and in subterranean cavities, as various vein-stones, quartz, etc. Vein-stones, with their associated metallic minerals, are generally treated apart from other rocks on account of their special economic importance, and are known as metallic veins or ore-deposits. Ice as geological bodies, glaciers, etc., is a sedimentary rock formed by precipitation or crystallization.

Metamorphic rocks are of three categories: those demonstrably produced by the alteration of igneous rocks; those proved to be metamorphosed sedimentary rocks; and all rocks resembling these two groups, whose original character can not be determined. Since the petrographical features of the rocks of the third category are so nearly identical with those of the first two groups, it is probable that they also were either igneous or sedimentary originally. When stages of metamorphism can be traced from slightly altered to extremely altered forms, it is found that the final products of metamorphism, both of igneous and of sedimentary rocks, may in some cases be identical, so that highly metamorphosed rocks may possess no petrographical characteristics suggestive of the original nature of the rock. Thus the structure, texture, and mineralogical composition of highly metamorphosed rocks may shed no light on the nature of the original rock. It is customary to name and classify metamorphic rocks according to the most prominent petrographical features, regardless of the origin of the rock, or of the processes by which metamorphism has been brought about. Most metamorphic rocks exhibit a foliation, either in the ability of the mass to separate in thin plates, or in the arrangement of the minerals in parallel planes. This fissile or schistose structure is so universally present in all series of these rocks that they are commonly called the Crystalline Schists (*q. v.*). However, it does not occur throughout all bodies of metamorphic rock, some of which are massive, but these are related to the schistose rocks so intimately in geological position, being usually intercalated

between layers of schist, and have so nearly identical mineralogical composition and characters that they are generally considered together, and the whole series is classified on a basis of mineral composition—that is, rocks having similar mineral constituents are grouped together with little or no regard to the relative proportions of these minerals. At present this seems justifiable because of the lack of constancy in the composition of any considerable body of metamorphic rock, and because of the abrupt and frequent changes in the proportions in which the minerals occur together. The principal kinds of metamorphic rocks are—

I. *Feldspar-quartz Rocks* are those rocks whose predominant minerals are feldspar and quartz. They include:

Gneiss, a crystalline rock composed of potash-soda-feldspar and lime-soda-feldspar with quartz, and one or more minerals of the mica, amphibole, pyroxene groups, besides other minerals, and having a banded or laminated structure, produced by the parallel arrangement of some of the mineral constituents. It varies from quite massive forms to finely schistose ones. It bears a close analogy to granite in texture and composition, in some cases being scarcely distinguishable from it. When lime-soda-feldspars predominate over alkali-feldspars, the rock corresponds closely to quartz-diorite. According to the ferro-magnesian mineral prevalent, gneisses are subdivided into mica-gneiss (biotite, muscovite, or both), hornblende gneiss, augite gneiss, sericite-gneiss, etc.

Granulite, schistose rock consisting of feldspar, quartz, and garnet, with other minerals subordinate, according to which the rock is subdivided into cyanite-granulite, tourmaline-granulite, etc.

Hälleflinta and Adinole, dense, aphanitic or felsitic rocks, composed of minute particles of feldspar and quartz, and sometimes mica.

II. *Mica-rocks*, *chlorite-rocks*, or *talc-rocks* are:

Mica schist, laminated rock consisting of mica and quartz in variable proportions. According to the kind of mica, or of the other prominent constituents, they are muscovite-schist, biotite-schist, sericite-schist, paragonite-schist, and numerous other mica-schists depending on the accessory mineral, as staurolite, andalusite, epidote, etc. With increase of quartz it passes into micaceous quartzite; with more feldspar, into gneiss; with calcite, into micaceous limestone.

Chlorite-schist, laminated rock composed of chlorite and quartz, with other minerals subordinate.

Phyllite, *Argillaceous Schist*, *Argillite*, micaceous, argillaceous, schistose or slaty rock intermediate between clay-slate and mica-schist. Subdivisions are chiastolite-slate, staurolite-slate, ottrelite-slate, sericite-phyllite, etc.

Talc-schist, laminated rock composed of talc, with quartz or feldspar and other minerals.

III. *Amphibole-rocks.*—Rocks whose predominant mineral is amphibole, either schistose or massive; the former is *amphibole-schist*, the latter *amphibolite*. With amphibole may be associated feldspar, quartz, garnet, etc. According to the variety of amphibole present the rock is hornblende-schist, or hornblendite, actinolite-schist, glaucophane-schist. Nephrite, a variety of jade, is a compact microfibrous variety. Subdivisions are also established upon the character of the accessory mineral, as epidote-amphibolite, etc. When lime-soda-feldspar becomes prominent, the rock grades into diorite-schist; by increase of quartz and feldspar, into gneiss.

IV. *Pyroxene-rocks* are augite-schist, when laminated; augitite, when massive; enstatite-rock, jadite (jade). As lime-soda-feldspar increases, and the augite becomes more like diallage, the rock passes into schistose gabbro.

V. *Other rocks* are eclogite, crystalline massive rock, seldom schistose, composed of omphacite (light-green pyroxene), and garnet, with other minerals subordinate. Olivine-rocks are essentially olivine, with pyroxenes, hornblende, or mica in varying amounts, corresponding closely in mineral composition to the peridotites.

Epidote-schist and tourmaline-schist are schists in which epidote and tourmaline are prominent minerals, in combination with others less characteristic. Greenstone-schists are schistose and green, and generally very fine-grained. The color is due to fibrous amphibolite (actinolite), chlorite, or serpentine with epidote, combined with other minerals.

Quartz-rocks are chiefly composed of quartz, quartzite when massive, quartz-schist when schistose, usually with mica.

Calcite-rocks are crystalline limestone and MARBLE (*q. v.*).

BIBLIOGRAPHY.—General works on rocks are: Rutley, *The Study of Rocks* (London, 1879); Roth, *Allgemeine chemische Geologie* (Berlin, 1879, *et seq.*); Jannetaz, *Les roches* (Paris, 1884); von Lasaulx, *Einführung in die Gesteinslehre* (Breslau, 1886); Kalkowsky, *Elemente der Lithologie* (Heidelberg, 1886); Zirkel, *Lehrbuch der Petrographie* (2d ed., 3 vols., Leipzig, 1884); also Dana, *Manual of Geology* (latest edition); Dana, *Manual of Mineralogy and Petrography* (4th ed.; New York, 1887); and Geikie, *Text-book of Geology* (3d ed.; London and New York, 1893). Works treating of the microscopical characters of rocks and of the rock-making minerals include a part of those just noted, and the following: Rosenbusch, *Mikroskopische Physiographie der Mineralien und Gesteine* (2 vols.: vol. i., 3d ed. 1892; vol. ii., 2d ed. 1887, Stuttgart; vol. i., translated by J. P. Iddings, *Microscopical Physiography of the Rock-making Minerals*, New York, 3d ed. 1893); Fouqué and Michel Lévy, *Minéralogie micrographique des roches éruptives françaises* (2 vols., Paris, 1879); Teall, *British Petrography* (London, 1888); Zirkel, *Microscopical Petrography* (vol. vi. of *Geol. Explor. of 40th Parallel*, Washington, 1876); Hawes, *Mineralogy and Lithology of New Hampshire* (part iv. of Geology of New Hampshire, Concord, 1878); Wadsworth, *Lithological Studies* (part i., Cambridge, Mass., 1884); Lehmann, *Enstehung der altkrystallinischen Schiefergesteine* (Bonn, 1884); Williams, *Greenstone Schist Areas of the Menominee and Marquette Region of Michigan* (Bull. 62, U. S. Geol. Survey, Washington, 1890).

JOSEPH P. IDDINGS.

Rock-salt: See SALT.

Rock-snake: See BOA.

Rock Springs: town; Sweetwater co., Wyo.; on the Bitter creek, and the Union Pac. Railway; 258 miles W. of Laramie (for location, see map of Wyoming, ref. 12–G). It is in an extensive coal-mining region, and has 2 national banks with combined capital of $110,000, and 2 weekly newspapers. Pop. (1880) 763; (1890) 3,406; (1900) 4,363.

Rockville: city (set off from the town of Vernon and chartered as a city in 1889); Tolland co., Conn.; on the Hockanum river, and the N. Eng. Railroad; 15 miles E. N. E. of Hartford (see map of Connecticut, ref. 7–I). The river, which is the outlet of Lake Snipsic, has here a series of falls aggregating 280 feet, and affords abundant power for manufacturing. The principal industries are the manufacture of woolens, envelopes, silk goods, satinets, ginghams, and warps. There are 8 churches, a fine high school, a public library, 2 national banks with combined capital of $500,000, 2 savings-banks with aggregate deposits of over $1,750,000, and 2 weekly newspapers. Electric cars connect the city with Hartford and Ellington. Pop. (1880) 5,902; (1890) 7,772; (1900) 7,287.

Rockweeds: the popular name of the brown seaweeds of the genera *Fucus* and *Ascophyllum*, common on rocks between tide-marks along the U. S. coasts. See FUCOIDS.

Rockwood: town; Roane co., Tenn.; on the Queen and Cresc. Route and the Rockw. and Tenn. Rivers railways; 6 miles N. of the Tennessee river, 45 miles W. S. W. of Knoxville (for location, see map of Tennessee, ref. 6–H). It is in a coal and iron mining region, and contains several blast furnaces, a national bank with capital of $50,000, and two weekly newspapers. Pop. (1890) 2,305; (1900) 2,899.

Rocky Mountain Goat [so called on account of its goat-like appearance]: a species of antelope (*Mazama montana*)

Rocky Mountain goat.

with short legs, round, black, decurved horns, long, white, woolly hair, and a short beard on the chin. It is very much

larger than the domestic goat. It is found from Northern Idaho S. into Colorado, in the higher parts of the Cascade and Saw-tooth Mountains. It extends northward for some distance into the Kootenai district of British Columbia, and thence ranges in some places down to the coast. The horns and hide are used extensively by the Indians of some parts of British Columbia. F. A. L.

Rocky Mountains: all the mountains of North America between the Great Plains and the Pacific Ocean. The term Stony Mountains was originally applied, but was finally replaced by the name Rocky Mountains.

Usage is not entirely consistent in the application of this name. To some extent, both by geographers and popular writers, it is restricted in its application to parts only of the western mountain system. Some apply it only to the ranges of Montana, Wyoming, and Colorado; others include, in addition, the ranges of Idaho, Utah, and New Mexico; while still others would add the desert ranges of Oregon, California, Nevada, Utah, New Mexico, and Arizona, excepting from it only the Cascades, the Sierra Nevada, and the Coast Ranges; but its application to all the mountains of North America W. of the Great Plains is the only clear and definite one. The name Cordilleras of North America has been proposed as a substitute for Rocky Mountains as comprising the entire mountain system, but has not received general acceptance.

The name Rocky Mountains is very appropriate. On the mountains and plateaus of the greater part of the region naked rocks are seen to an extent rarely known elsewhere on the globe. Chief among the causes of this are extreme aridity and great elevation, the lack of moisture preventing the growth of vegetation, and great elevation promoting rapid denudation of the rock-material disintegrated at the surface. The mountains are composed of crags and peaks of naked rock, and the mountain streams run at the feet of towering cliffs in deep gorges beset with rocks. The hills, unprotected by vegetation, are swept clean of sands and soil by the winds. The water-courses rarely have flood-plains, and the steep sides of the valleys are strewn with fragments of rock. In the plateau region the streams run in deep cañons, whose walls rise hundreds or thousands of feet above the waters, and the channels below are choked with rocks which tumble from the cliffs. By reason of unequal erosion of the general surface, due to petrologic structure under conditions of great aridity, long lines of cliffs or towering escarpments of rock stand athwart the plateaus.

In very late geological time the whole region has been the scene of much volcanic activity. Extinct volcanoes are found on high plateaus and on the flanks of great mountain ranges; broad mesas are covered with sheets of lava; great valleys have been filled with extravasated matter, and scoria and ashes are scattered over the land. Some of this extravasation is so recent that the congealed floods are yet preserved in all their forms of stream and wave, and these naked rocks often appear without soil, and without even mosses and lichens. Extreme aridity is not a characteristic of the entire country. Those ranges near the Pacific coast N. of the 42d parallel of N. lat. are abundantly supplied with water, and here the indurated beds are greatly masked by dense forests and deep overplacement.

This great mountain system extends through the U. S. from its southern border, through British America and Alaska, to the Arctic Ocean, or from the 30th to the 70th parallel N. lat. Its greatest development in longitude is between the 38th and 42d degrees of N. lat.; here the system has a breadth of about 1,000 miles. Its highest peak is Mt. Logan, lat. 60° 30′ and lon. 140° 24′, which rises to an altitude of 19,500 feet above sea-level, as determined by the U. S. Coast and Geodetic Survey. In the same system are included the mountains of Mexico and Central America, though the term Rocky Mountains has rarely been applied to them. The mountains of Central America are composed of cordilleras and volcanoes, the geological characteristics of which are little known. The system is connected with the Andes of South America by the narrow Isthmus of Panama, where the elevation does not exceed a few hundred feet, and where a pass is found from Atlantic to Pacific waters, having its summit not more than 180 feet above the level of the sea. The mountains of Mexico are usually termed by geographers the Mexican Cordilleras, but locally the term cordilleras is applied only to certain ranges; the other great mountain-masses, whether their origin be by extravasation or upheaval and degradation, have their special names. They consist of many ranges trending in general parallelism with the coast, and of enormous volcanic peaks, a few of which are active. Among the celebrated mountains of this country are Orizaba, altitude 18,300 feet; Popocatepetl, altitude 17,887 feet; and Ixtaccihuatl, altitude 17,343 feet.

Passing from Mexico to the U. S. the Rocky Mountains proper are reached; and here the geography and geology of the region have been studied to such an extent as to warrant a partial classification of the system into minor groups or systems. The mountain system in the U. S. is extremely broad and complex, composed of hundreds of ranges and ridges, and covering a vast extent of country.

The general plateau or upland on which the ranges stand in Mexico extends across the U. S. from N. to S., widening westward nearly to the Pacific coast. Its maximum elevation is in Colorado, where it reaches an extreme altitude of 10,000 feet; thence northward its summit descends, entering Canada at an elevation of perhaps 4,000 feet. It descends also westward into the basin of the Colorado river, but rises again in Nevada, where it reaches an altitude of about 6,000 feet, descending thence westward to the foot of the Sierra Nevada in California. On the E. it descends to the low country traversed by the Mississippi river, by a long, undulating, treeless slope, known as the Great Plains. In the U. S. are the following systems: The Desert Ranges, the Park Ranges, the Plateaus, the Sierra Nevada, the Coast Ranges, the Cascade Mountains, and provisionally the Geyser Ranges.

The Desert Ranges occupy Southern Oregon and Idaho, Western Utah, all of Nevada, Southeastern California, Southern Arizona, and Southwestern New Mexico, extending southward into old Mexico. This region is limited on the E. by the plateau region drained by the Colorado river, and on the W. by the Sierra Nevada and Cascade Range. The northern and greater part is known as the Great Basin, since it has no outlet to the ocean. Though known collectively as the Great Basin, it is in fact a group of many large and small basins. Owing to the fact that this region has a very slight rainfall, nowhere exceeding 20 inches and in some parts not greater than 2 or 3 inches, its drainage system is in an extremely undeveloped condition. The rains which fall upon these mountain ranges and flow down their gorges are absorbed by the thirsty soil of the valleys or by the equally thirsty atmosphere. The detritus carried down the mountain-sides by these (and the amount is not inconsiderable when they are in flood) collects in the valleys as the streams disappear, thus filling them to a great depth with the ruins of the mountains.

The greater of the basins composing the Great Basin are (1) that of the Great Salt Lake, upon the eastern side of the basin in Utah, receiving drainage from the Wasatch Range, which limits this region on the E.; (2) the Humboldt-Carson Basin upon the W. in the shadow of the Sierra Nevada. Into this basin flow and sink the streams from the Sierra Nevada and from the ranges of the basin. Other basins are those of the Malheur and Harney Lakes in Oregon, Owens Lake in California, and Sevier Lake, Utah.

The ranges of this region are narrow and simple in structure. They are separated by broad level desert valleys filled with detritus from their sides. The trend is commonly N. to N. W. So far as their geological structure is known, they are of one type—i. e. a monoclinal ridge of displacement, or a displacement due to a fault on one side and a flexure on the other, which may otherwise be described as the half of an anticlinal fold. The typical ridge is composed of strata dipping one way, the front or face of the range being the escarped edges of the strata, and the back of the ridge conforming to some extent with the dip of the strata. Very few of the ranges are as simple as the type described, as they are complicated by secondary faults and flexures, transverse, oblique, and sometimes even longitudinal with the principal structure. Simple anticlinals are rarely found. The ridges described are composed of granites, schists, and Palæozoic sandstones and limestones; but these rocks and the monoclinal structure are often masked by extravasated beds found on the flanks or sometimes partly burying the ranges, and many of the mountains are chiefly of eruptive origin. It is probable that this region has been above the level of the sea since Jurassic time, and some portions of it longer, but the great orographic displacement which produced the present ranges is of very late date, and it is probable is yet in progress. One of the characteristics of these ranges is that they usually rise abruptly from the desert plain without intervening foot-hills, and rarely do

the ranges coalesce. Of the age of the dry land there is no certain knowledge, but the mountain forms due to upheaval and atmospheric degradation, and also the mountain forms due to extravasation, are of very late geological origin.

There are about 100 ranges in this group. The highest, broadest, and most massive is the Wasatch. In this are found the principal geological formations of the other ranges of the system, and also some of the sedimentary beds of the Plateau System. The escarpment faces the W., and the highest peak, Mt. Nebo, is found at the southern extremity. The streams which are used to fertilize the Great Salt Lake and Utah valleys have their sources in these lofty mountains.

The Park System extends from Southern Wyoming through Central Colorado into New Mexico; bounded on the N. by the Laramie Plains, on the E. by the Great Plains, and on the W. by the plateaus; the southern limits can not yet be defined. There are a great number of ranges in New Mexico, on either side of the Rio Grande del Norte, having a N. and S. trend, the general structure and geological relations of which are unknown. They may constitute a system or sub-system by themselves, or they may be considered as a part of the Park System, probably the latter. The general trend of the Park Ranges is a few degrees W. of N., but there are exceptions. These mountains are drained by the Platte and Arkansas, which flow into the Mississippi; by the Rio Grande del Norte, which flows into the Gulf of Mexico; and by the Colorado river of the West, which flows into the Gulf of California. The axial ridges of the system—i. e. those which separate the Atlantic from the Pacific drainage—constitute a part of the continental divide. The system is composed of ranges and irregular groups which stand as walls about the great parks. In North Park heads the North Platte; in Middle Park heads the Grand, a tributary of the Colorado; in South Park heads the South Platte; and the Rio Grande del Norte drains the San Luis Park. These parks are elevated valleys, nearly or completely surrounded by mountains. Besides the larger parks mentioned, there are many of smaller extent—mountain-valleys of great beauty in midsummer, but mantled with snow during many months of the year. Most of the ranges are known to be of the Uinta type—i. e. broad, plateau-like masses carved from blocks upheaved in part as integers and in part as bodies of many parts—a structure more fully described below. Many of the park-spaces are zones of diverse displacement. These mountains are composed of granites, schists, Palæozoic, Mesozoic, and Tertiary sediments, and the sedimentary groups are separated by many and well-defined unconformities, giving evidence of alternating periods of dry-land condition and oceanic sway; but the last great orographic movement which upheaved the great masses from which the mountains have been carved began in Tertiary time. These ranges are arranged *en échelon*, the eastern mountain-front running N. and S., while the ranges trend somewhat E. of S. Hence, proceeding southward, one finds the front range dropping down and disappearing, while its place is taken by that behind, which in turn comes to the front. The following are the principal ranges and groups of this system in succession from E. to W.: Rising from the plains in full view of Denver is the Front Range, which on the N. is nearly continuous with the Medicine Bow Range, the latter being the eastern wall of North Park. To the S. it becomes broken and spreads out into a mass of short ranges and hills, through which the South Platte makes its way to the plains. Just N. of Pueblo, on the Arkansas, it gathers itself and rises suddenly into the great mass of Pike's Peak, and then drops down to the level of the plains. Between North and Middle Parks is the Park View Mountain, an eruptive mass which, with its spurs and outliers, separates the two parks. Next in order to the westward is the Park Range, which extends from Buffalo Peaks northward nearly to the junction of the Sweetwater with the North Platte river. This range forms the western wall of South, Middle, and North Parks. The South and Middle Parks are separated by a series of eruptive mountains, among them Silverheels and Mt. Guyot. From the north end of this range, W. of North Park and the north end of Middle Park, long spurs and irregular mountains extend westward to the plateaus. W. of the south end of the Park Range is the valley of the Arkansas, and W. of the valley is the Sawatch Range, with the Mount of the Holy Cross at its northern extremity. This range trends 30° W. of N. Still farther W. is the Elk Mountain Group, which consists of a series of short, parallel ranges closely massed, trending in the same direction as the Sawatch Range.

Returning to the border of the plains, the first range S. of the Arkansas is the Wet Mountain, a short range, fronting the plains for a few miles only. Its trend is the same as the last. To the W., and parallel with this range, is the Sangre de Cristo, called in one portion of its course the Sierra Blanca. This is a long, high range, fronting the plains for hundreds of miles, and breaks up near Santa Fé. To the W. of it lies San Luis Park, and beyond the park is the enormous irregular rugged mass known as the San Juan Mountains, and beyond are the plateaus.

The Plateaus.—The great plateaus stretch from Southern Wyoming through Western Colorado and Eastern Utah far into New Mexico and Arizona. They are bounded on the N. by the Wind river and Sweetwater Mountains, on the E. by the Park Mountains, and on the S. and W. by the Desert Range region. The region is drained chiefly by the Colorado of the West; on the S. W. by the Sevier river, and a small portion on the S. E. by the Rio Grande del Norte. The general elevation is about 7,000 feet above sea-level, but the range in elevation is great. The ascent from the low desert plains on the S. is very abrupt, in many places by a steep and almost impassable escarpment. Geologically, the plateaus are separated into blocks by faults or their homologues, monoclinal flexures—a structure to which the name Kaibab has been given, where the blocks are displaced as integers. These geological features serve in part to divide the region into many topographic blocks. The streams which traverse the plateaus have their sources in the Wind River Mountains on the N., in the Park Mountains on the E., and in the Wasatch on the W., and in their courses through the plateaus they run in profound gorges or cañons, further dividing the area into blocks; and this division is completed by lines of cliffs due to the unequal erosion of harder and softer beds under conditions of aridity. Thus, by faults and monoclinal flexures, by deep cañons, and by lines of cliffs, this region is cut into a great number of plateaus. Some of the larger or more important of these plateaus are as follows: The Colorado Plateaus, lying S. of the Grand Cañon of the Colorado—general elevation, 7,500 feet; Shiwits Plateau, N. of the Grand Cañon, W. of the Grand Wash, E. of the Hurricane Cliffs, and S. of the Vermilion Cliffs—general elevation, 6,000 feet; Uinkaret Plateau, N. of the Grand Cañon, E. of the Hurricane Cliffs, W. of Kanab Cañon, and S. of the Vermilion Cliffs—general elevation, 6,000 feet; Kaibab Plateau, N. of the Grand Cañon and W. of the Marble Cañon—general elevation, 7,500 feet. The last three plateaus extend from Northern Arizona into Utah. Farther to the N., on the west side of the Sevier river, the Markagunt Plateau—general elevation, 8,500 feet; on the east side of the Sevier the Paunsagunt Plateau—general elevation, 8,000 feet; the Aquarius Plateau, N. of the Paunsagunt—general elevation, 11,000 feet. S. W. of the Paria river, near the head of the Marble Cañon, are the Paria Plateau—general elevation, 6,000 feet; the Kaiparowits Plateau, N. of the Paria and E. of the Paunsagunt—general elevation, 7,500 feet. The Tavaputs Plateau is in Eastern Utah, bounded on the N. by the Uinta and White river valleys, and on the S. by the Book Cliffs, and is cut in twain by the Green river—general elevation, 7,000 feet. There are many other plateaus of nearly equal importance.

On these plateaus stand buttes, lone mountains, and groups of mountains. The buttes are of cameo structure—i. e. mountains of circumdenudation, with horizontal strata and escarped sides. The mountains, composed in whole or in part of extravasated matter, exhibit many interesting types of structure. The grand structure-lines of these plateaus have a N. and S. trend, but with important and diverse exceptions. In addition to the plateaus proper, there are many mountains due to upheaval and degradation, some of which are found in zones of diverse displacement, others are of simple anticlinal structure, and still others of the Uinta structure. The more important of these mountains of diverse type are the Zuñi Range, far to the S., and the Uinta Range, far to the N. The Uinta Range is carved from a broad upheaval having an E. and W. axis. On either flank of the upheaval there is a line or zone of maximum displacement, where the upheaval is by flexure or by faulting. Between these zones there is a gentle flexure either way to the axis. Thus the upheaval is in part by general flexure from the axis as an anticlinal, and in part by faulting and monoclinal flexure, as in the Kaibab structure, thus behaving in part as an integer and in part as a body of many parts. The Uinta Range, as before mentioned, has been taken as a type of this structure.

The plateaus have been continuously above the sea since the close of the Cretaceous period, but during earlier Tertiary times the region was an area of lacustrine sedimentation, and during late Mesozoic and early Tertiary time the basin province was the dry land that fed the sea and lakes of the plateau province. The great displacements by which the region was broken into blocks began in early Tertiary time, and is probably yet in progress. The plateaus are composed of Tertiary, Mesozoic, and Palæozoic sediments. Crystalline schists and granites are found in some of the deep cañons.

Herewith is presented a table containing the principal mountains of the different ranges, groups, etc., of the plateaus, giving their name, location, height, and the authority for the measurements:

The Sierra Nevada is one great range, stretching from the 35th parallel of N. lat. to about 41° 35′, where the range topographically terminates at Mt. Shasta, or perhaps S. of this, at Lassen Peak. These mountains are carved from a great plateau more than 400 miles in length and 100 miles in breadth. The axis of the range is near the eastern side, and trends about 30° W. of N. Here the streams head, the greater number running westward into the Pacific, the remainder running eastward and rapidly descending into desert valleys where they are lost in the sands. On the eastern side a bold front rises abruptly from the desert plains, presenting a grand façade of storm-carved rocks. On the western side, though the descent to the Sacramento and San Joaquin rivers is greater, the general slope is more gentle, but is broken by many profound gorges or deep cañons, some of which are due to faults; others are cut by streams and fashioned by glaciers. At the southern extremity the range is broken into small subsidiary ranges and spurs. At the northern end, from Lassen Peak to Mt. Shasta, the plateau-like character is much broken by volcanic masses, and there the general topographic characteristics are greatly changed. On the western flank of the range there are many table-mountains, covered with sheets of lava. This broad, massive range is crowned with peaks which rise to higher altitudes than any other in the U. S.

The Coast System is composed of the low, narrow ranges near the Pacific Ocean, and separated from the Sierra Nevada by the valleys of the Sacramento and San Joaquin rivers, which, after uniting, burst through the ranges, di-

viding them into two sub-systems, the Northern and Southern Coast Ranges. To the N., beyond the head-waters of the Sacramento, the Coast Ranges topographically coalesce with the Cascade Mountains, and to the S., beyond the head-waters of the San Joaquin, with the Sierra Nevada; but here the geological separation is plain, as shown by Whitney. The general trend of these ranges is 30° W. of N. The Coast Ranges are composed of more or less closely oppressed folds of strata degraded by rains and rivers—i. e. they have the Appalachian structure, but complicated and more or less masked by extravasated matter. The summits or axial planes are in general tipped westward or toward the Pacific. The Appalachian type is not known to occur elsewhere in the Rocky Mountain region. The upheaval of these mountains began in the late Tertiary times, and may yet be in progress.

PRINCIPAL MOUNTAINS OF THE COAST RANGE SYSTEM.

Mt. Diablo	3,856	"
Mariposa Peak	3,700	"

The Cascade Mountains stretch from Southern Oregon northward far into British America. On the E. they are bounded by the great valley of the Columbia river, and on the W. by the Pacific Ocean. The Columbia river, where it bursts through this zone of mountains, plunges to the level of the sea in a series of great cascades, and from these the mountains take their name. They consist of an irregular volcanic plateau, upon which stand many volcanic peaks. They can not be separated topographically, nor is there yet sufficient data to separate them geologically from the northern extremity of the Coast Ranges and Sierra Nevada. Little is known of their general topography and geology, except that the group is characterized by many lofty volcanoes now extinct. The trend of this zone of mountains is a little W. of N.

PRINCIPAL MOUNTAINS OF THE CASCADE SYSTEM.

NAME.	Height.	Authority.
Mt. Logan	19,500	Coast Survey.
Mt. St. Elias	18,101	" "
Mt. Rainier	14,444	" "
Mt. Adams	13,258	Vansant.
Mt. Hood	11,225	Williamson.

In Northern California and Southern Oregon the Coast and Cascade Ranges are united by a mass of mountains having little apparent system, in which heads the Klamath river, and from which the group receives its name. These form apparently no part either of the Coast or Cascade System, but are too little known to enable one to speak definitely concerning their relationship.

N. of the Front and Park Ranges there is a break in the mountain system in Central Wyoming. The Union Pacific Railway traverses this region, a great stretch of barren, elevated plateaus. On the N. the mountains rise again in a complex system which extends into Canada. These ranges will be called provisionally the Geyser Ranges. The easternmost of them, known as the Bighorn Range, separates the head-waters of Tongue river from those of Bighorn river, both being tributaries of the Yellowstone. W. of this is a broad, high range, known as the Wind River Range, in which heads Wind river, the upper waters of the Big Horn, and Green river, one of the two forks of the Colorado. The northward extension of this range, known as the Absaroka, separates the head-waters of the Yellowstone from its main affluent, Bighorn river. W. of this range follows a succession of short, broken ranges, the Tetons, the Gallatin, Madison, Ruby, and others.

In Northern Montana the Front Range, which faces the plains, bears the continental divide, separating the waters of the Missouri from those of the Columbia. This range terminates in latitude 46°, where the divide swings to the westward, following a succession of low passes until it reaches the Bitter Root Range. So far as the limited geographical knowledge concerning this range informs us, this is a long, continuous range forming most of the western boundary of Montana, and bearing for a long distance the continental divide upon its crest, separating the head-waters of the Missouri from those of the Salmon river, a tributary of the Columbia. W. of this range in Central Idaho is a section of ranges separating branches of the Salmon river, a region which is probably as little known as any part of the U. S.

An outlying range to the E., known as the Black Hills of Dakota, is of the Uinta structure, as shown by Newton.

In Canada the Rocky Mountain System is much narrower than in the U. S., and the platform upon which the ranges stand is much lower. From the boundary as far N. as Peace river three members are distinguished: a front range, comparatively simple, known to Canadian geographers as the Rocky Mountains proper, and bearing the continental divide; a broken volcanic plateau; and, bordering the Pacific coast, a northward extension of the Cascade Range, also of volcanic origin and capped with enormous extinct volcanoes.

Still farther northward the Rocky Mountains continue their northwesterly trend, greatly diminishing in importance as they near the Arctic Circle, and finally disappearing between the Mackenzie and Yukon rivers. The Cascade Range continues through British Columbia and Southeast Alaska, following the coast closely and rising in the latter territory until in the neighborhood of Mt. St. Elias it attains a great altitude, having many peaks exceeding 14,000 feet in height and culminating in the great mass of Mt. Logan, 19,500 feet above the sea. The valleys and gorges among these mountains are filled with numerous glaciers which extend very nearly to sea-level. Thence westward, following the coast-line, this range diminishes in altitude, and finally drops into the sea, appearing above its surface in the chain of the Aleutian islands.

In the U. S. the Rocky Mountains, with the Great Plains that stretch eastward, constitute the great arid region where irrigation is necessary to agriculture. In Northern California and Western Oregon and Washington the precipitation of moisture from the Pacific currents is very great, and hence this region is not embraced in the arid district. The arid region is about two-fifths of the area embraced in the U. S., excluding Alaska. From surveys and careful comparative estimates it is shown that it will not be possible to redeem 4 per cent. of the entire region by irrigation when every brook, creek, and river is utilized. Less than 10 per cent. of the region is forest-clad. These forests are on the sides of the high mountains, and extend over the more elevated plateaus. This does not include large districts of country covered with a scant growth of dwarf cedars and pines which can be used for fuel, but are of no value in mechanical industries. Some portions of this forest region are capable of being cultivated without irrigation, but only such crops can be raised as will mature in the short summers of a sub-arctic climate. Of the remaining lands, a large portion is covered with grasses and other plants which may be utilized to some extent for pasturage. The land most suitable for cultivation lies along the streams, and is confined principally to the little valleys nestling among the mountains. The mountains, hills, and plains can furnish nutritious but scant pasturage for herds and flocks, but altogether the agricultural resources of the region are limited. Gold, silver, iron, copper, lead, salt, coal, and many other minerals are found in abundance, and the region is chiefly valuable for its mines.

J. W. POWELL.

Rocky Mountain Sheep: See Big-horn.

Roco'co: a style of debased and extravagant ornamentation for buildings, interiors, furniture, etc., which has several times prevailed in parts of Europe.

Rodber'tus, Johann Karl, known as **Rodbertus-Jagetzow**: political economist, regarded by many as the founder of scientific socialism; b. at Greifswald, Pomerania, Aug. 12, 1805; was educated at Göttingen and at Berlin, studying law at the latter university; held legal appointments under the Prussian Government, but continued his studies, devoting himself especially to political economy, and finally in 1836 retired to his estate of Jagetzow, in Pomerania. He was returned to the provincial Landtag in 1847, to the National Assembly in May, 1848, and was a prominent figure in Prussian politics in 1848 and 1849, holding office for a short time as Minister for Public Worship and Education. After the failure of the movement for German national unity he retired from public life and resumed his economic studies. Though democratic in his principles he found much to approve in the policy of Bismarck. D. Dec. 6, 1875. The cardinal principle of his economic creed may be summed up in his statement "that all commodities can only be considered economically as the product of labor, and cost nothing but labor." The aim of his work was to increase the share of the working classes in the national income, but this was to be attained by a gradual process of social evolution, and not by political agitation. For this reason, though an admirer and sincere friend of Lassalle, he resisted to the last the latter's appeal for cooperation in his efforts to organize a workingman's party of reform. Rodbertus proposed the establishment of a normal work-day, in which the number of hours of labor and the quality of the work performed should be fixed by the Government, and form a basis for a standard of income. The most important of his writings are *Zur Kenntniss unserer staatswirthschaftlichen Zustände* (1842); *Soziale Briefe an v. Kirchmann* (1850–51, the 4th ed. published in 1884 under the title *Das Kapital*); *Zur Erklärung und Abhülfe der heutigen Kreditnoth des Grundbesitzes* (1868–69); *Der normale Arbeitstag* (1871); *Briefe und sozialpolitische Aufsätze von Dr. Rodbertus-Jagetzow* (1884).

Ro'denberg, Julius: poet; b., of Jewish parentage, June 26, 1831, at Rodenberg, a village in Hesse-Nassau, the name of which he adopted in lieu of his original surname, Levy; studied law at the Universities of Heidelberg, Göttingen, and Berlin, and devoted himself to literature. He traveled extensively and published interesting accounts of his journeys in France, England, Ireland, and Belgium. He is also author of a collection of poems and of several novels. Since 1874 he has been the editor of the *Deutsche Rundschau*, the foremost German literary monthly. J. G.

Roden'tia, or **Glires** [*Rodentia* is Mod. Lat., from Lat. *rodentia*, neut. plur. pres. partic. of *ro'dere*, gnaw]: an order of mammals of the sub-class *Monodelphia* or *Placentalia*, comprising the gnawing animals, such as the rats, mice, squirrels, rabbits, etc. These may be briefly defined as ineducabilian placentiferous mammals, with the incisors in pairs in the upper and lower jaws, rootless and ever-growing, and in their growth describing the segment of a circle or open spiral. The order is the most numerous in species of the class of mammals, between 1,000 and 1,200 being known. Two well-defined sub-orders are recognizable: (1) the *Simplicidentati* and (2) the *Duplicidentati*. The *Simplicidentati* have the incisors strictly limited to two in each jaw, and the enamel is entirely confined to their anterior faces; the skull has a true alisphenoid, as well as an external alisphenoid, canal; the bony palate is well developed; the fibula never articulates with the calcaneum; the testes are abdominal, but descend periodically. This group contains the majority of the order, distributed in from fifteen to twenty families, according to the views of different writers. The *Duplicidentati* are distinguished by the presence of four incisors above, but two below; the external incisors are, however, very small, and situated behind the principal ones; in early life even six incisors are present in the upper jaw; the enamel is developed behind as well as in front, although behind it is in a very thin layer; the skull has no true alisphenoid canal; the bony palate is represented by a simple bridge between the alveolæ; the fibula articulates distally with the calcaneum; the testes are external. Of this sub-order two families are known—viz., (1) *Lagomyidæ* and (2) *Leporidæ*. These are the only groups represented by living species. Several peculiar families have been also constituted for the reception of typical forms of extinct simplicidentate rodents. See also the names of the families.

Revised by F. A. Lucas.

Rod'eric: the last King of the Visigoths in Spain; ascended the throne in 709 in consequence of a revolution by which King Witiza was overthrown. He fell in the battle of Xeres de la Frontera (July, 711) against the Arabs under Tarik, who then took possession of the southern and central parts of Spain. The Spanish and Arab historians disagree very much with respect to the events which raised Roderic to the throne, his death, and his character, and with respect to the causes which brought about the Arab invasion; but it seems most probable that an insurrection of the Roman and Celtic elements of the Spanish population took place against Witiza, followed by a rising of the partisans of Witiza against Roderic, and that the Arabs, after conquering Mauritania, would have crossed over to Spain, even if they had received no invitation from any dissatisfied party there.

Rodgers, Christopher Raymond Perry: rear-admiral; son of George Washington Rodgers, naval officer; b. in Brooklyn, N. Y., Nov. 14, 1819; entered the navy as a midshipman Oct. 5, 1833. He served in the Seminole war and on the east coast of Mexico during the war with that country; commanded the Wabash at the battle of Port Royal, and Battery Sigel at the reduction of Fort Pulaski, and acted as Rear-Admiral Dupont's fleet-captain in the attack on Fort Sumter of Apr. 7, 1863; chief of the bureau of yards and docks from 1871 to 1874, and superintendent of the Naval Academy from then till July 1, 1878. D. at Washington, D. C., Jan. 8, 1892. Revised by C. Belknap.

Rö'diger, Emil: Orientalist; b. at Sangerhausen, Thuringia, Oct. 13, 1801; studied theology and philology at Halle 1821–26; became privat docent there in 1828; Professor extraordinary in 1830; ordinary Professor of Oriental Languages in 1825; transferred in the same capacity to the University of Berlin 1860. D. June 17, 1874. His chief works are: *Commentatio quo vulgata opinio de interpret. arab. libri V. T. histor. refut.* (1828); *De origine et indole arab. libr. V. T. historicorum interpretat. libri duo* (1829); *Locmani fabulæ* (1839; 2d ed. 1839); *Chrestomathia Syriaca* (1838; 2d ed. 1868; 3d ed. 1892); *Versuch über die himjaritischen Schriftmonumente* (1841). Rödiger finished and brought out Gesenius's *Thesaurus philologicus criticus* (1853–58), and editions 14–21 of the same author's *Hebräische Grammatik* (1845–72). He likewise edited Wellsted's *Reisen in Arabien* (1842); wrote two articles on the Neo-Syriac dialect of Urmia (*Zeit. f. Kunde des Morgenl.*, vols. ii., iii.); a number of papers on Semitic palæography (*Zeit. d. Deutsch. Morgenl. Gesell.*, vols. iii., ix., x., xi.), and five yearly *Literaturberichte* in the same journal (vols. v., viii., ix., x.). Richard Gottheil.

Rodin, rō'dăń', Auguste: sculptor and etcher; b. in Paris, France, 1840. He began as marble-worker under Albert Ernest Carrier-Belleuse. For a long time he remained in subordinate positions, working under the direction of or in company with Antoine Louis Barye in Paris and the sculptors employed on the new bourse at Brussels. He exhibited in the Salon for the first time in 1875. Since that time a considerable number of large and small sculptures have been exhibited by Rodin, though more commonly in private or separate collections than in the Salon, each one exciting vigorous discussion as to its value as fine art, and exciting both warm praise and severe blame from critics and from other artists. This work is all exceedingly unusual; it is unacademical, and that means more in Paris than elsewhere; it is at once as expressive of emotion and of action as if the artist were willing to sacrifice everything else to expression, and as sculpturesque as the work of Michelangelo, which it somewhat resembles. He has received several medals and other rewards, and was made chevalier of the Legion of Honor in 1888. Some of his best-known productions are the following: *The Brazen Age* (*Âge d'airain*), exhibited in 1877 in plaster, and after a long discussion cast in bronze for the Government and set up in the gardens of the Luxembourg in Paris; *John the Baptist Preaching*, in the Luxembourg Museum; a large door, of which the reliefs are of subjects taken from Dante's *Inferno*; a group of the *Burghers of Calais*; a group of Francesca di Rimini and her lover, known as *The Kiss*; several portraits of great and peculiar interest, such as the statue of *Jules Bastien-Lepage*, the painter, and busts of *Victor Hugo*, *Henri Rochefort*, and *Jules Daloux*, the sculptor.

Russell Sturgis.

Rodman, Thomas Jefferson: soldier; b. at Salem, Ind., July 30, 1815; graduated at the U. S. Military Academy and commissioned brevet second lieutenant of ordnance July, 1841; promoted through consecutive grades up to lieutenant-colonel Mar., 1865. His whole life was devoted to the interests of his profession. To him is due the honor of inventing the method of hollow casting and, from the results of his experiments upon metal for cannon and cannon powder, the design and construction of the 15 and 20 inch cast-iron cannon, with their projectiles and suitable powder. The principles involved in giving to the gun its correct exterior form, the proper distribution of strains in the metal, and the regulation of the interior pressure by the progressive burning of the powder were developed by him largely through the use of his pressure-gauge. The path he marked out has been followed by other investigators, and has resulted in the development of modern guns. He was the author of a valuable *Report of Experiments on Metals for Cannon and Cannon Powder* (1861). D. at Rock Island, Ill., June 7, 1871.
Revised by James Mercur.

Rodney, Cæsar: signer of the Declaration of Independence; b. at Dover, Del., Oct. 7, 1728; inherited a large landed property; was sheriff of Kent County 1755–58; member of the Legislature many years, and its Speaker 1769–73; delegate to the Stamp Act congress at New York 1765; was chairman of the Delaware popular convention 1774; elected to the Continental Congress Mar., 1775; was soon afterward elected brigadier-general; signed the Declaration of Independence; served under Washington in the New Jersey campaign 1776–77; appointed judge of the Supreme Court, but refused the office; defended Delaware from British invasion; was made major-general of Delaware militia; was president or executive officer of Delaware 1778–82, and was again elected to Congress, but did not take a seat in that body. D. at Dover, June 29, 1784.

Rodney, Cæsar Augustus: jurist; nephew of Cæsar Rodney; b. at Dover, Del., Jan. 4, 1772; graduated at the University of Pennsylvania; studied law; was a prominent member of Congress 1803–07; Attorney-General of the U. S. 1807–11; commanded an artillery company 1813; went to South America 1817 as member of a commission to report upon the insurrection against Spain; was member of Congress 1821–22, U. S. Senator 1822–23, and in the latter year became first minister to the Argentine provinces. Author, with J. Graham, of *Reports on the Present State of the United Provinces of South America* (London, 1819). D. in Buenos Ayres, June 10, 1824.

Rodney, George Brydges Rodney, Lord: admiral; b. at Walton-upon-Thames, Surrey, England, Feb. 19, 1718; entered the British navy in his twelfth year; was governor of Newfoundland 1748; re-entered the navy 1752, rear-admiral 1759; in 1762 he captured Martinique, St. Lucia, and Grenada; vice-admiral 1762, baronet 1764, master of Greenwich Hospital 1765, commander-in-chief in Jamaica 1771, admiral and commander-in-chief at Barbados in Dec., 1779, when he sailed from England with a fleet of 30 vessels; defeated a Spanish squadron off Cape St. Vincent Jan. 16, 1780, and broke through the French fleet near Martinique Apr. 17, 1780, for which achievement he received the thanks of both houses of Parliament and a pension of £2,000. In the war against Holland (1781) he captured Dutch Guiana; as commander-in-chief of the West India squadron engaged the French fleet under Count de Grasse Apr. 9, and again Apr. 12, 1782, capturing seven ships of the line and two frigates; was thanked and pensioned by Parliament, and created Baron Rodney of Rodney Stoke, Somersetshire, 1782. D. in London, May 23, 1792. See Hannay's *Rodney* (Men of Action Series, 1891).

Rodos'to (anc. *Rhœdestus*, Turk. *Tekirdagh*): town of European Turkey; in the vilayet of Adrianople, on the Sea of Marmora; 77 miles from Constantinople (see map of Turkey, ref. 4–D). Rising upon hills and surrounded by thriving gardens and orchards, it presents an enchanting spectacle as seen from the water. It exports grain, cotton, silk cocoons, wool, skins, and wine, and largely supplies the capital with vegetables, fruit, and fish. Pop. estimated at 25,000, of whom 14,000 are Ottomans, 5,500 Armenians, 4,000 Greeks, and 1,000 Jews. E. A. Grosvenor.

Rodrigues Lobo, Francisco: See Lobo, Francisco Rodrigues.

Rodriguez, rō-dree'ges: an island in the Indian Ocean; the easternmost of the Mascarene group and of the African islands, lat. 19° 41′ S., lon. 63′ 23′ E.; 365 miles E. N. E. of Mauritius, of which it is administratively a dependency. Area, 42·5 sq. miles. It is of volcanic origin, and consists of a mountain ridge running E. and W., with considerable plains N. and S. The highest point (Le Piton) is 1,160 feet high. It is surrounded by a coral reef through which there are only two passages, each leading to one of the two ports. It is relatively arid, with a maritime tropical climate, and is subject to hurricanes during the northwest, or winter, monsoons. It is devoted to agriculture and fishing. The turtles which once formed an important article of export have disappeared. Rodriguez was not permanently inhabited until 1691, when it was occupied by a Protestant refugee. In time it had a considerable population, mostly slaves, but, on their emancipation, they emigrated, leaving in 1843 a population of only 250. In 1893 it was 2,068, mostly blacks or of mixed Negro blood. The island is of strategic importance and belongs to Great Britain. The language is French.

Roe, Charles Francis: See the Appendix.

Roe, Edward Payson: novelist; b. at Moodna, Orange co., N. Y., Mar. 7, 1838. He studied at Williams College, and one year at Auburn and part of a year in Union Theological Seminary; in 1862 became chaplain of Second New York Volunteers; was subsequently a hospital chaplain at Fortress Monroe; at the close of the civil war became pastor of a Presbyterian church at Highland Falls, N. Y.; in 1874 removed to Cornwall, N. Y., and began the cultivation of small fruits, publishing *Success with Small Fruits* (1880). He wrote many novels, including *Barriers Burned Away* (1872); *Opening of a Chestnut Burr* (1874); *A Knight of the Nineteenth Century* (1877); and *Miss Lou* (1888). D. July 20, 1888.

Roe, Francis Asbury: See the Appendix.

Roe, Henry: See the Appendix.

Roe, Sir Thomas: diplomat, traveler, and author; b. at Low Leyton, Essex, England, about 1568; educated at Magdalen College, Oxford; was knighted 1604; explored the river Amazon in Brazil 1609; was sent as envoy to the Great Mogul, Jahangir, and penetrated to Delhi 1614–18; was ambassador to Constantinople 1621–28, to Poland and Sweden, charged with negotiating a peace between those kingdoms, 1629; sat in Parliament for Oxford University 1640; was sent to the Diet of Ratisbon 1641. He brought from Constantinople a valuable collection of Oriental MSS., which he presented to the Bodleian Library, and procured the Alexandrian MS. of the Greek Bible, now in the British Museum. D. in England, Nov., 1644.

Roebling, rō'bling, John Augustus: civil engineer; b. at Mulhausen, Prussia, June 12, 1806; graduated at the Royal Polytechnic School in Berlin, the subject of his thesis being suspension bridges. In 1831 he emigrated to the U. S., locating near Pittsburg, Pa., and began the practice of his profession on the slack-water improvement of the Beaver river, and later made surveys for a railroad route across the Alleghany Mountains from Harrisburg to Pittsburg. Having begun the manufacture of wire rope at Pittsburg, he obtained the contract for replacing the wooden aqueduct of the Pennsylvania Canal across Allegheny river by a suspension aquednct, which was opened in May, 1845. This aqueduct consisted of seven spans, each 162 feet in length, the wooden trunk which held the water being supported by two continuous wire cables 7 inches in diameter. The construction of the Monongahela suspension bridge next followed, and in 1848–50 four suspension aqueducts were completed on the line of the Delaware and Hudson Canal. In 1851 the great suspension bridge at Niagara river was begun, and in Mar., 1855, the first locomotive crossed. This structure was erected in the face of most critical opposition by British engineers, who then regarded the suspension system as inapplicable to heavy traffic. (See Bridges.) The elegant bridge over the Allegheny at Pittsburg and that over the Ohio at Cincinnati were his next works. His last and greatest undertaking was the bridge across the East river, connecting Brooklyn and New York, which at the time of its erection was the longest bridge in the world. (See Brooklyn.) The reports, plans, and specifications for this work were all completed and operations begun when he was severely injured in the foot; lockjaw succeeded amputation, and he died in Brooklyn, July 22, 1869. His *Long and Short Span Bridges*, in press at the time of his death, treats of the advantages of combined suspension and arched bridges.—His son, Washington A. Roebling, succeeded him as engineer of the East river bridge, and under his direction it was completed in 1883. Revised by Mansfield Merriman.

Roebuck [*roe* < M. Eng. *ro* < O. Eng. *rāh*: Icel. *rā*: Germ. *reh*, roe]: a small species of the deer family (*Cervidæ*), the *Capreolus capræa*, found in Europe. It is more nearly related in some respects to the small common deer (*Cariacus*) of the U. S. than to any other of the European forms, agreeing with the former in the structure of the legs. It is characterized, however, by the antlers being destitute of an interior basal snag, the first branch arising considerably above the burr, and the tail being very rudimentary or wanting. The muffle is broad and naked; the color in summer is reddish brown, and in winter olive; there is a large white spot surrounding the anus; the height is about 2¼ to 2½ feet at or near the shoulder, and the length is about 4 feet. The species is generally distributed throughout Europe, and frequents woods and copses. F. A. L.

Roemer, Ole: See Römer.

Roentgen, Wilhelm Conrad: See Röntgen.

Rogation Days [*rogation* is from Lat. *roga're*, ask, supplicate]: the Monday, Tuesday, and Wednesday of Rogation Week, which contains Ascension Day. In the Roman Catholic Church the recital of the Litany of the Saints is a special feature of these days, and public processions are held in some countries. The second and third Rogation Days are *feriæ*, and not holy days of obligation. Tuesday is a *feria* of the first and Wednesday of the second class.

Roger: the name of the first two rulers of the Norman dynasty in Sicily. Roger I., the twelfth son of Tancred of Hauteville, born in Normandy about 1031; joined in 1058 his elder brother, Robert Guiscard, who had made large conquests in Southern Italy; participated in the conquest of Calabria, and received a part of that country; crossed over to Sicily; took Messina in 1060, Palermo in 1071, was then invested with the countship of Sicily, and completed the conquest of the island by the year 1090. His other great exploit was the abolition of the Greek Church in Sicily and the introduction of the Roman, for which the pope, Urban II., rewarded him by making him apostolic legate, with permission to appoint bishops, etc. D. at Mileto, Calabria, in 1101.—His son, Roger II., born about 1095, became Duke of Apulia and Calabria in 1127 on the extinction of the elder line, and in 1130 received the title of King of Sicily, and was crowned at Palermo by his brother-in-law, Anacletus, whom he established in Rome as antipope and sustained against Innocent II. The latter was captured in 1139 and forced to recognize Roger as King of Sicily. Subsequently Roger made war successfully on the Greek emperor and on the Saracens in Africa. His internal administration was also successful. Commerce and industry, poetry, art, and science flourished, and Sicily was one of the richest and happiest states of Europe. D. in Feb., 1154.
Revised by F. M. Colby.

Roger of Wendover: an early Latin chronicler of English history, of whom little more is known than that he was a monk in the abbey of St. Albans and died prior of Belvoir 1237. He was author of the part of *Historia Major* which is called *Flores Historiarum* and goes from 1189 to 1235. This was continued by Matthew of Paris (*q. v.*). It was edited by Henry O. Coxe (1841–44), and translated into English by J. A. Giles (Bohn's Antiquarian Library, 1849).

Rogers, Franklin Whiting: See the Appendix.

Rogers, Henry: essayist; b. in England, Oct. 18, 1806; educated at Highbury College; was for some years pastor of an Independent church; was chosen Professor of the English Language and Literature in University College, London, 1839; was afterward Professor of Philosophy in Spring Hill Independent College, Birmingham, and became in 1858 president of the Lancashire Independent College at Manchester; author of *Life and Character of John Howe* (London, 1836); *General Introduction to a Course of Lectures on English Grammar and Composition* (1838); *The Eclipse of Faith, or a Visit to a Religious Skeptic* (1853); *Vindication of Bishop Colenso* (1863); *Reason and Faith* (1866); *The Superhuman Origin of the Bible* (1873); and two series of *Essays*, reprinted from *The Edinburgh Review* and from *Good Words*, besides other works. D. in North Wales, Aug. 20, 1877. Revised by H. A. Beers.

Rogers, Henry Darwin, LL. D., F. R. S. E.: geologist; brother of William B. Rogers; b. in Philadelphia, Pa., Aug. 1, 1808; became Professor of Physical Sciences in Dickinson College, Carlisle, 1830; studied science in London in 1831; was many years Professor of Geology in the University of Pennsylvania; was employed on the geological survey of New Jersey, of which he published a report and geological map 1836, and the final report 1840; was occupied from 1836 to 1855 as director of the geological survey of Pennsylvania, making five annual reports (1836, 1838, 1839, 1840, 1841), and issued his final report under the title *The Geology of Pennsylvania* (3 vols., Edinburgh and London, 1859). In 1858 he was appointed Regius Professor of Natural History in the University of Glasgow. He published an *Atlas of the United States* (Edinburgh, 1857, 1861), prepared other American maps for the atlases of the Messrs. Johnston, published many papers in the *Transactions* of learned societies, and was one of the editors of the Edinburgh *New Philosophical Journal*. D. near Glasgow, May 29, 1866.
Revised by G. K. Gilbert.

Rogers, Henry Wade, LL. D.: lawyer and educator; b. at Holland Patent, N. Y., Oct. 10, 1853; graduated at the University of Michigan in 1874; admitted to the bar 1877; became Professor of Law in the University of Michigan 1883, and dean of the law school there 1885; was elected president of Northwestern University in 1890; Professor of Law at Yale in 1901. He edited *The American Law Register* (Philadelphia, 1887–89), and is author of *Illinois Citations* (Chicago, 1880); *Expert Testimony* (St. Louis, 1883; 2d ed. 1891), besides the introduction to a work on *Constitutional History* (New York, 1889).

Rogers, James Edwin Thorold: economist; b. in Hampshire, England, in 1823; graduated at Oxford with honors in 1846; took holy orders, but subsequently renounced them. In 1862 he was elected Professor of Political Economy at Oxford, but though a successful teacher he failed of a re-election in 1868, owing to the opposition of the Conservatives in the university to his radical views. He sat in Parliament as member for Southwark 1880–85 and for Bermondsey 1885–86. On the death of Prof. Bonamy Price, who had been chosen to the chair of Political Economy in place of Rogers, the latter was reinstated in 1888. D. at Oxford, Oct. 13, 1890. His chief work is the *History of Agriculture and Prices in England* (6 vols., 1866–88), of which *Six Centuries of Work and Wages* (1885) is an abridgment. Among his other writings are *Cobden and Modern Political Opinion* (1873); *The First Nine Years of the Bank of England* (1887); *The Economic Interpretation of History* (1888); and *The Industrial and Commercial History of England* (1892), edited by his son. F. M. C.

Rogers, John: the first of the Marian martyrs; b. at Deritend, a suburb of Birmingham, England, about 1505; graduated at Pembroke Hall, Cambridge, 1525; was rector of the Church of the Holy Trinity, London, 1532–34; chaplain to the Merchant Adventurers at Antwerp 1534–48; embraced Protestant opinions; compiled, by the aid of the translations of Tyndale and Coverdale, a revised edition of the English Bible, which he published under the assumed name of *Thomas Matthew*, probably at Antwerp (1537); returned to England 1548; became canon of St. Paul's; preached a sermon in denunciation of Romanism after the accession of Mary in 1553; was burned at the stake at Smithfield in 1555. See his *Life*, by Chester (London, 1861).

Rogers, John: sculptor; b. at Salem, Mass., Oct. 30, 1829; was two years a commercial clerk at Boston; began the study of civil engineering, but, having strained his eyes, went into a machine-shop at Manchester, N. H., 1848, and was ultimately put in charge of a railway repair-shop at Hannibal, Mo., 1856. Having amused himself at spare intervals with modeling in clay, he acquired a thirst for art, which led him to make a tour in Europe in 1857, and to spend some time at Paris and at Rome. On his return, learning of a peculiar mode of casting intricate figures, he modeled the groups of the *Checker-player* and the *Slave Auction*, with which, in Dec., 1859, he went to New York, where they attracted notice. He produced in 1861 his *Picket Guard*, followed by a succession of small groups of war-subjects, which soon gained popular favor. Among them were *Taking the Oath*; *One More Shot*; *The Wounded Scout*; *Union Refugees* (1864); *The Camp Fire*; *The Home Guard*; *The Returned Volunteer*; also *The Country Post-office* and *The Town Pump*. Among his later works are *The Fugitive's Story* (1869); *The Favorite Scholar* (1872); a series illustrative of Irving's *Legends of Sleepy Hollow* and *Rip Van Winkle* (1868–71); an equestrian statue of Gen. John F. Reynolds (1881–83); and a bronze group, *Ichabod Crane and the Headless Horseman* (1887).
Revised by Russell Sturgis.

Rogers, Randolph: sculptor; b. at Waterloo, N. Y., July 6, 1825; was in early life engaged in mercantile pursuits at Ann Arbor, Mich., and in New York; became a sculptor in Rome; returned to New York after a few years with the statues of *Nydia, A Boy and Dog*, and others, which procured him reputation; designed and modeled the bronze doors representing scenes in the life of Columbus, for the eastern entrance to the Capitol extension at Washington (1858); was several years engaged in finishing the designs for the Washington Monument at Richmond, Va., including statues of Mason, Nelson, and the two Marshalls; executed a statue of John Adams, now in Mt. Auburn Cemetery; *The Angel of the Resurrection*, for Col. Colt's monument at Hartford, Conn.; a colossal memorial monument, 50 feet high, for the State of Rhode Island, erected at Providence 1871, and one still larger for Michigan, erected at Detroit 1873, surmounted respectively by statues representing America and Michigan. He designed, among other works, the colossal bronze statue of Lincoln unveiled at Philadelphia 1871, and a *Genius of Connecticut* for the State Capitol at Hartford, Conn. He presented the entire collection of casts taken from his clay models to the University of Michigan. D. in Rome, Italy, Jan. 15, 1892. Revised by Russell Sturgis.

Rogers, Richard: clergyman; b. in England about 1550; became a Puritan minister 1575. His *Seven Treatises* (London, folio, 1605; also 1610, 1616, 1627, and 1630) constituted a kind of theological manual much used by the Brownists, and highly esteemed by Wilson, Hooker, and the early divines of New England. D. at Weathersfield, Essex, Apr. 21, 1618.

Rogers, Robert: soldier and author; b. at Dunbarton, N. H., in 1727; commanded during the "old French war" (1755–63) the celebrated corps of frontiersmen known as Rogers' Rangers, distinguishing himself in the campaigns on Lake George, and taking a prominent part in the defense of Detroit against Pontiac; went to England and published *A Concise Account of North America* (London, 1765) and *Journals of Major Robert Rogers* (1765; new ed. Albany, N. Y., 1883); was appointed governor of Mackinaw, Mich., but was soon accused of plotting to deliver that post to the French, and was sent in irons to Montreal and tried by court martial. On a visit to England in 1769 he was presented to the king; after imprisonment for debt went to North Africa, where he fought two battles in Algiers under the dey; was in Philadelphia 1775, and on suspicion of being a spy was imprisoned by order of Congress; was paroled, but again arrested by Washington, Jan., 1776; was sent to New Hampshire, where he raised a company of loyalists known as the Queen's Rangers, of which he became colonel. He went to England about 1777; was proscribed and banished in 1778; returned to England, where he died in 1800. Besides the works already mentioned, Rogers wrote *Ponteach, or the Savages of America*, a tragedy in blank verse (1766), and left in MS. a *Diary of the Siege of Detroit in the War with Pontiac* (Albany, 1860; new ed. 1883).

Rogers, Robert Vashon: See the Appendix.

Rogers, Robert William, M. A., Ph. D., D. D.: educator; b. in Philadelphia, Feb. 14, 1864; educated at the University of Pennsylvania, Johns Hopkins University, and at the Universities of Leipzig and Berlin; was Professor in Haverford College 1887–90; Professor of English Bible, Dickinson College, Carlisle, Pa., 1890–93; Professor of Hebrew and Old Testament Exegesis in Drew Theological Seminary, Madison, N. J., since 1893. He has published *Two Texts of Esarhaddon* (Cambridge, England, 1889); *Catalogue of Manuscripts (chiefly Oriental) in the Library of Haverford College* (Cambridge, England, 1890); *Unpublished Inscriptions of Esarhaddon* (Cambridge, England, 1891); *The Inscriptions of Sennacherib* (London, 1892). A. Osborn.

Rogers, Samuel: poet; b. at Newington Green, London, July 30, 1763; son of a London banker, whose counting-house he entered in boyhood; published some poetical trifles in *The Gentleman's Magazine* about 1780, and issued a small volume of verse 1786, but attracted no attention until the appearance of his best poem, *The Pleasures of Memory*, in 1792. Succeeding to his father's large estate 1793, he soon retired from active business, published another volume of verse 1798, and in 1803 established himself in the house No. 22 St. James's Place, London, which he made for half a century a kind of headquarters of literary society. He was the intimate (and often the useful) friend of nearly all the noted literary men in Great Britain, and his wealth, liberality, and social qualities gave his productions a vogue to which they intrinsically had no claim. He issued editions of his own works which are much prized for their illustrations, among them *The Voyage of Columbus* (1812); *Jacqueline* (1813); *Human Life* (1819); and *Italy* (1822); D. Dec. 18, 1855. See his *Table-talk* (1856), by Rev. A. Dyce, and *Recollections of Rogers* (1859), by William Sharpe.

Rogers, William A.: See the Appendix.

Rogers, William Barton: geologist and physicist; brother of Henry Darwin Rogers; b. in Philadelphia, Pa., Dec. 7, 1804; gave scientific lectures at the Maryland Institute 1827; succeeded his father, Dr. Patrick K. Rogers, as Professor of Natural Philosophy and Chemistry at William and Mary College, Virginia., 1829; filled a similar position in the University of Virginia 1835–53; organized the Virginia geological survey 1835, and conducted it until its discontinuance in 1842; removed to Boston, Mass., 1853; lectured before the Lowell Institute on the application of science to the arts; aided in founding the Massachusetts Institute of Technology, and was its first president 1862–68; was president of the American Association for the Advancement of Science 1876, and of the National Academy of Science from 1878. Among his physical papers are *Strength of Materials* (Charlottesville, Va., 1838) and *Elements of Mechanical Philosophy* (Boston, 1852). In conjunction with his brother, he published an essay *On the Physical Structure of the Appalachian Chain, as Exemplifying the Laws which have Regulated the Elevation of Great Mountain Chains Generally* (in *Transactions* of the Association of American Geologists and Naturalists, 1842). His geological writings are reprinted in *Geology of the Virginias* (1884). D. in Boston, May 30, 1882. Revised by G. K. Gilbert.

Rogersville: village; capital of Hawkins co., Tenn.; on the Tenn. and Ohio Branch of the Southern Railway; 3 miles N. W. of the Holston river, 50 miles E. N. E. of Knoxville (for location, see map of Tennessee, ref. 5–J). It is in an agricultural region, and contains McMinn Academy, Synodical Female College (Presbyterian, chartered in 1848), several quarries of variegated marble, a roller flour-mill, furniture-factory, a national bank with capital of $75,000, a private bank, and three weekly newspapers. Pop. (1880) 740; (1890) 1,153; (1900) 1,386. Editor of "Herald."

Roget, rō-zhā', Peter Mark, M. D., F. R. S.: physician; b. in London, England, Jan. 18, 1779; graduated in medicine at Edinburgh 1798; became physician to the infirmary at Manchester 1804; settled in London 1808; was an esteemed lecturer in several scientific institutions, and the first Fullerian Professor of Physiology at the Royal Institution; for twenty years secretary of the Royal Society 1827–47; became a member of the senate of London University 1826; was president of the Medical and Chirurgical Society 1829–30, and became examiner in physiology to London University 1839. D. at Malvern, Sept. 17, 1869. He published *Animal and Vegetable Physiology* (Bridgewater Treatises, No. v., 1834); *Physiology and Phrenology* (1838); and *A Thesaurus of English Words and Phrases* (1852; 12th ed. 1881).

Rogue River Indians: See Athapascan Indians; also Takilman Indians.

Rohilkhand': a division of the Northwestern Provinces, British India; bounded E. by Oude, W. by the Ganges. Area, 10,884 sq. miles. It is traversed by the railway from Saharanpur to Lucknow. It received its name from the Rohillas, an Afghan tribe, which settled here in the middle of the eighteenth century. Pop. (1891) 5,345,740. M. W. H.

Rohlfs, Anna Katharine (*Green*): novelist; b. in Brooklyn, N. Y., Nov. 11, 1846. She was married in 1884 to Charles Rohlfs, and afterward removed to Buffalo, N. Y. Her first novel, *The Leavenworth Case* (1878), was a very successful "detective" story, somewhat after the school of Gaboriau. This was followed by others of the same sensational character, including *A Strange Disappearance* (1879); *The Sword of Damocles* (1881); *Hand and Ring* (1883); *The Mill Mystery* (1886); besides a volume of verse, *The Defense of the Bride* (1882), and a drama, *Risifi's Daughter* (1887). H. A. Beers.

Rohlfs, Gerhard: explorer; b. at Vegesack, near Bremen, Apr. 14, 1831; studied medicine at Heidelberg, Würzburg, and Göttingen; served in the foreign legion of the French army in Algeria; went in 1860 to Morocco, where he lived for some time at Fez, and traveled widely in Mohammedan attire. In 1862 he explored the oases of Tafilet. He explored (1863) the eastern part of the Greater Atlas, and pushed south to Tuat in the desert. In 1865 he started on his famous journey from Tripoli to Lake Tchad, crossed the Sudan

states of Bornu and Sokoto, reached the Benue branch of the Niger, and descended to the mouth of that river. This journey ranks among the greatest of African explorations. He took part in the British expedition against Abyssinia (1867). He traveled (1868) across the northern part of the Libyan desert, and discovered the depressions below sea-level S. of the Mediterranean coast plateau. The years 1873 and 1874 were also spent in researches in the Libyan desert at the expense of the Khedive of Egypt. He was the bearer of a letter (1880) to King John of Abyssinia from the Emperor of Germany. In 1885 he was appointed German consul-general for Zanzibar, but soon resigned and settled in Weimar. D. near Godesberg, Rhenish Prussia, June 3, 1896. His writings are voluminous, and among them are *Reise durch Marokko* (Bremen, 1869); *Im Auftrage des Königs von Preussen in Abessinien* (1869); *Land und Volk in Afrika* (1870); *Von Tripolis nach Alexandria* (2 vols., 1871); *Mein erster Aufenthalt in Marokko* (Bremen, 1873); *Quer durch Afrika* (2 vols., 1874–75); *Drei Monate in der Libyschen Wüste* (1875); *Beiträge zur Entdeckung und Erforschung Afrikas* (1876); *Neue Beiträge zur Entdeckung und Erforschung Afrikas* (1881); *Kufra, Reise von Tripolis nach der Oase Kufra* (1881); *Meine Mission nach Abessinien* (1883); *Angra Pequena* (1884); *Quid novi ex Africa?* (1887). His *Adventures in Morocco* were published (1874) in London. C. C. Adams.

Rojas y Zorrilla, rō′*kh*aas-ee-thō-reel′yăă, Francisco, de: dramatist; b. at Toledo, Spain, Oct. 4, 1607. There is practically no information as to his life, and the difficulties in the matter are much increased by the appearance in the seventeenth century of several other persons of the name Francisco de Rojas. From certain of his works it has been conjectured that he studied in the Universities of Toledo and Salamanca. He had already become famous in 1632, for Montalván speaks of him in his *Para todos* of that year as *poeta florido, acertado y galante*. He was a member of the group of great Spanish dramatists of his time, and not only produced plays of his own, but also wrote in collaboration with Calderón, Montalván, Vélez de Guevara, and others. A curious rumor was afloat in Apr., 1638, to the effect that he had been assassinated in a quarrel; but this must have been wholly untrue, or an exaggerated account of a real disaster, for in 1644 he obtained the honor of the mantle of the Order of Santiago, a sign of court favor. The date of his death is unknown, but he may have lived till 1680. He wrote a large number of plays (*comedias*) and sacred pieces (*autos*), but, with the customary carelessness of the dramatists of his time, was at slight pains to collect and preserve his works. He did indeed publish two *Parts* of his dramas (1640 and 1645), and announced a third. The latter never appeared, and many of his best plays were printed in a scattered and probably piratical way. His most famous piece is undoubtedly that entitled *Del Rey abajo ninguno* (None below the King), in which the peculiarly Spanish motive of personal honor seeking redress, but held in check by loyalty to the king, is admirably developed. Excellent also are the comedies of intrigue, *Entre bobos anda el juego* (The Simpleton's Sport), and *Lo que son mujeres* (What Women Are). Like so many of his Spanish contemporaries, Rojas was freely pillaged by the French dramatists—among others by Thomas Corneille and Scarron. Le Sage also plundered his *Casarse por vengarse* for the story of *Le Mariage de Vengeance* (*Gil Blas*, iv., 4). There is no complete edition of the plays of Rojas, but a good selection is given in vol. liv. of Rivadeneyra's *Biblioteca de Autores Españoles* (Madrid, 1866). A. R. Marsh.

Rokitan′sky, Karl, Baron von: anatomist; b. at Königgrätz, Bohemia, Feb. 19, 1804; studied medicine at Prague and Vienna; was appointed Professor of Pathological Anatomy in the University of Vienna in 1834, and retired in 1875. In 1869 he was made president of the Austrian Academy of Sciences. His *Handbuch der pathologischen Anatomie* (5 vols., 1842–46; 3d ed. 1855–61) was translated into English at the expense of the Sydenham Association (4 vols., 1849–52), and is considered the foundation of the science of pathological anatomy. D. in Vienna, July 23, 1878.

Roland: the name of one of the principal representatives of mediæval chivalry, but whether he is an entirely fictitious personage, or whether he was one of Charlemagne's paladins and fell at Roncesvalles in 778, is doubtful. His life and exploits form the subject-matter of numerous ballads, epics, romances in prose, rhymed and unrhymed chronicles in French, Spanish, English, Italian, German, and Danish.

Roland, Manon Jeanne Philipon, Madame: wife of Jean Marie Roland de la Platière, whom she married in 1780; b. in Paris, Mar. 17, 1754, daughter of an engraver. From her reading of classical literature and from Rousseau she imbibed republican ideas, and greeted the Revolution with enthusiasm. Her salon in Paris was a gathering-place for the Girondist party. She bore an equal share in her husband's labors, and was active, even after his arrest and flight, in support of the moderate cause. She was suspected of treasonable correspondence, imprisoned in June, 1793, and executed Nov. 8, 1793, meeting her end with great courage and fortitude. Her *Mémoires*, written in prison, were edited by Dauban (4 vols., Paris, 1864), as also her *Lettres* (2 vols., Paris, 1867). See Dauban, *Étude sur Madame Roland* (Paris, 1864). A. G. Canfield.

Roland de la Platière, rō′lăăṅ′de-lăă-plăă′ti-ār′, Jean Marie: author and statesman; b. at Villefranche, Rhône, France, Feb. 18, 1734. By study and wide observation he became an authority on the industrial arts, and wrote a *Dictionnaire des manufactures et des arts qui en dépendent* (3 vols., 1785). He was inspector-general at Lyons when the Revolution broke out, and was chosen in 1791 to represent the Lyons workmen in the National Assembly, where he allied himself with the Girondists. He became Minister of the Interior under Dumouriez in 1792, was removed because of his attitude toward the king, but restored after the fall of the throne Aug. 10; he opposed the Jacobins, was arrested May 31, 1793, escaped, and fled to Rouen, where he killed himself Nov. 15, 1793, on hearing of the execution of his wife. A. G. Canfield.

Rolf: See Rollo.

Rolfe, Robert Monsey: See Cranworth.

Roll, Alfred Philippe: genre and portrait painter; b. in Paris, Mar. 10, 1847; pupil of Bonnat and Gérome; third-class medal Salon 1875; first-class 1877; officer Legion of Honor (1889); one of the strongest painters of the younger school of French artists. His *In Normandy* (1883) is in the Luxembourg Gallery, Paris. *The Festival of Silenus* (1879), in the museum at Ghent, and *The Strike of the Miners* (1880), in the museum at Valenciennes, are two of his most important works. Studio in Paris. W. A. C.

Rolla: city; capital of Phelps co., Mo.; on the St. Louis and San Fran. Railway; 50 miles S. S. E. of Jefferson City, 111 miles S. W. of St. Louis (for location, see map of Missouri, ref. 6–H). It is in an iron-mining region, is the seat of the Missouri School of Mines and Metallurgy (a branch of the State University, organized in 1871), and contains several smelting furnaces, flour and grist mills, a national bank with capital of $50,000, and three weekly newspapers. Pop. (1880) 1,582; (1890) 1,592; (1900) 1,600.

Rollers: birds of the family *Coraciidæ*, many species of which have the habit of rolling over in the air like tumbler pigeons. The family, which is related to the *Alcedinidæ* (kingfishers) and *Caprimulgidæ* (goatsuckers), includes the genera *Coracias*, *Eurystomus*, and their allies. The rollers are birds of moderate size with stout beaks, wide gape, weak legs, and short toes. Most are of brilliant plumage, in which blue, green, reddish brown, and dark red predominate, and thousands are used in the millinery business. They nest in holes in trees and lay white eggs. They feed largely upon insects, which they dart upon like bee-eaters, but mice, small reptiles, eggs, young birds, and fruit also form part of their diet. The rollers are restricted to the Old World; Asia and Africa are their headquarters, a number are found in Malaysia, a few in Australia, and one species ranges into Europe. This, the blue roller, *Coracias garrula*, is about a foot long; the back is cinnamon brown, head, neck, and wing-coverts pale blue, rump ultramarine, this color also appearing on the under side of the primaries; upper tail-coverts greenish blue, tail-feathers blackish brown, blue at the base; under parts pale greenish blue. A monograph of the family has been published by H. E. Dresser. F. A. Lucas.

Rolleston, rōls′tŭn, George, M. D., F. R. S.: anatomist and physiologist; b. at Maltby, Yorkshire, England, July 30, 1829; graduated at Oxford; studied medicine; became physician to the Radcliffe Infirmary and Lee reader in anatomy at Christ Church, Oxford, 1857; Linacre Professor of Anatomy and Physiology in Oxford University 1860. His principal published treatise was *Forms of Animal Life* (1870). He was reputed one of the ablest modern investigators of comparative physiology. D. June 9, 1881. See his *Scientific Papers and Addresses* (2 vols., 1884).

Rollin, rō'lăn', CHARLES: historian; b. in Paris, France, Jan. 30, 1661; studied theology at the Sorbonne, but did not take orders; was appointed professor in the Collège de France in 1688; became the rector of that university in 1694, and two years later was appointed coadjutor at the Collège de Beauvais. He lost his position in 1712 because he was believed to hold Jansenist opinions, but was reinstated in 1720. D. in Paris, Sept. 14, 1741. His best-known work is *Histoire ancienne* (13 vols., 1730–38), which has often been reprinted both in French and in English. His other works include *Histoire romaine* (9 vols., 1738–48), continued by Crevier, Lebeau, and Ameilhon, and *Traité des études*.

Revised by F. M. COLBY.

Rollin, LEDRU: See LEDRU-ROLLIN.

Rolling-mills: establishments provided with machinery for rolling metal (generally in a heated state) into sheets, bars, rails, rods, or wire. The most important are for iron and steel, and it is these that are described in this article; but in general the processes are the same for other metals. In such establishments the typical machine, also called rolling-mill, is an apparatus consisting of two or more cylindrical rolls, with smooth, rough, or grooved surfaces, so constructed and operated as to reduce a billet or pile of heated iron from an initial form as received from the heating furnace to an intermediate or a final shape called for by the market or by the operations to which the metal is to be submitted.

This reduction of a mass to forms of smaller cross-section is performed with great ease and rapidity, and at comparatively small cost where the alternative is hammering or the use of the hydraulic press. The introduction of the rolling-mill by Henry Cort in 1783 was the most effective step in the production of cheap wrought iron and malleable steel, with the exception of the Bessemer process, which has signalized the progress of invention in that important field. The first operation preparatory to the manufacture of wrought iron is that of puddling (see IRON), or the removal of the carbon and silicon from the cast iron, and the production of a puddle-ball, or a bloom, which is then sometimes given a preliminary shaping under the hammer, but is more often taken directly to the rolls. In steel-making, preliminarily to the use of the rolling-mill, the oxidizable constituents of the cast iron are removed by burning out, in the Bessemer converter or in the Siemens-Martin furnace (open-hearth furnace), and the resulting ingot or bloom is treated as is wrought iron.

The first milling operation is that of roughing down, in the roughing-mill (a pair of rolls with roughened surfaces); the second reduces the slabs thus formed to muck-bars, between smooth-surfaced rolls, and these bars are then rolled into the forms required for the market by a third set of rolls. The speed of rotation of the rolls is the greater as the size of bar, rod, or wire is less, or as the sheet is thinner. In making heavy armor-plate rolls 3 feet or more in diameter, turning at the rate of fifty revolutions per minute, are used; thin plates and small rods are often rolled at speeds several times as great, in mills having rolls 8 or 10 inches in diameter. In merchant mills a number of stands of rolls are arranged in such manner as to permit the convenient passing of the metal from the larger to the smaller, the ingot being gradually reduced to the finished rod, sheet, or wire. Tires of iron are rolled from a ring, which is made by first forging a disk of proper dimensions and punching out its center by a heavy press or hammer, and then rolling the rim thus left in a mill made especially for the purpose. If made of steel, the ingot is cast in the desired form for introduction into the mill.

Mills for cold-rolling are given exceptional strength, and reduce rods and bars very slightly, in the cold state, thus greatly increasing their strength and still more their elasticity. The effect of this process was found by Fairbairn, Whipple, and Thurston, who made a long and complete study of the subject, to raise the tenacity of the metal 50 to 100 per cent., to elevate the elastic limit in still higher proportion, and greatly to reduce the ductility and malleability of the iron and steel. (*Engineering*, 1878, p. 347.) A slitting-mill consists of a set of rolls with deep collars and grooves alternating, the upper collars fitting the grooves in the lower roll. Between these rolls sheets of thin metal are passed, and by them divided, by slitting, into a number of rods of rectangular section, the collars and grooves acting as shears.

Nearly all the members of machines and structures for which iron and steel are suitable—ships, roofs, boilers, bridges, railways and their rolling stock, and those adapted to the purposes of general engineering—are so designed that they can be rolled or compounded of rolled forms, for this method of manufacture is essential to their uniformity and cheapness, and this condition does not seriously embarrass designers, because the great majority of desirable forms can be rolled. If the direct products of the rolling-mill, the leading types of which are shown in Fig. 1, are of unsuitable

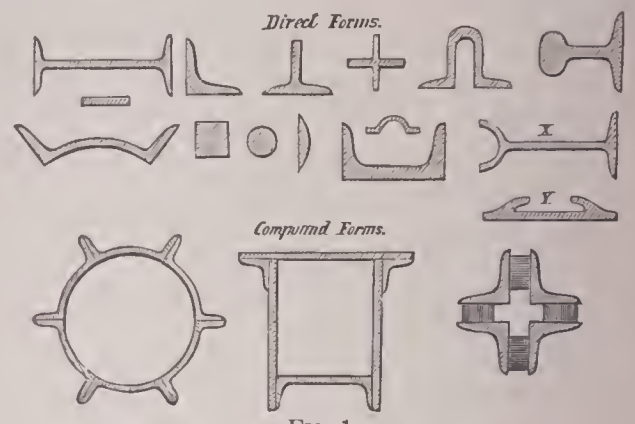

FIG. 1.

figure or size, endless modifications may be produced by compounding them. It is only necessary in any rolled bar that the cross-section shall be uniform throughout its length, and that none of the grooves required in the rolling shall be wider at the bottom than at the top. The chair-bar Y and the form X (Fig. 1) could not be rolled directly; the flanges must be folded down by a subsequent operation.

The leading features of improvement have been (1) increased capacity, due to larger size, better proportions, stronger materials, and notably to better workmanship. (2) The arrangement of the rolls so as to work both ways. In a simple two-high mill (Fig. 2), running constantly in one direction, the bar, after passing between the rolls, must be drawn back by hand over the top roll, and entered again for another compression; thus half the time and a considerable amount of heat are wasted, and unproductive labor is performed. The first remedy was to reverse the motion of the rolls after the bar had passed through, so that they would draw the bar back again, and in so doing compress it.

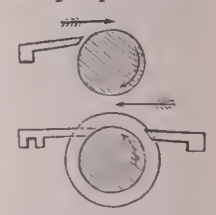

FIG. 2.—Two-high mill.

The reversing is usually effected by gearing and clutches, and sometimes by reversing suddenly a double engine running without a fly-wheel. In any case the reversing machinery is costly to construct, wastes power, and requires many repairs. In the three-high mill (Fig. 3) the bar is entered at the front of the train, between the middle and bottom rolls, and at the rear of the train between the middle and top rolls. The engine runs constantly in one direction, thus avoiding the shock and delay of reversing; and the additional labor, as compared with the reversing mill, is the lifting of the bar on the back of the train through the height of the middle roll. In light work, such as rails, which are in any case passed to and fro by the workmen on hooks or swinging levers, this additional labor is very small, while heavy work is raised by tables moved by steam-power.

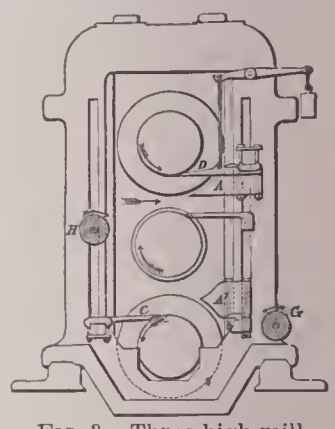

FIG. 3.—Three-high mill.

The other notable means of performing work on the bar at both passes is Brown's double mill (Fig. 4), introduced in England. It consists of two complete and distinct sets of two-high rolls in double housings, the two sets moving in opposite directions. The bar being entered at H, passes between the rolls A A without touching them, deep grooves being cut in the rolls for the purpose. The bar is caught and reduced by the rolls B B. Before the return pass the bar is moved laterally, and then it is entered in another groove and passes between the

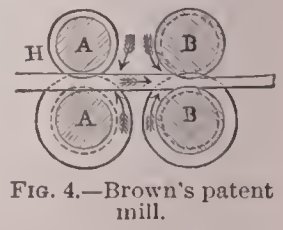

FIG. 4.—Brown's patent mill.

rolls B B without touching, and is caught by the rolls A A. Brown's mill avoids both the shock of reversing and the necessity of raising the bar. It is, however, costly, requiring on many kinds of work more aggregate length of rolls and more bearings than the three-high mill in the proportion of $2\frac{2}{3}$ to 1.

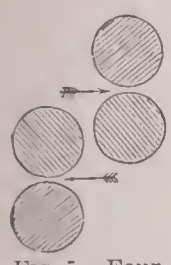

Fig. 5.—Four-high mill.

In the four-high mill (Fig. 5) the passes are made between the two upper rolls and between the two lower rolls, in order to keep the bar constantly the same side up.

The third improvement in rolling-mill practice is the utilization of the waste heat of the iron-heating furnaces for making steam to drive the machinery. A plain cylinder boiler, communicating with the chimney-flue of a heating furnace, will furnish steam-power enough to roll all the iron that the furnace will heat. The temperature of steel-heating furnaces is lower, and multitubular boilers and the highest economics in the transmission and application of steam are necessary to furnish the required power.

The fourth radical improvement is the twofold improvement of the Siemens gas-furnace. (See Furnace.) First, the coal, instead of being wastefully burned in each individual furnace, is converted into gas in a system of producers. The gas is led to the furnace, and there properly mixed with air and perfectly burned. Second, the waste heat of the furnaces is employed in regenerators, to heat the air and gas before they mingle in the furnace, and it is thus fully utilized; 300 lb. of coal will by this means heat a ton of ingots or rail piles, while 800 lb. of coal are used for the same work in the best practice with an ordinary furnace.

The fifth great improvement in rolling-mill arrangements is the application of independent and direct-acting steam-engines, not only to the different trains of rolls, but also to the other machines, such as saws, punches, and shears. For these smaller engines the necessity of carrying steam-pipes all over the mill involves the difficulty of excessive condensation in the pipes; but a more serious objection to the old practice of driving everything by a single engine is the costly maintenance of long lines of belts and shafting. Another objection is the expense of running all this shafting and a large engine in order to drive a single machine if the other machines are not working. Power-distribution by the electric current is sometimes employed with encouraging financial results.

In addition to these principal changes, many valuable improvements have been made in shaping the roll-grooves to do a greater variety and better quality of work. Improvements have also been made in devices for feeding the bar into the mill, in guides and guards for promoting the smooth delivery of the bar out of the mill, and in the arrangements of these and their associated parts.

Let us now analyze the roll-train, considering first, and in its simplest form, a two-high mill with smooth rolls for making plates. There are first laid down two bed-pieces or shoes for supporting the housings. These are bolted to masonry foundations, a strip of oak being laid beneath them to give a close continuous bearing, and to provide a slight but most helpful elasticity. A stratum of oakum three-quarters of an inch thick, driven between the shoe and the masonry, is sometimes used, and it makes a better fit and is more durable. The housings must be of sufficient height and width to permit changing rolls from front or rear; they must be accurately fitted to the movable bolsters that hold the rolls, and must give them firm lateral support; they must be furnished with the screws to receive the thrust of the top-roll and to vary the distance between the rolls; they must sustain the various guiding and feeding machinery; and, while they give room for all these parts and their functions, they must be strong enough to resist all strains and the heavy shocks of rolling. When one roll only is coupled to the engine, the other is turned by the friction of the bar passing between the two. This, however, is practicable only for planishing or finishing rolls, where the work is extremely light. In reducing all ordinary shapes the resistance of the uncoupled roll bends the bar and interferes with smooth working; and for this reason the two pinions, one of which is coupled to the engine, are interposed between the engine and the rolls to impart to them a perfectly uniform rotation. The coupling between a pinion and a roll, or between two stands of rolls—seven or eight stands of rolls being often coupled end to end from one set of pinions—is a form of clutch, consisting of a cast-iron spindle and two cast-iron rings or boxes, fitting partly over the spindle and partly over the roll-necks. Fig. 3 is an end view of a three-high mill, and in this the rolls are held at fixed distances apart. In the plate-mill, the rolls being of uniform diameter, the same part of the rolls may be used for all the passes, the reduction in thickness being produced simply by decreasing the space between the rolls vertically at each pass, and the edges of the plate are not finished at all. In rolling bars, however, it is necessary to preserve a uniform width and a smooth finish on the sides or edges of the bar, and hence the work must be done in grooves.

The simplest form of plate-mill is a pair of smooth rolls, one of which is adjustable vertically by means of a screw, so that the pile may be reduced definitely in thickness at each pass. This mill wastes time and heat, as previously observed, by requiring the plate to be drawn over the top roll after each pass, without receiving any work. A very ingenious means of reducing the plate at both passes is Lauth's system, in which a small roll is interposed between the top and bottom rolls. This roll requires no pinion, because it is powerfully driven by the friction of the roll against which it bears, while the plate passes alternately under and over it. It requires no transverse strength, for that is provided by the large roll, against which it bears from end to end. It may thus be of small diameter, and the plate need only be lifted through its diameter, instead of through the diameter of the large top roll.

In rail-finishing trains the rolls must be rigidly fixed at a definite distance apart, for to screw them together would change only the thickness of the bar, and not its outline. In rolling blooms, however, and some other rectangular or nearly rectangular forms, the same groove may be used over and over again by screwing the rolls together, and a considerable economy in machinery is thus effected. A three-high mill with vertically moving instead of fixed rolls for this class of work and for plate-rolling was erected at the Bessemer steel-works in Troy, N. Y., in 1870, with entire success. Another form, with a fixed middle roll and vertically moving top and bottom rolls, was erected shortly afterward at the Cambria steel-works at Johnstown, Pa., with equal success. The compression of a 2,000-lb. ingot is chiefly a question of the strength of parts, but the handling of the ingot so that the rolls can get hold of it, and the quick adjustment of the middle roll after each pass, involve some new and complex combinations.

Ramsbottom's blooming-mill consists of a pair of reciprocating cams or segments of rolls. The blooms must be short unless the mill is excessively large, and the continuous rotary mill would appear to be the more economical machine.

The universal mill consists of an ordinary two-high mill standing horizontally and another two-high mill standing vertically, so that the four rolls press the bar on all four sides at the same pass. In some cases there are two vertical sets of rolls—one at the front and the other at the rear of the horizontal rolls. This mill is very useful for making uncommon sizes of flat and square bars, for which it would not pay to make special grooved rolls.

The grouping of mill machinery depends, of course, largely upon the locality, the available space, and the direction in which raw materials arrive and finished products depart. These conditions, however, should rarely prevent a good internal arrangement. The important point to be considered is economy in handling the materials used; but in many mills, especially those rambling structures which have grown up little by little, and in which no provision was made for future enlargement, the materials are rehandled three or four times when once should suffice. Another point is to leave room enough for each operation without embarrassing any other. In a well-arranged mill all materials should be received and all the heating done at one end, the rolling machinery should be near the middle, and the finishing and shipping should take place at the other end, the product thus passing as nearly as possible in a direct line.

In reference to the construction of large and costly works, two features are found to be of vital importance: (1) Machinery for making steel and iron must be thoroughly strong, well built, and trustworthy, and in some parts even duplicated, so that it will stand crowding to the utmost limit of endurance. (2) In order to save manual labor in handling the materials—for this is the trying element in nearly all manufacturing—an establishment must be large enough to keep the maximum amount of steam-power employed. Hydraulic feeding-tables and other similar machines, steam-hoists and locomotive engines, and all kindred appliances

must be kept at work in order to be profitable; and this can be done only in extensive works.

Later improvements have included the extensive employment of automatic devices in all departments and of hydraulic transmission of power, and the use of often enormous hydraulic presses in place of the steam-hammer for reducing ingots and shaping heavy plates, as well as in forging large masses of all descriptions.

Revised by R. H. Thurston.

Rollo: the celebrated conqueror of Normandy. According to the saga of Harald Haarfager he was a son of Ragnvald, jarl of More, and was called Ganger Rolf—that is, Walking Rolf—because he was so large and heavy that no horse could carry him. Harald Fairhair drove him into exile, and this led to his crossing the seas and founding Normandy. According to Dudo, of St. Quentin, who wrote the history of Normandy in the eleventh century, Rollo was the son of a Danish chief, and on account of trouble with the Danish king fled from his native country, fought for many years in France, and finally got possession of Normandy. The Icelandic version making him a Norwegian is that most generally accepted. In 912 Rollo made peace with Charles the Simple in St. Clair. He received for himself and his followers the country along the banks of the Seine river, between the little rivers Epte and Eure. He and his men accepted the Christian religion, and Rollo was baptized at Rouen and took the name and title Duke Robert. He is thought to have been over eighty years of age at the time of his death in 930. William the Conqueror was his great-grandson. See Normans. Rasmus B. Anderson.

Rolls, Master of the: See Master.

Romagnosi, rō-măăn-yō'scĕ, Gian Domenico: jurist and philosopher; b. at Salso Maggiore, near Piacenza, Italy, Dec. 13, 1761; in 1786 took his legal degree at Pavia; at thirty years of age published his *La Genesi del Diritto Penale*, which was highly esteemed both in Germany and in Italy. In 1791 he occupied important civil offices in Trent, where he continued to practice as an advocate; in 1803 was appointed Professor of Law at Parma, a position which he retained till 1806, when he was called to Milan to assist in digesting a code of penal procedure, which was afterward adopted. Later a chair was created expressly for him in Milan. Upon the fall of the Bonapartist kingdom of Italy he had to endure poverty and imprisonment. Being set at liberty, he continued his labors under great privations, supporting himself by private lessons. D. in Corfu, June 8, 1835. An edition of his works in 19 vols. was published in Florence (1832–35) and in Milan (15 vols., 1836–45). The most noted of his philosophical writings are *Che cosa e la mente sana?*, *La suprema economia dell' umano sapere*, and *Vedute fondamentali sull' arte logica*.

Romaic: the name applied to the vernacular language of the modern Greeks. See Greek Language.

Romaine, William: clergyman; b. at Hartlepool, Durham, England, Sept. 25, 1714; studied in Oxford; was ordained a clergyman of the Church of England in 1736, and was appointed Professor of Astronomy in Gresham College, and rector of St. Ann's, Blackfriars, London, where he died July 26, 1795. His sermon on *The Lord our Righteousness*, published early in his career, was so strongly Calvinistic that immediately after its delivery he was practically excluded from the pulpit in Oxford, but in London his preaching was much appreciated. He became an acknowledged leader in the evangelical party in the English Church, and his writings have a reputation among the adherents of this school of theological thought.

Roman Archæology: the history of ancient Rome, as illustrated by the remains of its architecture and works of art.

Development of Art in Rome.

The Period of Hellenic and Etruscan Influence.—Before the establishment of Greek colonies in Southern Italy the site of Rome was occupied by Latins of a low civilization. Roman culture first received a higher impulse when the colonies from Magna Græcia began to extend their civilizing influence toward Latium and Etruria. This was felt by Rome, partly in a direct and partly in an indirect way, through the coast towns of Southern Etruria, where in early times a rich industrial art, inspired by Greek models, had been developed. The Etruscan temple, the *templum Tuscanicum*, followed, as far as our knowledge extends, the Grecian Doric type. The ground plan, however, approached more to a square, the pediments were higher, the intercolumniations wider, and the building rested upon a high, oblong terrace, up to the front of which led an open flight of steps. The oldest temple in Rome, the temple of Jupiter upon the Capitol, built by Tarquinius Priscus, was in the Tuscan style. Also, the clay image of the god placed in the temple, and the *quadriga* of the same material over the pediment, were works by an Etruscan artist. The statue held the thunderbolt in its right hand, and in its left probably a scepter. The flesh was painted red, and the color was renewed from time to time. The costume of the figure consisted of a removable wreath, probably of gold, and of the *toga palmata*, a garment decorated with Asiatic designs, in which the statue was draped on festal occasions. On the other hand, the wooden image of Diana placed in the temple dedicated to this goddess by Servius Tullius, on the Aventine Hill, appears to have been a Greek work, or at least a copy of one, for it exactly resembled an idol that the Phocæans had brought with them to Massilia (the modern Marseilles).

Only a few examples of building in stone remain to us from this ancient period. First among these is the Servian city wall, built of colossal blocks of tufa, without cement; then the reservoir (*Tullianum*), at the foot of the Capitol, the covering of which is formed with layers of stone placed over each other, gradually projecting inward as they rise; and finally the vaulted Cloaca Maxima, built by Tarquinius Priscus in order to collect the subterranean springs that percolated through the Roman soil, as well as to drain and dry the morasses of the Velabrum and Forum. The original form of this gigantic work has been greatly modified by later restorations. Other sewers have been discovered which almost surpassed the Cloaca Maxima in size and length of channel and drained almost as vast an area.

Of the first centuries of the republic evidences remain, showing an increase of the direct Greek influence. When it was decided to decorate the temple of Ceres (dedicated 485 B. C.) near the Circus Maximus, two Greeks, Damophilus and Gorgasus, distinguished both as modelers in clay (*plastæ*) and as painters, were called to Rome. The types of the Roman copper coinage (which begins under the Decemvirs, 451–449 B. C.) are formed after Greek patterns. The statue erected upon the Comitium to the interpreter of the Decemvirs, the Ephesian Hermodorus, appears also to have been the work of a Greek hand. Still we must not be blind to the fact that the earliest producers of works in bronze were called by the Romans Volkani (hence Vulcanus), from Vulci their place of origin and center of activity.

Especially indicative of the physiognomy of Rome, as it appeared in the fifth, fourth, and in some quarters of the city also during the two following centuries, is the known fact of the employment of Damophilus and Gorgasus as architects. The manner of ornamentation employed by these artists was that of a polychrome, terra-cotta style, early abandoned in Greece, but long in vogue in Latium and Etruria. The walls, whether of brick or of timber, were incrusted with plates of terra-cotta, upon which were painted ornamental, and sometimes also figurative, representations. Polychrome figures in terra-cotta adorned the pediments of the temples. Fragments of stucco decorations made in this manner have been found as well in the Etruscan cities as in Rome upon the Esquiline. They show the vast extension, and, since they represent a succession of different stages of style following each other, the long duration as well, of this method of ornamentation.

A contrast to this gay variety was offered by the dark-gray blocks of peperino, of which the substructions of the temples and of the public buildings generally were formed, although it is probable that even of these the most prominent architectural members were rendered more conspicuous by the addition of color or of metallic incrustations.

A fact of much significance, in reference to the diffusion of Hellenic views of art among the Romans, occurs at the end of this period. In the year 301 B. C. a Roman patrician, C. Fabius, executed with his own hand paintings in the temple of Salus; and the branch of this distinguished family that descended from him received the surname of "the painters" (*Pictores*). The forms of the designs, however, assumed in many respects a peculiarly Italic character—a different stamp from the true Greek art. This fact is proved by the discovery of a copy from one of the original paintings by Fabius Pictor. This is illustrated by Visconti in vol. xvii. (1889) of the *Bullettino archeologico Comunale*, p. 340. This copy, dating from the seventh century of Rome,

has been found in one of the oldest tombs of the Esquiline. The ornamentation upon the peperino sarcophagus of Cornelius Scipio Barbatus (beginning of the third century before Christ—Vatican) consists of motives from the Doric style.

The Hellenic Period.—The extension of the Roman dominion over Magna Grecia, Sicily, and finally over Greece itself, was productive of most important results. By this means the Romans were brought into intimate relation with Grecian culture. The taking of Syracuse by M. Marcellus (B. C. 212), and the wars waged against Macedonia and Greece, successfully terminating in the conquest of Corinth (B. C. 146), opened the way for the transportation of numerous works of Greek art to Rome. First the public squares and buildings, and then the town and country houses of prominent Romans, were adorned with these treasures of Greek sculpture and painting. The statues were placed on rough stone pedestals, on which a statement of their origin was engraved. Moreover, this new capital of the world offered a better opportunity for remunerative labor than the declining cities of Greece proper and the hopelessly shattered empires of Alexander's successors, and consequently there began at this time an extensive immigration of Greek artists to Rome. As early as the middle of the second century some of them were engaged upon important public works. After the triumph of Q. Metellus over Macedonia (B. C. 146), Hermodorus of Salamis erected a portico which bore the name of that general, and the same architect was commissioned ten years later, by Brutus, to build the temple of Mars lying in the vicinity of the Circus Flaminius. The temples connected with the portico of Metellus were adorned with sculpture by the Greek artists Polycles, Dionysius, Timocles, and Timarchides. Thus Rome became gradually the center of activity for Greek art. In comparison with the high degree of development attained in art in former times, there was now clearly a decline in the creative power; still, Greek art had enough of vitality, even upon Roman ground, to bring to maturity a beautiful aftergrowth. As at this period Roman civilization became more thoroughly Hellenized, and as the literature almost universally assimilated itself to the Grecian type, so also in the realm of the fine arts Greece had almost completely crowded the Italic element out of the field. We have here, in fact, the spectacle of essentially pure Greek art carrying out on Italic soil the same tendency in its exercise which had prevailed in Greece and in the Hellenic East in the third and second centuries before Christ.

Later Years of the Republic and the Empire: Architecture and Architectural Ornamentation.—In architecture the Romans seem to have better preserved their originality against Greek influence, although in this period comparatively few sculptors and painters with Roman names are known, and these few are by no means of great importance. We have strong evidence that even in Greece the merit of Roman architects was acknowledged, in the remarkable fact that when the Syrian king, Antiochus Epiphanes (B. C. 176–169), determined to finish the temple of the Olympian Jupiter at Athens, he intrusted the direction of this undertaking to the Roman knight Cossutius. On the other hand, it is difficult to decide how far in architecture the Romans were really creative in the highest sense—how far they invented new elements in construction and ornamentation. There is a hiatus in the history of art for this period which renders impossible the satisfactory investigation of this interesting question. No period of Greek development was better adapted to influence the Romans, either as to architecture or in other directions, than that of the Diadochi (i. e. successors of Alexander), which was nearest to them in point of time and best suited to their views and requirements. Cities like Alexandria in Egypt, Antioch on the Orontes, Seleucia on the Tigris, founded with the direct object of establishing great centers of intercourse and commerce, must have furnished the Romans with the most suitable models for the reconstruction of their own capital in a manner adapted to its newly attained position of power; but, unfortunately, very little is known concerning the architecture of these Hellenic cities. It can not be positively decided therefore how far the Romans acted independently in the use of the arch, the vaulted roof, and the dome which were favorite elements in the architecture of the empire. The double purpose of use and ornament was served by the arch and vaulted roof in the construction of the fornices, or covered archways, which stood at certain important points as monuments to mark the direction of the main avenues of intercourse. From the time of the republic are known to us the two fornices erected by L. Stertinius (B. C. 196), one on the Forum Boarium, and one in the Circus Maximus; a third was erected by Scipio Africanus (B. C. 190) on the Capitoline Hill; and besides these the Fornix Calpurnius on the slope of the same hill, and the Fornix Fabianus in the Forum. The motive of these structures was Hellenic. A passageway of this kind existed at Antioch as far back as the time of the Seleucidæ. But at the beginning of the time of the emperors this originally Hellenic idea underwent a peculiar ornamental change. It was an old Roman custom on festal occasions to decorate temporarily the façades of the buildings, sometimes even the fornices, near where festivals were to be celebrated. Traces of this custom may be found in Italy on church festivals even at the present day. For such decoration paintings on linen were made use of, which represented scenes appropriate to the festival. During the time of the emperors art gave this temporary decoration a monumental character by substituting relief for painting. In this manner, out of the fornices, decked in their festive attire, grew the triumphal arches of the imperial age. The reliefs upon these clearly show, in their pictorial effects, a relation to the sister art of painting—a relation which becomes all the more apparent when our imagination supplies the polychromy, of which many traces still remain. The Tabularium, a building used for the state archives (finished B. C. 78), is a most majestic combination of the vaulted roof and the arch. This building is situated on the west side of the Forum, directly upon the walls which once surrounded the Capitoline Hill. It rests on a fivefold row of vaults, the outermost of which, still visible, faces the Forum as an open corridor with half columns of the Doric order. The main feature in the construction of the theater and amphitheater was likewise the arch and vault. Of the theater of Marcellus, which Augustus completed B. C. 13, and which was named from his nephew, the son of Octavia, there are still magnificent remains of the exterior, showing the Doric order in the lower and the Ionic in the upper stories. Of this style of building the grandest structure is the amphitheater called the Colosseum (see AMPHITHEATER), built A. D. 80 under the reign of Titus.

Among the buildings with domes, the Pantheon (erected in its present form about 120 A. D.) stands foremost as probably the most beautiful, and certainly the best preserved, structure of ancient Rome. (See PANTHEON.) The domed roof was also especially employed in the construction of vast halls in the public baths or *thermæ*. In the construction of the Roman temples the massive substructure and the steps leading up to the front, which were characteristics of the Tuscan temple, were retained. The architectural and ornamental parts of the temple proper, on the other hand, were thoroughly Greek, although very variously, and not always appropriately, modified. In the construction of the more ancient peperino or travertine buildings the Greek forms were simplified. This arose clearly from the character of the material, which did not admit of delicate ornamental finish. But in the marble structures of a later period these Greek forms were loaded with excessive ornament and intermingled one with another, the ornate Corinthian taking the precedence over the simpler Doric and Ionic orders.

From the time that Rome became the metropolis of the world it was evident that the old Forum was not adequate to the demands of public intercourse. The older Cato, in order to attract the public to the north side, erected there the Basilica Portia (B. C. 184); the Basilicas Æmilia (B. C. 179) and Sempronia (B. C. 169) soon followed. Cæsar carried out the task most energetically, and erected on the south side of the Forum the Basilica Julia, consisting of five aisles. Adjoining the original Forum were built, one by one, the Forums of Augustus, Trajan, and other emperors. See FORUM.

A great deal was done to supply the city with water, and that in a most sumptuous manner. (See AQUEDUCTS.) Agrippa, during his ædileship, constructed in a single year (B. C. 33) 700 basins, 500 fountains, 130 reservoirs, and employed in the decoration of these works 400 marble columns and 300 bronze and marble statues. The Palatine Hill, on which Augustus had dwelt, was adorned on the south side with the palace of Tiberius, of which hardly more than the foundations remain. Caligula extended the work in the direction of the Forum. As is evident from the remains still existing, the hill was enlarged by extensive substructions in order to obtain a larger area for the imperial buildings. Farther to the W. the Flavian emperors erected their palace, the

ruins of which bear witness to the simple grandeur of the work.

Meanwhile the terrible conflagration under Nero (A. D. 64) had occurred. Of the fourteen city wards (*regiones*) three were entirely, and seven well-nigh entirely, destroyed. A countless number of Roman monuments venerable for age, as well as many masterpieces of Greek art, were sacrificed. Yet this misfortune was not without its advantage to the city, for the government, in rebuilding the city after the conflagration in Nero's time, took measures to make the streets wider and straighter. In consequence of the destruction of entire quarters of the city, room was obtained for the erection of large public buildings. Nero's Golden House, on the south side of the Esquiline Hill, with its surrounding houses and parks extending into the valley between the Esquiline and Cælian Hills, requires only a passing notice; for immediately after the emperor's death (A. D. 68), the whole establishment, with all its luxurious appointments, fell into decay. On the site of the artificial lake, within the gardens of the Golden House, Vespasian began to build the Colosseum. The palace itself was utilized by Titus, in part, as a foundation for his baths.

Architecture received a new impulse under Trajan, who employed an excellent Greek architect, Apollodorus of Damascus. Under the direction of this artist the Forum of Trajan was erected to the N. of that of Augustus. The constructive activity of the Emperor Hadrian is exemplified in the double temple of Venus and Roma on the Velia, the plan of which the emperor designed with his own hand (A. D. 135). It was composed of two temples, having a single roof covered with tiles of gilded bronze. The cellæ of the two temples adjoined each other, and the whole was surrounded by a double portico of granite columns. The Mausoleum of Hadrian (Castle of St. Angelo), begun by that emperor and completed (A. D. 140) by Antoninus Pius, consisted of a square substructure, upon which stood a terrace-like superstructure covered with marble and adorned with statues. From the time of the Antonines, besides the column in honor of M. Aurelius, we have remaining only the temple of the elder Faustina, erected A. D. 141, on the north side of the Forum, and afterward likewise dedicated to the memory of Antoninus Pius. The portico, with its ten columns of costly Eubœan (cipollino) marble, left unfluted, is still standing, besides a portion of the cella, which is, however, well-nigh robbed of its marble facing. The back part of the cella has been turned into the Church of S. Lorenzo in Miranda. After the Antonines many sumptuous buildings were erected in Rome. Caracalla strove to surpass all his predecessors in the colossal baths, capable of holding 1,600 bathers, which he commenced on the southeast side of the Aventine Hill, near the Via Appia, but which were not completed until the time of Alexander Severus. Only the brick-faced masonry walls which formed the main body of the building remain. The city wall of Aurelian was constructed in view of the constantly increasing danger from the encroachments of the barbarians. The baths of Diocletian, on the Viminal, were still more extensive than those of Caracalla. Two large halls, which once formed a portion of the baths of Diocletian, are now included in the churches of S. Bernardo and Sta. Maria degli Angeli. The basilica on the Velia, with its three aisles, was built by Maxentius, and remodeled by his successful rival, Constantine. Three of the arches still stand, though robbed of their original ornamentation. They are of an enormous span, and have served as models to many architects of modern times. Constantine presented the city of Rome with baths which were situated on the Quirinal; but the architectural energy of that emperor was mainly expended upon his new capital in the East.

Interior Decoration.—In interior decoration much was done with rare and beautiful colored marbles, and this manner of ornamenting wall-surfaces was maintained to the very end of the imperial epoch. Inlaying of one marble or other fine-veined stone with another was freely used. Glass also, either colored in its body or with the surface moulded in ornamental reliefs, was used for wall-tiles. In the earlier stages of the same period the decoration of interiors was chiefly fresco, and in private houses the Greek manner of the time of Alexander's successors was, for the most part, followed. During this period the spoliation of the Grecian republics, partly by plunder and partly by purchase, brought into the possession of the conquerors a considerable collection of panel-paintings, and the custom was then introduced of using these pictures as the central ornament of the wall. Not every one, however, was able to obtain a sufficient number even to meet the demands of a moderately sized dwelling. It was necessary, then, to call in the aid of the fresco-painter, who supplied the lack of the actual panels by imitations executed on the stucco of the walls. This mode of decoration, originating on the eastern shores of the Mediterranean, was imitated by the Romans even in the the third century before Christ, and continued among the less opulent down to the period of the decline of classical culture. In Rome and Pompeii, the pictures which occupy the center of the walls are clearly imitations of panel-paintings, as may be seen from the simulated frames which surround them. Where more extensive compositions were to be represented, the imitation of panel-paintings would have given a heavy, cumbersome effect; to avoid this the artists resorted to the device of representing the walls with imaginary openings, the pictures appearing as if seen through these openings. In this manner, for instance, the pictures of Io and Galatea on the Palatine Hill were treated. More extensive spaces, such as corridors, courts, and garden-porticoes, were sometimes decorated in fresco with imaginary outlooks upon parks, grounds, and seaports. The best discovery in this line is that of the "painted house" in the Trastevere. It came to light in 1880, near the banks of the Tiber, at La Farnesina. Its magnificent set of frescoes, dating from the age of Augustus, is now exhibited in Michelangelo's cloisters at La Certosa.

Sculpture.—In the Roman sculpture of this period two tendencies, the idealistic and the realistic, may be distinguished. The first occupies itself specially with mythology, but also sometimes takes to the portrait and to the representation of scenes from daily life. Its work is not original, in the highest sense of the word, but is limited, in a greater or less degree, to models from the preceding Greek development. This already shows itself among the artists employed in the service of Metellus Macedonicus. Several evidences lead to the conclusion that these artists sometimes re-treated archaic Greek types in the spirit of free art. Through a series of works that have been preserved we are made acquainted with a group of Athenian artists who lived in the last century before Christ. The most distinguished among these are Apollonius, son of Nestor, the sculptor of the Hercules torso in the Vatican (probably identical with that Apollonius who, after the burning of the Capitoline Jupiter in the time of Sulla, executed the statue of the god designed for the new building); Cleomenes, son of Apollodorus, the artist of the Medicean Venus; Cleomenes, son of Cleomenes, author of the fine portrait-statue in the Louvre mistakenly called *Germanicus*. This last statue repeats the motive of an archaic type of Hermes. The Medicean Venus belongs to those figures which through a series of intermediate stages are gradually derived from the Cnidian Aphrodite of Praxiteles. Glykon, one of the latest artists of the group referred to, in the execution of his statue of Herakles (Farnesian Hercules, Naples), followed a type probably designed by the second Attic school in the fourth century B. C. The naturalistic treatment and the exaggerated expression of physical strength belong only to the artists of the imperial times. We may with entire certainty formulate our judgment concerning these artists, that for the conception they were substantially dependent upon ancient works, but that in the execution they showed independence, and thus lent a new charm to the motives reproduced.

A peculiar direction was taken by the school of Pasiteles, himself a versatile artist of the last century before Christ. There is extant the statue of an Ephebus, with an inscription (Villa Albani), executed by a scholar of Pasiteles, Stephanus; also a marble group (Villa Ludovisi), generally considered to represent the meeting of Orestes and Electra, and shown by the inscription to be the work of Menelaus, a pupil of Stephanus. Eclecticism, which presupposes, in all cases, a dependence upon earlier works, must be considered the essential characteristic of the school of Pasiteles, while the kind and degree of that dependence may in some instances be disputable. The manner of treatment, however, remains as an unquestioned merit of these artists. The same is claimed for Arcesilaus, who wrought the statue of the goddess for the temple of Venus Genetrix, dedicated by Cæsar in 46 B. C.

In other works of sculpture also, belonging to the epoch under consideration, the authors of which are unknown, recent investigations have shown the same dependence upon ancient models. The well-known group representing Venus and Mars, probably connected with a work placed in the

temple consecrated by Augustus to Mars Ultor (2 B. C.), is strictly derived from two types of the earlier development. One is the well-known figure of Aphrodite holding a shield; the artist of the imperial period, omitting the shield, made the arms of the goddess rest upon the shoulders of Mars, who stands before her; this last figure probably originating in a Peloponnesian school. From the same type, the shield-bearing Aphrodite, is derived the Victory writing upon a shield, of which we have examples in an excellent statue in Brescia and in the reliefs of the Column of Trajan. The celebrated statue of the Nile (Vatican) is the reproduction of an original from the Ptolemaic period. We come to a similar conclusion from the investigation of the portrait-statues, of which the early imperial period presents several very prominent examples, as, for instance, that of Augustus from the Villa of Livia near Prima Porta, now in the Vatican, that of the older Agrippina, now in the Capitol, etc. From a considerable series of these portrait-statues it is evident that the clearly thought-out and beautifully expressed motives of the figures belong, in fact, to the earlier development of art, which took place on Greek soil. The merit of these portrait-sculptors of the imperial period is essentially limited to the skill with which they managed to impress the personal likeness upon the heads.

In view of these facts we are justified in saying that the plastic art of this period was rather reproductive than original—that when called to poetic creation in the higher sense, it found itself incapable, and fell back upon older productions. On the other hand it possessed to the fullest extent the power of delicately seizing and reproducing with artistic correctness the forms presented by nature. A considerable decline in this power is first perceptible in the time of Hadrian. Under this emperor arises a peculiarly dry and smooth modeling of forms, and also the custom of brilliantly polishing the surface of the marble. To this early stage of decline belongs the last important type to be seen in the history of classic art, the type of the favorite of the Emperor Hadrian, the Bithynian Antinous, with whose statues and busts the museums are filled.

After the age of the Antonines the decline in plastic art was most precipitous. So far as our positive knowledge of the monuments extends, there exists of this period no worthy representation of any god from the classic Olympus. On the other hand, the statues of Mithras and the repulsive figures of the Ephesian Artemis are everywhere prevalent. A bad tendency is seen in the use of rich colored material, since the costliness of this came to be considered of primary importance, and the artistic treatment was regarded as only secondary. For important and enduring monuments the kinds of stone selected offered, from their very hardness, insuperable obstacles to the development of true form. In the hard, red porphyry, for example, from which the sarcophagus of Helena, the mother of Constantine, and that of Constantia, the sister of the emperor (Vatican), are wrought, it would have been impossible even for a skillful artist familiar with anatomy to bring the human form to any seeming of organic development. Colossal dimension, as well as richness of material, was a great object of admiration. Alexander Severus caused a multitude of gigantic statues to be erected in Rome. A bronze figure, representing the Emperor Gallienus as the sun-god, measured about 240 feet, and the marble statues of the Emperor Tacitus and his brother Florianus at Terni, about 30 feet.

The most pleasing, comparatively, and certainly for the history of art the most interesting, productions of this age of decline are the sarcophagi, adorned with figures in relief, which came into vogue from Hadrian's time. The reliefs, mostly mythological subjects, scenes from the story of Bacchus, the myths of Meleager, Hippolytus, etc., repeat motives from the older Greek art, especially from that development of painting which began in the time of Alexander. These sarcophagi show a reflection, however feeble, of the prominent works of Greek art; and since the originals, especially the paintings, are irrevocably lost, these copies are of the greatest importance in the history of art.

The realistic tendency, which was fostered together with the ideal one, remains secondary and limited to a lower sphere, at least until the time of Hadrian. The realistic portrait of this period is distinguishable from the ideal by certain mechanical methods of producing expression. In the latter, the eyelids are elaborated with a strong feeling for style, and there is no intimation of the eyebrows; the realistic school makes the edges of the lids rest upon the eye, as is the case in nature, and marks the form of the brow. Sometimes the pupils are indicated by grooves, a practice which first became general in the third century after Christ. Traces of a similar tendency in portraiture are already perceptible in the time of Alexander the Great and of the Diadochi. While, judging from the few monuments remaining, art at that time reproduced the elements offered by nature with a certain reserve, and distinguished between that which she intended and that which was accidental, the Roman tendency was to copy faces exactly as they appeared to the eye. This confirms the supposition that this unreserved realism was encouraged by the Roman custom of fabricating waxen images of their ancestors (*imagines majorum*), in which a precise copy of nature, or what passed for it, was obviously required. Still, the portrait statues, especially those made in the capital during the first century of the imperial time, adhere, as a whole, to the principle of ideality. In the second century the realistic principle prevailed, and preserved its vital force even longer. During the whole of the third century this school produced admirable works, as is proved, among others, by the busts of Caracalla, which represent in a masterly manner the brutal nature of this emperor. The same phenomenon appears in the province of *genre* representation. In the earlier portion of this period a realistic tendency appears only in the reliefs on the monument of the baker Eurysaces of the time of Sulla—a work of very plain, not to say coarse, execution, representing the various processes in the preparation of bread.

Unlimited, on the other hand, is the sway of the realistic tendency in the historical representations with which triumphal arches and other similar monuments were adorned in the imperial ages. Already, during the period of Alexander the Great and of the Diadochi, may be seen in the representations of contemporary events—battles, festal processions, hunts, etc.—an endeavor to portray characteristic scenes from real life. The historical reliefs of the imperial times appear as a further development of these works—a development in which the endeavor to be true to the real emancipates itself more and more from artistic fetters. The band of figures winding up the triumphal columns narrates, chronicle-wise, the principal events of the campaign according to the imperial bulletins. Then follows another peculiarly picturesque mode of treatment, explained by the fact that the historical relief of the imperial times stands in close relation to a preceding development of painting, and was, in fact, used for decorative purposes in much the same way as the sister art has since been employed. By the multiplication of the planes of relief an attempt was made to obtain an effect corresponding to perspective in painting. Bold foreshortenings, intimations of landscape detail, and other means of expression properly belonging to the pictorial art, became, with the advance of this development, more and more frequent. As late as under Trajan it continues to be characterized by a freshness and energy which reconcile us, in a certain degree, to the violation of the rules of plastic composition that frequently occurs in these monuments. After his time there is a rapid decline even in this form of art. The defects, which in the Trajan monuments appear in isolated cases and without exaggeration, are now multiplied. The reliefs of the Arch of Septimius Severus show a multitude of planes, piled one above another, each filled with a crowd of figures which confuse the eye.

Painting under the Later Empire.—The pictorial art shows, in every respect, a development analogous to that of the plastic. It is true that the writers preserved to us make very little mention of the painting of this period. In works of the first century of the empire there are passages which speak very disparagingly of the state of contemporaneous painting. Petronius, the best art connoisseur among the Roman authors whose works are preserved, and who probably lived under Nero, says in plain terms that painting was entirely a thing of the past, and Pliny characterizes it as a dying art. These individual statements are corrected by an examination of the wall-paintings found in Rome and in the Campanian cities that were buried under the eruptions of Vesuvius. These place us at once in a position to estimate rightly the severity of the contemporaneous criticisms. The execution of the frescoes, however hastily sketched they may have been, is on the whole excellent. Since the execution of decorative fresco maintained itself at so considerable an elevation, we have a right to suppose the same to be true in a greater degree of the contemporaneous pictorial panel-painting. Thus the condemnatory verdict of competent contemporaries does not refer

so much to the execution, of which there was no reason to complain, as to the conception; and this supposition is strikingly confirmed by an investigation of the originals reproduced by the mural painters. The compositions occurring in these frescoes, representing scenes from Grecian mythology and from ancient daily life ideally depicted, are by no means conceptions of the imperial period, but rather creations of true Greek art, reproduced here with more or less freedom. Some of these compositions have been traced back with certainty, or at least probability, to known Greek masters. We can easily understand that the selection of the compositions to be reproduced in fresco should fall especially upon those of the Alexandrian period; for this development lay nearest the Romans in respect to time, and exercised also in other directions a manifold influence upon their civilization. Very few wall-paintings can, with any probability, be traced to originals earlier than the time of Alexander. Among the examples found in Rome we may reckon as properly belonging to these only the Nozze Aldobrandini (Vatican Library), the composition and forms of which do not show the artistic principle which was brought to full development in the time of the Macedonian hero. On the other hand, the art of the Alexandrian and Diadochi age occupied itself less with grand subjects of a monumental character (megalographia) than with those suited for cabinet pictures intended for private enjoyment. As these cabinet pictures were not rich in figures, and were of proportionally small dimensions, and as they did not so much attempt powerfully to strike the spectator by the grandeur of the subject as to impress him agreeably by graceful representations of situations easily understood, they were well adapted for reproduction in Roman mural painting. In Roman dwellings these pictures, being placed in the centers of walls generally very limited as to space, satisfied all the demands which could reasonably be made upon such a style of decoration, and afforded an agreeable resting-point for the eye, without absorbing the attention. The subject of the scenes represented, and the sentiments associated with them, were as perfectly comprehensible to the Roman even if he did not understand the Greek language, as to the Greek of the Diadochi period; for the Latin poetry of the Augustan age had borrowed many of its themes from the Alexandrian poetry which had inspired these very pictorial compositions, and they treated the same subjects as their predecessors had done, and in the same spirit.

In Roman fresco-painting an important place is occupied by the landscape, a province of art which also came into independent development during the age of the successors of Alexander. The most beautiful extant paintings of this kind are the landscapes discovered on the Esquiline, with scenes from the *Odyssey* (Vatican Library). The essential merit of the artist who originated the Odyssean pictures lies in the plastic development of the landscape, in the clear arrangement of the planes, the harmony of the proportions, and the nobility of form in the figures introduced.

An exclusively realistic tendency manifests itself only in the mural painting of a very inferior kind. In Pompeii this class of pictures is almost entirely confined to houses of a very poor character. After the year 79 A. D., in which the Campanian towns were buried by the unexpected eruption of Vesuvius, we can no longer follow with any certainty the history of this art; however, the few frescoes of later date which are preserved to us show that then, as before, they repeated the traditional mythological motives transmitted from the earlier antiquity, but that at the same time the execution deteriorated from generation to generation. The paintings of a tomb on the Via Latina, belonging to the Hadrian period, show already a considerable decline, as far as the freshness and energy of the work are concerned, when we compare them with the average of the mythological pictures of Pompeii. The rise of Christianity did not tend to arrest this decline, but rather hastened its downward course. Unlike paganism, which in all times had permitted a high degree of independence in the treatment of the forms of the gods and of all mythological subjects, the Church kept art closely hampered by the bands of an orthodox discipline which could not but be detrimental to it. The programme of the Christian faith was especially announced by means of pictures in mosaic, a species of art which makes any individual rendering of the outlines difficult, but which answered admirably the purpose of the Church, to bring before the eye sacred forms and histories under orthodox types and clothed with great brilliancy.

W. HELBIG.

RESULTS OF RECENT EXCAVATIONS.

The works for the extension and embellishment of Rome executed since 1870 have been the occasion of a great number of archæological discoveries, which will be described briefly in order to show what immense progress knowledge of the history and topography of the ancient metropolis of the world has recently made. Properly, this description should classify the new monuments according as they belong to architecture, to painting, to sculpture, to epigraphy, but as most of the discoveries relating to the three latter classes must necessarily be mentioned in connection with the edifice to which they belong, it will be simpler to give a topographic description of the architectural monuments.

Fortifications.—Rome has been defended at three different periods by three different walls—that attributed to Romulus, which surrounds the Palatine; that of Servius Tullius, which encircles the Seven Hills; that of Aurelian, which forms the inclosure of the city at present. Four fragments of the wall of the Palatine have been discovered, as well as the sites of the gates Mugonia and Romanula.

A third ascent to the primitive city has lately been traced on the side facing the Circus Maximus. It is cut in steps and gradients, and well deserves its classic name of *Scalæ Caci*. The prehistoric walls of the Palatine are built with tufa quarried on the spot, the quarries being afterward turned into reservoirs for rain-water in case of siege. As to the walls of Servius Tullius, they can be traced to-day at fifty-six different points. They start from the left bank of the Tiber near the Porta Flumentana, skirt the northern cliffs of the Capitoline (discovered 1715, 1873, 1892) and Quirinal Hills (discovered in the Via di Marforio in 1865, in the Piazza di Magnanapoli 1875, in the Colonna gardens, in the Via delle Quattro Fontane 1873, in the Barberini gardens 1627, etc.). Near the Collina gate (Via 20 Settembre) the system of defense and fortification of the city suddenly changes. From a simple wall, built on a ledge of the craggy slopes, half way between the bottom of the valleys and the plateau above, it becomes an *agger* or bulwark composed of a ditch 100 feet wide, 30 deep, of a wall 40 feet high, and of an embankment inside the wall 100 feet wide, from 30 to 40 feet high. The agger runs southward to the Porta Esquilina (transformed in 262 A. D. into a triumphal arch of the Emperor Gallienus). It has been discovered since 1870 in its entire length. From the Porta Esquilina to the banks of the Tiber the Servian walls follow the slopes of the Esquiline (discovered in the Via Buonarroti 1887), of the Cælian (discovered in the Via della Navicella 1890, in the villa Mattei 1582), and of the Aventine (discovered at Santa Balbina 1884, at San Saba 1858, in the Villa Torlonia 1854 and 1867, at Santa Sabina 1857), and fall into the river near the modern Arco della Salara. The river front inside the city was likewise fortified with a powerful embankment, the remains of which were destroyed in the nineteenth century in widening the bed of the river itself. The Transtiberine region was not protected by walls, but by a detached fort on the top of the Janiculum (the present villa Savorelli-Heyland).

Of the nineteen gates of Servius, seven have been found, and three are left standing. The Ratumena was found in 1865 in the Via di Marforio; the Fontinalis in Nov., 1875, under the Palazzo Antonelli; the Sanqualis in 1866 under the Piazza del Quirinale; the Salutaris in Sept., 1892, under the Palazzo Crawshey, Via delle Quattro Fontane; the Collina in 1872 under the Treasury building, Via 20 Settembre; the Viminalis in 1877 near the railway station; the Capena in 1865 near the Church of St. Gregory on the Cælian.

In Dec., 1875, were discovered some vestiges of the citadel, or *arx*, which occupied the northeast summit of the Capitoline, and which seems to have been defended by a double inclosure, the one contemporary with the wall of Romulus, the other with that of Servius.

Temples.—The number of temples, either standing or uncovered, which in 1870 was twenty-one, was thirty in 1894. Among those recently unearthed are the temple of Cybele, discovered in 1870 on the Palatine, with the statue of the goddess; the temple of the Dea Dia (Ceres), discovered in 1868 outside the Porta Portese, at the station of the Magliana, with 1,750 lines of the *Acta Fratrum Arvalium* engraved on marble; the temple of the Fortuna Primigenia, discovered in 1873 between the baths of Diocletian and the Pretorian Camp, with many inscriptions and a statue representing the Roman lady Claudia Justa, with the attributes of

the goddess; the temple of Julius Cæsar, discovered in 1873 at the south extremity of the Forum; the temple of Jupiter Capitolinus (1865–76), on the west summit of the Capitoline; the temple of the Palmyrene Sun (1857), outside the Porta Portese; the temples of Bellona and of Honor and Virtue, discovered in 1873 in the foundations of the ministry of finance; that of Augustus under the Palatine (1881); of Dius Fidius on the Quirinal near the Church of San Silvestro (1884); of Isis and Serapis near the Church of Sant' Ignazio (1881); of Mars in the Campus Martius (1874); of Vesta with the adjoining *atrium* of her priestesses (1881). The temples of Castor and Pollux (1872), of Jupiter Stator (1867), and Victor (1868), of Neptune, of Venus, and Rome already known, have been entirely uncovered or explored. The latest find in this line is that the Pantheon, which has come down in its entirety, is not the work of Agrippa, as stated in the inscription of the pediment, but the work of Hadrian. Agrippa's temple was discovered under the foundations of Hadrian's rotunda at a depth of 12 feet (Dec., 1892).

Basilicas.—The whole of the surface covered by the Basilica Julia, which occupied the west side of the Forum, has been completely laid open. The pavement, enlivened by polychrome marbles, is tolerably well preserved, but the triple range of porticoes which surrounded it has almost completely disappeared. The basilica of Constantine has also been delivered from the mediæval buildings which concealed and disfigured its apse. Under the floor of the basilica the remains of the Horrea Piperataria (stores for Eastern spices) have been found, as well as a tunnel which connected the Sacra Via with the Carinæ.

Theaters.—In Jan., 1876, in the course of some restorations of the Palace Savelli-Orsini, which occupies the site of the theater of Marcellus, there was discovered a considerable portion of the lower portico, filled with architectural fragments of every kind. An imperfect imperial inscription, found in the same place, mentions a restoration of the stage of the theater by Antoninus Pius. The porticoes which surrounded Pompey's theater have been discovered in four places, with a number of granite columns still *in situ*. As regards the theater of Cornelius Balbus, the northeast corner of the scæna came to light during the construction of the new Via Arenula. A fourth theater was discovered in the gardens of Ælius Lamia on the Esquiline.

Amphitheaters.—During the whole of 1874 excavations were made in the interior of the Colosseum. It is now possible to study the system employed for raising and lowering the cages of the wild animals; the small cells in which they were kept before the commencement of the games have been found; in short, all the details of the service of the amphitheater have been revealed with the greatest minuteness. Almost all the architectural fragments found in these excavations belong to a portico or gallery which crowned the interior of the edifice. Some inscriptions have also been found indicating the place reserved at the games for personages of the court and for the higher order of magistrates.

Circuses and Stadia.—The palace of Augustus on the Palatine was separated from the palace and the Septizonium of Septimius Severus by a stadium built by Domitian and restored by Hadrian. This stadium was mostly uncovered in 1872; the portico which surrounds it is composed of pillars of brick cased with marble, but the imperial tribune was decorated with surprising richness, if we may judge by the shattered columns of Oriental marble, the fragments of sculptured frieze, and other ornamentation found in the excavations. In building a new quarter N. of the castle of St. Angelo remains of Hadrian's circus have been found. They had already been seen and ransacked at the time of Benedict XIV.

Thermæ.—Rome in the period of her splendor had eleven large thermæ and 926 baths of an inferior order for the use of the lower classes. These last have almost totally disappeared, but many of the thermæ still exist, and several of them have been explored since 1870. Scellier de Gisors, a French architect, made excavations in the baths of Titus, bringing to light certain details of the plan hitherto unknown. The baths of Antoninus Caracalla have been cleared under the direction of the Government. The superb mosaic pavements of the halls are nearly all preserved, as well as many fragments of architectural decoration and three mutilated statues—the Farnese Bull, the Hercules, and the Flora. In the piazza of S. Eustachio and in the neighborhood of the Pantheon several halls and chambers of the baths of Agrippa, filled with fragments of columns, entablatures, and basreliefs, have been discovered. The open space paved with travertine in front of the Pantheon has been uncovered to an extent of 120 sq. meters. In the Aldobrandini and Rospigliosi gardens, on the Quirinal, considerable remains of the baths of Constantine have also been brought to light—the theater, or *hexedra*, and the rooms which formed the southeast angle of the baths. All the foundations of these baths are constructed from the spoils of older monuments, such as columns, capitals, broken statues, friezes, marble roofings, etc. The thermæ of Diocletian, which covered an area of some 800,000 sq. feet, and which could accommodate at one time 3,600 bathers, have been cleared of modern superstructures and made more accessible to the public by the institution of a new museum of antiques in some of their spacious halls. The baths of Novatus in the Vicus Patricius, of Decius Albinus on the Aventine, of Helena near the Lateran, may also be included in the list of modern explorations. Taking 1,500 as the average number of places disposable in each of the great thermæ, and 50 as that of each of the private baths, it is evident that 62,800 citizens could bathe at the same time in ancient Rome.

Forums.—The exploration of the Roman Forum may be considered as complete. It has the form of a parallelogram, and is bounded on the E., W., and S. by streets, on the N. by the Rostra. The pavement is composed of blocks of travertine. Along the west side—that is, in front of the Basilica Julia—may be seen seven pedestals of honorary columns; the south side, facing the temple of Cæsar, was shut in by a line of shops. In the center of the Forum may still be seen the pedestal of the equestrian statue of Constantine the Great, called in the Middle Ages the Caballus Constantini, and farther to the N. the two *plutei*, or parapets, discovered in Jan., 1873, the sculptures of which are regarded as the most perfect that have been found in this locality. These *plutei* indicated the place where all the citizens on their way to the elections were to go and present their *tesseræ*, or tickets of admission. The whole area of the Forum is strewn with remains of historical monuments, such as pedestals raised in honor of victorious emperors, consuls, generals, triumphal arches and pillars, statues, bas-reliefs, etc. The most important topographical details ascertained by recent excavations are the pavement of streets radiating from the Forum itself, such as the *vici* Jugarius, Tuscus, Argentarius, ad Janum, the Nova and Sacra Via, the Argiletum, etc.: the foundations of the triumphal arches of Augustus (1888), and of Fabius Maximus (1881), the area of the Comitium (1887), the Rostra Iulia, the site of the Græcostasis, and many other such landmarks familiar to the student of Roman history. The pavement of the Forum Olitorium has been uncovered for an extent of 360 feet between the theater of Marcellus (Piazza Montanara) and the Temple of Piety (San Nicolà in Carcere).

The excavations consequent upon the building of the new quarters upon the Esquiline led to the discovery of the Forum Esquilinum, and of the public markets (Macellum Liviæ) which surrounded it. In the center of the square lay the pedestal of a statue, with an inscription relating to the embellishments of the Forum executed by order of Flavius Epitynkanus, prefect of the city, in the fifth century. The center of the market was occupied by a large fountain. The Forum Boarium, the Forum of Peace, the Forum Transitorium (Domitian's) and the Forum Palatinum have been partially explored, while the beautiful Forum of Augustus is (1895) in course of excavation. Its preservation is surprising—in its marbles are engraved the names of Appius Claudius, Cornelius Sulla, Fabius Maximus, Scipio Asiaticus, Augustus, Nigrinianus—and here also have been found beautiful architectural fragments of the golden age.

Honorary Monuments and Triumphal Arches.—In the sixteenth century a triumphal arch, erected in honor of Gordian the Pious at the entrance of the Pretorian Camp, was demolished by Bramante in order to use the material in constructing the Palace Della Cancellaria. Remains of this arch were discovered in 1872 in digging a drain in the Via Gaeta. These remains comprise portions of the entablature, as well as fragments of the inscriptions relating to restorations made by Diocletian. The small arch raised in honor of Septimius Severus by the cattle-dealers from the Forum Boarium has been isolated from the adjacent buildings, and so has the arch of Gallienus on the Esquiline. The seven pedestals of honorary columns found on the west side of the Roman Forum have already been mentioned. Three of these columns have also been discovered. They measure 26 feet in length, and, judging from the deep holes with which the shafts are pierced, they must have been covered with

plates of bronze ornamented with historical reliefs. Among the ruins of the temples of Isis and Serapis, which stood near the Church Della Minerva, had already been found the obelisks erected afterward in the open squares of the Pantheon, of the Minerva, and in the grounds of the Villa Mattei. Recent excavations in the same place have given a fourth obelisk, entirely covered with hieroglyphics, with the cartouches of Ramses the Great.

Military Establishments (*Castra*).—The military barracks were sumptuous edifices, built, or rather rebuilt, by Septimius Severus, except that of the pretorians, which dates from the reign of Tiberius, and which was restored under the Gordians. Of this latter it was already known that three sides were incorporated into the city walls by Aurelian. The fourth—that is, the west side—has been discovered in consequence of the works in the new quarter of the Viminal (*Castro Pretorio*). It contains seventy-eight small chambers, each capable of lodging six or eight soldiers. A little beyond was found a small apartment, reserved perhaps for the superior officers, the pavement of which was in mosaic, representing scenes of combat, the names of the warriors or the gladiators being marked by the side of each figure. The site of the Castra Equitum Singularium—that is, of the barracks of the imperial horse-guards—has been made known by the discovery of thirty-two magnificent monuments, dedicated to their gods by the men who had honorably finished their service (*missi honesta missione*). Hundreds of names are engraved upon them, with indications of paternity, place of birth, dates and duration of service, etc. The men are grouped by squadrons, which are indicated by the name of their commanders, such as the squadron of Marcellus, the squadron of Tranquillinus, etc. These monuments were found in the Lateran district crossed by the Via Tasso. The seven battalions of the vigiles, or policemen, were distributed through the city in such a way that each one occupied the boundary-line between two *regiones*. Recent discoveries established the fact that the barrack of the first cohort (or battalion) was situated below the Palace Savorelli, on the boundary between the VII. (Via Lata) and IX. (Circus Flaminius) *regiones*. That of the second has been found on the Esquiline, very near the Arch of Gallienus; that of the third at the southeast angle of the baths of Diocletian; that of the fifth in the Villa Mattei, by the Church of the Navicella; that of fourth near the Church of San Saba (Aventine). The sites of the sixth and seventh are unknown. Besides the main barracks there were fourteen outposts called *excubitoria*. One of these, belonging to the men of the seventh cohort, has been discovered in the Piazza di Monte de' Fiori, near the Church of San Crisogono. Its preservation is surprising.

Palaces and Houses.—The palace of the Cæsars on the Palatine has no unity of plan or of decoration, but is composed of a suite of palaces, differing one from another, built at different epochs, and separated sometimes by streets and squares accessible to the public. The most ancient portion is the house of Augustus, situated on the side of the Circus Maximus. Then follow the house of Tiberius, at the northwest angle of the hill, on the Velabrum; the house of Caligula, at the northeast angle upon the Forum; the house of Nero, at the southeast corner, toward the Colosseum; the house of Vespasian, which occupies the very center of the hill; and, finally, the house of Septimius Severus, at the southwest angle, toward the Porta Capena. Although the condition of these remains is in general very ruinous, yet many apartments preserve sufficient traces to render possible a decision as to their decoration and primitive destination; and the whole plan of the entire group has been reconstructed with as much precision as can be obtained in a house of Pompeii. Among the palaces and private houses of which the position or new details have been discovered should be mentioned the palace of the Laterans, considerable portions of which have been explored, especially in the garden of the hospital of St. John, where fragments of an imperial statue in porphyry and several mosaic pavements have been found; the house of Germanicus, on the Palatine, in perfect preservation, the pictures which decorate the walls being considered as the best among those thus far found at Rome; the house of Asinius Pollio, discovered in the Vigna Gnidi, at the southeast angle of the baths of Caracalla; the house of Q. Fabius Cilo, the site of which is occupied by the church and convent of Santa Balbina, and where have been found two superb busts of Caius and Lucius, nephews of Augustus; the house of the Cornelii, discovered in 1873 under the new ministry of finance. In the house of Avidius Quietus, governor of Galatia under Domitian, discovered Mar., 1876, near Sant' Antonio all' Esquilino, bronze tablets have been found on which are engraved the decrees in honor of Quietus awarded by the cities of the province which he had administered. On one of the walls of the vestibule of the house of Memmius Vitrasius Orfitus, a consul of the fourth century, inscriptions were found dedicated to their master by the officers of the household. Similar inscriptions preserved on the spot have determined the position of the palace of Neratius Cerialis, prefect of the city in the fourth century, on the piazza of Santa Maria Maggiore; of Numicius Pica Cæsianus, quæstor under Trajan, on the Via Strozzi; of the senator Q. Octavius Felix, near the Church of Santa Bibiana; of Nummius Albinus and of Martial, the poet, under the new War offices, Via 20 Settembre; of Vettius Agorius Prætextatus, in the Via Merulana, etc. The number of private mansions the ownership of which has been established by late excavations may be estimated as 175.

Villas and Gardens.—The gardens of Mæcenas, on the Esquiline, have been in a great measure excavated, from the Church of Sant' Eusebio as far as the Via Merulana. The most interesting monument as yet found is a magnificent conservatory in the form of a small oblong theater, the walls of which are decorated with beautiful landscapes. In the neighborhood of this conservatory have been found six Caryatides of Pentelic marble, as well as three *Hermes* of fauns, which were generally placed at the intersections of garden avenues; two fountains, one of which is in the form of a rhyton, or drinking-horn, marvelously sculptured by Pontios of Athens; three busts of philosophers; and several other fragments of sculpture worthy of the age of Augustus and of the artistic taste of Mæcenas. Still more important are the discoveries made on the site of the Horti Lamiani, which adjoined those of Mæcenas, occupying the whole of the rectangle comprised between Via Labicana, Via Merulana, Santa Croce, and San Matteo. In the very center of these gardens the remains of a palace have been found, the east and west sides of which were adorned by porticoes with columns of *giallo antico*. On the two other sides—that is, on the N. and S. of the rectangle—were found bath-rooms of extraordinary splendor. The floors were paved with slabs of precious marble, such as *occhio di pavone*, fleece-alabaster (*a pecorelle*), jasper, agate, etc. Some of the walls were covered with slate ornamented with arabesques in gold; others were incrusted with *opus sectile marmoreum*, or what is called "Florentine mosaic." It was in one of these rooms that on Dec. 24, 1874, there was discovered the group of sculptures which forms the principal ornament of the new museum of the Capitol. This group includes a statue of Venus, a Greek work anterior to the type of that goddess, created by Praxiteles; statues of the muses Terpsichore and Polymnia; a bust of Commodus, represented as the Roman Hercules, perhaps the most perfect work of the kind which antiquity has bequeathed; and a head of the young Commodus. In the same room was found an inscription relating to the improvement of the gardens and the reconstruction of the palace by the Emperor Alexander Severus—that is, by the same who restored the gardens of Sallust, as is proved by another inscription found Apr. 2, 1876, in the villa Spithöver on the Quirinal.

Recent researches also show that almost the whole surface of the Esquiline was occupied by gardens, which, laid out at first for private use, had fallen by degrees into the hands of the emperors, who opened them to the public; so that Rome became perhaps as rich in parks and delightful promenades as is London or Paris. Among the gardens recently discovered may be mentioned those of Vettius Agorius Prætextatus, the site of which is very near the Porta San Lorenzo. Nearly all the foundations of the buildings belonging to these gardens are composed of fragments of statues. A single one of these walls, scarcely 100 feet in length, has yielded 2,500 pieces of sculpture, which, united with infinite patience, have already furnished the museum of the Capitol with seventeen statues and two sculptured vases. It is enough to say that the single statue of a Hercules carrying off the mares of Diomed has been recomposed out of nearly 250 fragments. Foundation-walls built with fragments of statuary are the work of the semi-barbaric Romans of the sixth to the ninth century of our era. They are discovered by hundreds. One, found in 1890 on the banks of the Tiber by San Giovanni de' Fiorentini, contained the now famous account of the Ludi Sæculares celebrated by Augustus in 17 B. C. and by Septimius Severus in A. D. 204.

Another, found Dec., 1892, near the entrance to the Ponte Sant' Angelo, was built with pieces of statues from the mausoleum of Hadrian. Besides the gardens and parks already named, excavations have been made and discoveries obtained in the gardens of Sallust (1880–88), of Lollia Paulina (1886), of Domitia (the Prati di Castello), of Geta, in the grounds of the villa Corsini (1883), of Julius Cæsar on the Janiculum (1890), of Pompey and Agrippa in the Campus Martius, of Herodes Atticus on the Via Appia, of Varius Helagabalus on the Via Labicana.

Tombs.—The burial-place of the ancient inhabitants of Rome was not confined to the borders of the great consular highways, but outside the gates were found vast cemeteries called *campi*, which took their name from the gate nearest them. Thus we know already the Campi Viminalis, Esquilinus, Cælimontanus, Aventinensis, etc.; another is found between the Viæ Aurelia and Campana in the present inclosure of the villa Pamphili Doria; still another between the Viæ Appia and Latina, in which are the celebrated columbaria of Hylas and Vitaline, as well as the hypogæum of the Scipios. The tombs laid open in the Esquiline necropolis may be divided into two groups—the one contemporary with the first centuries of Rome, the other belonging to the age of the emperors. The first occupy the whole of the space included between the Churches of Sant' Antonio, Sant' Eusebio, and San Vito; the most ancient of the tombs are excavated in the rock according to Etruscan usage; the disposition of the bodies is also Etruscan, each being placed on the funeral couch with the feet toward the entrance of the sepulcher; the manufacture of the objects found in these tombs, such as household utensils, vases, personal ornaments, etc., is also Etruscan. All these details belong to the first three centuries of Rome. The second system of burial, which dates from the beginning of the fourth century, is that of sarcophagi and cinerary urns in volcanic stone; several hundreds of these have been found, with a large quantity of objects, the manufacture of which, departing from the Etruscan type, begins to show the progress of the native art of Latium. The third method is that of sepulchral chambers, either isolated or united in groups, built of square blocks of stone, without cement, but already possessing inscriptions and pictures. One of these inscriptions says that the tomb belonged to the college of flute-players (*tibicines*); another is described as the property of the family Ælutia. Among the frescoes discovered in this cemetery two are especially interesting: the first represents the scourging and execution of a criminal performed by six lictors under the orders of the pretor; the other relates to the history of the 300 Fabii and their glorious defeat in the war against Veii. On the opposite side of the Esquiline—that is, in the neighborhood of Porta Maggiore—fourteen columbaria of the first century of the empire have been discovered, containing 994 tombstones, 150 of which refer to the household of Messalina. In the triangle formed by the Via Appia, the Via Latina, and the walls of Aurelian 1,559 tombs have been discovered in modern times, not including the family vault of the Scipios; 855 between the Salaria and the Pinciana, and so on. The pagan epitaphs registered in vol. vi. of the *Corpus Inscriptorum Latinorum* number 30,000; and we may assume that Rome was surrounded by a belt of some 300,000 tombs.

The existence of a Rome anterior to the Rome of history has been revealed by objects, such as arrow-heads of silex, axes of bluish jadeite, knife-handles of deer-horn, necklaces of burnt clay, pottery made by hand, etc. All these palæoethnological objects belong to the age of polished stone and to the age of bronze. In comparing these discoveries with those which have been carried on at the same time on the Alban Hills, where a prehistoric town or village has been exhumed from beneath three volcanic layers produced by eruptions from the crater of Monte Cavo, and with those made at Gabii, Antemnæ, Faleria, Veii, and Fidenæ, knowledge of Rome's origin may be completely established.

Bibliography.—*The Remains of Ancient Rome*, by J. Henry Middleton (a later and enlarged edition of the work first published in 1885 as *Ancient Rome*); August Choisy, *L'Art de bâtir chez les Romains* (1873); Helbig, *The Collections of Classical Antiquities in Rome*; Furtwängler's *Meisterwerke der griechischen Plastik* (reproduced in English under the title *Masterpieces of Greek Sculpture*, edited by Eugénie Sellers); Rodolfo Lanciani, *Ancient Rome in the Light of Recent Discoveries* and *Pagan and Christian Rome*; and Prof. William Ramsay's *Manual of Roman Antiquities*, revised and partly rewritten by Lanciani (New York, 1895).

R. Lanciani.

Roman Catholic Church: that body of Christians which is united by the profession of the same faith and the participation of the same sacraments under the rule of their lawful pastors, and principally of the Roman pontiff. In the New Testament the Church is repeatedly called the "body of Christ." He is the head, his followers the members; and as in the natural body we distinguish structure and function, so in the Church we find an organization "compactly and fitly joined together," whereby "according to the operation in the measure of every part," certain spiritual functions are carried on.

Organization.—In the mystical body of Christ there are many members, "but all the members have not the same office." Broadly, the Church is composed of clerical members and lay members. Under the generic term "clergy" are included all those who exercise spiritual authority. Since this authority may be communicated in various degrees there are various ranks of the clergy, which, taken in their totality, constitute the *hierarchy*. The essential hierarchical grades are of divine institution. Christ not only appointed the apostles to continue his mission, but also gave to Peter certain special attributes, making him the rock on which the Church is built (Matt. xvi. 16–19), empowering him to confirm his brethren (Luke xxii. 32), and commanding him to feed both the sheep and the lambs of the flock (John xxi. 15–17). The office of the apostles is perpetuated in the bishops, the primacy of Peter in the Roman pontiff. (See Pope.) As the successor of Peter the pope enjoys not merely a pre-eminence of honor, but a real, immediate jurisdiction over the entire Church and over each of its members. Nevertheless, each bishop in his own diocese is possessed of a real authority in virtue of which he governs the faithful committed to his charge, ordains priests and ministers, and grants them the jurisdiction necessary for performing their sacred duties. These "ministers," finally, are of two classes: those who receive *major orders*—deacons and subdeacons, and those who receive *minor orders*—acolytes, exorcists, lectors, and ostiarii.

A number of dioceses are united into a province under an archbishop or metropolitan, of whom the bishops are said to be *suffragans*. In early times the powers of the metropolitan were extensive; but since the Council of Trent they are restricted to the convocation of provincial synods, the visitation of dioceses, the correction of negligent bishops, the hearing of appeals from the episcopal court, and the appointing, under certain circumstances, of an administrator in case of a suffragan's death. The title of primate is given to the bishop whose see was at one time an "apostolic vicariate" the vicar holding special powers from the Roman pontiff. Special jurisdiction over several provinces was granted by St. Peter to the patriarchs of Antioch and Alexandria. Later on Jerusalem and Constantinople were raised to the dignity of patriarchates, while in the Western Church the honorary rank of patriarch was conferred on a number of bishops.

In the exercise of his supreme jurisdiction the pope is aided by the College of Cardinals. These are seventy in number, are created by the pope, and grouped, for the administration of ecclesiastical affairs, in twenty-one congregations. These, with various subordinate officials, form the Roman *curia*, the ordinary organ of papal government. Furthermore, when circumstances require it, the pope sends his nuncios and legates to different portions of the Church, and empowers them to represent his person. For further details concerning the organization of the Church, see works on canon law, especially Gréa, *De l'Église et de sa divine Constitution* (Paris, 1885); Laemmer, *Institutionen des Katholischen Kirchenrechts* (2d ed. Freiburg, 1892); Smith, *Elements of Ecclesiastical Law* (New York, 1893).

Functions of the Church.—Christ is Teacher, Pontiff, and King; hence for the Church the threefold mission of imparting his doctrine (*magisterium*), of sanctifying his members (*ministerium*), and of governing his flock (*imperium*).

1. *Doctrine.*—The fundamental element in the Catholic Church is the permanent existence of a living teaching authority (Matt. xxviii. 19, 20). Through the abiding assistance of the Paraclete (John xiv. 16, 17), this authority is infallible in matters of faith and morals. Its subject is twofold: The teaching Church, i. e. the pastors in union with their head the pope, and the pope himself speaking *ex cathedra*. (See Infallibility of the Pope.) The immediate sources of doctrine are the ordinary teaching of the Church, the definitions of the pope, or those of an œcumenical council. Such definitions do not invent new dogmas, but give

explicit form to beliefs that are implicitly contained either in Scripture or in tradition. The sources of tradition are in general whatever makes known to us the belief held by the Church at any time on any subject. The documentary sources are the writings of the early apologists, the acts and epistles of the apostolic churches, the works of the Fathers, doctors, and theologians. Moreover, the articles of faith have at various times been summarized in creeds or symbols. Such are the Apostles' Creed; the Nicene, promulgated by the Council of Nice (325); the Athanasian, by St. Athanasius, Bishop of Alexandria (d. 373); and that published by the Council of Constantinople (381).

2. *The Means of Sanctification.*—These consist in the application to each soul of Christ's merits. The sacraments, the ordinary channels of grace, are seven in number: Baptism, confirmation, Holy Eucharist, penance, extreme unction, orders, and matrimony. These are administered with ceremonies peculiar to each prescribed by the ritual of the Church. The Eucharist is not only a sacrament, but also a sacrifice, and as such is offered in the Mass. This is the principal act of worship in the Church and the center of her liturgy. The Office, or public prayer of the Church, is a collection of psalms, extracts from both Testaments, commentaries of the Fathers, and short lives of the saints. It is divided to suit the different hours of the day, and is either chanted in common, as is the case in monastic orders and canonries, or is recited in private, its recitation being obligatory on all who have received the subdiaconate. Both in the Mass and Office there are certain portions which vary according to the liturgical season and the festival which is observed on a given day. Ecclesiastical *feasts* are days set apart for honoring in a special way some event in the life of Christ, of the Blessed Virgin Mary, or of the other saints. The greater of these feasts are preceded by seasons of a penitential character—such as Advent before Christmas, Lent before Easter, and the vigil of many other festivals. The chief practices enjoined for this preparation are fasting, abstinence, and prayer. Beside the administration of the sacraments, the Church attaches a sacred and symbolical character to various objects, the use of which is destined to inspire reverence and devotion. Hence the blessing of ashes, water, palms, candles, etc., in virtue of which these *sacramentals* profit those who employ them according to the intention of the Church and with proper dispositions. The language of the Liturgy in the Western Church is Latin, while in the churches of the East the vernacular, mostly in its archaic form, is employed. There exist also differences in the form of the Liturgy itself, and consequently a variety of *rites*, such as the Coptic, the Armenian, and the Greek. Along with these general means of sanctification for all the faithful, the Church has encouraged the founding of *religious orders*, i. e. of associations whose members are bound by special vows, live under particular rules, and labor for some peculiar purpose, such as caring for the poor and sick, spreading the Gospel, and carrying on the work of education.

3. *The Government of the Church.*—To fulfill her mission of teaching and sanctifying men the Church must enact laws to be obeyed both by clergy and laity. While her doctrines are unchangeable, her discipline varies according to circumstances of time and place. Ecclesiastical legislation is incorporated in the canon law. It is either general—decrees of the pope and of general councils, or particular—statutes of national, provincial, and diocesan synods. As regards its subject, it is either public (*jus ecclesiasticum publicum*) or private (*jus ecclesiasticum privatum*). The former is for the government of the clergy; the latter for that of the laity. The penalties inflicted for violation of ecclesiastical law are of two sorts: the *pœnæ communes*—excommunication and interdict—which may be incurred by clerical and lay offenders, and the *pœnæ particulares*—suspension and deposition—to which clerics only are liable. The penal law of the early Church was severe; but this rigor has been mitigated in the course of time. (See PENANCE.) Finally, as the members of the Church are at the same time subjects of the civil power, it has often been found necessary for Church and state to define their relations and settle upon a *modus vivendi*. These agreements regarding the external relations of the Church are termed concordats.

STATISTICS.—1. *General*: The number of Roman Catholics in the world is about 230,000,000. There are 64 cardinals and 12 patriarchs. In the Latin rite there are 820 archbishops and bishops, and in the Oriental rites 56; while the titulars, i. e. those who have no diocese, number 322. 2. *In the United States*: The Catholic population is about 10,000,000. The Church has 1 cardinal, 1 apostolic delegate, 14 archbishoprics, 79 bishoprics, and 11,636 priests.

See also the articles PAPAL STATES, JESUITS, GALLICAN CHURCH, TRENT, COUNCIL OF, and VATICAN COUNCIL.

STATISTICAL LITERATURE.—For the statistics of the mediæval Church, the works of Carolus a Sancto Paulo, Miræus, Holstein, Clericus, Schelstrate, and Weidenbach may be consulted with profit. In the nineteenth century Stäudlin, Wiggers, Neher, Silbernagl, Carolus a Sancto Aloysio, Wiltsch, Petri, and others have treated the subject with more or less accuracy. The episcopal catalogues of the Roman Catholic Church have been edited or compiled down to modern times by the Benedictine Gaius: *Series Episcoporum Ecclesiæ Catholicæ . . . a Beato Petro Apostolo* (Ratisbon, 1873). Diocesan, provincial, or national religious almanacs and directories are published in most places, to which may be added the reports of the various missionary bodies made known from time to time. The actual state of the Roman Catholic hierarchy is made known yearly in *La Gerarchia Cattolica*, a quasi-official Roman publication; *Les Missions Catholiques*, and the *Annales de la propagation de la foi* furnish details of great value. The Propaganda issues an official yearly bulletin entitled *Missiones Catholicæ*. The best and newest general summary of the public administration of the Roman Catholic Church is by O. Werner, S. J., *Orbis terrarum Catholicus*, etc. (Freiburg, 1890), and for the Catholic missions, the same, *Atlas des Missions Catholiques* (*ibid.*, 1886), and *Katholischer Kirchenatlas* (*ibid.*, 1888). Official reports of all dioceses, vicariates, prefectures, etc., are made to the proper Roman authorities at stated intervals, and are preserved in the special archives of the respective Roman congregations. For the actual working of the latter bodies, cf. Bangen (Catholic), *Die Römische Curie* (Münster, 1854), and O. Meyer (Protestant), *Die Propaganda* (Göttingen, 1852), and the sixth volume of Phillips's *Kirchenrecht* (Regensburg, 1864). The latest statistics of the Roman Catholic Church in the U. S. are found in Sadlier's *Catholic Directory* (New York) and Hoffman's *Catholic Directory and Clergy List* (Milwaukee). Special Catholic directories are annually published for Canada, England, Scotland, and Ireland. J. J. KEANE.

Romance Languages, or **Romanic Languages** [*Romanic* is from Lat. *Roma'nicus*, Roman, deriv. of *Roma'nus*, Roman, deriv. of *Ro'ma*, Rome]: those modern languages which, as the result of continuous oral transmission, are the current forms of spoken Latin. The languages grouped together under this name are French, Provençal and Catalan (the latter is hardly more than a dialect of Provençal), Spanish, Portuguese, Italian, Roumanian, and the Rhæto-Romance dialects. The territory is in general that of the Roman empire, excepting those parts which by later popular migrations or conquest were afterward removed from the sway of the Latin language, and those regions which were never completely Romanized.

The Latin spread in the conquered provinces was naturally the vulgar speech of the soldiers and colonists, not the Latin of the classic writers. Though in the beginning differing from the latter only as careless conversational speech always differs from the more elaborate usage of literary works, it was more subject to local variations, and changes were more rapid than in the literary language. The latter was also studied, however, in the provinces, and there were writers of a certain eminence in Spain and Gaul long after those countries had become Roman provinces. Borrowings from the Latin of literature became later very considerable; they are numerous in mediæval times after the modern languages began to be used in literature, and they have continued up to modern times. In general, the old popular words can be distinguished by their strict observance of the laws of phonetic change, while learned or semi-learned words have been less altered. Compare Fr. *peu*, from *paucum*, with *paucité*, *père* with *paternité*, *chose* with *cause* (both from *causa*).

The vulgar Latin of post-classic times was in the beginning very similar over the whole territory. In its vocabulary it differed somewhat from the literary Latin, more or less vulgar words or meanings being used, as for "horse," *caballus*, a nag, for "fire," *focus*, for "to strike," *batuere*, for "to turn," *tornare*, etc., and derivative words, especially diminutives, were used sometimes instead of the simple ones. Some words from foreign languages were added to the vocabulary. The oldest borrowings from Greek show Greek sounds to have been imitated as heard in Italy. Many of the

words from Greek are church words, as ἐκκλησία (Fr. *église*, Ital. *chiesa*, Span. *iglesia*), ἐπίσκοπος (Fr. *évêque*, Old Fr. *evesque*, Ital. *vescovo*, Span. *obispo*). The word *torŭare*, mentioned above, is from Greek. Of importance and interest are the borrowings from Germanic dialects after Germanic peoples came over the border and established themselves on Roman or Romanized territory. These newcomers became finally absorbed in the Romanized population, and after a time their descendants used only the Romance speech, but many Germanic words (not all retained to the present day) became familiar, and in France at least the Germanic influence extended somewhat beyond additions to the vocabulary. Only the Roumanian shows few or no traces of early Germanic influence. The influence of Arabic was later, and was felt especially in the Spanish Peninsula, where it began early in the eighth century, and in Sicily. The effect of the Iberian and of the Celtic languages seems to have been small. Even in the vocabulary Celtic influence was apparently considerably less than that of Germanic speech, and it is still doubtful whether Celtic habits of pronunciation had any traceable effects on Romance phonology. Slavic and other languages, as Greek, Turkish, Hungarian, Albanian, and perhaps others of which little or nothing is known, have affected Roumanian.

In the phonology of the native (far the most important) element of vulgar Latin and the modern Romance languages, the first thing to be noted is that the position of the accent remains in general the same as in classic Latin. It is of course not possible here to state the laws of sound-change for the different Romance languages completely, and it is to be remembered that the characteristic phenomena here mentioned did not all arise at the same time. In the vulgar speech many words were shortened by the change of *e* or *i* before a vowel to the consonant *y*, or by loss of an unaccented penult vowel. A short vowel, *i* or *e*, developed before *s* in words beginning with *s* followed by a consonant; compare Fr. *été*, Old Fr. *esté*, Ital. *stato* (under certain conditions *istato*), from *statum*. The classic distinctions of quantity soon produced distinctions of quality, the short vowels becoming open and the long becoming close, except that no such distinction between old long *a* and short *a* is clearly shown to have existed. The old short vowels were probably after a considerable time lengthened when accented and ending the syllable, and the old long vowels were sometimes shortened before following consonants. The diphthong *æ* early became a monophthong identical in quality with short or open *e*, and the diphthong *œ* became identical in quality with long or close *e*. In consequence of these changes short *i* came to be nearly like long *e* in sound, and ultimately, like old *œ*, became identical with it. Less universally short *u*, approaching long *o* in sound, became like that a close *o*, distinct both from open *o* and from old long *u*. The diphthongs *au* (except perhaps in some regions) and *ui* (as in *cui*, *huic*) remained long unchanged.

Among the modern literary languages (we shall not in general consider dialects) French has changed most the vulgar Latin accented vowels; for *a* compare Fr. *chaut*, *main*, *chanté* from *cantum*, *manum*, *cantatum*, with Ital. *cauto*, *mano*, *cantato*; and, for close *e*, compare Fr. *moi* with Ital. *me*. Latin *ĕ*, *æ*, vulgar open *e*, have become the diphthong *ie*, under certain conditions, over a large territory, as in Italian, Roumanian, French, Provençal (sometimes), Spanish, but the rules vary somewhat for different regions: compare, from *pĕtra*, Fr. *pierre*, Ital. *pietra*, Span. *piedra*, but Port. *pedra*. Similarly Latin short *o*, vulgar open *o*, was in some regions, as Portugal, retained as *o*, while in others a diphthong was often developed; in Italian *uo*, in Spanish and Old Fr. *ue* (from older *uo*). This Old French *ue* has since become the monophthong commonly written *eu*; compare vulgar Latin *potet* for classic *potest*, O. Fr. *puet*, Fr. *peut*, Prov. *pot* (Prov. has in some cases the diphthong *uo* or *ue*), Span. *puede*, Port. *pode*, Ital. *può*, Roum. *poate*. Latin long *u* all over France, in the west and center of the Rhæto-Romance territory, and in much of Northern Italy, became and to a great extent is still the sound now written *u* in French. The diphthong *au* has very generally, though not universally, become *o*. Of the unaccented vowels the most important to notice are those of Latin final syllables. The one best preserved is *a*, only French and Roumanian regularly changing it. The French form for it is its so-called mute *e*, and the Roumanian shows its vowel *ă*. In general these vowels have suffered most in French and least in Italian. In the case of unaccented vowels in the syllable immediately before the accent the treatment is very similar to that of vowels in final syllables. Following or preceding sounds often caused a modification of the vowel; this was especially the case with palatal sounds, as *y*, *c*, *g*, and the influence of a following nasal consonant has produced nasal vowels extensively, especially in Portuguese and French. In the latter the resulting changes in sound have been very considerable, but the older orthography is for the most part preserved.

The Latin consonants underwent also various changes. The sound of *h* was lost very early. In the group *us* the vulgar speech had no *n*, and the preceding vowel had the value of an old long vowel; the adjective ending *-ensis*, through *-ēsis* (with close *e*), gives Ital. *-ese*, Fr. *-ois*. When *t* was brought immediately before *l* through the loss of a formerly intervening vowel, *cl* was the result, as in *veclus* for *vetulus*; compare Ital. *vecchio*. The consonantal *u* (*v* in *vinum*) soon became a spirant, a bilabial (or perhaps locally even a labio-dental) *v*, and intervocalic *b* acquired, also at an early time, the same pronunciation. The modern value is generally labio-dental *v*, but the bilabial sound is common in Spain. Consonantal *i* (*y*. the Latin *j*), at least when initial, *g* before *e* and *i* sounds, and *di* (with consonantal *i*), all received the value of spirant *y*, and this very extensively became later the sound of English *j* in *jest*, as in Italian and Old French; but this latter sound has since often become that of English *z* in *azure*, especially in modern French, Portuguese, and locally in Rhæto-Romance dialects and Italian. In Spanish the older *y* is sometimes preserved, as in *ya* from *jam* (cf. Ital. *già*), *yerno* from *generum* (cf. Fr. *gendre*), and sometimes a written *h* (now silent) is found, as in *hermano* from *germanum*, but a very common result is the aspirate sound now written *j* or *g*, as in *joven* from *juvenem*; this is the descendant of an earlier sound like that of French and Portuguese (English *z* in *azure*).

The time when *c* before *e* or *i* began to assume a sibilant sound, instead of remaining *k*, was varied in different regions. The sound *k* is still preserved in one or two places, notably in a Sardinian dialect; but over almost all the Romance territory the assibilation took place. When *c* was before *e* or *i* not followed by another vowel the assibilation is not shown to have existed before the sixth century. (See G. Paris, *L'altération romane du c latin* in *Annuaire de l'école pratique des hautes études*, 1893.) The result was either *ts* or about the sound of English *ch* in *chin*, or later changes from one or the other of these sounds, though the letter *c* in general continued to be written as it is still. In modern French and modern Provençal the sound is *s*, from older *ts*, as also in Portuguese; in Spanish it is that of English *th* in *thin*, also from older *ts*; in Italian and Roumanian it is that of English *ch* in *chin*. Between vowels the *c* before simple *e* or *i* does not always give the same results: compare Fr. *plaisir* from *placere*, *croix* (in Old French better spelt *crois*) from *crucem*. Vulgar Latin *ty* (*ti* before a vowel) early became assibilated, producing *ts* and modern sounds resulting from *ts*. Before *a* the Latin *c* and *g* (and so were treated Germanic *k* and *g* also), if initial or preceded by a consonant, produced in a large part of France and of the Rhæto-Romance territory, by becoming palatalized or "fronted," sounds more or less like *ky* (*ty*), *gy* (*dy*), or (as in many Old French and Provençal dialects) those of English *ch* in *chin* (for old *c*) and English *j* in *jest* (for old *g*); hence in modern French appear in these cases the sounds of English *sh* in *shine* and *z* in *azure*; compare Fr. *champ* from *campum*, *vache* from *vacca*, *jambe* and Ital. *gamba*, *jardin* and Germ. *garten*. Initial consonant groups containing *l* as the second member show in Italian an *i* (= *y*) in place of the *l*, as in *piano* from *planum*, *fiamma* from *flamma*, *chiamare* from *clamare*, etc.; compare Span. *llano*, *llama*, *llamar*, Port. *chão*, *chamma*, *chamar*. from the same Latin words.

The changes thus far described are in great part obviously due to the influence of adjacent sounds, and many of them might be considered as instances of partial assimilation. The same influence is strikingly evident in the treatment of consonants which were not initial, some of which have already been noticed. Consonants standing alone between vowels were subject to alteration in vulgar Latin, the Italian and Roumanian preserving the older Latin sounds best. So intervocalic *p*, *t*, *c* were in the other Romance languages commonly voiced, as they sometimes were in Italian also, becoming *b*, *d*, *g* (or something like *dz* if assibilation of the *c* took place), and these voiced stops sometimes, like the old *b*, *d*, *g*, progressed further to become voiced spirants, or were even lost altogether. French shows the greatest amount of change for these sounds; it has now lost the original intervocalic *t* and *d* entirely, though in the oldest French they

were at the stage of voiced (except when unvoiced at the end of the word) spirants; compare *chantée* from *cantata(m)*, *nouer* from *nodare*. The doubled consonants of Latin were simplified except in Italian, which language has by assimilation produced a number of new doublings, as in *fatto* from *factum*, *freddo* from *frig(i)dum*. The Roumanian treatment of some consonant groups is remarkable; compare *opt* from *octo*, *demn* from *dignum*. The phenomena of palatalization can not be discussed here.

The most important final consonants in Latin are *m*, *s*, *t*. Of these, final *m* early disappeared entirely except in a few cases where it followed an accented vowel; compare Fr. *rien* from *rem*. Final *s* and *t* were lost in Italian and Roumanian, but elsewhere *s* was retained, and final *t*, which was for the most part lost, was in French, under certain conditions, retained. The retention of old final *s* and *t* in modern French is to a great extent only for the eye.

The Latin inflections of nouns and adjectives have suffered considerable change. The fourth and fifth declensions disappeared, the former being absorbed in the second declension, the latter in the first and third, so that only three of the old classes remain at all. The neuter gender is no longer distinguished in nouns, but neuter uses of adjective words (as in Spanish) and pronouns are not wholly lost. The old neuters became for the most part masculine, but there are many traces of Latin neuter forms. The Latin cases were reduced in number, partly by the results of phonetic change, partly by the substitution of prepositions with the accusative. The Roumanian still has, in the singular of feminine nouns, a case corresponding in use to the Latin genitive and dative, and the same language has a vocative which may be in part descended from the Latin vocative, but it has no distinction in form between nominative and accusative in nouns. In the other languages of the family the dative in nouns was soon lost, as were also the genitive and the ablative, except in a few instances. In Old French and Provençal a declension with two cases, representing the Latin nominative and accusative, existed; thus in Old Fr. nom. sing. *murs* (from *murus*), obj. sing. *mur*, nom. plur. *mur*, obj. pl. *murs*. Feminine nouns, however, from the Latin first declension were generally alike in both cases, as in modern French. Traces of a similar declension exist in Rhæto-Romance dialects still; but the modern forms of the languages which had this declension have, with some exceptions, lost the old nominatives, and it can be said that, with the exception of Roumanian, nouns in the Romance languages no longer have any cases, the inflection being reduced to a distinction of plural and singular forms, and even this distinction is largely lost in spoken French. The modern forms as a rule represent the Latin accusative, but in Italian and Roumanian the single form of the plural is from the Latin nominative in nouns coming from the Latin first and second declensions: Ital. *rose*, Roum. *roase* from *rosae*, Ital. *anni*, Roum. *anĭ* from *anni*; but Fr. *roses*, *ans*, Span. *rosas*, *años*, from *rosas*, *annos*. The declension of adjectives is very similar to that of nouns. Some comparative forms of Latin are widely retained; compare Fr. *meilleur*, Ital. *migliore*, Span. *mejor* with Lat. *meliorem*; but commonly the comparative is expressed by the aid of an adverb meaning "more" (modern forms of *plus* or *magis*), and for a superlative the comparative with the definite article is regularly used, there being no true superlative.

Among pronouns occur some forms which go back to Latin nominatives, accusatives, genitives, and datives, and these four cases are still more or less living, partly through the aid of new formations, as Fr. *en*, Ital. *ne*, from the adverb *inde*. Ital. *loro*, Fr. *leur* are from *illorum*, though they are now used as datives (Ital. *loro* can also be used as an accusative or even as a nominative) or as possessives. Ital. *lui*, *colui*, etc., Fr. *lui*, *celui* go back to vulgar Latin datives (as *illui*; compare Latin *cui*, *huic*). It is true that these forms are no longer confined to use as object cases. Nominative forms from *ego*, *tu*, and vulgar Latin *illi* or *ille* are also preserved; as from *ego*, Ital. *io*, Roum. *eŭ*, Fr. *je* (Old Fr. also *jo*, *jou*), Prov. *eu*, *ieu*, Span. *yo*, Port. *eu*, while the accusative is shown, for example, in Ital. *me*, Fr. *moi*, etc. Among the descendants of Latin pronouns is to be especially noted the definite article which comes from *ille* (in some dialects from *ipse*) in an unstressed form. Fr. *le*, *la*, Ital. *lo*, *la* represent respectively *illum*, *illa(m)*, just as the same forms are also used as unstressed personal pronouns in the accusative, while the stressed form *illa* gave Fr. *elle*, Ital. *ella*. The indefinite article goes back to Lat. *unus*.

In verb inflexion the passive voice is entirely lost, except the past participle, which is used to form the passive (over most of the territory) and tenses for completed action in the active voice; further are lost the future indicative, the future or emphatic imperative, the perfect infinitive, the future participle, the supines (in Roumanian the form of the past participle is used also with prepositions in a sense like that of the Latin supines), the imperfect subjunctive (retained in Sardinia), and perhaps also the perfect subjunctive (see below). But of the remaining forms not all are found in every one of the Romance languages. The pluperfect indicative was retained in Spanish, Portuguese, Provençal, and the oldest French among the recognized literary languages, and in these its sense has generally been changed to that of a conditional or (as in Old French) to that of a simple preterite. The future perfect remains in Spanish, Portuguese, and the older Roumanian (but the perfect subjunctive may be in part the source of these forms). The present participle (lost in Roumanian) is mostly found only as a verbal adjective, its place being largely taken by the gerund. The old pluperfect subjunctive is now mostly an imperfect subjunctive; in Roumanian it has become a pluperfect indicative. The perfect indicative where retained has become simply a preterite. By the aid of auxiliaries, however, and of new formations all deficiencies are well supplied. New formations are those for the future indicative and the so-called conditional mood. The former is the result of an old combination of the infinitive with the present indicative of *habere*, the latter of a similar combination of the infinitive with the imperfect or perfect indicative of the same auxiliary. "I shall sing" was expressed by "I have to sing," *cantare habeo*, and "I should sing" by "I had to sing," *cantare habebam* or *cantare habui* (the latter is the basis for the usual Italian form). As such phrases coalesced into single words contraction somewhat disguised the original forms, but the terminations still show the connection with the verb "to have." This method of formation is not the only one in use. Roumanian uses an auxiliary corresponding to Latin *volo* to form the future, and in the western part of the Rhæto-Romance territory is found a formation for the future corresponding to *venio ad cantare*. To the Romance formations are to be added, besides the future and the conditional, many new past participles, needed to form compound tenses for intransitive verbs, and some others of less importance.

The four Latin conjugations are still more or less well preserved in much of the Romance territory, but the second and third are to a great extent confused, and the greatest vitality is shown by the first and fourth conjugations. In personal endings and in tense formation the influence of analogy has been strong, no conjugational type having escaped it. Remarkable are the variations in the form of the stem, due to different positions of the accent; compare Fr. *tient* and *tenir*, Ital. *tiene* and *tenere*, Fr. *meurt* and *mourir*, Ital. *muore* and *morire*, Old Fr. *aime* and *amer* (now *aimer*), etc. In most verbs of the fourth conjugation an inchoative ending, originally *-isc-*, was added to the stem, appearing in only some forms of the present tenses, in Italian and Roumanian, spreading in French somewhat more, and in Spanish and Portuguese appearing in all the forms of the verb, so that the infinitive in these last ends in *-ecer* instead of *ir*, and these verbs cease to belong to the fourth conjugation. Compare Fr. *finis* (pres. indic.), *finissais*, *finissant*, with the infinitive *finir*, Ital. *finisco* with *finire*. The formation of the preterite indicative and the past participle is somewhat complicated, especially in the so-called irregular verbs. The occasional Latin reduplication, as in *cucurri*, is lost and other formations substituted, especially with *s* and *u* (cf. Ital. *corsi*, Fr. *courus*); but the perfects *dedi* and *steti* (or vulgar *stetui*) extended their endings to other verbs considerably in vulgar Latin. The past participle also shows influences of analogy, notably for the many forms going back to the ending *-utum*, as in Fr. *eu* (formerly *eü*, *oü*), Ital. *avuto*.

The Romance languages are well supplied with derivative endings or suffixes forming nouns, adjectives, and verbs. One of the most interesting suffixes is the descendant of Latin *mens*, *mentis*, mind, now widely used as an adverbial suffix: Fr. *-ment*, Ital., Span., and Port. *-mente*. These suffixes are mostly of Latin origin, but some are from Greek, as Fr. *-esse*, Ital. *-essa*, forming feminines, from Greek *-ισσα*, Fr. *-oyer*, Ital. *-eggiare*, Span. *-ear*, and, in less popular form, Fr. *-iser*, Ital. *-izzare*, Span. *-izar*, from *-ίζειν*; others are from the Germanic, as Fr. *-ard*, Ital. *-ardo*; and the origin of yet others is not quite certain, as of the diminutive *-et* in Fr., *-etto* in Ital. Slavic and other languages have supplied some suffixes to Roumanian.

Questions of syntax are largely involved in the inflectional changes outlined above, and a fuller treatment of the development of Romance syntax is not here possible. Reference may be made to Diez's grammar, vol. iii. (see below); K. Foth, *Die Verschiebung lateinischer Tempora in den romanischen Sprachen* in *Romanische Studien*, ii., 243 ff.; Vising, *Die Tempora der Vergangenheit*, etc., in *Französische Studien*, vi. and vii.; E. Wölfflin, *Lateinische und romanische Comparation* (1879); Tobler, *Vermischte Beiträge zur französischen Grammatik*, i. (1886), ii. (1894).

Further references: Diez, *Grammatik der romanischen Sprachen* (3d ed. 3 vols., 1870–72, and since without change), and *Etymologisches Wörterbuch der romanischen Sprachen* (5th ed. 1887); Thurneysen, *Keltoromanisches* (1884); Gröber's *Grundriss der romanischen Philologie* (i., 1888); W. Meyer-Lübke, *Grammatik der romanischen Sprachen* (i., 1890; ii., 1893–94; vol. iii. is to treat the subject of syntax); G. Körting, *Encyklopädie und Methodologie der romanischen Philologie* (3 vols., with index, etc., 1884–88), and *Lateinisch-romanisches Wörterbuch* (1891). For vulgar Latin may be specially mentioned Schuchardt, *Vokalismus des Vulgärlateins* (3 vols., 1866–68); Wölfflin's *Archiv für lateinische Lexikographie und Grammatik* (1884 and since; contains among other things Gröber's articles on *Vulgärlateinische Substrate romanischer Wörter*); Bonnet, *Le latin de Grégoire de Tours* (1890); G. Cohn, *Suffixwandlungen im Vulgärlatein*, etc. (1891); P. Meyer, *Recueil d'anciens textes bas-latins, provençaux et français* (i.–ii., 1874–77); W. Foerster (for the *Appendix Probi*) in *Wiener Studien* (xiv., 278 ff.), etc. Many periodicals are devoted wholly or in great part to Romance philology; among the most important are: (in France) *Romania*, *Revue des langues romanes*, *Revue de philologie française et provençale*, etc.; (in Germany) *Zeitschrift für romanische Philologie*, which succeeded the *Jahrbuch für romanische und englische Sprache und Literatur*, *Romanische Studien*, *Romanische Forschungen*, *Französische Studien*, *Zeitschrift für französische Sprache und Litteratur*, *Archiv für das Studium der neueren Sprachen und Litteraturen*, *Literaturblatt für germanische und romanische Philologie*, *Kritischer Jahresbericht über die Fortschritte der romanischen Philologie*, etc.; (in Italy) *Archivio glottologico italiano*, *Giornale storico della letteratura italiana*, *Rivista di filologia romanza*, succeeded by the *Giornale di filologia romanza*, and this by the *Studj di filologia romanza*, *Il Propugnatore*; (in America) *Modern Language Notes*, *Publications of the Modern Language Association*, *Harvard Studies and Notes in Philology and Literature*, etc. Further may be noted collections like Stengel's *Ausgaben und Abhandlungen*, the publications of the academies of Berlin, Vienna, etc. E. S. Sheldon.

Romance of the Rose: a famous French poem. Guillaume de Lorris (see Lorris) composed the first portion (4,680 verses) about 1237, and about 1277 Jean Clopinel, commonly called Jean de Meun (see Meun), completed it in a total of 22,817 verses. The former wished to write an allegorical art of love, and so represented the whole as a dream, designating the object of the lover's pursuit as a rose which must be plucked, an idea taken from the earlier *Dit de la rose*. His originality was shown in allegorizing as actors in the drama the inclinations and motives of the lover and the lady, as well as the kindly and malevolent judgments of society. Essentially, therefore, the poem was a study of the psychology of passion and its social environment. Jean de Meun preserved the form and the allegorical characters of the story, but used them only as a pretext for bringing out his own erudition, speculations, and observations. The former part is delicate and filled with the peculiar sentiment of the period, while the second part is copious and varied, but also cynical and at times unspeakably coarse, women in particular being treated with a most brutal insolence.

The *Romance of the Rose* became at once the most popular poem in the French tongue. It was reproduced in Flemish and Italian in the thirteenth century, and in English by Chaucer—a version which has probably not come down to us, though the *Romaunt of the Rose* of about this time, printed in the editions of Chaucer's works, has found able defenders (e. g. Lounsbury). Editions of the *Roman de la Rose* are by Fr. Michel (2 vols., Paris, 1864); P. Marteau, with introduction, notes, and modern French translation (5 vols., Orleans, 1878–79); J. Croissandeau, with notes and glossary (5 vols., Orleans, 1881). Very important for an understanding of the poem is E. Langlois, *Origines et sources du Roman de la Rose* (Paris, 1891). A. R. Marsh.

Romances [so called from the *lingua Romana*, or vernacular, in which they were mainly composed]: the expression of that desire for the adventurous, the new, foreign or marvelous, and the ideal which characterized the early vigor of European literature in the interval between the Dark Ages and the revival of learning. This definition leaves out of account the late Greek romances, such as *Daphnis and Chloe* and *Apollonius of Tyre*, the latter a great favorite in Western Europe; it reached England probably in a Latin version, was soon translated as one of the earliest prose romances in our tongue, and furnished the plot of Shakspeare's *Pericles*. It also excludes consideration of romances in Latin, like the *Ruodlieb*, written by a Bavarian about 1050 and called (Scherer, *Gesch. d. deutsch. Lit.*, p. 68) the earliest romance of Europe.

The romance was meant mainly for aristocratic hearers or readers, and along with its exaggerated adventures of chivalry it struck the new note of sentimental love. Incident is the main consideration, but ideals of character, types rather than individuals, are developed in such figures as Launcelot and the courteous Gawain. Romances differ from the older *chanson de geste* (see Geste) in this echo of chivalry, in a greater range of invention and in a disposition to avoid the local and the popular.

The Arthurian romances, foundation of the whole edifice, have for their corner-stone the *Historia Britonum* of Geoffrey of Monmouth, who died in 1154. The work is based partly on Nennius, partly on Breton traditions; also perhaps on Geoffrey's invention. Among other astounding feats it matches the facts of Celtic loss with a fable of Celtic triumphs mainly due to King Arthur. Nennius had mentioned Arthur merely as a chieftain, a *dux bellorum*; with Geoffrey he is of supernatural origin and a monarch of boundless power. The daring imagination of this book met most happily a new spirit in European literature. The contact, moreover, was on Norman or French soil, and in these chivalrous surroundings the romances of Arthur and his Round Table—the latter was first noticed by Wace in his *Geste des Bretons*—rapidly became an international possession. Conspicuous for novelty and merit were the romances of Chrestien de Troyes, who brought the adventurous material into unison with the new ideals of chivalry. Translations and paraphrases followed; among the best, as well as more independent, versions is the English romance of *Sir Gawain and the Grene Knight*, mainly based on an episode in Chrestien's *Conte de Graal*. A successful German version, with strong ethical leanings, is the *Parzival* of Wolfram von Eschenbach. Meanwhile important facts and characters had been added to the Arthurian legend—Launcelot, with his love for the queen, the Cornish Tristan, and, above all, the story of the Grail, in the later romances merely a miraculous jewel, but commonly regarded as the cup or dish used by Christ at the Last Supper. Here one sees the interpenetration of the two great elements of late mediæval literature—the sacred legend and the chivalrous romance. The story of the Grail was evidently influenced by a legend of Joseph of Arimathea. (See Birch-Hirschfeld, *Die Sage vom Gral*, 1877.) Finally, all these characters and incidents were combined in a single narrative by Sir Thomas Malory (see Malory), whose *Morte d'Arthur* has been the source of subsequent Arthurian literature.

Out of the materials of the popular epic, which had reached its height in the *Chanson de Roland*, the age of chivalry built up for aristocratic patrons, and according to more refined ideals, a cycle of romances which centered in the person of Charlemagne. This cycle touches that of Arthur in many points, the Saracens of course taking the place of the Saxons. It was long supposed that what Geoffrey did for Arthur was done for Charlemagne by the Latin chronicle falsely attributed to Turpin, but really the work of several hands, and finished about 1150. This chronicle, however, is based on the *Chanson de Roland* and other popular poems. Later there sprang up in France a number of prose romances on the same subjects, such as *Fierabras* and the interesting *Huon de Bordeaux*; the latter was sung in the twelfth century as a *chanson de geste*, and appeared as prose romance about 1450. It was translated into English by Lord Berners, but is best known in the charming *Oberon* of the German poet Wieland.

Another cycle goes back to pseudo-classic sources, as in the romances about Alexander and those which belong to the "tale of Troy divine," for example, Benoît de Sainte-More's *Roman de Troie* (1185). The Spanish *Amadis de Gaula* owed much to the Arthurian cycle, and is chief of the

numerous family to which Cervantes paid his respects. It is impossible, however, to follow all the later and divergent paths of the romance, which lead not to distinct persons so much as to special subjects. Such are romances of the innocent wife, like Griseldis; romance interwoven with allegory, like the *Roman de la Rose*; romance with satiric leaning, as in *Reynard the Fox*, which lays the beast-epic under contribution; pastoral romances, like Sidney's beautiful *Arcadia*; and long romances of later date, such as those of Mlle. de Scudéry.

The literature of the romances is enormous, but two works contain ample bibliographical as well as direct information: Ward, *Catalogue of Romances in . . . the British Museum* (i., 1883), and Dunlop, *History of Prose Fiction* (revised ed. London, 1888). For English romances, see G. Ellis, *Specimens of Early English Metrical Romances* (1848), and the various editions in the publications of the Early English Text Society. For the French, see Nyrop, *Den oldfranske Heltedigtning*, and G. Paris, *Histoire Poétique de Charlemagne*. FRANCIS B. GUMMERE.

Romanes, rō-mānz', GEORGE JOHN, F. R. S., LL. D.: biologist; b. at Kingston, Canada, May 20, 1848; graduated with honors at Cambridge, England, 1870; fellow of Royal Society 1879; became an intimate friend of Charles Darwin while in Cambridge; was Fullerian Professor of Physiology in the Royal Institution of London, and Rosebery Lecturer on Natural History in the University of Edinburgh. He devoted himself principally to extending evolutionary doctrines in the field of psychology; published *Animal Intelligence* (1881); *Mental Evolution in Animals* (1883); *Mental Evolution in Man* (1888); *Origin of Human Faculty* and *Philosophy of Natural History before and after Darwin*, and numerous scientific essays. D. at Oxford, May 23, 1894. C. H. THURBER.

Roman Law: primarily, the body of rules which governed the city of Rome and its citizens. As the power of Rome grew, this system of law was extended over a large part of Italy, but it was not generally introduced into other territories nor made applicable to Rome's subjects as distinguished from her citizens. For the conquered provinces and their inhabitants a different body of rules was worked out. This new law was only in small part a further development of the law of the city; in the main it was a distinct and superior system. It was based on the customs of the various Mediterranean peoples, and representatives of nearly all those peoples ultimately played some part in its development. During the imperial period these two systems were gradually fused into one, and in the codification of Justinian they are presented as a single and substantially homogeneous body of law.

Much of the Roman law has only an historical interest. This is the case with the older law of the city as a whole; this is the case also with the public law of the empire. On the other hand, the principles governing private relations, which were worked out in the later republic and the early empire and which were incorporated with little change in the law-books of Justinian, have more than an historical significance—they are to-day a living force. It was in large part on the basis of the Roman law that the mediæval Church worked out for all Christendom its law of family and of testament. Toward the close of the Middle Ages the law-books of Justinian, as modified by the Roman canon law, became the chief basis of adjudication in the secular courts of continental Europe, and in the so-called "modern Roman law" Europe obtained a body of substantially uniform rules for property and obligations. The principles of the Roman law have not exercised a controlling influence upon the English common law; but in all modern states, except those founded by Englishmen, the existing law is based on Roman conceptions of private right, reveals in its form the influence of Roman legal science, and expresses itself in Roman terms. The modern civil codes of Europe and of Central and South America are Roman in much the same sense in which the existing law of the self-governing British colonies and of the U. S. is English; and in this sense the Roman law and the English law are the two great systems that rule the modern civilized world.

1. THE LAW OF THE CITY (*Jus Civile*).—According to one tradition the city was governed during the first three centuries of its existence (i. e. during the royal period and the first half-century of the republic) by unwritten custom. According to another tradition the earliest laws were royal enactments. A considerable body of ancient rules, described as royal laws (*leges regiæ*), existed and were collected in the republican period. Many of these have come down to us, and it is evident that they are simply rules of early custom, similar to those which prevailed among other Aryan peoples. Precepts of a religious or moral nature are blended with rules of a legal character. Their formulation suggests a strong sacerdotal influence—an assumption which is corroborated by other Roman traditions.

The Twelve Tables.—Early in the republican period the plebeians complained that the ancient customs of the city were misinterpreted by the patrician priests and misapplied by the patrician magistrates. They therefore demanded that the law be reduced to writing and enacted in statutory form. In compliance with this demand the *law of the Twelve Tables* was drafted by a commission of ten elected for the purpose, and was approved by the popular assembly (451 and 450 B. C.). Much of this early code has come down to us. It is clearly nothing but a compilation of the older customary law. It differs from the so-called royal laws in that it contains fewer religious precepts and gives a clearer formulation of personal and property rights. It was regarded by the Romans as the great charter of their liberties. As late as Cicero's time Roman schoolboys learned its text by heart; and during the greater part of the republican period it was practically impossible to secure the adoption of any law which directly and overtly abrogated or changed the provisions of the Tables.

The Republican Jurists.—Under these circumstances the development of the law was accomplished mainly by interpretation. The scanty and rude provisions of the Twelve Tables were supplemented and modified by a free use of analogy and of fiction. For nearly two centuries after the enactment of the Twelve Tables the priests of the pontifical college controlled the forms of pleading and retained a practically exclusive power of interpreting the law; and it was not until the plebeians had forced their way into this last stronghold of the conservative party (300–254 B. C.) that Roman jurisprudence was secularized. Thenceforward the Roman who wished to study the great body of rules that had grown up around the Twelve Tables was no longer forced to seek an election as pontifex; he placed himself under the instruction of some older jurist. The knowledge of the law was not treated as a means of gaining a livelihood; legal advice was given gratuitously. Next to conspicuous service in war the knowledge of the law furnished the ambitious Roman with the best opportunity of recommending himself to the favor and the suffrages of his fellow citizens. The jurists did not plead cases; this was the business of the orators. They did not directly decide cases unless they happened to be elected judges or appointed referees (*judices*); but in a doubtful case the opinion of some eminent jurist was brought to the referee or was solicited by him, and such an opinion was regularly conclusive.

Character of the Jus Civile.—The civil law of the republic presents many interesting analogies to the older common law of England. It was essentially a body of case law, shaped by decisions. It was very strict and very formal, certainty of law being held in higher regard than equity. It was very technical, but nearly all its technical distinctions were based upon sound principles. The great advance which the Roman civil law represents in universal history is found (1) in the unprecedented clearness with which private rights were marked out and the extent to which the individual was permitted to shape his own legal relations; and (2) in the separation of law and religion. This last step was one which no Asiatic or European people had previously taken.

2. THE LAW OF THE ANCIENT WORLD (*Jus Gentium*).—With the extension of Roman rule over the Mediterranean basin, legal problems were presented which could not be solved by the law of the city. The protection of the civil law could be accorded to aliens only through interstate treaties, and the conquered provincials (as distinguished from the favored allies of Rome) were not merely aliens—they were stateless aliens. The states of which they had been citizens had been destroyed by war. They themselves were simply subjects of Rome. In theory they were the slaves of the Roman people, and their property belonged to the republic. In fact, they were treated as freemen, and it was necessary to administer justice to them.

A more serious difficulty lay in the inadequacy of the city law to meet the needs of the new empire. The Roman civil law had been worked out by and for a people whose chief

occupation was agriculture. Among the subjects of Rome were the great trading nations of the ancient world, the Greeks and the Phœnicians. Rome itself became more and more the center of Mediterranean commerce, and when piracy had been crushed out by her fleets, this commerce rose to unexampled importance. A new and very different body of rules was required to govern the relations between the provincials themselves and between them and the Romans.

These problems were solved in a thoroughly Roman way —tentatively and gradually. A second prætor had been elected at Rome since 247 B. C., and to this magistrate was assigned the duty of administering justice to foreigners in the city. The governors of the several provinces were charged from the outset with similar duties. No rules were laid down for their guidance; they were left to make their own law. In accordance with the old Roman rule that cases should not be actually decided by the magistrate, these officers, after hearing the allegations of the parties, sent each case to a referee (*judex*), with a brief note of instruction (*formula*) which ran somewhat as follows: "If it appear that such and such allegations are true, condemn the defendant; if not, absolve him." Each formula contained, by implication, a rule of law; and a collection of the formulas regularly issued would, in course of time, have amounted to a digest of the new law. From the very outset, however, the prætor of the foreigners and each provincial governor published at the beginning of his term an edict (*edictum*), in which he stated the grounds upon which he would give actions and "exceptions" or defenses. Each successive magistrate adopted the edict of his predecessor, with such additions and improvements as the latter's experience or his own might suggest; so that the codification of the new law kept pace with its development. The foreign edict at Rome served as a general model for the provincial edicts, and was itself steadily enriched by provisions which first made their appearance in this or that provincial edict. In this whole development the Roman jurists exercised a controlling influence, partly through actual possession of the magistracies, but far more through their activity as councilors. Every Roman magistrate, before entering upon his duties, selected a body of advisers (*consilium*); and those magistrates who were charged with the administration of justice naturally sought the assistance of jurists of established reputation.

Character of the New Law.—In matters which bore no relation to commerce no effort seems to have been made to create uniform law for all the provinces. Family relations and questions of inheritance seem to have been differently regulated in the various provincial edicts, in accordance with national or local customs. As regarded property and obligations, however, the foreign edict at Rome and the various provincial edicts were kept in substantial harmony, so that a uniform system of commercial law was established for the entire civilized world. This law, as the Romans themselves declared, was based upon the rules which prevailed among all the nations (or rather upon the common elements found in all their various rules), and upon natural reason.

As compared with the law of the city, the new law was far less formal, far broader, freer, and more equitable. It gave remedies against mistake and fraud which the civil law did not give. It went back of the form of transactions, and regarded their substance. It laid the greatest stress, in contractual relations, upon the demands of "good faith."

3. Fusion of the Two Systems.—*The City Edict.*—As soon as the *jus gentium* was fairly developed, the impulse to reform the law of the city became irresistible. The method by which the new system had been developed naturally suggested itself as a method by which the old system might be reformed. The *jus gentium* had been created by magistrates whose activity was unfettered by forms and whose authority was unrestrained by law. The basis of its development was the power of the magistrate to instruct the referee. The city prætor, who administered justice to Roman citizens, had not this power. Under the technical forms of civil pleading (*legis actiones*), the litigants themselves formulated the issue and the judges or referees were bound to decide according to established law. By a *lex Æbutia*, passed about 150 B. C., informal pleadings were permitted and the city prætor was empowered to instruct the referee. The edict of this magistrate at once became the central factor of legal development. The law of the city was not only supplemented, but "corrected." The principles of the *jus gentium* were applied to Roman property and Roman contracts, and received further improvements. As far as these matters were concerned, the city edict now set the pace of development for the provincial edicts. The city prætors also reformed and modernized the law of the family and of inheritance. The reform of the civil law by the prætors is a movement which presents striking analogies to the reform of the English common law by the English chancellors.

The growth of the prætorian law practically ceased with the overthrow of the republic. In the reign of Hadrian a noted jurist, Salvius Julianus, was charged with a final revision of the edict. From this time the development of the law was accomplished by interpretation and by legislation. Legislative power had been transferred from the people to the emperor and the senate. The controlling influence was exercised by the emperors. At first they legislated with the advice and consent of the senate; but the *oratio principis*, or proposal of the emperor, was invariably accepted, and in the second and following centuries the emperors habitually employed the form of direct decree or "constitution." In the field of private law, however, the dominant influence was that of the jurists, and the development of the law was carried on by juristic interpretation far more than by legislation.

The Jurists of the Empire.—The recognition and influence which were accorded to the jurists, under the republic, by opinion and custom, now received legal sanction. To the most noted jurists the emperor gave a formal right of response (*jus respondendi*), and the judges or referees were bound to follow the responses of these "patented jurists" unless conflicting responses were submitted. In the second and third centuries, when jurisdiction at Rome had been transferred from the prætors to imperial prefects, when all the provincial governors were imperial appointees, and when, in consequence of the disappearance of the reference (*judicium*), these officials were judges of both law and facts, the leading jurists were regularly charged with the direct administration of justice. The office of prætorian prefect, to whose court appeals were carried from all parts of the empire, was successively occupied, in the first half of the third century, by Papinian, Ulpian, and Paul, the three writers whose names stand highest in the roll of Roman jurists; and Ulpian and Paul, before their promotion to the chief-justiceship, had served as "assessors" or associate justices in the court of Papinian. The great body of new law which was worked out by the jurists of the early empire was therefore judge-made law. The decisions by which it was gradually elaborated were reported and digested by the jurist-judges themselves.

Juristic Literature.—Toward the close of the republican period the leading jurists began to write legal treatises. Early in the imperial period law schools were established, and the development of systematic instruction gave an important impulse to the systematic presentation of the law. The famous *Institutes* of Gaius, written in the second century, is apparently a course of lectures. Most of the great jurists, including Ulpian and Paul, published detailed commentaries upon the civil and the prætorian law, as well as monographs upon special subjects. All of them, including Papinian, published books of "questions," "opinions," or "responses." These latter works, as their names imply, were collections of cases, and the systematic treatises were full of illustrative decisions.

In the fourth and following centuries a peculiar degree of authority was attached to this body of literature. The laws of the republic, the prætorian edict, the decrees of the senate, the constitutions of the earlier emperors were no longer cited in the courts; the great jurists alone were cited. Their writings were identified with the law existing in their time; *jus* came to mean the juristic literature of the first three centuries. A "law of citations," issued by the West Roman emperor Valentinian III. (426), recognized and regulated the use of this body of jurisprudence. In case of divergent dicta that opinion was to be followed which was supported "by the greater number of authorities." "If the number on each side be the same, that opinion shall prevail which has the support of Papinian." Only when these tests failed was the judge to employ his discretion. Citations were limited to the writings of Gaius, Papinian, Ulpian, Paul, and Modestine, and of the earlier jurists cited and approved by these five.

A considerable portion of this literature has come down to us in the *Digest* of Justinian. Outside of the *Digest* little remains except the *Institutes* of Gaius (a palimpsest of this work was found in Verona in 1816), and parts of treatises by Ulpian and Paul.

The Edict of Caracalla.—During the first two centuries of the Christian era Roman citizenship had been conferred upon great numbers of provincials. Early in the third century Caracalla declared all free inhabitants of the empire to be Roman citizens. This edict swept away the last remaining differences between civil and provincial law. Technically speaking, the empire was henceforth governed by the law of the city; but as the civil law had been completely remodeled in accordance with the principles of the *jus gentium*, the substantial triumph rested with the latter system.

The Later Empire and the Codification of Justinian.—The list of the great jurists is abruptly closed about the middle of the third century. After Paul but one name of note occurs, that of Modestine. The development of the law was henceforth carried on by imperial decrees or "constitutions." The breach with the old order, however, was less complete than it appears to be. Most of the constitutions issued during the last half of the third century were "rescripts." These were responses rendered in the name of the emperor to petitions requesting imperial decision of concrete cases. Such applications had been made throughout the early empire. In some cases the emperor decided these cases in council; more frequently he assigned their decision to the ordinary judges, with instructions, however, touching the principles which should be applied. In substance, therefore, these rescripts were decisions rather than statutes. The rescripts issued in the reigns of Gordian and of Diocletian are similar in form, and not inferior in the quality of their legal reasoning, to the average responses of Ulpian and Paul. Jurisprudence had not yet sensibly waned, as it did in the fourth and following centuries, but the jurists had disappeared behind the throne, and spoke only with the voice of the emperor.

Technically, however, the rescripts, as well as the general decrees of the later emperors, were imperial "laws" (*leges*), and were distinguished from the older law (*jus*) very much as we distinguish statutes from common law.

The first attempts at *codification* were confined to the imperial constitutions. A private collection of rescripts was made at the end of the third century (*codex Gregorianus*), and a supplement was issued late in the fourth century (*codex Hermogenianus*). In the year 429 the East Roman emperor Theodosius appointed a committee of codification. It was clearly his intention to have the entire law, both the *jus* and the *leges*, brought into manageable compass; but nothing came of his initiative except an official revision of the imperial constitutions (*codex Theodosianus*). This code was transmitted to the Emperor Valentinian III., and was published in both the Eastern and the Western empire in the years 438 and 439.

The Emperor Justinian (527–565) and his minister Tribonian took up the wider plan of Theodosius. A new collection of imperial constitutions was published in the year 529. A committee was then appointed to digest the juristic literature, omitting all that was antiquated and avoiding contradictions. The result of their labors was the *Digest* or *Pandects*, which consisted of more than 9,000 excerpts from the writings of thirty-nine jurists, arranged under 429 titles and grouped into fifty books. Each excerpt or fragment is preceded by the name of the writer and the title of his work. As a rule, the excerpts were literally reproduced, without condensation or other change. During the progress of this work an official text-book was drafted, intended primarily for use in the imperial law schools. It was based on the *Institutes* of Gaius, and bore the same title. The *Institutes* and the *Digest* of Justinian were published Nov. 21 and Dec. 16, 533. In the meantime the codex of 529 had become antiquated. A number of controversies had been discovered in the juristic literature, and no less than fifty new constitutions had been issued for their decision. A *Codex* "of the second reading" (*repetitæ prælectionis*) was therefore published Dec. 29, 534. It contains more than 4,600 constitutions (more than half of them "rescripts"), arranged in twelve books. The *Institutes*, *Digest*, and *Codex* were declared to be henceforth the sole sources of the law, and to forestall further controversy it was made a penal offense to write commentaries upon these books. During the remaining years of his reign Justinian issued many new constitutions. Of these *Novels* (*novellæ leges*) only private compilations were made.

The value of Justinian's work lies mainly in the fact that the Roman law was not codified in the modern sense of the word; i. e. no attempt was made to set forth the entire law as a body of positive rules. In the excerpts from the juristic literature which make up the *Digest* and in the rescripts contained in the *Codex* we have a great body of rules stated only by implication, and therefore capable of reformulation. This gives the Roman law that elasticity which is inherent in all case law. This made it possible to apply the underlying principles of the Roman law to the new and different social conditions of the Middle Ages, and this makes the law-books of Justinian of value to-day to the student of legal science.

4. Roman Law in Mediæval and Modern Europe.—*In the East.*—The collections made by Justinian continued to be employed in the East Roman or Byzantine empire until the close of the ninth century, when they were displaced by a less bulky compilation, known as the *Basilica* (sc. *nomima*), royal laws. This book remained nominally in force until the fall of Constantinople (1453), but it was superseded in practice by a series of private digests and compendiums, each briefer than its predecessor. One of these, the *Hexabiblos*, compiled in the fourteenth century, was extensively used among the Christian subjects of the Ottoman empire, and was in force in the kingdom of Greece as late as the middle of the nineteenth century. It is said that the Roman law in its later Byzantine form exercised a considerable influence upon the development of the Turkish law.

In the Teutonic Kingdoms.—Half a century before Justinian ascended the throne at Constantinople the West Roman empire had fallen. In most of the Teutonic kingdoms established in Western and Southern Europe the conquered provincials were permitted to live by the Roman law (the so-called system of the "personal statute"), and several of the kings had handbooks of Roman law compiled for the use of their Roman subjects. The most important of these was the so-called *Breviary* of Alaric II., King of the Visigoths (A. D. 506). It included a condensation of the *Institutes* of Gaius, a portion of the *Opinions* of Paul, and a considerable number of constitutions from the older codices, particularly the Theodosian.

Local Law.—As the Romanic and Teutonic elements in Western and Southern Europe were gradually fused into new nations, the system of the "personal statute" was necessarily abandoned, and the Roman law became the local law of those districts in which the Romanic element was preponderant. In France, for example, the southern provinces, where it was regularly applied, were known as the "lands of written law" (*pays de droit écrit*), in distinction from the "lands of custom" (*pays coutumiers*), where Frankish usages prevailed. Until the latter part of the Middle Ages, however, the economic conditions prevailing throughout Europe were so simple that the Roman law which was required and applied was but a slight part of the jurisprudence which had grown up in the second and third centuries. Until the twelfth century the *Breviary* was almost the only source of Roman law employed in Western Europe.

The Canon Law.—Of greater importance was the survival and development of Roman law in the mediæval Church. It was an unquestioned maxim that the Church lived by the Roman law. Its entire sacerdotal personnel stood outside of the tribal and local laws which governed the laity, and in many matters which are to-day regarded as secular (marriage and the family relations, testamentary succession, etc.) it claimed and obtained a practically exclusive jurisdiction over all Christians. From the court of the bishop (see Ordinary) appeals ran to Rome and by the decisions of the popes a great body of new law was gradually built up—the *jus canonicum*. See Canon Law and Marriage.

Study and Reception of the Law-books of Justinian (1100–1600).—Toward the close of the eleventh century the lawyers of Lombardy began to have recourse to the *Digest* of Justinian for the solution of questions upon which their local law was silent. In the twelfth century flourishing law schools existed at Bologna and other Italian university centers in which the Roman law, both civil and canon, was systematically taught, and to which students from Western and Central Europe (*ultramontani*) thronged by thousands. In the course of the same century Roman law was read at Montpellier, at Paris, and at Oxford. In the following centuries it became a regular branch of instruction in the new universities established in the Netherlands and in Germany. In those countries where Roman law was already in force the law-books of Justinian began to be cited in the courts, and in countries where the Roman law had previously

gained no foothold (except indirectly, through the ecclesiastical courts) these books were gradually received as positive law. Such a "reception" of the Roman law took place in Germany and in the Netherlands in the course of the fifteenth and sixteenth centuries.

The prime cause of this phenomenon was the need of a more highly developed system of law. With the revival of commerce which followed the crusades economic conditions became more complex, and the simple customs by which the greater part of the continent was governed became inadequate. One of the first results of the commercial revival was the extension of the mercantile law of the Mediterranean, which was largely Roman in character, along the coasts of Western and Northern Europe (see MERCANTILE LAW); but this body of law was applied only to merchants and to transactions of a distinctly commercial character. The new needs of the rest of the community were amply met by the law-books of Justinian. In those parts of Europe which were not at first touched by the revival of commerce, and in which simple economic conditions continued to prevail (e. g. Switzerland and the Scandinavian countries), the Roman law was not received.

A further and negative cause of the reception was the inability of the mediæval state to furnish the kind of law that was needed. Feudalism had so disintegrated political authority that in most parts of Europe there was no real legislative power nor any supreme judicial control. The principal exception was England, where the Norman conquest had so solidified the state that the king in Parliament could enact statutes for the realm, and the king's courts were able to develop the national law by their decisions. A second exception was Northern France, where, at the close of the thirteenth century, the crown had obtained power enough to reform procedure in the provincial courts and to draw cases to the king's courts on appeal. In England therefore the Roman law was not received at all; and in Northern France the reception was "partial" only—i. e. single rules were received, but the Roman law was not adopted as a whole. A third factor of importance was the conviction which prevailed throughout Europe, and which was especially strong in Germany and Italy, that all political authority was derived from the Roman empire, and that all the Roman emperors from Augustus to Justinian were the legal predecessors of the mediæval rulers. This fiction of "continuous empire" did much to facilitate and legitimize the reception.

Closely connected with the reception of the Roman law was the disappearance of popular courts and lay judges and the development of the "learned judiciary." Each of these movements was in part a result and in part a cause of the other.

From the broadest point of view the reception of the Roman law may be regarded as a first step in that reception of the ancient culture which culminated in the humanistic movement of the fifteenth and sixteenth centuries.

Character of the Reception.—(1) The Roman law was adopted in the form and with the modifications which it had received in the Italian practice of the twelfth and thirteenth centuries. The Italian jurists had combined with the *Institutes*, *Digest*, and *Codex* of Justinian the greater portion of his *Novels*, and to distinguish this mass of law from the canon law they termed it "the body of the civil law" (*corpus juris civilis*). They had also "glossed" or annotated its provisions, and their notes, as digested in the "ordinary gloss" of Accursius (about 1250), enjoyed an authority almost greater than that of the text. (2) The "civil law" was received subject to the changes introduced by the canon law. (3) It was received nominally as subsidiary law—i. e. it was to be applied only in the absence of local rules. In Germany, however, the learned judges were generally hostile to local custom, and by throwing upon the party who alleged a local rule the burden of proving its existence and its nature they did much to destroy local custom and substitute Roman rules.

Modern Codes.—A reaction against the Roman law began almost simultaneously with its complete reception. Codification of local customs was first demanded; later, under the influence of the "natural law" school (see JURISPRUDENCE), there arose a general demand for modern codes better adapted to modern conditions. The decisive factor in modern European codification, however, has been the desire to substitute uniform national law for divergent local and provincial laws. In many branches of the law (notably in the field of contract) the existing codes of Europe are substantially Roman, and the non-Roman rules which have found acceptance are usually formulated in a manner which shows the influence of Roman ideas to be still dominant. In several countries in which the law-books of Justinian were never received a "scientific reception" of the Roman jurisprudence has taken place; so in Switzerland and in the Scandinavian countries.

SOURCES AND LITERATURE.—For the older Roman legislation and jurisprudence, see Bruns and Mommsen, *Fontes Juris Romani*, and Huschke, *Jurisprudentia antejustinianea*. The *Institutes* of Gaius have been translated into English by Poste and by Muirhead; the *Rules* of Ulpian by Muirhead; the *Institutes* of Justinian by Moyle. The best edition of the *Corpus Juris Civilis* is that of Mommsen and Krüger; the latest edition of the *Corpus Juris Canonici* is that of Friedberg. Histories of the Roman law (to Justinian) are numerous; the best in English is that of Muirhead. The best brief exposition of the Roman law in English is the translation of Sohm's *Institutes*. For the mediæval history of Roman law the best book is still that by Savigny. For the reception, see the works of Schmidt and Modderman. MUNROE SMITH.

Romano, GIULIO: See GIULIO ROMANO.

Roma'noff: the name of the family from which the present dynasty of Russia derives its origin. Michael Feodorovich Romanoff, the descendant through his grandmother of the royal house of Ruric, was the first of the name to ascend the imperial throne, being chosen by the higher nobility and the clergy in 1613. His successors in the male line ruled till the death of Peter II. in 1730, when the succession reverted to the female line. Another change took place on the death of Elizabeth in 1762, when her nephew, the son of the Duke of Holstein-Gottorp, ascended the throne under the title of Peter III., founding the dynasty of Romanoff-Oldenburg, to which the present sovereign of Russia belongs. See RUSSIA and the articles on the Russian rulers.

Romansch, or **Romansh**: See RHÆTO-ROMANCE DIALECTS.

Romans, Epistle of St. Paul to the: one of the most important of the Pauline books; probably written from Corinth. It affords so many fine examples of the noble and altogether peculiar style and reasoning of the great apostle that its authenticity has never been seriously called in question. Its contents are largely doctrinal, but it contains fine hortatory passages and directions for practical conduct. Its exegetical literature is extensive. The Epistle contains a thorough and comprehensive statement of the theology of Paul. He wrote the epistle to the Church at Rome, which had been already established, probably by some of his own disciples, in order to prepare the way for a visit which he was anxious to make to them (xv. 23). At the time of writing he was under the necessity of going to Jerusalem (xv. 25–27). He therefore stood at the point described in Acts xx. 3; that is, about the year 58. For literature see PAULINE EPISTLES, to which add the English translation of the work of Godet on the Pauline Epistles (Edinburgh and New York, 1894). Revised by S. M. JACKSON.

Romanticism [deriv. of *romantic*, from O. Fr. *romantique*, romantic, deriv. of *romant*, romance]: a term applied to a literary school or movement which is opposed to the methods and ideals of classicism.

Definitions.—The following are some of the definitions given by well-known writers. Heine: "The romantic school in Germany was simply the reawakening of the poetry of the Middle Ages." Mme. de Staël: "The name romantic was introduced in Germany to designate the poetry which was born of chivalry and Christianity." Walter Pater: "It is the addition of strangeness to beauty that constitutes the romantic character in art." Dr. F. H. Hedge: "The romantic feeling has its origin in wonder and mystery. It is the sense of something hidden, of imperfect revelation. . . . The peculiarity of the classic style is reserve, self-suppression of the writer. . . . The romantic is self-reflecting." Prof. Boyesen: "Romanticism is really on one side retrogressive, as it seeks to bring back the past, and on the other hand progressive, as it seeks to break up the traditional order of things." George Saintsbury: "The terms classic and romantic apply to treatment, not to subject, and the difference is that the treatment is classic when the idea is represented as directly and with as exact an adaptation of form as possible, while it is romantic when the idea is left to the reader's faculty of divination assisted only by suggestion and symbol." Victor Hugo: "Roman-

ticism, so many times badly defined, is simply liberalism in literature."

Essential Qualities.—All these definitions have something in common. There are evidently three essential qualities in romanticism: Subjectivity, love of the picturesque, and a reactionary spirit. By the first is meant that the aspiration and vague longing of the writer will be manifest in his literary production; by the second, that element of strangeness added to beauty, which Pater declares is fundamental; this may appear mildly, as where the writer is fond of ivy-mantled towers and moonlit water, or may turn into a passion for the unnatural and the horrible, as in tales of ghosts and of deeds of blood. By the third is meant that the romantic movement in any country will always be reactionary to what has immediately preceded; it may be gently and unconsciously reactionary, as in England, or proudly and fiercely rebellious, as in France.

Mediævalism.—Taking these three elements, subjectivity, picturesqueness, and reaction, it is easy to see why the romantic movement in Great Britain, in Germany, and in France, went for its inspiration back to the Middle Ages. In the Middle Ages lay just the material for which the romantic spirit yearned. Its religious, military, and social life can hardly be better characterized than by the word *picturesque*; and souls weary of form and finish, and of the monotony of rules, naturally sought the opposite of all this in the literature and thought of the Middle Ages. And as the classicists had neglected this period above all others, and treated it with contempt, the reactionists began with an attempt to revivify and brighten this mediæval life.

English Romanticism.—The most striking difference between the romantic movement in France and in Great Britain is that in the former the movement was conscious, while in the latter it was only instinctive. French romanticism had a definite programme, backed almost from the start by a critical school, and headed by one supreme creative genius. English romanticism was a totally different thing. Its beginnings are so faint and so far below the surface that many writers seem to believe that English romanticism began with the nineteenth century, and that in the "age of prose and reason" there was no such thing as a romantic movement at all. It is certainly impossible to name any author as the chief pioneer; for even at the height of Augustan taste there were feeble signs of reaction shown by such writers as Parnell, Croxall, Lady Winchelsea, William Hamilton of Bangour, and Allan Ramsay. The reaction in form, which resulted in the overthrow of the heroic couplet, was brought about by Thomson, Blair, Dyer, Young, Akenside, and others, who cultivated blank verse. The sonnet was revived by Thomas Edwards, Thomas Warton, Stillingfleet, and Mason. Perhaps the most marked change, both in thought and style, is indicated by the Spenserian revival—the renewed study of his poetry and the metrical imitations of his stanza. The latter began as early as 1706, with an ode by Prior, and the fad reached its highest popularity in the years 1735–55, when about forty poems by various writers appeared in Spenserian form. The influence of Milton's poems—especially his *Il Penseroso*—was very effective after 1750, giving to literature a dreamy, melancholy cast, which aided in developing the churchyard school. The Warton brothers, happily re-enforced by the lyrical genius of Collins, were the leaders of the Miltonic group, and became prominently identified with the romantic movement. Joseph Warton wrote blank verse and odes, but his most important contribution was his *Essay on Pope* (1756), in which he maintained that Pope, being deficient in the higher qualities of poetry, imagination, and passion, could not be classed in the first rank of British poets. Thomas Warton wrote sonnets and poems on romantic themes, and aided the Spenserian school by his *Observations on the Faery Queen* (1754). Following the influences just mentioned came the rage for mediævalism, shown in the revival of Gothic architecture, begun by the dilettante Horace Walpole. He did pioneer work by building a fantastic structure at Strawberry Hill (1750), and by writing the extravagant Gothic romance, *The Castle of Otranto* (1764). The love and study of chivalry, for which Thomas Warton made a strong plea in his *Observations*, was greatly aided by Hurd's *Letters on Chivalry and Romance* (1762). Meanwhile a taste for old ballads, which was created in 1723 by a very popular collection of old ballads (anonymous) and in 1724 by Ramsay's *Evergreen*, received a tremendous impetus by the publication of Percy's *Reliques* (1765). The love of mediævalism showed itself also in the opening of a new romantic storehouse—the Northern mythology. In 1755 Paul H. Mallet published the first part of his *Histoire de Dannemarck*, which treated of the religion, laws, and customs of the ancient Danes, and which gave a translation of a large portion of the Eddaic mythology. Percy and Gray became enthusiastic students of this, and made Odin nearly as familiar to readers as Jupiter. Old Welsh poetry was also cultivated; and everything old or wild or sentimental leaped into popularity by the publication of Macpherson's Ossianic poetry (1760–63), which ultimately was taken more seriously on the Continent than in Great Britain. It was fortunate for the movement that the greatest poet of the time, Gray, finally threw his whole influence in its favor. Beginning as a classicist and disciple of Dryden, Gray came strongly under the influence of the *Il Penseroso* group, and finally ended in downright romanticism. Gray was also the first man of note in the eighteenth century to appreciate natural scenery, and his *Journal in the Lakes*, written 1769, published 1775, is full of the Wordsworthian spirit. By 1770 the romantic movement was in full swing; Chatterton's poems were an important contribution, and two great sides of the movement—the taste for ballads and for chivalry—culminated in the poetry and prose of Walter Scott. Byron belongs to sentimentalism more strictly than to romanticism, but his influence on the romantic schools in France and Germany was enormous. Coleridge and Keats are identified with romanticism, and Wordsworth's methods and theories would certainly give him a place in the history of the movement. After 1830 romanticism in Great Britain became less pronounced, because everything in a sense was romantic; there was nothing to fight.

French.—Speaking generally of the literary history of the two countries, Great Britain has almost consistently stood for romanticism; France for classicism. The romantic movement in Great Britain in the eighteenth century was really the heart of the people asserting itself, timidly and instinctively at first, against the domination of a critical school; while the romantic movement of 1830 in France was a bitter, desperate fight between a band of young reformers and the national literary instinct. The beginnings of French romanticism may be seen in the writings of Chateaubriand and Madame de Staël, but it was with Victor Hugo that the school definitely began (and ended) its work. In the preface to *Cromwell* (1828) he laid down plainly and defiantly the romantic programme, which was fought for by the presentation of his *Hernani* in 1830, and the publication of his great romance *Notre Dame de Paris* (1831). A group of young writers followed enthusiastically in Hugo's wake; they and the movement are well set forth in Gautier's *Histoire du Romantisme*. The school directed its sharpest attacks against the classic French drama, and this reform was the most important literary result they accomplished. The emancipation proclaimed, and at last established, the movement naturally spent its force.

German.—The German romantic movement is not so easy to follow. Between the years 1770 and 1832 it flourished, drooped, and flourished again, Herder's enthusiastic interest in the past kindled a flame of mediævalism, which was re-enforced by Ossianic sentimentalism from Great Britain. Ossian's influence on Goethe's *Werther* is well known, and *Götz von Berlichingen* (1773) came from the heart of Goethe's youthful romanticism. Twenty years later, however, the interest in Greek antiquity put mediævalism in the shade, and classicism became supreme. Then in the early years of the nineteenth century the romantic school asserted itself with renewed force, and a younger generation of poets took up eagerly the cultivation of old patriotic German literature. The Schlegel brothers, Tieck and Novalis, were the leaders of the romantic school proper; the younger, or new romantics, were represented by Uhland, Brentano, the Grimm brothers, Arnim, and others.

WM. LYON PHELPS.

Romany Language: the language of the GYPSIES (*q. v.*).

Rome [from Lat. *Ro'ma* (whence Gr. Ῥώμη) > Ital. *Roma*: Fr. *Rome*: Span. *Roma*]: the chief city of ancient Italy, giving its name also to a great republic and empire; the capital of the modern kingdom of Italy.

I. ROME FROM 753 B. C. TO 476 A. D.

THE EPOCH OF THE KINGS (*Legendary Dates, 753–509 B. C.*).—According to the legends current during the later republic, the city was founded in 753 B. C. by a settlement from Alba Longa led by ROMULUS (*q. v.*). The earliest set-

tlement on the Palatine Hill grew by the addition of numerous fugitives, who were welcomed to an asylum on the Capitoline, and by union with the neighboring Sabines, whose king, Titus Tatius, was associated with Romulus in the government. Romulus was the founder of the political and military institutions of the Romans, as his successor, Numa Pompilius, was the organizer of their religious institutions. After the reigns of Tullus Hostilius, the conqueror and destroyer of Alba Longa, and the peace-loving Ancus Marcius, an Etruscan dynasty gained possession of Rome. Under the three kings of this house—Lucius Tarquinius, Servius Tullius, and Tarquinius Superbus—Rome grew rapidly in power, but the rule of the last Tarquin became so oppressive and hateful that the people drove him out and established a republic in 509.

First subjected to systematic criticism early in the nineteenth century by Niebuhr, the legends of the regal period are no longer accepted by competent scholars as a true account of the early history of Rome. They rest upon no contemporary authority. The earliest historians of Rome wrote in the time of the Punic wars, and had to depend almost entirely on oral tradition, since the greater part of the records of the city had been burned when Rome was taken by the Gauls in 390 B. C. Moreover, the legendary narrative contains many inconsistencies and chronological impossibilities, much that would appear improbable even if supported by the best of evidence, and much that is obviously the result of invention. No confidence can be placed in the detailed history of the regal period, but it is still possible to reconstruct the broad features of the development of the early Roman state when studied in the light of the later history of the city, its archæology and topography, and the comparative history of institutions. The tradition gains in value as we approach the end of the regal period, and becomes fairly trustworthy soon after the establishment of the republic.

However and whenever founded—and it may well be believed that the foundation of Rome was due to the influence of some dominant leader—the earliest Rome was a small Latin town on the Palatine and the small adjacent hills, an easily defended site whose position on the Tiber gave it important commercial advantages. The history of the Roman state begins with a community of three tribes—the Ramnes of the Palatine and their neighbors whom they had absorbed, the Sabine Tities on the Quirinal, and the Luceres on the Cælian. Each tribe was divided into ten *curiæ*, and these again into several clans or *gentes*. The members of the gentes—the patricians—alone had political rights. The government consisted of a king, who was chief priest, judge, and commander in war; of a senate of 300 heads of families, who gave counsel to the king and took charge of the government in case of an interregnum; and of a popular assembly (*comitia curiata*), composed of all patricians capable of bearing arms. Besides the fully qualified citizens there were three other social classes which in time united to form the class of plebeians—the clients or serfs of the clans, a number of resident foreigners engaged in trade, and the rural plebeians or inhabitants of conquered Latin cities who had not been admitted to citizenship. That the last kings of Rome belonged to an Etruscan dynasty there is no good reason to doubt, although it is not likely that their number has been correctly handed down. Under their rule the walls were built and important public works erected, and the Roman territory, which had previously extended along the Tiber and in the direction of Alba Longa, came to include the greater part of Latium. Closer relations with outside nations were established, resulting in the introduction of new elements of culture. To this period probably belong the important constitutional changes which ancient writers ascribe to Servius Tullius. As a means of strengthening the army, hitherto composed only of patricians, the people were grouped into five classes on the basis of landed property, so that every possessor of land bore a share of the public burdens proportionate to his ability. This organization soon acquired political importance, and the 193 military divisions or centuries into which the classes were divided became the basis of the *comitia centuriata*, a popular assembly which soon rivaled and finally superseded the older *comitia curiata* in its most important political functions.

The Struggle of Patricians and Plebeians (*B. C. 509–286*). —After the expulsion of the last Tarquin from Rome, a republic was established under the presidency of two consuls chosen only from the patricians and invested, except in religious matters, with the full authority of the kings. From their decision an appeal lay to the popular assembly; in time of great public danger a dictator was given sovereign power for a term not to exceed six months. Although the plebeians had joined with the nobles in the movement which put an end to the rule of the kings, dissensions between the orders broke out almost immediately. The plebeians were excluded from the magistracies, and, while all who possessed land had a vote in the *comitia centuriata*, the assembly was so organized that the wealthy members of the first class were able to control it. The condition of the poor was rendered particularly hard by the oppressive burden of military service and the harsh law of debt, which gave the creditor absolute power over the person of the debtor. Matters came to a head in the year 494, when the plebeians marched in a body to the Sacred Mount, and were only induced to return by measures of relief from debt and by the institution of tribunes of the people, elected by the plebeians and empowered to annul the acts of any magistrate. Shortly afterward (486) Spurius Cassius made an unsuccessful attempt to break the patrician monopoly of the public land by proposing a division of newly acquired territory among the plebeians. Centering at first about the agrarian law, the struggle between the orders continued with great bitterness. The plebeians organized a tribal assembly of their own, the *concilium tributum plebis*, which sought to make its decrees binding upon the whole body of citizens, and the tribunes usurped the power of banishing or even condemning to death those who opposed their policy. The plebeians protested especially against the exclusive knowledge and administration of the law by the patricians, and after repeated demands for a code which should introduce equality and certainty into the legal system, it was agreed in 451 to elect a board of ten commissioners (decemvirs) with power to revise and codify the laws. Their work was continued by a second commission appointed in the following year, and the results of the decemviral legislation, called from the twelve tablets on which they were engraved the Laws of the Twelve Tables, became the foundation of the whole legal system of Rome. The civil equality of the patricians and plebeians was completed in 445 by the Canuleian law, which legalized intermarriage between the two orders. The same year marks an important landmark in the struggle of the plebeians for political rights. Instead of throwing open to them the consulship, which conferred membership in the senate and important social privileges on those who had held it, the patricians agreed that each year the people might determine to elect, in place of the consuls, military tribunes with consular power, chosen indifferently from the two orders. Two years later, with the purpose of reducing this concession as much as possible, the office of censor was created and invested with the powers which the consuls had exercised in taking the census and making up the list of citizens. Unimportant as the institution of military tribunes proved to the plebeians—no plebeian was chosen to the office until 400—it seemed to quiet their demands, and it was not until 367 that the patricians were finally forced to admit them to the consulship. In that year the Licinian laws abolished the military tribunate and provided that at least one of the consuls should be a plebeian, while they also made the plebeians eligible to the body of priests who had charge of the Sibylline books. These laws also made an ineffectual attempt to remedy economic evils by reducing debts and limiting to 500 *jugera* the amount of public land that could be held by one individual. In political matters, however, the laws mark the end of the long struggle between the orders. It is true that in the same year all judicial functions were taken from the consuls and conferred upon the newly created patrician office of prætor, and that the "sulking patricianism" yielded slowly and sought to destroy the effect of its concessions as far as possible; but with the consulship once granted to the plebeians, eligibility to the other magistracies was sure to follow. A plebeian held the office of dictator in 356, of censor in 351, and of prætor in 337. The quæstors, who had charge of the public treasury, had been elected from both orders since 421, and the priesthoods were divided between the orders in 300. With all the magistracies in the state thus open to them, the plebeians also gained influence in the popular assemblies. The decrees of their own assembly, the *concilium tributum plebis*, first organized in 471, were by the Publilian law of Philo in 339 and the Hortensian law of 286 given legal force and made binding on the whole people. The *comitia curiata* lost all importance in the state; its earlier

functions passed to the *comitia centuriata*, reorganized on a democratic basis at some time in the third century, and to the *comitia tributa*, in which the whole people met in their tribal divisions. "As a righteous retribution for their perverse and stubborn resistance," the patricians saw "their former privileges converted into so many disabilities," since they were forced to share these privileges with the plebeians, and were excluded from election to the tribunate and from membership in the special plebeian assembly.

While the popular assemblies thus "acquired the semblance, the senate acquired the substance of power." The assemblies were unwieldy, the power of the magistrates was weakened by division and by the shortness of their terms; the senate alone had a continuous policy, and it drew to itself the control of elections and legislation and the general direction of the policy of the state. On the ruins of the old nobility of birth arose a new patricianism based upon wealth and possession of office.

The Conquest of Italy (*509–275 B. C.*).—The same generation that saw the formal completion of plebeian rights by the Hortensian law witnessed the establishment of Roman supremacy in Italy. The wars that followed the expulsion of Tarquinius Superbus deprived Rome of her hegemony over Latium and reduced her almost to her original limits, so that for a time the very existence of the state was threatened. The chief enemies of Rome in this period were the Volscians, situated to the southeast, the Sabine and Æquian mountaineers to the east and northeast, and the powerful Etruscan confederacy across the Tiber. Against these, in 493, an alliance was formed between Rome and the towns of the Latin confederacy, and in 486 this league was joined by the neighboring Hernicans. The long and doubtful wars which followed, embellished by Roman annalists with poetic details and the half-fabulous stories of Coriolanus and Cincinnatus, brought little advantage to Rome. The state was weakened by civil dissensions, and only after these were temporarily healed by the decemviral legislation and the reforms which immediately followed it, did the Romans begin the steady advance which brought them in 406 before the gates of the important Etruscan city of Veii. The capture of Veii, after a ten years' siege, was an event of great importance in the territorial growth of Rome, since it removed the most serious obstacle to the advance of Roman power. In the year 390 Rome was taken and burned by the Gauls, a Celtic people from the north of Italy. In spite of the immediate loss, the Gallic invasion seems in the end to have favored the growth of the Roman power by weakening Rome's great rival, the Etruscans, and putting Rome into the position of a defender of the rest of Italy against the foreigner. A war with the Latins ended in 338 in the dissolution of the Latin league and the incorporation of most of its members into the Roman state. In 306 the Hernican confederacy met a similar fate. The overthrow of the powerful tribe of the Samnites in 290, after a struggle which had lasted with little intermission for more than fifty years, led to the subjection of their Etruscan and Umbrian allies, and the defeat of Pyrrhus at Beneventum in 275 put an end to the independence of the Greek cities in the south, and left Rome mistress of Italy. The Roman territory (*ager Romanus*) received considerable additions, but Roman supremacy was most effectively secured by the founding of colonies, by the building of military roads, and by the grant of municipal rights and the establishment of treaties of alliance with the conquered cities.

The Establishment of Roman Supremacy in the Mediterranean (*264–133 B. C.*).—Rome's attempt to extend her dominion beyond Italy brought her at once into conflict with Carthage, the leading power in the western Mediterranean. The immediate occasion of the first Punic war was the interference of Rome in the affairs of Sicily, which was then in dispute between the Carthaginians and the city of Syracuse. The war lasted from 264 to 241, and resulted in the victory of Rome only after she had created a navy and learned to compete with the Carthaginians on the sea. Shortly after the conclusion of peace, Rome took advantage of the mutiny of the Carthaginian mercenaries to annex the possessions of Carthage in Sardinia and Corsica. While Rome was engaged in subduing the Gallic tribes in the valley of the Po, Hamilcar Barca conquered Spain for Carthage. His son Hannibal began the second Punic war in 218 by leading his army over the Alps into Italy. Important victories on the Trebia, at Lake Trasimenus, and at Cannæ, gave him control of the Po valley and the southern part of the peninsula, but he was unable to attack successfully the city of Rome or to shake the loyalty of the peoples of Central Italy. The defeat of his brother Hasdrubal on the Metaurus destroyed Hannibal's hope of re-enforcements, and he was compelled to return to Africa, where the victory of the Roman general Scipio at the battle of Zama put an end to the war. Spain was ceded to Rome, and the political and commercial supremacy of Carthage was at an end.

The alliance of Philip of Macedon with Hannibal gave Rome a pretext for interference in the East, and the second Macedonian war resulted (197) in the destruction of the Macedonian supremacy in Greece and the independence of the Greek states. In 190 Antiochus of Syria was defeated at Magnesia and compelled to surrender Asia Minor, which went to increase the territories of Rome's allies. Illyricum became a Roman province in 167. The third Macedonian war ended in 168 in the division of the Macedonian kingdom into four republics under Roman supremacy. In 146 these republics became the Roman province of Achaia, and in the same year a desperate revolt led to the destruction of Carthage and the formation of the Roman province of Africa. In 133 Attalus, King of Pergamus, bequeathed his dominions in Asia Minor to Rome.

This rapid extension of territory was accompanied by far-reaching changes in Roman society. The increase of slavery and the growth of large estates in Italy hastened the decline of the class of small proprietors, who formed the backbone of the old Roman state. Foreigners and dispossessed farmers flocked to the capital, where they formed an idle and dangerous proletariat. In spite of the efforts of such men as Cato, the simple and austere life of earlier times gave way before the spread of a cosmopolitan Hellenism. Political institutions had not adjusted themselves to the changed conditions; Rome was trying to govern an empire with the constitution of a city. The provinces had no share in the government, and were considered a legitimate source of plunder by the governors and tax-gatherers. The senate sank "from its original high position, as the aggregate of those in the community who were most experienced in counsel and action, into an order of lords filling up its ranks by hereditary succession, and exercising collegiate misrule." Reform was imperatively needed.

The Decline of the Republic (*B. C. 133–27*).—The last century of the republic is a period of civil struggles, under the strain of which the republican constitution broke down and gave way to the empire. "It is a sign of the decay of genuine republicanism at Rome, and the approach of autocratic government, that from this time on its history centers about the names of individuals." Controversy first arose over the efforts of Tiberius Gracchus to remedy the evils growing out of the Roman land system. Elected tribune of the people in 133, Gracchus at once proposed an agrarian law which provided for the enforcement of the act of Licinius, limiting the amount of public land which any citizen could possess. Land thus held in excess of the legal amount was to be parceled out among the citizens and Italians in inalienable holdings of thirty *jugera*. The measure was only carried after the deposition of a tribune who interposed his veto; and in seeking re-election the following year Gracchus was killed by his political opponents. In 123 Gaius Gracchus brought forward a more comprehensive scheme of reform. Besides re-enacting the agrarian law of his brother, the execution of which had been suspended after farms had been given to 80,000 citizens, he struck directly at the power of the senate by restricting its control over the government of the provinces. As a counterpoise to the senate, he sought to strengthen the influence of the equestrian order, a class of wealthy capitalists to whom the collection of the provincial taxes was let. The people were won over by public sales of grain at a reduced price. Gracchus hoped to direct the policy of the state by securing his regular re-election to the tribunate, but he was defeated in 122 and soon afterward murdered. After the death of Gracchus the selfish policy of the nobles ruled supreme. The occupied public land was granted to the possessors as absolute private property, and the condition of Italy and the provinces grew steadily worse. The crowning example of aristocratic misrule is seen in the war with Jugurtha, King of Numidia, who bribed one after another of the inefficient generals sent against him. The war was finally brought to an end by Gaius Marius, a man of humble origin, whose further success in repelling the invasion of the Cimbri and Teutones made him the leading man at Rome. Marius was the first of the line of military heroes under whom the republic went out and the empire came in. He lengthened the term of enlistment and abolished the

property qualification for service in the army, so that military service became a regular profession, and the interests of the soldiers were bound up with those of the general. At this time Rome's Italian allies, while they possessed the private rights of citizenship, did not have the suffrage, and were largely at the mercy of the Roman magistrates at home and in war. Repulsed in their demands, they arose in revolt in the year 90, establishing an independent state under the name of Italia, and were only subdued after the rights of citizenship had been extended to all of Italy south of the Po. Scarcely had Rome put an end to the Social war, as the war with the allies was called, when an important war broke out in the East, led by Mithridates, King of Pontus. The command was intrusted to Sulla, a brilliant member of the aristocratic party, who had already distinguished himself against Jugurtha and in the Social war. While Sulla was absent in the East, Marius, Cinna, and Carbo, the leaders of the popular party, raised a revolt in Rome and put to death many of their opponents. On Sulla's return in B. C. 83 a civil war ensued, and Sulla's victory resulted in a series of cruel proscriptions in which several thousand citizens perished. Master of Rome, Sulla devoted his attention to restoring the shattered government. He re-established the power of the senate, and took away those functions of the tribunate which had made it so effective an engine of revolution under the Gracchi. At the same time the system of provincial government was reorganized, and important reforms were made in the courts of law.

Useful as was the Sullan constitution in restoring orderly government, it could not stand the strain of the age that followed. The people were "divided into two opposing factions, each hating the other and struggling to secure its own advantage," while the foreign difficulties of the period made necessary the creation of extraordinary commands, wholly inconsistent with the republican constitution. After the death of Sulla, Pompey was the leading general of Rome. Victorious over the remnant of the Marian party in Spain, he cleared the Mediterranean of pirates, put an end to the wars with Mithridates, and annexed Syria as a Roman province. While Pompey was absent in the East, the dangerous conspiracy of Catiline was suppressed by the prompt action of the consul Cicero. On Pompey's return to Rome he was coldly received by the senate, and formed a coalition with Cæsar and Crassus, the leaders of the popular party—the so-called First Triumvirate—B. C. 60. The death of Crassus in a war against the Parthians (B. C. 55) left Cæsar and Pompey sole rivals for the headship of Roman affairs. While Cæsar was engaged in conquering Gaul and thus establishing Roman influence in the heart of Western Europe, Pompey remained at Rome, where the course of events brought him into close alliance with the senatorial party. War broke out upon the expiration of Cæsar's command in Gaul, and Pompey was defeated at Pharsalus in 48, and shortly after murdered. After the overthrow of the Pompeian party in the battles of Thapsus and Munda, Cæsar was created perpetual dictator, with the title of Imperator. He began a series of important reforms which were cut short by his assassination in B. C. 44. Cæsar's murderers, led by Brutus and Cassius, were vanquished at Philippi, and the defeat of his principal rival, Antony, at Actium left Cæsar's nephew Octavian master of Rome (B. C. 31).

The Early Empire (*27 B. C.–180 A. D.*).—While the extraordinary commands of the last century of the republic had accustomed the people to imperial methods, and while the authority conferred upon Cæsar had been essentially imperial in character, the formal establishment of the Roman empire is usually dated from the year 27 B. C., when Octavian laid aside his exceptional powers and took the title of Augustus. More cautious than Cæsar, Augustus was careful to preserve the forms of the republican constitution. The magistrates were still elected, although their powers were by successive acts conferred upon the emperor; the senate was given a share in the government, and regularly consulted; but the real authority lay in the hands of the emperor, who alone controlled the army. Under Augustus the frontier was pushed north and east to the Danube, but in the west the Romans were compelled to withdraw from Germany after a disastrous defeat in the Teutoburg forest (A. D. 9). Augustus's stepson and successor, Tiberius, was an able administrator, but grew morose, and disfigured his reign by many acts of cruelty. He was followed by three other emperors of the Claudian house—Caligula, Claudius, and Nero. Britain was made a Roman province under Claudius. Under Nero the burning of Rome was followed by a cruel persecution of the Christians. After a year of revolutions marked by the brief reigns of Galba, Otho, and Vitellius, the imperial authority was restored by Vespasian, whose sons, Titus and Domitian, were the last of the so-called Twelve Cæsars.

The reigns of the "five good emperors"—Nerva, Trajan, Hadrian, Antoninus Pius, and Marcus Aurelius—who ruled from 96 to 180, constituted a period of peace and prosperity. The emperors were in themselves good rulers, and they were not thwarted by the opposition of the republican faction, which had been a serious obstacle in previous reigns. The Romanization of the provinces and the consequent unification of the various parts of the empire went on rapidly; men from the provinces even acquired the imperial dignity. The conquests of Trajan in Dacia and the East extended the Roman empire to its widest limits; but Hadrian gave up the newly acquired province of Mesopotamia, and the wars of Marcus Aurelius with the Marcomani began the long conflict with the Germanic invaders. See map of Europe under the Romans.

The Age of Transition (*A. D. 180–284*).—The century which followed the death of Marcus Aurelius marks the transition from the early empire to the absolute monarchy of Diocletian and Constantine. The practice of associating a capable administrator as colleague and prospective emperor came to an end with the accession of Commodus, son of Marcus Aurelius, and no fixed rule of succession took its place. The reigns which followed were generally short and troubled; of the twenty-three emperors who actually held the throne between the years 180 and 284, excluding claimants and the so-called Thirty Tyrants, all except three met a violent death. The "barrack emperors" of this period were mostly soldiers who rode rough-shod over the forms of the older constitution, and devoted their energies to defending the frontier against the Germans in the North and the rising power of the Sassanidæ in the East. The Franks and Alemanni crossed the Rhine, the Goths plundered the eastern provinces and settled in Dacia. The assimilation of Italy and the provinces, hastened by the edict of Caracalla, which conferred citizenship on all free inhabitants of the empire (212), was accompanied by a decline in patriotism and public spirit. The free Roman population steadily decreased, and large numbers of Germans entered the empire as soldiers or as *coloni*. The empire was rapidly falling to pieces.

The Later Empire (*A. D. 284–476*).—The reign of Diocletian (284–305) begins a new era in the history of Rome. A series of reforms inaugurated by him and carried out by Constantine checked the disintegration of the empire and enabled it to hold out for two centuries longer. In order to counteract the tendency of the various parts of the empire to split off into independent kingdoms, the provinces were grouped into thirteen dioceses, and these again into the four prefectures of Gaul, Italy, Illyricum, and the East. Over each of these divisions were placed separate civil and military heads directly responsible to the emperor, in whom the official hierarchy culminated. Italy took its place in the new organization on a footing of complete equality with the rest of the empire, and Rome ceased to be the capital. The senate lost all importance, and the emperor became an absolute despot surrounded by an Oriental court. At the same time the government attempted to check the dissolution of society by encouraging the formation of fixed social classes, each with its own legal privileges and disabilities. Effective as was the new political machinery in certain directions, the growth of the imperial bureaucracy destroyed what still remained of local independence in the cities of the empire, and increased the financial burdens which fell with crushing weight upon the local units. Besides completing the political reorganization begun by Diocletian, Constantine founded a new capital at Constantinople and issued an edict granting toleration to Christianity, which soon became the official religion of the state.

After the death of the Emperor Theodosius in 395 the empire was administered by his sons Honorius and Arcadius, ruling respectively at Milan and Constantinople. In law there was still one empire, but the two administrative divisions corresponded to deep-seated differences of civilization, and were never again united except in name. While the East remained Greek, the western provinces fell away to the Germanic invaders who poured into the empire. Rome was sacked by the Visigoths in 410 and by the Vandals in 455. The Visigoths founded a permanent kingdom in Southern France and Spain, the Vandals took possession of Africa, and the Burgundians occupied the valley of the

Rhone. With scarcely an exception the emperors of this period were weak and incompetent; control passed more and more into the hands of German leaders, until in 476 Odoacer deposed the Emperor Romulus Augustulus and ruled Italy as a German king. The sovereignty of the emperor at Constantinople was nominally recognized in the West, but the real power was in the hands of the kings of the German tribes.

Authorities.—The best general history of the Roman republic is that of Mommsen. Use should be made of Ihne's *History of Rome* and Nitzsch's *Geschichte der römischen Republik*. For modern views on early Roman history, Niebuhr's *History of Rome*, Schwegler's *Römische Geschichte*, and Lewis's *Credibility of Early Roman History* should be consulted. Arnold's *History of Rome* follows Niebuhr on the earlier period; it is most useful for the Punic wars (to 206). Long's *Decline of the Roman Republic* is a careful narrative of the last century of the republic. Drumann's *Geschichte Roms* treats the same period biographically.

There is no work on the empire equal to Mommsen's on the republic. Merivale's *History of the Romans under the Empire* extends to the death of Marcus Aurelius, where the narrative of Gibbon's *Decline and Fall of the Roman Empire* begins. Schiller's *Geschichte der römischen Kaiserzeit* covers the period to the death of Theodosius. Duruy's *History of Rome* contains a fairly complete account of the empire. The work is particularly useful because of its illustrations. Bury's *History of the Roman Empire* covers briefly the same period as Merivale. Clinton's *Fasti Romani* is of value to the student of the chronology of the empire. Hertzberg's *Geschichte des römischen Kaiserreichs* is valuable, as are also the volumes of Ranke's *Weltgeschichte* which treat of the empire. Mommsen's *Provinces of the Roman Empire* describes an important phase of imperial history. For the years after the death of Theodosius, see Kuhn's *Städtische und bürgerliche Verfassung des römischen Reichs*, Bury's *History of the Later Roman Empire*, and Hodgkin's *Italy and her Invaders*. Among the accounts of particular periods, Gardthausen's *Augustus und seine Zeit* and Burckhardt's *Die Zeit Constantin's des Grossen* should be mentioned. Representative works on the social history of the period are Friedländer's *Sittengeschichte Roms* and Schultze's *Geschichte des Untergangs des griechisch-römischen Heidenthums*.

Roman institutions are most completely presented in the great work of Marquardt and Mommsen, *Die römischen Staatsalterthümer*. Good briefer works are Mommsen's *Abriss des römischen Staatsrechts*, Schiller's *Römische Staats- und Rechtsalterthümer* (in Müller's *Handbuch der klassischen Alterthumswissenschaft*), Madvig's *Verfassung und Verwaltung des römischen Staates*, Willem's *Droit Public Romain*, and Bouché-Leclercq's *Manuel des Institutions Romaines*. Herzog's *Geschichte und System der römischen Staatsverfassung* is a valuable work which treats the Roman constitution historically as well as descriptively.

For a study of the original sources of Roman history, Schäfer's *Abriss der Quellenkunde der römischen Geschichte* gives useful material. Charles H. Haskins.

II. Rome from 476 to 1870.

Upon the ruins of the ancient Roman empire, which fell in 476, there arose gradually a new empire, which soon became all the more powerful as it claimed control over the souls of men as well as over their bodies. Rome became, after a short interregnum, once more the seat of the central power in Europe, and thus earned its historic name of the Eternal City. It owed this supremacy to the gradual development of Christianity. The full supremacy of Rome as the capital of the new Church-empire may be referred to the time of Pope Gregory I. (590–604), through whose energy and political wisdom the authority of the Church was everywhere established.

Rome itself—and with Rome the whole of Italy—had in the meantime been the easy prey of the new races which at that time broke forth from their unknown home in the East, overran the whole of Europe, and gradually obtained the supreme power. Under various names, as Goths and Germans, as Lombards, Franks, and Avares, they conquered one province after another. Large portions of Italy were laid waste, cities were sacked and razed to the ground, and whole populations butchered or carried into captivity. The surviving inhabitants remained in possession of the land, which they were forced to cultivate for the benefit of the conquerors. The ancient laws of Rome ceased to be enforced, the municipalities became extinct, the country was divided into duchies and governed by foreign masters. Although the Lombards at no time were masters of the whole of Italy, their influence was powerful enough to give a new German character to the whole peninsula. Repeated efforts made by the Roman emperors at Constantinople to recover possession of Italy led to bloody wars, but remained unsuccessful. A greater danger threatened Rome when the Church was violently agitated by a great schism between the followers of Arius, who denied the divinity of Christ, and the Roman Catholics, who condemned Arianism. Thanks to the skillful management of Gregory the Great and his influence over Theodelinda, the Queen of the Lombards, the latter were won over to his side, Rome was saved from destruction, and Roman Catholicism became supreme in Italy. This great triumph not only relieved the Church in Rome, but enabled it to increase its strength at home and to extend its power abroad, untrammeled by the irksome authority of Greek emperors or the barbarous interference of German invaders. About the same time that the laws of the Lombards were collected (644) the decrees of councils and the canons of the Church also were codified.

The influence of Rome grew with the power of the popes. The Germans were converted by St. Boniface, and even the Eastern nations of the Slavonic race began to acknowledge the authority of the Church, but the appeal of the Frankish king, Pepin, first established the claim of the popes to judge in secular matters as well as in matters of faith. Pepin rewarded the pope's assistance by a grant of land in Italy, and thus the foundation of the secular power of the popes was firmly laid. Pepin's successor, Charlemagne, relieved the pope of great danger, defeated his enemies the Lombards, and after several bloody campaigns entered Rome, where he accepted at the hands of Pope Leo III. the dignity of Emperor of Rome and protector of Christendom (800). It was little more than a restoration in name of the old Roman empire; Charlemagne acquired no new provinces and no new powers, but the deep-rooted reverence felt all over the world for ancient Rome was silently transferred to the new Cæsar. Thus the emperors gained much by this consecration of their power, while Rome resumed its sway over the world.

Italy was, however, not long to enjoy this newly won greatness in peace. New enemies arose on all sides, and in 846 the Saracens invaded the country and threatened Rome. Leo IV., a Roman by birth and a man of extraordinary vigor, inclosed that part of the city which has ever since been known as the Leonine City with strong walls, and made it for a time impregnable. After a period of turbulent warfare an appeal was made by John XII. to Otho, the German emperor, and the journey of the latter to Rome inaugurated a series of expeditions made by the emperors of Germany into Italy. Otho was, like Charlemagne, crowned in Rome (962), and confirmed and enlarged the donations made by his predecessors, but reserved to himself and his successors the sovereignty of Rome. Unfortunately, this divided authority led to the commission of atrocious political crimes by the popes and the three Othos, and this period of Roman history is full of shame and disgrace. The papal party and the imperial party—later known as the Guelphs and the Ghibellines—were in constant conflict, and Italy was the blood-stained battle-field on which the war was waged. At times the popes triumphed, as when the celebrated Hildebrand (Gregory VII.) compelled the Emperor Henry to do penance at Canossa, a fortress in Lombardy, and, kissing the pope's foot, to swear a formal oath of submission. Hildebrand was deposed, Rome devastated by Norman troops under Guiscard, the city burned, the inhabitants slaughtered or sold into slavery, and he himself driven to seek refuge at Salerno, where he died (1085). Crusaders, German armies, and lawless bands of soldiers ravaged Rome by turns, and in the thirteenth century, a period of unbroken faction and fighting, the city suffered fearfully. Ancient tombs and monuments were transformed into fortresses, towers were built everywhere, and the houses of the tyrannical nobles were so many impregnable strongholds. Within the walls vast districts were lying waste, gardens were planted where once stood the proudest temples and loftiest palaces, and the inhabited portions of the city were filled with perpetual tumult. The popes were confined to their castle, and yet their power abroad was greater than ever. Emperors, kings, and princes bowed before Innocent III., who claimed the government of

the whole world, basing his rights upon divine ordinance and sustaining them by the fearful weapons of excommunication and interdict. When, by a turn of fortune, his successors were compelled to abandon Rome and to reside in France at Avignon (1309–77), the city became a prey to complete anarchy, a fate which the adjoining country shared. Rome was virtually left without a government, the Guelphs and the Ghibellines, Neapolitan and German armies, and the noble families of Orsini and the Colonna being alternately masters. The provinces were ravaged by robbers and freebooters, and commerce and industry ceased to exist. For a time peace was restored, order secured, and law resumed by the marvelous success of Cola di Rienzi, a a man of the people, who by the rare power of genuine enthusiasm made himself master of Rome, and even of most of the Italian states (1347). But this last "tribune of the people," as he called himself, was murdered, and when he fell Rome had been so depopulated by wars and tumults that it counted less than 20,000 inhabitants. Herdsmen pastured their cattle on the Forum, flocks of wild fowl haunted the streets, and beasts of all kinds roamed through the deserted quarters. The record of this period is one of unbroken violence, murder, and battle. The family of Borgia, which furnished two popes, became identified with the most shameful crimes. With the termination of the great schism (1378–1417) began a new era, during which vast wealth accumulated in Rome, and all Italy bloomed forth in the Renaissance. Popes like Julius II. and Leo X., one of the Medici, encouraged these efforts by their liberality, and thus Rome was enabled to recover from a terrible calamity—the pillage of the city by the infuriated troops of the constable of Bourbon (1527). But still the popes were either unable to restore peace and order or were held in subjection by foreign powers; for in the meantime the end of the long wars between France and Spain had secured the supremacy in Italy to the latter power. Milan and Naples, Sicily and Sardinia, were Spanish provinces, and the other princes of Italy willingly yielded to the paramount influence of Spain. The increasing power of Protestantism absorbed all the energies of the popes; Pius V. in vain persecuted heretics with increased rigor, and Gregory XIII. was rendered almost powerless by the overwhelming number of banditti. His reform of the calendar, known henceforth as the Gregorian, though at first rejected by Protestant nations and never adopted by the Greek Church, gave him unusual eminence in the annals of Rome. At last the papal scepter fell into the hands of Sixtus V., whose restless energy and stern administration of justice once more restored peace to Rome. From this time the aspect of the city was changed, the reckless power of the nobles was broken, brigandage was rooted out, and property and life were once more safe. The next epoch, the seventeenth century, was a period of political death in Italy. The popes lost their influence in the world; inveterate libertinage took the place of political strife, and nepotism prevailed in the Church. At last, the French Revolution broke out, and the overflowing current of loosened passions found its way to Rome also. A French army entered Italy (1796), conquered the northern provinces, and threatened Rome. For a time the payment of large sums of money averted the storm, but soon after Gen. Berthier invaded the papal states and took possession of Rome. The pope, Pius VI., became a prisoner—first at home and then in France—and Rome was formally annexed to France (1809). It was not until 1814 that the city became free once more and saw the pope return to his palace. In 1848, however, the people rose in rebellion, drove out Pius IX., and established a republic under the triumvirate of Mazzini, Armellini, and Saffi. An appeal to France brought once more a French army to the gates of the city, and a siege was begun. Garibaldi was in the open field with his soldiers, and the Romans within fought with the valor of their ancestors—so bravely that the French were disgracefully defeated. Overwhelming numbers, however, soon put an end to the short-lived republic. Rome was taken, the assembly, convened at the Capitol to meet the invaders, was dispersed, and the pope brought back to Rome. For twenty years French troops garrisoned the Eternal City, and when they were at last withdrawn (1870) Italy had become a nation. Soon afterward Rome, having been made the capital of the new kingdom, saw the temporal power of the Holy See abolished, and Victor Emmanuel enter as its new master. It presents the strange anomaly of being the residence of two sovereigns, the King of Italy and the pope —the one ruling over the whole peninsula from the Alps to the island of Sicily, the latter ruling in undiminished authority over the consciences of all the members of the Roman Catholic Church.

Literature.—On the mediæval history of Rome few books of value have been written since Gibbon published his *Decline and Fall of the Roman Empire*. The work of F. Gregorovius, *Geschichte der Stadt Rom im Mittelalter, V.–XVI. Jahrhundert* (Stuttgart, 1859–72, 8 vols.; 4th ed. 6 vols., 1886–93), refers mainly to the city; T. Dyer's *History of Rome* (London, 1865) is more comprehensive. Bryce's *Holy Roman Empire* (1864; 9th ed. 1888) is a standard authority on the theory of the restored empire, and on the points at issue in the great papal-imperial struggle. The Very Rev. Dr. Donovan's *Rome, Ancient and Modern* (Rome, 1842), is specially rich in matters of interest to English students and in information on Christian edifices and worship in early times. P. M. Letarouilly's *Édifices de Rome moderne* (Paris, 1840–57, 3 vols.) mentions incidentally much of the history of the great noble families whose palaces form the subject of the work. Valuable information may also be obtained from the works of Sir George Head, Burgess, and Burton, while the *Beschreibung der Stadt Rom*, by Bunsen and others (Stuttgart, 1830–42, 3 vols.), gives the fullest description of the city. By far the most valuable contribution made to the subject in our day is A. de Reumont's *Geschichte der Stadt Rom* (Berlin, 1867–69, 3 vols.). William W. Story's *Roba di Roma* or *Walks and Talks about Rome* (Philadelphia, 1862) and Augustus Hare's *Walks in Rome* (London, 1871) are of great value, though more confined in their purpose. For the ecclesiastical features of the history, see C. F. B. Allnatt, *Cathedra Petri* (2d ed. 1878); A. Harnack, *Dogmengeschichte* (Freiberg im Breisgau, 2d ed. 1888); and Rudolph Sohm, *Kirchenrecht* (Leipzig, 1892, vol. i.). For additional information, see the articles on Italy, Papal States, Pope, and Roman Archæology.

Revised by S. M. Jackson.

III. Rome since 1870.

Rome, the capital of the kingdom of Italy, is situated on both sides of the Tiber, about 15 miles from its mouth, in lat. 41° 53′ 52″ N., lon. 12° 28′ 40″ E. (observatory in the Collegio Romano). It lies in an undulating volcanic plain, which, with a breadth of 25 miles between the Apennines and the sea, extends from Capo Linaro to Promontorio Circeo, a distance of about 85 miles. The city is surrounded by walls about 14 miles in circuit, of which 10 are on the left bank of the Tiber. These are constructed of brick, about 55 feet high on the outside, generally less than 30 feet on the inside, and surmounted with 300 towers and pierced by 13 gates, besides two that have been walled up. The wall on the left side of the river was begun in 271 by Aurelian and completed by Probus; the principal restorations are due to Honorius, Theodoric, Belisarius, and several of the popes. The wall on the right side dates mainly from Pope Urban VIII. Since 1870 Rome has been further surrounded by forts forming a circle about 30 miles in circumference.

Of the gates the most remarkable is the Porta del Popolo, through which passes the road which crosses the Tiber by the Ponte Molle, a mile and a half distant, and leads to Northern and Eastern Italy. In the S. E. is the Porta Maggiore, originally an archway of the Aqua Claudia; it was made a city gate by Aurelian and was used as a fort by the Colonnas. Near this gate passes the railway which starts from the central station on the Quirinal and joins the railways proceeding to all parts of Italy.

The Tiber traverses the city from N. to S. in three wide curves, and is spanned or partially spanned by twelve bridges. Among these are Ponte Sant' Angelo, the ancient Pons Ælius, built by Hadrian; Ponte Sisto, built by Sixtus IV. in 1474 on the ruins of the ancient Pons Janiculensis, and crossing from the Trastevere; Ponte Cestio, the ancient Pons Cestius, connecting the Trastevere with the island of the Tiber (Isola Tiberina di Bartolomeo); Ponte de' Quattro Capi, or Ponte Fabricio, the ancient Pons Fabricius, the oldest bridge of Rome existing, built in B. C. 62 by L. Fabricius—it leads from the island of the Tiber to the left bank of the river; and the Ponte Rotto, below the island, a suspension bridge, which replaced an older bridge that was partly composed of the ancient Pons Æmilius, built in 181 B. C. The city is divided into two unequal parts by the river. The smaller and more modern part, situated on the right bank, consists of a northern and southern portion. The former contains the palace of the Vatican (*q. v.*), the Church of St. Peter (see Peter's, St.), and the castle of Sant'

Angelo. The last structure (*Moles Hadriani*), commenced by Hadrian and finished in 140 by Antoninus Pius, was intended for a mausoleum for Hadrian and his family, and connected with the Monte Pincio by the Pons Ælius. When the Goths conquered Rome under Vitiges, it was used as a fortress, and during the feuds of the early Middle Ages constantly formed a stronghold in the hands of the ruling faction. Urban V. constructed the outworks; in 1500 the covered passage which connects it with the Vatican palace was built; and in 1527 Clement VII. sustained here a long siege, in which Benvenuto Cellini was engaged and the constable of Bourbon was killed. The later popes used the structure principally as a dungeon. The southern portion of the city on the right bank, Trastevere, occupies the ancient Mons Janiculus. Here was in the oldest time a fortified outpost against the Etruscans, and in the time of Augustus a populous suburb. The Trastevere is mostly inhabited by workingmen, who claim to be the descendants of the ancient Romans. The most remarkable points here are the Church of S. Pietro in Montorio, erected in 1500 by Ferdinand and Isabella of Spain on the spot where St. Peter is said to have suffered martyrdom, and the magnificent fountain Acqua Paola, built in 1611, under Paul V., by Fontana and Maderno, after the restoration of the ancient Aqua Trajana, an aqueduct erected by Trajan for the purpose of carrying the waters of the Lago di Bracciano (*Lacus Sabatinus*), over 30 miles distant, into the city. These two portions of the western part of the city are connected by the Via della Lungara, three quarters of a mile long, constructed by Sixtus V. It contains the Villa Farnesina, which was built in 1506 by Baldassare Peruzzi, and came into the possession of the Farnese family in 1580, and the Palazzo Corsini, in which Queen Christina of Sweden died Apr. 19, 1689. The Villa Farnesina contains a celebrated series of frescoes representing the myth of Psyche, after designs by Raphael, and the Palazzo Corsini, which has been assigned by the Government to the R. Accademia dei Lincei, contains a picture-gallery, one of the largest collections of engravings in the world, and a valuable library.

The larger, eastern part of the city, situated on the left bank of the Tiber, occupies the famous seven hills. Farther to the N., near the Porta del Popolo, rises Monte Pincio (*Collis Hortorum*), 175 feet above the level of the sea, which in ancient times was covered with gardens and not reckoned a part of the city; the famous gardens of Lucullus were situated here. Here are the Pincian gardens, a fashionable drive and promenade, which command a fine view of the city. Separated from Monte Pincio by the Piazza Barberini extend the Esquiline hill, the Quirinal, and the Viminal. Farther to the S. rises the Cælian, and between this and the river the Aventine. In the southern part of the plain, between this range of hills and the Tiber, rise, isolated, two other hills—the Palatine and the Capitoline. The latter formed the most prominent point of ancient republican and imperial Rome, the principal part of which extended over the Capitoline, Aventine, Cælian, and the southern part of the Esquiline. On the Capitoline hill are the Church of Sta. Maria in Araceli, which was erected before the tenth century on the site of the temple of Juno Moneta; the Piazza del Campidoglio, designed by Michelangelo, and begun in 1536 by Paul III., with a bronze equestrian statue of Marcus Aurelius in its center; the Palazzo del Senatore, erected by Boniface IX., with steps by Michelangelo—it contains a hall for the meetings of the municipal council, offices, etc.; the Palazzo dei Conservatori, containing the Protomoteca, a collection of busts of celebrated Italians, the new Capitoline Museum, in which are antiquities chiefly found during the construction of the new streets in the east quarter of the city, and a picture-gallery founded by Benedict XIV.; and the Capitoline Museum, founded by Innocent X., which is rich in admirable specimens of ancient sculptures and other antiquities. From the Capitoline, toward the Palatine, extends the ancient Forum Romanum. The Palatine contains the ruins of the ancient imperial palaces. Between the Palatine and the Aventine lay the Circus Maximus; to the S. E. of the Aventine the baths of Caracalla. In the depression between the Palatine, Esquiline, and Cælian stands the Coliseum. (See AMPHITHEATER.) Between the Cælian and the Esquiline stand San Giovanni in Laterano, the oldest church of Christendom, and the Museum Gregorianum Lateranense. (See LATERAN.) The latter contains statues and mosaics, and a large collection of sculptures and inscriptions from the Catacombs. Near the Lateran is the building containing the Scala Santa, a flight of twenty-eight marble steps brought from the palace of Pilate at Jerusalem by the Empress Helena in 326. Beyond the southern slope of the Esquiline the ruins of ancient Rome become scarcer and the monuments of mediæval and modern Rome more frequent. Here are the Church of Sta. Maria Maggiore, also called the Basilica Liberiana, erected by Pope Liberius 352–366, altered in 432 by Sixtus III., enlarged in 1292 by Nicholas IV., and restored in 1575 by Gregory XIII.; the Palazzo Rospigliosi, founded in 1603 by Cardinal Scipio Borghese, and the Casino Rospigliosi, containing many fine frescoes and pictures: the Palazzo Barberini, begun by Maderno, finished by Bernini, with a library containing 7,000 MSS. of Latin and Greek authors; the Villa Albani, built in 1760 by Cardinal Albani, with admirable works of art collected with the co-operation of Winckelmann; the railway station, opposite the Thermæ Diocletiani; and the Porta Pia, designed by Michelangelo in 1564, and restored by Pius IX. 1861–69. Through the Porta Pia the Italian army entered Rome Sept. 20, 1870.

The modern city, occupying the space between the river and the hills, is divided into two parts by the Corso, which, running in a straight line for a distance of nearly a mile from the Piazza del Popolo to the Piazza di Venezia, is the finest and gayest street of the city. Among the many elegant buildings which line it on both sides are the Palazzo Doria, one of the most extensive and most magnificent palaces of Rome, containing the Doria Gallery, a fine collection of pictures of different schools, and the Palazzo Colonna with rooms beautifully decorated and a collection of pictures. The portion of the city situated between the river and the Corso contains many admirable monuments, among which is the mausoleum of Augustus, erected by that emperor as a burial-place for himself and his family; it consists of an immense substructure containing the burial-chambers, and covered with a terraced mound of earth adorned with cypresses and a statue of the emperor. It was used in the Middle Ages as a fortress by the Colonnas, and is fitted up as a theater. Here is the Palazzo Borghese, built in 1590 by the elder Longhi; the Church of Sta. Maria Rotonda, or the PANTHEON (*q. v.*), the only ancient edifice in Rome which has been preserved entire. Near the Pantheon is the church of Sta. Maria sopra Minerva, erected about 1285 on the ruins of a temple of Minerva; it contains Michelangelo's *Christ with the Cross.* Here is also the Palazzo Farnese, one of the finest palaces of Rome, begun under Paul III. after the designs of da Sangallo, continued under the direction of Michelangelo, and completed by della Porta. It afterward came into the possession of the Kings of Naples, and many of the sculptures and antiquities which it contained were removed to Naples. It is now the home of the French embassy to the papal court. It contains a series of fine frescoes by Annibale Caracci and Agostino. Here are the Palazzo di Venezia (now the Austrian embassy), the Palazzo Massimi alle Colonne, containing the chapel of S. Filippo Neri, and many other palaces of the papal nobility. The splendid new streets Corso Vittorio Emanuele and Via Nazionale connect the head of the Corso with the Ponte Sant' Angelo and with the central railway station respectively. Important streets too are the Via 20 Settembre from the Porta Pia to the Quirinal, and the Via Cavour, which leads from the railway station to the Forum. From the Piazza del Popolo the Via di Ripetta diverges from the Corso on the right, and on the left the Via del Babuino leads to the Piazza di Spagna.

Among churches not already mentioned is S. Paolo fuori le Mura, originally founded in 388, burnt in 1823 and rebuilt in a magnificent style. S. Lorenzo fuori le Mura, rebuilt in 578 on the site of a church founded by Constantine, and remodeled afterward, still retains its ancient columns; Sta. Agnese fuori le Mura, founded by Constantine and rebuilt in the seventh century, has many early inscriptions; Sta. Croce is a basilica said to have been founded by the Empress Helena; S. Clemente is remarkable in that it consists of three structures—the upper one is a twelfth-century church, underground is a church of the fourth century, and below this are remains dating from the imperial and republican periods; Sta. Maria in Cosmedin retains ten of the columns of the temple of Ceres, out of which it was partly built. Outside the Porta Pia is Sta. Constanza, founded by Constantine, with mosaics of the fourth century. On the Cælian is SS. Giovanni e Paolo, founded in the fifth century and rebuilt in the twelfth; also S. Gregorio, founded in 575 on the site of the house of the father of Gregory the Great. On the Esquiline is Sta. Pudenziana, with mosaics of glass cubes dating from

the fourth century; also S. Pietro in Vincoli with ancient Doric columns, containing Michelangelo's statue of Moses. On the right bank of the Tiber is Sta. Maria in Trastevere, dating from the fifth century and rebuilt in the twelfth, with ancient columns, mosaics, and a fine marble pavement; also S. Crisogono with a mosaic pavement of the twelfth century. Among modern churches is the gorgeous Gesù, on the Corso Vittorio Emanuele, with the tomb of Ignatius Loyola. Among Protestant churches are All Saints, in the Via del Babuino, and the American Episcopal Church of St. Paul, a brick edifice by Street in the Via Nazionale.

Among the public libraries are the Biblioteca Alessandrina in the university, the Biblioteca Angelica with over 100,000 volumes and 2,945 MSS., and the Bibliotheca Casanatensis with 200,000 volumes and 1,000 MSS.; but the principal one is the Biblioteca Centrale Vittorio Emanuele in the Collegio Romano. It was originally formed in 1871 from the library of the Jesuits and those of the suppressed convents; it contains 500,000 volumes and several thousand MSS. In the Collegio Romano there is also the Museo Kircheriano with a collection of antiquities. Since 1876 it has been united with a rich and extensive ethnographical and prehistoric collection. Besides the new Capitoline museum for the results of the new excavations there are also the museums in the Thermæ of Diocletian and at the old villa of Pope Julius III. The Villa Medici contains a large collection of casts from ancient statues. The university (Università della Sapienza) was founded by Boniface VIII. in 1303, and prospered greatly under Leo X.; it has faculties of law, medicine, physics, and philology. In 1891 it had 1,543 students and 81 teachers.

The manufactures and industries are of little importance. Woolens, silks, velvets, leather, hats, gloves, and neckties are made, but the principal manufactures are of mosaics, bronzes, casts of statuary, and other articles connected with the fine arts. All the necessaries of life have to be brought from a distance, as the Campagna surrounding Rome is barely habitable on account of malaria. The Campagna is an open, untilled space, over which herds of half-wild cattle roam. The prosperity of the city depends upon the expenditure of the courts of the Quirinal and the Vatican, of the large number of officials, and of the visitors who fill the hotels in the winter. The city is fairly healthful. The rainfall is slight, averaging $16\frac{1}{10}$ inches annually. In the winter the mean temperature is about 46° F., and in July and August 75° F. In the latter month and September the malaria is prevalent, but there are several parts of the city in which it is not found. The water-supply is exceptionally good, and few towns are better supplied with public fountains. There is a good omnibus service, and horse-cars traverse the more important streets. The streets are mostly well lighted and well paved with hard lava.

The area within the walls is 3,880 acres. The population of Rome has increased rapidly since it became the capital of Italy: in 1870 it was 226,022; in 1880, 300,467; in 1891, 407,936; in 1899, 512,423. During that period over 3,000 houses have been built, 82 miles of streets formed, and 140,000,000 lire expended in the improvement of the city. The villas of the nobility, with the extensive gardens surrounding them, have been to a great extent destroyed and replaced by modern houses and blocks of buildings. The Tiber has been embanked and its channel deepened and straightened; but the further reconstruction of the city, which had been planned upon a magnificent scale, has been abandoned owing to the financial difficulties of the municipality.

History.—On Aug. 19, 1870, the last detachment of the French garrison evacuated Rome, and the following month an Italian corps entered the papal territory. After a slight resistance Rome surrendered on Sept. 20. A provisional government was formed and a popular vote on the question of annexation to the kingdom of Italy was decreed. This was carried in the affirmative by an overwhelming majority, and on Dec. 21 the Italian parliament, then sitting in Florence, decided to transfer the seat of government to Rome. Accordingly, on July 2, 1871, King Victor Emmanuel, accompanied by the officers of state and the members of the foreign diplomatic corps, made his formal entry into the new capital, and on Nov. 27 opened the first session of the Italian parliament in Rome. R. A. Roberts.

Rome: city (incorporated as a city in 1847); capital of Floyd co., Ga.; at the confluence of the Etowah and the Oostenaula rivers, which form the Coosa river; on the Chattanooga, Rome and Columbus and the Rome railways; 39 miles S. by W. of Dalton, 79 miles N. W. of Atlanta (for location, see map of Georgia, ref. 2–F). It occupies an elevated and picturesque site, is in an agricultural region, and is an important business center for the northwest part of the State. The Etowah and Oostenaula rivers are navigable to this point, and both are here crossed by iron bridges. The city has excellent water and sewerage systems, electric-lighting plant, several public parks, 2 cotton-compressing works, and a large trade by rail and water in grain, grass, cotton, and lumber. There are 9 churches for white and several for colored people, a public high school, and 3 grammar schools; Shorter College for Women (Baptist, opened 1873), the Rome Female College (founded 1845), a gynæcologic infirmary, 2 national banks, and 2 daily and 4 weekly newspapers. Pop. (1890) 6,957; (1900) 7,291.

Rome: city (incorporated as a village in 1819, chartered as a city in 1870); Oneida co., N. Y.; on the Mohawk river; at the junction of the Erie and Black river canals; on the Rome, Watertown and Ogdensburg, the N. Y., Ont. and W., and the N. Y. Cent. and Hud. River railways; 15 miles N. W. of Utica, 109 miles W. of Albany (for location, see map of New York, ref. 4–H). It is built on a plateau at the head of the Mohawk valley and at an elevation of 445 feet above sea-level, and is laid out in the form of a polygon, the principal streets being 100 feet wide, with road-beds of 65 feet. The water-supply for fire and domestic purposes is from the Mohawk river at Ridge Mills, 2 miles N., where the water is pumped into a reservoir and distributed thence by pipe. The city is lighted by electricity, and a complete system of sewers gives the city thorough drainage. It contains 16 churches, high school, 8 graded public schools, a hospital, State Custodial Asylum for Incurable Insane, the Central New York Institution for Deaf Mutes, St. Peter's Academy (Roman Catholic, opened in 1865), 3 libraries (the Jervis, the Union Free School, and Y. M. C. A.), 2 national banks with combined capital of $250,000, 2 savings-banks with deposits of more than $3,500,000, and a daily, a monthly, a tri-weekly, 2 semi-weekly, and 1 weekly periodicals. Rome is in a noted dairying region, and the central factory system of cheese and butter making originated here. The other industries include locomotive-works, brass and copper mills, metal bedstead works, knitting-mills, brick-yards, breweries, canning-factories, etc. The assessed valuations in 1900 aggregated $7,279,540, and the debt in Jan., 1900, was $427,564, nearly all on account of the water-works and sewers. The heart of the city is the site of Fort Stanwix, erected in 1758, at a cost of about £60,000, which was a formidable work, and a post of great importance during the French war of that year, as it was the chief protection of the "carrying place," as the region was then called, because it was the only break in a continuous water-communication between the Atlantic Ocean and the Great Lakes. The fort was also the scene of stirring events in July and Aug., 1777, when the British under St. Leger were defeated by the Tryon County militia under Gen. Herkimer in the battle of Oriskany. The first United States flag unfurled before the enemy is claimed to have been raised on Fort Stanwix August 3, 1777. Official description of the flag had just reached the fort from Philadelphia. The garrison made the flag from white shirts, a woman's red petticoat, and a blue camlet cloak. The U. S. Government in 1814 established in Rome an extensive arsenal-plant, which was sold in 1873 and converted into a factory building. Pop. (1890) 14,991; (1900) 15,343. A. C. Kessinger.

Romeo: village; Macomb co., Mich.; on the Grand Trunk railway; 50 miles N. of Detroit (for location, see map of Michigan, ref. 7–K). It contains flour and planing mills, iron-foundries, carriage-factories, agricultural-implement and steam-engine works, 2 national banks, and 2 weekly newspapers. Pop. (1890) 1,687; (1900) 1,580.

Römer, or **Roemer**, Ole: mathematician and astronomer; b. at Aarhuus, Denmark, Sept. 25, 1644; studied mathematics and astronomy at the University of Copenhagen; attracted the attention of Picard, who went to Denmark to visit Uranienborg; was invited to Paris by him and Colbert in 1672; appointed teacher in mathematics to the dauphin, and made a member of the Academy of Sciences; assisted Picard in his meridional measurements, invented the transit instrument, and determined the velocity of light (see Light); was appointed Professor of Mathematics and Astronomy at the University of Copenhagen in 1681, and held several civil offices in Copenhagen, where he died Sept. 19, 1710.

Romero, Matias: See the Appendix.

Romescot: See Peter's Pence.

Rom'illy, John, Baron Romilly of Barry: lawyer; son of Sir Samuel Romilly; b. in London in 1802; graduated at Cambridge, 1826; called to the bar at Gray's Inn 1827; sat in Parliament as a Liberal 1832–35 and 1846–52; knighted and made solicitor-general 1848, attorney-general and privy councilor 1850, and was master of the rolls 1851–72, in which capacity he was instrumental in causing the publication of the very valuable Rolls Series of *Calendars of State Papers* and other documents illustrating the earlier history of England; was made Baron Romilly of Barry, Glamorganshire, Jan. 3, 1866. D. in London, Dec. 23, 1874.
Revised by F. Sturges Allen.

Romilly, Sir Samuel: statesman and jurist; b. in London, England, Mar. 1, 1757; entered Gray's Inn May 11, 1778; was called to the bar 1783; became eminent as a chancery lawyer, and was appointed king's counsel in 1800; chancellor of the county palatine of Durham 1805; knighted, and made solicitor-general and elected M. P. 1806; enjoyed the friendship of Mirabeau, and through him acquired the friendship and patronage of Lord Lansdowne. His great work was his attempt to reform English criminal law, which he began in 1807, and urged in Parliament with great eloquence and persistence; besides which he advocated the abolition of the slave-trade, Catholic emancipation, and electoral reform. The number of capital offenses without benefit of clergy in 1797 was 160, and it rose to 222, when the efforts of Sir Samuel Romilly for reform succeeded only so far as to have pocket-picking, which was capital if above five shillings, taken out of the list. Although his bills reducing the number of capital offenses repeatedly failed to pass, being opposed by the Government of the day, by the bishops, and even by the most eminent judges, as Lord Ellenborough, as dangerous innovations, his perseverance, his continual protesting against the severity of the criminal law, and the barbarous frequency of capital punishment (which was the cause of the laxity in its enforcement), led to the final reformation of the criminal law of England. D. Nov. 2, 1818. His speeches were published in 1820, and his biographical memoirs in 1840, with notes by his sons. He wrote *Thoughts on the Probable Influence of the Late Revolution in France upon Great Britain; Observations on the Criminal Law of England as it relates to Capital Punishments, and on the Mode in which it is administered* (London, 1810), an able pamphlet. Revised by F. Sturges Allen.

Rommany Race and Language: See Gypsies.

Romney, George: portrait-painter; b. at Dalton, Lancashire, England, Dec. 26, 1734. He was apprenticed to a Cumberland painter named Steel. At the age of twenty-two he married. For some years he wandered about the north of England painting portraits—heads for two guineas, as is related—and at last went to London, leaving his wife and two children in Lancashire. From 1762 to 1798 he was either traveling on the Continent or residing and painting in London. He gained fame and popularity as a portrait-painter, and was able to secure prices as high as those paid to Reynolds, especially after Reynolds's abandonment of his art, about 1788. He was far less skillful and accomplished than either Reynolds or Gainsborough, and his pictures, other than portraits, have but little value. In 1798, broken in health, he joined his wife at Kendal, Lancashire; soon afterward he sold his studio and his collection of works of art, and settled in the north. D. at Kendal, Nov. 5, 1802. Among his best pictures are a number of portraits of the celebrated Lady Hamilton. The National Gallery in London has one of these in the character of a Bacchante, and a fancy portrait, *The Parson's Daughter*. In the National Portrait Gallery at South Kensington is another *Lady Hamilton* and a *Portrait of Flaxman*, the sculptor. Romney's portraits are mostly in private hands. Russell Sturgis.

Rom'ulus: mythical founder of the city of Rome; the twin-brother of Remus and a son of Mars by Rhea Silvia, who was a descendant of the Trojan Æneas, and had been made a priestess of Vesta when her father, Numitor, King of Alba Longa, was dethroned by his brother, Amulius. The two infants were thrown into the Tiber by the order of Amulius, but the river landed them safely at the foot of the Palatine Hill; a she-wolf carried them to her den and suckled them, and a shepherd afterward found them and educated them together with his own children. The legend goes on narrating how the two brethren discovered their descent, reinstated Numitor, emigrated from Alba Longa, determined to build a city on the Palatine Hill, but then fell out with each other; how Romulus killed Remus, built the city, procured wives for the citizens, carried on many wars, and was finally translated and worshiped as a god under the name of Quirinus. It is impossible to distinguish the ætiological and mythical from the truly traditional element in these stories, though there can be no doubt that the latter is present. See Rome. Revised by G. L. Hendrickson.

Roncesvalles, rōn-thes-vaal'yes (Fr. *Roncevaux*): a small Spanish village, province of Navarre; in a narrow valley on the southern side of the Pyrenees. It is famous as the place where Charlemagne, on his retreat from his campaign against the Mohammedans in 778, was attacked and his whole rearguard destroyed. Among those slain in this battle was the half-mythical hero Roland, whose name became the center of the romantic poetry which sung of Charlemagne and his paladins. In the French-Spanish wars several bloody encounters (in 1793, 1794, and 1813) occurred in the same valley, and in 1833 Don Carlos was first proclaimed king here.

Ron'da: town of Southern Spain, 42 miles W. of Malaga; at an elevation of 2,300 feet above the sea, on a precipitous promontory of the Sierra Nevada, on the Guadiaro, which here is crossed by lofty bridges built by the Moors (see map of Spain, ref. 19–D). A large annual fair is held here in May, attended by a great number of merchants, and enlivened by bull-fights. Elegant arms, fine woolen fabrics, and saddlery are the principal manufactures of the city. Pop. 19,181.

Rondo [from Ital. *rondò*, from Fr. *rondeau* < O. Fr. *rondel*, dimin. of *rond*, round, a round]: in music, a composition, in which the theme, as it is given in the first strain, returns upon itself in the last, after passing through various expansions and elaborations.

Ronge, rōng'e, Johannes: religious leader; b. at Bischofswalde, Prussian Silesia, Oct. 16, 1813; studied theology at Breslau; appointed a chaplain at Grottkau in 1840, but was opposed by the ultramontane clergy on account of his liberal views, and was suspended in 1843 because of an article, *Rom und das breslauer Domkapitel*, which he published in the *Sächsische Vaterlandsblätter*. In 1844 he was excommunicated on account of a letter to Bishop Arnoldi, denouncing as idolatrous the exhibition at Treves of the holy coat. Through a number of pamphlets, and by traveling from town to town preaching and lecturing, he exhorted people to secede from the Roman Catholic Church, and, supported by the general irritation against the ultramontane hierarchy he succeeded in forming several congregations of the so-called German Catholic denomination. By degrees he was himself attracted by the political fermentation, sided in 1848 with the radicals, and fled in 1849 to England. Returning in 1861, he lived at Breslau and Frankfort-on-the-Main, where he founded a reform association in 1863; after 1873 at Darmstadt. D. in Vienna, Oct. 26, 1887.

Ronsard, rōñ'saar', Pierre, de: poet: b. at the Château de la Poissonnière, Vendômois, France, Sept. 11, 1524: was educated at the French court as page to the Duke of Orleans: followed James V. to Scotland and lived nearly three years at his court (1538–41); returned to the Duke of Orleans, and was sent on various embassies to Flanders, Holland, and England; ruined his health and lost his hearing, and retired to the Collège de Coqueret, where he spent seven years studying the Latin and Greek languages and literatures. Among his companions here were Baïf, Belleau, Muret, Jodelle, and Du Bellay, and among them sprang up that new literary ideal whose first representative Ronsard became, and which for centuries reigned not only in France, but in all European literatures. It broke completely with the ideals and traditions of the Middle Ages and the older native literature, and substituted the classical models of the Latin and Greek literatures. Ronsard and his eager followers, styling themselves the *Pléiade*, threw themselves upon the task of creating a French literature in the image of the classical models. In 1550 appeared four books of *Odes*; in 1552 his *Amours*; in 1555 his *Hymnes*; other poems, including *Élégies* and *Discours*, at intervals; and in 1572 four books of his epic, *La Franciade*, never finished. The enthusiasm he awakened at home and abroad was extraordinary. His influence on the French language and letters was enormous, though his popularity waned rapidly after the advent of Malherbe. D. Dec. 27, 1585. Good editions of his works are by P. Blanchemain (8 vols., Paris, 1857–67) and Marty-Laveaux (6 vols., Paris, 1887 ff.). A. G. Canfield.

Röntgen (or **Roentgen**), Wilhelm Conrad, Ph. D.: physicist; b. near Zurich in 1845; educated there and at Utrecht; became Assistant Professor of Physics in Strassburg in 1873; Professor of Mathematics and Physics in the Agricultural Academy at Hohenheim, near Stuttgart, in 1875; professor and director of the University and Institute of Physics in Giessen in 1879; and Professor of Physics at Würzburg, Bavaria, in 1888. In 1896 he made use of the power of penetrating metals and other opaque bodies, possessed by certain rays emanating from tubes with high vacua (see Geissler's Tubes), to photograph hidden objects, such as the bones of the hand within the flesh, a set of weights in a box, a compass-card and needle inclosed in a metal case, etc. This property was first noted by Hertz (*q. v.*), and in 1894 Lenard published a memoir upon it (see Wiedemann's *Annalen*, vol. li., p. 225), in which he showed, among other things, that photographs could be taken by means of these rays through an intervening shutter of aluminium. See *Nature*, vol. liii., p. 274. See X-rays.

Rood, Ogden N., LL. D.: physicist; b. at Danbury, Conn., Feb. 3, 1831; graduated at Princeton 1852; studied at Sheffield Scientific School and at the Universities of Munich and Berlin; elected Professor of Physics and Chemistry in Troy University 1858; Professor of Physics in Columbia College, New York, 1863; member of the National Academy of Sciences, 1864. He was among the first to apply photography to the microscope, and the first to construct fluid prisms of highly dispersive power for the study of the spectrum. He has made several original investigations in photometry and physiological optics. See his *Modern Chromatics* (1881).

Roodhouse: city; Greene co., Ill.; on the Burlington Route and the Chi. and Alton R. R.; 21 miles S. W. of Jacksonville (see map of Illinois, ref. 7–C). It is in an agricultural region, and has 2 private banks, a daily and 2 weekly newspapers. Pop. (1890) 2,360; (1900) 2,351.

Rood-screen: See Choir.

Roof [M. Eng. *rof* < O. Eng. *hrōf*]: the covering of a building. As generally used, the term includes the covering and the framework which supports it, though in carpentry the use of the word is restricted to the latter meaning. Roofs vary greatly in form and material, and require a higher degree of skill and science than any other part of a building. Greek temples were covered with long thin pieces of marble; the roofs of the halls of the ancient Assyrians and Babylonians consisted of exceedingly large stones, some of them so big as to cover a whole room singly. In the East there are remains belonging to prehistoric times of buildings of a circular shape, in which a column standing in the center was evidently intended to support rafters whose outer ends rested upon the inclosing wall.

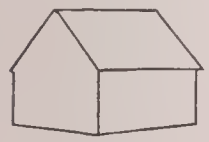

Fig. 1.

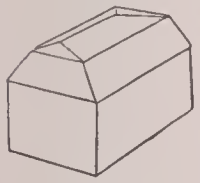

Fig. 2.

The inclination or pitch of a roof is generally a matter of taste alone, and not of climate, though with some coverings a certain inclination is necessary. In England and in France in the later times of mediæval architecture the roof underwent a very different development; in the former country, though of a higher latitude, it became flatter; in France and in Germany high and steep. To the flat roofs were added parapets, and the church-towers were built without spires and were furnished with parapets. In France the roof grew with the rest of the building, and on the tower, when spires had fallen into disuse, it assumed almost the inclination if not the place of the spire. In Persia and Arabia the roofs are flat; in Greece invariably sloping, made on an angle of about 16° with the horizon; in Rome on an angle of about 24°. In hot climates the chief reason for the flatness of the roofs is that they may serve as terraces in the cool of the evening and morning, and for this purpose they are covered with concrete or cement carried on joists like a floor.

Fig. 3.

When the base is a circle, an ellipse, or a polygon, and its vertical section a curved line concave toward the interior, the roof is termed a dome or cupola. Different names are given to roofs according to their forms; thus Fig. 1 is a gabled roof; Fig. 2 a gambrel, curb, or mansard roof (the term mansard is from a French architect, Mansart, who died in 1666); Fig. 3 a conical roof. Fig. 4 shows a very simple frame for a roof, consisting of two rafters resting at their lower ends upon the wall or frame of the house; sometimes the rafters are prevented from spreading by a collar-beam uniting them near their lower ends. Fig. 5 is a king-post frame or truss, suitable for a span of 35 to 40 feet, where A is the ridge; B, purlin (a beam at right angles to the rafters); C, king-post; D, strut; E, tie-beam; F, pole-plate; G, wall-plate; H, common rafter; I, principal rafter. Fig. 6 is a Norman roof. Fig. 7 is the celebrated roof of Westminster Hall, completed in A. D. 1399, of which the span is 68 feet. The horizontal pieces resting upon the walls are termed hammer-beams. This span is unusually large, as the span of the Gothic roofs seldom exceeded 35 feet. The builders of these roofs aimed to construct them of very short pieces of timber, always oak or other hard wood, which were very strongly fastened together. The thrust of this roof against the walls is prevented to a great extent by the rigidity of the frame, which causes it to act somewhat as a beam. The woodwork of the Gothic roofs was very elaborately carved and ornamented. In the roof of St. Paul's, Rome (Fig. 8), destroyed by fire during the nineteenth century after having stood over 400 years, the king and queen posts were not framed into the tie-beam, but attached by iron straps. This is one of the earliest instances where iron has formed a feature in the construction of roofs. The span of this was 78 ft. 4 in.

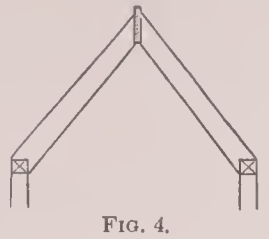

Fig. 4.

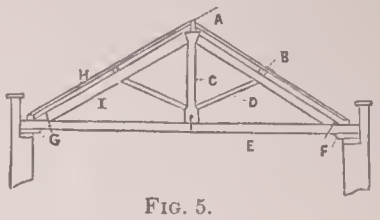

Fig. 5.

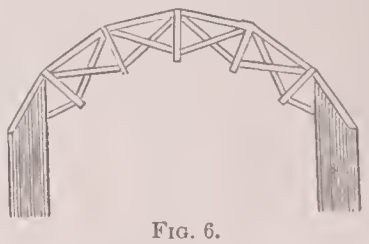

Fig. 6.

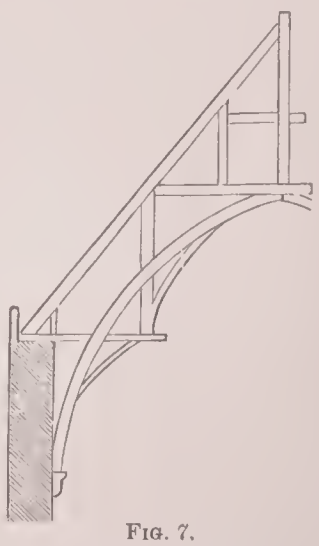

Fig. 7.

The use of iron for roofs has become very general on account of the many advantages which it possesses, such as economy, lightness, and facility of transportation and erection. Figs. 9, 10, 11, and 12 illustrate some of the simpler and more generally used forms of trusses made of iron; they are so tied as to prevent any outward thrust against the walls. The roof over the central transept of the Crystal Palace, Sydenham, England, is arched and composed of two semicircular ribs connected by double-lattice bracing. The whole of the roof is of wrought iron, the covering being entirely of glass on the ridge-and-furrow principle. The span is 120 feet, and the arch is of such depth that it exerts but little horizontal thrust upon the supporting walls. The roof of the Royal Albert Hall, Kensington, is oval, with four centers; the half of one of the trusses is shown in Fig. 13, the span being 219 feet by 185 feet. The roof of the rotunda of the Vienna Exhibition of 1873 was conical, the span being 343 ft. 9 in. One of the largest roofs ever built is that of the machinery hall of the Paris Exposition of 1889, whose length is 1,390 feet, and whose trusses have the span of 346 feet, each side being flanked by a gallery which increases the total width to 492 feet.

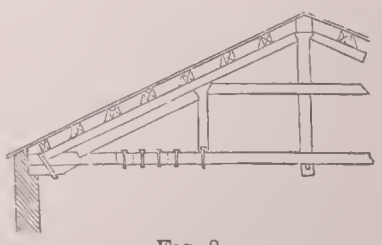

Fig. 8.

Fig. 9.

Fig. 10.

The trainshed of the Pennsylvania Railroad at Jersey City, N. J., has roof-trusses with a span of 252 feet, while its total length is 650½ feet. The roof of the St. Pancras Station in London is 690 feet long, with a span of 243 feet. The dimensions of the building for the exhibition of manufactures at the Columbian Exposition of 1893 in Chicago were 787 feet by 1,687 feet, and the main roof-trusses had a span of 368 feet.

Fig. 11.

Fig. 12.

Fig. 13 shows the iron framing of a mansard roof. These roofs (which have since their invention formed so common a feature of French architecture) of different styles, slopes, and coverings have been very generally adopted for many classes of buildings both in the city and in the country. They were at first built almost exclusively of wood and covered with slate, but the great liability to take and communicate fire has caused the use of iron and steel for framing purposes.

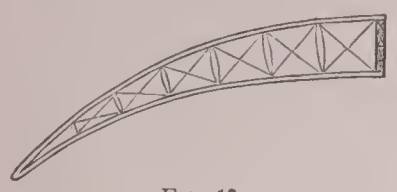

Fig. 13.

The coverings for roofs are made of various materials, among which may be mentioned the following: Thatch of straw, reeds, and heath, used probably in primitive times, and even in the present age, in rude dwellings; tiles of various shapes, which have been used from the Roman period to the present, and which probably covered the Saxon buildings; thin slabs of stone or flag; slate; lead, which was always used on mediæval roofs; tin, iron, zinc, copper; asphalted felt coated with a hot preparation of tar on which gravel is spread; shingles; canvas covered with cement and glass.

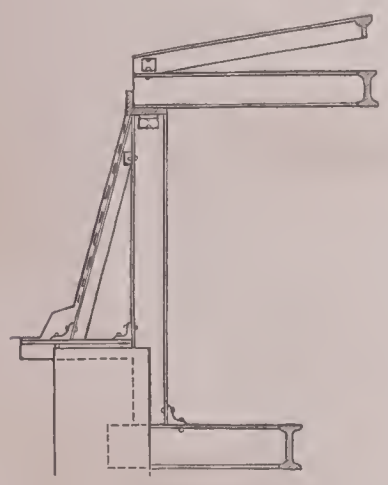

Fig. 14.

The principles governing the design of roof-trusses are similar to those for bridge-trusses, the main differences being in the data regarding snow and wind loads. The snow load is taken at various values, depending on climate, up to 15 or 20 lb. per square foot of horizontal area. The wind pressure on a vertical plane is taken at from 30 to 50 lb. per square foot. See the articles Arch, Bridges, and Stresses; also Greene's *Graphical Analysis of Roof Trusses* (1876); and Ricker's *Construction of Trussed Roofs* (1885).

Revised by Mansfield Merriman.

Rook [O. Eng. *hrōc*: O. H. Germ. *hruoh*: Icel. *hrōkr*; cf. Goth. *hrukjan*, to crow: Sanskr. *kruç-*, cry out, croak]: a bird (*Corvus frugilegus*) of the family *Corvidæ*, closely related to the common crow, which it also resembles nearly in size (it is a little smaller), as well as black color; but distinguished therefrom by the bill being little longer than the head, and in the adult naked at the base; the first primary is shorter than the eighth, the second shorter than the fifth, and the third and fourth are the longest. It is generally distributed throughout Europe and Eastern Asia. It lives in communities known as rookeries; these sometimes are very populous, occasionally containing from 2,000 to 3,000 nests, and a corresponding number of birds of different ages and sizes. In Great Britain they are considered by many an attractive feature in the landscape, and are therefore protected. The nests are generally made in tall trees. The female lays, early in the spring, about four or five greenish-blue and spotted eggs. The species is omnivorous, but does not trouble the farmer, like the crow. It is capable, like its congeners, of mimicking the sounds of other animals. The young are to some extent used as food in Great Britain and on the Continent.

Revised by F. A. Lucas.

Roon, rōn, Albrecht Theodor Emil, Count von: soldier; b. near Kolberg, Prussia, Apr. 30, 1803; entered the army in 1821; attended the military school of Berlin 1824–27; appointed teacher to the cadets in 1828, member of the topographical survey of the staff in 1833, teacher in the military school in 1835, and captain on the staff in 1836. In 1842 he was made a major, and subsequently took charge of the military instruction of Prince Frederick Charles. During the campaign in Baden he was chief of the staff of the Eighth Army-corps; was made a colonel in 1851, commander of the Twentieth Brigade of infantry in 1856, and commander of the Fourteenth Division at Düsseldorf in 1858. On Dec. 5, 1859, the prince-regent called him to take charge of the ministry of War, and (Apr. 16, 1861) also of the ministry of the Marine. After the war of 1866, which gave evidence of his talent for organization, he received from the king the cross of the Black Eagle and a dotation, and after the war with France (1870–71) he was made a count and received a new dotation. The office of Minister of the Marine he resigned Dec. 31, 1871. In the Prussian Government he represented a specific Prussian tendency in opposition to the policy of Prince Bismarck, and (Dec. 21, 1872), having handed in his resignation, he was made president of the cabinet, and a few days afterward field-marshal, but resigned in 1873. D. in Berlin, Feb. 23, 1879. See von Gossler, *Graf Albrecht von Roon* (Berlin, 1879).

Roosa, D. B. St. John: See the Appendix.

Roosevelt, Robert Barnwell: Congressman and author; b. in New York, Aug. 7, 1829; studied law, and was engaged in active practice for many years, but finally devoted himself to literature, rural sports, and politics, and in 1870 was elected to Congress; became president of the New York Sportsmen's Club; was one of the State commissioners of fisheries for many years; U. S. minister to the Netherlands 1888–89; edited *The Citizen*, a weekly journal devoted to literature and politics; published *The Game Fish of North America* (New York, 1860), *The Game Birds of the Coast and Lakes of the Northern States* (1866), and similar works; and edited, with a biographical sketch, *The Poetical Works of Charles G. Halpine* (1869).

Roosevelt, Theodore, LL. D.: twenty-sixth President of the U. S.; b. in New York city, Oct. 27, 1858. His father, also named Theodore, a merchant and philanthropist, was of Knickerbocker stock, and his mother was a descendant of Archibald Bulloch, the first President of Georgia in the Revolution. He was prepared for college in private schools, and was graduated at Harvard in 1880. After traveling in Europe he began the study of law, but abandoned it for politics. In 1881 he was elected by the Republicans to the Assembly from the Twenty-first District of New York city, and was twice re-elected. The first two Legislatures in which he sat were Democratic. In his second year he was leader of the minority in the Cities Committee, and he became its chairman in the Republican Legislature of 1884, after being an unsuccessful candidate for Speaker. He was active in promoting the passage of the first New York civil-service laws, was chairman of a committee that investigated abuses in New York city, and secured acts abolishing the fee system in county offices and depriving the aldermen of veto power over the mayor's appointments. He favored a bill reducing elevated-railroad fares, but when Gov. Cleveland vetoed it he sustained the veto. In 1884 he was a delegate at large to the Republican National Convention, where he advocated the nomination of George F. Edmunds, but he supported Mr. Blaine in the campaign. The Republicans nominated him for mayor of New York in 1886 against Henry George, the United Labor candidate, and Abram S. Hewitt, the Democratic candidate, who was elected. President Harrison appointed him a civil-service commissioner in 1889. He served efficiently until May, 1895, when he resigned, and became president of the New York city Board of Police Commissioners in the administration of Mayor Strong. He established a policy of strict enforcement of liquor and Sunday laws, which aroused much opposition.

Mr. Roosevelt was appointed Assistant Secretary of the Navy in April, 1897, and took an important part in the preparations for the Spanish War. At the outbreak of hostilities he resigned his office and raised, largely among the Western cowboys, a regiment of volunteer cavalry, who were popularly known as Rough Riders. He became lieutenant-colonel, with Dr. Leonard Wood, of the regular army, in command. From 1884 to 1888 he had been a member of the Eighth Regiment, National Guard of New York. The Rough Riders (unmounted) were with the army before Santiago, and took part in the fight at Las Guasimas, June 24,

1898, and in the capture of San Juan Hill on July 1. Col. Wood was promoted brigadier-general on July 8, and Lieut.-Col. Roosevelt became colonel. He was mentioned in the reports for gallant conduct in battle, and was distinguished for care of his men in camp.

Col. Roosevelt returned with his regiment to Montauk Point in August, 1898, was nominated for Governor of New York by the Republicans at Saratoga, Sept. 27, 1898, and was elected for the two years' term beginning Jan. 1, 1899, by a plurality of 17,786 over Augustus Van Wyck, Democrat. As Governor he reformed the administration of the canals, favored the enactment of an improved civil-service law, and applied the merit system in county offices. By a special message he induced the Legislature of 1899, at the end of the session, to pass an act taxing as real estate the value of railroad and other franchises to use public streets. Corporations and Republican leaders protested, but the Governor said he would sign it as it stood unless they could improve it without destroying its essential features. He called an extra session, secured the passage of the bill in modified form, and established the principle of street-franchise taxation.

Columbia University made Gov. Roosevelt a doctor of laws in 1899. Early in 1900 he was mentioned for Vice-President, but he desired a second term as Governor, and repeatedly announced that under no circumstances would he accept the vice-presidency. But New York party leaders joined Western delegates who were enthusiastic over Gov. Roosevelt's military record, and at the Philadelphia convention on June 21, 1900, forced him to accept the nomination for Vice-President. He made an extended speaking tour through the Western States, and was elected for the term beginning March 4, 1901, receiving 292 electoral votes, while 155 were cast for Adlai E. Stevenson, the Democratic candidate.

After the assassination of President McKinley, Sept. 6, 1901, the Vice-President hurried to Buffalo, but he left the city upon the apparent assurance of the President's recovery. He returned upon the news of President McKinley's death, Sept. 14, 1901, and on the afternoon of the same day, at the residence of Mr. Ansley Wilcox, in Buffalo, took the oath as President of the U. S. He outlined his policy in these words, spoken to the cabinet members and a few friends gathered for the occasion: "In this hour of national peril and sorrow I will say that it is my purpose to continue unbroken the policies of President McKinley for the peace, prosperity, and honor of the United States."

In 1882 he published a *Naval History of 1812*. This was followed by *Hunting Trips of a Ranchman*, in 1885; a *Life of Thomas H. Benton* in 1886, and a *Life of Gouverneur Morris* in 1887, both in the American Statesmen Series; and in 1888 by *Essays in Practical Politics* and *Ranch Life and Hunting Trail*. The first two volumes of his most important work, *The Winning of the West*, were issued in 1889. In 1890 he wrote a *History of New York City* for the Historic Towns Series; in 1893, *The Wilderness Hunter*; and the next year published the third volume of *The Winning of the West*. In 1897 he collected a volume of essays entitled *American Ideals*, which he followed with *The Rough Riders* in 1899, and *Oliver Cromwell* and a volume of addresses entitled *The Strenuous Life*, in 1900. He is also the author, in collaboration with Henry Cabot Lodge, of *Hero Tales from American History*, and he was one of the assistants of William Laird Clowes in the preparation of *The Royal Navy*.

Root, George Frederick: See the Appendix.

Roots: See Botany.

Ropes and Rope-making [*rope* is from O. Eng. *rāp*, rope: O. H. Germ. *reif*, cord, circular band > Mod. Germ. *reif*, hoop, circular band]: Rope is a general name of the stouter forms of cordage, and especially of those whose circumference exceeds an inch. They are generally made of hemp, which is first hackled or combed out to remove the dust and tow. The hackle consists of a strong board with long vertical steel prongs sharply pointed and polished. The hackling is done by hand.

The preparation machines hackle the hemp still finer for spinning into yarn. The first of these is the spreader, a machine having two endless chains fitted with gill-bars and gill-pins (steel teeth), which combs or straightens out and evens the fibers. Its spreader is fed with the hackled hemp at one end, which it throws out in a sliver from the other. From the spreader the sliver is passed through two or more drawing-frames, by which it is drawn down still more and the fibers still further combed out straight, the size of the sliver being reduced at each step. The drawing-frame is similar to the spreader, but has only one chain. The sliver is then passed to the spinner, where it is spun into yarn, and at the same time reeled upon a bobbin. An improvement in the spinner, the invention of John Good, of Brooklyn, N. Y., tubes the yarn, rendering it smoother and more even than any process yet devised. The yarn is spun right-handed. The size of the yarn varies according to the kind of rope for which it is intended. Forties—so called because forty yarns will just fill a half-inch tube—are for the finer kinds of rope; twenties, requiring twenty to fill the tube, are for cables, hawsers, etc. From the spinning-room the bobbins containing the yarn are taken to the tar-house, where they are placed in frames conveniently arranged with reference to the tar-box. This is a long box filled with tar kept during the operation of tarring at a temperature of 220° F. by means of steam-heaters. The yarns are led from the bobbins in the frame through two or more guide-plates working in a vertical plane over the tar-box, and convenient for lowering into the tar; thence to the further end between metal rollers, which press out and return to the box the superfluous tar, on to a large wooden drum to cool them; through fair-leaders, and finally to a fresh set of bobbins, where they are wound up with the utmost regularity. The bobbins containing the tarred yarn go to the laying-ground, where they are placed in frames, when the yarns are ready for hauling down, or making into strands. The laying-ground, where the rope is laid up, occupies the entire length of the ropewalk. The yarns for the strands, generally three in

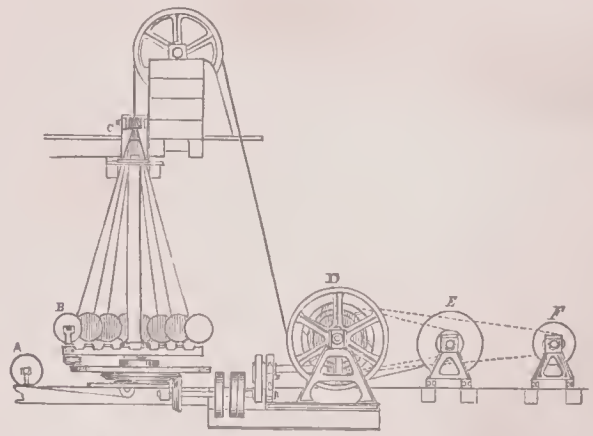

Fig. 1.—A twelve-flyer machine, for forming the strands: A, heart; B, bobbins; C, top and tube; D, draw-off drum; E, bobbin for larger sizes; F, bobbin for smaller sizes.

number, are led from the bobbins in the frame through holes bored on concentric circles in a metallic plate, thence through a tube adapted to the size of the strand, and attached to a hook on the end of a spindle in a movable machine like a car, called the former. There are a plate, a tube, and a hook for each strand, and the number of yarns to a strand is regulated by the size of the intended rope. When the machinery is put in motion, the former is drawn down the walk, and the yarns as they are hauled through the tubes are formed into left-handed strands. Closing the strands is the next step, for which two machines are used. The lower one—the layer—lays up or closes the rope, and is movable; the upper one, which keeps the proper twist in the strand while laying, is stationary. Each strand being secured to its proper spindle, the machinery is put in motion and the strands hardened. A press attached to the layer prevents too much drawing up, as the strands shorten in by the additional twisting. After hardening, the strands are placed together on a central spindle of the layer and closed, a top inserted between them preventing too rapid closing. The top is a wooden cone with grooves cut to hold the strands, while tails of soft rope attached to it, by being applied to the rope as it is made, still further prevent, by the additional friction, the too rapid closing of the strands. The layer makes two revolutions to one of the upper machine. The skill of the rope-maker consists in knowing how to gear his preparation machines so as to draw a clean and uniform sliver, in giving the proper degree of twist to the yarn and strand, the amount of hardening, and the speed of the top in closing. The foregoing process gives right-handed tarred rope of three strands (plain laid). By not tarring the yarns white rope is produced. This is the strong-

est, though when exposed to the weather not the most durable, of all in common use.

In the manufacture of manila rope the first step in the foregoing description, hackling by hand, is omitted, as unnecessary: the manila is oiled to enable the harsher fiber to pass the more readily through the preparation machines,

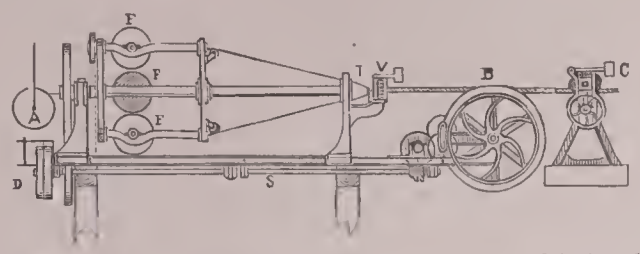

Fig. 2.—Wire rope: A, heart; B, draw-off drum; C, friction-drum; D, driving-pulley; F, bobbins; T, top; V, tube; S, driving-shaft.

and the yarns are not tarred; the remainder of the process is the same in both cases. The size of rope is designated by its circumference; when smaller than $1\frac{1}{4}$ inch it goes under the general name of small stuff. Three ropes laid up together form a cable or hawser of nine strands.

Wire rope may be made either of 49 coarse wires or 133 fine wires, put in 6 strands, and 7 or 14 hearts, and laid up right-handed; strands are laid left-handed. To make a 7-inch fine wire rope, as in the annexed diagram, fill the bobbins of a 6-flyer machine, similar to Fig. 1, with No. 8 wire, Birmingham gauge, and for the heart lead a single wire from its bobbin up through the vertical shaft. This will

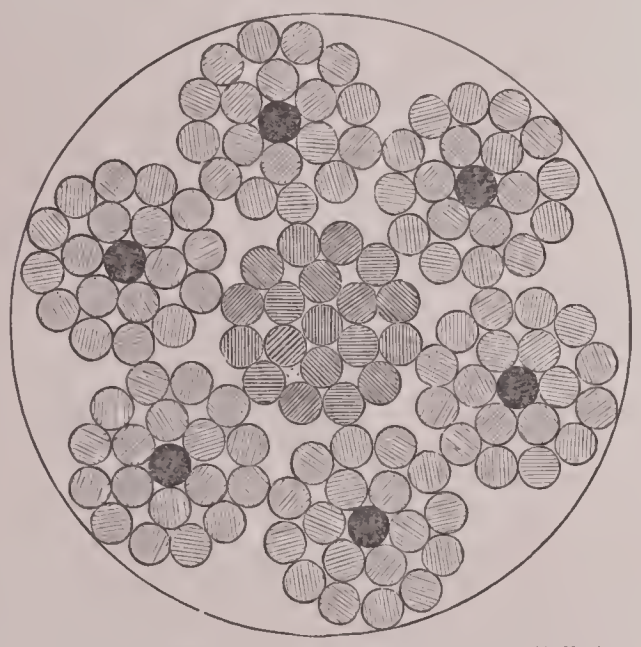

Fig. 3.—Cross-section of wire rope of 133 wires (full size).

form a 7-wire heart for the strands. Next fill the bobbins of a 12-flyer machine (Fig. 1) with the same size wire, placing the heart just made as in the figure. Pass all the wires up through holes past the top, arrange the wires through the grooves of the top, twist them together by hand, splice in a piece of rope, and pass it five or six times around the draw-off drum. Friction-straps attached to the bobbins preserve an equal tension on the wires. Putting the machine in motion, the 7-wire heart is drawn up the shaft, and at the same time the 12 single wires are wrapped about it as the disk revolves, each separate bobbin turning on its own center in an opposite direction, so as to avoid twisting the wire. As the strand is formed it is reeled upon a bobbin. Having filled 7 bobbins, 6 are placed in a machine similar to Fig. 2, and 1 in the rear for a heart. The heart, on motion being given to the machinery, is drawn through, and the 6 strands wrapped about it, giving 1 central and 6 outer strands of 19 wires each. In making strands for wire rigging it is the practice to substitute hemp for the single wire of the heart, and to make a hemp heart for the rope. It is plain from the preceding diagram that the diameter of the required rope, divided by 15, will give the diameter of the single wire, from which, by tables in common use, the proper gauge may be found.

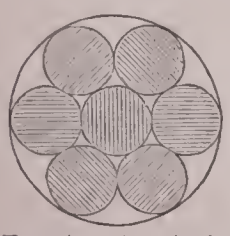

Fig. 4. — A single strand of a 49-wire rope.

Fig. 4 shows the cross-section of a single strand of a 49-wire rope, the 6 strands and the heart all being of the same size. The size of the required rope being given, divide the diameter by 9 to find the diameter, and from the tables the gauge of the wire to be used. Knowing by the old rules the proper size to make a given piece of hemp rigging for a ship, the corresponding size of wire rope may be found from tables giving the comparative strength of ropes of the two materials. When flexibility is required, annealed wire is used and hemp hearts supplant the wire ones, as indicated by the deeply shaded centers of the 6 strands in Fig. 3, and a hemp heart takes the place of the central strand or wire heart (Fig. 3). In this case there will be 18 wires to each of the 6 strands, making a total of 108 wires in all, instead of 133 as before. So, in Fig. 4, if a twine heart in each strand be substituted for the wire, there would be a wire heart in the rope of 6 wires, laid up in 6 strands of 6 wires each; total, 42 wires, instead of 49, as above stated. The size of the wire, it is evident, determines the size of the rope. Steel wire is about 56 per cent. stronger than iron wire and 65 per cent. stronger than annealed iron wire. Both steel and iron wire may be galvanized without detracting from its strength. S. B. Luce.

Roquefort, Fr. pron., rōk′fōr′: a small town in the department of Aveyron, France; on a mountain 4,800 feet high, 10 miles S. W. of Millau (see map of France, ref. 8–F). It is famous for its cheese made from ewe-milk. (See Cheese.) The limestone mountain is honeycombed with caverns, in which the cheeses are kept through the summer. Pop. about 1,000.

Roqueplan, rōk′plăăṅ′, Joseph Étienne Camille: painter; b. at Mallemort, department of Bouches-du-Rhône, France, Feb. 18, 1802; studied painting at Paris under Gros and Pujol; began to exhibit in 1822; attracted great attention in 1827 by two pictures for which he had chosen the subject from Walter Scott's romances, and became soon one of the leaders of the modern French school of painting. The most remarkable of his pictures are *The Amateur Antiquary*, in which there is very skillful painting of rich and varied objects of decorative art, and his genre pieces and landscapes from the Pyrenees, among which is *The Well near the Tall Fig-tree.* For several years in the latter part of his life he suffered much from ill-health. D. in Paris, Oct. 15, 1855.

Roraima: See the Appendix.

Rorqual: same as Fin-back (*q. v.*).

Rosa, Euphrosyne (*Parepa*): singer: b. in Edinburgh, Scotland, May 7, 1836; daughter of Demetrius Parepa, Baron de Boyescu, a Wallachian nobleman, and Elizabeth Seguin, a professional singer; was carefully trained by her mother; made her *début* on the operatic stage at Malta as a soprano singer; appeared with success at London 1857; married Captain Carvell of the East India service 1863; became a widow 1865; sang in the U. S. with the Bateman troupe 1865, and again 1866–67; enjoyed great popularity, especially in oratorios; married the violinist Carl Rosa 1867; organized with her husband an English opera-troupe, with which they sang in the principal cities of the U. S. 1869–72; was at the khedive's court in Egypt during the winter of 1872–73, and afterward made another tour in the U. S. (1873). D. in London, England, Jan. 21, 1874.

Rosa, Francisco Martinez, de la: See Martinez de la Rosa, Francisco.

Rosa, Pietro: archæologist; b. in Rome, Italy, about 1815. He was educated as an architect, but as early as 1848 he became almost exclusively interested in archæological researches in Rome and its vicinity. One of his early undertakings was a large-scale map of Latium, with the ancient sites determined, but the constant succession of new discoveries, overturning old theories, has kept this work in hand and unfinished for many years. Meantime he was busied upon the tombs of the Appian Way and their theoretical restoration. In 1861 the French Government charged him with the study of the camp of the Pretorian Guard at Albano, and of the buildings on the Palatine Hill. In 1872 and later he conducted important researches in the Roman Forum, and was director of these at the time of the discovery of the Basilica Julia. His publications are chiefly papers in the archæological journals and monographs of no great extent, but his services as a discoverer and organizer are generally recognized. He was senator of the kingdom of Italy and a member of the Legion of Honor. D. in Rome, Aug. 15, 1891.

Russell Sturgis.

Rosa, Salvatore: painter; b. at Renella, near Naples, July 21, 1615. A relative (Ciceio Fraeanzano) first gave him instruction in art. Eneouraged by Lanfranco, who bought one of his landseapes, he went to Rome in 1635, where he was patronized by the Neapolitan cardinal Braneaeei, Bishop of Viterbo. After painting for the cardinal at Viterbo, he returned to Naples. His pieture of *Prometheus* having made a great sensation in Rome, he established himself there in 1638. D. Mar. 15, 1673. He chose as subjeets wild and romantic aspects of nature, which he always treated appropriately. Examples of his work are to be found in most eolleetions. The National Gallery in London has several fine landscapes by this master. Passeri, *Vite de' Pittori*, is a reliable authority to eonsult for further details, as he was a personal friend of Salvatore Rosa. Many improbable stories have been told of Rosa; these Lady Morgan eolleeted in her romanee *The Life of Salvator Rosa*. He was also an eteher. W. J. Stillman.

Rosa'ceæ [Mod. Lat., named from *Ro'sa*, the typieal genus, from Lat. *ro'sa*, rose]: an important family of polypetalous dieotyledonous trees, shrubs, and herbs, eomprising over 1,000 species, mostly of northern temperate regions. The rose, apple, pear, quinee, cherry, plum, peach, aprieot, almond, blackberry, raspberry, strawberry, ete., belong to this family. In general, it is distinguished by having alternate leaves with stipules, along with regular flowers, generally indefinite or numerous perigynous stamens and definite seeds without albumen. It divides into marked sub-orders, of which the following are the prineipal: (1) *Amygdaleæ*, or the almond family, with a single simple and free pistil, beeoming a stone-fruit, sueh as that of peaeh, plum, and cherry. (2) *Rosaceæ* proper, with dry or berry-like fruits, from numerous or few (seldom single) free pistils, and stipules joined with the petiole. To this belong the small fruits above mentioned and a great variety of useful and ornamental plants, both herbs and shrubs. (3) *Pomeæ*, the apple family, with two or more pistils combined with eaeh other and with a fleshy ealyx-tube, which forms the edible fruit. The fruits of the *Rosaceæ* are all innoeent, exeept that of the eherry-laurel, but the kernels of the stone-fruits contain a poisonous prineiple identical with or analogous to prussie acid, along with a bitter essential oil; and these qualities extend more or less to the bark and foliage. The most aetive artiele of the materia mediea furnished by this family is from the koso-tree of Abyssinia (*Brayera anthelmintica*), the flowers of which are a powerful vermifuge. Astringency generally prevails in the herbage of the family. It yields many useful products, but is most important for its fruits and its ornamental flowers.

Rosamund: a Lombard queen. See Alboin.

Rosan'iline: See Aniline Colors.

Rosa of Lima (secular name, Isabel Flores): saint; b. at Lima, Peru, in 1586. Her parents, who were wealthy Spaniards, lost their property, and she supported them by her labor while living as a reclusc in the habit of the third order of St. Dominic. D. at Lima, Aug. 24, 1617. She was canonized by Pope Clement X. in 1671, and is the only saint of American birth in the Roman calendar.

Rosa'rio, or **Rosario de Santa Fé, El**: a city of the province of Santa Fé, Argentine Republic; on the west side of the delta of the Paraná, 214 miles by the river above Buenos Ayres (see map of South America, ref. 8–D). Until 1852 it was an insignificant village. Urquiza, in his struggle against the supremacy of Buenos Ayres, made it the chief port of the confederated provinees (1854), and sinee then it has grown rapidly. It is the second eity of the republic in size and importanee, and is conneeted with the interior by a network of railways; transatlantic steamers ascend regularly to this point. The city, on flat land 65 feet above the river, is laid out in regular squares, with wide streets; it is substantially built, resembling a town in the eastern part of the U. S. Almost exclusively a commercial place, it is chiefly remarkable for its great elevators and storehouses. It has numerous banks, shops, and hotels. Therc is a large foreign element. The most important exports are wheat and flour; steamers load direetly at the wharves. The climate is temperate and salubrious. Pop. (1895) 94,025. Herbert H. Smith.

Rosary [from Late Lat. *rosa'rium*, string of beads, liter., garland, garland of roses < Lat. *rosa'rius*, pertaining to or made of roses, deriv. of *ro'sa*, rose]: (1) a series of prayers prescribed by the Roman Catholic Chureh. The greater rosary is a synonym for the whole series, and is made up of three lesser rosaries. Each of the three lesser rosaries eontains five deeades or mysteries. Eaeh deeade contains one meditation upon one of the fifteen mysteries of the faith, one Pater Noster, or repetition of the Lord's Prayer, ten Ave Marias, and one Gloria Patri. (2) The ehaplet or string of beads used in the repetition of the rosary. The Pater Nosters are marked by large beads, and the Ave Marias by smaller ones. The beads are of various materials, and are blessed by the pope or by some duly authorized eeelesiastic. The beads serve as counters during the reeitation. They are also in use among Arabs and Hindus, but they are, nevertheless, of eomparatively late oeeurrenee in Europe. They were first used by the Dominicans, though St. Dominic himself seems not to have known them. Probably they were introdueed into Europe by the crusaders. There are various forms of rosaries; that generally used has fifty-five beads—namely, five deeades of Ave Maria beads and five Pater Noster beads. The confraternity of the Rosary was founded at Cologne in 1475.

Rosas, Juan Manuel, de: dictator; b. at Buenos Ayres, Mar. 30, 1793. He first became prominent as a leader of the gaucho eavalry, and in 1827 was made eommander of the rural militia or poliee of Buenos Ayres under Dorrego. After Dorrego's deposition and death (1829) he assumed the leadership of the federalist party, and for some months carried on a civil war with the *unitario* ehief, Lavalle, who was forced to resign. Rosas then beeame governor of Buenos Ayres 1829–32; his sueeessor, Balcaree, was deposed, and Rosas again beeame governor, with extraordinary powers, Mar. 7, 1835. From this time he was praetically dietator of Buenos Ayres, and by intrigue, foree, or foul means he obtained control of most of the other provinees, putting his ereatures in command of them; thus a loose confederation was formed, a number of petty dietators reigning like so many kings in their provinces, but nearly all taeitly aeknowledging the supremaey of Buenos Ayres. Rosas used his power in the most tyrannieal manner, and often with savage though hidden eruelty. His poliey was to keep the country isolated and ignorant. Commeree was plaeed under severe restrietions; few foreigners were permitted to enter the republic; the press was muzzled; and hundreds of persons were assassinated or exiled. Many fled to Montevideo, whieh beeame the focus of opposition to Rosas, and eonsequently the objeet of his espeeial hatred. Hoping to make it subservient to him like the provinees, he aided the exiled president, Oribe, who maintained a eivil war in Uruguay from 1842 to 1851, but did not sueeeed in taking Montevideo. Rosas perseeuted foreign residents, and paid little heed to the repeated remonstrances of Franee and Great Britain. A Freneh fleet bloekaded Buenos Ayres intermittently from 1838 to 1845, and finally Great Britain and France actively interfered to protect Montevideo; their combined fleets bombarded and captured Rosas's intrenehed eamp at Punta de Obligado (Nov. 20, 1845), but nothing further was done. The leaders of the *unitario* party repeatedly ineited rebellion in the interior, and the attempts of Lavalle (1838–41) for a time promised sueeess; but in the end all were beaten, and the eivil wars only increased the miseries of the eountry. In 1851 Brazil interfered to proteet the independence of Uruguay, and was joined by Urquiza, dietator of Entre Rios. Their eombined forees, under Urquiza, raised the siege of Montevideo, invaded Buenos Ayres, and defeated the army of Rosas at Monte Caseros Feb. 3, 1852. The fallen dictator fled to a British vessel, and was taken to England. He purehased an estate near Southampton, where he lived in retirement until his death Mar. 14, 1877. Rosas was the worst because the most powerful of the South Ameriean dictators. His name is execrated throughout Spanish America.

Herbert H. Smith.

Roscelin, ros'lăn' (*Roscellinus*, *Rousselin*, *Rucelinus*): the so-called founder of nominalism; b. in the diocese of Soissons in the middle of the eleventh century, and educated at Rheims; was attached to the Cathedral of Chartres; lived at Compiègne as eanon; while there he greatly startled people by his tritheistic eonception of the Trinity. He could not understand how God could be a person without being an individual, and thus he dissolved the Trinity into three Gods. A synod was convened at Soissons in 1092 to consider the matter, and, as Roscelin had quoted both Lanfrane and Anselm as being in favor of his views, Anselm drew up his *De fide Trinitatis*, which is a complete refuta-

tion of Roscelin, and laid it before the synod. Roscelin was condemned and recanted, but continued, nevertheless, after his return to Compiègne, to propagate his tritheistic doctrines. He afterward settled as a teacher at Tours, and later at Loc-menach, near Vannes, in Brittany, and to this last period of his life belongs his controversy with Abelard. Abelard was a pupil of his, but in his *De Trinitate* (*Introductio in Theologiam*) he found it expedient, evidently with an eye to the decisions of the Synod of Soissons, to emphasize the unity of the Trinity with great strength. Enraged, Roscelin denounced him to Gisbert, Bishop of Paris, for various other heresies, and Abelard answered by a direct and violent attack (Ep. xxi.). After that time (1121) Roscelin disappears from history. The only writing of his extant is a letter supposed to be addressed by him to Abelard. It is probable that he wrote little. His importance in the history of nominalism has led to the close study of such representations of his teachings as are to be found in the writings of his opponents. See the histories of philosophy by Ueberweg and Erdmann. Revised by S. M. Jackson.

Roscher, Wilhelm Georg Friedrich, Ph. D.: political economist; b. in Hanover, Germany, Oct. 21, 1817; educated in Hanover and at the Universities of Göttingen and Berlin; professor at Göttingen University 1844–48; became professor at Leipzig University 1848; was Doctor Honorarius of Law in the Universities of Königsberg, Edinburgh, and Bologna; Doctor Honorarius of Political Economy in the University of Tübingen; member honorarius of the Universities of Kasan and Kiev, and *Ehrenbürger* of Leipzig University. His principal works are *De historicæ doctrinæ apud sophistas majores vestigiis* (Göttingen, 1838); *Leben, Werk und Zeitalter des Thukydides* (1842); *Grundriss zu Vorlesungen über die Staatswirthschaft* (1843); *System der Volkswirthschaft* (4 vols., Stuttgart, 1854–86; vol. i., 20th ed. 1892; vol. ii., 12th ed. 1888; vol. iii., 6th ed. 1892; vol. iv., 3d ed. 1889); *Kolonien, Kolonialpolitik und Auswanderung* (1847; 3d ed. 1885); *Ueber Kornhandel und Theuerungspolitik* (Stuttgart, 1847; 3d ed. 1852); *Zur Gründungsgeschichte des Zollvereins* (Berlin, 1870); *Geschichte der Nationalökonomik in Deutschland* (2 vols., Munich, 1874); *Andichten der Volkswirthe aus dem geschichtlichen Standpunkte* (2 vols., Munich, 1861; 3d ed. 1878); *Umrisse zur Naturlehre des Cäsarismus* (1888); *Umrisse zur Naturlehre der Demokratie* (1890); and *Politik, geschichtliche Naturlehre der Monarchie, Aristokratie und Demokratie* (1892). D. in Leipzig, Saxony, June 4, 1894.

Roscius, Quintus: a celebrated Roman actor, a contemporary of Sulla and Cicero, who in his youth received instruction from him, and subsequently defended him in a civil lawsuit in an oration which is still extant. He was especially great in comedy, and carried his art to the highest degree of perfection which the Roman stage ever witnessed, accumulating an immense fortune. Cicero speaks often of him, and always with enthusiasm for his art and respect for his character. D. 62 B. C. Revised by M. Warren.

Roscoe, Sir Henry Enfield, LL. D., D. C. L.: chemist; grandson of William Roscoe; b. in London, Jan. 7, 1833. He was educated at University College, London, and at Heidelberg; graduated at London University in 1852; appointed Professor of Chemistry at Owens College, Manchester, in 1858, and resigned in 1885. He was elected a fellow of the Royal Society in 1863, and received the royal medal of the society in 1873 for his chemical researches. In 1884 he was knighted for his services as a member of the royal commission on technical instruction; was elected Liberal M. P. for South Manchester in 1885, 1889, and 1892. He was president of the British Association in 1887, and in 1889 received the decoration of the Legion of Honor in recognition of his services at the Paris Exposition of that year. In conjunction with Prof. Bunsen he has published several investigations on the measurement of the chemical action of light, and is the author of numerous papers in scientific journals. His *Lessons in Elementary Chemistry* has been translated into several European and Eastern languages. He is the author of *Lectures on Spectrum Analysis* (1869; 5th ed. 1888), and conjointly with Prof. Schorlemmer of a *Treatise on Chemistry* (8 vols., 1877–90).

Roscoe, William: historian and biographer; b. near Liverpool, England, Mar. 8, 1753; was admitted to the bar 1774; began practice at Liverpool; wrote several pamphlets against the slave-trade; published in 1796 *The Life of Lorenzo de' Medici*, and in 1805 a *History of the Life and Pontificate of Leo X.*; sat in Parliament 1806–07; edited Pope's works (10 vols., 1824), and was author of many political and miscellaneous treatises. He was distinguished for his labors in the cause of philanthropy and his encouragement of younger literary aspirants. D. at Toxteth Park, Liverpool, June 27, 1831. His *Life* (2 vols., 1833) was written by his youngest son, Henry (1799–1836), who was distinguished at the bar, wrote numerous legal works, and was author of the *Lives of Eminent British Lawyers* (1830; often reprinted). Revised by H. A. Beers.

Roscom'mon: an inland county of Ireland, in the province of Connaught, bordering E. on the Shannon. Area, 949 sq. miles (see map of Ireland, ref. 8–F). The surface is level, with the exception of the northern parts, where ranges of low hills are found; the soil is light but fertile, affording excellent pasturage in many places. Agriculture and the rearing of sheep are the principal occupations. Pop. (1891) 114,397. Chief town, Roscommon, which contains remains of a castle and a fine abbey of the thirteenth century, and has an important cattle-market.

Roscommon, Wentworth Dillon, Earl of: poet; nephew of Wentworth, Earl of Strafford; b. in Ireland about 1633; educated at Caen under Bochart; spent a large part of his life in France; obtained several offices about the court of Charles II.; went to Ireland as captain in the Guards; squandered his estate by gaming; returned to England; reformed his habits; married a daughter of the Earl of Burleigh; devoted himself to literature in conjunction with Dryden, and produced some poems, the best being the *Essay on Translated Verse* (1660); a blank-verse paraphrase of Horace's *Ars Poetica* (1684); and a revision of *Dies Iræ*. D. in London, Jan. 17, 1684, and was buried in Westminster Abbey.
Revised by H. A. Beers.

Rose [conjointly from O. Fr. *rose* (< Lat. *ro'sa*) and < O. Eng. *rōse*, from Lat. *ro'sa*, rose; cf. Gr. *ῥόδον*, rose]: a flowering plant of the genus *Rosa* and family *Rosaceæ*, which consists of shrubs, usually prickly, natives of the northern hemisphere from the Arctic zone to Mexico in the New World, and to Abyssinia and the Indian Peninsula in the Old. The genus is characterized by unequally pinnate leaves with serrate leaflets, or rarely simple leaves, which in one species (*R. berberifolia*) are entirely wanting, adnately stipulate petioles, and single or corymbose terminal flowers, with five foliaceous sepals imbricated in æstivation, five petals readily multiplying under cultivation, indefinite stamens, and numerous one-seeded carpels inclosed in the receptacular calyx-cup, which becomes fleshy when ripe. The most widely distributed North American species are the Michigan prairie-rose (*R. setigera*), with high-climbing branches, armed with stout, straight prickles, showy corymbose pink flowers, and globular fruit—a native of the Western and Southern States from Michigan to Louisiana and Georgia; the swamp-rose (*R. carolina*), with stems 4 to 8 feet high, armed with stout hooked prickles, corymbose pink flowers, and bristly, depressed globular fruit—a frequent inhabitant of low swampy ground from Canada to Florida and westward to the Mississippi; the dwarf wild rose (*R. lucida*), with stems 1 or 2 feet high, armed with unequal bristly prickles, mostly deciduous flowers, solitary or in clusters of two or three, and smooth globular fruit—common through Canada and the U. S., E. of the Rocky Mountains.

The sweet-brier (*R. rubiginosa*), a native of Europe, has escaped from cultivation, and become widely naturalized in the Atlantic States. The Cherokee rose (*R. sinica*), a native of China, with high-climbing branches, armed with stout hooked prickles, coriaceous evergreen leaves, and large white flowers, has been naturalized in the Southern States for over 100 years, where it is also extensively cultivated as a hedge-plant. Where sufficient room can be given it, few plants equal the Cherokee rose for winter blooming in Northern conservatories. *R. bracteata*, a native of China and Northern India, with erect branches, armed with stout recurved prickles and large, white, solitary flowers surrounded by conspicuous bracts, has also become naturalized in some of the Gulf States, where it is successfully employed as a hedge-plant, especially in deep rich soils.

From the dried petals of *R. gallica*, an Old World species of doubtful geographical limits, an infusion is made which is employed as an agreeable vehicle for tonic and astringent medicines. From the petals of *R. centifolia*, a native of the Caucasus, and *R. damascena*, whose native country is unknown, rose-water, the principal ingredient in astringent collyria, is distilled. (See Attar of Roses.) In the south of France, Egypt, and other Mediterranean

countries, and in India, roses are also largely cultivated for the manufacture of rose-water. The dog-rose (*R. canina*), widely distributed throughout Europe, Northern Africa, the Canary islands, Persia, and Siberia, is also of some importance to man. The pulp of its fruit, mixed with twice its weight of sugar, constitutes the *confectio rosæ caninæ*, which is employed as an astringent antiseptic preserve; an infusion of its young leaves has been used as a substitute for tea; its seeds are a vermifuge; while the root was formerly considered a specific against hydrophobia.

A classification dividing garden-roses into two sets—the first, of summer or once-blooming, the second, of autumnal or ever-blooming—although open to several objections, is the most convenient for the horticulturist.

To the first section belong the Provence roses or cabbage-roses, double forms of *Rosa centifolia*, favorite garden-plants from the time of the Romans, and of which the pompon-roses are dwarf varieties; also moss-roses, descendants from a sport or accidental bud-variation of the Provence rose, with the glands and bristles of the calyx and peduncle developed into a mossy substance. The original moss-rose was introduced into England about three centuries ago from Holland, but the garden where it originated and the name of its discoverer are lost. Hybrid China roses originated from a cross of the Provence and other summer roses with the Chinese rose and its offspring, the tea-scented, Noisette, and Bourbon roses. China roses are remarkable for vigor of growth, often surpassing both parents in this respect, splendid blooms, and great hardiness. They are particularly adapted for growing on pillars or over arbors, and in similar situations. Scotch roses, descendants of *R. spinosissima*, are of dwarf stature and great hardiness, producing early in the season an abundant crop of red, white, and yellow flowers. Austrian briers, descendants of *Rosa lutea*, in Harrison's Yellow give the best yellow rose for general cultivation. Queen-of-the-prairie and Baltimore belle (a hybrid with evident traces of the blood of one of the tender Noisette group) are the most generally cultivated of the descendants of the prairie-rose.

To the summer roses also belong the sweet-brier (*R. rubiginosa*), of which many forms and varieties are in cultivation; the Bursault rose, a descendant of *R. alpina*, the evergreen rose, of which many varieties, descendants of the European *R. sempervirens*, are in cultivation. The many-flowered rose, *R. multiflora*, is a native of China and Japan, and several double forms derived from it are in cultivation in the Southern States. The Banksian rose, generally cultivated only in its double state, has its origin in the Chinese *R. banksiæ*.

To the second section (ever-blooming roses) belong Chinese roses, descendants of *R. indica* and *R. semperflorens*, now rarely cultivated. Tea-roses, descendants of *R. indica*, and two varieties of this species with sweet-scented flowers, the blush-tea and the yellow-tea, were introduced into England from China early in the nineteenth century. From the intermingling of these two varieties has sprung the whole race of tea-scented roses so extensively cultivated. The musk-roses, double forms of *R. moschata*, a native of the Mediterranean basin, are occasionally cultivated. Noisette roses, generally climbing, with flowers in clusters, were originated by M. Noisette, a French florist of Charleston, S. C., by crossing the China rose with the musk-rose, the offspring being again crossed with the tea-scented roses. Bourbon roses are a race of hybrids introduced into Europe from the Isle of Bourbon, where it was produced by crossing the China rose with some other rose of Eastern origin naturalized in that island. Bourbon roses are valuable for their habit of blooming late in autumn. A French cultivator, M. Laffroy, of Bellevue, near Paris, first, in 1840, produced the hybrid perpetual rose, which has as a basis some hardy once-blooming rose, often the hybrid China, with which has been mingled in sufficient quantities to impart their ever-blooming qualities the blood of the China rose, tea-rose, or Bourbon rose, or a combination of all three.

Roses should be cultivated in situations fully exposed to the sun, in deep strong loam well drained and heavily manured. Indeed, too much rich food can hardly be given them to develop their greatest beauties. The soil in which they grow should be constantly stirred and kept free from other plants, and especially from the roots of neighboring trees, while a careful watch must be kept for the many insects which find a favorite food in their leaves and petals. Next to the selection of soil and situation, pruning is the most important operation in the culture of the rose. Strong-growing roses must be pruned slightly, that they may not be stimulated to excessive growth at the expense of the flowers; weak-growing roses must be pruned severely, to encourage more vigorous growth, or, in the words of Francis Parkman, a master in rose-culture, "Roses should be pruned in inverse proportion to the vigor of their growth." See Francis Parkman's *Book of Roses* (Boston, 1866); Thomas Rivers, *The Rose Amateur's Guide* (London, 1872); S. Reynolds Hole, *A Book about Roses* (11th ed., London, 1891); J. Lachaume, *Le Rosier* (Paris, 1874); and Thomas Afflicks, *Hedging and Hedging Plants in the Southern States* (Houston, 1869).

C. S. Sargent.

Rose (in heraldry): a conventionally drawn flower, having always five petals, and usually also five smaller inner petals and five green points of leaves showing on the outer rim. The rose gules was the badge of the Plantagenets, of the house of Lancaster, and the rose argent of that of York. The Tudor rose is a combination of the two, adopted after the marriage of Henry VII. to Elizabeth of York; this is sometimes a white rose charged upon a red one, and sometimes a single rose quartered red and white. The rose was sometimes surrounded with rays, as of the sun, and termed *rose en soleil*. As a mark of cadency, the rose has been used as the difference of the seventh son.

Revised by Russell Sturgis.

Rose, Ernestine Louise Süsmund Potoski: philanthropist; b. at Peterkoff, Poland, Jan. 13, 1810, of Jewish parents; abandoned early the Jewish creed; visited England in 1829; became a disciple of Robert Dale Owen, and was married to William E. Rose. In 1836 she went to New York and circulated the first petition for the property rights of married women, as there was a bill pending in the Legislature, introduced by Judge Hurtell in 1837. She lectured in all the chief cities; was a delegate from the National Woman Suffrage Association to the woman's industrial congress, held in Berlin, Nov. 9, 1869, and subsequently attended all the woman's rights conventions, and frequently addressed legislative assemblies. She was one of the most logical and eloquent orators on the woman suffrage platform. In her later years she spent most of her time in France and England, speaking on many public occasions on religion and the enfranchisement of women. She died in London in 1892.

Susan B. Anthony.

Rose, rō'ze, Gustav: mineralogist; b. in Berlin, Mar. 18, 1798; took his degree of Ph. D. at Berlin 1820; studied with Berzelius; instructor of mineralogy in the University of Berlin from 1823 till his death; in 1829 visited the Ural Mountains with Humboldt and Ehrenberg. D. in Berlin, July 15, 1873. He published many papers on mineralogy, crystallography, and kindred subjects, mostly in *Gilberts Annalen* and in *Poggendorffs Annalen*; also *Elemente d. Krystallographie* (1829; 3d ed. 1873); *Mineralogisch-geognost. Reise nach d. Ural, d. Altai u. d. Kaspischen Meere* (1837–42); *Das Krystallo-chemische Mineralsystem* (1852).

Rose, Heinrich: chemist; brother of Gustav Rose; b. in Berlin, Aug. 6, 1795. His grandfather, Valentin Rose, Sr., and his father, Valentin Rose, Jr., were distinguished chemists. He studied with Berzelius at Stockholm, and took his degree of Ph. D. at Kiel 1821. D. in Berlin, Jan. 27, 1864. He devoted his attention chiefly to analytical chemistry, and contributed more than any other chemist to advance this branch of science. His *Handbuch der analytischen Chemie* (Berlin, 1829) has run through many editions, and is still the standard authority. He published more than 200 papers on chemical subjects, largely in *Gilberts Annalen* and *Poggendorffs Annalen*. In 1851 he read before the Berlin Academy of Sciences his *Gedächtnissrede auf Berzelius*. He was an instructor in the University of Berlin from 1822 till his death.

Revised by Ira Remsen.

Rose, Hugh Henry: See Strathnairn.

Rose, Hugh James: clergyman and author; b. at Little Horsted, Surrey, England, in 1795; graduated at Cambridge 1817; became curate of Uckfield 1818, vicar of Horsham 1821, select preacher to the University of Cambridge 1825; was Professor of Divinity in the University of Durham 1833–38, chaplain to the Archbishop of Canterbury 1834–38, and principal of King's College, London, from 1836 to his death, in Florence, Italy, Dec. 22, 1838. Author of many sermons and theological treatises; founded *The British Magazine* 1832; became editor of *The Encyclopædia Metropolitana* 1836; was joint editor (with Archdeacon W. R. Lyall)

of *The Theological Library*, and projected *Rose's New General Biographical Dictionary*, a design carried into effect after his death by his brother, Henry John, and other writers. He was one of the founders of the Tractarian movement.

Rose-acacia: an ornamental shrub, the *Robinia hispida*, of the order *Leguminosæ*, growing wild in the mountains of the southern parts of the U. S. It has large, very showy, inodorous flowers of a deep rose-color in drooping loose racemes. It is common in cultivation.

Rose-apples: See EUGENIA.

Rosebery, ARCHIBALD PHILIP PRIMROSE, LL. D., Earl of: statesman; b. in London, 1847; educated at Eton and Oxford; succeeded to his title on the death of his grandfather, the fourth Earl of Rosebery, 1868; seconded an address in reply to a speech from the throne in Parliament 1871; president of the social science congress Glasgow, 1874; elected lord rector of the University of Aberdeen Nov. 16, 1878; lord rector of the University of Edinburgh Nov., 1880; Under-Secretary of State for the Home Department 1881; first commissioner of works 1884; Secretary of State for Foreign Affairs in Mr. Gladstone's government Jan. to June, 1886, and in this position won general approval for the firmness with which he conducted the difficult questions devolving upon him. He was appointed to the same post in 1892, became Prime Minister on Mr. Gladstone's retirement in 1894, but gave place to Lord Salisbury June 29, 1895, and relinquished the leadership of the Liberal party Oct., 1896. C. H. T.

Rose-bug: a very common beetle, *Macrodactylus subspinosus*, of North America, belonging to the family *Scarabæidæ*. It is small and dusky yellow, and is very destructive, not only to the rose, but to other vegetation. In warm weather it will suddenly appear in swarms and then suddenly disappear again, having completed its devastations, against which there seems to be no effectual remedy. In some cases air-slacked lime scattered over the bushes and under them seems to have the desired effect, but in other cases it has proved a complete failure. The same may be said of syringing the bushes with a decoction of whale-oil soap or of ailanthus leaves.

Roseburg: city; capital of Douglas co., Ore.; on the Umpqua river, and the S. Pac. Railroad; 76 miles S. of Eugene City, 197 miles S. of Portland (for location, see map of Oregon, ref. 6–B). It is in an agricultural, stock-raising, fruit-growing, and mining region; is an important market for the fertile Umpqua valley; and contains flour-mills, breweries, wagon-shops, the Oregon State Soldiers' Home, a national bank with capital of $50,000, a private-bank, and a semi-weekly and a weekly newspaper. Pop. (1880) 822; (1890) 1,472; (1900) 1,690.

MANAGER OF "REVIEW."

Rose'crans, WILLIAM STARKE: soldier; b. at Kingston, O., Sept. 6, 1819; graduated at the U. S. Military Academy; promoted brevet second lieutenant of engineers July 1, 1842. With the exception of four years (1843–47), when he was at West Point as Assistant Professor of Engineering and of Natural and Experimental Philosophy, he was engaged in the construction of fortifications until Apr. 1, 1854, when he resigned from the army and established himself in Cincinnati, O., as civil engineer and architect; was president of a coal company in Virginia 1855–57, and engaged in the manufacture of kerosene in Cincinnati 1857–61. As volunteer aide to Gen. McClellan he served in organizing Ohio State troops; was appointed colonel and chief engineer of Ohio June 9, and colonel Twenty-third Ohio Volunteers June 10, 1861. He was commissioned brigadier-general in the regular army, and in the West Virginia campaign commanded a brigade at Rich Mountain, July 11; succeeded to command of the department of the Ohio on July 21, and of the department of West Virginia in Sept., 1861; appointed major-general of volunteers Mar., 1862; in May he commanded a division of the Army of the Mississippi at the siege of Corinth: succeeding to command of that army in June, he fought the battles of Iuka (Sept. 19) and Corinth (Oct. 3–4); was transferred to the command of the Army of the Cumberland Oct. 27. His exertions did much to win the battle of MURFREESBORO (*q. v.*), fought Dec. 31, 1862–Jan. 3, 1863, after temporary reverse on the first day. Advancing on Tullahoma June 24, he occupied Bridgeport and Stevenson July 24; crossed the Cumberland Mountains, and Sept. 19–20 fought the battle of CHICKAMAUGA (*q. v.*), where, defeated and falling back on Chattanooga, he was relieved Oct. 30, 1863 (see CHATTANOOGA, SIEGE AND BATTLE OF): was placed in command of the department of the Missouri Jan., 1864; repelled the invasion of Missouri by Price; was mustered out of the volunteer service in 1866; again resigned from the army 1867; was for a short time (1868–69) U. S. minister to Mexico, after which he became a resident of San Rafael, Cal., and was in Mexico 1871–73, engaged in an unsuccessful effort to negotiate the construction of a vast system of narrow-gauge railways. He was member of Congress from California 1881–85, and register of the Treasury 1885–93. On Mar. 2, 1889, he was restored to the rank of brigadier-general and retired. D. near Redondo, Cal., Mar. 11, 1898.

Rose-gall: See GALL INSECTS.

Ros'egger, PETRI KETTENFEIER: poet and novelist; b. at Alpl, a small village in the Styrian Alps, July 31, 1843; passed his youth in great poverty and was apprenticed to a tailor at the age of seventeen. Through the aid of a number of patrons, whose attention he attracted by his exceptional poetic talent, he was enabled to make up for his defective education and devote himself entirely to literature. In 1869 he published his first book, *Zither und Hackbrett*, a collection of poems in the Styrian dialect, which met with success. Since then he has produced a great number of stories, sketches, and novels, most of which describe the peasant life of his native country with great originality and power of characterization. The best known of his stories are *Aus dem Walde* (1874); *Geschichten aus den Alpen* (1873); *Der Gottsucher* (1883); *Jacob der Letzte* (1888); *Hoch vom Dachstein* (1892); *Peter Mayr* (1894). JULIUS GOEBEL.

Rosellini, ros-el-lee'nĕe, IPPOLITO: Orientalist; b. at Pisa, Italy, Aug. 13, 1800. After graduating at Pisa in 1821, he studied Oriental languages at Bologna, and in 1824 was made Professor of Oriental Philology in the University of Pisa. Having been commissioned by the Grand Duke of Tuscany to examine the antiquities of Egypt, he visited that country and spent fifteen months (1827–28) with Champollion, who was under appointment by the French Government, in careful exploration. After the death of Champollion, Rosellini became to some extent his literary executor. The remainder of his life, after his return from Egypt, was spent in editing and publishing his monumental volumes, *I Monumenti dell' Egitto e della Nubia* (9 vols. octavo, and 3 vols. folio, containing 394 plates, Pisa, 1832–44). Ungarelli's *Elementa linguæ Ægyptiacæ vulgo Copticæ* (Pisa, 1837) contained the material delivered by Rosellini, who in turn depended upon Champollion's *Grammaire Copte*. D. at Pisa, June 4, 1843. Biographies of him were written soon after his death by Bardelli (1843), Dei (1843), and Cavedoni (1845). CHARLES R. GILLETT.

Roselly de Lorgues, rō'ze'lee'de-lōrg', ANTOINE FRANÇOIS FÉLIX: religious writer; b. at Grasse, Alpes-Maritimes, France, Aug. 11, 1805; studied law, but soon left the bar and devoted himself to religious writing and to researches in philosophy; became a member of the Legion of Honor in 1837, and officer in 1855. His best-known works are those in defense of the Roman Catholic Church, especially *Le Christ devant le siècle* (1835; 16th ed. 1847), translated into several languages, and *La Croix dans les deux mondes* (1844; 3d ed. 1852). He also wrote several works with the purpose of obtaining the beatification of Columbus, among them *Christophe Colomb* (1856: 3d ed. 1886) and *Histoire posthume de Christophe Colomb* (1885).

Rose-mallow: See HIBISCUS.

Rosemary [by analogy of *rose* and *Mary* < M. Eng. *rosmarine*, viâ O. Fr. from Lat. *rosmari'nus*, liter., sea-dew; *ros*, dew + *mari'nus*, of the sea, marine, deriv. of *ma're*, sea]: a labiate evergreen shrub, *Rosmarinus officinalis*, of Europe and Asia, having fragrant aromatic leaves which yield a pungent volatile oil, valued as a stimulant medicine and sometimes used as an ingredient in perfumery, in hair-dressings, and in liniments. Oil of rosemary is a principal ingredient of the perfume called Hungary water or queen of Hungary water. The shrub, which reaches a height of from 4 to 8 feet, has linear leaves which are covered beneath with a short whitish-gray down and emit a penetrating camphor-like odor; the flower is pale bluish. It grows in sunny places, on rocks, old walls, etc., in the countries around the Mediterranean, and is generally cultivated as an ornamental and aromatic shrub in the west of Europe. The rosemary may sometimes be smelled for many leagues off the Spanish coast. It affords excellent bee-pasture. Revised by L. H. BAILEY.

Rosen, rō′zen, Friedrich August, Ph. D.: Orientalist; b. at Hanover, Germany, Sept. 2, 1805; educated at Göttingen, Leipzig, and Berlin; published in 1826 his *Corporis Radicum Sanscritarum Prolusio*, expanded in the following year into *Radices Sanscritæ* (Berlin, 1827); was from 1829 Professor of Oriental Languages in the University of London (now University College). Becoming honorary foreign secretary to the Royal Asiatic Society and secretary to the Oriental Translation Committee, he became intimate with H. T. Colebrooke, by whose advice he published the Arabic text (with English translation and notes) of Mohammed ben Musa's *Algebra* (1831); prepared for publication Ibn Khallikan's great *Biographical Dictionary*, and undertook a work (never completed) on *Indian Jurisprudence*; edited Sir Graves Houghton's *Dictionary, Bengali, Sanscrit, and English* (1833–34), and 2 vols. of Colebrooke's *Miscellaneous Essays* (1837); he planned an edition of the *Vedas*, and in 1830 published his *Rig-Vedæ Specimen*, and began in 1836 to print the Sanskrit text with a Latin translation and explanatory notes. He had not completed the first volume when he suddenly died in London, Sept. 12, 1837. The Oriental Translation Committee issued the work under the title *Rig-Veda-Sanhita, Liber Primus, Sanscrite et Latine* (1838).

Rosendale Cement: See Cement.

Ro'senkranz, Johann Karl Friedrich: philosopher; b. at Magdeburg, Prussia, Apr. 23, 1805; at the age of nineteen took up his residence in Berlin, devoting himself to philosophy. He completed his university course at Halle, receiving the degree of doctor of philosophy in 1828. In 1833 he entered upon the duties of Professor of Philosophy at Königsberg, occupying the chair formerly filled by Herbart and Kant till his death in 1879. He was the best representative of the "center" of the school of Hegel, and did much valuable work in rearranging and reclassifying the several parts of the system. His chief works are a *History of German Poetry in the Middle Ages* (1830); a *Handbook of the General History of Poetry* (Halle, 1833); *Encyctopædia of Theological Sciences* (Halle, 1831); *Critique of Schleiermacher's Glaubenslehre* (Königsberg, 1836); *Psychology, or Science of Subjective Mind* (Königsberg, 1837); *Critical Explanations of Hegel's System* (1840); *History of Kant's Philosophy* (Leipzig, 1840); *Life of Hegel* (Berlin, 1844); *Modifications of Logic* (Leipzig, 1846); *Goethe and his Works* (Königsberg, 1847); *Pedagogics as a System* (Königsberg, 1848; Eng. trans. New York, 1886); *System of Science* (Königsberg, 1850); *Æsthetics of the Ugly* (Königsberg, 1853); *Science of the Logical Idea* (Königsberg, 1859); *On Vera's Translation of Hegel's Philosophy of Nature* (Berlin, 1868); *Hegel as the National Philosopher of Germany* (Leipzig, 1870; nearly all of this work has appeared in English); *From Magdeburg to Königsberg: Autobiography* (Leipzig, 1873); *New Studies*—vol. i., *The History of Culture*; vol. ii., *The History of Literature* (1875). D. June 17, 1879. William T. Harris.

Ros'enmüller, Ernst Friederich Karl: Orientalist; b. at Hessberg, near Hildburghausen, Germany, Dec. 10, 1768; studied theology at the University of Leipzig 1813, where he became Extraordinary Professor of Arabic 1796 and Ordinary Professor of Oriental Languages in 1795. D. at Leipzig, Sept. 17, 1835. His principal works are *Scholia in Vetus Testamentum* (16 parts, Leipzig, 1788–1817): *Scholia in Vetus Testamentum in compendium redacta* (5 parts, 1828–35); *Handbuch der biblischen Alterthumskunde* (4 parts, 1823–31). Revised by S. M. Jackson.

Rosenmüller, Johann Georg: preacher and writer; b. at Ummerstadt in Hildburghausenschen, Dec. 18, 1736; studied at Altdorf till 1760; pastor in Hessberg 1768; diakonus in Königsberg in Franken 1772; pastor and professor in Erlangen 1773; professor and superintendent in Giessen 1783; professor and pastor in Leipzig 1785; prelate of the Hochstift Meissen 1802. D. Mar. 14, 1815. Among his works are *Hist. interpret. lib. Sacr. in eccles. Christiana* (1795–1814); *Scholia in N. T.* (1777); *Emendationes et supplementa* to the foregoing (1789–90); *Morgen und Abendandachten* (7th ed. 1820); and *Ausertes. Beicht und Kommunionsbuch* (12th ed. Nuremberg, 1827). See Dolz, *Rosenmüllers Leben und Wirken* (Leipzig, 1816). R Gottheil.

Rose-noble, or **Gold Penny**: an ancient English gold coin, first current in the reign of Edward III., and last coined under Henry V. It bore a rose on one side, and was worth 1 noble—6*s.* 8*d.* sterling.

Rosenthal, Albert: See the Appendix.

Rosenthal, rō′zen-tăăl, Isidor, M. D.: physiologist; b. in Labischin, near Bromberg, Prussia, July 16, 1836; studied medicine at the University of Berlin; in 1867 elected Extraordinary and in 1872 Ordinary Professor of Physiology at the University of Erlangen. He was editor of the *Centratbtatt für die medicinischen Wissenschaften* (1869–80), and co-editor of the *Biologisches Centralbtatt* in 1881. Among his works are *Allgemeine Physiotogie der Muskeln und Nerven* (Leipzig, 1877); *Vorlesungen über die öffentliche und private Gesundheitspflege* (Erlangen, 1887).

Rosenthal, Max: See the Appendix.

Rosenthal, Moriz: See the Appendix.

Rosenthal, Moriz, M. D.: neurologist; b. in Grosswardein, Hungary, in 1833; graduated M. D. at the University of Vienna in 1858; in 1875 appointed a Professor of Nervous Diseases, and assigned to a division in the general hospital in Vienna. He is universally known as an able neurologist and careful investigator. Among his works are *Handbuch der Diagnostik und Therapie der Nervenkrankheiten* (Erlangen, 1870); *Klinik der Nervenkrankheiten* (Stuttgart, 1875).

Rosenthal, Toby Edward: See the Appendix.

Rose of Jericho, or **Rose of the Virgin**: a cruciferous herb. the *Anastatica hierochuntica* (resurrection-flower of Jericho), of the Levant and of Arabia. It is fabled that the rose of Jericho first bloomed at the Nativity, and that it remains in flower from Christmas until Easter. Others say that it sprang up wherever the Virgin alighted during the journey to Egypt. See Jericho, Rose of.

Rose of Sharon: the popular name of the *Hibiscus syriacus*. See Hibiscus.

Roseola, rō-zee′ō-la [Mod. Lat., dimin. of Lat. *ro'sa*, rose. Named from the color induced in the skin]: any one of various forms of disease attended with an erythematous rash. Very often mild cases of measles and scarlet fever were so designated, and the term has more recently been used as a designation of German measles. It is not properly applied excepting to the rash itself, and this may occur in a variety of conditions including gastric disturbances, mild fever from any cause, and various infectious fevers. W. P.

Rose-quartz: a variety of Quartz (*q. v.*).

Roses, War of the: the name given to the civil war, lasting thirty years (1455–85), between the princes of the rival houses of York and Lancaster, each claiming the throne of England by right of descent from Edward III. See the articles England (*History*), Edward IV., Henry VI., Henry VII., and Richard III.

Roset'ta [=Arab. *Reshîd*, or *Rashîd*]: an Egyptian town; 40 miles N. E. of Alexandria, near the mouth of the westerly branch of the Nile, and near Fort St. Julien, where the famous Rosetta Stone (*q. v.*) was found (see map of Africa, ref. 2–F). The place was founded in 870 A. D., near the site of the ancient Bolbotinum. Its history is obscure, and the name does not appear in the literature of the Coptic period. (See Amélineau, *Géographie de l'Égypte*, Paris, 1893, p. 404.) Before the opening of the canal that connects Alexandria with the Nile it had some importance as a port for trade, but this has almost entirely disappeared. Its native population is about 13,000, with very little foreign admixture. Charles R. Gillett.

Rosetta Stone: a large slab of black basalt, now in the British Museum, which was found in 1799 by a French engineer in the trenches of Fort St. Julien near Rosetta (*q. v.*) in Egypt. It measures 3 ft. 9 in. in height, 2 ft. 4½ in. in width, and 11 inches in thickness in its present broken condition, but originally it was probably about 12 inches higher, and had a rounded top. It contains parts of fourteen lines of hieroglyphic text, in the upper register, nearly the whole of the original thirty-two lines of demotic or enchorial writing, and fifty-four lines (twenty-eight of them complete) in uncial Greek letters. The mutilations at the top have destroyed about fourteen lines of hieroglyphic text, and the piece lost from the lower right-hand corner has deprived us of the endings of twenty-six lines of the Greek. Judging by internal evidence it has been concluded that the original text was the Greek, and that the native writing contains only versions. (For an account of the Egyptian graphic systems, see Egyptian Language and Literature and Hieroglyphics.) The stone itself speaks of the three styles of caligraphy as "writing of divine words" (hieroglyphic), "writing of letters" (demotic), and "writing of the Greeks."

The stone contains a copy of a decree promulgated by the Egyptian priesthood assembled at Memphis in 195 B. C., in honor of Ptolemy V. Epiphanes (205–182 B. C.) on account of certain benefits that he had conferred upon Egypt in his eighth year, by remitting certain taxes and reducing others, by conferring privileges upon the priests and soldiers, by dedicating certain revenues to the temples, and by averting serious damage from the land by damming and regulating the waters of an unusually high Nile. According to the decree it was directed that its text be engraved in three sorts of characters upon hard stone, and set up in all Egyptian temples of the first, second, and third order, to commemorate these beneficent deeds of "Ptolemy, the saviour of Egypt." It was also directed that statues of the king should be placed in all the temples, and that a shrine containing his image in wood should be carried with those of other deified kings of Egypt in solemn processions. The first five days of the month of Thoth were set apart for the celebration of special services in his honor.

The inscriptions on this stone were similar to those on the Tablet of Tanis, also known as the Stela of Canopus, discovered at Tanis by Lepsius in 1866. The latter was set up in 238 B. C., the ninth year of Ptolemy III., Euergetes I. (246–221 B. C.) to commemorate his good deeds, and particularly his restoration of the images of the gods, which had been carried off to Mesopotamia. These texts served to confirm the results of the decipherment based upon the Rosetta Stone. In the original work of decipherment great assistance was rendered to Champollion in 1822 by inscriptions on an obelisk then recently brought from Philæ to London, which contained the names of Ptolemy Euergetes and Cleopatra, to whose identification he was led by the Greek inscriptions on the base of the obelisk. The name of Ptolemy was already known, and the decipherment of the name of Cleopatra added several alphabetic signs to those that had been previously determined on the basis of the Rosetta Stone. For an account of the decipherment, see article EGYPTOLOGY. See also Budge, *The Mummy* (Cambridge, 1893), pp. 144 ff.; Ebers, *Cicerone durch Ægypten*, ii., pp. 24 ff. Budge, pp. 109–110, gives an extensive bibliography of works bearing upon the decipherment and interpretation of the Rosetta Stone. CHARLES R. GILLETT.

Roset'ti, or **Roseti**, CONSTANTIN: poet and politician; b. in Bucharest, Roumania, June 14, 1816; in the army from 1833 to 1836; wrote translations from Byron and others, and in 1843 published a volume of original poems under the title *Ceasurĭ de mulţumire* (Hours of Contentment). He was concerned in the political disturbances of 1848, being a secretary of the provisional government. When the uprising was put down his journal, *Pruncul român* (The Roumanian Child), was suppressed, and he went to Paris, where he was active as a political writer. After the Crimean war he returned to Roumania and founded the journal *Românul* (The Roumanian), and as an ardent liberal was influential in politics. He became a member of the chamber of deputies, and held other public positions. He urged the proclamation of independence, and the alliance with Russia against Turkey in 1877. From 1878 to 1880 he was Minister of the Interior, and was a senator at the time of his death, Apr. 20, 1885. A new edition of his poems, translations, and political writings appeared in 1885 at Bucharest. E. S. SHELDON.

Rosewood: (1) the beautiful and fragrant wood of several leguminous Brazilian trees of the genera *Machærium* and *Triptolemæa*, highly valued as a veneer for furniture, pianos, etc.; (2) the almost equally beautiful wood of an East Indian leguminous tree, *Dalbergia latifolia*; (3) Canary island rosewood, the fragrant woody root of the convolvulaceous *Rhodorrhiza scoparia* and *R. florida*. The last is a delightful incense, and its powder is mixed with snuff. From it is obtained the oil of rhodium, much vaunted as a charm for horses and highly prized by trappers. (4) Burmese and African rosewoods are the timber of leguminous trees of the genus *Pterocarpus*.

Revised by L. H. BAILEY.

Rosicrucians [Lat. *ro'sa*, rose + *crux*, *crucis*, cross]: a secret society reported to have been founded in the fourteenth century. The first mention of the society appeared in the *Fama Fraternitatis des löblichen Ordens des Rosenkreuzes*, anonymously published at Cassel in 1614, and in the *Confession oder Bekenntniss der Societät und Brüderschaft R. C.*, published the following year. In these the most wonderful stories were told of the Rosicrucians, who were said to be possessed of the deepest wisdom, and most potently at work for the weal of mankind. Concerning the founder of the society, Christian Rosenkreutz—his residence among the Arab and Egyptian magicians, his life in Spain and Germany as head of the new order, his death and burial—the most stirring revelations were made in a third book, *Chymische Hochzeit Christian Rosenkreutz'*, which appeared at Strassburg in 1616. Some theologians considered the society a means of salvation, others the organ of a foul scheme. Some physicians thought that it would give the fulfillment of the golden prophecies of Theophrastus Paracelsus concerning an elixir of life; others, that it was only an impudent opposition to Galen. The alchemists particularly were anxious to join it, sure that it had found the philosopher's stone and could make gold, but the whereabouts of the brotherhood remained unknown. For several years the secret society of the Rosicrucians was the all-absorbing topic of the day. Some think that the books were written by Johann Valentin Andreä, simply as a satire. Of the real existence of such a society there never was found the slightest trace. Soon there arose a multitude of Rosicrucian societies, and at the end of the eighteenth century Cagliostro pretended to be a Rosicrucian. See Semler, *Impartial Collections for the History of the Rosicrucians* (Leipzig, 1768); and Waite, *The Real History of the Rosicrucians* (London, 1887).

Rosin, or **Col'ophony** [*rosin* is appar. dial. form of *resin* (see RESINS); *colophony* is from Lat. *colopho'nia* (sc. *resi'na*, rosin) = Gr. κολοφωνία (sc. ῥητίνη, rosin), Colophonian rosin, rosin, liter., fem. of Κολοφώνιος, pertaining to Colophon (Gr. Κολοφών)]: the residue which is obtained by distilling off the water and volatile oil from the crude turpentine from pine-trees. The yield is from 70 to 90 per cent. of the whole. (See TURPENTINE.) It is largely manufactured, together with oil of turpentine, at Wilmington, Newbern, and Beaufort, N. C. When entirely freed from water it is translucent. The color depends upon the purity of the original turpentine and the care taken to distill at a low temperature. It is chiefly the anhydride of abietic acid.

Colophony is pale yellow and transparent (virgin rosin), or brownish yellow and translucent, according to the care taken in its preparation. It may be obtained nearly colorless by distillation with steam or some inert gas, as hydrogen, carbon dioxide, or nitrogen, under a pressure of ten atmospheres at a temperature not higher than 600° F. It has a peculiar luster, called resinous, is brittle when cold, and breaks with a conchoidal fracture; sp. gr. 1·07 to 1·08. It is insoluble in water, soluble in alcohol, ether, wood-spirit, and in fixed and volatile oils; partially soluble in petroleum. Nitric acid dissolves it, forming chiefly isophthalic acid, together with trimellitic acid and a resinous acid. It dissolves in caustic alkalies and alkaline carbonates. Colophony softens at 160° F. and melts at 275° F. At higher temperatures it gives off volatile oils, acquiring a dark color.

Colophony is extensively used in making varnishes and cements, in the calking of ships, in the preparation of plasters and ointments, and as a reducing agent in the soldering of metals. Large quantities are consumed in the manufacture of yellow soap. A well-known use of it is for covering the bows of violins to prevent the bow from slipping over the strings without producing vibration. Before the introduction of petroleum, rosin-oil was used to some extent in lamps. The rosin-spirit is sometimes used as a substitute for oil of turpentine. The viscid oil is used in paints, for the manufacture of printer's ink, in soap-making, in cheap lubricators, etc. Revised by IRA REMSEN.

Rosin Bible: See BIBLE.

Rös'kilde: town; in the island of Sealand, Denmark; on a hill on a branch of the Isefjord. In the early Middle Ages it was a great city, the royal residence, with 100,000 inhabitants, and 27 churches and monasteries, but conflagrations, the plague, and the growth of Copenhagen destroyed its prosperity. It has a magnificent cathedral, built 1047–84, which contains many splendid monuments; the Danish kings are buried here. Pop. (1890) 6,972.

Roslyn: village; Queens co., Long Island, N. Y.; now a part of the Borough of Queens, New York city; at the south end of Hempstead harbor, on the Long Island Railroad; 23 miles E. N. E. of Brooklyn. It was named by William Cullen Bryant, who had a residence here and presented the village with a public hall. It has an English classical school, a savings-bank, a weekly newspaper, flour, paper, and planing mills, and canning-factories. Many New York business men have summer residences here. Pop. (1880) 1,101; (1890) 1,251; (1893) 1,409. EDITOR OF "NEWS."

Roslyn: town; Kittitass co., Wash.; on the Northern Pac. Railroad; 32 miles N. W. of Ellensburg, the county-seat (for location, see map of Washington, ref. 4–E). It is in an agricultural and coal-mining region; has a local output of about 2,500 tons of coal per day, shipped chiefly to Eastern Washington; and has a weekly newspaper. The town is reached by a branch railway from Clealum, 4 miles distant. Pop. (1890) 1,484; (1900) 2,786.

Rosmar'idæ: now usually called ODOBÆNIDÆ (*q. v.*).

Rosmini, ros-mee'nĕe, ANTONIO: ecclesiastic and philosopher; b. at Roveredo, Tyrol, Mar. 25, 1797; at an early age devoted himself to philosophical studies, and in his youth wrote a number of miscellaneous works. In 1827 he formed a friendship with Manzoni, and in 1830 went to Rome to obtain the sanction of the pope to his Instituto dei Preti della Carità, an order founded by himself; in the same year published his principal work, *Nuovo Saggio sull' Origine delle Idee*; in 1834 returned to Roveredo as archdeacon, and there gave himself entirely to philosophy, producing works upon ontology, theosophy, theodicy, pedagogy, supranatural anthropology, ethics, methodology, and many other subjects, which in all form thirty volumes. The *Cinque Piaghe della Chiesa* and *Il Progello di Cosliluzione* are applications of his philosophical doctrines to politics. English translations of his *Psychology* and *Pedagogy* have appeared, and a work expounding his doctrines at length has been published in London by T. Davidson; this work contains also (p. lii.–lxxxviii.) a full biography. He carried on long polemical controversies with Gioberti and Mamiani. D. at Stresa, July 1, 1855. Revised by W. T. HARRIS.

Rosny, rō'nĕe', LÉON, de: Orientalist; b. at Loss, department of Nord, France, Aug. 5, 1837; studied in Paris; was attached as interpreter to the Japanese embassy which visited Europe in 1863, and became Professor of Japanese in Paris in 1868. He published *Diclionnaire japonais-français-anglais* (1858); *Les Écrilures figuralives el hiéroglyphiques des Différents Peuples, anciens el modernes* (1860); *Dictionnaire des Signes idéographiques de la Chine* (1864–67); *Éludes asialiques de Géographie et d'Hisloire* (1864); *Aperçu de la Langue coréenne* (1867).

Rosol'ic Acid, Coralline, Pseudo-Coralline, or **Aurine** [*rosolic* is from *rose* + carb*olic*; *aurine* is from Lat. *au'rum*, gold]: names formerly applied to red coloring-matters which were supposed to be identical, but have been shown to be distinct. *Rosolic acid* was obtained by Runge in 1834 by treating coal-tar naphtha with milk of lime. It is now prepared by treating a cold dilute solution of rosaniline in hydrochloric acid with sodium nitrite, and subsequently boiling the product to convert the diazo-compound formed into rosolic acid. Rosolic acid, previously boiled with water, appears as a dark-greenish, amorphous substance, with the greenish metallic luster of cantharides. Its powder is red, and assumes a bright gold-like luster when rubbed or pressed with a hard body. Thin films are orange-red by transmitted and metallic by reflected light. When precipitated from alcohol by water, it is a bright-red powder. At 170° F. it cakes together, and in boiling water it melts. It is not volatile; dissolves readily in alcohol, ether, wood-naphtha, phenol, creosote, concentrated acetic, hydrochloric, and sulphuric acids. From all of these solvents, which are miscible with water, it is precipitated unchanged when that is added. It is not decolorized by sulphurous acid. Its acid properties are very feeble; it is even weaker than carbonic acid. It forms dark-red compounds, soluble in alcohol and in water, and a magnificent red with ammonia, caustic alkalies, and caustic alkaline earths; carbonic acid decomposes them, and the prolonged action of air and light destroys the rosolic acid completely. The formula of rosolic acid is $C_{20}H_{16}O_3$. It is the tri-para-oxytolyl-diphenyl-carbinol-anhydride. Rosolic acid has been suggested as an indicator in Pettenkofer's process for determining carbonic acid, and in nitrogen determinations with standard acid. It was sold in a crystalline form at one time under the name of *aniline scarlet*.

Coralline was first prepared by Persoz in 1859, by heating 3 parts of phenol, 2 of oxalic acid, and 2 of sulphuric acid for several hours. The mass effervesces, and becomes thick and deep red. The process is terminated when a drop of the mixture is found to dissolve with a deep red in dilute ammonia. The mixture is then poured into hot water. A resinous mass, with the luster of cantharides, separates. Persoz's process was not published till after Kolbe and Schmitt in 1861 announced their discovery of a similar process. They use 3 parts of phenol, 2 of oxalic acid, and 4 of sulphuric acid, and heat to 285°–300° F. four to six hours, in a vessel furnished with a cohobator. The product is treated as in Persoz's process. Coralline (known as crude or yellow coralline) is a mixture of pseudo-rosolic acid, $C_{20}H_{16}O_4$ (70 per cent.), aurin or para-rosolic acid, $C_{19}H_{14}O_3$, oxidized aurine, $C_{19}H_{16}O_6$, and methyl-aurine, $C_{20}H_{16}O_3$. Coralline gives fine red shades in dyeing, which are easily modified by the use of proper reagents. The liability to change renders it somewhat difficult to fix. The calcic carbonate lake of coralline is largely used by paper-stainers.

Red coralline, pæonine, or *pœonine* (J. Persoz, 1859), is obtained by heating 9 parts of crude coralline with 22 parts of concentrated ammonia to 270° F. for three hours in a strong iron vessel. A thick solution with a golden-crimson reflection is obtained, from which acids precipitate the new dye as a deep-red powder, the composition of which is not determined. It is probably an amide or imide of coralline. It is almost insoluble in water, soluble in alcohol (red), and in alkalies (red, turning brown in the air). Pæonine is much used for dyeing wool, although it has the disadvantage of being changed to yellow by acids. This can be prevented by the use of magnesia, dissolving the dye in alcohol. It produces a rich Turkey red, the intensity of which is retained for years, at a cost of two-thirds that of cochineal, and possesses the advantage of not turning blue on washing in water containing bicarbonate of lime. Cotton must be mordanted with tin and sumac or galls. The color obtained is between that of cochineal and magenta. It resists washing, but is affected by soap and by exposure to sunlight.

Azuline was formerly prepared by heating aurine with aniline. It is not now used.

Aurine, or *para-rosolic acid*, $C_{19}H_{14}O_3$, is formed (1) by the action of nitrous acid on para-rosaniline; (2) together with pseudo-rosolic acid, oxidized aurine, and methyl-aurine by the action of oxalic acid and sulphuric acid on phenol, the product being known as crude or yellow coralline, described above.

Aurine is insoluble in water, soluble in hot alcohol and acetic acid. It crystallizes in dark rose-red crystals with a sky-blue reflection. Hydrochloric acid precipitates it from hot alkaline solutions in hair-like needles, which do not melt to a resinous mass, as rosolic acid does.

Pseudo-coralline, or *corallin phlhalin*, $C_{20}H_{16}O_4$, is the chief constituent of oxide coralline. It dyes orange-yellow shades on mordanted wool.

Poisonous Properlies of Woolens dyed with Coralline, etc.—Much has been written on this subject, but it appears that the irritation of the skin, etc., which results from wearing red and scarlet flannel dyed with these colors is due not to the coralline, but to the picric acid, phenol, etc., which are often associated with them. Washing removes these substances. See Guyot, *Comptes Rendus* (Aug. 6, 1869).

Revised by IRA REMSEN.

Ross: county of Scotland. See ROSS AND CROMARTY.

Ross, ALEXANDER: poet; b. in the parish of Kincardine-O'Neil, Aberdeenshire, Scotland, Apr. 13, 1699; graduated at Marischal College, Aberdeen, about 1716; engaged in teaching, and was parish schoolmaster at Lochlee, Forfarshire (or Angus), from 1732 until his death at that place May 20, 1784. He wrote verses from his childhood, but was sixty-nine years of age when he first appeared as an author, through the advice of Dr. Beattie, by the publication of *Helenore, or the Forlunate Shepherdess, a Pastoral Tale in lhe Scotlish Dialecl, to which are added a few Songs by lhe Author* (Aberdeen, 1768), a poem which in the north of Scotland has rivaled in popularity the writings of Burns and Allan Ramsay. Ross left in MS. eight volumes of miscellanies, of which an account is given in the *Life* prefixed to the best edition of *Helenore* (1866), edited by John Longmuir, LL. D. See also A. Campbell's *Introduction to lhe History of Poelry in Scotland* (1799). Revised by H. A. BEERS.

Ross, ALEXANDER MILTON: See the Appendix.

Ross, ARTHUR WELLINGTON: lawyer; b. at East Williams, Middlesex, Ontario, Canada, Mar. 25, 1846; graduated at Toronto University. He was head master of Cornwall schools 1868–69; inspector of public schools for the county of Glengarry 1871–74; removed to Manitoba in 1877, and was admitted to the bar in 1878. He soon became the largest real-estate owner in the province; has been vice-president of the Manitoba and Northwest Railway Company, and was chosen to represent Manitoba and the Northwest in

the Howland syndicate to build the Canadian Pacific Railway. He was a member of the Manitoba Legislature 1878–82, and in the latter year was elected to the Canadian Parliament, where he remained until 1896. NEIL MACDONALD.

Ross, GEORGE WILLIAM, LL. D.: educator; b. in Middlesex, Ontario, Canada, Sept. 18, 1841; educated at Normal School, and became a teacher. In 1871 he was appointed county inspector of schools in East Lambton; subsequently became inspector of county model schools, and was appointed Minister of Education for Ontario Nov. 23, 1883. He was a member of the Dominion Parliament 1872–83, and since then has held a seat in the Ontario Legislature. For many years he has been a leader in temperance and prohibition movements; was an honorary commissioner at the Colonial and Indian Exhibition, London, 1885, and has been editor of the Strathroy *Age* and of the Seaforth *Expositor*. NEIL MACDONALD.

Ross, Sir JAMES CLARK: navigator; b. in London, Apr. 15, 1800; nephew of Sir John Ross; entered the navy in 1812, and accompanied his uncle on his first voyage in search of a northwest passage, and was also with Capt. Parry (1819–27) in the latter's expeditions having the same object in view, being on one occasion wrecked in the Fury; in 1827 was appointed commander, and in 1829 again sailed with his uncle as second in command, and was absent four years. On June 1, 1831, he discovered the position of the north magnetic pole. Promoted to be post-captain on his return, he was engaged in a magnetic survey of Great Britain and Ireland 1835–38; in Apr., 1839, was appointed to the command of the Erebus, and in September of that year, in company with the Terror, sailed for the Antarctic seas, reaching lat. 78° 10′ S., the highest southern latitude ever reached. A volcano was discovered in lat. 77° 32′ S., nearly 13,000 feet in height, which was named Mt. Erebus. It is in Victoria Land, discovered and named by him, and the most extensive Antaretic land yet seen. In 1844 the honor of knighthood was conferred upon him, and in 1847 he published *A Narrative of a Voyage in the Antarctic Regions*. He was a fellow of the Royal Society, and of many continental scientific bodies. D. at Aston Abbots House, near Aylesbury, Apr. 3, 1862. Revised by C. C. ADAMS.

Ross, Sir JOHN, K. C. B.: explorer; b. in the parish of Inch, Wigtonshire, Scotland, June 24, 1777; entered the navy in 1786; in Jan., 1818, received his commission as commander of the Isabella, and Apr. 25, in company with the Alexander, Lieut. Parry, sailed from London to ascertain the existence or non-existence of a northwest passage, returning in Nov., 1818; in May, 1829, again sailed in the steamer Victory, equipped by Sir Felix Booth, sheriff of London, but in Sept., 1830, became ice-bound in the Gulf of Boothia, making but little subsequent advance, and May 29, 1832, the Victory was abandoned. In Aug., 1833, the party was rescued by the Isabella, formerly commanded by Capt. Ross, but at that time engaged in the whaling business. He arrived in London Sept. 19, 1833, was knighted the following year, and admitted to the companionship of the Bath. From 1839 to 1845 he was consul at Stockholm: in 1850 departed, in command of the Felix, 90 tons, in search of Sir John Franklin, returning the following year; in July, 1851, attained the rank of rear-admiral. D. in London, Aug. 30, 1856. (See POLAR RESEARCH.) He published (1819) *A Voyage of Discovery, made under the Orders of the Admiralty for the purpose of exploring Baffin's Bay*, and in 1835 a *Narrative of a Second Voyage, including the Reports of Commander James Clark Ross, and the Discovery of the Northern Magnetic Pole*; also published a treatise on steam-navigation and numerous other papers. Revised by C. C. ADAMS.

Ross, Sir JOHN, K. C. B.: general; b. at Stonehouse, Cumberland, England, Mar. 18, 1829; entered the army as second lieutenant in the Rifle Brigade in 1846; served with that regiment during the Crimean war, where he won distinction and received the brevet rank of major and Turkish medal and order of the Medjidie. During the Indian mutiny he was present at the action at Cawnpur and the capture of Lucknow; subsequently commanded the Camel Corps at the capture of Calpee and in the ensuing campaign in Central India, and for his services received the rank of lieutenant-colonel, the companionship of the Bath, and a medal. He commanded the Bengal troops during the operations in the Malay Peninsula 1875–76, and was assigned to the command of a large force of Indian troops sent to the Mediterranean in 1878, when war with Russia was threatened. He afterward commanded the second division of the Cabul army during the war with Afghanistan 1878–79, and received the thanks of Parliament and was knighted for his services. He was appointed to the command of the troops in Canada in 1888, and stationed in Halifax. NEIL MACDONALD.

Ross, JOHN JONES, M. D.: Canadian senator; b. at Ste. Anne de la Pérade, Aug. 16, 1833. He is president of the Provincial College of Physicians and Surgeons; was a member of the agricultural council of Quebec 1862–90; and elected vice-president of the North Shore Railway Company 1875. He was Speaker of the Legislative Council of Quebec 1873–74 and 1876–81; commissioner of agriculture and public works 1881–82, and held this office together with that of Premier of the province 1884–87. He was a member of the Canadian Assembly 1861–67, of Parliament 1867–74, was called to the Senate in 1887, and was its Speaker 1891–96.

Ross, LUDWIG: archæologist; b. at Altekoppel, Holstein, Germany, July 22, 1806. Endowed with a traveling scholarship by the Danish Government, he went to Athens in 1832 for the scientific exploration of Greek antiquities. When about to return home, he was appointed in 1833 by the Greek Government as superintendent of antiquities of the Peloponnesus, and subsequently of the entire kingdom. In 1845 he became Professor of Archæology at the University of Halle. Ross was one of the great pioneers in the field of Hellenic archæology, topography, and epigraphy. He traveled all over Greece, excavating, copying inscriptions, and fixing the topography of classical localities with such accuracy, scientific method, and descriptive talent that his works have retained their value. Among his many publications the following are the most important: *Wanderungen in Griechenland* (1851); *Reisen auf den Griechischen Inseln des ägeischen Meeres* (4 vols., 1840–52); *Die Demen von Attika* (1846); *Das Theseion und der Tempel des Ares zu Athen* (1852); *Archäologische Aufsätze* (1855–61), the second volume of which also contains a biographical sketch by Otto Jahn. D. at Halle, Aug. 6, 1859. ALFRED GUDEMAN.

Ross, WILLIAM: member of privy council of Canada; b. at Boularderie island, Cape Breton, in 1825; represented Victoria in Nova Scotia Assembly from 1858 till 1867, and in the Canadian Parliament till 1874; collector of customs at Halifax 1874–88. He was sworn of the privy council Nov. 7, 1873, and was Minister of Militia and Defense from that date till Nov. 5, 1874. N. M.

Ross, Sir WILLIAM CHARLES, R. A.: painter; b. in London, England, June 3, 1794; son of a miniature-painter and teacher of drawing, from whom he received artistic training; gained a prize from the Society of Arts at the age of thirteen; in 1817 became an assistant to Andrew Robertson, an eminent miniature-painter; was appointed miniature-painter to Queen Victoria 1837; was knighted 1842; was patronized by all the court circle, and occasionally executed historical and imaginative pieces, having obtained a premium of £100 in the great cartoon competition for his *Angel Raphael discoursing with Adam* (1842). D. in London, Jan. 20, 1860.

Ross and Cromarty: a northern county of Scotland, washed on the E. by the German Ocean and on the W. by the Atlantic, and bounded N. and S. by Sutherlandshire and Inverness-shire respectively. It comprises the districts of Easter and Wester Ross, the Black Isle, the island of Lewis, and the ten detached districts which formerly made up the county of Cromarty. Area, 3,078 sq. miles. Pop. (1901) 76,149. The surface is wild and mountainous, but the soil affords good pastures, on which large herds of sheep and cattle are fed; agriculture and fishing are carried on. The royal burgh of Dingwall, 166 miles N. W. of Edinburgh, is the county-town. Pop. (1891) 2,300.

Rossa'no (anc. *Roscianum*): town; province of Cosenza, Italy; on a hill near the Gulf of Taranto, which it overlooks (see map of Italy, ref. 8–H). There are quarries of marble and alabaster in the neighborhood. Fish are abundant, and silk and cotton are raised in the vicinity, as well as grain, olives, grapes, etc. The town, still walled and defended by a castle, was once a very strong fortress. Rossano is the seat of an archbishop. Pop. of commune about 18,000. Revised by M. W. HARRINGTON.

Rosse, WILLIAM PARSONS, third Earl of: astronomer: b. at York, England, June 17, 1800; studied first at Trinity College, Dublin, and then at Magdalen College, Oxford, where he graduated in 1822; sat in the House of Commons as Lord Oxmantown, representing King's County from 1821

to 1831; succeeded to the peerage in 1841, and was elected a representative peer of Ireland in 1845 and chancellor of the University of Dublin in 1862. He studied astronomy and optics, and concentrated his attention on the improvement of the telescope. For several years he was engaged in experiments referring to the construction of fluid lenses, the results of which researches are communicated in the *Philosophical Transactions* (1840); but although he failed in this particular object, he succeeded at last, after a long series of experiments, in constructing a speculum of a reflecting telescope in which the spherical aberration and the absorption of light were reduced to a minimum, at the same time that his process of construction did away with that cracking and warping of the surface of the speculum while cooling after the casting which so often had proved fatal under the old method of operation. In 1842 a telescope was successfully constructed on his plan, 6 feet in diameter, and mounted at his residence near Parsonstown. Since his death, Oct. 31, 1867, his work with the great telescope has been continued by his son, the fourth earl. Revised by S. Newcomb.

Rosseau, Rodolphe: See the Appendix.

Rossel'li, Cosimo: painter; b. at Florence, Italy, 1439. He began as a mason, and Neri de' Bicci instructed him in art. He remained with Bicci till the age of seventeen. At an early age his work was recognized and admired; among the earliest examples are the frescoes at Sant' Ambrogio, still existing. About 1480 Sixtus IV. invited Cosimo Rosselli, together with other great masters, to come to Rome and decorate the Sixtine chapel. Cosimo, feeling his work inferior to that of his competitors, Ghirlandajo, Luca Signorelli, and Perugino, loaded his figures with ultramarine and gold, so that the pope was satisfied with their decorative effect. These frescoes still exist. He became a mannerist in his later days, and his work lost the excellent qualities it had when he followed in the footsteps of Masaccio. Rosselli died in Florence, Jan. 7, 1507. Fra Bartolommeo and Piero di Cosimo were his pupils. W. J. Stillman.

Rosselli'ni, Bernardo: sculptor and architect; b. in Florence, Italy, 1409. The mausoleum of Beata Villana, in Santa Maria Novella, and the monument of Leonardo Bruni (called Aretino) in Santa Croce, which is very remarkable both in design and in perfection of execution, are by him. Pope Nicholas V. made great use of Rossellini in his capacity of architect, though some of his designs were not carried out on account of their vastness. In Rome he restored the Churches of Santa Maria in Trastevere, Santa Prassede, San Teodoro, San Pietro in Vincola, San Giovanni Laterano, Santa Maria Maggiore, San Stefano, and San Lorenzo. He was also employed at Spoleto, Gualdo, Assisi, Civita Vecchia, Narni, Orvieto, Viterbo, and at Pistoia, where the monument to Filippo Lazzari in the Church of San Domenico may be regarded as one of his principal works. D. in 1464. W. J. Stillman.

Rosser, Leonidas, D. D.: minister and author; b. at Petersburg, Va., July 31, 1815; graduated at the Wesleyan University in 1838; joined the New York Conference in 1838; was transferred to the Virginia Conference of the Methodist Episcopal Church South in 1839; served in the pastorate until 1852; was presiding elder 1852–59; was editor of the Richmond *Christian Advocate* 1858–59; pastor in Richmond 1860; general missionary 1861–64; again presiding elder for a time, and afterward an evangelist both North and South. Author of *Baptism* (Richmond, 1843); *Experimental Religion* (1854); *Class Meetings* (1855); *Recognition in Heaven* (1856); *Reply to Howell's Evils of Infant Baptism* (1856); *Open Communion* (1858); and *Initial Life* (1885). D. Jan. 24, 1892. Revised by A. Osborn.

Rosser, Thomas Lafayette: See the Appendix.

Rosset'ti, Christina Georgina: poet; sister of Dante G. Rossetti; b. in London, England, Dec. 5, 1830; published *The Prince's Progress* (1866); *Commonplace, and other Short Stories in Prose* (1870); *Sing-Song, a Nursery Rhymebook* (1872); *Speaking Likenesses, Annus Domini* (1874); *Seek and Find* (1879); *A Pageant, and other Poems* (1881); and *Letter and Spirit* (1883). D. Dec. 30, 1894.

Rossetti, Dante Gabriel: painter and poet; b. in London, England, May 12, 1828. He was the son of Gabriele Rossetti, the author and patriot, and was named Gabriel Charles Dante, and he signed at least one early work "Gabriel Rossetti, Jr." He studied painting while a boy at Cary's school of art and at the schools of the Royal Academy, and showed very early a great and peculiar poetical gift both in verse and in design. His *Blessed Damosel* was published when he was nineteen, and the picture *The Girlhood of Mary, Virgin*, was exhibited when he was twenty. It was in the same year (1848) that was formed the Pre-Raphaelite Brotherhood (see Prerapiiaelites) of which Rossetti was to be the most distinguished member. In 1851 he wrote the remarkable poem *Sister Helen*, and made the strange design *How They Met Themselves*, showing a pair of lovers who meet their ghostly wraiths or doubles. In 1856 he was at work on the powerful designs which partly illustrated the Tennyson poems of 1859. In 1857–58 he painted in distemper one of several large pictures of the *Legend of King Arthur* on the walls of the Union Debating Society at Oxford. This picture has perished, apparently because the artist did not understand the medium. He wrote many poems before the year 1862, and these were announced for publication under the title of *Dante at Verona, and other Poems*; but his wife died in the last-named year, and Rossetti's manuscripts were buried with her. Six years later they were exhumed, and in 1870 there was published the volume entitled *Poems*. In 1872 his health began to give way, and the use of chloral to induce sleep weakened him still more. His second volume of original verse, *Ballads and Sonnets*, was published in 1881. In his later years he lived in a house with a large garden on the Thames at Chelsea, and spent some time at Kelmscott Manor in Oxfordshire. In Dec., 1881, he went to Birchington, Kent, for his health, and died there Apr. 9, 1882. His most important publication besides the poems was the volume of *Early Italian Poets* (1861), reissued as *Dante and his Circle*.

Russell Sturgis.

Rossetti, William Michael; poet and art critic; brother of Dante G. Rossetti; b. in London, Sept. 25, 1829. He was educated at King's College School, London, and has held positions in the Excise Office since 1845. Author of *Dante's Comedy—The Hell, translated into Literal Blank Verse, with Introduction and Notes* (1865); *A Life of Percy Bysshe Shelley, with a Revised Edition of his Poetical Works* (2 vols., 1869); *Life of John Keats* (1887); *Poems and Ballads, a Criticism* (upon A. C. Swinburne, 1866), and editor of the poems of Coleridge, Milton, Campbell, Blake, and Walt Whitman. Revised by H. A. Beers.

Rossi, Ernesto: actor; b. at Leghorn, Italy, in 1829; began to study law at Pisa, but joined in 1846 one of the better Italian troops of actors; played at Milan 1847, at Turin 1852, at Paris, with Madame Ristori, 1855, subsequently at Vienna, especially in the comedies of Goldoni; returned to Paris in 1866; appeared in the *Cid* at the Théâtre Français on the anniversary of the birthday of Corneille; performed several of the principal characters of Shakspeare—Hamlet, Othello, etc.—in Lisbon in 1869. He aroused extraordinary admiration by his performances in 1874, in Breslau, Berlin, Dresden, and Prague. He also achieved great success in South America. In 1881 he visited the U. S. There was a diversity of opinion as to his conception of Shakspearean characters, and the verdict on the whole was unfavorable. He wrote a treatise on Hamlet, and several plays. D. June 4, 1896. Revised by B. B. Vallentine.

Rossi, Francesco, de', called *De' Salviati*, from his patron Cardinal Salviati: painter; b. in Florence in 1510. He studied under Andrea del Sarto. In 1540 when living at Venice he painted a portrait of Pietro Aretino, which the poet gave to Francis I. Salviati visited France in 1554, during Henry II.'s reign, but returned in 1555. He painted in Rome, and completed the altarpiece in the Chigi chapel in Santa Maria del Popolo, which Del Piombo had left unfinished. D. in Rome, Nov. 11, 1563. W. J. S.

Rossi, Giovanni Battista, de': epigraphist and archæologist; b. in Rome, Italy, Feb. 23, 1822; under Father Marchi he devoted himself to the study of archæology and of the Christian inscriptions of the first centuries of the Church, and was complimented by being made a member of the Berlin Academy of Sciences and also foreign member of the French Institute. The discoveries made by him in the catacombs are of special importance, particularly those in the cemetery of St. Calixtus. His most valuable works are *Inscriptiones Christianæ Urbis Romæ septimo sæculo antiquiores* (vol. i., 1861; vol. ii., 1888); *Roma Sotterranea Cristiana* (3 vols., 1864–77): he was one of the chief editors of the *Inscriptiones urbis Romæ* (vol. vi. of the *Corpus Inscriptorum Latinorum*). To these must be added numerous treatises contributed to archæological and epigraphical journals. D. in Rome, Sept. 20, 1894. Revised by A. Gudeman.

Rossini, ros-see'nĕe, Gioacchino Antonio: composer; b. at Pesaro, Italy, Feb. 29, 1792. In 1807 he entered the musical school of Bologna, studying counterpoint under the Abbate Mattei, and in 1810 he produced his first opera, *La Cambiale di Matrimonio*, at Venice. Other operas, since forgotten, followed, and in 1813 his *Tancredi* excited an immense enthusiasm, first in Venice, and soon on every stage on which Italian opera was given. In 1815 he went to Naples as director of the opera, and composed among other operas *Elizabetta* (1815), *Otello* (1816), *La Gazza Ladra* (1817), *Mosè in Egitto* (1818), *La Donna del Lago* (1819), and *Zelmira* (1820): but his most celebrated production of this period is *Il Barbiere di Seviglia* (originally called *Almaviva*), first performed in Rome in 1816, and generally considered the masterpiece of the whole genre of opera buffa—irresistibly gay, and as characteristic as graceful and brilliant. *Semiramide* (1823), composed at Bologna for the Fenice theater, Venice, was not appreciated on the occasion of its first representation. Rossini went to London in 1823, and next year to Paris, where he was made successively director of the Italian opera, inspector-general of song in France, and first composer to the Grand Opera. In bringing out his old compositions on the Paris stage he felt compelled to make considerable alterations: the melodies required a greater simplicity and more character, the chorus a deeper connection with the whole organism and a fuller significance, the instrumentation greater variety and elaborateness. He made a penetrating study of his task before he ventured to represent any new composition, but when at last, in 1828, he made the attempt with *Count Ory*, and in 1829 with *William Tell*, his success was astonishing. A few days after the performance of the last work he left Paris and retired to his villa near Bologna, where he lived till 1847, declining all offers, even the most tempting, made in order to induce him to compose a new opera. In 1847 he removed to Florence, in 1856 to Paris, where he died Nov. 13, 1868. In the last forty years of his life he published only a *Stabat Mater*, and a *Messe solennelle*, which was performed at his burial. See Edwards's *Life of Rossini* (1869), and the biography by Azevedo (1865).

Rossiter, Thomas Prichard: figure and portrait painter; b. at New Haven, Conn., Sept. 29, 1818. He was a pupil of Nathaniel Jocelyn in New Haven, and studied in Paris, London, and other places in Europe 1840–46; National Academician 1849; gold medal, Paris Exposition, 1855. Many of his portraits are excellent. He devoted the later years of his life to painting the *Life of Christ* in a series of pictures. *Rebekah at the Well* is in the Corcoran Gallery, Washington. D. at Cold Spring, N. Y., May 17, 1871. W. A. C.

Rost, rost, Reinhold, LL. D., C. I. E.: Orientalist; b. at Eisenberg, Germany, Feb. 2, 1822; studied in the gymnasium at Altenburg; graduated in 1846 at Jena; went to England 1847; from 1851 instructor in Oriental languages in St. Augustine's College, Canterbury; became secretary to the Royal Asiatic Society 1863, and librarian to the India Office 1869. He prepared a descriptive catalogue of the palm-leaf MSS. in the Imperial Library of St. Petersburg 1852; edited Dr. H. H. Wilson's *Essays on the Religion of the Hindus and on Sanskrit Literature*. Editor of the Trübner series of *Simplified Grammars* 1882–88, and of the *Oriental Record*. D. at Canterbury, Feb. 7, 1896.

Ros'tock: town of Northern Germany; in Mecklenburg-Schwerin; on the Warnow, 9 miles from its mouth in the Baltic (see map of German Empire, ref. 2–F). It has a university founded in 1419, with a library of 140,000 volumes; many other good educational institutions; manufactures of linen, leather, and tobacco, and an active trade. Vessels which draw more than 12 feet must load and unload at Warnemünde, its port at the mouth of the Warnow. Pop. (1895) 49,912.

Rostof': town of European Russia, in the government of Yaroslaf (see map of Russia, ref. 6–E). It has 33 churches and large manufactures of linen and candles, and holds an annual fair from Feb. 21 to Mar. 11, in which transactions to the amount of about 2,000,000 rubles are carried out. Pop. 17,439.

Rostof: town of European Russia, government of Ekaterinoslaf; on the Don, at the beginning of its delta; founded in 1749 as a fortress, and rapidly growing into one of the commercial centers of Southern Russia (see map of Russia, ref. 10–E). Ropes, linen, leather, soap, and tobacco are extensively manufactured. Pop. (1897) 119,889.

Rostoptchin', Fedor Wasilievich, Count: general; b. in the government of Orel, Russia, Mar. 23, 1763; was educated at the court as a page of Catherine II.; became Minister of Foreign Affairs under Paul I., and was governor-general of Moscow in 1812, when Napoleon approached. He was long believed throughout Western Europe to have set fire to the city before leaving it to the French, but in his *La Verité sur l'Incendie de Moscou* (Paris, 1823) he denies this. It is certain, however, that he set fire to his own palace and made preparations for the burning of the magazines. D. in Moscow, Feb. 12, 1826. See Schnitzler, *Rostoptchine et Koutousof, ou la Russie en 1812* (Paris, 1863). F. M. Colby.

Rostra [Lat., liter., beaks. So called because decorated with the beaks of the galleys of Antium, taken in the first naval victory of the republic, 338 B. C.]: the platform for public speaking at Rome; originally situated between the Comitia and the Forum. It was used also as a place for setting up statues of distinguished men, and on its sides were displayed some of the most important public documents, such as the laws of the Twelve Tables, international treaties, etc. At Cæsar's initiative the old rostra was torn down, and a new one constructed (probably not earlier than 42 B. C.) at the west end of the Forum, before the temple of Concord. This was about 10 feet high, 80 feet long, and 33 feet deep, its great size being accounted for by the necessity of providing a place for statues, as above indicated. The rostra was restored with great magnificence in the second century A. D. (by Trajan or Hadrian). G. L. Hendrickson.

Roswitha: See Hrotsvitha.

Rot (in vegetable pathology): any one of many diseases of plants, all due to the attacks of fungi or other low vegetable organisms.

The *bitter-rot* of apples causes upon the surface of the mature fruit brownish or blackish spots, which at length become studded with minute black raised points. On cutting through a diseased spot it is seen to extend far into the tissues of the apple. The fungus causing this disease

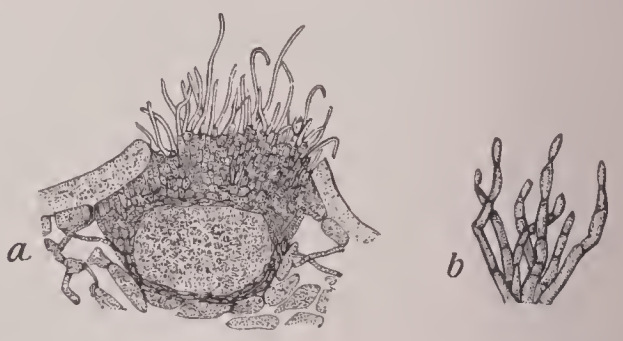

Fig. 1.—*a*, section through black point of bitter rot; *b*, spore-bearing threads (highly magnified).

is *Glœosporium fructigenum*, one of the so-called imperfect fungi of the family *Melanconiaceæ*. Its threads grow parasitically through the tissues of the apple, killing the

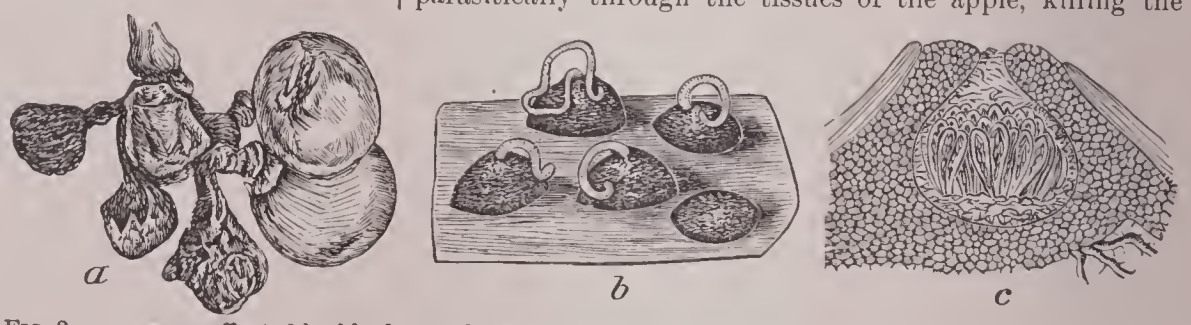

Fig. 2.—*a*, grapes affected by black-rot; *b*, escape of the conidia; *c*, section showing ascospores (*b* and *c* magnified).

cells, and finally come to the surface and produce the minute black points mentioned above, in which spores are produced (Fig. 1). Spraying the fruit in August with a 1-per-cent. solution of ammoniacal copper carbonate is a preventive. Another rot of the apple is called *black-rot* from the black color of the decayed portion, in which are found little points or pustules containing spores. The fungus (*Macrosporium malorum*) is closely related to the preceding.

Black-rot of grapes attacks the fruit, leaves, and shoots,

causing brown and finally black spots of dead tissue, resulting eventually in the shriveling of the berries into hard black masses. The disease is caused by a black fungus (*Læstadia bidwellii*) of the family *Sphæriaceæ* (Fig. 2, *a*). In its earlier stage (*Phoma* stage) it produces stalked spores, which are emitted from the black pustules in gelatinous strings (Fig. 2, *b*). Later in its perithecia it produces ascospores, which are always eight in each ascus (Fig. 2, *c*).

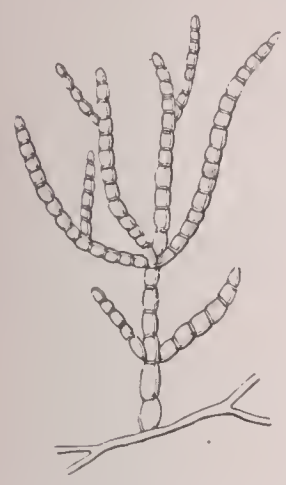

Fig. 3.—Conidia-bearing threads of plum-rot (highly magnified).

The *brown-rot* of grapes is caused by one of the downy mildews (*Plasmopara viticola*; see Mildews). The grapes turn brown and hard, and finally shrivel up. Brown spots appear upon the leaves also. Both kinds of rot on grapes may be prevented by freely spraying the vines five or six times during the season with a 1-per-cent. solution of ammoniacal copper carbonate. The *bitter-rot* of the grape which gives to the fruit a bitter taste is due to a minute species of the "imperfect fungi." Closely related to this is the *white-rot*. No remedy is known for either, but Bordeaux mixture is recommended. *Bird's-eye rot* of grapes is known also as *anthracnose* and *grape-scab*. See Scab.

Fig. 4.—*Armillaria mellea* of the root-rot of the grape (reduced).

One form of *potato-rot* or *blight* is caused by a downy mildew (*Phytophthora infestans*) whose parasitic threads penetrate the tissues of the leaves, stems, and tubers, and quickly destroy them. (See Mildews.) Spraying with some of the fungicides is said to be a remedy. Another form of potato-rot is produced by bacteria, which infest the tissues of the tubers, as well as of the parts above ground, causing their speedy death and decay. This bacterial disease of the potato appears to be more prevalent in the U. S. than that caused by the downy mildew. The bacterial disease appears to be checked by a rotation of crops.

Plum-rot is a common disease of the nearly ripe fruits of plum and peach trees. It is caused by a so-called imperfect fungus (*Monilia fructigena*) of the order *Hyphomyceteæ* and family *Mucedinaceæ*. Only the conidial stage (Fig. 3) is known. The threads grow through the tissues of the affected fruit, and appear here and there in tufts of bead-like rows of spores (conidia). The latter readily germinate in water or upon the injured surface of the fruit. The speedy removal of all diseased fruit and the early application of poisonous sprays will serve to check the disease.

Tomato-rot, in which the fruit decays when nearly ripe, is due to the minute *Macrosporium tomato*, one of the "imperfect fungi." Growing the plants so as to admit light and air decreases this disease, and spraying with Bordeaux mixture has been recommended.

Root-rot is an affection of several cultivated plants, and appears to be due, in some cases at least, to the growth of some of the larger fungi. In the grape the mycelium of one of the toadstools (*Armillaria mellea*) penetrates and destroys the tissues of the roots, finally producing the characteristic fruiting, as shown in Fig. 4. The same fungus causes the decay of the roots and trunks of timber-trees, and it or a related species often attacks the roots of apple-trees.

Dry-rot of timber is a destruction of the tissues of the wood, resulting from the growth of the mycelium of one of the pore-fungi, *Merulius lacrymans* (Fig. 5). It attacks timber which is kept damp, as the supports in mines, cellars, etc., the foundation-timbers of buildings, and, in wooden ships, the interior timbers below the water-line. Thorough painting or saturation with poisonous solutions reduces the

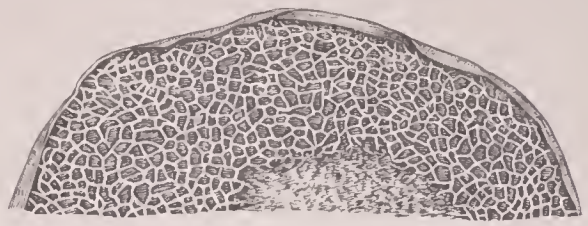

Fig. 5.—Portion of the fungus of dry-rot, in the fruiting state (slightly reduced).

danger of dry-rot. Especial care should be taken to avoid the use of timber in which dry-rot has made any beginning whatever. *Wet-rot* is a disease of timber-trees caused apparently by one or more species of the larger fungi, in some cases possibly the same as the preceding, and sometimes referred to *Trametes* and *Polyporus*.

Literature.—F. L. Scribner, *Fungous Diseases of the Grape and Other Plants* (1890); H. M. Ward, *Timber and some of its Diseases* (1889); also various papers by F. L. Scribner and B. T. Galloway in the U. S. Agricultural Reports (1887 to 1892). Charles E. Bessey.

Rotary Presses: See Printing-presses.

Rotation: See Motion.

Rotation, in agriculture: See Agricultural Chemistry.

Rotato'ria: another name for Rotifera (*q. v.*).

Rotch, rōch, Abbott Lawrence, M. A., F. R. M. S.: meteorologist; b. in Boston, Mass., Jan. 6, 1861; studied at the Boston Institute of Technology. In 1885 he founded the Blue Hill meteorological observatory on Blue Hill, Mass., the highest point on the Atlantic coast of the U. S. south of Maine. From 1886 till 1892 he was associate editor of *The American Meteorological Journal*, and in 1891 he was appointed by the international meteorological committee a member of its commission on the classification and nomenclature of clouds. In 1889 he represented the U. S. at the Paris Exposition, and was made Chevalier of the Legion of Honor. He is author of many meteorological papers in the scientific journals, and of regular annual reports of the work of the Blue Hill observatory (since 1887 published in the *Annals of the Astronomical Observatory of Harvard College*).
Mark W. Harrington.

Roth, rōt, Rudolf, von: Orientalist; b. in Stuttgart, Germany, Apr. 3, 1821; studied at Berlin, Paris, and London; in 1856 became Professor of Oriental Languages and chief librarian at Tübingen University. With Böhtlingk (*q. v.*) he prepared a great Sanskrit dictionary. Among his other works are *Vedic Literature and History* (1846); *Nirukta* (1852); and *Atharva-Veda* (1856), written in conjunction with W. D. Whitney. D. at Tübingen, June 23, 1895.

Rothe, rō'te, Richard: theologian; b. at Posen, Prussia, Jan. 28, 1799; studied at Heidelberg and Berlin, and was appointed preacher to the Prussian embassy at Rome in 1823; professor at Wittenberg in 1828, at Heidelberg in 1837, at Bonn in 1849, and again at Heidelberg in 1854, where he died Aug. 20, 1867. His principal work is *Theologische Ethik* (3 vols., Wittenberg. 1845–48), edited, with his posthumous notes, by Holtzman (5 vols., 1869–71). But he also occupied a most prominent place in the historical and dogmatic divisions of his science—*Die Anfänge der christlichen Kirche* (Wittenberg, 1837) and *Zur Dogmatik* (Gotha, 1863; 2d ed. 1869). An English translation of his *Sermons for the Christian Year* appeared in Edinburgh 1877, and of his *Still Hour* (London and New York, 1886). After his death appeared his *Dogmatik* (Heidelberg, 1870); *Vorlesungen über Kirchengeschichte* (2 vols., 1875–76); *Geschichte der Predigt* (Bremen, 1881); *Gesammelte Vorträge und Abhandlungen aus seinen letzten Lebensjahren* (Elberfeld, 1886). He was a noble, broad-minded, speculative theologian, imbued with the inspiring idea that no line of demarkation should be drawn between sacred and secular, for religion and morals are absolutely identical. See his *Life*, by F. Nippold (2 vols., Wittenberg, 1873–75).
Revised by S. M. Jackson.

Roth'ermel, Peter Frederick: painter; b. in Luzerne co., Pa., July 18, 1817, of German extraction; was educated in Philadelphia for the profession of land-surveyor; opened a studio as a portrait-painter, but soon adopted historical painting as his branch of art; visited Europe in 1836–37, and painted in Italy. With the exception of his *Columbus*

before Queen Isabella, The Martyrs of the Colosseum, Cromwell breaking up Service in an English Church, his best-known pictures are suggested by American themes—*De Soto discovering the Mississippi, Patrick Henry before the Virginia House of Burgesses, The Battle of Gettysburg.* Rothermel belongs to the class of sensational artists, but his talent for composition and color gives him a high rank among these. D. near Pottstown, Pa., Aug. 15, 1895.

Rothesay, roth'sā: a royal burgh and favorite watering-place of Scotland; capital of the county of Bute; pleasantly situated at the head of a spacious and sheltered bay on the northeastern coast of the island of Bute. Though the first cotton-mill established in Scotland was located here, the place has now no industries worth mentioning. Considerable fishing, however, is carried on. Near the center of the town are the ruins of Rothesay Castle, founded in 1098. Pop. of burgh (1891) 9,034.

Rothesay, David Stewart, Duke of: See Stewart.

Rothrock, Joseph Trimble, B. S., M. D.: botanist; b. at McVeytown, Pa., Apr. 9, 1839; educated at Harvard College and the University of Pennsylvania. He has been Professor of Botany in the Pennsylvania Agricultural College and the University of Pennsylvania, and was the botanist of the U. S. geographical surveys W. of the 100th meridian, made by Lieut. Wheeler in 1873–74–75. Among his scientific publications are the following: *Morphology of the Androecium in Fumariaceæ* (1863); *Revision of the North American Gaurineæ* (1864); *Flora of Alaska* (1867); *Botany of the Wheeler Expedition* (1878). He has also written many papers on forestry. Charles E. Bessey.

Rothschild. Germ. pron. rōt'shĕĕlt, Meyer Anselm: financier and founder of a family celebrated for its great wealth; b. at Frankfort-on-the-Main, 1743; was intended for the Jewish priesthood, but was placed in a counting-house at Hanover, whence he returned to Frankfort and started in business for himself on a small scale as a banker and broker. Devoting himself closely to his new business, he obtained a reputation for ability and integrity, and was intrusted with the money affairs of the landgrave, afterward Elector of Hesse, who during Napoleon's possession of Germany confided to Rothschild the keeping of his immense private fortune without interest. D. in Sept., 1812, leaving a large fortune to his five sons, Anselm, Solomon, Nathan, Charles, and James, who established themselves respectively in the cities of Frankfort, Vienna, London, Naples, and Paris. All of these were created in 1822 barons of the Austrian empire.—The third son, Nathan, b. Sept. 16, 1777, who established a branch of the house in England, employed with great judgment the immense sums confided to his father, and raised the firm to the position of one of the leading banking-houses of the world. D. at Frankfort, July 18, 1836.—Lionel Nathan, b. Nov. 22, 1808, eldest son of Nathan, was repeatedly elected to the British Parliament, but declining to take the prescribed oath, "on the true faith of a Christian," was not admitted until the act for removing the disabilities of the Jews was passed in 1858, when he took his seat, being the first Jew admitted to Parliament. D. June 3, 1879.—His son Nathan was raised to the peerage as Baron Rothschild in 1885. See Reeves, *The Rothschilds* (London, 1887). F. M. Colby.

A rotifer.

Rotif'era [Mod. Lat.; Lat. *ro'ta*, wheel + *ferre*, to bear]: a group of microscopic animals which are of interest not only on account of their motions and powers of withstanding desiccation, but from the fact that they represent as adults a structure which occurs only in the embryos of other worms. The scientific name, as well as the popular term of wheel-animalcules, is due to the fact that around the anterior end of the body is a more or less modified circle of cilia, the motions of which convey the impression of a wheel in rapid rotation. Just behind the wheel is the mouth, which communicates with a complicated apparatus of jaws (mastax) in the throat. There is a large stomach, and the vent is on the dorsal surface of the body. The nervous system consists of a ganglion above the throat, from which nerves run to all parts of the body. Eyes are not infrequently present, as well as organs apparently tactile in character. Two tubes with funnel-shaped openings into the body-cavity serve as excretory organs. Organs of circulation and respiration are lacking. The sexes are separate, and the males are usually smaller than the females, and are further characterized by the lack of intestine and vent. Most of the rotifers live in fresh water, and are noticeable because they are able to withstand prolonged drying, and upon the return of moisture again begin their active life. See Hudson and Gosse, *Rotifera* (London, 1886), and papers by Plate, Salensky, Leydig, Jennings (*Report* Michigan Fish Commis., 1893), etc. J. S. Kingsley.

Rot'teck, Karl Wenzeslaus Rodecker, von: historian; b. at Freiburg, Baden, July 18, 1775; studied law, afterward history; was appointed Professor of History at the university of his native city; took part with much energy, though with moderation, in the opposition against the political reaction which set in after 1815; was elected to the upper chamber of Baden in 1819, to the lower chamber in 1831, and was one of the foremost men of the liberal opposition. This brought upon him the hostility of the Government, and in 1832 he was deprived of his professorship. D. at Freiburg, Nov. 26, 1840. By his *Allgemeine Geschichte* (9 vols., 1813–27) and the minor compendium of it, *Allgemeine Weltgeschichte* (4 vols., 1830–34), he exercised a great and beneficial influence on the German middle classes. Both books were often reprinted, and have been translated into several European languages. F. M. Colby.

Rottenstone: a fine earth or softened aluminous stone, much employed in polishing glass and metals. True rottenstone comes from Wales and Bakewell, Derbyshire. The name is also extended so as to include tripoli and the infusorial earths. See Infusorial Earth.

Rotterdam: the second commercial town in Holland; on the right bank of the Maas, about 14 miles from the North Sea and 36 miles S. W. of Amsterdam (see map of Holland and Belgium, ref. 6–E). It occupies a site in the form of a nearly equilateral triangle, the base of which is the Maas and the vertex the Delft Gate. The city is intersected by numerous canals (*grachten* or *havens*), and is traversed by the Rotte, a small stream, at the junction of which with the Maas there is a large dike or dam; whence the name Rotterdam. The numerous vessels lying in the canals and harbors, which are deep enough to accommodate those of heavy tonnage and admit of their discharging their cargoes in the very heart of the city, always present a busy and picturesque scene. Along the river, which opposite the town is 30 to 40 feet deep, is a fine quay 1¼ miles long, called the *Boompjes* (Little Trees), from a line of elms planted in 1615, now grown to a large size. Here is the birthplace of Erasmus (*q. v.*), to whom a bronze statue is erected. Rotterdam is the entrepôt of a large cattle-trade with England, and the point of departure of numerous lines of steamships, and, besides being the seat of an extensive commerce with the East Indian possessions of Holland and with Europe and America, has important manufactures. The railway route between Belgium and Holland, connecting the cities of Brussels, Antwerp, Rotterdam, The Hague, and Amsterdam, crosses the Holland Deep (*Hollandsche Diep*) by the great bridge at Moerdijk. Pop. (1899) 319,866.
Revised by M. W. Harrington.

Rotti: a volcanic island of the Malay Archipelago; S. W. of Timor; in lat. 10° 40′ S. and lon. 123° E.; is 36 miles long, 11 miles broad, hilly, and produces rice, millet, and maize, ebony and other valuable woods, sheep, buffaloes, horses, swine, and fowls, edible birds' nests, and wax. Pop. 64,000. M. W. H.

Roubaix, roo'bā': a large manufacturing town of France, department of Nord; 6 miles N. E. of Lille (see map of France, ref. 1–F). It has extensive manufactures of woolen and cotton fabrics, furniture cloth, carpets, and twists, large dye-works and tanneries, and carries on a very active trade. Pop. (1896) 124,661.

Roubiliac, roo'bĕĕ'li-ăăk', Louis François: sculptor; b. at Lyons, France, about 1695; became a distinguished sculptor; settled in England probably during the reign of George I., and executed many important works of art, among which were the celebrated monuments of Mrs. Nightingale, that of John, Duke of Argyle, and the statue of Handel, all in Westminster Abbey, the statue of Shakspeare in the British Museum, and of Sir Isaac Newton at Cambridge. D. in London, Jan. 11, 1762.

Rouble, or **Ruble** [from Russ. *rubli*, ruble]: the principal Russian money of account. The rouble is equal to 100

kopecks. The nominal rouble of gold is worth 77·2 cents of U. S. money, while the current paper rouble has two different values, viz., the official value in gold as determined by the government for each year and the exchange value. These are usually about 50 cents.

Roudaire, roo′dâr′, François Elie: soldier; b. at Guéret, in the department of Creuse, France, Aug. 6, 1836; entered the Academy of St.-Cyr in 1854 and was made a lieutenant in 1858, a captain in 1861, and chief of squadron in 1878. In 1873 he was charged with the geodetic surveys necessary for the determination of the meridian of Biskra, and, having observed that the level of Sahara lay considerably lower than that of the Mediterranean, he conceived the idea of transforming the desert into an inland sea by piercing the dunes which separate it from the Mediterranean. In 1874 he began a new series of explorations at the expense of the Government, and after his return, in 1876, he laid before the Government a scheme which was very warmly supported by Waddington. D. at Guéret, Jan. 13, 1885. He published *Une Mer intérieure en Algérie* (1874) and *Rapport sur la Mission des Chotts en Algérie* (1876).

Rouen, roo′ăn′ (anc. *Roto′magi*): city of France, the ancient capital of Normandy, at present the capital of the department of Seine-Inférieure; on the right bank of the Seine, 67 miles N. W. of Paris, and connected with its suburb, St.-Sever, on the opposite bank, by three bridges (see map of France, ref. 3–E). The quays along the river and the boulevards occupying the site of the former ramparts are new and elegant; the central part of the city is old and more interesting than beautiful. Of the many remarkable public buildings the most noticeable are the cathedral, a Gothic structure of great beauty, 434 feet long, 103 broad, 89 high at the nave, with a tower and spire over the crossing of the nave and the transept rising 470 feet, and two elegant towers flanking the front, built by Philip Augustus (1200–20), and containing, besides a number of other interesting monuments, the tomb of Richard Cœur de Lion; the Church of St. Ouen, built in the fourteenth century, and considered one of the finest specimens of Gothic architecture; the Palais de Justice, of the fifteenth century, etc. In the Place de la Pucelle stands a statue of the Maid of Orleans, who was burned here in 1431. Monuments have also been raised in honor of Corneille and Boieldieu, who were born here. The city has a public library of 110,000 volumes, a very valuable collection of pictures, an excellent botanical garden, a theological seminary, an academy of science and art, and numerous other educational and benevolent institutions; and it is one of the most important manufacturing centers of France. The principal manufactured articles are cotton and cotton velvet, mixed silk and woolen fabrics, flannels, blankets, and hosiery, chemicals, paper, etc. Its commerce is very extensive; the river forms an excellent harbor, and vessels of 400 to 500 tons can enter it. Pop. (1896) 113,219.

Revised by M. W. Harrington.

Rouen Ware: See Pottery and Porcelain.

Rouge, roozh [= Fr., liter. red]: a powder used for adding an artificial bloom to the complexion. Rouge is finely powdered talc colored with safflower by an elaborate process. It is harmless to the skin. Much of the so-called rouge is colored with carmine and other pigments. These are considered injurious.

Rouge: French name of the Songkoi (*q. v.*).

Rougé, roo′zhā′, Olivier Charles Camille Emmanuel, Vicomte de: Orientalist; b. in Paris, Apr. 11, 1811. After studying law, he devoted himself to Oriental studies, particularly to Hebrew, Arabic, and Coptic. Finally he confined himself more exclusively to the study of Egyptology. Having obtained celebrity in this line through his *Examen critique de l'ouvrage de M. le Chevalier de Bunsen*, and through his contributions to the *Revue archéologique*, in 1849 he was made keeper of Egyptian antiquities in the Louvre. In 1851 he published a *Mémoire sur l'inscription du tombeau d'Ahmès*, which Lepsius declared to be the only work then published which could lay claim to be a philological analysis of a hieroglyphic text. In fact he was the first to attempt the translation of long Egyptian texts such as his *L'histoire des deux frères* (1852, from the papyrus d'Orbiney), and he was the founder of the French school of scientific investigation. He was chosen member of the French Institute in 1853, and Professor of Egyptology in the Collège de France in 1860. In 1855 he published a *Notice sommaire des monuments égyptiennes du Louvre*, and in 1856–59 an *Étude sur une stèle égyptienne de la Bibliothèque Impériale*. He made an Egyptian tour in 1863, whose results were published by his son in *Inscriptions hiéroglyphiques copiées en Égypte pendant sa mission scientifique* (Paris, 1877–79, 4 vols.). His most important historical work was his *Recherches sur les monuments qu'on peut attribuer aux six premières dynasties de Manéthon* (Paris, 1866), and his great service to grammatical investigation was rendered in his *Chrestomathie égyptienne . . . précédée d'un abrégé grammatical* (4 vols., Paris, 1867–76), in which he remodeled the whole subject. Among his works upon Egyptian religion and mythology were the following: *Explication d'une inscription égyptienne, prouvant que les anciens Égyptiens ont connu la génération du fils du Dieu* (Paris, 1851); *Études sur le Rituel Funéraire des anciens Égyptiens* (Paris, 1860); *Conférence sur la religion des anciens Égyptiens et sur le monothéisme primitifs* (Paris, 1869). He held to a monotheistic conception of the supreme solar deity of Egypt, explaining polytheism by the doctrine of emanation. He also held that the grouping of local deities in triads was an attempt to signify the passage of conception from the supersensuous to the sensuous, and from the invisible to the visible. In these views he has been followed in the main by Pierret and Brugsch. He is also credited with the discovery of the Egyptian doctrine of immortality. In his *Mémoire sur l'origine égyptienne de l'alphabet phénicien* (published after his death, from an imperfect draft, in 1874) he endeavored to trace our modern alphabet through the Greek and Phœnician back to an Egyptian prototype. He died Dec. 31, 1872, at Bois Dauphin, in the department of Sarthe.

Charles R. Gillett.

Rouge-et-Noir, roozh′ā-nwăr′ [Fr., red and black], also called **Trente-et-Un** [thirty-one], or **Trente-et-Quarante** [thirty and forty]: a game of chance played with six packs of cards on a table, each end of which is divided alike into spaces known as *rouge*, *noir*, *couleur*, and *inverse*. The players make even bets with the bank by placing the sums risked on these spaces. The *taitteur* (dealer or banker) deals first for *noir*, and places the cards in a row until the number of pips amounts to more than thirty, the face cards counting 10 each. He then deals for *rouge* in the same manner, and that row whose value is nearest to 31 wins. If the first card dealt is of the color whose row wins, *couleur* wins; if it be of the color of the losing row, *inverse* wins. If the value of the two rows is equal, it is a *refait*, a new dealing commences, and the players neither win nor lose unless the value of each row is 31; in that case the players lose half the stakes. Were it not for this provision as regards the *refait* of 31 (which occurs once in about sixty-four times), the chances of the players and the bank would be equal. In 1789 this game and roulette were invented in Paris, and superseded faro and biribi, but both were forbidden by law in 1838. In 1873 they were also forbidden in Germany, but they are still much played and very popular at Monaco.

Rouget, roo′zhā′, Georges: painter; b. in Paris in 1781; studied painting in the Academy of Art and in the studio of David, in the execution of whose pictures he often assisted; began to exhibit in 1812; achieved great success both by his portraits and historical pictures. D. Apr. 9, 1869. The best known of his works are the *Marriage of Napoleon and Marie Louise* (1838, at Versailles); the *Death of Napoleon* (1846); and the portraits of Napoleon, Marshal Soult, Louis XVIII., and Charles X.

Rouget de Lisle, -de-leel′, Claude Joseph: author of words and music of the French national song, the Marseillaise (*q. v.*); b. at Lons-le-Saulnier, May 10, 1760; entered the army, and was an officer of engineers at Strassburg when he composed the *Marseillaise* in the night of Apr. 25, 1792; served afterward in La Vendée, retired to civil life, and was given a pension by Louis Philippe in 1830. D. June 27, 1836. He wrote other poems, stories, libretti for operas, etc., but nothing of merit. A. G. C.

Rouher, roo′ā′, Eugène: minister of Napoleon III.; b. at Riom, France, Nov. 30, 1814; was admitted to the bar in 1838, elected to the Constituent Assembly in 1848, and to the Legislative Assembly in 1849, in which latter year he was made Minister of Justice by Louis Napoleon. In July, 1851, he resigned, but was reappointed Dec. 2, 1851, the day of the *coup d'état*. Upon the confiscation of the Orleans property (Jan. 22, 1852) he again resigned, but a few days later was made vice-president of the council of state; in Feb., 1855, was appointed Minister of Agriculture, Commerce,

and Public Works, among the important acts of his administration being the negotiation, with Cobden, of the commercial treaty of 1860, when the grand cross of the Legion of Honor was bestowed upon him. He was raised to the rank of senator in 1856, and in 1863 succeeded M. Billault as Minister of State, which position he resigned on the occasion of the celebrated letter of the emperor's of Jan. 19, 1867, announcing a more liberal policy, but was immediately reinstated, and the additional portfolio of Minister of Finance was confided to his charge. Following the election of May, 1869, the ministry resigned July 13, and Rouher was nominated president of the senate a week later. During the Franco-German war he was prominent, but on the downfall of the empire fled to England. Returning to France, he was arrested and held for a brief time. He became a member of the Assembly, where he took the lead of the Bonapartist party. D. in Paris, Feb. 3, 1884. F. M. Colby.

Roulers, rōō'lā' : town of Belgium, province of West Flanders; on an affluent of the Lys, 13 miles by rail N. W. of Courtrai (see map of Holland and Belgium, ref. 10–B). It has large manufactures of linen and lace, and trade in flax, which is largely grown in the vicinity. Pop. (1891) 20,339.

Roulette, rōō'let' [= Fr., dimin. of O. Fr. *roule*, wheel < Lat. *ro'tula*, dimin. of *ro'ta*, wheel]: a game of chance played on a table in whose center is a cavity, the sides of which are firm and divided at equal distances into thirty-eight compartments painted half black, half red, and designated by the first thirty-six numbers, besides a zero and a double zero. The bottom of the cavity is movable by the aid of a handle in the form of a cross. When the banker puts the bottom in motion he throws down in the cavity a small ivory ball, and when the movement stops the ball drops into one of the painted compartments. Each end of the table is divided into spaces on which the players place the stakes they wish to risk. Each number has one, and a player betting on the winning number receives thirty-six times his stake. There are devices also by which a player may bet on two numbers, with odds of 1 to 17; three numbers, with odds of 1 to 11; or twelve numbers, with odds of 1 to 2. Finally, there are six spaces, with even odds, on which the player bets respectively that the winning number will be (1) odd, (2) even, (3) one in a red compartment, (4) in a black one, (5) less than 19, and (6) more than 18. The advantage of the bank in the first bets described is evidently as 38 to 36. For the last six methods zero counts as odd, red, and less than 19, and double zero as even, black, and more than 18; but if a player wins on either of these compartments he loses half his stake instead of receiving it double. See Rouge-et-Noir.

Roum: See Roumelia.

Rouma'nia [from Lat. *Roma'nus*, Roman]: a kingdom of Europe, comprising the former principalities of Moldavia and Wallachia, together with the Dobrudja, a territory E. of the Danube, ceded by the Ottoman empire at the Congress of Berlin (1878). It is situated between 43° 38′ and 48° 20′ N. lat. and 22° 20′ and 30° 15′ E. lon. (see map of Turkey); bounded N. by Austria-Hungary and Russia, E. by the Pruth, which separates it from Russia, and by the Black Sea, S. by Bulgaria and the Danube, W. by the Danube, which separates it from Bulgaria and Servia, and by Austria-Hungary. Area, 48,307 sq. miles.

Roumania is a crescent-shaped territory, rising gradually from the Danube and Pruth to the inland frontier, the crest of the Carpathian Mountains, the loftiest of whose peaks, the Ciacleul or Pion, attains a height of 8,920 feet. It is drained entirely by affluents of the Danube. The principal rivers are the Aluta or Olto, 220 miles long, which rises in Transylvania, cuts through the Carpathians, and empties at Islar; the Sereth, 215 miles long, which rises in Bucovina and flows by Roman to Galatz; the Dumbovitza, on which Bucharest, the capital, is situated; and the Pruth, 247 miles long. The Danube is navigable from the Austrian-Hungarian frontier to the Black Sea for vessels of several hundred tons, and hence is a great commercial artery. The other rivers, save the Pruth, are not available for transport trade. Both salt and fresh water lakes abound in the interior, and the coast is skirted by brackish lagoons. In the Danube are over 300 islands belonging to Roumania.

The territory naturally divides into three regions: the mountainous, where are the forests and mines; the hilly, devoted to vineyards and pasturage; and the lowland or rich alluvial tracts, occupied by grain-fields, along the lower Danube and the Pruth. Sixty-eight per cent. of the total area is productive, 29 per cent. being under cultivation, 22 per cent. for pasturage, and 17 per cent. forest. The residue is waste. The upland plain between mountains and lowland is of Quaternary formation; the foot-hills of the Carpathians are of Tertiary formation, containing Pliocene and Miocene deposits, while the mountain summits represent the Secondary, Primary, and Metamorphic or Azoic rocks. All the birds and mammals of similar climate, large and small, abound in the forests, and the rivers and lakes teem with every variety of fish found in Europe. The forests consist mainly of pine, oak, fir, beech, box, birch, poplar, and plane. The apple, pear, plum, and cherry are extensively cultivated, as also all the cereals and garden vegetables known to Europe. The vines are excellent. The climate varies according to situation and elevation; extremes of temperature, 98° F. and −19°. There are three distinct seasons: winter passes almost without transition into summer, just as autumn, the agreeable season lasting through November, suddenly becomes winter, when all the rivers and even the Danube are frozen over. The soil is exceedingly fertile, not exhausted by over-cultivation, and would be most productive but for the scorching and long-continued droughts of summer. The chief agricultural products are maize (average yield, 32,000,000 bush.), wheat (average yield, 30,000,000 bush.), rye, barley, oats, millet, flax, hemp, and tobacco. Various marbles are found in the valley of the Aluta; millstones, alabaster, and gypsum abound; fuller's earth and hydraulic lime are common; carbonate and sulphate of sodium, sulphate of aluminium, and magnesia and native sulphur occur in certain localities. Gold, iron, copper and lead ores, as well as cobalt and arsenic, exist. Salt-works and petroleum-wells especially yield valuable returns. Live stock is a main source of wealth. In 1897 there were 670,909 horses, 1,079,312 swine, 2,138,315 cattle, and 6,847,825 sheep and goats.

The decimal system for money, weights, and measures was introduced in 1876. The unit of value is the leŭ (plu. leĭ), or franc. Gold is scarce, and silver the common medium of exchange. In the financial year 1898–99 the state received 221,935,617 leĭ and expended 206,042,202. The chief budget estimates of the revenue for 1901–02 were: direct and indirect taxes, 106,280,000 leĭ; state monopolies, 55,930,000 leĭ; agriculture, 23,363,000 leĭ. The chief expenses were: interest on public debt, 91,270,238 leĭ; war department, 41,560,609 leĭ; financial department, 31,195,666 leĭ; education and worship, 23,451,251 leĭ; public works, 5,020,824 leĭ. The public debt on Apr. 1, 1900, was 1,451,497,307 leĭ, an enormous amount for so poor a country. In 1899 the imports, chiefly from Germany, Austria-Hungary, and Great Britain, amounted to 333,267,938 leĭ: the exports, chiefly to Great Britain, Belgium, Germany, and Austria-Hungary, 149,119,657. Grain forms nearly five-sixths of the entire exports: other exports were fruits and vegetables, animal and animal products, woven fabrics, lumber. Nearly half the imports were woven goods, amounting to 130,987,296 leĭ; other imports were metals and objects in metal, fruits and vegetables, and combustible materials. Foreign commerce is almost exclusively in the hands of foreigners. In 1899 26,246 vessels of 5,701,177 tons entered, and 25,876 of 5,200,487 tons cleared. In 1899 the merchant navy included 382 vessels of 69,072 tons, of which 55 of 12,785 tons were steamers. Railways, posts, and telegraphs all belong to the state. In 1900 there were 1,932 miles of completed railways, and 72 in construction. Postal communication was formerly conducted by Russian and Austrian commercial agencies, but in 1869 a regular postal service was organized. In 1892 15,645,630 letters, 4,787,565 postal-cards, and 7,960,771 newspapers and parcels passed through the mails; 1,091,819 domestic telegrams and 446,775 foreign telegrams were sent. Receipts for posts and telegraphs, 6,149,043 leĭ; expenses, 6,022,011 leĭ. Number of post-offices, 352; of telegraph stations, 411. Length of telegraph lines, 3,503 miles, generally with two wires.

The government is an hereditary constitutional monarchy. The constitution, one of the most liberal in Europe, guarantees to every Roumanian equality under the law, and liberty of conscience, with freedom of the press and right of assembly. Legislation is vested in a senate of 120 members and a house of 183 deputies. The person of the king is inviolable, but his seven ministers, of the Interior, Finance, Foreign Affairs, War, Worship and Public Instruction, Commerce and Public Works, and Justice, are responsible to the legislative bodies. The kingdom is administratively divided into the four provinces of Little and Great Wallachia with 17 districts, Moldavia with 13 districts, and

Dobrudja with 2 districts. These are further divided into 227 departments, subdivided into 2,979 communes comprising over 30,000 villages and hamlets. Military service for seven years in active service or *congé*, and two years in the reserve is obligatory on every able-bodied male citizen on reaching the age of 21; from 30 to 36 he belongs to the militia, and from 36 to 46 to the Landsturm; the latter takes the field only in national emergency. There are 4 army-corps, comprising 33 regiments of infantry, 4 regiments of hussards, 12 regiments of artillery, 2 regiments of heavy artillery, and 2 regiments of engineers, with an effective force in time of peace of 2,960 officers, 354 employees, 46,000 men, 600 cannon, and 10,000 horses. In war 250,000 men can be put under arms. The fleet in 1893 consisted of 33 vessels, of which 19 were steamships of various kinds, carrying 65 cannon, and of 3,175 tons tonnage. In 1892 there were 98 officers and engineers, 25 mechanicians, and 1,480 sailors. Three torpedo-boats were added in 1894.

The following figures from the fiscal census of 1889 are not absolutely exact: Population, 5,038,342 (Roumanians, 4,265,642; Israelites, 400,000; gypsies, 200,000; Slavs, 85,000; Germans, 39,000; Hungarians, 29,000; Armenians, 8,000; Greeks, 5,500; French, 2,000; English, 1,000; Italians, 500; other nationalities, 2,700). As to religious connection, about 4,300,000 belong to the national or Greek Orthodox Church; 400,000 are Israelites, 114,200 Roman Catholics, 13,800 Protestants, and less than 2,000 Mussulmans. The population in 1899 was, according to provisional returns of the census, 5,912,520. Population of principal cities in 1889: Bucharest, the capital, 194,633, now probably 230,000; Jassy, 72,859, now perhaps 85,000; Galatz, 59,143; Braïla, 46,715; Ploështi, 34,474; Botosani, 31,024; Craïova, 30,081; Berlad, 20,008; Piatra, 20,000; Buzeü, 17,307; Tulcea, 17,257; Focsani, 17,039; Turnu-Severin, 14,669; Bacaü, 12,675; Husi, 12,660; Giurgevo, 12,559; Alexandria, 12,308; Pitesci, 12,126. Though increasing attention is paid to education, it is still in a backward state and not generally diffused. In 1891 there were 3,566 primary schools with 220,683 pupils, 52 high schools with 10,227 pupils, and 8 normal schools with 770 pupils. The two admirable universities of Bucharest and Jassy, with faculties in law, philosophy, science, and medicine, have 100 professors and 900 students. The wealthier Roumanians are educated abroad, especially in France. The Roumanian Church is absolutely independent, though acknowledging the spiritual superiority of the Patriarch of Constantinople. The country is divided into 8 dioceses; the Archbishop of Bucharest is Primate of Roumania, and next in rank is the Metropolitan of Jassy, who is called Archbishop of Moldavia. The monasteries, numerous during the Ottoman domination, when they served as refuges from oppression, are rapidly decreasing. The Mussulmans and Israelites, while not possessing political rights, enjoy full religious privileges.

The kingdom of Roumania does not include more than half of the Roumanians or of the territory they inhabit. Independent Roumania, Austro-Hungarian Roumania (the Banat, part of Hungary, Transylvania, and Bukovina), and Russian Roumania (Bessarabia) territorially correspond with ancient Dacia, which was subjugated by Trajan (107) and, when almost depopulated, colonized from Rome. It became a most prosperous province (*Dacia Felix*), but was overrun by the Goths (270), and a partial emigration ensued. It endured every possible vicissitude of invasion and dismemberment, till in the thirteenth century the two principalities of Wallachia (1241) and Moldavia (1293) emerged from the general confusion. They long and fiercely resisted the Ottomans, but were forced to become vassal provinces. From 1511 to 1849 their hospodars, or governors, were chosen by the sultan. These rulers were usually Phanariote Greeks, but in 1822 natives began to be appointed. Constant interference of Russia in their behalf and remoteness from Constantinople assured Moldavia and Wallachia privileges which they could not otherwise have enjoyed. During the Crimean war they were occupied by Austrian troops. In 1858 a European convention for their reorganization was signed at Paris. In 1859 both Moldavia and Wallachia elected Prince Cuza hospodar, and declared themselves united in 1861. The despotic Cuza was compelled to abdicate in 1866, and Prince Charles of Hohenzollern called to the throne. A constitution was speedily promulgated. The Roumanians distinguished themselves in the Russo-Turkish war (1877–78), and largely contributed to the capture of PLEVNA (*q. v.*). Their independence was recognized by the Congress of Berlin (1878), and the country proclaimed itself a kingdom Mar. 26, 1881. King Charles having no children, his nephew, Prince Ferdinand, was decreed heir presumptive Mar. 18, 1889. Since achieving independence, Roumania has made constant, solid progress. Her people are frugal, temperate, industrious, and patriotic. Their aspiration to unite all the Roumanians under one scepter is itself a source of danger, and they occupy a geographical situation of great difficulty.

See Quinet, *Les Roumains* (Paris, 1857); White, *Report on the Kingdom of Roumania* in *Reports of H. M.'s Diplomatic and Consular Officers*, part vi. (1883); Ubicini, *Les Provinces Roumaines* (Paris, 1856); Vaillant, *La Romanie* (1845); Mrs. Walker, *Untravelled Paths in Roumania* (London, 1888); Xenopol, *Istoria Romînilor* (Yassy, 1888–93); Samuelson, *Roumania Past and Present* (London, 1882); Laveleye, *La Péninsule des Balkans* (Paris, 1886; English translation, London, 1887). E. A. GROSVENOR.

Roumanian Language: the national language of Roumania. It is not limited exactly by the political boundaries; in the south and southeast the language limit is almost identical with the Danube, the Dobrudja being not linguistically Roumanian except along that river; in the east it occupies most of Bessarabia in Russia, in the north much of Bukovina, and it covers most of Northern and Western Transylvania and the adjacent parts of Hungary, as well as a small region in the northeastern part of Servia S. of the Danube. In this territory dialect differences are slight, but there are numerous communities in European Turkey and Northern Greece, especially in Macedonia, Thessaly, and Albania, with dialects generally grouped together under the name Macedo-Roumanian, and in Istria are some small remains of a dialect called Istro-Roumanian. Since the ancient Dacia, which corresponds roughly to the present territory where Roumanian is spoken N. of the Danube, did not become a Roman province until 107 A. D., and the Roman occupation ended under Aurelian (270–275), it is probable that the present language of Roumania is the descendant of the vulgar Latin of the regions S. of the Danube, brought in by later immigrations in the Middle Ages, and combined with some remains of the vulgar Latin of such older inhabitants of Dacia as had become thoroughly Romanized at the time of the abandonment of the province, and had succeeded in preserving their form of Latin, perhaps taking refuge in part in the mountains of Transylvania. It is probable that the eastern part of Roumania, the modern Moldavia, was never really Romanized. The closest relations of Roumanian are with Italian. The number of those whose mother tongue it is probably considerably exceeds 9,000,000, about 3,000,000 of these being under Austria-Hungarian rule.

The recognized sounds of Roumanian, not including dialects, are the seven vowels *i*, *e* (close and open *e* and *o* are not distinguished), *a*, *o*, *u*, and two peculiar vowels, one *î* (also written *â*, and sometimes *é* or even *û*), pronounced like Polish *y* (somewhat like *i* in *pit*), the other *ă* (also in some words written *ĕ*), pronounced somewhat like English *u* in *cut* or *curt*; and the twenty consonants *p*, *b*, *f*, *v*, *w* (not always counted, written *o*, *u*), *m*, *t*, *d*, *l*, *r* (trilled with the tip of the tongue), *n*, *s*, *z* (written *z*, *s*, and sometimes *ḑ*), two other sibilants, one like English *sh* in *shine* (written *ş*), the other like English *z* in *azure* (written *j*), *y* (written commonly *i*, but sometimes not expressed at all in writing), *k* (written commonly *c* or, before *e* or *i*, *ch*, with a slight difference in sound), *g* (as in English *go* or *give*, written *g* or, before *e* or *i*, *gh*), the sound of German *ch* in *ach* (written *h*), and that of English *ng* in *sing*, *song* (written *n*, and occurring only before *k* or *g* sounds). Besides these are to be noted the common consonant groups *ts* (written *ţ*), the sounds of English *ch* in *chin* (written *c* before *e* or *i*, *ce* or *ci* in other cases), and English *j* in *jest* (written *g* before *e* or *i*, *ge* or *gi* in other cases). The two vowels *i* and *u* are also written often with the sign ˘ (*ĭ*, *ŭ*) to indicate that they are not fully sounded, but are very short, and in some cases indeed they are entirely silent. Instead of the group *şt* is often written *sc* for etymological reasons. The language was formerly written with the Cyrillic alphabet borrowed from Slavic use, and this alphabet was long retained, gradually giving way in the nineteenth century to the Latin alphabet, which did not entirely replace it till after 1860. Roumanian spelling has suffered from an excessive influence of Latin etymology, which led to the use of silent letters (especially *u*) and several inconsistencies, and it is still not well settled, though the phonetic principle has gained ground and seems likely to prevail.

Exposed as the language has been to very different conditions from those under which the other Romance languages have developed, it is not strange that it shows some peculiar features. It has preserved some Latin words lost in the others, and has lost some which they have preserved. Its vocabulary has been much affected by foreign languages, which have also furnished it some suffixes, and have even perhaps somewhat affected its structure. Very many words are of Slavic origin, and it has also words from mediæval or modern Greek, from Turkish, Hungarian, and Albanian, while the origin of a number is unknown. A remarkable feature of the language is its post-positive article: (*un*) *socru* (a) father-in-law, *socrul*, the father-in-law; *loc*, place, *locul*, the place; *casă*, house, *casa* (from *casă* + *a*), the house. A similar use appears in Albanian and in Bulgarian. In some matters of phonology and inflexion, particularly its genitive and dative case (one form for both uses) in articles, feminine nouns, and adjectives, Roumanian is nearer to the Latin than is any other language of the family. (See Romance Languages.) There are so-called neuter nouns, which are masculine in the singular and feminine in the plural; this peculiarity is due to old Latin neuter nouns. The simple parts of verbs, or those formed without auxiliaries, are the present, imperfect, preterite, and pluperfect indicative, the present subjunctive and imperative, the present infinitive, the gerund, and the past participle; this last can also be used with prepositions so as to correspond in sense to the Latin supines. The auxiliaries used for other verb forms are not always the same as those common in other Romance languages.

Apart from a few scattered words found, for example, in Slavic documents, the earliest specimens of the language preserved to us date from near the end of the fifteenth century. The first grammar was that of Klein, *Elementa linguæ dacoromanæ sive valachicæ* (Vienna, 1780). Among modern works should be mentioned particularly Gröber's *Grundriss der romanischen Philologie* (i., 1888), where full references may be found; here are added some other works, in part more recent, as Tiktin, *Gramatica română* (i., 1892; ii., 1894), and *Manual de ortografia română* (1889); *Indreptariŭ pentru ortografia română* (contains orthographical rules for schools in Bukovina, Vienna, 1893); G. Weigand, *Die Sprache der Olympo-Walachen* (1888), *Vlacho-Meglen* (1892), and *Die Aromunen*, ii., 1894 (planned for 5 vols.). A short grammar in English is Torceanu, *A Simplified Grammar of the Roumanian Language* (1883). Dictionaries: Ion Costinescu, *Vocabolaru româno-francesŭ* (1870); L. Şăinéanu, *Dicţionar româno-german* (1889); F. Damé, *Nouveau dictionnaire roumain-français* (i., A–E, 1893; ii., F–L, 1894); Hasdeu, *Etymologicum magnum Romaniæ* (in the letter B in 1895). The dictionary of the Roumanian Academy (see Laurianu) is not to be recommended, and Cihac's *Dictionnaire d'étymologie daco-romane* (i. 1870; ii. 1879) contains many errors. Gaster's *Chrestomatie română* (2 vols., 1883) has texts with a glossary, and an introduction on the literature and the grammar. Some periodicals published in Roumania also deserve mention, as *Columna lui Traian*, *Convorbiri literare*, *Revista pentru istorie, archeologie şi filologie*, etc. See also Roumanian Literature and the references under Romance Languages.

E. S. Sheldon.

Roumanian Literature: the literature of the people speaking the Roumanian or Wallachian language. It begins, so far as documents are preserved, about the end of the fifteenth century or the beginning of the sixteenth, with translations from the Bible, followed by other religious writings, such as catechisms, prayers, legends, etc., by legal documents, public and private, and by chronicles, of which there are many in the seventeenth and eighteenth centuries. The oldest texts published thus far are a psalter (*Psaltirea Scheiană*, i., 1889), which the editor Bianu dates in 1482 or 1485, and the Voronetz manuscript (*Codicele Voroneţean*, edited by Sbiera, 1885), which contains a part of the Acts and of some of the Epistles, and belongs probably to about the same time. Hasdeu's *Limba română vorbită între 1550–1600*, i., 1878, ii., 1879 (commonly referred to as *Cuvente den betruni* or *Cuvinte din bĕtrânĕ*), contains texts of the second half of the sixteenth century, with linguistic and literary discussions. The Roumanian Academy has published (1881), among other texts, the psalter printed in 1577 by Coresi in Transylvania (Coresi was probably of Greek descent); this was, it seems, printed from the same translation as that used in the psalter mentioned above. All these early texts have rather linguistic than literary interest; but it is to be noticed that some of the religious productions were results of the Reformation, showing themselves in Transylvania through the Saxons. Of chronicles may be mentioned those of Ureche (see E. Picot's edition, *Chronique de Moldavie*, 1878–83) and Miron Costin (lived about 1628–92; two volumes of an edition by V. A. Urechiă were published, 1886–88). M. Cogălniceanu has published *Cronicele Românieĭ* (1852; 2d ed. 3 vols., 1872–74).

It was not until the nineteenth century that Roumanian literature began to develop in sympathy with the literatures of the great nations of Europe. A powerful stimulus to the growth of a truly national literature has been the national spirit, developing after the French Revolution and after the changed political aspect, as Wallachia and Moldavia attained practical independence of Turkey and later became united, and finally the independent kingdom of Roumania was established. The new era began in the eighteenth century under the leadership of Roumanians in Transylvania, where they were aided by Catholic schools, from which some went to Rome to study. Klein's *Grammar* (see Roumanian Language) was followed by some other grammatical writings. Klein wrote also many theological and historical works. Naturally the connection with the Romans and their language was emphasized during this period of awakening, as indeed it has been since. Other noteworthy writers are Petru Maior (about 1753–1821), whose historical work marks the beginning of a more critical period, and who was one of the authors of the lexicon published at Buda in 1825; Şincai (about 1754–1826), whose most important work is his *Cronica Romînilor*, a history of all the Roumanians from the year 86 to 1741; Ienache Văcărescu (about 1740–99), ban of Wallachia, remarkable for his grammatical work on the language, and author, among other things, of some verses. George Lazăr (1779–1823) came into Wallachia in 1816, and was allowed after a time to open a Roumanian school in Bucharest (previously the schools had been Greek); he may be considered the founder of the national schools in Wallachia. Veniamin Costache (1768–1846) and George Asachi (1788–1871) were similarly active even earlier in Moldavia; the many works of the latter (lyric verse, dramatic and historical writings) belong largely to the next period. Costache Conache (1777–1849) was distinguished for his learning, and was active in public affairs. His poems were not published until 1856 (2d ed. 1888). Budai Deleanu (1770–1830), among other things, wrote the heroi-comic *Ţiganiada saŭ tabăra Ţiganilor* (The Camp of the Gypsies).

The next period, beginning about 1830, is that in which the influence of Western Europe shows strongly, combined with a national feeling, which, however, still rests too much on pride of assumed Roman ancestry. The strongest influence is that of French, but an Italian influence shows itself in Eliade (see Héliade), who, like Asachi in Moldavia, founded journals in Wallachia, and stirred up the youth of the country to an interest in education and literary pursuits. Since about 1860 comes the most modern period, in which the excessive admiration for French models is somewhat tempered by a wider knowledge of modern European culture, and which may be considered as introduced by T. Maiorescu's critical writings. (See Maiorescu.) In this time are to be noticed the organization of the society Junimea (Youth) and the establishment of literary and critical periodicals, such as the *Convorbiri literare* (Literary Conversations; since 1867). Both Maiorescu and Eminescu (1850–89), the latter one of the foremost poets of modern Roumania, made themselves acquainted with German literature. Many journals and periodicals have been started in Roumania, from those of Eliade and Asachi on, for political, literary, or scientific purposes, which have had various degrees of merit and success; some of them are mentioned under Roumanian Language. (See also Hasdeu.) In these much of the work of modern writers first appears. Not least important are the popular songs, tales, etc., collected by Alecsandri, Ispirescu (1830–87), and others. Many of these have been translated into German, notably by the Queen of Roumania. See Carmen Sylva.

Only Alecsandri (or Alexandri; see Alecsandri) among Roumanian writers has made his name well known outside of Roumania for purely literary work; but several others are of some note in the country itself. (See Alecsandrescu, Bolintineanu, C. and I. Negruzzi, C. Rosetti.) Verse has been written, among others, by G. Sion (b. 1822; has also written comedies), Şerbanescu (b. about 1839), and Vlăhuţă

(b. 1859; has also written stories). There are dramatic productions by Alecsandri, Slavici (b. 1848; has also written tales), Caragiale (comedies published in 1889, stories in 1892), and others. C. Dobrogeanu, commonly called I. Gherca (b. 1855), is the author of *Studii critice* (Critical Studies). Historical writings have been published by Bariţiu (b. 1812), E. Hurmuzachi (1812–74), M. Cogălniceanu (1817–91), Xenopol (b. 1843), Tocilescu (b. 1850), Hasdeu, and several others. The history of the language or the literature, or both, has been treated by several writers; some names are mentioned below. Elena Ghica, later Princess Koltzoff Massalsky, though of Roumanian birth, wrote mostly in French, not in Roumanian. See DORA D'ISTRIA.

REFERENCES.—W. Rudow, *Geschichte des rumänischen Schrifttums* (1892, with a supplement in 1894; the best general work thus far covering the whole subject, but excessively condensed and very ill written); A. Roume'lia, Rou'meli, or **Roum**: the name formerly applied by the Ottomans to their European provinces in distinction from those in Asia, which were called Anatolia or Anadoli. Roumelia was divided into 197 judicial districts, under the judicial supremacy of the cazi-asker of Roumelia, an officer who, with the cazi-asker of Anadoli, then ranked next to the grand vizir. The Ottoman sultan is still called by the Tartars Sultan of Roum, by which, however, they often mean Asia Minor. In a restricted sense Roumelia is supposed to comprise ancient Thracia and parts of Illyricum, Epirus, and Macedonia. The province of Eastern Roumelia, created by the Congress of Berlin (1878), and comprising territory S. of the Balkans, mainly inhabited by Bulgarians, united itself to the principality of Bulgaria (Oct., 1885), but this union *de facto* has not been officially recognized by the Ottoman empire or the European governments. E. A. G.

Round, WILLIAM M. F.: See the Appendix.

Roundheads: the Puritans or supporters of Parliament during the civil war in England, so styled probably from having the hair cut close, while the Cavaliers or adherents of the king wore theirs long. See ENGLAND (*History*).

Round Table: See ARTHUR and ROMANCES.

Round Towers: remarkable stone towers found chiefly in Ireland, but also in Scotland, Switzerland, Corsica, and other countries. It has been customary to assign these structures to the pagan and even the prehistoric period; another opinion is that they were attached to churches and other ecclesiastical buildings of a very remote period.

Roundworms: See NEMATHELMINTHES.

Roup: See POULTRY (*Management*).

Rouphia, or **Ruphia**: See ALPHEUS.

Rouquette, rōō'ket', ADRIEN EMMANUEL: poet; b. in New Orleans, La., Feb. 13, 1813; educated at the College of Nantes, France, where he studied law; was afterward ordained a Roman Catholic priest, and was for many years professor in the Roman Catholic Seminary at New Orleans, and subsequently chaplain to that institution, being known as the Abbé Rouquette. He wrote with equal elegance in French and English. His chief works were *Les Savanes*, *Poesies américaines* (Paris and New Orleans, 1841), a book highly praised by Sainte-Beuve; *Wild Flowers*, *Sacred Poetry* (New Orleans, 1848); *La Thébaïde en Amérique* (1852); *L'Antoniade, ou la Solitude avec Dieu* (1860); and *Poëmes patriotiques* (1860). D. in New Orleans, July 15, 1887.—His brother, FRANÇOIS DOMINIQUE, b. in New Orleans, Jan. 2, 1810, was also educated at Nantes; studied law in Philadelphia: published in Paris two volumes of poems, *Les Meschacébéennes* (Paris, 1839) and *Fleurs d'Amérique* (New Orleans, 1857); has resided much in France, and has written a work in French and English on the Choctaw Indians.

Revised by H. A. BEERS.

Rouses (rows'iz) **Point**: village; Clinton co., N. Y.; on Lake Champlain, at the mouth of Richelieu river, and on the Canada Atlantic, the Cent. Vt., the Del. and Hudson, and the Gr. Trunk railways; 21 miles N. by E. of Plattsburg, 24 miles N. W. of St. Albans, Vt. (for location, see map of New York, ref. 1–J). The lake is here crossed by a railway bridge nearly a mile long, which cost $300,000, and is protected by Fort Montgomery, situated on the frontier at its outlet. The village has a large lake commerce with Canada, and receives the greater part of the customs receipts of the Champlain district, which in the year 1900 had total exports of $5,211,770 and imports of $15,309,725. There are railway repair-shops, manufactories of lumber and smoking-pipes, and a large printing-establishment. Pop. (1880) 1,485; (1890) 1,856; (1900) 1,675.

Rousseau, rōō'sō', JEAN BAPTISTE: poet; b. in Paris, France, Apr. 6, 1670; the son of a shoemaker; received a liberal education, and won from his contemporaries the title of "prince of lyric poets" by his odes, epistles, allegories, cantatas, and epigrams. These are written with talent and even brilliancy, but lack poetic spirit, and are no longer read. He was suspected, probably justly, of the authorship of verses against persons of consideration, tried to free himself and fasten the authorship upon the geometrician Saurin by bribed witnesses, and was condemned in 1712 to perpetual banishment. D. at Brussels, Mar. 17, 1741. Editions: *Œuvres complètes* (5 vols., Paris, 1820); *Œuvres lyriques*, ed. by Manuel (Paris, 1852). A. G. CANFIELD.

Rousseau, JEAN JACQUES: philosopher; b. at Geneva, Switzerland, June 28, 1712; second son of a watchmaker. His family was originally from Paris, and had moved to Geneva in the sixteenth century. His mother died at his birth, and he was left to the care of two aunts and his father, who let him grow up at random and stuff his mind with Plutarch and unwholesome novels, which the two read together. In 1722 his father fled from the city in consequence of some trouble, leaving him to the care of an uncle, who put him for board and instruction into the family of a clergyman, with whom he remained two years. Then he was sent (1723) to a notary, who could make nothing of him, and to an engraver, who beat him, and with whom he developed the boyish vices of lying and stealing. Finally (1728) he ran away, and for several days tasted the delights of a roving, irresponsible life, the charm of which he could never quite forget. A Roman Catholic priest picked him up and sent him to Madame de Warens, at Annecy, a zealous convert from Calvinism to Roman Catholicism, gay, volatile, flighty, and of easy morals, who was to have a great influence over the formative years of his life. She sent him to a hospice in Turin, where he made no opposition to his conversion. Turned adrift, he lingered about Turin, tried being a valet, but was discharged for theft, found regularity of life and industry irksome, and wandered back on foot to Madame de Warens, who became from 1729 to 1738 the real center of his life. After each new failure, as his study for the priesthood and his attempt to teach music, and after each fit of restless wandering to Lyons, Lausanne, Neuchâtel, or Paris, he returned to her, and was long an inmate of her house. By 1738 his relations with her began to cool, and he broke away and went to Paris in 1741 with a comedy, *Narcisse*, and a new system of musical notation. Neither found favor, and in 1743 he went to Venice as secretary of the French ambassador, but soon quarreled with him and returned to Paris, where he was forced to copy music for a livelihood. But he began to make literary acquaintances and to get literary employment; he also formed a union with Theresa Levasseur, an ignorant kitchen-girl, which lasted till his death, and was regularized by a marriage ceremony in 1768. The five children of this union were sent to the foundling asylum, in strange contradiction to the educational theories of their father. In 1750 he achieved his first literary notoriety by the essay which won the prize offered by the Academy of Dijon, in which he brought great ingenuity and eloquence to support the paradox that the progress of the arts and sciences has done more to corrupt than to purify morals. Still greater was the impression produced by his *Discours sur l'inégalité parmi les hommes* (1754). In these essays appeared that notion of the perfection of the natural man that became so fascinating and so fruitful, and that involved so thorough a criticism of existing institutions. His literary reputation was still further increased by the success of his opera, *Le Devin de village* (1752); he became at once the object of attention, praise, and flattery. But his nature was not social; he was refractory to the conventionalities, arts, and graces of polite intercourse, sensitive, proud, suspicious, and despised money. The roving spirit and the native delight in fields, woods, and sky were unconquered in him; he loved to roam the field and botanize better than

to be imprisoned in a drawing-room, and in the spring of 1756 he removed to a little cottage on the skirts of the forest of Montmorency, put at his disposal by Madame d'Épinay. He soon quarreled with her and took a house at Montmorency. Thence he issued the novel, *La Nouvelle Héloïse* (1761), which, by the eloquence and authority lent to the voice of passion and the glow and fervor of a new and wonderful style, created intense enthusiasm and was read with feverish eagerness; the *Lettre sur les spectacles* (1758), condemning the theater for its moral influence; the *Contrat social* (1762), which contains the fullest statement of his political ideas, maintains radically the sovereignty of the people, and supplied the positive ideas of the Revolution; *Émile* (1762), which unfolds his fruitful views on education. This last work offended the authorities; the Sorbonne condemned it; the Parlement had it burned, and ordered Rousseau's arrest. He was warned and fled to Geneva, Neuchâtel, and finally to England (1765), where Hume gave him a refuge at Wootton. But his irritability, sensitiveness, and suspicion were sharpened by his experiences to an unhealthful degree; he fancied himself the object of a conspiracy, and fled back to France. He spent a year under a false name with the Prince of Conti and then fled from imagined pursuit to different parts of France. In 1770 he returned to Paris and resumed the copying of music for his support, still haunted by the idea of persecution. In 1777 he accepted a house on a friend's estate a few miles from Paris, and died there July 2, 1778, under circumstances that to some have suggested suicide. In 1794 his body was transported amid great popular enthusiasm to the Pantheon. The main work of the latter years of his life was his *Confessions*, one of the most remarkable works of the kind ever written, surprisingly free from reticence, and unsparing in the revelation of himself, but not always exact. It is hard to overestimate the influence of Rousseau upon his country and Europe. At the center of his ideas was his sincere belief in the goodness of nature and whatever is in accord with her. The primitive natural instincts and affections were sacred: the primitive natural state of society furnished criteria for the criticism and renewal of institutions. The sentimentalists date from him, and the view that to show that an act is natural is to prove that it is right. The standard editions of his *Œuvres* are by Musset-Pathay (23 vols., Paris, 1823–26), and by Auguis (25 vols., Paris, 1822). One must add L. Borscha, *Correspondance inédite de J. J. Rousseau* (Paris, 1858); Streckeisen-Moultou, *Œuvres et Correspondance inédites de J. J. Rousseau* (2 vols., Paris, 1861–65); H. de Rothschild, *Lettres inédites de J. J. Rousseau* (Paris, 1892). See H. Beaudoin, *La vie et les œuvres de J. J. Rousseau* (2 vols., Paris, 1871); Saint-Marc Girardin, *J. J. Rousseau, sa vie et ses œuvres* (2 vols., Paris, 1875); A. Chuquet, *J. J. Rousseau* (Paris, 1893); J. Morley, *J. J. Rousseau* (2 vols., London, 1873).

A. G. Canfield.

Rousseau, Lovell Harrison: soldier; b. in Lincoln co., Ky., Aug. 4, 1818: received little early education, but subsequently studied law at Louisville and at Bloomfield, Ind.; admitted to the bar in 1841; member of the Indiana Legislature 1844–45, and of the State Senate 1847. In the war with Mexico, as captain in the Second Indiana Volunteers, he served with gallantry at Buena Vista; returned to Louisville in 1849; became a successful criminal lawyer, and in 1860 was a member of the State Senate, where he boldly opposed the secession of Kentucky. On the outbreak of the civil war he raised the Third Kentucky Infantry, of which he became colonel Sept., 1861; appointed brigadier-general U. S. volunteers Oct. 1, 1861; was distinguished at the battle of Shiloh Apr. 7, 1862; in command of division and conspicuous for gallantry at Perryville, Ky., Oct. 8, 1862, for which he was made major-general of volunteers; participated in the battle of Murfreesboro, Dec. 31, 1862; commanded the district of Tennessee from Nov., 1863, till the close of the war. He resigned Nov. 30, 1865; member of Congress 1865, and in Mar., 1867, was appointed a brigadier-general in the regular army and brevetted major-general. Assigned to command the department of Louisiana July 28, 1868, he died in New Orleans, Jan. 7, 1869. Revised by James Mercur.

Rousseau, Philippe: still-life and animal painter; b. in Paris, France, Feb. 22, 1816; pupil of Bertin and Baron Gros; third-class medal, Salon, 1845, first-class 1848; second-class, Paris Exposition, 1855; first-class, Paris Exposition, 1878; officer Legion of Honor, 1870. D. at Acquigny, Dec. 4, 1887. His pictures of still life are notable for excellent technical qualities and strong sober color schemes. *Importunate* (1850) and *The Rat Retired from the World* (1885) are in the Luxembourg Gallery, Paris; and there are works in the museums at Chartres, Valenciennes, and Nantes. W. A. C.

Rousseau, Pierre Étienne Théodore: landscape-painter; b. in Paris, France, Apr. 15, 1812; first-class medal, Salon, 1849, Paris Exposition, 1855; medal of honor, Paris Exposition, 1867; Legion of Honor, 1852. D. at Barbizon, Dec. 22, 1867. He was the friend and fellow worker of Millet and Diaz, and worked with them at Barbizon on the borders of the Forest of Fontainebleau, finding in the forest and the surrounding country the subjects for his pictures. He was one of the greatest of the modern French painters of landscape, and his works are characterized by profound sentiment, extraordinary technical qualities, and great truth to nature. He represented detail in a marvelous fashion without sacrificing breadth or harmony of color. One of his finest works is *The Hoar Frost*, in the collection of W. T. Walters, Baltimore. The *Woods of Fontainebleau* (1885), a magnificent picture of sunset effect, and a number of other landscapes are in the Louvre. *Morning on the Oise*, a masterpiece of color-harmony and unity of effect, is in the collection of Henry Graves, Orange, N. J. W. A. C.

Rousset, rōō'sā', Camille Félix Michel: historian; b. in Paris, France, Feb. 15, 1821; became in 1843 Professor of History at Grenoble, in 1845 at the Lycée Bonaparte, and was from 1864 to 1876 historiographer to the ministry of War. Among his works are *Histoire de Louvois* (4 vols., 1861–63); *Les Volontaires de 1791–94* (1870); *Histoire de la Guerre de Crimée* (2 vols., 1877); and *Les Commencements d'une conquête: L'Algérie de 1830 à 1840* (2 vols., 1887). He became an academician in 1871. D. Oct. 19, 1892. A. G. C.

Routh, rowth, Martin Joseph, D. D.: educator and editor; b. at South Elmham, Suffolk, England, Sept. 18, 1755; graduated at Oxford 1774; became college librarian 1781, and in 1791 president of Magdalen College, which post he retained till his death at Oxford, Dec. 22, 1854. He is best known by his collection of writings of Christian Fathers under the title *Reliquiæ Sacræ, sive Auctorum fere jam perditorum*, etc. (5 vols., 1814–18; new ed., 5 vols., 1846–48).

Routhier, Adolfe Basile: See the Appendix.

Rove-beetles: beetles belonging to the family *Staphylinidæ*, in which the wing-covers are very short, leaving a large part of the abdomen uncovered. The beetle when irritated turns this abdomen about in such a way as to convey the impression that it is armed with a sting. The rove-beetles are small, frequently minute; they live under stones, in moss, on composite flowers, etc.

Roveredo, rō-vā-rā'dō: town of Austria; in the Tyrol; picturesquely situated on the Leno, near its junction with the Adige; 14 miles by rail S. of Trent (see map of Austria-Hungary, ref. 7–A). Napoleon Bonaparte here defeated the Austrians in 1796. It is the center of Tyrolean silk-manufacture and has a large transit trade. Pop. (1890) 9,030.

Rovigno, rō-veen'yō: town of Austria; in Istria, on a rocky promontory in the Adriatic; 40 miles S. by W. of Trieste (see map of Austria-Hungary, ref. 8–C). It has two harbors, ship-building yards, ropewalks, manufactures of sailcloth, tunny-fisheries, and an active trade in wine and oil. Pop. (1890) 9,662.

Rovigo, rō-vee'gō: town of Italy; province of Rovigo; lying between the Po and the Adige on the Adigetta, an emissary of the Adige; 38 miles S. W. of Venice (see map of Italy, ref. 3–D). It has an octagon-shaped church (1594), a cathedral (1696), a picture-gallery, and a town-hall with a library of 80,000 volumes. Mediæval Rovigo belonged sometimes to Venice, sometimes to the house of Este. Pop. 7,272.

Rovigo, Duke of: See Savary.

Roving: See Cotton Manufactures.

Rowan, rō'an, Stephen Clegg: sailor; b. near Dublin, Ireland, Dec. 25, 1808; entered the U. S. navy as a midshipman Feb. 15, 1826; was distinguished for ability and courage on the west coast of Mexico during the war with that country, and during the civil war in the rivers of Virginia, the sounds of North Carolina, and at Charleston, S. C.; for his long, honorable, and gallant service received a vote of thanks from Congress; was made vice-admiral Aug. 15, 1870; became superintendent Naval Observatory, and was chairman of lighthouse board; retired Feb. 26, 1889. D. at Washington, D. C., Mar. 31, 1890. Revised by C. Belknap.

Rowan-tree: See Mountain-ash.

Rowe, Nicholas, dramatist; b. at Little Barford, England, June 30, 1674; was educated at Westminster School; studied law; became a successful courtier and politician, but is best known as a dramatic author and as translator of Lucan's *Pharsalia* (1718). He published an edition of Shakspeare (1709), preceded by the first biography of that poet; became Under-Secretary of State under Queen Anne (1708–11), and was made poet-laureate by George I. D. Dec. 6, 1718, and was buried in Westminster Abbey. Among his plays the most successful were the tragedies *Tamerlane* (1702), *The Fair Penitent* (1703), *Jane Shore* (1714), *Lady Jane Grey* (1715). Revised by H. A. Beers.

Rowing [O. Eng. *rōwan*, row, akin to M. H. Germ. *rüejen*; cf. Lat. *rēmus*, oar]: the art or practice of propelling a boat or vessel by means of oars. As a pastime rowing was introduced into England by the Saxons, and to Alfred the Great was due the introduction of the long galleys of the Mediterranean. On the accession of the Normans, boat-tilting, a passage-at-arms on the water, became popular, and the success of the contestants depended much on skillful handling of the oars.

Accounts of early rowing-matches are rare, and the first authentic account of boat-racing of comparatively modern times is dated 1715, when the Coat and Badge race was established by the comedian Thomas Doggett, in honor of the anniversary of the accession of the house of Hanover, in the person of George I., to the throne. A red coat having a silver badge on the arm, bearing an imprint of the white horse of Hanover, was given as a prize. The conditions of the race were that it was to be rowed annually, on Aug. 1, on the Thames, by six young watermen who had served an apprenticeship in their calling of not more than six months. The first regatta held in England was in 1775. The next records are in 1798 or 1799 when annual pair-oared races were instituted, the prize being a new wherry, presented by the proprietor of the Vauxhall Gardens.

Until about 1800 all the racing in England was done by professional watermen, when the pleasure of engaging in the sport began to be recognized by gentlemen, and as a result there were soon in and about London several amateur clubs. The schools took up the sport, and in 1816 there was a race between the Fly, a heavy six-oared boat of the Westminster School and a six of the Temple School. The race was rowed from Johnson's dock to Westminster bridge, was won by the Fly, and was the first interscholastic race. In 1817 Eton College rowed a four-oared race against the watermen and won, but until 1828 all her crews were coached and stroked by professional watermen. In 1818 Eton challenged Westminster, but the authorities interfered, and it was 1829 before the two crews met. Oxford rowed in 1815. Cambridge had no eight-oared boat until 1826. The first race between the two took place June 10, 1829, on the Thames; the course was from Hambledon lock to Henley bridge, and Oxford won in 14 min. 30 sec., by 60 yards. Cambridge and Oxford next met in 1836 and rowed from Westminster bridge to Putney bridge, nearly 5½ miles. Cambridge won. Their next race was in 1839, and from then until 1856 Cambridge won seven and Oxford five of the twelve races rowed.

Since 1856 the race has been held annually. The course is from Putney bridge to Mortlake church, or the reverse, depending upon the nature of the tide at the time of the race, since it is always rowed with the tide, a distance of 4⅝ miles. Of these races, from the first in 1829 up to 1901, Oxford has won thirty-four and Cambridge twenty-four, with one dead heat in 1877.

In 1839 the first Henley Regatta was held, it being due to the efforts of the inhabitants of Henley, who subscribed 100 guineas for the purchase of the Grand Challenge Cup, which was to be rowed for annually by amateur crews in eight-oared boats, over the Henley course, which is 1 mile and 550 yards in length. At the same time it was arranged to have a race for the Town Challenge Cup by four-oared amateur crews.

Although boat-racing in the U. S. is known to have existed since about the beginning of the nineteenth century, yet no races of importance occurred before 1811, when oarsmen of New York challenged the best of Long Island to a race in four-oared barges with coxswains. The course was from Harsimus, N. J., to the flagstaff on the Battery. New York won easily. This race excited so much interest that the winning boat was exhibited for many years in a public museum.

Distinctively amateur rowing was not recognized until 1834, when the Castle Garden Boat Club Association was formed. From this time until 1873, when the National Association of Amateur Oarsmen was founded, the amateur's rating was purely local, being judged by each regatta committee, and it was not an uncommon occurrence for an oarsman to compete as an amateur on one river and as a professional on another. To put an end to this unsatisfactory state of affairs was the main object in the convention of boat clubs held in New York on Aug. 28 and 29, 1892, which culminated in the National Association of Amateur Oarsmen of America.

The most important rowing events of the year among amateurs is the regatta of the National Association, and its rulings in respect to amateurs and all other affairs of general rowing interest are accepted by the other associations of America. According to the National Association an amateur is "one who does not enter in an open competition; or for either a stake, public or admission money or entrance fee; or compete with or against a professional for any prize; who has never taught, pursued, or assisted in the pursuit of athletics as a means of livelihood; whose membership of any rowing or athletic club was not brought about, or does not now continue, because of any mutual agreement or understanding, expressed or implied, whereby his becoming or continuing a member of such club would be of any pecuniary benefit to him whatever, direct or indirect, and who has never been employed in any occupation involving the use of oar or paddle"; and who shall otherwise conform to the rules and regulations of the National Association of Amateur Oarsmen.

In 1876 an international regatta was held on the Schuylkill in which three crews from Great Britain were entered, representing the London Rowing Club, Dublin University, and Trinity College, Cambridge. The two latter crews were defeated in the trial heats, while the London men were beaten in the finals by the crew of the Beaverwycke Boat Club, of Albany, N. Y., by the small margin of only 3 feet. On Aug. 17, 1869, Harvard and Oxford met in a four-oared race with coxswains over the Putney course, which Oxford won in 22:17.

In 1878 the Columbia College eight won the Visitors' Cup at the Henley Regatta from Dublin University, University College of Oxford, and Hertford College, Oxford. In 1881 the Cornell University four and Shoewaessemette crew of Michigan visited England, but lost in all the races they entered. In 1882 the champion four-oared Hillsdale crew won a number of minor races, although not allowed to compete in the Henley Regatta, and they were beaten by the Thames Boat Club only by reason of their bow-oar breaking his seat while they were leading by a good length.

It was not until 1843 and 1844 that boat clubs were formed or boats owned at either Yale or Harvard. The first intercollegiate race was held at Center Harbor, on Lake Winnipiseogee, Aug. 3, 1852. Harvard was represented by the Oneida, while Yale was present with two boats, the Shawmut and Undine, all three being eight-oared lapstreaks, rowed on the gunwale, and carrying coxswains. The Oneida won. In 1855 Yale again challenged Harvard, and this race was rowed on the Connecticut river, July 22, Yale having entered two six-oars with coxswains and Harvard a four-oar without and an eight-oar with coxswain. The Harvard boat Iris, eight oars, won in 22 min. A handicap of 11 sec. per oar was allowed the other boats. In 1853 Harvard suggested a convention of colleges with boat clubs, which met at New Haven, May 26, with Harvard, Yale, Brown, and Trinity represented by delegates. Arrangements were set on foot for a regatta under rulings adopted by the convention. On July 26 of the following year the first intercollegiate regatta was held on Lake Quinsigamond with Harvard, Yale, and Brown represented. Harvard entered two boats and Yale and Brown one each. Harvard won in 19:11½, the distance being 1½ miles to stake and back to place of starting. In 1860 the intercollegiate race was again contested by Harvard, Yale, and Brown, and finished in order named, 18:53 being the winner's time. In 1871 the Rowing Association of American Colleges was formed by Harvard, Brown, Massachusetts Agricultural, and the various other colleges with aquatic facilities. Yale refused to enter, and the races were contested only by the three colleges named above. Massachusetts Agricultural won easily from Harvard in 16:46½ over a straight-away 3-mile course. The next year Yale and Cornell entered the association, which then represented eleven colleges. The race was at Springfield, Mass., was entered by only six crews, and was won by Amherst.

The regatta of 1873 was held over the course at Saratoga, and eleven crews entered. Yale won. Columbia won the regatta of 1874 in 16:42½. In the following year the regatta was again held at Saratoga, and participated in by thirteen representative crews. Cornell won in 16:53, Harvard third, Yale fifth. In 1876 the Yale-Harvard races were again established for eight-oared shells with coxswains over a 4-mile straight-away course at Springfield on the Connecticut. Yale won by 21 sec. in 22:02. That year Yale was not present at the American College Regatta, but Harvard sent entries for all three events—University and Freshmen crews, also a single scull—each of which secured second place in their respective races, Cornell winning the three honors. Since 1876 the Yale-Harvard race has been an annual occurrence. Of the twenty-three races rowed, including that of 1901, Yale has won fifteen and Harvard eight. The best time has been made by Yale in 1888, being 20:10, which stands as the record for eight-oared shells over a 4-mile straight-away course. All but the first two of these latter races have been rowed at New London, Conn., with varying tide and wind. In 1883 an annual race between Cornell and the University of Pennsylvania was initiated.

Rowing at Cornell dates from 1869 with the formation of the Undine Boat Club. In 1870 the Cornell navy was organized, and has existed as such ever since. In 1873 Cornell sent her first crew to compete with other colleges in the regatta of the American Colleges Rowing Association, and was annually represented in this contest thereafter until the association came to an end. In the first two contests her crews finished fifth, but led in the latter two. In the last year of the regatta not only did the 'Varsity win, but also the Freshmen crew and her single sculler, Francis. Following these events, both Harvard and Yale withdrew from the association, and have declined races with other colleges since.

From 1895 neither Cornell's 'Varsity nor Freshmen crews met defeat in a series of nineteen races, the summary of intercollegiate races from 1873 to 1894, both 'Varsity and Freshmen included, being thirty-two victories and seven defeats.

Since the introduction of rowing as a pastime in Great Britain there has been a vast change in all the departments of the sport—in the training for a race, selection of a crew, style of rowing, and, greatest of all, in the boats. Formerly the boats were built with a proportion of breadth to length of 1 to 6, but the present usage is 1 to 30 and even 1 to 40. Their finest racing boats were about 6 ft. 2 in. beam, 35 feet in length, weighed 700 lb., and were rowed by oarsmen of 200 lb. weight, with two spare men to act as ballast and assist at the oars. A shell 24 inches beam. 66 feet long, and weighing 250 lb., can be rowed by eight men with coxswain, having total weight of 1,350 lb., at a rate of 12 miles an hour. This great reduction in width, with a corresponding increase of length and also speed, is due almost entirely to the outriggers and consequent improvement in design and materials of construction.

To Harry Clasper, probably, more than any other oarsman, credit is due for the adoption of the outrigging and many other improvements in race-boat building. In 1828 Anthony Brown had fastened various pieces of wood, now known as false outriggers, to the side of the Diamond, of Ouseburn, preparatory to its race with the Fly, of Scotswood-on-Tyne, and in 1830 Frank Emmett had contrived a more perfect plan of iron outriggers for his boat, the Eagle, yet it was not until 1844 that Clasper's four-oared outrigged boat fully overcame the prejudice of the time, and racing boats began to be modeled with regard to the new innovation. Yet Clasper's first outriggers were but 8 inches long. To Clasper also are we indebted for improving the spoon oar.

James Mackay, who appeared in 1857 at the Portland City Regatta in a shell of his own construction, was probably the first builder of shells with outriggers in the U. S. He received an order from Harvard for a six-oared shell, which he completed in December of that year. It was 40 feet long, 26 inches amidships, built of white pine, with iron outriggers and spoon oars, and was the first six-oared shell launched in the U. S.

Another improvement which added materially to the speed of racing boats was the sliding seat, from which has been evolved the roller seat. The distance through which the seat moves varies according to the style of the stroke rowed. The sliding seat is claimed to have been first used by J. C. Babcock, of the Nassau Boat Club, in a sculling boat in 1857, but it was not until 1870 that its merits were fully appreciated. The change to roller seats was made by Charles E. Courtney in 1878, and first used by him in 1879 in a race at Toronto, Canada.

Charles E. Courtney is authority for the following general directions as to one style of stroke: The beginning of the

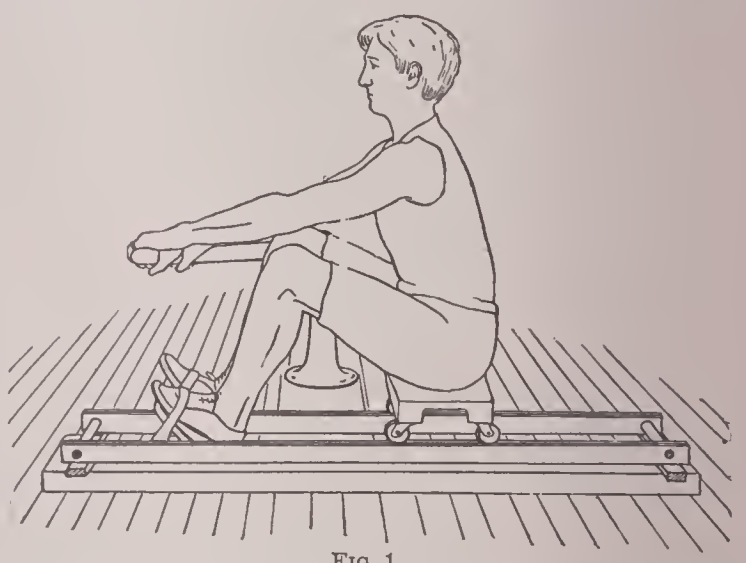

FIG. 1.

stroke, known as the forward reach, is illustrated in position 1. In this the seat is pulled forward with the feet until it is from within 9 to 12 inches from the bottom of the foot-

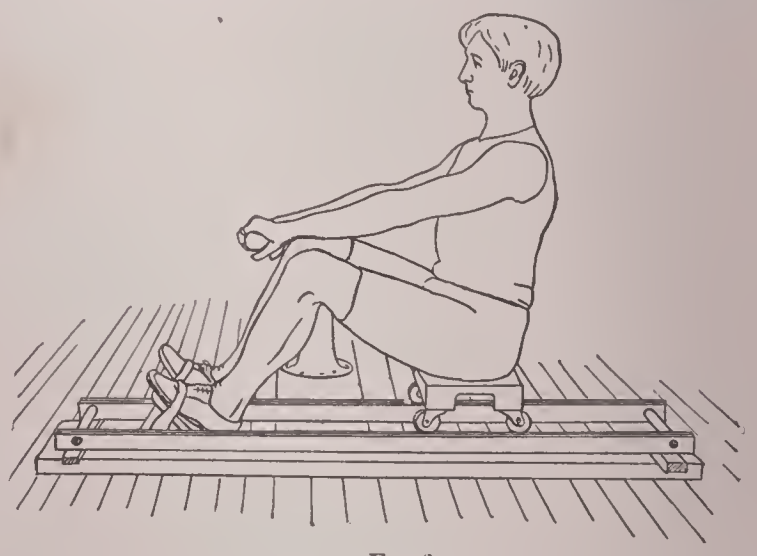

FIG. 2.

brace, the distance varying with individuals. The seat is held in position 1 while the oar catches the water, being so dipped as to just fairly cover the oar-blade, and until swinging the body at the hips the shoulders are in position 2. The shoulders go back no farther, and the stroke is finished by the legs and arms, as in position 3. The arms are kept straight until just before the legs are fully straightened, when the elbows are bent and the hands brought sharply in to the body, and are then dropped almost into the lap to bring the oar cleanly out of the water. Then the wrist is turned to

feather. On the recover, the hands are shot forward and the seat started quickly forward and slowed down as it reaches its limit, when the oarsman will again be in position 1.

Brickwood (London, 1876); Woodgate's *Oars and Sculls* (London and New York, 1874); Macmichael's *Oxford and Cambridge Boat-Races* (London, 1870); and *Boating* in Badminton Library (London). For racing records, see *New York Clipper Annuals* 1884 and 1894, and Janssen's *American Amateur Athletic and Aquatic History* (New York). EDWARD HITCHCOCK, Jr.

Rowland, HENRY AUGUSTUS: See the Appendix.

Roxa'na (in Gr. Ῥωξάνη): the beautiful daughter of the Bactrian prince Oxyartes. She became the wife of Alexander the Great in 327 B. C., and shortly after the death of Alexander in 323 B. C. bore him a son, Alexander IV. Her fortunes varied with those of the successors of Alexander. She and her son were murdered by Cassander in 311 B. C.

Roxburgh: county of Scotland. It comprises the districts of Teviotdale and Liddesdale, and is bounded on the S. by the English counties of Northumberland and Cumberland. Area, 665 sq. miles. Its southern and western parts are hilly, covered with the Cheviots and Lauriston Hills; in the northern and eastern parts the surface is generally level, and the fertile and productive soil is cultivated with the utmost care. Large herds of sheep are kept on the pastures of the hills; manufactures of woolens are carried on; coal, lime, marl, and freestone are found. Pop. (1901) 48,793. The county town is Jedburgh (pop. 3,397), 49 miles S. E. of Edinburgh. The county returns one member to Parliament.

Royal, JOSEPH, D. C. L.: Canadian official; b. at Repentigny, P. Q., May 7, 1837; educated at the Jesuits' College, Montreal, and admitted to the bar in 1864. He edited the Montreal *Minerve* 1857–59; established *L'Ordre* 1859, *La Revue Canadienne* 1864, *Le Nouveau Monde* (Montreal) 1867, *Le Métis* (Manitoba) in 1871: has been vice-chancellor of Manitoba University since 1877; and was appointed a commissioner for the consolidation of the statutes of Manitoba in 1877. He was Speaker of the first Legislative Assembly of Manitoba 1871–72; Provincial Secretary 1872–74; Provincial Secretary and Minister of Public Works 1874–76; Attorney-General 1876–78; and Minister of Public Works for a short time in 1878. He was the first superintendent of education appointed for Manitoba 1871; commanded a troop of cavalry during Fenian raid in 1871; was appointed a member of the executive council of the Northwest Territories in 1873; and discharged the administrative duties of Attorney-General 1874–78. He was a member of the Legislature of Manitoba 1870–79; and of the Dominion Parliament from 1879 until July 4, 1888, when he was appointed Lieutenant-Governor of the Northwest Territories. He is the author of the School Law (1871); contributed largely to a readjustment of the financial arrangements of Manitoba with the Dominion in 1875; author of *Vie Politique de Sir Louis H. Lafontaine* (1864), and of many important contributions to French-Canadian literature.

NEIL MACDONALD.

Royal Academy: See ACADEMY.

Royal Geographical Society: an institution founded by royal charter in London in 1830 for the promotion and encouragement of geographical research. It annually awards several medals to successful workers in the cause of geography, and distributes prizes among training-colleges for proficiency in geographical knowledge. The society's *Journal* reports the progress of explorations and discoveries. On May 1, 1900, the society had 4,026 fellows, each entitled to append the letters F. R. G. S. to his name.

Royall, ISAAC: soldier; b. in Massachusetts about 1720; was a wealthy resident of Medford, which he long represented in the general court; was for twenty-two years a member of the executive council; took part in the French war; was appointed brigadier-general 1761, and was the first resident of New England who bore that title; adhered to the crown in the preliminaries of the Revolutionary contest, for which reason he left the country Apr. 16, 1775; was proscribed and his estate confiscated 1778. He died in England, Oct., 1781, taking a noble revenge upon his persecutors by leaving 2,000 acres of land in Worcester County as the endowment of a law-professorship in Harvard College, now known by his name. There were other bequests equally liberal and patriotic. The town of Royalston, Worcester County, of which he had been one of the original proprietors (1752), commemorates his name.

Royal Society: See ACADEMY.

Royce, JOSIAH, Ph. D.: educator and author; b. in Grass Valley, Cal., Nov. 20, 1855; educated at the University of California, and at Göttingen, Leipzig, and Johns Hopkins Universities; became instructor in English in the University of California in 1878, instructor in philosophy in Harvard College in 1882, assistant professor there in 1885, and full Professor in the History of Philosophy in 1892. His writings comprise *The Religious Aspect of Philosophy* (Boston, 1885); *California* (American Commonwealth Series, Boston, 1886); *The Feud of Oakfield Creek* (novel; Boston, 1887); *The Spirit of Modern Philosophy* (Boston, 1892); with many articles and lectures. J. MARK BALDWIN.

Royer-Collard, rwäă'i-ā'kō'laar', PIERRE PAUL: statesman; b. at Sompuis, Marne, France, June 21, 1763. He studied law, and at first took an active part in the Revolution, but, being moderate and royalist, fled from Paris after the fall of the king Aug. 10, 1792, and lived concealed at Sompuis during the Reign of Terror. He represented Marne in the Council of Five Hundred in 1797, but was removed from the Assembly in the same year as a royalist, after the Revolution of Sept. 4. At the creation of the empire he retired to Sompuis and devoted himself to the study of philosophy, being much influenced by the Scottish philosophers, from whose standpoint he successfully opposed the sensualism of Condillac. He wrote little, but wielded a great influence through his lectures as Professor of Philosophy at the University of Paris from 1811 to 1814; Jouffroy, Cousin, Guizot, etc., became his disciples. Under the ultra-royalist tendencies of the Restoration he founded in 1820 the party of the Doctrinaires and became the powerful champion of constitutional monarchy, contributing much to produce the Revolution of 1830. Afterward he gradually withdrew from public life. D. near St.-Aignan, Sept. 4, 1845. His *Life* has been written by Barante (1861) and Lacombe (1863). A. G. CANFIELD.

Royersford: borough; Montgomery co., Pa.; on the Schuylkill river, and the Phila. and Reading Railroad; opposite Spring City, 15 miles W. N. W. of Norristown (for location, see map of Pennsylvania, ref. 6–I). It contains a high school, two national banks with combined capital of $200,000, a private bank, and a weekly newspaper, and has manufactories of stoves, machinery, glass, building and fire brick, sashes, and meters. Pop. (1890) 1,815; (1900) 2,607.

Royle, JOHN FORBES, M. D., F. R. S.: botanist; b. at Cawnpore, India, in 1800; became a physician in the service of the East India Company; spent much time in the Himalayas, where he was superintendent of the company's botanical garden at Saharanpur; published his great work, *Illustrations of the Botany and other Branches of the Natural History of the Himalaya Mountains* (2 vols., 1839–40); wrote many valuable scientific papers upon India; was a promoter of the culture of tea, cotton, and other foreign plants in India; became lecturer on materia medica at King's College, London, and secretary of the British Association. D. at Acton, near London, Jan. 2, 1858.

Rshef, or **Rzhef**: town; in the government of Tver, Russia; on both sides of the Volga (see map of Russia, ref. 6–D). It is on the railway line from Moscow to St. Petersburg, is well built, has many educational and benevolent institutions, and carries on an extensive trade in fish, hemp, linen, and agricultural produce. Pop. (1890) 30,278.

Ruatan', or **Roatan**: an island in the Bay of Honduras (Caribbean Sea), 30 miles from the northern coast of Honduras, to which it belongs; area about 80 sq. miles. It is long and narrow, partly hilly, wooded, and has a good soil and climate; its inhabitants (about 1,000) are engaged in fishing and turtle-catching. In 1742 this island was seized by Great Britain, and in 1797 about 5,000 Caribs were transported to it from St. Vincent; most of them since passed over to the mainland. Subsequently Great Britain gave the island to Honduras, but temporarily held it again 1841–42.

Rubasse: a variety of crystallized quartz, discolored and stained with specks of red and yellow iron oxide, which give it a fine red. Artificial rubasses of all colors are made from rock-crystal heated and dipped in cold colored aniline solutions, which cracks the crystal, when the color fills the cracks throughout the mass.

Rubber: See INDIA-RUBBER.

Rubefacients [from Lat. *rubefa'ciens*, pres. partic. of *rubefa'cere*, make red; *rube're*, be red + *fa'cere*, make]: in medicine, agents capable of producing congestion, and thus redness of the skin, by local contact. Such irritant applications have often the power of relieving congestion, pain, spasm, or undue irritability of deep-seated organs, and are much used for the purpose in therapeutics. Very many drugs have the property of reddening the skin, all blistering agents producing simple hyperæmia as the initial effect of their irritation, but the means most employed strictly as rubefacients are the following: *Heat*, by means of hot baths, cloths wrung out in hot water, bottles of hot water, or heated solids, as earthen platters, bricks, bags of sand, etc.; *mustard*, in the form of prepared mustard-paper moistened, or thick poultices of mustard-meal mixed with cold water; *oil of turpentine*, applied by means of flannels first wrung out in hot water and then in the oil previously warmed; *capsicum* (cayenne pepper), in the form of poultice, or, better, as a lotion mixed with hot spirits; and *ammonia*, in the form of liniment of ammonia (volatile liniment). Plaster of Burgundy pitch and resin cerate are also feebly rubefacient. Revised by H. A. HARE.

Rubens, PETER PAUL: painter; b. at Siegen, Westphalia, June 29, 1577. He was of middle-class family, but his parents were persons of influence. He was well educated, and for a time was a page in the household of the Countess of Lalaing at Brussels. His masters in painting were first Tobias Verhaecht, or Vanderhaecht, then Adam Van Noort, and finally Otto Van Veen, or Vaenius, all of Antwerp. At the age of twenty-two he was received as a master painter by the Antwerp guild of painters. In 1600, during the summer, he made the journey to Italy, and seems to have gone first to Venice. Soon after he attached himself to the ducal court of Mantua, then very brilliant and artistic in a certain way. The Duke Vincenzo Gonzaga employed Rubens permanently, and in 1601 sent him to Rome with letters of recommendation to the Cardinal Alessandro Montalto. There he copied pictures and also produced original works, painting pictures at the order of the Archduke Albert VII., who at this time had become sovereign of the Spanish Netherlands. His high character, thorough education, especially in languages, and dignified bearing seem to have given him a peculiar position among artists; he was trusted and treated as a person of high rank by the sovereigns with whom he came in contact as a painter. In 1603 he was sent by the Duke of Mantua on a private mission to Madrid, where he had an exceptional opportunity to study the paintings of Titian. Many pictures of his own are in the Madrid Gallery, and it is thought that several of these were painted during this visit. He was in Mantua from 1604 to 1606, a second time in Rome, and left Italy finally in 1608, after nearly eight years' employment by the Duke of Mantua. Once in Antwerp the Archduke Albert and his wife, Isabella Clara Eugenia, daughter of Philip II. of Spain, forbade his departure; in 1609 he was made their court painter, and in the same year he married. In the next year he painted the *Elevation of the Cross*, now in the cathedral at Antwerp, and in 1611 the *Descent from the Cross*, also in the cathedral, and commonly called the painter's best work. Until 1620 he remained at Antwerp, master of a large studio, with many pupils and assistants, many of whom rose to great distinction. Jakob Jordaens, Franz Snyders, Gaspar de Crayer, Jan Breughel, and even Antony Van Dyck were among his fellow workmen.

In 1620 Rubens undertook a series of pictures for the Luxembourg Palace at Paris for the Queen Dowager Marie de Médicis. This business called for his presence in Paris on several occasions, but the pictures were painted at Antwerp. They are now at Munich. In 1626 he went to Holland, and in 1628 again to Madrid, on business almost wholly diplomatic in character. In 1629, while still in Madrid, Rubens was appointed secretary of the privy council for the Spanish Netherlands, and was commissioned as envoy to London, where he arrived in May. He left London in Mar., 1630, having previously received knighthood from King Charles I., who also granted him an augmentation of his escutcheon. In Dec., 1630, he married Helena Fourment, niece of his former wife. Her portrait occurs very frequently in his pictures from this time on. The remaining years of his life were filled with artistic work. In 1635 he had to design a most elaborate decoration of the whole city of Antwerp as a welcome to Ferdinand of Austria, son of King Philip III. of Spain, the new governor-general of the Netherlands, appointed on the death of the archduchess. This was a prodigious undertaking, and many vestiges of it yet remain in published and unpublished drawings, and in the pictures which formed part of it. Many large paintings were under way and were left unfinished at his death, which occurred May 30, 1640.

In spite of his active and varied life the amount of work left behind him was enormous, and a great deal of it is preserved. His works are singularly even in quality. They seem to moderns to be lacking in charm, but they are full of vigorous drawing and strong color. They are easy to understand, both in subject and in the more pictorial qualities.

Besides the two great pictures in the Cathedral of Antwerp, named above, it is generally thought that the best places to study this master are the gallery at Antwerp and the old Pinakothek at Munich. Of those at Antwerp, *The Crucifixion between the Two Thieves*, *The Adoration of the Magi*, and *The Virgin with the Body of Christ* are especially important. At Munich there are about fifty canvases, most of them large; there may be named *The Fall of the Rebel Angels*, and another of nearly the same subject, *The Massacre of the Innocents*, *St. Peter and St. Paul*, a picture in which something of the Italian feeling is seen, a remarkable *Silenus with Satyr and Bacchante*, and a number of portraits of the highest interest and value, as *Helena Fourment*, *Lord and Lady Arundel*, the *Archduke Ferdinand*, ruler of the Netherlands, *Philip IV. of Spain*, the *Artist with his First Wife*. In the National Gallery in London are the *Abduction of the Sabine Women*, the *Plague of the Brazen Serpents*, two large *Landscapes*, and a remarkable decorative drawing, *The Birth of Venus*. At the Madrid Gallery, at the Hermitage, St. Petersburg, at the Museums of Berlin, Vienna, Brussels, Darmstadt, and Dresden, at the Louvre, at the Pitti and the Uffizi in Florence, and in such important private collections as Blenheim and the Lichtenstein Palace are pictures impossible to enumerate —perhaps 300 in number in actual public view.

There are many books which treat of Rubens, among them C. Ruellens, *Pierre Paul Rubens, ses Lettres*, etc. (Brussels, 1877); A. Michiels, *Rubens et l'École d'Anvers* (Paris); and Charles W. Kett, in the Great Art Series (1879). A good study of him exists in the *Gazette des Beaux-Arts* (1867–68), and many other notices scattered through the later volumes. RUSSELL STURGIS.

Ruberyth'ric Acid [*ruberythric* is from Lat. *ru'bia*, madder + Gr. *ἐρυθρός*, red]: a glucoside, $C_{26}H_{28}O_{14}$, found in madder-root by Rochleder. It is crystalline, and forms yellow prisms having a silky luster; has a faint taste; is sparingly soluble in cold, readily in hot water; gives a golden-yellow solution in alcohol and in ether, and a blood-red solution in alkalies. It gives red precipitates with baryta-water, with an alum solution after the addition of ammonia, and with basic acetate of lead after addition of a little alcohol. Schunck did not find this acid in madder, and considers it a product of the decomposition of rubian. Rochleder considers rubian to be impure ruberythric acid. See RUBIAN, ALIZARIN, MADDER, etc. Revised by IRA REMSEN.

Rubia'ceæ: See MADDER FAMILY.

Rubian [from Lat. *ru'bia*, madder]: a glucoside ($C_{16}H_{16}O$) discovered in madder-root by Schunck in 1847. It is obtained by treating a hot decoction of madder with bone-black, washing this to remove chlorogenine, extracting it repeatedly with boiling alcohol, and evaporating to dryness. It is then dissolved in water, precipitated with acetate of lead; the lead compound is decomposed by sulphuretted

hydrogen, and the filtrate is evaporated to dryness. As thus obtained, it is a brittle, amorphous mass, resembling gum arabic, deep yellow in thin layers, and dark brown in masses. It is very soluble in water, less soluble in alcohol, and insoluble in ether, which precipitates it from alcohol in brown drops. It is very bitter. Boiled with dilute acids or caustic alkalies, or treated with erythrozyne (madder ferment), it is resolved into glucose, alizarin, and perhaps other products:

Rubian. Alizarin. Glucose.

$$2C_{16}H_{16}O_8 + 6H_2O = C_{14}H_8O_4 + 3C_6H_{12}O_6.$$

Others consider the reaction as follows:

Rubian. Alizarin. Glucose.

$$C_{26}H_{32}O_{16} = C_{14}H_8O_4 + 2C_6H_{12}O_6.$$

It is not determined whether there are several glucosides in madder which are decomposed by the ferment, one yielding alizarin, another purpurin, etc., or whether there is but one, from which all the coloring-matters are developed. Schunck favors the former view, while the investigations of Kopp, Schützenberger, and Bolley favor the latter. See Alizarin, Madder, Ruberythric Acid, etc.

Revised by Ira Remsen

Rubicelle: See Spinel.

Ru'bicon: a small river of Northern Italy emptying into the Adriatic, immortalized by the passage of Cæsar 49 B. C. It then formed the boundary between Italy and his province of Cisalpine Gaul. To pass it would be a declaration of war against the senate. Whether the modern Luso or the Fiumicino was the Rubicon can not be determined. A papal bull in 1756 pronounced for the Luso, which the peasants also call il Rubicone. The weight of argument, however, identifies it with the Fiumicino. E. A. G.

Rubid'ium [Mod. Lat., from Lat. *ru'bidus*, red, deriv. of *rube're*, be red]: one of the alkali metals, discovered by Kirchhoff and Bunsen in 1860 as one of the first fruits of spectroscopic investigation. It occurs in extremely minute proportions in some saline mineral waters, in association with Cæsium (*q. v.*). The water of Bourbonne-les-Bains contains in 1,000,000 parts 19 parts of chloride of rubidium. Some lepidolites contain it, associated with lithium and cæsium. Among these are the lepidolite of Hebron, Me., which contains about $\frac{1}{400}$th of its weight. The ashes of some plants, as the tea and the coffee plants, show it. It is a white metal with a yellowish tinge and silvery luster. Density = 1·52. It is as soft as wax, melts at 101·5° F., and yields even below a red heat a greenish-blue vapor. It is more easily oxidized by the air than potassium, and is more electro-positive than the latter. It kindles on water, and burns like potassium. Revised by Ira Remsen.

Rubies, Cape: See Cape Rubies.

Ru'binstein, Anton Gregor: composer and pianist; b. at Wechwotynetz, Roumania, of Jewish parents, Nov. 30, 1830; received instruction from his mother, Villoing in Moscow, Liszt in Paris, and Dehn in Berlin. After two years spent in Vienna in teaching, he returned to Russia in 1848, and studied in St. Petersburg for eight years. All this time he was composing, and when he made a concert tour in 1857 he created a remarkable sensation, both by his playing and his works. In 1858 he was appointed imperial concert conductor in St. Petersburg with a life pension. In 1862 he founded the St. Petersburg Conservatory, and remained its principal till 1867. In 1869 the emperor ennobled him. He visited every European country and the U. S. in his concert tours. His compositions include fifteen operas, some of them being what he called sacred operas, such as *Paradise Lost*, *The Tower of Babel*, and *Moses*; six symphonies, of which the best known are the *Ocean*, No. 2, op. 42, and the *Dramatic*, No. 4, op. 95; overtures, piano sonatas and concertos, sonatas and concertos for other instruments, much chamber music, and numerous piano solos, and vocal pieces for one or more voices. D. at Peterhof, Russia, Nov. 20, 1894. D. E. H.

Ruble: See Rouble.

Rubric [from O. Fr. *rubriche* < Lat. *ru'brica*, red earth, red chalk, the title of a law (because written in red), deriv. of *ru'ber*, red]: any writing or printing in red ink. In MS. and printed missals the directions preceding the prayers and offices were usually written or printed in red ink; hence the term rubric is commonly used to denote the rules and directions for the performance and celebration of divine service. As the date and place on a title-page were sometimes printed in red ink, and the place where the book was sold was given instead of that where printed, the word rubric has also been used to signify the false name, as many books printed at Paris bear the *rubric* of Genoa, London, etc. W. S. P.

Rubruk (or **Rubruquis**), **William of**: a distinguished Franciscan monk and missionary; b. at Rubrouck, in French Flanders; was sent to Tartary by Louis IX. to open communication with the Tartar prince Sartak, who was alleged to be a Christian (1253–55). The narrative of his journey was written in Latin, and is one of the best of its kind in existence. The best edition is that in the *Recueil de voyages* (vol. iv., 1839) of the Paris Geographical Society. There is an English translation in *Purchas his pilgrimes* (vol. iii.), and a French one, Paris, 1877. The name often given to him, William of Ruysbroeck, arose by confounding him with the Flemish mystic, John of Ruysbroeck. D. after 1293. Roger Bacon speaks of him, and may very likely have seen him; and, as gunpowder was then in use among the Tartars, it has been conjectured that Rubruk may have given Bacon a clew to the discovery.

Ruby, or **Red Sapphire**: a variety of Corundum (*q. v.*). The finest and most highly prized rubies are of the so-called pigeon's-blood color; they are found in the valley of Mogok, in Burma, where the mines have been worked by the Burmese for centuries, and are now leased by the British Government to a London syndicate. Lighter-colored rubies, sometimes almost pink, often very beautiful, occasionally with a tinge of purple or currant-wine color, are found at Ratnapura, Ceylon. More recently the mines in Siam have been extensively worked, and some fine gems have been found, although nearly all of the rubies found there are very dark red, almost garnet-colored, frequently with a brownish tinge. Small rubies have been found in the vicinity of Franklin, N. C., and in the government of Perm, in Russia. Rubies from 1 carat upward, when fine, are of great value, and when from 2 to 4 carats in weight command from five to ten times the price of a white diamond of similar quality. A ruby of 10 carats has been sold in the U. S. for about $50,000. The so-called reconstructed rubies are not, as generally believed, made by fusing small bits of ruby, but are artificial rubies made by a direct process, and are distinguishable by the presence of round bubbles and other peculiarities. They are sold only under the name of artificial rubies in France, with heavy legal penalties for failure so to designate them. The so-called Cape, Arizona, Colorado, and Utah rubies, often very beautiful, are fine pyrope garnets, possessing only very slight value compared with the true ruby. G. F. Kunz.

Ruby-spinel: See Spinel.

Rückert, Johann Michael Friedrich: poet; b. at Schweinfurt, Bavaria, May 16, 1788; studied law at Jena; lived in Stuttgart, where he edited, 1816–17, the famous *Morgenblatt*; traveled in Italy 1818; studied Oriental languages under Hammer in Vienna; was appointed Professor of Oriental Languages at Erlangen in 1826, at Berlin in 1840, but retired in 1848 to his estate, Neuses, near Koburg, where he died Jan. 31, 1866. Under the pseudonym *Freimund Raimar* he published in 1814 his *Deutsche Gedichte*, in which were the famous *Geharnischte Sonette*, a collection of sonnets directed against Napoleon. They are full of strong patriotic sentiment, and display an extraordinary command of the poetical form. The character of Rückert's lyrics in general is rather philosophical than naïve and spontaneous, a fact which may account for the poet's immense productivity. In the six volumes of his *Gesammelte Gedichte* (1834–38), and especially in the collection *Liebesfrühling*, there are many bits of genuine lyric poetry, but there is also much that is insignificant. His translations from the Arabic, *Die Makamen des Hariri* (1826), *Hamasa* (1846), the Chinese *Schi King*, *Chinesisches Liederbuch* (1833), and the Sanskrit *Nal und Damajanti* (1828), etc., reproduce the difficult meters of the originals with skill and ease. In *Weisheit des Brahmanen* (1836–39) he successfully imitated the didactic style of Hindu poetry and exhibited a wealth of wisdom and philosophic thought. See Fortlage, *Friedrich Rückert und seine Werke* (1867); C. Beyer, *Friedrich Rückert* (1868); F. Muncker, *Friedrich Rückert* (1890); P. de Lagarde, *Erinnerungen an Friedrich Rückert* (1886). Julius Goebel.

Rūdagī, roo-dăă-gee': Persian poet of the tenth century, sometimes called the father of Persian literature. His name Rūdagī comes from the village of Rūdag, in the region of Bokhara or Samarkand, where he was born toward

the end of the ninth century. His full name is given as Farīd ad-dīn Muḥammad Rūdagī. Biographical tradition makes him a sort of blind Homer, but as to his blindness there is doubt. His poetical renown won him a position at the court of the Sāmanīd Nasar II., ben Ahmad of Khorassān. The literary activity of Rūdagī appears to have been great; he is said to have composed more than a million verses. The remains that have been preserved are comparatively meager, but they are of high merit. Among the deplorable losses may be mentioned his translation of the Indian book of fables, *Kalilah and Dimnah*, rendered into Persian from the Arabic version of Abd-allah ibn al Muḳaffa. Rūdagī outlived his royal patron, and fallen on evil days he seems to have died about A. D. 954. See Ethé's *Rūdagī der Sāmanīdendichter* in *Göttinger Nachrichten* (1873, pp. 663–742). A. V. Williams Jackson.

Rudbeck, Olof: scientist; b. at Vesteraas, Sweden, Sept. 30, 1630. He studied natural science at the University of Upsala, where he became a professor in the faculty of medicine. By his discovery, at the age of twenty-three, of the lymphatic canal he gained European renown. In addition to investigations in several branches of science, he devoted himself to the study of archæology and literature, both classical and Scandinavian, publishing several sagas and Swedish provincial laws (from 1679). His great botanical work, *Campi elysii eller Glysisvald*, was left uncompleted. He is best known by his ingenious and learned *Atland eller Manhem* (4 vols., Upsala, 1675–1702), commonly called *Atlantica*, in which he sought to establish the identity of Sweden with Plato's fabled land and the Garden of Eden. By the fire in Upsala in May, 1702, his library and collections, including the unpublished continuation of *Atlantica*, were destroyed, and his death followed a few months later (Dec. 12).—His son, Olof Rudbeck (d. 1740), acquired considerable eminence as a zoölogist, and his grandson, also of the same name (d. 1777), was the author of a number of comic poems.

D. K. Dodge.

Ruddiman, Thomas: Latin grammarian; b. at Raggel, Banffshire, Scotland, Oct., 1674; graduated at King's College, Aberdeen; was afterward a publisher and printer to the University of Edinburgh (1728), and principal keeper of the Advocates' Library (1730). He is chiefly known as the author of a once very famous work on *Latin Grammar* (1732), whose learned Latin introduction and appendices are still of value. In 1739 he brought out a magnificent folio edition of Anderson's *Diplomata et Numismata Scotiæ*, and produced his celebrated "immaculate" edition of Livy (4 vols. 12mo, 1751). D. at Edinburgh, Jan. 19, 1757. See G. Chalmers, *Life* of Ruddiman (1794).

Revised by A. Gudeman.

Rude, rüd, François: sculptor; b. at Dijon, France, Jan. 4, 1784. His father was a blacksmith and made stoves, and young Rude was kept at this work, receiving instruction in drawing, during leisure hours only, at an art school in the town. Medals were won for drawing, etc., by the young man, who in 1804 made a bust of the engraver and medalist, Louis Gabriel Monnier. In 1807 he went to Paris, taking with him his statuette of *Theseus picking up a Quoit*. In 1809 he gained a second prize for sculpture at the Imperial Academy, and in 1812 the Grand Prix de Rome, but did not go at once to Italy. At the second restoration Rude went to Belgium with the Frémiet family of Dijon, settled in Brussels, and in 1821 married Sophie Frémiet, who was afterward known as a portrait-painter. In 1827 he returned to Paris, where he was invited to take the atelier for students formerly managed by David d'Angers (see David, Pierre Jean). Except for a short visit to Italy, Rude remained faithful to steady and arduous work. He was a man of singular strength of body and simplicity and direct force of character, a republican by conviction, but primarily and all his life long an artist. D. in Paris, Nov. 3, 1855. Of his work there must be named the group of the *Departure for the War*, on the Arc de l'Étoile at Paris, the northern group on the side toward the Champs Élysées, a noble composition, well known to all students; *Mercury fastening his Winged Sandal*, in the Louvre; *Neapolitan Fisher-boy*, also in the Louvre; *Joan of Arc*, in the Luxembourg Garden; and *Hebe and the Eagle of Jupiter* and *Love the Conqueror*, in the Museum of Dijon. There are also a great many portrait-statues and busts, as *La Pérouse*, the explorer, in the Louvre, *Louis David*, *General Cavaignac*; and what may be called historical portraits, as of men whom he had no chance to study from life, *Napoleon*, at Fixin in Burgundy, *Marshal Ney*, at Paris, *Marshal Bertrand*, at Chateauroux; and as decorations of the new buildings of the Louvre, statues of *Houdon*, the sculptor, and *Nicholas Poussin*. There exists a life of Rude, published at Dijon in 1856, and Hamerton wrote an account of him in his *Modern Frenchmen*.

Russell Sturgis.

Rü'dinger, Nicolaus, M. D.: anatomist; b. at Rüdesheim, Germany, Mar. 25, 1832; studied medicine at the Universities of Heidelberg and Giessen, where the teachings of Henle, F. Arnold, and T. Bischoff inclined his attention to anatomy; graduated M. D. at the University of Giessen in 1855; and became prosector and adjunct to Bischoff at the University of Munich. In 1881 he was elected Professor of Anatomy, and raised the standard of anatomical teaching at that school, utilizing photography to depict his dissections. D. Aug. 23, 1896. His most important works are *Atlas des peripherischen Nerven-systems des menschlichen Körpers* (Stuttgart, 1872); *Topographisch-chirurgische Anatomie des Menschen* (Stuttgart, 1873–79); *Atlas des menschlichen Gehörorganes* (Munich, 1875). He was coeditor of *Monatsschrift für Ohrenheilkunde* 1867–70, and of the *Beiträge zur Anthropologie und Urgeschichte Bayerns* in 1877.

S. T. Armstrong.

Rudolph: the name of two German emperors. Rudolph I. of Hapsburg, b. in 1218, founder of the house of Austria, and German emperor 1273–91, was the oldest son of Albert IV., Count of Hapsburg and Landgrave of Alsace, which countries he inherited after the death of his father in 1240. He was successful in enlarging his possessions, but it was, nevertheless, not the importance of his political position, but the righteousness and valor of his personal character, which gained for him the German crown. In order to strengthen his authority among his vassals and procure the necessary support, he married his daughters to the two most powerful among them, the count-palatine, Louis, and Duke Albert of Saxony, and then marched against two others who refused to do homage, King Ottocar of Bohemia and Duke Henry of Bavaria. The latter was easily defeated; and Ottocar submitted on the approach of the imperial forces and made peace in 1276. Later, however, he broke the truce, and in the new war was killed in the battle of Marchfield in 1278. Rudolph gave Bohemia and Moravia to the sons of Ottocar, but Austria, Styria, Carinthia, and Carniola he separated from the heritage and gave to his own son, Albert, thus founding the state of Austria. Against his external enemies, the Count of Savoy, the Duke of Burgundy, etc., he was also successful, and his internal government was distinguished by justice and love of order and peace. He traveled from place to place in the empire, and sat in court on all important occasions, for which reason his people called him the living law—*lex animata*. D. in 1291, and was buried at Spires. His *Life* has been written by Lichnowski (1836), Schönhuth (1843), and Hirn (1847).—Rudolph II. (1576–1612), b. July 18, 1552, a son of the Emperor Maximilian II. and Marie, daughter of Charles V.; was educated at the Spanish court; crowned King of Hungary in 1572, of Bohemia in 1575, and elected Emperor of Germany after his father's death Oct. 12, 1576. He was superstitious, weak, and entirely in the hands of the Jesuits. Immediately after his accession to the throne the Protestant worship was forbidden throughout his Austrian dominions, the Protestant schools were closed, and the preachers and teachers banished. In the empire he espoused the cause of the Roman Catholic Church with violence, and the formation of the Protestant Union (May 4, 1608) and the Roman Catholic League (July 10, 1609) brought Germany to the verge of civil war. Meanwhile, the Hungarians arose and Bohemia revolted. The house of Austria seemed near its ruin when Matthias, a younger brother of the emperor, took the lead in the affairs of the family, and compelled Rudolph to cede to him all his hereditary possessions. Unable to maintain his authority in the empire, and embittered by his misfortunes, the emperor retired into private life, and died at Prague, Jan. 20, 1612. He felt some interest in science and literature, and several great scholars and scientists lived at his court. His *Life* has been written by Gindely (1863–65) and von Bezold (1885).

Revised by F. M. Colby.

Ru'dolstadt: town of Germany; capital of the principality of Schwarzburg-Rudolstadt; beautifully situated on the Saale, 18 miles S. of Weimar (see map of German Empire, ref. 5–E). It has a fine palace with a picture-gallery and a library, and manufactures of woolens, porcelain, and dyestuffs. Pop. (1895) 11,907.

Rue [viâ O. Fr. from Lat. *ru'ta* (whence O. Eng. *rūde*, rue) = Gr. ῥυτή, rue]: an herb, *Ruta graveolens*, of the Old World (order *Rulaceæ*), having a strong smell and poisonous qualities. It was once used as an aspergil for sprinkling holy water. It was believed by the superstitious to be a powerful charm against witches, and is used in some places for flavoring food. By some persons it is employed as a means of produeing abortion. This it rarely succeeds in doing, and if that event occurs often costs the woman her life. Revised by H. A. Hare.

Ruff: the *Philomachus pugnax*, a sandpiper, or wading bird of the sub-family *Tringinæ*. It was formerly very common in the fens and marshes of England, but has nearly disappeared sinee its favorite haunts have been so largely reclaimed and eultivated. It is still found throughout Northern Europe and Asia, and it migrates southward in winter. It is aecidental on the eastern coast of the U. S. The ruff derives its name from a circlet of long, closely set feathers upon the neck of the adult male, whieh he raises or lowers at pleasure. The male ruff is polygamous and courageous, is about 10 inches in length, with the head and shoulders of a dark purple, barred with chestnut, the back chestnut spotted with black, the wings brownish black, eaeh feather having a white shaft, and the tail brown mottled with black. The species is remarkable from the fact that no two male birds in the breeding plumage are colored exactly alike. The female is called a reeve. F. A. Lucas.

Ruffed Grouse: the *Bonasa umbellus*, a species of the family *Tetraonidæ*, distinguished from other grouse by the absence of feathers on the lower half of the tarsi. It has also, on the sides of the neck, a ruff of soft, broad, and truncate feathers, to which the name refers; the tail is somewhat convex, and about as long as the wings; the color of the cervical tufts is a glossy black or brown, with a semimetallic steel-blue or grcenish border; the tail has two bands of gray, and between them a broad blaek one. The species, as understood by Baird, Brewer, and Ridgway, is generally distributed throughout the north temperate parts of North America, but is differentiated into several sub-species, or geographieal races, viz.: (1) *umbellus*, inhabiting the eountry E. of the Roeky Mountains; (2) *umbelloides*, inhabiting the Roeky Mountains and the interior of British America up to Yukon river; (3) *sabini*, found in Oregon, Washington, British Columbia, etc.; and (4) *logata* from Eastern Oregon and Washington to Nova Scotia and Maine, ranging southward to the mountains of New England and New York; these are distinguished by slight differences of color. The species in some sections (New England and the Western States) is known under the name of partridge; in others (the Middle States) as the pheasant; and in some of the British provinces as the birch-partridge. It is chiefly found in hilly and woody regions and along the borders of watereourses, but also in the lowlands and cane-brakes, as in Kentucky; rarely or never, however, on open plains. F. A. Lucas.

Ruffin, Edmund: agrieulturist; b. in Prinee George co., Va., Jan. 5, 1794; was for many years president of the Virginia Agricultural Society; edited *The Farmer's Regisler* 1833–42, and other agricultural papers; published treatises on scientific methods of agriculture; editor of Col. William Byrd's *Weslover Manuscripls* (1841); was an ardent seeessionist, beeame a member of the Palmetto Guard of South Carolina, and fired the first gun at Fort Sumter Apr. 14, 1861. He committed suicide near Danville, Va., June 15, 1865, because unwilling to live under the U. S. Government.

Rug: See the Appendix.

Rugby: town; in Warwickshire, England; on the Avon; 83 miles by rail N. W. of London (see map of England, ref. 10–H). It is the center of a great hunting distriet. Its eelebrated sehool, founded in 1567 by Lawrence Sheriff, acquired a national reputation under Thomas Arnold as head master (1828–42). Pop. (1891) 11,262.

Ruge, roo'ge, Arnold: author; b. at Bergen, island of Rügen, Sept. 13, 1802; studied philology and philosophy at Halle, Jena, and Heidelberg, but was sentenced in 1824 to a five years' imprisonment in the fortress of Colberg as a member of a secret political soeiety; published in 1830 a translation of *Œdipus Coloneus* and *Schill und die Seinen*, tragedy; was appointed Professor of Æsthetics at the University of Halle in 1831, and attracted much attention as a philosophical eritic in the *Hallische Jahrbücher* (1838–43); joined Karl Marx in Paris, and published with him the *Deutsch-französische Jahrbücher* (1843–45); published in 1845 *Zwei Jahre in Paris*; at Zurich and Leipzig published *Poetische Bilder* (2 vols.) and *Polilische Bilder* (2 vols., 1847); was eleeted a member of the German Parliament in 1848, and founded in the same year the *Reform* at Berlin. This paper was soon suppressed, and, after some attempts at revolutionary intrigue in Dresden and Carlsruhe, he went in 1849 to London, where he formed a European Democratie Committee with Ledru-Rollin and Mazzini. He published *Unser System* (1850); *Aus früherer Zeil* (1862–67); *Manifest an das deulsche Volk* (1886), etc. D. at Brighton, Dec. 31, 1880.

Rü'gen: an island in the Baltie, a mile off the coast of Pomerania; comprises an area of 361 sq. miles, with (1895) 46,732 inhabitants, and belongs to Prussia. The soil is fertile, and the fisheries are very rich. Capital, Bergen.

Ruger, Thomas Howard: soldier: b. in New York, Apr. 2, 1833; graduated at the U. S. Military Academy 1854; promoted brevet seeond lieutenant of engineers; resigned Apr. 1, 1855; praeticed law at Janesville, Wis., 1856–61; in June, 1861, entered the army as lieutenant-colonel and colonel Third Wisconsin Volunteers; was appointed brigadier-general U. S. volunteers Nov., 1862; served in the Army of the Potomac, participating in its eampaigns and battles from Winchester, May, 1862, to Gettysburg. In Oct., 1863, he was transferred to the West, and at the battle of Franklin, in command of a division, he won the brevet of major-general. He was in command of the department of North Carolina until June, 1866; colonel Thirty-third Infantry July, 1866; transferred to the Eighteenth in 1869; superintendent of the U. S. Military Academy 1871–76; brigadier-general Mar. 19, 1886; major-general 1895, becoming commandant of the department of the East. Retired Apr. 2, 1897.

Ruggles, Timothy: lawyer and soldier; b. at Roehester, Mass., Oct. 20, 1711; graduated at Harvard 1732; praeticed law at Sandwieh and Hardwick; was seeond in command at the battle of Lake George 1755; served as brigadier-general under Lord Amherst 1758–60; judge of common pleas 1756; chief justice 1762; Speaker of Assembly 1762–63; delegate to Stamp Act congress at New York 1765; was an inactive loyalist at the outbreak of the Revolutionary war, but lost his property by confiseation; removed to Nova Scotia 1775, and was a founder of the town of Digby. D. at Wilmot, N. S., Aug. 4, 1795.

Ruhmkorff, Heinrich Daniel: eleetrieian; b. in Hanover, Germany, in 1803: settled in Paris in 1839; brought out a convenient form of thermo-battery in 1844; in 1851 produced his famous coil. (See Induction Coil and Electricity.) D. in Paris, Dec. 21, 1877.

Ruhnken, roon'ken, David: Greek scholar; b. at Stolpe, Pomerania, Prussia, Jan. 2, 1723. After studying some time in his native land, he emigrated to Holland, attracted by the fame of Hemsterhusius, whose devoted disciple he became. Together with Valckenaer, Ruhnken sueceeded in establishing the study of Greek upon a firm basis in Dutch universities, Latin having, before the time of his great teacher, received almost exclusive attention. His principal works are *Timæi lexicon* (1754); *Historia critica oratorum Græcorum* (1768); *Homeric Hymns to Demeter and Dionysos*; *De vita et scriptis Longini*, parts of whose works he discovered amid the *Rhetoric* of Apsines; Velleius Paterculus, and *Elogium Hemsterhusii*. See D. Wyttenbaeh, *Vita D. Ruhnkenii*, edited with notes by Bergmann (1824). A. G.

Ruisdael, or **Ruysdael**, rois'daăl, Jacob, van: landseape-painter; b. at Haarlem, Holland, in 1629 or 1630; was under the influence of Allaert von Everdingen; went to Amsterdam in 1659 and established himself there, receiving the rights of citizenship. Ruisdael died in an almshouse at Haarlem, Mar. 14, 1682, and was buried in that city. His pietures were not appreciated in his day. Ruisdael also produeed a few etchings. The figures in his landscapes are said to have been put in by A. van de Velde, Ph. Wouverman, or Lingelbaek. Hobbema was a pupil of Ruisdael; Jan van Kessel and J. R. de Vries were his followers. Ruisdael's works are to be found in all important European galleries. W. J. S.

Rule Britannia: a British national song or hymn, the words of which were composed by David Mallet (1698–1765), and the music by Arne. It was first performed in 1740 as part of *Alfred, a Masque*, by Mallet and James Thomson.

Ruled Surface: in mathematies, a surface generated by a right line, which moves subject to three conditions, or, in other words, whose position involves one indeterminate eonstant. Thus an hyperboloid of one sheet is generated by a line which intersects three given lines in space, and a ruled

hyperboloid of revolution is generated by a line revolving round an axis which it does not intersect. Ruled surfaces of the second order, such as those mentioned, can be generated by the movement of a line in two distinct ways; and each line of one system intersects all the lines of the other system. This is not the case with other ruled surfaces. The surface is called a developable, that is, capable of being opened out into a plane, if two consecutive generating lines intersect. If the intersection is a fixed point, the surface is a cone, and if the lines are parallel the surface is a cylinder. See CONE and HYPERBOLOID. R. A. ROBERTS.

Rule Nisi: in law, a rule or order obtained on an *ex parte* motion, which, after due service upon the party against whom the rule is obtained, will be made absolute, unless (*nisi*) the party appears and shows good cause why it should not be made absolute. F. S. A.

Rule of the Road: See ROAD, LAW OF THE.

Ruling-machines: instruments designed for the subdivision of a given unit of length into any required number of parts, either equal or unequal. These are called "line-dividing engines" or "circular-dividing engines," according as the unit to be subdivided is a rectilineal measure or a circular arc.

The circular-dividing engine consists of a disk capable of accurate movement about a true center and of suitable mechanism for making this movement automatic. A graduating attachment produces automatically the marks upon the metal surface which correspond to the movement in revolution. There are, in general, two types of mechanism by which the movement in revolution is effected. According to the first type, the disk is moved by means of a gear and a worm cut in the periphery of the disk. In this type, the accuracy of the subdivision depends entirely upon the accurate workmanship of the worm and gear. Since the action is automatic there is no chance for the correction of known errors during the operation of graduation. In the second type the subdivision is effected by means of an arm attached to the disk, by which it is carried a definite distance, determined by the position of two metal stops, one of which is fixed, while the other is adjustable by means of a stout micrometer screw. The arm is connected with the revolving disk by means of electro-magnets. These clamp the arm to the disk during the forward motion and are released during the backward motion.

In the operation of the engine it is assumed that the master circle has been graduated without sensible error by successive approximations; at least to single degrees. When the stops are set at the proper distance apart the master circle can be exactly copied, and still further subdivision can be effected by setting the stops at the distance apart required to produce aliquot subdivisions. Suppose, for example, that it is required to graduate a circle to ten minutes of arc. First the stops are set to correspond to this distance approximately. It is not to be expected that this can be done with the utmost exactness, but when the machine is started in operation the microscope under which the lines of the master circle are viewed, having a high magnifying power, will easily detect any deviation as small as one-tenth of a second of arc. As soon as the slightest deviation is detected it can be corrected by the motion of the adjustable stop, since ten divisions of the micrometer screw by which this movement is effected are equivalent to this distance. Thus an accumulation of errors can be prevented while the engine is in operation, and before any sensible error has been introduced.

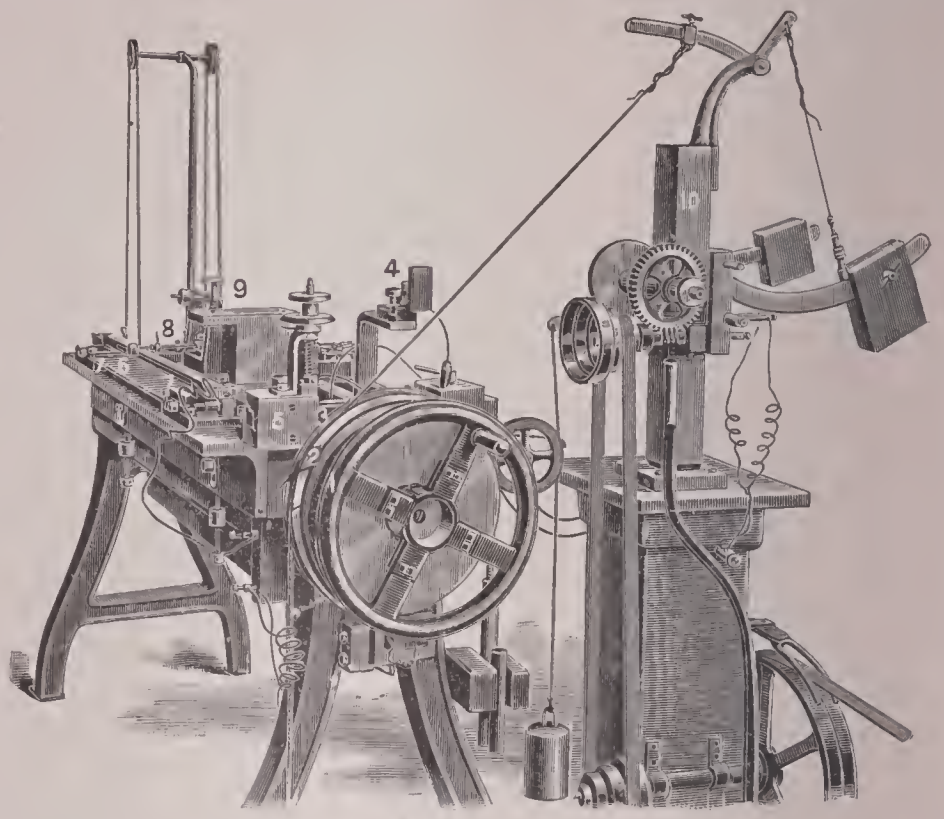

FIG. 2.—The Rogers dividing-engine, front view.

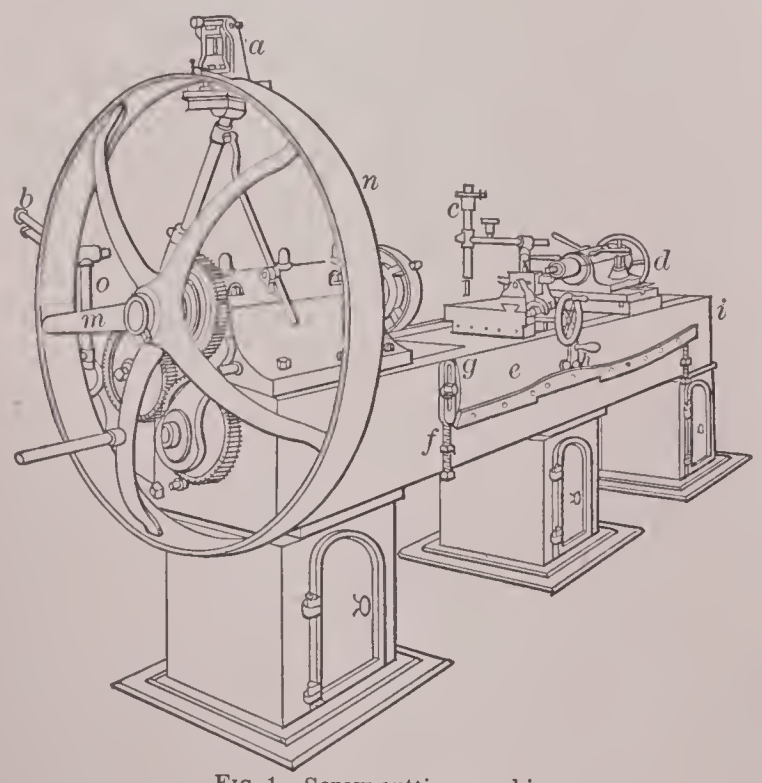

FIG. 1.—Screw-cutting machine.

The Line-dividing Engine.—The movement by which the subdivision of a given unit may be effected, as shown in Figs. 2 and 3, is usually produced by a screw of superior construction. A perfect screw, however, can give good results only when it is properly connected with the ruling carriage. If the screw has considerable length and a relatively small diameter the flexure must be taken into account. All kinds of constrained motion must be avoided, since under changes of temperature the effect of this constrained action will be variable. Usually the carriage to which motion is given by the nut moves over V-shaped ways. Since, in the construction of ways of this form, it is, to say the least, exceedingly difficult to maintain plane surfaces upon both surfaces of the ways and at the same time to maintain them straight and parallel, this form of construction is to be avoided in a dividing-engine in which great precision is desired. The form of ways shown in Fig. 3 is to be preferred. In this form each way is perfected independently by measurement tests made during the process of construction. It has been found to be not at all difficult to reduce the departure from a true plane to a limit corresponding to a radius of curvature as great as 500 miles for a distance of 40 inches.

The carriage moved by the nut and the screw is kept in contact with the face of the vertical wall by means of cylindrical plugs backed by springs acting against the opposite wall. In Fig. 3 the plate shown at 2 is pressed against the left wall at 1, and the spring plugs act against the right wall.

In the construction of a screw for a dividing-engine four difficulties must be overcome if great precision is desired. (1) Every half of every revolution of the screw must at every point be equal to every other half. Errors which depend upon a single revolution of the screw are called periodic errors of single revolution. The writer has had good success in the elimination of errors of this class by grinding the

screw with a nut made up of four symmetrical sections which are made interchangeable without affecting the position of the axis of revolution. (2) Every revolution of the screw must be equal to every other revolution; in other words, the screw must have no linear errors. Errors of this class may be eliminated by means of an arm attached to the nut, at the other end of which is attached a roller. The latter in turn acts upon a template which is filed away to match the observed errors of the screw, as shown in Fig. 1 at *fi*. Since the nut is mounted so as to be practically free with respect to the carriage during a revolution of the screw, the template arm can give to the screw a motion which is independent of the forward motion of the nut. This construction is shown at *h* in Fig. 1. (3) The nut, which is supposed to have been made free from the two kinds of errors described above, must have a perfectly free action in its movement upon the screw. This is accomplished by means of four cylindrical plugs fitted to four arms which project downward from the under side of the carriage. When feeling contacts have been made with the end faces of the nut, they are clamped in position by means of set-screws. These four plugs guide the nut during the independent revolution of the nut by means of the correction-arm. (4) Even if the screw has no errors of appreciable magnitude after it has been ground, when supported in a vertical position, the errors due to flexure must be taken into account. There are two methods of overcoming this difficulty. First, a following nut may be mounted so that its supports shall rest upon the ways and take up the flexure during the progressive motion of the nut. The writer has not found this method satisfactory, chiefly owing to the constrained motion between the nut and the screw. It has been found far better to admit the flexure of the screw and to eliminate its effect by means of a template, in the manner already described. In the case of a screw 2 inches in diameter and 5 feet in length the change in length at the middle point, under a load of 40 lb., was found to be a little over one-thousandth of an inch.

In the screw-cutting machine which is represented in Fig. 1 an attempt has been made to fulfill the following conditions, viz.: (1) The ways upon which the tool-carriage is supported and moves must lie in a horizontal plane. (2) The vertical wall against which the tool-carriage is pressed must lie in a vertical plane which is at right angles to the horizontal ways at every point. (3) The line between the centers must be parallel to both sets of ways. (4) The movement of the tool-carriage must be parallel to the line between the centers at every point.

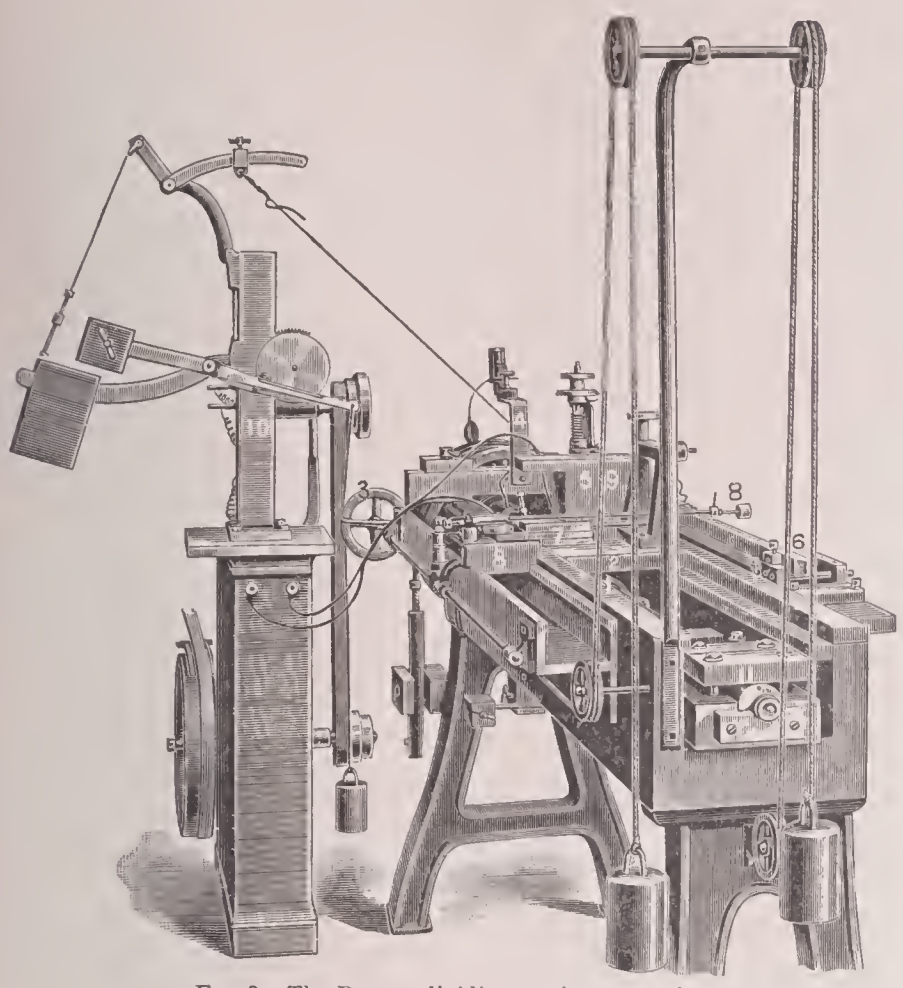

FIG. 3.—The Rogers dividing-engine, rear view.

Two views of the dividing-engine are given in Figs. 2 and 3. The automatic driving attachment is shown at 10. The index, which is subdivided into 1,000 equal parts, is shown at 2. At 3 is shown the circular electro-magnet arm, which moves between two stops, one of which is seen at 5. At 4 is a holder for the microscope with which the divisions of the index-wheel are read. A microscope is clamped to the carriage, which is driven by the screw, at 9. This microscope is adjusted over a graduated bar which rests upon adjustable supports at 7. If another bar rests upon a second set of supports at 7 and is viewed by a second microscope, the instrument is converted into a convenient form of comparing apparatus. See the article MEASURING-MACHINES.

In Fig. 3 the automatic ruling attachment is shown at 8. It is carried along independently of the screw by a weight movement. When the index-wheel at 4 has been set, a line can be ruled by a slight movement at 3, the cutting tool being automatically lifted during the backward motion and released in time for action during the forward motion. The instrument is therefore adapted either to continuous automatic action or to an isolated movement at the will of the observer.

WILLIAM A. ROGERS.

Rum [apparently abbreviated from *rumbullion*, a great tumult, a strong distilled liquor. The Fr. *rhum*: Germ. *rum* are from Eng.]: a spirituous liquor distilled from molasses and the refuse juice and scum from the manufacture of sugar. It is largely produced on the sugar-plantations in the West Indies; that from Jamaica is considered the best, and the product of Santa Cruz also has a high reputation. The wort is prepared by mixing about 100 gal. of molasses, 300 gal. of skimmings from the clarifiers, 200 gal. of lees from previous fermentations, called dunder, and 400 gal. of water. This mixture averages about 15 per cent. of sugar. The fermentation is complete in from nine to fifteen days. The mixture is then distilled, and a quantity of molasses or caramel is added to color and flavor it. The peculiar flavor of rum is chiefly due to butyric ether, produced during the fermentation. Acetic and other ethers are present. Pineapples and guavas are often thrown into the still. Rum is greatly improved by age. It was formerly largely manufactured in New England, especially at Newport, R. I., and was a prominent article of exportation to Africa in connection with the slave-trade. Great quantities of liquor sold for rum are produced by flavoring and coloring rectified proof spirit.

Revised by IRA REMSEN.

Rumford, BENJAMIN THOMPSON, Count: statesman; b. at Woburn, Mass., Mar. 26, 1753; educated at Woburn and Medford; became a student of natural science, attending the lectures of Prof. Winthrop, of Harvard; sympathized with the early movements for resistance to British oppression, but went over to the British. He went to London, where he gave valuable information to the government as to the state of the colonies. He lived for several years in England, where he continued his studies and was chosen F. R. S. 1778, but returning to the colonies in 1781 he raised a regiment of loyalists; served in the Carolina campaign against Marion 1782. In 1783 he entered the service of the Elector of Bavaria; settled at Munich; acquired great influence with the elector, who took his advice on nearly every subject, made him major-general, councilor of state, lieutenant-general, commander-in-chief of the general staff, Minister of War, and Count of the Holy Roman empire 1790, on which occasion he chose as his title the name of the town in New Hampshire where he had resided and married. Many vigorous reforms were effected by Count Rumford in the Bavarian administration, as well as improvements in military training, in methods of agriculture, stock-raising, and in the practice of mechanic arts. Continuing his scientific studies he published in pamphlets accounts of a large number of scientific experiments, which he collected under the title *Essays, Political, Economical, and Philosophical* (London, 1796, 1798), and several times reprinted; left the Bavarian service on the elector's death 1799; was chiefly

instrumental in founding the Royal Institution in London in that year; settled at Paris and published his *Philosophical Papers* (vol. iv. of his *Essays*, 1802); married the widow of Lavoisier 1804, and spent the remainder of his life in quiet prosecution of his scientific studies at his wife's villa at Auteuil, near Paris, where he died Aug. 21, 1814. He contributed to science a considerable number of valuable observations and discoveries, especially upon his favorite subject, that of heat, of which he came near discovering the mechanical equivalent; made a series of experiments which directly led at a later period to the discovery of the correlation of forces; was also one of the pioneers of modern researches in optics and magnetism; left prizes to be awarded by the Royal Society of London and the American Academy of Sciences at Boston for discoveries on light and heat, and was himself the recipient of the first Rumford prize from the Royal Society; and endowed in Harvard College the Rumford professorship of the physical and mathematical sciences as applied to the useful arts. See his *Life*, by Rev. Dr. George E. Ellis (1871), and his *Works*, edited by the same gentleman (4 vols., London, 1876).

Rūmī, roo-mē′, Jalāl ad-dīn: Persian Sūfī poet and philosophic teacher; b. at Balkh, A. D. 1207. He was descended of high ancestry and his father, Bahā ad-dīn Valad was so famous for his learning and the influence of his teaching as to excite the enmity of the jealous sultan, and to be obliged in consequence to leave Balkh with his family. After various travels he found his way to Asia Minor and settled at Iconium, where he founded a college under the patronage of the Sultan of Rūm, as Asia Minor is termed in the Orient. Hence the appellation Rūmī, by which his more distinguished son is known. Jalāl ad-dīn was an enthusiastic student, and his thirst for spiritual knowledge was fostered under his father's teaching. His father died in 1231, and Jalāl continued under scholarly guidance zealously to pursue his studies, and he succeeded ultimately to his father's chair and to the superintendence of the colleges of Iconium. Sorrow, which came to him in the untimely death of his son and in the sad fate of a beloved teacher, seems to have deepened his religious devotion, to have given tone to his mystic philosophy, and at the same time to have enriched his poetic talents. He became the founder of the Maulavī sect of dervishes, and his zealous devotion to this order seems to have been a source of inspiration for his spiritual and mystic odes. His great work is the *Masnavī*, or *Mathnavī*, a production of high poetic merit, religious fervor, and philosophic thought. It is a huge collection of precepts and tales, and it comprises between 30,000 and 40,000 rhymed couplets. Jalāl ad-dīn Rūmī died in 1273, shortly after the completion of this monument, by which his name is known to fame. His teachings and doctrines continued to be cherished by the Maulavī sect that he had founded, and the leadership of this dervish order has traditionally remained in the direct line of his descendants. There is a versified translation of the first book of the *Masnavī*, by J. W. Redhouse (London, 1881, Trübner's Oriental Series). Selected portions have been rendered into German by Rosenzweig (Vienna, 1838). For other details, see Sir Gore Ouseley, *Biographical Notices of Persian Poets*, pp. 112–116 (London, 1846); H. Ethé, in *Morgenländische Studien*, p. 95, *seq.* (Leipzig, 1870); S. Robinson, *Persian Poetry for English Readers*, pp. 367–381 (Glasgow, 1883).

A. V. Williams Jackson.

Rummell, Franz: See the Appendix.

Rumohr, roo′mōr, Theodor Wilhelm: novelist; b. in Copenhagen, Denmark, Aug. 2, 1807. His romances, of which he wrote a great number, treat for the most part of popular national heroes, such as Niels Juel and Tordenskjold. His collected works, *Fædrelands historiske Malerier* (14 vols.), were published at Copenhagen, 1850–65. D. K. D.

Rump Parliament: the popular name applied in English history to a remnant of the Long Parliament. It consisted of sixty members, who, after the expulsion of three-fourths of that body, Dec. 6, 1648 (known as Pride's Purge), were allowed by Cromwell to carry on the farce of legislation, and cooperated with him and with the army in effecting the trial and condemnation of Charles I. The Rump, having attempted to resist certain encroachments of the army, was dissolved by Cromwell Apr. 20, 1653; was restored by a military movement during the protectorate of Richard Cromwell; was a second time expelled by the army Oct. 13, 1659; reassembled on the advance of Gen. Monk from Scotland 1660, and decreed its own dissolution Mar. 16, 1660.

Rumsey, James: inventor; b. at Bohemia Manor, Cecil co., Md., about 1743; became a machinist; made several improvements in the mechanism of mills; in Sept., 1784, exhibited on the Potomac river, in the presence of Gen. Washington, a boat which ascended the stream by mechanical appliances; in 1785 was granted by the Assembly of Pennsylvania exclusive right for ten years "to navigate and build boats calculated to work with greater ease and rapidity against rapid rivers." A year later he introduced a steam-engine of his own construction into his boat on the Potomac; obtained a patent for steam-navigation from the State of Virginia 1787; published at Philadelphia his *Short Treatise on the Application of Steam* (1788), which involved him in a controversy with John Fitch; organized at Philadelphia a Rumsey Society for the promotion of steam-navigation 1788; went to England soon afterward; organized there a similar society; built a new steamboat; obtained patents in England, France, and Holland, and made a successful trip on the Thames in Dec., 1792. D. suddenly in London, Dec. 23, 1792.

Runcorn: town; in Cheshire, England; on the estuary of the Mersey; 12 miles E. S. E. of Liverpool (see map of England, ref. 7–F). The Mersey is crossed here by a railway viaduct 1,500 feet long and 95 feet above high water. There is a large traffic by the Bridgewater Canal, which enters the river at Runcorn by a succession of locks. The industries include ship-building, rope-making, quarrying, etc. Pop. (1891) 20,050.

Runeberg, roo′ne-bārch, Johan Ludvig: poet; b. at Jakobstad, Finland, Feb. 5, 1804; studied at the University of Åbo from 1822 to 1827. In 1830 he became lector of æsthetics at the University of Helsingsfors, and published his first collection of poems, but removed in 1837 to Borgå, and in 1842 became Professor of Greek Literature at that gymnasium. Although he was born in Finland and spent his whole life in that country, he wrote in Swedish; and although he was liberally supported by the Russian Government, he sang the valor and perseverance of his countrymen in resisting the invading and conquering Russians. The immense popularity which his poems acquired both in Finland and Sweden was principally due to his talent. His genius was lyric-epic, and his lyrical faculty was delicately harmonious. His numerous minor poems evince a strong sense of reality. His idyls, *Hanna* (1836) and *Julqvällen* (Christmas Eve, 1841), and his tales in verse, *Elgskyttarne* (The Elk-hunters, 1832) and *Nadeschda* (1841), are true epics, with a lyrical swing in the outlines. His dramas, of which *Kungarne på Salamis* (1863), a tragedy in antique form, is the most remarkable, contain real characterization. The most celebrated of his works is *Fänrik Ståls Sägner* (Ensign Staal's Tales, i., 1848; ii., 1860), a collection of ballads treating subjects taken from the war between Sweden and Russia, when Finland was conquered by the latter. D. at Borgå, May 6, 1877.

Revised by D. K. Dodge.

Runes [O. Eng. *rūn*, rune, secret, mystery: Icel. *rūn*: O. H. Germ. *rūna*: Goth. *rūna*, secret, mystery; cf. Gr. *ἐρευνᾶν*, track out, deriv. of *ἔρευνα*, search]: the earliest graphic system used among the Germanic tribes. The name rune, first mentioned by Venantius Fortunatus (sixth century A. D.), and most probably older than the letters themselves, may in its first meaning have been applied to the *notæ* of Tacitus (*Germ.*, c. 10), which were cut on staves and used for divination by the priests for sorcery and as charms. Whether the runes were already known at the time of Tacitus is very doubtful, though the Germans were not ignorant of writing; the *litterarum secreta* (*Germ.*, c. 19) refers to secret correspondence. The investigations of Kirchhoff and Wimmer are the only ones that satisfactorily account for the origin of the runes; the Latin alphabet of the early empire is the source of the twenty-four runes of the oldest alphabet. The question as to the date of its introduction is more difficult to settle. The fact that Ulfilas (died 381 A. D.) chose two runic characters in devising his Gothic alphabet justifies us in fixing the date with certainty as early as the close of the second century. That this alphabet was common to all Germanic peoples is proven by the corresponding names of the letters and by the inscriptions on three monuments: the Swedish *bractea* of Vadstena, with twenty-three signs; the clasp found at Charnay, in Burgundy, with twenty runes; and the short sword found in the Thames, containing twenty-eight characters. The first two are the older, and date probably from the seventh century. The latter inscription (about 800 A. D.) slightly deviates from the original order, and shows

some characters of a later Anglo-Saxon alphabet. This had developed out of the general Teutonic system, several signs being modified and others added to suit the phonetic system of the language. In Scandinavia six of the runes were gradually dropped; this later Norse alphabet of only sixteen signs is found in inscriptions beginning with about 850 A. D. Still later (about 1000 A. D.) diacritical marks were added. The form and arrangement of the original alphabet, called *futhark* after its first six letters, are as shown here.

General Teutonic runes.

That the distribution of the runes in sets of eight, as marked in the Vadstena inscription, was original appears, besides, from the fact that one sign had no meaning, and from a peculiar kind of secret writing in which lines and dots noting the number of the row and the position of the character indicated the value of the latter. The form of the runes was to some extent determined by the material employed for inscriptions. Wood seems to have been used first, metal afterward; stone monuments are considerably younger, and occur only in England and Scandinavia. That the runes were not drawn or painted is proven by the etymology of the verb *to write*, O. Eng. *wrîtan* = Germ. *ritzen*, to scratch. This necessitated avoiding curves and horizontal bars along the grain of the wood, and explains the many changes the letters underwent in their transition from the Latin to the runic alphabet. The runes were written from left to right originally; in later inscriptions the letters sometimes run in the opposite direction; instances of boustrophedon (writing alternately from right to left and left to right) occur also. No relics have been found in Central Germany, Austria, and Bavaria. Only two of the few specimens found on the Continent are unquestionably Gothic; one is Burgundian, the others are of West Germanic origin. Of the numerous English monuments none (with the single exception of a coin of about 600 A. D.) is older than the eighth century. The vast majority are Norse, the oldest going back to about 400 A. D. The use of the runes was gradually discontinued after Christian missionaries introduced the Latin alphabet. Otfrid complains of the neglect of the native alphabet; Rabanus Maurus asserts that the runes were used only in pagan rites. England followed in the adoption of the Latin characters; in Scandinavia the runes were preserved longest and used till late in the Middle Ages, especially in rural districts. Here are also found the only MSS. written exclusively in a runic alphabet—e. g. the Schonic laws (about 1300). W. Grimm (*Ueber deutsche Runen*, 1821, and *Zur Literatur der Runen*, 1828) laid the foundation to a scientific study of the runes. A. Kirchhoff, *Das gotische Runenalphabet* (2d ed. 1854), and Z. Zacher, *Das gotische Alphabet Vulfilas und das Runenalphabet* (1855), prepared the ground for L. Wimmer's excellent and exhaustive treatise, *Runeskriftens Oprindelse og Udvikling i Norden* (1874). A German translation by F. Holthausen, with valuable additions, appeared under the title *Die Runenschrift* (Berlin, 1887). The articles by S. Bugge and R. Henning, *Die deutschen Runendenkmäler* (1889), deserve special mention.

H. Schmidt-Wartenberg.

Runjeet' Singh: maharajah of the Punjaub, commonly known as the King of Lahore; b. at Gugaranwalla, Nov. 2, 1780; poisoned his mother when he was seventeen years old, and assumed the government himself. He was faithful to treaties, and was bent not only on conquest, but also on raising his people to a higher standard of civilization. By the aid of French officers he organized and disciplined his army and subjugated the neighboring Sikh chiefs. Those, however, whose dominions were situated between the Sutlej and the Jumna asked for help from the East India Company in 1809, and obtained it. A British army was sent against Runjeet Singh, but a friendly agreement was concluded by which the Sutlej was established as the boundary of his dominions. He then attacked the Afghans, conquered Kashmir in 1819 and Peshawur in 1829, and at his death at Lahore (June 27, 1839) he left an empire comprising more than 20,000,000 inhabitants and a disciplined army of 70,000 men. See H. T. Prinsep, *Origin of the Sikh Power in the Punjaub, and Political Life of Runjeet Singh* (1839), and Sir L. Griffin, *Ranjit Singh* (Oxford, 1892).

Runkle, John Daniel, LL. D.: mathematician; b. at Root, N. Y., Oct. 11, 1822; graduated at the Lawrence Scientific School at Cambridge, Mass., 1851; developed a remarkable talent for mathematics and astronomy: was employed in 1849, while still a student, to assist in preparing *The American Ephemeris and Nautical Almanac*; founded and edited *The Mathematical Monthly* (1869–71); became Professor of Mathematics in the Massachusetts Institute of Technology 1865; was president of that institute 1870–78, and has since been Walker Professor of Mathematics. He is the author of *New Tables for Determining the Values of the Coefficients in the Perturbative Function of Planetary Motion* (*Smithsonian Contrib.*, 1856).

Revised by S. Newcomb.

Running: See Gaits.

Runnymede, or **Runnimede**: a long slip of green meadow stretching along the right bank of the Thames, near Egham, in Surrey, England; memorable as the spot where the signature of King John to Magna Charta (*q. v.*) was extorted by the insurgent barons June 19, 1215. Charter island, in the river close at hand, is sometimes claimed as the locality of this event, it being alleged that the river has since then changed its channel. Runnymede has been from time immemorial noted for the annual Egham horse-races in August, whence some authorities derive the name (i. e. Running-mead).

Rupee [from Hind. *rūpiyah* < Sanskr. *rūpya-*, silver, coin, deriv. of *rūpa-*, form, pattern]: a silver coin current in India. There were a large number of rupees struck by different Indian princes, varying considerably in weight and value. A lakh of rupees is 10,000, and a crore 10,000,000. The rupee is the monetary standard of India, which rests upon a silver basis. The constant fluctuations in its gold value, tending on the whole to a much lower level, led to an agitation to secure stability. After the failure of the international monetary conference at Brussels to secure any change, the Indian Government closed the mints to the coinage of silver (June, 1893). In the budget estimate of 1893–94 the exchange value was taken at 1*s.* 2¾*d.*, and in U. S. money the value was proclaimed by the Secretary of the Treasury as $0.22 on Oct. 1, 1894.

Rupert, or **Robert**, Prince: soldier; b. at Prague, Bohemia, Dec. 18, 1619; son of Frederick V., elector palatine and King of Bohemia, by his wife Elizabeth, daughter of James I. of England; took part in the Thirty Years' war from childhood, having become a colonel of cavalry in active command at the age of eighteen years; was placed in command of a regiment of cavalry at the beginning of the civil war in England, and distinguished himself in nearly all the battles as the most dashing leader of the royalists. At the Restoration he was made a privy councilor and admiral of the fleet; was one of the founders of the Royal Society; first governor of the Hudson Bay Company 1670; governor of Windsor Castle during the later years of his life; spent much of his time in painting and engraving, in experiments in mechanics, chemistry, and alchemy, and has been credited with the invention of mezzotint, of pinchbeck or prince's metal, and of the glass bubbles called Rupert's drops. D. in London, Nov. 29, 1682, and was buried in Westminster Abbey.

Rupert's Drops: See Prince Rupert's Drops.

Rupert's Land: a geographic designation used in the older literature for the region about the southern part of Hudson Bay, being the territory granted by Charles II. to his cousin, Prince Rupert.

Ruphia, or **Rouphia**: river of Greece. See Alpheus.

Ru'pia [Mod. Lat., from Gr. *ῥύπος*, filth, dirt]: a severe and chronic skin disease, usually syphilitic in its origin. It generally begins in blebs filled with a sanious fluid. These finally become ulcers covered by a thick scab. The disease appears in broken-down patients, and is to be met with tonics, good food, cleanliness, the use of iodide of potassium, etc. Locally, the ulcers may be poulticed and then touched with caustic.

Rupture: See Hernia.

Rupture (of the heart): See Heart Disease.

Rurik (Old Norse, *Hrörikr*): founder of the Russian empire, a Varangian from Sweden. Invited by the Slavs living

on the shores of Lake Ladoga, he and his brothers Sineus and Truvor crossed the Baltic and subjugated this region. He soon extended his dominion to the east and south, and in 862 he established himself in Novgorod and ruled the country as absolute monarch until his death, which occurred about 880. His descendants ruled Russia for more than 700 years until 1598, and Russian princes still trace their pedigrees to Rurik. See RUSSIA; also C. C. Rafn, *Antiquités Russes.* RASMUS B. ANDERSON.

Rush [M. Eng. *rusche, rische* < O. Eng. *risce.* Cf. Lat. *rus'cum*, butcher's broom, whence probably the O. Eng. form]: any plant of a family (*Juncaceæ*) of monocotyledonous herbs, of which the genus *Juncus* is the type; also any one of various plants belonging to the *Cyperaceæ* (mostly species of *Scirpus*), with naked, tough, and flexible stems. There are many species, mostly in wet and cold regions. They are employed in making chair-bottoms, mats, etc. Rushes are used in Europe for strewing the floors of cottages instead of carpets. The pith of some kinds is used sometimes for a candle-wick; hence the name rushlight. Most of the numerous species found in the U. S. are also European and Asiatic. *Juncus bulbosus* is the black grass of the salt-marshes, and makes excellent hay. *Scirpus lacustris* is called bulrush in the East, and tule in California, where it covers vast areas of wet land. Revised by CHARLES E. BESSEY.

Rush, BENJAMIN, M. D., LL. D.: signer of the Declaration of Independence; b. at Byberry, near Philadelphia, Pa., Jan. 4, 1746; graduated at Princeton 1760; studied medicine at Philadelphia, Edinburgh, London, and Paris; began practice at Philadelphia Aug., 1769, being at the same time chosen Professor of Chemistry in the medical college of that city; was a member of the provincial conference of Pennsylvania 1776, in which he moved the resolution to consider the expediency of a declaration of independence; was chosen to the Continental Congress to fill a vacancy in June, and was one of the signers of the Declaration of July 4, 1776. He was surgeon to the Pennsylvania navy 1775–76, was appointed in Apr., 1777, surgeon-general, and in July physician-general, of the military hospitals for the middle department; resigned that post Feb., 1778, and resumed his duties as professor and practitioner in Philadelphia; established in 1785 the first dispensary in the U. S.; was a member of the Pennsylvania convention of 1787 for the ratification of the Federal Constitution; published four letters to the people of Pennsylvania pointing out the defects of the Constitution of 1776; sat in the convention which formed the constitution of 1780; exchanged his professorship for that of the theory and practice of medicine on the death of Dr. John Morgan, Oct., 1789; rendered eminent services to humanity during the yellow-fever epidemic of 1793, which were subsequently recognized by testimonials from the King of Prussia (1805), the Queen of Etruria (1807), and the Emperor of Russia (1811); was one of the founders of Dickinson College, vice-president of the Philadelphia Bible Society and of the American Philosophical Society, president of the Philadelphia Medical Society and of the Society for the Abolition of Slavery, and was treasurer of the U. S. mint from 1799 until his death, in Philadelphia, Apr. 19, 1813. From his nineteenth year he was a frequent writer upon professional, scientific, political, religious, social, and ethical topics. Selections from his productions were republished under the title *Medical Inquiries and Observations* (5 vols., 1789–98; 2d ed., 4 vols., 1804; 3d. ed., 4 vols., 1809), and the best of his miscellaneous works were collected by himself into three vols., *Medical Inquiries and Observations upon the Diseases of the Mind* (1812; 5th ed. 1835); *Sixteen Introductory Lectures to Courses of Medicine* (1811); and *Essays, Literary, Moral, and Philosophical* (1798; 2d ed. 1806). He had published an early volume of *Medical Tracts*, and left unfinished a treatise on *The Medicine of the Bible.*

Rush, RICHARD: statesman; son of Dr. Benjamin Rush; b. in Philadelphia, Pa., Aug. 29, 1780; graduated at Princeton 1797; was admitted to the Philadelphia bar 1800; became attorney-general of Pennsylvania Jan., 1811; comptroller of the State treasury Nov., 1811; was Attorney-General of the U. S., Feb. 10, 1814–Dec. 15, 1817, having temporarily acted as Secretary of State in the latter year; was minister to England 1817–25; negotiated treaties respecting the fisheries (1818), the northeastern boundary, the Oregon question, and the slaves carried from the U. S. in British vessels after the Treaty of Ghent; was Secretary of the Treasury under President J. Q. Adams 1825–29; was a candidate for the vice-presidency on the ticket with Adams 1828; negotiated in Holland a loan for the corporations of the District of Columbia 1829; was a commissioner to adjust the boundary between Ohio and Michigan 1835; went to Great Britain in 1836 as commissioner to lay claim in the chancery court to the Smithsonian legacy (see SMITHSON, JAMES); returned with the money Aug., 1838; was minister in France 1847–51, after which he spent his closing years in retirement at Sydenham, near Philadelphia, where he died July 30, 1859. He wrote much in periodicals in support of the war of 1812, against the U. S. Bank, and on other subjects; superintended the publication of an edition of the laws of the U. S. (5 vols., Philadelphia, 1815); edited a pamphlet, *Washington in Domestic Life, from Original Letters and Manuscripts* (1857), and published two volumes of reminiscences of court life in London. His sons published in 1860 his *Occasional Productions, Political, Diplomatic, and Miscellaneous.*

Rushville: town; capital of Schuyler co., Ill.; on the Chi., Burl. and Quincy Railroad; 11 miles N. W. of Beardstown, 50 miles E. N. E. of Quincy (for location, see map of Illinois, ref. 6–C). It is in a coal-mining, grain, and fruit-growing region, and contains a number of manufactories, a State bank with capital of $25,000, a private bank, a public library, and a tri-weekly, a monthly, and two weekly periodicals. Pop. (1880) 1,662; (1890) 2,031; (1900) 2,292.

Rushville: city; capital of Rush co., Ind.; on Flat Rock creek, and the Cin., Ham. and Dayton, the Cleve., Cin., Chi. and St. L., the Ft. Wayne, Cin. and Louisv. and the Pitts., Cin., Chi. and St. L. railways; 39 miles E. S. E. of Indianapolis, 84 miles N. W. of Cincinnati (for location, see map of Indiana, ref. 7–F). It is in an agricultural region; has manufactories of flour, lumber, furniture, bent wood, washing-machines, clay-working machinery, drain-pipe, shirts and trousers, extension-tables, and other articles; and contains electric-light and natural-gas plants, 8 churches, 2 national banks with combined capital of $200,000, a private bank, and a semi-weekly and 2 weekly newspapers. Pop. (1880) 2,515; (1890) 3,475; (1900) 4,541.
EDITOR OF "REPUBLICAN."

Rushworth, JOHN: historical writer; b. in Northumberland, England, about 1607; educated at Oxford; studied law at Lincoln's Inn; began in 1630 to take notes of proceedings in the higher courts and in Parliament; was assistant clerk to the Long Parliament; became secretary to Lord Fairfax; took an active part in negotiations during the civil war; was for many years a member of Parliament, and afterward secretary to Lord Keeper Bridgman, but becoming involved in debt spent his last years (from 1684) in the King's Bench prison, London, where he died May 12, 1690. In 1659 he began the publication of *Historical Collections of Private Passages of State, Weighty Matters in Law, and Remarkable Proceedings in Five Parliaments* (from 1618 to 1648); issued vols. ii. and iii. in 1680, and in the same year his *Tryall of Thomas, Earl of Strafford.* He left in MS. the materials for vols. iv. and v., which were issued in 1692, and for vols. vi. and vii., completing the work, which appeared in 1701. A new and better edition of the whole, together with the *Tryall*, was reprinted in 1721 (7 vols. folio).

Rusk: town; capital of Cherokee co., Tex.; on the St. Louis S. W. Railway; 16 miles S. E. of Jacksonville (for location, see map of Texas, ref. 3–J). It is in an agricultural and iron-mining region; contains a branch of the State penitentiary, the convicts of which are chiefly employed in developing the iron interests of the vicinity; has an iron furnace at the penitentiary and another between Rusk and New Birmingham, and a national bank with capital of $50,000, a private bank, and two weekly newspapers. Pop. (1880) 626; (1890) 1,383; (1900) 527.

Rusk, JEREMIAH MCLAIN: agriculturist; b. in Morgan co., O., June 17, 1830; brought up on a farm; at fifteen became a driver of a stage-coach between Zanesville and Newark; removed to Wisconsin 1853, where he managed a farm and drove a stage; elected sheriff 1855; member of Wisconsin Legislature 1861; enlisted in Twenty-fifth Wisconsin Volunteer Infantry 1862; served to the close of the war, obtaining the rank of brigadier-general; elected State bank comptroller of Wisconsin 1865; re-elected 1867; elected to the Forty-second Congress by the Republicans 1870; re-elected to the Forty-third and Forty-fourth Congresses; elected Governor of Wisconsin 1881; twice re-elected. The

Department of Agriculture was created a month before the inauguration of President Harrison (1889), on whose accession the office of secretary of the department was tendered to Gen. Rusk, who occupied it until the close of the administration. D. at Viroqua, Wis., Nov. 21, 1893. C. H. T.

Rusk, Thomas Jefferson: U. S. Senator; b. at Camden, S. C., Aug. 8, 1802; became a lawyer in Georgia; went to Texas 1835; was a member of the convention that declared Texan independence Mar., 1836; was the first Secretary of War; took command of the army at San Jacinto after Gen. Houston was wounded; became chief justice of Texas; was president of the convention which effected annexation to the U. S. 1845, and U. S. Senator 1846–56. D. at Nacogdoches, Tex., July 29, 1856.

Ruskin, John: art critic; b. in London, England, Feb. 8, 1819; only son of a wealthy wine-merchant, a Scotchman by birth, from whom he derived in childhood a fondness for art, and from whom he inherited a fortune of £200,000, most of which he spent in charities and philanthropic schemes and for the promotion of sound art. He accompanied his father on many of his professional trips through England and Scotland, and afterward on pleasure-tours to France, Switzerland, and Northern Italy, studying architectural remains and mountain scenery, and making drawings after Prout's *Sketches in Flanders and Germany* and the vignettes from Turner in Rogers's *Italy*, a copy of which last had been presented to him on his fourteenth birthday. In 1836 he entered Christ Church, Oxford, where he graduated in 1842, having gained the Newdigate prize in 1839 by a poem entitled *Salsette and Elephanta*. Up to 1846 he continued to write verses for *The Keepsake*, *Friendship's Offering*, and other annuals and miscellaneous periodicals. A collection of his poems was issued in 1850 and another in 1891, but Ruskin's poetry is amateurish and comparatively unimportant.

He first drew public attention by his *Modern Painters* (vol. i., 1843; ii., 1846; iii. and iv., 1856; v., 1860). This was an assertion of the superiority of Turner and his school in the art of landscape-painting to all the ancient masters. The doctrine of the book, and Ruskin's lifelong message in art criticism, is "sincerity." He attacked academic traditions and the imitators of Claude and Poussin, and insisted upon the duty of the artist to render not merely the general but the specific truth of rocks, plants, cloud-shapes, and other landscape details, treating nature with humble and loving fidelity, "selecting nothing, rejecting nothing." In preparation for the later volumes of *Modern Painters* and for the other works that followed the author spent many years in the study of art, residing for protracted periods in Italy, doing a great deal of mountain-climbing among the Alps, and filling his portfolios with sketches. He is an accomplished draughtsman, but has used his pencil almost entirely for the purpose of illustrating his own books on art, among which are *The Seven Lamps of Architecture* (1849); *The Stones of Venice* (vol. i., 1851; ii. and iii., 1853); *Pre-Raphaelitism* (1851); *Giotto and his Works in Padua* (1853–60); *The Elements of Drawing* (1857); *The Political Economy of Art* (1857); several series of *Notes* on the exhibitions of the Royal Academy and the Society of Painters in Water-colors (1855–59); *The Two Paths* (1859); *The Elements of Perspective* (1859); *Lectures on Art* (1870); *Aratra Pentelici* (1872); *The Relation between Michael Angelo and Tintoret* (1872); *The Laws of Fesole* (1877-78); *The Art of England* (1883); *Verona and other Lectures* (1893); besides many notes, reports, and catalogues of Turner's works and of other collections, numerous addresses, and articles in periodicals relating to different branches of the fine arts. In 1853 he delivered a series of lectures on architecture and painting at Edinburgh; was appointed professor at the Cambridge School of Art in 1858; became Rede lecturer at Cambridge in 1867; was elected to the Slade professorship of the fine arts at Oxford in 1869, and re-elected in 1876. He resigned the Slade professorship in 1879, was again re-elected in 1883, and resigned it finally at the end of the following year in consequence of the vote endowing vivisection in the university, a measure against which he strongly protested. See *The Bishop of Oxford and Prof. Ruskin on Vivisection* (1885).

The movement known as Preraphaelitism, was largely due to a study of Ruskin's earlier works, and received his cordial support. (See Prerapiiaelites.) In 1871 he gave £5,000 for the endowment of a mastership of drawing in the Taylor Galleries, Oxford. Since 1860 his writings have taken a wider range, including speculations in ethics, social science, and political economy, with studies in mythology, botany, and miscellaneous æsthetics, set forth in a multitude of little volumes under fanciful titles, such as *Unto this Last* (1860); *Munera Pulveris* (1862–63); *Sesame and Lilies*, one of his most popular works (1865); *The Ethics of the Dust* (1866); *The Crown of Wild Olive* (1866); *The Queen of the Air* (1869); *The Eagle's Nest* (1872); *Love's Meinie* (1873; part iii., 1881); *Proserpina* (1875–86); *Deucalion* (1875–83); *St. Mark's Rest* (1874–84), etc. In these writings the influence of Carlyle is plainly seen. The author denounces competition in trade and the *laissez-faire* theory in government; approves of paternalism and a modified form of state socialism, and praises the guild system of the Middle Ages; declaims against railways, factories, and machinery, and proposes to restore artistic handiwork by trained workmen. From 1871 to 1884 he published a series of letters, at first monthly and afterward at irregular intervals, entitled *Fors Clavigera*, addressed to workingmen, inviting them to join him in establishing a fund for rescuing English country life from the tyranny and defilement of machinery. In pursuance of this object, the St. George's Guild was formed, Ruskin devoting to it £7,000. Trustees were chosen to administer the fund; a building was bought at Walkley, in the suburbs of Sheffield, for use as a museum; and the money subscribed has been used to promote co-operative experiments in agriculture, manufacturing, and education.

Ruskin is one of the greatest modern masters of English prose, especially in the department of imaginative and poetic description. His influence as a thinker has been impaired by his whims and crotchets, his puzzling contradictions, and his over-vehemence of statement. His strong religious feeling has coexisted with heterodox views in theology; his moral earnestness has led him to identify good art with good ethics; while in politics his description of himself as a "king's man" and a "violent Illiberal" has by no means prevented him from holding some very un-Toryish opinions. Later he lived mostly in retirement at Brantwood, a property which he bought in 1871, at Coniston, in the English lake-country. Among his numerous publications should also be mentioned *The King of the Golden River* (1851), a favorite fairy tale which has been through many editions; *Arrows of the Chace* (1880), a collection of his letters in two volumes; and the fascinating but incomplete *Præterita* (1885–89), an autobiography issued in twenty-eight parts. See also *The Life and Work of John Ruskin*, by W. G. Collingwood (2 vols., Boston and New York, 1893). D. Jan. 20, 1900.

Russell, Charles Russell, Baron: jurist; b. at Newry, Ireland, in 1833; educated at Trinity College, Dublin; became a writer of political articles for a Catholic journal. Admitted to the bar in 1859, he won recognition by his keenness as a cross-examiner and power as an advocate, and was appointed a Q. C. in 1872. He sat in Parliament in the Liberal interest from 1880 till 1886, when he was appointed Attorney-General in Gladstone's cabinet, and was knighted. Among the many famous cases in which he has appeared was the Parnell investigation, in which he acted as Parnell's counsel. In 1892 he again became Attorney-General; was one of the British counsel in the Bering Sea arbitration case; became in 1894 a Lord of Appeal in Ordinary (with a life peerage); and in the same year was made lord chief justice and a baron.

Russell, Henry: See the Appendix.

Russell, James Earl: See the Appendix.

Russell, John, R. A.: painter and draughtsman in pastel and crayon; b. at Guildford, Surrey, England, Mar. 29, 1745. He was sent to the studio of Francis Cotes, R. A., in London, and worked under him, as pupil and assistant, until 1767, when he received his first order to paint portraits at Lord Montague's house at Cowdray. He continued work at Guildford, and returned to London in 1768. At this time he was a most ardent religious reformer. In 1770 he was married, and in 1772 was made an associate of the Royal Academy. Little of his painting of this epoch is preserved or is accessible. From the year of his becoming an A. R. A. he exhibited at the Royal Academy every year until his death, often sending the full number of eight pictures. In 1780 he was made an academician. He enjoyed great popularity as a portrait-painter, and obtained prices equal to those paid to Sir Joshua Reynolds, the first portrait-painter of the time and president of the Royal Academy. He published a

work on oil-painting, and one which had a large circulation on pastel, under the title *Elements of Painting with Crayons.* He was greatly interested in astronomy, and drew and engraved a lunar map and also an elaborate machine called the selenographia, for showing the moon's phases. D. Apr. 20, 1806. In the National Portrait Gallery, London, are portraits in oil-color of *William Wilberforce* when a child, and the *Rev. Dr. Dodd*; also a pastel portrait of *Richard Brinsley Sheridan*, the dramatist and orator. At the Royal Academy permanent exhibition is Russell's diploma picture, *Ruth and Naomi*, in pastel. At the South Kensington Museum are several pastel drawings. In the Louvre is a pastel painted in 1781, *A Child holding Cherries.* The greater number of the pictures known to exist are in private collections. A valuable monograph on the artist and his work, with many illustrations, has been published by George C. Williamson (London, 1894). RUSSELL STURGIS.

Russell, JOHN RUSSELL, Earl: statesman; third son of the sixth Duke of Bedford; b. in London, England, Aug. 18, 1792; educated at Westminster School and at the University of Edinburgh; traveled in Spain and Portugal during the Peninsular war 1809–10; entered Parliament as a Whig 1813, representing the family borough of Tavistock; displayed great zeal in his opposition to the Tory ministry and in advocacy of Roman Catholic emancipation and parliamentary reform; became intimate with the literary men of the time; published the *Life* of his ancestor, William, Lord Russell (1819), *An Essay on the History of the English Government and Constitution* (1821), *Memoirs of the Affairs of Europe from the Peace of Utrecht* (2 vols., 1824–29), and several other works; was the parliamentary leader of the great movement which effected in 1828 the repeal of the Test and Corporation Acts, in 1829 the emancipation of the Roman Catholics, and in 1832 laid the foundation of the modern era of English history by the long-delayed victory of the Reform Bill. In 1830–34 Lord John Russell was paymaster of the forces in the Grey administration; was Secretary of State for the Home Department 1835–39, and afterward for War and the Colonies (1839–41) in the second Melbourne ministry, of which he was the leader in the House of Commons. He carried several important measures of reform in regard to ecclesiastical and municipal affairs, education, marriage, and civil and criminal law; was returned to Parliament in the election of 1841 for the city of London, which he continued to represent for many years; was the leader of the opposition to the Peel ministry 1841–45; declared in favor of the immediate repeal of the Corn-laws Nov., 1845, upon which basis he was invited to form a ministry Dec., 1845, but failed through the dissensions of Earl Grey and Lord Palmerston, and had to yield to Sir Robert Peel the honor of procuring the enactment of the repeal. Upon the dissolution of the old Tory party in 1846, Lord John Russell became Prime Minister and First Lord of the Treasury, and conducted the affairs of state through the difficult period embracing the Irish famine, the Chartist agitations, and the continental revolutions of 1848–49. His ministry was overthrown in Feb., 1852, but the Earl of Derby having been unsuccessful in his attempt to carry on the government, the Aberdeen cabinet was formed Dec., 1852, in which Lord John Russell accepted the position of Secretary of Foreign Affairs. He introduced a new Reform Bill 1854; became Colonial Secretary in the first Palmerston ministry Feb., 1855, and soon afterward went as commissioner to the Vienna Conference, intending to put an end to the Crimean war, but lost public favor by his support of the Austrian programme, and retired from the cabinet July 16. In June, 1859, he returned to office as Secretary of Foreign Affairs in the second Palmerston ministry; was elevated to the peerage as Earl Russell of Kingston-Russell July, 1861; favored the cause of Italian unity and independence, and protested against the annexation of Nice and Savoy by France; incurred severe criticism by his course toward the U. S. during the civil war, especially in the Trent and Alabama affairs, as also by his fruitless manifestations of sympathy for Poland and Denmark in their struggles with Russia and Germany. On the death of Lord Palmerston, Earl Russell again became Prime Minister, Oct., 1865, Mr. Gladstone being, however, the real leader of the cabinet, which resigned in June, 1866. After that period he accepted no office, but took an active part in the debates of the House of Lords and devoted himself anew to literature. He edited the *Correspondence of John, Fourth Duke of Bedford* (3 vols., 1842–46), the *Memorials and Correspondence of C. J. Fox* (4 vols., 1853–57), the *Memoirs, Journal, and Correspondence of Thomas Moore* (1852–56) and selections from his own *Speeches and Dispatches* (1870); and wrote the *Life and Times of C. J. Fox* (1859–66), *The Rise and Progress of the Christian Religion in the West of Europe* (1873), and an autobiographical work, *Recollections and Suggestions, 1815–73* (1875). D. at Richmond Park, Surrey, May 28, 1878. Revised by F. M. COLBY.

Russell, JOHN SCOTT, F. R. S.: naval engineer; b. in the Vale of Clyde, Scotland, in 1808; studied at the Universities of Edinburgh, St. Andrews, and Glasgow, graduating at the latter 1824; devoted himself to applied mechanics, engineering, and natural philosophy; delivered a course of lectures on the last subject in the University of Edinburgh in 1832; engaged at Edinburgh in the construction of small steamboats for canal and river navigation, and of steam-carriages which ran upon the common roads between Paisley and Glasgow; introduced the wave system into the construction of ocean steamships 1835; established himself in London 1844 as a builder of the largest class of steamships, and built the Great Eastern, which was designed by Brunel upon his system; read in 1857 to the British Association a paper upon *The Mechanical Structure of the Great Ship*; was one of the founders of the Institution of Naval Architects, of which he was vice-president, and contributed largely to its *Transactions.* He published an elaborate and costly illustrated work, *The Modern System of Naval Architecture for Commerce and War* (1864) and of *Systematic and Technical Education for the English People* (1869). He was well known as a philanthropist. D. in the Isle of Wight, June 8, 1882.

Russell, JONATHAN, LL. D.: statesman; b. at Providence, R. I., in 1771; graduated at Brown University 1791; studied law, but exchanged its practice for commercial pursuits; was an accomplished and effective writer and an active politician; was U. S. minister to Sweden 1814–18; signed the Treaty of Ghent 1814 as one of the five American commissioners, and was member of Congress 1821–23. D. at Milton, Mass., Feb. 19, 1832.

Russell, WILLIAM, Lord: statesman; son of the fifth Earl of Bedford; b. in England, Sept. 29, 1639; educated at Cambridge; entered Parliament 1660; married Lady Rachel, daughter of Thomas Wriothesley, Earl of Southampton, and widow of Lord Francis Vaughan, 1669; first became prominent in 1673 as one of the leaders of the Protestant or "country party," which carried on a vigorous opposition to the unscrupulous measures of the court; proposed in Nov., 1678, the removal of the Duke of York from the royal councils, and on June 16, 1680, appeared before the king's bench in Westminster to present that prince as a recusant, and headed the deputation of 200 members of the House of Commons which carried up to the House of Lords the bill for the exclusion of James as a papist from the succession. When a reaction had set in against the Protestant alarmists, the court determined to be revenged upon Russell, Sidney, and other prominent Whigs, who were accordingly accused by suborned witnesses of participation in the Rye House plot. Arraigned for treason at the Old Bailey, July 13, 1683, Russell was refused counsel, but his wife was permitted to act as his secretary during the trial. Condemned to death and attainted July 14, he was beheaded in Lincoln's Inn Fields July 21, 1683. The trial was in violation of the forms of law, and no evidence was given to prove him guilty of the specific offense charged—i. e. conspiring against the life of the king. His attainder was reversed after the revolution of 1688, and in 1694 his father was made Duke of Bedford, to which title Lord William's son, Wriothesley, succeeded. Lady Russell, born 1636, survived her husband forty years, and died at Southampton House, Sept. 29, 1723. Her *Letters* to her husband were published 1773, became widely popular, and have been often reprinted. See *Life of Lord Russell*, by Lord John Russell, 1819.

Russell, WILLIAM CLARK: novelist; b., of English parents, in New York, Feb. 24, 1844. He spent much of his early life at sea, and afterward resided near Ramsgate, England, and became a contributor to London journals. His published sea stories and novels include *The Wreck of the Grosvenor* (1878); *A Sailor's Sweetheart* (1880); *My Watch Below* (1883); *A Sea Queen* (1883); *Round the Galley Fire* (1883); *Jack's Courtship* (1884); *The Frozen Pirate* (1887); *The Death Ship* (1888); *Marooned* (1889); *The Romance of Jenny Harlowe* (1889); *The Good Ship Mohock* (1895).

Russell, William Howard, LL.D.: journalist; b. in Dublin, Ireland, Mar. 28, 1821. He was educated at Trinity College, Dublin; went to England in 1842, and after serving as reporter and correspondent to the London *Times*, *The Sporting Magazine*, and *Morning Chronicle*, became permanently attached to the staff of *The Times* in 1847. He was special correspondent of that journal in the Crimea (1854–55), in India during the Sepoy mutiny (1857–59), and in the U. S. during the civil war (1861), where he earned the nickname of Bull Run Russell. He was also war correspondent of the London *Times* in the Franco-German war of 1870, and in 1875 became honorary secretary to the Prince of Wales, whom he accompanied on his visit to India. He has published his Crimean war correspondence (2 vols., 1855–56); *My Diary in India*; *My Diary during the Last Great War* (1873); *The Prince of Wales's Tour* (1877); *Hesperothen* (1882), etc. In 1860 he established *The Army and Navy Gazette*. H. A. Beers.

Russellville: town; Pope co., Ark.; on the Dardanelle and Russellv. and the St. L., Iron Mt. and Southern railways; 75 miles N. W. of Little Rock, the State capital (for location, see map of Arkansas, ref. 2–C). It contains cotton, saw, and grist mills, a national bank with capital of $50,000, a State bank with capital of $28,000, and a weekly and a semi-monthly periodical. Pop. (1890) 1,321; (1900) 1,832.

Russellville: town; capital of Logan co., Ky.; on the Louisv. and Nashv. Railroad; 29 miles W. S. W. of Bowling Green, 50 miles N. by W. of Nashville, Tenn. (for location, see map of Kentucky, ref. 5–E). It contains Bethel College (Baptist, organized in 1854), Logan Female College (Methodist Episcopal South, chartered in 1867), flour-mills, carriage and tobacco factories, 3 state banks with combined capital of $156,000, and 2 weekly newspapers. Pop. (1880) 2,058; (1890) 2,253; (1900) 2,591.

Russia: the largest continuous empire in the world; covers Eastern Europe and Northern Asia; occupies about one-seventh of the earth's total land-surface, and extends from lat. 38° 20′ to 77° 30′ N., and from lon. 17° 38′ E. to 170° W. It has an extreme length from W. to E. of 6,000 miles, and a width from N. to S. of 2,300 miles. It is bounded N. by the Arctic Ocean, E. by the Pacific, S. by China, Independent Turkestan, Persia, Asiatic Turkey, and the Black Sea, W. by Roumania, Austria, Germany, the Baltic, and the Scandinavian Peninsula. Area, 8,645,803 sq. miles (excluding the Sea of Azov, 14,478 sq. miles), of which 6,564,778 belong to Asiatic Russia, including Siberia, Turkestan, the entire region of Caucasus (*qq. v.*), and the Trans-Caspian region, and 2,081,025 sq. miles to European Russia, to which this article is mostly restricted.

Physical Features.—European Russia forms one vast plain, broken occasionally by minor table-lands like the Valdai Hills in Novgorod and Tver, and stretching to the Ural Mountains on the east and the Caucasus in the southeast, which form the conventional division between Europe and Asia. In the Crimea is the isolated chain of the Yaila Mountains, rising at one point 5,000 feet. In the southwest are some slight spurs of the Carpathian Mountains and in the northwest branches of the Scandinavian range. To the north and northwest the plains are marked by immense forests and numerous lakes; to the south by dry and treeless steppes. In the middle, western, and central southern region is the fertile wheat land. From a broad central plateau the country naturally divides itself into the four great basins of the Arctic Ocean, the Baltic, the Black and the Caspian Seas, traversed by the greatest rivers of Europe. The frozen, swampy, sterile basin of the Arctic is coursed by the Onega, Dwina, Mezen, and Petchora. The Baltic receives the Neva, Duna, Niemen, and Vistula. To the Black Sea flow the Pruth, Dniester, Bog, Dnieper, and Don, and into the Caspian empty the Ural and the Volga, which is the great water highway of Russia.

Geological Structure.—This embraces almost every formation, but inasmuch as these cover one another horizontally it is marked by simplicity and immensity. The Tertiary formations cover much of South Russia and extend to Lithuania and Poland. The Silurian system, concealed in large part by more recent deposits, appears on the surface in Esthonia, Livonia, and the district of St. Petersburg. In the north the granite and the Permian formations prevail. The chain of the Ural Mountains exhibits the Silurian group, with eruptions of the most ancient period. The Crimea has the Jurassic formation which, with cretaceous rocks, marks the Caucasus. Carboniferous deposits cover much of Eastern Russia. There are three important coal-bearing regions, the Donetz and Moscow basins and the Urals.

Climate.—Climatic conditions, while exceedingly uniform over wide expanses, nevertheless present great differences in the extremes. Cold winters and hot summers are the rule. The mean temperatures of the hottest and coldest months in the different parts of the country vary as much as 83°. In many localities fluctuations of temperature exceed those in any other part of the earth's surface. There is no portion of the great domain in which tropical plants can be raised, but there is a small area in the south in which the climate corresponds to that of Central Italy or the eastern shore of Virginia. The mean yearly temperature varies from 28·4° F. in the far northeast to 59° on the southeastern coast of the Black Sea, and between 33·8° F. in the government of Perm and 53·6° on the Terek: the January temperature between 3·2° in the governments of Orenburg and Ufa, W. of the Ural chain, and 32° in Crimea; the July temperature from 60·8° in the southern parts of the governments of Archangel and Uleaborg to 77·9° at Astrakhan. A notable climatic condition of Central Russia is that the winter temperature rapidly declines from W. to E.; so marked is this that N. of 50° the temperature sinks faster from W. to E. than from N. to S. The most favored locality of the whole empire in climate is probably the government of Volhynia and adjacent region.

Soil.—In regard to the composition, properties, and fertility of the soil, Russia may be divided into two vast regions by a boundary taking in the main a direction from S. W. to N. E., from Bessarabia to Ufa, presenting, however, considerable deviations, the soil of the southern region sometimes encroaching upon the northern and *vice versa*, and in places each appearing in isolated patches in the midst of the other. The southeastern half is commonly called the region of the Chernoziom or "black earth," the northwestern that of the non-Chernoziom lands. In a botanico-geographical sense this difference in soils corresponds almost exactly to the division of Russia into the steppe (Chernoziom) region and the forest-land region. Within the Chernoziom region there occur considerable areas of gray forest land, also of lime soil, the largest of the latter being in the valley of the Volga below Simbirsk. Salt-marshes occur in patches, and vary in amount of their saline ingredients to such an extent that while some are comparatively fertile others are entirely barren. In the northern region, the non-Chernoziom, all possible soils are found, beginning with a heavy clay and ending with fine sand, including soils so rocky that their cultivation is impossible until after the removal of the stone. Formerly all of this region was covered by forest, and owing to this condition it has undergone less change than that of Southern Russia.

Agriculture.—In the greater portion of Russia the conditions of climate and soil permit of agricultural development. Cotton and rice are among the productions of the empire, and are to be found growing farther N. than in the U. S., or perhaps any other part of the world, appearing above 42° in the Trans-Caucasian region. The cereals can also be cultivated much farther N. than elsewhere on the globe, except Scandinavia. The most valuable portion of the empire is that S. of the Valdai Hills and of Moscow, extending to the Volga on the E. and to the frontier of Galicia on the W., and including the country of the Don almost to the Sea of Azov. The wheat grown in this region is exported in vast quantities to Europe and Asia, and also distributed to the less fertile parts of Russia. Besides wheat, rye, oats, barley, and maize are pretty generally grown, and the products far exceed the home consumption. In the Baltic provinces flax, hemp, and hops are cultivated. In Bessarabia and the Crimea vineyards are maintained with great success, and the vine is much grown in districts far more northern, even where it has to be laid upon the ground and covered in winter. The potato is everywhere raised, and the cultivation of the beetroot, for the manufacture of sugar, has become a very important branch of agriculture. Excellent apples, pears, apricots, peaches, plums, and cherries are grown in Bessarabia, the Crimea, and Taurida. Tobacco is cultivated along the Volga and the Don and in Bessarabia to the average annual amount of 1,280,000 cwt. The amount of the principal crops of European Russia (exclusive of Finland) for the year 1892 was, in quarters: Wheat, 31,519,000; rye, 78,600,000; barley, 22,730,000; oats, 58,087,000; potatoes, 83,207,000; various other crops, 20,292,000. For 1900, according to the estimates of the Minis-

ter of Agriculture, the production was, in thousands of pounds, wheat, 658,824; rye, 1,401,726; oats, 721,562; and barley, 309,475.

The ownership of the 1,098,507,780 acres of land (exclusive of Arctic islands and of 40,925,060 acres forming the pasture-grounds of the Kalmucks and Kirghiz) comprising European Russia proper was in 1892 distributed as follows: The state, 410,801,867; the imperial family, 19,890,835; the peasants, 373,310,496; private owners, 294,504,582. The area unfit for cultivation, in roads, etc., was 210,058,770 acres (19·1 per cent.). The amount of arable land was 287,969,552 acres (26·2 per cent.), orchards, meadows, grazing, etc., 174,958,734 (15·9 per cent.), forest, etc., 425,520,714 (38·8 per cent.).

The raising of stock constitutes a very important branch of farming, sometimes intimately related to agriculture and sometimes an independent and exclusive occupation of the peasant. In the northwestern governments, in the Baltic provinces, and in Finland, the most important branch is the dairy and the fattening of cattle for slaughter. In the southeastern districts and in Bessarabia work cattle and horses are of great importance, but sheep-breeding for wool is also a profitable industry. In Northeastern Russia the breeding of horses for work purposes heads the other departments of stock-raising, but milch cows are also largely raised for the production of high-grade butter and cheese. In the central region the fertility of the soil precludes profitable herding on a large scale, but the breeding of milch cows, the fattening of fine beeves and hogs, and the raising of good trotters and of large draft horses are much developed. In the southern and southeastern steppe districts, and also in the region of the Don, herding is of great importance, owing to the great amount of pasture land, but the most extensive branch there is that of herding fine-wool merino sheep, exclusively confined to rich estates, the peasants raising as a rule only horned cattle. Horse-breeding is also centralized in this region. In 1898 European Russia, including Finland, but not Poland, had 17,004,300 horses, 24,425,300 cattle, 38,140,300 sheep, 9,148,800 swine, 119,800 camels, 1,364,200 goats, and 300,000 stags. The wide range of stock-raising in Russia is indicative of the vastness of the country and the extremes of its climate. Thus while reindeer are largely kept in the north, camels are extensively herded in Caucasia and Turkestan. Of wild animals the ermine, sable, marten, bear, etc., are found in the north (Poland and Lithuania), the wolf, deer, and fox everywhere, and the average annual value of the export of furs is almost $3,000,000.

Forests.—Of the total area of Russia about one-third is forest. The decrease since the nineteenth century began has been about 23 per cent. An important measure was taken by the Government in 1888 for the protection of forests, most of which have been placed under a special committee appointed in each province. The total area of forest in European Russia, Poland, Finland, and Caucasia is 498,177,000 acres. In this forest region of the north there are immense districts in which the only roads are the rivers flowing between interminable walls of trees. The predominating species in this region are the conifers, the pine, and the fir, while in the lesser forests of the south the oak is most commonly to be seen, plentifully interspersed in the east with the linden and in the extreme west and the Crimea with the beech.

Mining and Metallurgy.—The mineral resources are exceedingly great, and the mining industry is carried on with advanced scientific system and very successfully. Prior to the time of Peter the Great only the most primitive beginnings of a metallurgical and salt industry existed, but that monarch gave origin and impetus to the development of the present extensive system, establishing in 1700 the first separate official mining administration, known as the Prikase of Mining Affairs. He founded the mining-college in 1719, and in every way unceasingly fostered the industry. From that time to the reign of Alexander II. the metal interests of the empire underwent various vicissitudes of rise and decadence, and were finally revolutionized by the liberation of the serfs and the consequent modifications of economic conditions. The direction of mining affairs in the empire (exclusive of Finland) is now mainly concentrated in the mining department of the University of State Domains, and this administration directs not only the raising of ores, but also their mechanical, metallurgical, and chemical treatment. The vast salt and petroleum producing industries are excepted from the direction of this department. In the most important branches of mining the figures of production were for the year 1898 (and in some instances for 1897 and 1899) as follows:

PRODUCTS.	1897.	1898.	1899.
Gold, pounds	84,188	85,498	.....
Silver, pounds	10,555	13,098	.....
Platinum, pounds	12,347	13,753	.....
Copper, tons	6,383	6,495	.....
Lead, tons	443	238	.....
Zinc, tons	5,784	5,580	.....
Mercury, tons	.....	357	.....
Tin, tons	2	.....	.....
Pig iron, tons	1,851,000	2,206,000	*2,638,820
Coal, tons	11,031,000	12,051,000	.....
Salt, tons	1,538,000	1,474,000	.....
Petroleum, barrels	.....	62,752,240	68,752,240
Manganese ore, tons	.....	319,400	.....
Chrome iron ore, tons	.....	15,500	.....
Cobalt ore, pounds	.....	5,777	.....
Asbestos, tons	.....	1,640	.....

* Exclusive of Finland, which produced 27,000 tons in 1898.

The number of men employed in mining industries in 1898 was 592,500, showing an increase in twenty years of almost 100 per cent. The coal-mining industry on the Don has grown rapidly, and the district, which produces about one-half the total output of the empire, increased its output more than 100 per cent. from 1884 to 1892. Besides the output of the Don—viz., 3,507,000 tons in the latter year—Poland produced 2,837,300, the Ural region 230,000, Moscow 176,800, and Altai 19,200 tons. The Caspian naphtha (petroleum) industry has also extended rapidly, the output of crude petroleum more than doubling from 1887 to 1892, with a correspondingly great advance in refining.

Manufacturing.—It is only in very recent years that Russia has exhibited strength as a manufacturing nation at all commensurate with her importance in other respects. The patriarchal state of domestic economy under which each family was its own producer and consumer longer held sway here than in most other countries of Europe, and in many places the breaking away was not noticeable until about the middle of the nineteenth century. But the vast and vigorous growth of manufacture began in the decade following the emancipation of the serfs (1861), expanding in the succeeding one in which railway-building was begun on a colossal scale. Manufactures (including mining industries) amounted in value to 905,000,000 roubles ($452,500,000) in 1878, and in 1890 the total valuation of the output reached 1,656,000,000 roubles ($828,000,000), irrespective of the smaller industries, of which statistics are unobtainable. First place among the manufactures of Russia is held by cotton, of which the manufactured output not only supplies the home demand, but furnishes a considerable amount for export. The enormous increase has brought cotton almost into the position of a staple crop in Southeastern Russia in Europe and the Southern Asian regions of the empire, notably Turkestan. The total valuation of the output of this industry in 1890 was 487,100,000 roubles ($243,550,000). The number of spindles in Russia is about one-fourth those of continental Europe and about one-seventh those of England.

The petroleum-refining industry affords perhaps the most interesting figures. Customs protection was granted in the sixties. In 1876 Russia imported a large amount of petroleum products from the U. S., 2,666,666 poods (95,999,876 lb.) of illuminating oil alone. In the eighties the importation ceased, but the export increased, reaching in 1890 1,728,000,000 lb., and the home consumption, which, owing to the high price, reached only 144,000,000 lb. in 1876, rose to more than 1,080,000,000 lb. in 1890 owing to the rapid fall of price.

The beet-sugar industry has reached considerable proportions. In 1891 the growth of beets amounted to 80,000,000 cwt. The manufacture of woolens is sufficiently developed to clothe the army and satisfy the home demand for low-grade goods. Silk is manufactured to the value of $6,955,000; paper, $9,000,000; tannery products, $19,000,000. Of beer there were brewed 99,606,087 gal. Tobacco-manufactures amounted to 34,202,000 lb. (of which 5,882,400 lb. was in cigarettes). The number of flour-mills in the empire in 1890 was 7,003, and they produced 2,462,569 tons of flour, valued at $73,000,000. The total number of manufactories in Russia (exclusive of Poland and Finland) is 65,000, employing about 1,000,000 work-people; Poland has 21,000, employing 142,900; Finland (1890), 6,496 manufactories, employing 59,176.

Trade and Commerce.—The exports of the empire have

increased and the imports decreased since 1870, the former in round numbers $50,000,000, the latter $34,000,000. Exports in 1899 (bullion not included) were valued at $322,634,625; imports, $331,030,670. The average quantity of wheat exported is 35,000,000 cwts.; of rye, 20,000,000; oats, 10,000,000. As to the trade with the U. S., in 1900 Russia's imports amounted to $7,438,317, and her exports to $7,245,973. The greater proportions of trade were with Great Britain (31·7 per cent.), Germany (29·6), France (5·5), Netherlands (5), Austria-Hungary (4·3), while the percentage with the U. S. was only 4·1.

The merchant sea-fleet of Russia numbers 2,143 sailing-vessels on foreign seas. At White Sea ports 396 vessels are registered; at Baltic ports, 586; on the Black and Azov Seas, 773; on the Caspian, 539. The steam merchant fleet on external seas numbered in 1898—on the Baltic, 95 vessels; White Sea, 33; Black and Azov Seas, 263; Caspian, 213. On an average 9,300 vessels leave the ports of Finland every year. The Caspian ports have 20,144 arrivals and in the coasting trade of the ports of the White, Baltic, and the Black Seas the entrances during the year are over 47,000. The interior trade is summarized as follows: Product of manufacturing and mining, $1,242,000,000; breadstuffs, $1,050,000,000; foreign imports, $312,000,000; turn-over for the transport of goods and passengers, $392,250,000—total, $2,996,250,000. The fairs still hold an important position. The greatest of all is the world-famous fair of Nijni-Novgorod, to which there were shipped (and nearly all sold) in 1898 goods to the value of $80,000,000.

Transportation, Rivers and Railways.—In 1900 Russia had 55,000 English miles of navigable rivers and 1,218 miles of canals, and 136,413 vessels and 282,359 rafts were unloaded at the ports upon them; the merchandise transported being 29,003,000 tons, valued at $241,320,538, to which should be added over 7,000,000 tons of lumber.

The first railway in Russia, from St. Petersburg to Tsarskoye Selo and Pavlovsk, was completed in 1836. In 1900 34,485 miles were open for traffic. Of these 20,111 miles belonged to and were worked by the Government; 9,591 miles belonged to public companies; 2,310 miles were unconnected or isolated railways; and 752 miles short local lines. On Dec. 28, 1899, the trans-Siberian trunk from the Lake Baikal to Sryetensk (685 miles) was opened, establishing uninterrupted steam communication between Western Europe and the Russian Empire on the Pacific coast. The trains are transported across Lake Baikal on an ice-breaking ferry-boat. Russian railways in 1898 carried 83,708,100 passengers and 118,106,000 tons of freight, their total gross receipts being $465,741,008, working expenses $277,576,194, and net receipts $188,164,814. In 1898 the length of the state telegraph lines, about nineteen-twentieths of all, was 93,052 miles; and of telephone lines, 35,300 miles.

Population and Political Divisions.—Ethnic Elements.—The general divisions of Russia, having a well understood significance among the people, are as follows: Great Russia, or Muscovy (comprising the whole of the northern and central part of the country); Little Russia, or Ukraine (Kieff, Chernigoff, Poltava, and Kharkoff); New Russia (Bessarabia, Kherson, Taurida, Ekaterinoslaf, and the Don Cossack territory); Red Russia (Lithuania, Volhynia, Podolia, and parts of the present Galicia); White Russia (Vitebsk and Moghilev); Black Russia, or Minsk; and the Baltic provinces (Courland, Livonia, St. Petersburg, and Esthonia. The division into governments, together with the area (in English square miles) and population of each in 1897, according to the imperial census taken on Feb. 9 of that year, is as follows:

DIVISIONS OF RUSSIA—CONTINUED.

GOVERNMENTS.	Square miles.	Population.
I. European Russia Proper—Cont.:		
Minsk	35,293	2,156,343
Moghilev	18,551	1,707,613

Kursk	17,937	2,394,893
Livonia	18,158	1,300,401

According to this table, 82 per cent. of the population of the empire dwell upon what is approximately 23 per cent. of its surface. The total population of both European and Asiatic Russia is about 129,000,000.

More than 110 nationalities, belonging to the branches and groups of the Mediterranean and Mongolian races, dwell in Russia, and they speak more than forty languages. The Slavs constitute about three-quarters of the entire population, however, and the Russian people proper about two-thirds of the whole. The smaller and exceedingly antipathetic race, the Poles, form about one-twelfth or one-thirteenth of the whole people, and number approximately 8,500,000. A vigorous national policy has been for many years in operation for the Russianizing of the Poles and also the small non-Slavic elements. The principal non-Slavic races are the Fins in Finland, the Germans in the Baltic provinces and Southern Russia, the Tartars, and other tribes of Mongolian derivation in the southwest, and the Jews, supposed to number over 3,500,000, chiefly concentrated in Poland and Western Russia. The Russians themselves are subdivided into Great, Little, and White Russians, the first greatly preponderating, and their tongue being the accepted language of the empire and used by the Government and a great majority of the people.

Government.—The Government is an absolute monarchy. The supreme legislative, executive, and judicial powers are united in the emperor. Their administration is exercised through four great councils. The first is the committee of ministers, each of whom is named by, and responsible directly to, the sovereign, there being no prime minister. The second is the council of the empire. It generally numbers from sixty to seventy members, appointed by the emperor,

including the ministers who have seats *ex officio* and several members of the imperial family. It is a consultative body in legislation, and its chief function is to review projects of laws presented by the ministers, and to consider the annual budget. It is divided into the three departments of legislation, administration, and finance, with a special department for the discussion of appeals to the emperor from decisions of the senate. The third of the councils is the ruling senate, whose members are appointed by the emperor chiefly from persons of high rank or office. While the council of the empire is consultative in its nature, the senate is partly executive and partly judicial. It promulgates the laws and constitutes the high court of justice. Seven of its nine departments are administrative, and two are courts of cassation. The former examine into the general administration, review the acts of governors and settle disputes with the zemstvos. A special department of seven members passes judgment in political offenses. The fourth council is the holy synod, which is composed of the metropolitans and bishops of the Church, and has the superintendence of religious affairs.

For administrative purposes the empire is divided into governments and districts. European Russia proper contains fifty governments, each of which is subdivided into districts varying from eight to fifteen. Poland, Finland, Moscow, Kieff, and Vilna constitute general governments, each composed of a number of the minor governments. Asiatic Russia embraces four general governments, Caucasus, Turkestan, Stepnoye, and Amur, comprising about thirty governments and territories, besides a number of districts which are treated as distinct. Each general government has a governor-general representing the czar, who has supreme direction of civil and military affairs. In the minor governments the governor is assisted by a council of regency, to which all measures must be referred. A council of control is also provided, depending directly on the ministry or Department of General Control. In the frontier provinces military as well as civil governors are established.

In European Russia the local administration is largely in the hands of the people. They do not dwell on scattered farms but are grouped in villages, and each of these villages constitutes a commune or mir, which is the unit of political organization. The number of communes reaches 107,493. The land held by a village is regarded as belonging to the whole community, and is apportioned among the families according to the number of their working units. The communal assembly is composed of all the householders, who elect one of their own number elder (starosta) or executive, and consider and decide all communal affairs. The communes are united into volosts, each containing about 2,000 householders. The volost assembly is composed of delegates from the village communes, one for every ten houses, who elect a volost elder (starshina), and who have the same powers for the volost which the communal assemblies have for the commune. Their freedom is, however, restricted by the supervision of an imperial official. The volost assemblies also choose a peasants' tribunal of several judges, who have jurisdiction of offenses of all classes and of property disputes involving not over 100 roubles. Disputes of larger amount come under chiefs of the districts who are taken from the nobility, and have a certain control over the peasants' tribunals. The system of local self-government is extended measurably to the district and province where the administration of economical affairs is placed in the hands of an assembly called the zemstvo, made up of nobles possessing a certain amount of land and delegates elected by other landed proprietors, by the householders in the towns, and the peasantry. The executive power rests with the uprava, who is nominated by the delegates. The powers of the zemstvos extend to matters of education, roads, saloons, public health, taxation, etc., and in many cases they have done valuable work and shown a progressive spirit; but their independence is affected by the supervision exercised by the governor as the representative of the imperial Government. Of the votes which elect the zemstvos, 64 per cent. belong to the peasants, 12 per cent. to nobles, and the remainder to the clergy, merchant, and artisan classes. Of the delegates elected 38 per cent. by the latest statistics belong to the peasants, and 35 per cent. to the nobles. In Central Russia two-thirds of the executives are nobles and in East Russia two-thirds are peasants.

The cities and towns have a municipal organization similar to that of the zemstvos. All houseowners and taxpayers are enrolled according to their assessment, and are then divided into three classes, each class holding an equal proportion of the total valuation, and each electing an equal number of representatives to the duma, or municipal assembly. The duma chooses the uprava, or executive.

The annual revenue of the imperial Government is about 1,600,000,000 roubles, or $824,000,000, and the expenditures about the same. The chief sources of revenue are the excise on spirits (about $200,000,000), tobacco and sugar, the customs (about $92,000,000) and stamp duties, and returns from state domains. The direct land and personal taxes for the imperial treasury amount to about $25,000,000. The annual receipts of the zemstvos, or provincial assemblies, approach $25,000,000, of which the bulk is in land taxes. The land paying the tax pays an average of 9·6 copecks, or 4·8 cents, per acre. The aggregate expenses of the zemstvos at the last accessible accounts averaged 1·6 roubles, or 80 cents, per male of population. The expenses of the village communes average 1·16 roubles, or 58 cents, per male. The total sum of direct taxes annually paid by the peasants to the imperial treasury amounts to 118,000,000 roubles, of which 41,000,000 are for the redemption of debt for the purchase of land, or about 5 roubles per head of adult males.

Theoretically, each able-bodied male in European Russia (with the exception of doctors, teachers, clergymen, etc.) should serve five years in the active army, thirteen years in the reserve, and five years in the second reserve (Zapas); in practice, however, over two-thirds are enlisted directly in the reserves, which drill six weeks twice a year. The peace footing for the entire empire is nearly 900,000 men and about 160,000 horses; the war footing is over 2,500,000 combatants and 575,000 horses. The navy embraces powerful flotillas on the Baltic and on the Black Sea, and smaller ones on the Caspian and on the Pacific coast of Siberia. See SHIPS OF WAR.

Religion and Education.—The established and official religion of the empire is that of the GREEK CHURCH (*q. v.*) or Orthodox Catholic faith. There are no very accurate figures as to membership in this Church and the various sects, but estimates made with care for 1888 show the number as follows: For Russia proper, Greek Church (without army and navy), 69,808,407; Roman Catholics, 8,300,000; Protestants, 2,950,000; Jews, 3,000,000; Mohammedans, 2,600,000; United Church and Armenians, 55,000; pagans, 26,000. In Poland the adherents in 1890 were: Roman Catholics, 6,214,504; Jews, 1,134,268; Protestants, 445,013; Greek Church (without army), 398,855. The number of Dissenters is estimated to be at least 12,000,000, and it is probable that many of them are wrongly accredited to the Greek Church. They have felt, like the Jews, but far less rigorously, the persecutions of the state and society. With the exception of these two bodies all religions enjoy freedom from restraint. The affairs of the Roman Catholic Church are centered in a collegium, and those of the Lutheran Church in a consistory, both located in St. Petersburg. The Protestants are mainly Lutherans, who came into the empire originally from Germany and are mostly settled in the provinces of the Baltic. The preponderance of the Roman Catholics is in Poland, the Jews inhabit mostly the towns and villages of Poland and Western and Southwestern Russia, while the Mohammedans are in the eastern and southern part of the empire. Besides these there are a great number of small sects, embodying almost every conceivable variety of fantastic fanaticism. See RASKOLNIKS.

The schools of the empire are for the most part under the ministry of Public Instruction, and the empire is divided into fourteen educational districts, corresponding to the large cities, but some special schools are under separate ministries. The money contributed for education in the budget for 1899 was $26,297,364. The educational system is as yet only in a formative condition, and though a good beginning has been made and many excellent schools of the higher class—universities and special schools—are in existence, the general level of education is low. Libraries are not numerous outside of St. Petersburg, Moscow, and Warsaw, but there are valuable ones in those cities, and the Imperial Library in the capital is one of the richest in the world. In the arts, sciences, and literature Russia has developed much that is admirable and exhibited occasionally the finest fruits of genius, sometimes startling and strange, and nearly always vigorous and virile. The press pours forth an immense production of books—10,651 in the year 1894 (exclusive of Finland), with an aggregate of 32,208,372 copies, the preponderance in Russian (8,082), and the remainder in the Polish, Hebrew, German, Lettish, and Estho-

nian languages. Periodicals numbered 743 in 1892 (exclusive of Finland), of which 589 were in the Russian language. The separate publications for 1893 (exclusive of Finland) reached 10,242, of which 33,875,200 copies were printed, and in 1894 there were 779 periodicals.

History.—It was not until the advent of Peter the Great (1689–1725) that Russia really entered the arena of modern civilization, and became a forceful factor in Europe. Its origin lies in obscurity, and for centuries its history consists of faintly traced migrations and conflicts of primitive and rude nomadic tribes and fragments of nations. Four centuries before Christ the Greeks founded commercial stations among semi-savages called Scythians and Sarmatians, whom they discovered upon the northern coast of the Black Sea, along the Sea of Azov, and in the Crimea. There, for 800 years, this barbarous horde hung upon the boundaries of an unknown expanse and the frontiers of the Greek and Roman world. But in the fourth century came other masses of semi-savages, the Goths and Huns, Avars and Alans, who swept over them in successive waves. Then in the sixth century the Slavs appeared on the pages of history. Believed to have been related to the Sarmatians, they occupied the country as far N. as the upper Volga. Encountering the Finns, they drove the major portion toward the Baltic and Arctic, and, absorbing the remainder, developed the composite Russian type with sallow complexion and flaxen hair. Flourishing in power the Slavs founded Kieff and Novgorod, each the capital in time of a principality. After the lapse of a century, which is a blank in their annals, they were overrun by a tribe of the Northmen, the Varangians, called by the Slavs the Rus, from whom the name Russian was derived, first appearing in the ninth century. The Rus dominated both the Finns and Slavs, but the latter, after throwing off the yoke, long suffered from outward attack and internal dissension, and at a crucial moment, to avert anarchy, importuned the Rus or Varangian chief Rurik to become their ruler. He went to Novgorod in 862, and it was he who laid the foundation of the Russian empire, over which his family reigned seven centuries. His cousin and successor, Oleg (879–912), a powerful and wise ruler, conquered Kieff, thus greatly enlarging his dominion, defeated various bordering tribes, and even attacked, with 900 vessels, the Emperor of Constantinople, with whom he concluded in 911 an advantageous peace. Igor, the son of Rurik (912–945), added to the country by conquest, made unsuccessful war against the Emperor of Constantinople in 941, and was killed in battle against the Drevlians, a Slavonic tribe. His widow, Olga, whose name to this day is a national word with the Russians, reigned during the minority of her son Sviatoslaff, and introduced Christianity into the country, she herself being baptized in Constantinople in 957. Sviatoslaff (945–972) remained a pagan, extended the borders of the empire to the Sea of Azov, and in 970 divided it among his three sons, Yaropolk I. (972–980), Oleg, and Vladimir. War arising between the brothers, Oleg was slain, Vladimir fled, and Yaropolk, originally ruling Kieff, reunited the empire, only to be reconquered and put to death by Vladimir, who returned in 980 with a horde of the Rus or Varangians, and became the sole ruler of all Russia. Surnamed The Great because of his conquests and his beneficent measures, he made Christianity the official religion of the empire, founded churches, schools, and new towns, and divided the empire among his twelve sons, who engaged in fratricidal war before the death of their father, after which Sviatopolk (son of Yaropolk I., but adopted by Vladimir) ascended the throne after murdering three of his brothers, only to be deposed in war with another brother, Yaroslaff (1019–54), who succeeded in reuniting and extending the empire by successful wars, and emulated his father's example in reforms. During the next three centuries events led to an ultimate enlargement of dominion, and a more thorough organization of the government, preceded by the breaking of the Russian monarchy into a confederacy, its restoration, the constant struggle of internecine war, and the seizure of large regions of Western Russia by the Poles, Lithuanians, Danes, and the Teutonic knights. The early part of this period was nevertheless one of general progress, and important cities were founded, among them Tver and Moscow, the latter in 1147. But in the beginning of the thirteenth century came the sweeping Mongol invasion from Eastern Asia under Genghis Khan, which the Russians, save at Moscow, could not withstand. This was followed by internal war, famine, and pestilence. In 1230 30,000 men died of the plague in Smolensk, and 42,000 in Novgorod. Then came another Mongol horde demanding tribute, and putting to fire and sword all who failed to render it. In the next century the Russians had gathered strength, and under the Prince of Moscow, Dmitri Donskoi, they repelled the incursions of 1378 and 1380, only to be overwhelmed by the numbers of the invaders in 1382, when Moscow was burned and 24,000 of its people slain. Ivan the Great (1462–1505) so built up the power of arms that the Mongols were defeated, and, decay having set in among them, an era of freedom from their assaults was entered upon, greatly to the relief of the Russians, who began to extend their dominion to the E., conquering Kazan in 1469 and parts of Siberia in 1499. It was under this ruler that one of the fixed features of the "Russian policy," a jealous regard for Constantinople, had its inception. Russia looked to Constantinople as its model of civilization, and took its initiatives in art, especially architecture, in literature, in religion, and in the externals of life, and when that city fell into the hands of the Turks in 1453 Ivan became the devotee of the Byzantine policy, which has influenced all subsequent Russian statesmanship. Ivan IV., The Terrible (1533–84), conquered Astrakhan (1556), the region of the Don Cossacks (1570), and a portion of Siberia (1581), opened a road to Archangelsk, established a printing-press in Moscow in 1569, and did many meritorious acts and a single infamous one, which gave him the surname of The Terrible, namely, the slaying and torture of 60,000 citizens of Novgorod, that city having revolted from his iron rule in 1570. The house of Rurik ceased to exist with the death of Ivan's son Feodor I. (1584–98), believed to have been poisoned, and, after the brief reigns of several rulers and much intrigue, revolution, war, and among other evils a great famine in 1601 by which 100,000 people perished in Moscow alone, the first of the Romanoffs, Michael Feodorovitch, was elected czar by the boyars or noblemen in 1613. He promoted the internal prosperity of the country, revived the long prostrate commerce, and in 1639 extended the borders of the Asiatic possessions to the Pacific. He was succeeded by his son Alexis (1645–76), and his son Feodor III. (1676–82), whose reigns were signalized by many important reforms; and then, after intrigue and conspiracy, in which his sister Sophia sought the rulership, and in fact exercised a regency which her brother overthrew, there ascended the throne as czar the most colossal figure in Russian history, Peter the Great. Within a few years under his guidance Russia became the most powerful nation of Northern Europe, and was recognized as a potent member in the political system of the Continent. Peter was the first to bear the proud title of Emperor of Russia. In 1703 he founded St. Petersburg as the new capital of the empire. In 1696 he took Azov from the Turks; in 1709, by his decisive victory at Poltava over Charles XII., he ended an arduous campaign in the destruction of Sweden's supremacy; in 1721, by the peace of Nystadt, he added Ingria and parts of Karelia, Esthonia, and Livonia to his realm, and in 1723, by his prowess and shrewd diplomacy, secured the provinces of Daghestan and other territory on the Caspian, ceded by Persia. Besides all this he introduced varied internal reforms and improvements of vast extent and importance. His surpassing service, however, was in opening the door of Russia to Western Europe, and putting his people in touch with a civilization superior to the Byzantine standard, which they had long accepted. Never probably in the history of the world were so obdurate and refractory a people absolutely impelled by the will of one man to so great an advance as that which the Russians made under the virile sway of Peter the Great. He died Feb. 8, 1725, but the reforms he instituted, the great public works he began, and the policy he introduced, were carried forward by his successors, for they and the people seemed to have become infused with something of his spirit and energy. Thus Catherine I. (1725–27), Peter II. (1727–30), Anne (1730–41), Elizabeth (1741–62), each contributed something to progress, the last named founding in Moscow the first Russian university, and Catherine II. (1762–96), more than all combined. Catherine was the most picturesque of the rulers of Russia, shrewd, brilliant, capricious, of lax morals and large intellect, cultivating the arts and letters, given to show and also to great enterprises. While surrounding herself with an imposing array of statesmen, soldiers, and courtiers of doubtful repute, she was the professed patron of public morality, and founded innumerable churches, schools, and benevolent institutions; more imperiously despotic than any of her immediate predecessors, she nevertheless convoked an assembly of delegates from all the districts to frame a new and more

liberal code of laws; apparently absorbed in the sensual pleasures of a sumptuous life, and the petty personal intrigues of a corrupt court, she yet accomplished such solidly practical works as bringing 50,000 high-class German and Swiss immigrants into the country. By wars, and by diplomacy which compelled admiration, she acquired 225,000 sq. miles of territory, carrying on simultaneously an immense internal improvement and elaboration of the plan of government. In several successful wars she took from the Turks the Crimea and Azov, with other territories, and in the final dismemberment of Poland (1796) secured to the empire two-thirds of that kingdom. Under her rule Russia made signal advance as an influential power in Europe. Her son Paul (1796–1801) joined the coalition against the French republic, but after the victories of Suwaroff in Italy, followed by disasters on crossing the Alps, the fickle monarch veered to the side of Napoleon. But his rule was unbearable, and he was assassinated. Alexander I. (1801–25), through the shifting scenes of the long Napoleonic struggle, played a leading *rôle* in the European drama, and raised Russia to the foremost place in the continental balance of power. Ardent, impulsive, and impressionable, he conceived large policies, and his imagination was easily moved. Entering the third coalition against Napoleon he shared with Austria the defeat at Austerlitz (1805), where he was present on the field. The fourth coalition with Prussia followed, and after the sanguinary and indecisive battle of Eylau (1807) and the conclusive defeat of the allies at Friedland, Alexander accepted the peace of Tilsit (July 7, 1807), by which he allied himself with his former adversary, and closed the ports of Russia to Great Britain. The two monarchs proceeded as if dividing the world between them, Napoleon to take the West and Alexander the East. Alexander moved against Persia and gained Shirvan. By the peace of Frederikshamn (1809) he acquired Finland from Sweden, and after a war with Turkey added Bessarabia to his possessions. Growing restive under the continental blockade, he broke with Napoleon, and the memorable invasion of Russia in 1812 followed. At the head of more than half a million men Napoleon defeated Alexander at Smolensk, again at Borodino, and entered Moscow, which the Russians themselves then fired and well-nigh burned to the ground. Vainly seeking to negotiate peace he turned in hasty retreat, and began the disordered and appalling winter flight which destroyed his great army. In 1813 Prussia and Austria joined Russia in war against France, and the battle of Leipzig decided the contest, leaving Alexander foremost among the victorious sovereigns, and acclaimed as the liberator of Europe. In the reorganization of European politics through the congresses of Vienna and Aix-la-Chapelle his influence was dominant. He founded the Holy Alliance and became the pillar of reaction against the progressive tendencies of the age. His internal policy experienced a similar change. During his earlier years he had shown a liberal disposition. He sought to improve public education, founded universities, advanced the condition of the serfs, fostered industrial and commercial enterprises, and relaxed harsh political and judicial methods. In his later years, suppression, censorship, and police rigor became the rule. Detested ministers aroused general hostility, and secret societies multiplied. The gay hero of other days became the conscious object of wide discontent, and sank into a morose and dejected state. His death quickened the outbreak of a revolutionary conspiracy, which found its immediate occasion in the change of succession from the elder to the next brother; but the new sovereign, Nicholas I. (1825–55), suppressed it with great vigor, and sternly executed or exiled the chief conspirators. Throughout his reign Nicholas displayed reactionary tendencies. Commanding, imperious, and autocratic, he upheld the principle of absolutism with a resolute hand. In a war with Persia, from 1826 to 1828, Russia completely triumphed, and gained the provinces of Erivan and Nakhitchevan, a heavy indemnity, and the exclusive control of the Caspian Sea. Next came war with Turkey in defense of the struggling Greeks. The alliance of Russia, France, and Great Britain led to the victory of Navarino (1827), annihilating the Turkish fleet. Russia continued the contest, achieved full success, and forced Turkey, through the peace of Adrianople, to cede the mouths of the Danube and pay indemnity. The heroic Polish insurrection of 1831 was energetically suppressed, and followed by measures which reduced the kingdom to a province, stripped of the distinct constitution granted by Alexander, of its own diet and its own army. The policy of Russianizing these and other alien fragments of the empire into a homogeneous people became one of the features of Nicholas's reign. The revolutionary epoch of 1848 emphasized his reactionary spirit. In 1849 he sent a Russian army to aid Austria in crushing the Hungarian revolt. In 1853 Russia's demands for the protection of Greek Christians in Turkey precipitated the Crimean war, wherein Great Britain, France, and Sardinia joined Turkey upon the plea that Russia's demands covered the design of Turkish dismemberment. The defeats of the Alma, Balaklava, and Inkermann, and the siege of Sebastopol, deeply chagrined Nicholas, who died in disappointment, and left the war as a legacy to his son Alexander II. (1855–81), who hastened to bring it to a conclusion.
